user@switch# set support l3-interface irb.1
```

Configuration Results Display the results of the configuration:

```
user@switch> show configuration
interfaces {
  xe-0/0/20 {
    unit 0 {
      description "Sales file server port";
      family ethernet-switching {
        vlan members sales;
      }
    }
  }
  xe-0/0/46 {
    unit 0 {
      description "Support file server port";
      family ethernet-switching {
        vlan members support;
      }
    }
  }
  vlans {
    unit 0 {
      family inet address 192.0.2.1/25;
    }
    unit 1 {
      family inet address 192.0.2.129/25;
    }
  }
}
```

```

    }
  }
}
vllans {
  sales {
    vlan-id 100;
    interface xe-0/0/0.0;
    interface xe-0/0/3.0;
    interface xe-0/0/20.0;
    interface xe-0/0/22.0;
    l3-interface irb0;
  }
  support {
    vlan-id 200;
    interface xe-0/0/24.0;
    interface xe-0/0/26.0;
    interface xe-0/0/44.0;
    interface xe-0/0/46.0;
    l3-interface irb1;
  }
}
}

```

TIP: To quickly configure the sales and support VLAN interfaces, issue the **load merge terminal** command. Then copy the hierarchy and paste it into the switch terminal window.

Verification

Verify that the **sales** and **support** VLANs have been created and are operating properly, perform these tasks:

- [Verifying That the VLANs Have Been Created and Associated with the Correct Interfaces on page 2118](#)
- [Verifying That Traffic Is Being Routed Between the Two VLANs on page 2119](#)
- [Verifying That Traffic Is Being Switched Between the Two VLANs on page 2119](#)

Verifying That the VLANs Have Been Created and Associated with the Correct Interfaces

Purpose Verify that the **sales** and **support** VLANs have been created on the switch and that all connected interfaces on the switch are members of the correct VLAN.

Action To list all VLANs configured on the switch, use the **show vlans** command:

```

user@switch> show vlans
Name      Tag      Interfaces
default
          xe-0/0/1.0, xe-0/0/2.0, xe-0/0/4.0, xe-0/0/5.0,
          xe-0/0/6.0, xe-0/0/7.0, xe-0/0/8.0, xe-0/0/9.0,
          xe-0/0/10.0*, xe-0/0/11.0, xe-0/0/12.0, xe-0/0/13.0*,
          xe-0/0/14.0, xe-0/0/15.0, xe-0/0/16.0, xe-0/0/17.0,

```

```

xe-0/0/18.0, xe-0/0/19.0, xe-0/0/21.0, xe-0/0/23.0*,
xe-0/0/25.0, xe-0/0/27.0, xe-0/0/28.0, xe-0/0/29.0,
xe-0/0/30.0, xe-0/0/31.0, xe-0/0/32.0, xe-0/0/33.0,
xe-0/0/34.0, xe-0/0/35.0, xe-0/0/36.0, xe-0/0/37.0,
xe-0/0/38.0, xe-0/0/39.0, xe-0/0/40.0, xe-0/0/41.0,
xe-0/0/42.0, xe-0/0/43.0, xe-0/0/45.0, xe-0/0/47.0,
xe-0/1/0.0*, xe-0/1/1.0*, xe-0/1/2.0*, xe-0/1/3.0*

sales      100
           xe-0/0/0.0*, xe-0/0/3.0, xe-0/0/20.0, xe-0/0/22.0

support    200
           xe-0/0/0.24, xe-0/0/26.0, xe-0/0/44.0, xe-0/0/46.0*

mgmt
           me0.0*

```

Meaning The **show vlans** command lists all VLANs configured on the switch and which interfaces are members of each VLAN. This command output shows that the **sales** and **support** VLANs have been created. The **sales** VLAN has a tag ID of 100 and is associated with interfaces **xe-0/0/0.0**, **xe-0/0/3.0**, **xe-0/0/20.0**, and **xe-0/0/22.0**. VLAN **support** has a tag ID of 200 and is associated with interfaces **xe-0/0/24.0**, **xe-0/0/26.0**, **xe-0/0/44.0**, and **xe-0/0/46.0**.

Verifying That Traffic Is Being Routed Between the Two VLANs

Purpose Verify routing between the two VLANs.

Action List the Layer 3 routes in the switch Address Resolution Protocol (ARP) table:

```

user@switch> show arp
MAC Address      Address      Name      Flags
00:00:0c:06:2c:0d 192.0.2.3    vlan.0    None
00:13:e2:50:62:e0 192.0.2.11   vlan.1    None

```

Meaning Sending IP packets on a multiaccess network requires mapping from an IP address to a MAC address (the physical or hardware address). The ARP table displays the mapping between the IP address and MAC address for both **vlan.0** (associated with **sales**) and **vlan.1** (associated with **support**). These VLANs can route traffic to each other.

Verifying That Traffic Is Being Switched Between the Two VLANs

Purpose Verify that learned entries are being added to the Ethernet switching table.

Action List the contents of the Ethernet switching table:

```

user@switch> show ethernet-switching table

Ethernet-switching table: 8 entries, 5 learned
VLAN      MAC address      Type      Age      Interfaces
default   *                Flood     -        All-members
default   00:00:05:00:00:01 Learn     -        xe-0/0/10.0
default   00:00:5e:00:01:09 Learn     -        xe-0/0/13.0

```

default	00:19:e2:50:63:e0	Learn	- xe-0/0/23.0
sales	*	Flood	- All-members
sales	00:00:5e:00:07:09	Learn	- xe-0/0/0.0
support	*	Flood	- All-members
support	00:00:5e:00:01:01	Learn	- xe-0/0/46.0

Meaning The output shows that learned entries for the **sales** and **support** VLANs have been added to the Ethernet switching table, and are associated with interfaces **xe-0/0/0.0** and **xe-0/0/46.0**. Even though the VLANs were associated with more than one interface in the configuration, these interfaces are the only ones that are currently operating.

Configuring VLANs

Switches use VLANs to make logical groupings of network nodes with their own broadcast domains. You can use VLANs to limit the traffic flowing across the entire LAN and reduce collisions and packet retransmissions.

NOTE: This task supports the Enhanced Layer 2 Software (ELS) configuration style. For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 41](#). If your switch runs software that does not support ELS, see [Configuring VLANs](#).

NOTE: Two logical interfaces that are configured on the same physical interface cannot be mapped to the same VLAN.

For each endpoint on the VLAN, configure the following VLAN parameters on the corresponding interface:

1. Specify the description of the VLAN:

```
[edit interfaces interface-name unit 0]
user@switch# set description vlan-description
```

2. Specify the unique name of the VLAN:

NOTE: Switches that run Junos OS with the ELS configuration style do not support a default VLAN. Therefore, on such switches, you must explicitly configure at least one VLAN, even if your network is simple and you want only one broadcast domain to exist.

```
[edit interfaces interface-name unit 0]
user@switch# set family ethernet-switching vlan members vlan-name
```

3. Create the subnet for the VLAN:

- ```
[edit interfaces]
user@switch# set vlan unit 0 family inet address ip-address
```
4. Configure the VLAN tag ID or VLAN ID list for the VLAN:
- ```
[edit vlans]
user@switch# set vlan-name vlan-id vlan-id-number
or

[edit vlans]
user@switch# set vlan-name vlan-id-list [vlan-ids | vlan-id--vlan-id-]
```
5. Specify a VLAN firewall filter to be applied to incoming or outgoing packets:
- ```
[edit vlans]
user@switch# set vlan-name filter (input | output) filter-name
```

## Configuring the Native VLAN Identifier (CLI Procedure)

**NOTE:** This task uses Junos OS for EX Series switches and Junos OS for QFX3500 and QFX3600 switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Configuring the Native VLAN Identifier (CLI Procedure)*. For ELS details, see “Getting Started with Enhanced Layer 2 Software” on page 41.

Switches can receive and forward routed or bridged Ethernet frames with 802.1Q VLAN tags. Typically, trunk ports, which connect switches to each other, accept untagged control packets but do not accept untagged data packets. You can enable a trunk port to accept untagged data packets by configuring a native VLAN ID on the interface on which you want the untagged data packets to be received. The logical interface on which untagged packets are to be received must be configured with the same VLAN ID as the native VLAN ID configured on the physical interface.

To configure the native VLAN ID by using the command-line interface (CLI):

1. On the interface on which you want untagged data packets to be received, set the interface mode to **trunk**, which specifies that the interface is in multiple VLANs and can multiplex traffic between different VLANs.:

```
[edit interfaces]
user@switch# set interface-name unit logical-unit-number family
ethernet-switching interface-mode trunk
```

2. Configure the native VLAN ID:

```
[edit interfaces]
user@switch# set interface-name native-vlan-id vlan-id
```

3. Specify that the logical interface that will receive the untagged data packets is a member of the native VLAN:

```
[edit interfaces]
user@switch# set interface-name unit logical-unit-number family
ethernet-switching vlan members vlan-id
```

## Creating a Series of Tagged VLANs

---

When you divide an Ethernet LAN into multiple VLANs, each VLAN is assigned a unique IEEE 802.1Q tag. This tag is associated with each frame in the VLAN, and the network nodes receiving the traffic can use the tag to identify which VLAN a frame is associated with.

Instead of configuring VLANs and 802.1Q tags one at a time for a trunk interface, you can configure a VLAN range to create a series of tagged VLANs.

When an Ethernet LAN is divided into VLANs, each VLAN is identified by a unique 802.1Q tag. The tag is applied to all frames so that the network nodes receiving the frames can detect which VLAN the frames belong to. Trunk ports, which multiplex traffic among a number of VLANs, use the tag to determine the origin of frames and where to forward them.

For example, you could configure the VLAN **employee** and specify a tag range of **10 through 12**. This creates the following VLANs and tags:

- VLAN **employee-10**, tag 10
- VLAN **employee-11**, tag 11
- VLAN **employee-12**, tag 12

Creating tagged VLANs in a series has the following limitations:

- Layer 3 interfaces do not support this feature.
- Because an access interface can only support one VLAN member, access interfaces also do not support this feature.

**NOTE:** This task uses Junos OS for Junos OS for QFX3500 and QFX3600 switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Creating a Series of Tagged VLANs*. For ELS details, see “[Getting Started with Enhanced Layer 2 Software](#)” on page 41.

---

To configure a series of tagged VLANs using the CLI (here, the VLAN is **employee**):

1. Configure the series (here, a VLAN series from 120 through 130):

```
[edit]
user@switch# set vlans employee vlan-id-list [120-130]
```

2. Associate a series of tagged VLANs when you configure an interface in one of two ways:

- Include the name of the series:

```
[edit interfaces]
user@switch# set interfaces xe-0/0/22.0 family ethernet-switching vlanmembers employee
```

- Include the VLAN range:

```
[edit interfaces]
user@switch# set interfaces xe-0/0/22.0 family ethernet-switching vlan members 120-130
```

Associating a series of tagged VLANs to an interface by name or by VLAN range the same result: VLANs **\_\_employee\_120\_\_** through **\_\_employee\_130\_\_** are created.

**NOTE:** When a series of VLANs is created using the `vlan-id-list` command, the VLAN names are preceded and followed by a double underscore.

## Understanding Integrated Routing and Bridging

---

To segment traffic on a LAN into separate broadcast domains, you create separate virtual LANs (VLANs). VLANs limit the amount of traffic flowing across the entire LAN, reducing the possible number of collisions and packet retransmissions within the LAN. For example, you might want to create a VLAN that includes the employees in a department and the resources that they use often, such as printers, servers, and so on.

Of course, you also want to allow these employees to communicate with people and resources in other VLANs. To forward packets between VLANs, you normally you need a router that connects the VLANs. However, you can accomplish this forwarding on a switch without using a router by configuring an integrated routing and bridging (IRB) interface. (These interfaces are also called routed VLAN interfaces, or RVIs). Using this approach reduces complexity and avoids the costs associated with purchasing, installing, managing, powering, and cooling another device.

An IRB is a special type of Layer 3 virtual interface named **vlan**. Like normal Layer 3 interfaces, the **vlan** interface needs a logical unit number with an IP address. In fact, to be useful an IRB needs at least two logical units and two IP addresses—you must create units with addresses in each of the subnets associated with the VLANs between which you want traffic to be routed. That is, if you have two VLANs (for example, VLAN **red** and VLAN **blue**) with corresponding subnets, your IRB must have a logical unit with an address in the subnet for **red** and a logical unit with an address in the subnet for **blue**. The switch

automatically creates direct routes to these subnets and uses these routes to forward traffic between VLANs.

**NOTE:** If you are using a version of Junos OS that supports Enhanced Layer 2 Software (ELS), you can also create a Layer 3 virtual interface named `irb` instead of `vlan`—that is, both statements are supported by ELS

Table 185 shows values you might use when configuring an IRB:

**Table 185: Sample IRB Values**

| Property                      | Settings                                                                                                                        |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| VLAN names and tags (IDs)     | blue, ID 100<br>red, ID 200                                                                                                     |
| Subnets associated with VLANs | blue: 192.0.2.0/25 (addresses 192.0.2.1 through 192.0.2.126)<br>red: 192.0.2.128/25 (addresses 192.0.2.129 through 192.0.2.254) |
| IRB name                      | interface <code>irb</code>                                                                                                      |
| IRB units and addresses       | logical unit 100: 192.0.2.1/25<br>logical unit 200: 192.0.2.129/25                                                              |

For the sake of consistency and to avoid confusion, Table 185 shows IRB logical unit numbers that match the IDs of the corresponding VLANs. However, you do not have to assign logical unit numbers that match the VLAN IDs—you can use any values for the units. To bind the logical units of the IRB to the appropriate VLANs, you use the `l3-interface` statement.

Because IRBs operate at Layer 3, you can use Layer 3 services such as firewall filters or CoS rewriting with them.

Table 186 shows the number of IRBs/RVIs that each QFX platform supports.

**Table 186: Number of Supported IRBs/RVIs by Platform**

| Platform  | Number of Supported IRBs/RVIs |
|-----------|-------------------------------|
| QFX3500   | 1200                          |
| QFX3000-G | 1024                          |
| QFX3000-M | 1024                          |

## Example: Configuring Routing Between VLANs on One Switch

To segment traffic on a LAN into separate broadcast domains, you create separate virtual LANs (VLANs). For example, you might want to create a VLAN that includes the employees in a department and the resources that they use often, such as printers, servers, and so on.

Of course, you also want to allow these employees to communicate with people and resources in other VLANs. To forward packets between VLANs you normally you need a router that connects the VLANs. However, you can accomplish this on a Juniper Networks switch without using a router by configuring an integrated routing and bridging (IRB) interface (also known as a routed VLAN interface—or RVI—in versions of Junos OS that do not support Enhanced Layer 2 Software). Using this approach reduces complexity and avoids the costs associated with purchasing, installing, managing, powering, and cooling another device.

- [Requirements on page 2126](#)
- [Overview and Topology on page 2126](#)
- [Configure Layer 2 switching for two VLANs on page 2127](#)
- [Verification on page 2130](#)

### Requirements

This example uses the following hardware and software components:

- One switch
- Junos OS Release 11.1 or later

### Overview and Topology

This example uses an IRB to route traffic between two VLANs on the same switch. The topology is shown in [Figure 23](#).

**Figure 23: IRB with One Switch**

This example shows a simple configuration to illustrate the basic steps for creating two VLANs on a single switch and configuring an IRB to enable routing between the VLANs. One VLAN, called **blue**, is for the sales and marketing group, and a second, called **red**, is for the customer support team. The sales and support groups each have their own file servers and wireless access points. Each VLAN must have a unique name, tag (VLAN ID), and distinct IP subnet. [Table 187](#) lists the components of the sample topology.

Table 187: Components of the Multiple VLAN Topology

| Property                      | Settings                                                                                                                        |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| VLAN names and tag IDs        | blue, ID 100<br>red, ID 200                                                                                                     |
| Subnets associated with VLANs | blue: 192.0.2.0/25 (addresses 192.0.2.1 through 192.0.2.126)<br>red: 192.0.2.128/25 (addresses 192.0.2.129 through 192.0.2.254) |
| Interfaces in VLAN blue       | Sales server port: xe-0/0/4<br>Sales wireless access points: xe-0/0/6                                                           |
| Interfaces in VLAN red        | Support server port: xe-0/0/0<br>Support wireless access points: xe-0/0/2                                                       |
| IRB name                      | interface irb                                                                                                                   |
| IRB units and addresses       | logical unit 100: 192.0.2.1/25<br>logical unit 200: 192.0.2.129/25                                                              |

This configuration example creates two IP subnets, one for the blue VLAN and the second for the red VLAN. The switch bridges traffic within the VLANs. For traffic passing between two VLANs, the switch routes the traffic using an IRB on which you have configured addresses in each IP subnet.

To keep the example simple, the configuration steps show only a few interfaces and VLANs. Use the same configuration procedure to add more interfaces and VLANs. By default, all interfaces are in access mode, so you do not have to configure the port mode.

## Configure Layer 2 switching for two VLANs

**CLI Quick Configuration** To quickly configure Layer 2 switching for the two VLANs (**blue** and **red**) and to quickly configure Layer 3 routing of traffic between the two VLANs, copy the following commands and paste them into the switch terminal window:

**NOTE:** The following example uses a version of Junos OS that supports Enhanced Layer 2 Software (ELS). When you use ELS, you create a Layer 3 virtual interface named **irb**. If you are using a version of Junos OS that does not support ELS, you create a Layer 3 virtual interface named **vlan**.

```
[edit]
set interfaces xe-0/0/4 unit 0 description "Sales server port"
set interfaces xe-0/0/4 unit 0 family ethernet-switching vlan members blue
set interfaces xe-0/0/6 unit 0 description "Sales wireless access point port"
set interfaces xe-0/0/6 unit 0 family ethernet-switching vlan members blue
set interfaces xe-0/0/0 unit 0 description "Support servers"
set interfaces xe-0/0/0 unit 0 family ethernet-switching vlan members red
set interfaces xe-0/0/2 unit 0 description "Support wireless access point port"
set interfaces xe-0/0/2 unit 0 family ethernet-switching vlan members red
set interfaces irb unit 100 family inet address 192.0.2.1/25
```

```
set interfaces irb unit 200 family inet address 192.0.2.129/25
set vlans blue l3-interface irb.100
set vlans blue vlan-id 100
set vlans red vlan-id 200
set vlans red l3-interface irb.200
```

**Step-by-Step  
Procedure**

To configure the switch interfaces and the VLANs to which they belong:

1. Configure the interface for the sales server in the blue VLAN:

```
[edit interfaces xe-0/0/4 unit 0]
user@switch# set description "Sales server port"
user@switch# set family ethernet-switching vlan members blue
```

2. Configure the interface for the wireless access point in the blue VLAN:

```
[edit interfaces xe-0/0/6 unit 0]
user@switch# set description "Sales wireless access point port"
user@switch# set family ethernet-switching vlan members blue
```

3. Configure the interface for the support server in the red VLAN:

```
[edit interfaces xe-0/0/0 unit 0]
user@switch# set description "Support server port"
user@switch# set family ethernet-switching vlan members red
```

4. Configure the interface for the wireless access point in the red VLAN:

```
[edit interfaces xe-0/0/2 unit 0]
user@switch# set description "Support wireless access point port"
user@switch# set family ethernet-switching vlan members red
```

**Step-by-Step  
Procedure**

Now create the VLANs and the IRB. The IRB will have logical units in the broadcast domains of both VLANs.

1. Create the red and blue VLANs by configuring the VLAN IDs for them:

```
[edit vlans]
user@switch# set blue vlan-id 100
user@switch# set red vlan-id 200
```

2. Create the interface named **irb** with a logical unit in the sales broadcast domain (blue VLAN):

```
[edit interfaces]
user@switch# set irb unit 100 family inet address 192.0.2.1/25
```

The unit number is arbitrary and does not have to match the VLAN tag ID. However, configuring the unit number to match the VLAN ID can help avoid confusion.

3. Add a logical unit in the support broadcast domain (red VLAN) to the **irb** interface:

```
[edit interfaces]
user@switch# set irb unit 200 family inet address 192.0.2.129/25
```

4. Complete the IRB configuration by binding the red and blue VLANs (Layer 2) with the appropriate logical units of the **irb** interface (Layer 3):

```
[edit vlans]
user@switch# set blue l3-interface irb.100
user@switch# set red l3-interface irb.200
```

**Configuration Results**

Display the results of the configuration:

```
user@switch> show configuration
interfaces {
```

```

xe-0/0/4 {
 unit 0 {
 description "Sales server port";
 family ethernet-switching {
 vlan members blue;
 }
 }
}
xe-0/0/6 {
 unit 0 {
 description "Sales wireless access point port";
 family ethernet-switching {
 vlan members blue;
 }
 }
}
xe-0/0/0 {
 unit 0 {
 description "Support server port";
 family ethernet-switching {
 vlan members red;
 }
 }
}
xe-0/0/2 {
 unit 0 {
 description "Support wireless access point port";
 family ethernet-switching {
 vlan members red;
 }
 }
}
irb {
 unit 100 {
 family inet address 192.0.2.1/25;
 }
 unit 200 {
 family inet address 192.0.2.129/25;
 }
}
}
vlands {
 blue {
 vlan-id 100;
 interface xe-0/0/4.0;
 interface xe-0/0/6.0;
 l3-interface irb 100;
 }
 red {
 vlan-id 200;
 interface xe-0/0/0.0;
 interface xe-0/0/2.0;
 l3-interface irb 200;
 }
}
}

```

**TIP:** To quickly configure the blue and red VLAN interfaces, issue the **load merge terminal** command, copy the hierarchy, and paste it into the switch terminal window.

## Verification

To verify that the **blue** and **red** VLANs have been created and are operating properly, perform these tasks:

- [Verifying That the VLANs Have Been Created and Associated with the Correct Interfaces on page 2130](#)
- [Verifying That Traffic Can Be Routed Between the Two VLANs on page 2130](#)

### Verifying That the VLANs Have Been Created and Associated with the Correct Interfaces

**Purpose** Verify that the VLANs **blue** and **red** have been created on the switch and that all connected interfaces on the switch are members of the correct VLAN.

**Action** List all VLANs configured on the switch:

```
user@switch> show vlans
Name Tag Interfaces
default 0 xe-0/0/0.0, xe-0/0/2.0, xe-0/0/4.0, xe-0/0/6.0,
blue 100 xe-0/0/4.0, xe-0/0/6.0,
red 200 xe-0/0/0.0, xe-0/0/2.0, *
mgmt * me0.0*
```

**Meaning** The **show vlans** command lists all VLANs configured on the switch and which interfaces are members of each VLAN. This command output shows that the **blue** and **red** VLANs have been created. The **blue** VLAN has a tag ID of 100 and is associated with interfaces **xe-0/0/4.0** and **xe-0/0/6.0**. VLAN **red** has a tag ID of 200 and is associated with interfaces **xe-0/0/0.0** and **xe-0/0/2.0**.

### Verifying That Traffic Can Be Routed Between the Two VLANs

**Purpose** Verify routing between the two VLANs.

**Action** Verify that the IRB logical units are up:

```
user@switch> show interfaces terse
irb.100 up up inet 192.0.2.1/25
irb.200 up up inet 192.0.2.129/25
```

**NOTE:** At least one port (access or trunk) with an appropriate VLAN assigned to it must be up for the irb interface to be up.

Verify that switch has created routes that use the IRB logical units:

```
user@switch> show route
192.0.2.0/25 *[Direct/0] 1d 03:26:45
 > via irb.100
192.0.2.1/32 *[Local/0] 1d 03:26:45
 Local via irb.100
192.0.2.128/25 *[Direct/0] 1d 03:26:45
 > via irb.200
192.0.2.129/32 *[Local/0] 1d 03:26:45
 Local via irb.200
```

List the Layer 3 routes in the switch's Address Resolution Protocol (ARP) table:

```
user@switch> show arp
```

| MAC Address       | Address     | Name    | Flags |
|-------------------|-------------|---------|-------|
| 00:00:0c:06:2c:0d | 192.0.2.7   | irb.100 | None  |
| 00:13:e2:50:62:e0 | 192.0.2.132 | irb.200 | None  |

**Meaning** The output of the **show interfaces** and **show route** commands show that the Layer 3 IRB logical units are working and the switch has used them to create direct routes that it will use to forward traffic between the VLAN subnets. The **show arp** command displays the mappings between the IP addresses and MAC addresses for devices on both **irb.100** (associated with VLAN **blue**) and **irb.200** (associated with VLAN **red**). These two devices can communicate.

**Related Documentation**

- [irb \(Interfaces\) on page 2292](#)
- [l3-interface on page 2295](#)

## Configuring IRB Interfaces

Integrated routing and bridging (IRB) interfaces enable a switch to recognize which packets are being sent to local addresses so that they are bridged whenever possible and are routed only when needed. Whenever packets can be switched instead of routed, several layers of processing are eliminated. Switching also reduces the number of address look-ups.

**NOTE:** In versions of Junos OS that do not support Enhanced Layer 2 Software (ELS), this type of interface is called a routed VLAN interface (RVI).

To configure the routed VLAN interface:

1. Create the VLAN by assigning it a name and a VLAN ID:  

```
[edit]
user@switch# set vlans support vlan-id 111
```
2. Assign an interface to the VLAN by specifying the logical interface (with the **unit** statement) and specifying the VLAN name as the member:

```
[edit]
user@switch# set interfaces ge-0/0/18 unit 0 family ethernet-switching vlan members
support
```

3. Create the subnet for the VLAN's broadcast domain:

```
[edit]
user@switch# set interfaces irb unit 111 family inet address 111.111.111.1/24
```

4. Bind a Layer 3 interface with the VLAN:

```
[edit]
user@switch# set vlans support l3-interface irb.111
```

**NOTE:** If you are using a version of Junos OS that does not support ELS, you create a Layer 3 virtual interface named `vlan`

**NOTE:** Layer 3 interfaces on trunk ports allow the interface to transfer traffic between multiple VLANs. Within a VLAN, traffic is bridged, while across VLANs, traffic is routed.

You can display the configuration settings:

```
user@switch> show interfaces irb terse
Interface Admin Link Proto Local Remote
vlan up up
irb.111 up up inet 111.111.111.1/24
```

```
user@switch> show vlans
Name Tag Interfaces
default
employee-vlan 20 ge-1/0/0.0, ge-1/0/1.0, ge-1/0/2.0
marketing 40 ge-1/0/10.0, ge-1/0/20.0, ge-1/0/30.0
support 111 ge-0/0/18.0
mgmt bme0.32769, bme0.32771*
```

```
user@switch> show ethernet-switching table
Ethernet-switching table: 1 entries, 0 learned
VLAN MAC address Type Age Interfaces
support 00:19:e2:50:95:a0 Static - Router
```

**Related Documentation**

## Adding a Static MAC Address Entry to the Ethernet Switching Table (CLI Procedure)

**NOTE:** This task uses Junos OS for EX Series switches and Junos OS for QFX3500 and QFX3600 switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Adding a Static MAC Address Entry to the Ethernet Switching Table (CLI Procedure)*. For ELS details, see “Getting Started with Enhanced Layer 2 Software” on page 41.

The Ethernet switching table, also known as the forwarding table, specifies the known locations of VLAN nodes and the addresses of devices within those nodes. There are two ways to populate the Ethernet switching table on a switch. The easiest method is to let the switch update the table with MAC addresses.

The second way to populate the Ethernet switching table is to manually insert addresses into the table. You can do this to reduce flooding and speed up the switch’s automatic learning process.

Before configuring a static MAC address, be sure that you have:

- Set up the VLAN. See *Configuring VLANs for EX Series Switches (CLI Procedure)*.

To configure an interface to have a static MAC address:

```
[edit vlans vlan-name switch-options interface interface-name]
user@switch# set static-mac mac-address
```

### Related Documentation

- *Understanding Bridging and VLANs on EX Series Switches*

## Configuring Static ARP Entries

You can create static ARP table entries, which are explicit mappings between IP addresses and MAC addresses.

- To configure a static ARP entry:

```
[edit interfaces interface-name unit logical-unit-number family inet address
address]
user@switch# set arp ip-address (mac | multicast-mac) mac-address
```

The IP address that you specify must be part of the subnet defined in the enclosing **address** statement.

To associate a multicast MAC address with a unicast IP address, use the **multicast-mac** statement.

Specify the MAC address as 6 hexadecimal bytes in one of the following formats: *nnnn.nnnn.nnnn* or *nn:nn:nn:nn:nn:nn*; for example, 0011.2233.4455 or 00:11:22:33:44:55.

## Troubleshooting Ethernet Switching

---

**Problem**    **Description:** Sometimes a MAC address entry in the switch's Ethernet switching table is not updated after the device with that MAC address has been moved from one interface to another on the switch. Typically, the switch does not wait for a MAC address expiration when a MAC move operation occurs. As soon as the switch detects the MAC address on the new interface, it immediately updates the table. Many network devices send a gratuitous ARP packet when switching an IP address from one device to another. The switch updates its ARP cache table after receipt of such gratuitous ARP messages, and then it also updates its Ethernet switching table.

Sometimes silent devices, such as syslog servers or SNMP trap receivers that receive UDP traffic but do not return acknowledgment (ACK) messages to the traffic source, fail to send gratuitous ARP packets when a device moves. If such a move occurs when the system administrator is not available to explicitly clear the affected interfaces by issuing the **clear ethernet-switching table** command, the entry for the moved device in the Ethernet switching table is not updated.

**Solution**    Set up the switch to handle unattended MAC address switchovers.

1. Reduce the system-wide ARP aging timer. (By default, the ARP aging timer is set at 20 minutes. The range of the ARP aging timer is from 1 through 240 minutes.)

```
[edit system arp]
user@switch# set aging-timer 3
```

2. Set the MAC aging timer to the same value as the ARP timer. (By default, the MAC aging timer is set to 300 seconds. The range is 60 to 1,000,000 seconds.)

```
[edit protocols 12-learning]
user@switch# set global-mac-table-aging-time 180
```

The ARP entry and the MAC address entry for the moved device expire within the times specified by the aging timer values. After the entries expire, the switch sends a new ARP message to the IP address of the device. The device responds to the ARP message, thereby refreshing the entries in the switch's ARP cache table and Ethernet switching table.

### Introduction to the Media Access Control (MAC) Layer 2 Sublayer

---

This topic provides an introduction to the MAC sublayer of the data link layer (Layer 2).

In Layer 2 of a network, the Media Access Control (MAC) sublayer provides addressing and channel access control mechanisms that enable several terminals or network nodes to communicate in a network.

The MAC sublayer acts as an interface between the logical link control (LLC) Ethernet sublayer and Layer 1 (the physical layer). The MAC sublayer emulates a full-duplex logical communication channel in a multipoint network. This channel may provide unicast, multicast, or broadcast communication service. The MAC sublayer uses MAC protocols to prevent collisions.

In Layer 2, multiple devices on the same physical link can uniquely identify one another at the data link layer, by using the MAC addresses that are assigned to all ports on a switch. A MAC algorithm accepts as input a secret key and an arbitrary-length message to be authenticated, and outputs a MAC address.

A MAC address is a 12-digit hexadecimal number (48 bits in long). MAC addresses are usually written in one of these formats:

- MM:MM:MM:SS:SS:SS
- MM-MM-MM-SS-SS-SS

The first half of a MAC address contains the ID number of the adapter manufacturer. These IDs are regulated by an Internet standards body. The second half of a MAC address represents the serial number assigned to the adapter by the manufacturer.

Contrast MAC addressing, which works at Layer 2, with IP addressing, which runs at Layer 3 (networking and routing). One way to remember the difference is that the MAC addresses apply to a physical or virtual node, whereas IP addresses apply to the software implementation of that node. MAC addresses are typically fixed on a per-node basis, whereas IP addresses change when the node moves from one part of the network to another.

IP networks maintain a mapping between the IP and MAC addresses of a node using the Address Resolution Protocol (ARP) table. DHCP also typically uses MAC addresses when assigning IP addresses to nodes.

- [Overview of Layer 2 Networking on page 2085](#)
  - [Understanding MAC Learning on page 2138](#)

---

## Understanding MAC Learning

*MAC learning* is the process of obtaining the MAC addresses of all the nodes on a network.

When a node is first connected to an Ethernet LAN or VLAN, it has no information about the other nodes on the network. As data is sent through the network, data packets include a data frame listing their source and destination MAC addresses. The data frame is forwarded to a target port, which is connected to the second device. The MAC address is learned locally at the target port, which facilitates communications for frames that later enter the target port and contain addresses previously learned from a received frame.

By default, MAC learning is enabled on the QFX Series.

- Related Documentation**
- [Introduction to the Media Access Control \(MAC\) Layer 2 Sublayer on page 2137](#)
  - [Overview of Layer 2 Networking on page 2085](#)

---

## Disabling MAC Learning

By default, MAC learning is globally enabled on all node. This topic describes how to disable MAC learning, as well as how to reenable and verify that MAC learning has been enabled or disabled.

**NOTE:** This task supports the Enhanced Layer 2 Software (ELS) configuration style. For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 41](#) If your switch runs software that does not support ELS, see *Disabling MAC Learning*.

---

Disabling dynamic MAC learning prevents a node from learning source and destination MAC addresses.

- To disable MAC learning:

```
[edit vlans vlan-name switch-options interface interface-name]
user@switch# set no-mac-learning
```

- To enable MAC learning:

```
[edit vlans vlan-name switch-options interface interface-name]
user@switch# delete no-mac-learning
user@switch# deactivate no-mac-learning
```

- To verify the status of MAC learning, view the Ethernet MAC learning statistics in operational mode.

```
user@switch> show ethernet-switching table
Ethernet-switching table: 2 entries, 1 learned
 VLAN MAC address Type Age Interfaces
 default * Flood - All-members
 default 00:1f:12:39:90:80 Learn 29 xe-0/0/0.0
```

#### Related Documentation

- [Understanding MAC Learning on page 2138](#)
- [Example: Disabling MAC Learning on page 2139](#)
- *no-mac-learning*

## Example: Disabling MAC Learning

By default, MAC learning is enabled on the QFX Series. This topic provides examples for disabling, enabling, and verifying the operation of MAC learning on the QFX Series. These examples require that you be logged in as the root user to the switch on which you wish to modify MAC learning.

**NOTE:** This task uses Junos OS for QFX3500, QFX3600, EX4600, QFX5100, and QFX10002 switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Example: Disabling MAC Learning*. For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 41](#).

- To disable MAC learning in a VLAN:

```
[edit]
user@switch# set vlans vlan10 switch-options interface xe-0/0/0.0 no-mac-learning
```

- To reenabling MAC learning:

```
[edit] vlans vlan10 switch-options interface xe-0/0/0.0
user@switch# delete no-mac-learning
```

- To verify the status of MAC learning on the QFX Series:

```
user@switch> show ethernet-switching table
Learning stats: 10 learn msg rcvd, 2 error, 0 forced update
Interface Local pkts Transit pkts Error
xe-0/0/0.0 0 6 1
```

|             |   |   |   |
|-------------|---|---|---|
| xe-0/0/22.0 | 0 | 0 | 0 |
| xe-0/0/1.0  | 0 | 4 | 1 |
| xe-0/0/2.0  | 0 | 0 | 0 |
| xe-0/0/3.0  | 0 | 0 | 0 |
| xe-0/0/4.0  | 0 | 0 | 0 |
| xe-0/0/19.0 | 0 | 0 | 0 |
| xe-0/0/18.0 | 0 | 0 | 0 |
| xe-0/0/9.0  | 0 | 0 | 0 |

- Related Documentation**
- [Understanding MAC Learning on page 2138](#)
  - [Disabling MAC Learning on page 2138](#)

## Configuring MAC Notification (CLI Procedure)

**NOTE:** This task uses the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Configuring MAC Notification (CLI Procedure)* or *Configuring MAC Notification*. For ELS details, see “[Getting Started with Enhanced Layer 2 Software](#)” on page 41.

When a switch learns or unlearns a MAC address, SNMP notifications can be sent to the network management system at regular intervals to record the addition or removal of the MAC address. This process is known as MAC notification.

The MAC notification interval defines how often Simple Network Management Protocol (SNMP) notifications logging the addition or removal of MAC addresses on the switch are sent to the network management system.

MAC notification is disabled by default. When MAC notification is enabled, the default MAC notification interval is 30 seconds.

To enable or disable MAC notification, or to set the MAC notification interval, perform these tasks:

- [Enabling MAC Notification on page 2140](#)
- [Disabling MAC Notification on page 2141](#)
- [Setting the MAC Notification Interval on page 2141](#)

### Enabling MAC Notification

MAC notification is disabled by default. You need to perform this procedure to enable MAC notification.

To enable MAC notification on the switch with the default MAC notification interval of 30 seconds:

```
[edit switch-options]
user@switch# set mac-notification
```

To enable MAC notification on the switch with any other MAC notification interval (here, the MAC notification interval is set to 60 seconds):

```
[edit switch-options]
user@switch# set mac-notification notification-interval 60
```

## Disabling MAC Notification

MAC notification is disabled by default. Perform this procedure only if MAC notification was previously enabled on your switch.

To disable MAC notification on the switch:

```
[edit switch-options]
user@switch# delete mac-notification
```

To disable MAC notification on a specific interface (here, the interface is ge-0/0/3):

```
[edit switch-options]
user@switch# set interface ge-0/0/3 no-mac-notification
```

## Setting the MAC Notification Interval

The default MAC notification interval is 30 seconds. The procedure to change the MAC notification interval to a different interval is identical to the procedure to enable MAC notification on the switch with a nondefault value for the MAC notification interval.

To set the MAC notification interval on the switch (here, the MAC notification interval is set to 5 seconds):

```
[edit switch-options]
user@switch# set mac-notification notification-interval 5
```

**Related Documentation**

- *Verifying That MAC Notification Is Working Properly*

## Verifying That MAC Notification Is Working Properly

**Purpose** Verify that MAC notification is enabled or disabled, and that the MAC notification interval is set to the specified value.

**Action** To verify that MAC notification is enabled or disabled and also to verify the MAC notification interval setting.

```
user@switch> show ethernet-switching mac-notification
Notification Status: Enabled
Notification Interval: 60
Notifications Sent : 0
Notifications Table Maxsize : 256
```

**Meaning** The output in the **Notification Status** field shows that MAC notification is enabled. The output in the **Notification Status** field would display **Disabled** if MAC notification was disabled.

The **Notification Interval** field output shows that the MAC notification interval is set to 60 seconds.

- Related Documentation**
- [Configuring MAC Notification](#)
  - [Configuring MAC Notification \(CLI Procedure\) on page 2140](#)

---

## Configuring MAC Limiting (CLI Procedure)

---

**NOTE:** This task uses Junos OS for EX Series switches and QFX3500 and QFX3600 switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see [Configuring MAC Limiting \(CLI Procedure\)](#). For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 41](#).

This topic describes various ways of configuring a limitation on MAC addresses in packets that are received and forwarded by the switch.

**NOTE:** On a QFX Series Virtual Chassis, if you include the shutdown option at the [edit vlans *vlan-name* switch-options interface *interface-name* interface-mac-limit packet-action] hierarchy level and issue the commit operation, the system generates a commit error. The system does not generate an error if you include the shutdown option at the [edit switch-options interface *interface-name* interface-mac-limit packet-action] hierarchy level.

The different ways of setting a MAC limit are described in the following sections:

- [Limiting the Number of MAC Addresses Learned by an Interface on page 2143](#)
- [Limiting the Number of MAC Addresses Learned by a VLAN on page 2143](#)

## Limiting the Number of MAC Addresses Learned by an Interface

To secure a port, you can set the maximum number of MAC addresses that can be learned by an interface:

- Set the MAC limit on an interface, and specify an action that the switch takes after the specified limit is exceeded:

```
[edit switch-options]
user@switch# set interface interface-name interface-mac-limit limit packet-action
action
```

After you set a new MAC limit for the interface, the system clears existing entries in the MAC address forwarding table associated with the interface.

## Limiting the Number of MAC Addresses Learned by a VLAN

To limit the number of MAC addresses learned by a VLAN, perform both of the following steps:

- Set the maximum number of MAC addresses that can be learned by a VLAN, and specify an action that the switch takes after the specified limit is exceeded:

```
[edit vlans]
user@switch# set vlan-name switch-options mac-table-size limit packet-action
action
```

- Set the maximum number of MAC addresses that can be learned by one or all interfaces in the VLAN, and specify an action that the switch takes after the specified limit is exceeded:

```
[edit vlans]
user@switch# set vlan-name switch-options interface interface-name
interface-mac-limit limit packet-action action
[edit vlans]
user@switch# set vlan-name switch-options interface-mac-limit limit packet-action
action
```

**NOTE:** If you specify a MAC limit and packet action for all interfaces in the VLAN *and* a specific interface in the VLAN, the MAC limit and packet action specified at the specific interface level takes precedence. Also, at the VLAN interface level, only the drop and drop-and-log options are supported.

After you set new MAC limits for a VLAN by using the **mac-table-size** statement or for interfaces associated with a VLAN by using the **interface-mac-limit** statement, the system clears the corresponding existing entries in the MAC address forwarding table.

### Related Documentation

- [Understanding Bridging and VLANs on EX Series Switches](#)
- [Configuring Persistent MAC Learning \(CLI Procedure\) on page 6035](#)

## Configuring MAC Table Aging

---

MAC table aging ensures that a switch tracks only active nodes on the network and that it is able to flush out network nodes that are no longer available.

To manage MAC entries more efficiently, you can configure the maximum time that entries can remain in the MAC address table before being deleted.

**NOTE:** This task uses Junos OS for QFX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 41](#).

You can use the **global-mac-table-aging-time** command to configure how long entries remain in the Ethernet switching table before expiring, as follows:

```
[edit protocols 12-learning]
user@switch# set global-mac-table-aging-time 200
```

**NOTE:** This command applies to all VLANs configured for the switch. You cannot configure separate MAC table aging times for specific VLANs.

## Overview of Spanning-Tree Protocols

---

QFX Series switches provide Layer 2 loop prevention through Spanning Tree Protocol (STP), Rapid Spanning Tree Protocol (RSTP), Multiple Spanning Tree Protocol (MSTP), and VLAN Spanning Tree Protocol (VSTP). The default spanning-tree protocol on the QFX Series is RSTP. RSTP provides faster convergence times than STP. However, some legacy networks require the slower convergence times of basic STP.

The STP support provided for the QFX Series includes:

- IEEE 802.1d
- 802.1w RSTP
- 802.1s MSTP

If your network includes IEEE 802.1D 1998 bridges, you can remove RSTP and explicitly configure STP. When you explicitly configure STP, the QFX Series products use the IEEE 802.1D 2004 specification, force version 0. This configuration runs a version of RSTP that is compatible with the classic, basic STP. If you use virtual LANs (VLANs), you should enable VSTP and use it on your network. See [“Understanding VSTP” on page 2191](#).

You can use the same operational commands (**show spanning-tree bridge** and **show spanning-tree interface**) to check the status of your spanning-tree configuration, regardless of which spanning-tree protocol has been configured.

STP uses bridge protocol data unit (BPDU) packets to exchange information with other switches. BPDUs send hello packets out at regular intervals to exchange information across bridges and detect loops in a network topology. There are two types of BPDUs:

- Configuration BPDUs—These BPDUs contain configuration information about the transmitting switch and its ports, including switch and port MAC addresses, switch priority, port priority, and port cost.
- Topology change notification (TCN) BPDUs—When a bridge needs to signal a topology change, it starts to send TCNs on its root port. The designated bridge receives the TCN, acknowledges it, and generates another one for its own root port. The process continues until the TCN reaches the root bridge.

STP uses the information provided by the BPDUs to elect a root bridge, identify root ports for each switch, identify designated ports for each physical LAN segment, and prune specific redundant links to create a loop-free tree topology. All leaf devices calculate the best path to the root device and place their ports in blocking or forwarding states based on the best path to the root. The resulting tree topology provides a single active Layer 2 data path between any two end stations.

## Understanding Spanning Tree Protocols on a QFabric System

Although there is no need to run STP in a QFabric system, you can connect a QFabric system to another Layer 2 device and use STP. STP traffic can only be processed on network Node groups. Other Node groups, such as redundant server Node groups and server Node groups, discard the STP bridge protocol data units (BPDUs) traffic and disable the

interface automatically. Server Node groups only process host-facing protocols, whereas Network Node groups process all supported protocols.

## Understanding MSTP

Although RSTP provides faster convergence time than STP does, it still does not solve a problem inherent in STP: all VLANs within a LAN must share the same spanning tree. To solve this problem, the QFX Series products use Multiple Spanning Tree Protocol (MSTP) to create a loop-free topology in networks with multiple spanning-tree regions.

An MSTP region allows a group of bridges to be modeled as a single bridge. An MSTP region contains multiple spanning-tree instances (MSTIs). MSTIs provide different paths for different VLANs. This functionality facilitates more efficient load sharing across redundant links.

An MSTP region can support up to 64 MSTIs, and each instance can support from 1 through 4094 VLANs.

## Example: Configuring Network Regions for VLANs with MSTP

**NOTE:** This example uses Junos OS for EX Series and QFX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Example: Configuring Network Regions for VLANs with MSTP on EX Series Switches*. For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 41](#).

Multiple Spanning Tree Protocol (MSTP) is used to create a loop-free topology in networks using multiple spanning-tree regions in which each region contains multiple spanning-tree instances (MSTIs). MSTIs provide different paths for different VLANs. This functionality facilitates better load sharing across redundant links.

Up to 64 MSTIs can be created for an EX Series switch, and each MSTI can support up to 4094 VLANs.

This example describes how to configure MSTP on four EX Series switches:

- [Requirements on page 2150](#)
- [Overview and Topology on page 2150](#)
- [Configuring MSTP on Switch 1 on page 2153](#)
- [Configuring MSTP on Switch 2 on page 2156](#)
- [Configuring MSTP on Switch 3 on page 2158](#)
- [Configuring MSTP on Switch 4 on page 2161](#)
- [Verification on page 2163](#)

## Requirements

This example uses the following software and hardware components:

- Junos OS Release 13.2X50-D10 or later for EX Series switches
- Four EX Series switches

Before you configure the switches for MSTP, be sure you have:

- Installed and connected the four switches. See the hardware documentation for your switch.
- Performed the initial software configuration on all switches. See *Connecting and Configuring an EX Series Switch (CLI Procedure)* or *Connecting and Configuring an EX Series Switch (J-Web Procedure)*.

## Overview and Topology

When the number of VLANs grows in a network, MSTP provides an efficient way of creating a loop-free topology by using MSTIs. Each MSTI in the spanning-tree domain maintains its own tree. Each tree can be mapped to different links, utilizing bandwidth that would be unavailable to a single tree. MSTIs reduce the demand on system resources.

Figure 24: Network Topology for MSTP

The interfaces shown in Figure 24 will be configured for MSTP.

**NOTE:** You can configure MSTP only on physical interfaces, not on logical interfaces.

Table 188: Components of the Topology for Configuring MSTP on EX Series Switches

| Property | Settings                                                                                                                                                                                                                                             |

| MSTI region            | <b>region1</b>                                                                                                                                                                                                                                                                 |

The topology in [Figure 24](#) shows a common and internal spanning tree (CIST). The CIST is a single spanning tree connecting all devices in the network. The switch with the lowest bridge priority is elected as the root bridge of the CIST. You can control the election of the root bridge by configuring the bridge priority. Switch 3 is the root bridge of the CIST.

The ports in an MSTP topology have specific roles:

- The *root port* is responsible for forwarding data to the root bridge.
- The *alternate port* is a standby port for the root port. When a root port goes down, the alternate port becomes the active root port.
- The *designated port* forwards data to the downstream network segment or device.
- The *backup port* becomes the active designated port and starts forwarding data when the designated port goes down.

In this example, one MSTP region contains Switch 1, Switch 2, Switch 3, and Switch 4. Within the region, four VLANs are created:

- **voice-vlan** supports voice traffic and has the VLAN tag identifier of **10**.
- **employee-vlan** supports data traffic and has the VLAN tag identifier of **20**.
- **guest-vlan** supports guest VLAN traffic (for supplicants that fail authentication) and has the VLAN tag identifier of **30**.
- **camera-vlan** supports video traffic and has the VLAN tag identifier of **40**.

The VLANs are associated with specific interfaces on each of the four switches. Two MSTIs, 1 and 2, are then associated with the VLAN tag identifiers, and some MSTP parameters, such as cost, are configured on each switch.

## Configuring MSTP on Switch 1

**CLI Quick Configuration** To quickly configure interfaces and MSTP on Switch 1, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans voice-vlan description "Voice VLAN"
set vlans voice-vlan vlan-id 10
set vlans employee-vlan description "Employee VLAN"
set vlans employee-vlan vlan-id 20
set vlans guest-vlan description "Guest VLAN"
set vlans guest-vlan vlan-id 30
set vlans camera-vlan description "Camera VLAN"
set vlans camera-vlan vlan-id 40
set interfaces ge-0/0/13 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/9 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/11 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/13 unit 0 family ethernet-switching interface-mode trunk
set interfaces ge-0/0/9 unit 0 family ethernet-switching interface-mode trunk
set interfaces ge-0/0/11 unit 0 family ethernet-switching interface-mode trunk
set protocols mstp configuration-name region1
set protocols mstp bridge-priority 16k
set protocols mstp interface ge-0/0/13 cost 1000
set protocols mstp interface ge-0/0/13 mode point-to-point
set protocols mstp interface ge-0/0/9 cost 1000
set protocols mstp interface ge-0/0/9 mode point-to-point
set protocols mstp interface ge-0/0/11 cost 1000
set protocols mstp interface ge-0/0/11 mode point-to-point
set protocols mstp msti 1 bridge-priority 16k
set protocols mstp msti 1 vlan [10 20]
set protocols mstp msti 1 interface ge-0/0/11 cost 1000
set protocols mstp msti 2 bridge-priority 8k
set protocols mstp msti 2 vlan [30 40]
```

**Step-by-Step Procedure** To configure interfaces and MSTP on Switch 1:

**NOTE:** Starting with Junos OS Release 15.1 for EX Series and QFX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style, you can configure spanning tree parameters globally on all spanning tree interfaces. See [“Configuring MSTP” on page 2170](#) for additional information.

1. Configure the VLANs **voice-vlan**, **employee-vlan**, **guest-vlan**, and **camera-vlan**:

```
[edit vlans]
user@switch1# set voice-vlan description "Voice VLAN"
user@switch1# set voice-vlan vlan-id 10
user@switch1# set employee-vlan description "Employee VLAN"
user@switch1# set employee-vlan vlan-id 20
user@switch1# set guest-vlan description "Guest VLAN"
user@switch1# set guest-vlan vlan-id 30
user@switch1# set camera-vlan description "Camera VLAN"
user@switch1# set guest-vlan vlan-id 40
```

2. Configure the VLANs on the interfaces, including support for the Ethernet Switching protocol:

```
[edit interfaces]
user@switch1# set ge-0/0/13 unit 0 family ethernet-switching vlan members [10 20 30 40]
user@switch1# set ge-0/0/9 unit 0 family ethernet-switching vlan members [10 20 30 40]
user@switch1# set ge-0/0/11 unit 0 family ethernet-switching vlan members [10 20 30 40]
```

3. Configure the port mode for the interfaces:

```
[edit interfaces]
user@switch1# set ge-0/0/13 unit 0 family ethernet-switching interface-mode trunk
user@switch1# set ge-0/0/9 unit 0 family ethernet-switching interface-mode trunk
user@switch1# set ge-0/0/11 unit 0 family ethernet-switching interface-mode trunk
```

4. Configure MSTP on the switch, including the two MSTIs:

```
[edit protocols]
user@switch1# mstp configuration-name region1
user@switch1# mstp bridge-priority 16k
user@switch1# mstp interface ge-0/0/13 cost 1000
user@switch1# mstp interface ge-0/0/13 mode point-to-point
user@switch1# mstp interface ge-0/0/9 cost 1000
user@switch1# mstp interface ge-0/0/9 mode point-to-point
user@switch1# mstp interface ge-0/0/11 cost 1000
user@switch1# mstp interface ge-0/0/11 mode point-to-point
user@switch1# mstp msti 1 bridge-priority 16k
user@switch1# mstp msti 1 vlan [10 20]
user@switch1# mstp msti 1 interface ge-0/0/11 cost 1000
user@switch1# mstp msti 2 bridge-priority 8k
user@switch1# mstp msti 2 vlan [30 40]
```

**Results** Check the results of the configuration:

```
user@switch1> show configuration
interfaces {
 ge-0/0/13 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members 10;
 members 20;
 members 30;
 members 40;
 }
 }
 }
 }
 ge-0/0/9 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members 10;
 members 20;
 members 30;
 }
 }
 }
 }
}
```

```

 members 40;
 }
}
}
ge-0/0/11 {
 unit 0 {

 }
 guest-vlan {
 vlan-id 30;
 }
}

```

```

 }
 camera-vlan {
 vlan-id 40;
 }
}

```

## Configuring MSTP on Switch 2

**CLI Quick Configuration** To quickly configure interfaces and MSTP on Switch 2, copy the following commands and paste them into the switch terminal window:

```

[edit]
set vlans voice-vlan description "Voice VLAN"
set vlans voice-vlan vlan-id 10
set vlans employee-vlan description "Employee VLAN"
set vlans employee-vlan vlan-id 20
set vlans guest-vlan description "Guest VLAN"
set vlans guest-vlan vlan-id 30
set vlans camera-vlan description "Camera VLAN"
set vlans camera-vlan vlan-id 40
set interfaces ge-0/0/14 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/18 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/14 unit 0 family ethernet-switching interface-mode trunk
set interfaces ge-0/0/18 unit 0 family ethernet-switching interface-mode trunk
set protocols mstp configuration-name region1
set protocols mstp bridge-priority 32k
set protocols mstp interface ge-0/0/14 cost 1000
set protocols mstp interface ge-0/0/14 mode point-to-point
set protocols mstp interface ge-0/0/18 cost 1000
set protocols mstp interface ge-0/0/18 mode point-to-point
set protocols mstp msti 1 bridge-priority 32k
set protocols mstp msti 1 vlan [10 20]
set protocols mstp msti 2 bridge-priority 4k
set protocols mstp msti 2 vlan [30 40]

```

**Step-by-Step Procedure** To configure interfaces and MSTP on Switch 2:

1. Configure the VLANs **voice-vlan**, **employee-vlan**, **guest-vlan**, and **camera-vlan**:
 

```

[edit vlans]
user@switch2# set voice-vlan description "Voice VLAN"
user@switch2# set voice-vlan vlan-id 10
user@switch2# set employee-vlan description "Employee VLAN"
user@switch2# set employee-vlan vlan-id 20
user@switch2# set guest-vlan description "Guest VLAN"
user@switch2# set guest-vlan vlan-id 30
user@switch2# set camera-vlan vlan-description "Camera VLAN"
user@switch2# set guest-vlan vlan-id 40

```
2. Configure the VLANs on the interfaces, including support for the Ethernet Switching protocol:
 

```

[edit interfaces]
user@switch2# set ge-0/0/14 unit 0 family ethernet-switching vlan members [10 20 30 40]
user@switch2# set ge-0/0/18 unit 0 family ethernet-switching vlan members [10 20 30 40]

```
3. Configure the port mode for the interfaces:
 

```

[edit interfaces]
user@switch2# set ge-0/0/14 unit 0 family ethernet-switching interface-mode trunk

```

- user@switch2# set ge-0/0/18 unit 0 family ethernet-switching interface-mode trunk
4. Configure MSTP on the switch, including the two MSTIs:

```
[edit protocols]
user@switch2# mstp configuration-name region1
user@switch2# mstp bridge-priority 32k
user@switch2# mstp interface ge-0/0/14 cost 1000
user@switch2# mstp interface ge-0/0/14 mode point-to-point
user@switch2# mstp interface ge-0/0/18 cost 1000
user@switch2# mstp interface ge-0/0/18 mode point-to-point
user@switch2# mstp msti 1 bridge-priority 32k
user@switch2# mstp msti 1 vlan [10 20]
user@switch2# mstp msti 2 bridge-priority 4k
user@switch2# mstp msti 2 vlan [30 40]
```

**Results** Check the results of the configuration:

```
user@switch2> show configuration
interfaces {
 ge-0/0/14 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members 10;
 members 20;
 members 30;

 vlan-id 20;
 }
 guest-vlan {
 vlan-id 30;
 }
 camera-vlan {
 vlan-id 40;
 }
}
```

### Configuring MSTP on Switch 3

**CLI Quick Configuration** To quickly configure interfaces and MSTP on Switch 3, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans voice-vlan description "Voice VLAN"
set vlans voice-vlan vlan-id 10
set vlans employee-vlan description "Employee VLAN"
set vlans employee-vlan vlan-id 20
set vlans guest-vlan description "Guest VLAN"
set vlans guest-vlan vlan-id 30
set vlans camera-vlan description "Camera VLAN"
set vlans camera-vlan vlan-id 40
set interfaces ge-0/0/26 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/28 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/24 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/26 unit 0 family ethernet-switching interface-mode trunk
set interfaces ge-0/0/28 unit 0 family ethernet-switching interface-mode trunk
set interfaces ge-0/0/24 unit 0 family ethernet-switching interface-mode trunk
set protocols mstp configuration-name region1
set protocols mstp bridge-priority 8k
set protocols mstp interface ge-0/0/26 cost 1000
set protocols mstp interface ge-0/0/26 mode point-to-point
set protocols mstp interface ge-0/0/28 cost 1000
set protocols mstp interface ge-0/0/28 mode point-to-point
set protocols mstp interface ge-0/0/24 cost 1000
set protocols mstp interface ge-0/0/24 mode point-to-point
set protocols mstp msti 1 bridge-priority 4k
set protocols mstp msti 1 vlan [10 20]
set protocols mstp msti 2 bridge-priority 16k
```

```
set protocols mstp msti 2 vlan [30 40]
```

### Step-by-Step Procedure

To configure interfaces and MSTP on Switch 3:

1. Configure the VLANs `voice-vlan`, `employee-vlan`, `guest-vlan`, and `camera-vlan`:

```
[edit vlans]
user@switch3# set voice-vlan description "Voice VLAN"
user@switch3# set voice-vlan vlan-id 10
user@switch3# set employee-vlan description "Employee VLAN"
user@switch3# set employee-vlan vlan-id 20
user@switch3# set guest-vlan description "Guest VLAN"
user@switch3# set guest-vlan vlan-id 30
user@switch3# set camera-vlan description "Camera VLAN"
user@switch3# set guest-vlan vlan-id 40
```

2. Configure the VLANs on the interfaces, including support for the Ethernet Switching protocol:

```
[edit interfaces]
user@switch3# set ge-0/0/26 unit 0 family ethernet-switching vlan members [10 20 30 40]
user@switch3# set ge-0/0/28 unit 0 family ethernet-switching vlan members [10 20 30 40]
user@switch3# set ge-0/0/24 unit 0 family ethernet-switching vlan members [10 20 30 40]
```

3. Configure the port mode for the interfaces:

```
[edit interfaces]
user@switch3# set ge-0/0/26 unit 0 family ethernet-switching interface-mode trunk
user@switch3# set ge-0/0/28 unit 0 family ethernet-switching interface-mode trunk
user@switch3# set ge-0/0/24 unit 0 family ethernet-switching interface-mode trunk
```

4. Configure MSTP on the switch, including the two MSTIs:

```
[edit protocols]
user@switch3# mstp configuration-name region1
user@switch3# mstp bridge-priority 8k
user@switch3# mstp interface ge-0/0/26 cost 1000
user@switch3# mstp interface ge-0/0/26 mode point-to-point
user@switch3# mstp interface ge-0/0/28 cost 1000
user@switch3# mstp interface ge-0/0/28 mode point-to-point
user@switch3# mstp interface ge-0/0/24 cost 1000
user@switch3# mstp interface ge-0/0/24 mode point-to-point
user@switch3# mstp msti 1 bridge-priority 4k
user@switch3# mstp msti 1 vlan [10 20]
user@switch3# mstp msti 2 bridge-priority 16k
user@switch3# mstp msti 2 vlan [30 40]
```

**Results** Check the results of the configuration:

```
user@switch3> show configuration
interfaces {
 ge-0/0/26 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members 10;
 members 20;
 members 30;
 members 40;
```

```
 }
 }
}
ge-0/0/28 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members 10;
 members 20;
 members 30;
 members 40;
 }
 }
 }
}
ge-0/0/24 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members 10;
 members 20;
 members 30;
 members 40;
 }
 }
 }
}
}
}
}
protocols {
 mstp {
 configuration-name region1;
 bridge-priority 8k;
 interface ge-0/0/26 {
 cost 1000;
 mode point-to-point;
 }
 interface ge-0/0/28 {
 cost 1000;
 mode point-to-point;
 }
 interface ge-0/0/24 {
 cost 1000;
 mode point-to-point;
 }
 msti 1 {
 bridge-priority 4k;
 vlan [10 20];
 }
 msti 2 {
 bridge-priority 16k;
 vlan [30 40];
 }
 }
}
```

```

 }
 }
 vlans {
 voice-vlan {
 vlan-id 10;
 }
 employee-vlan {
 vlan-id 20;
 }
 guest-vlan {
 vlan-id 30;
 }
 camera-vlan {
 vlan-id 40;
 }
 }
}

```

## Configuring MSTP on Switch 4

**CLI Quick Configuration** To quickly configure interfaces and MSTP on Switch 4, copy the following commands and paste them into the switch terminal window:

```

[edit]
set vlans voice-vlan description "Voice VLAN"
set vlans voice-vlan vlan-id 10
set vlans employee-vlan description "Employee VLAN"
set vlans employee-vlan vlan-id 20
set vlans guest-vlan description "Guest VLAN"
set vlans guest-vlan vlan-id 30
set vlans camera-vlan description "Camera VLAN"
set vlans camera-vlan vlan-id 40
set interfaces ge-0/0/23 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/19 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/23 unit 0 family ethernet-switching interface-mode trunk
set interfaces ge-0/0/19 unit 0 family ethernet-switching interface-mode trunk
set protocols mstp configuration-name region1
set protocols mstp bridge-priority 16k
set protocols mstp interface ge-0/0/23 cost 1000
set protocols mstp interface ge-0/0/23 mode point-to-point
set protocols mstp interface ge-0/0/19 cost 1000
set protocols mstp interface ge-0/0/19 mode point-to-point
set protocols mstp msti 1 bridge-priority 16k
set protocols mstp msti 1 vlan [10 20]
set protocols mstp msti 2 bridge-priority 32k
set protocols mstp msti 2 vlan [30 40]

```

**Step-by-Step Procedure** To configure interfaces and MSTP on Switch 4:

1. Configure the VLANs **voice-vlan**, **employee-vlan**, **guest-vlan**, and **camera-vlan**:

```

[edit vlans]
user@switch4# set voice-vlan description "Voice VLAN"
user@switch4# set voice-vlan vlan-id 10
user@switch4# set employee-vlan description "Employee VLAN"
user@switch4# set employee-vlan vlan-id 20
user@switch4# set guest-vlan description "Guest VLAN"
user@switch4# set guest-vlan vlan-id 30
user@switch4# set camera-vlan description "Camera VLAN"
user@switch4# set camera-vlan vlan-id 40

```

2. Configure the VLANs on the interfaces, including support for the Ethernet Switching protocol:

```
[edit interfaces]
user@switch4# set ge-0/0/23 unit 0 family ethernet-switching vlan members [10 20 30 40]
user@switch4# set ge-0/0/19 unit 0 family ethernet-switching vlan members [10 20 30 40]
```

3. Configure the port mode for the interfaces:

```
[edit interfaces]
user@switch4# set ge-0/0/23 unit 0 family ethernet-switching interface-mode trunk
user@switch4# set ge-0/0/19 unit 0 family ethernet-switching interface-mode trunk
```

4. Configure MSTP on the switch, including the two MSTIs:

```
[edit protocols]
user@switch4# mstp configuration-name region1
user@switch4# mstp bridge-priority 16k
user@switch4# mstp interface ge-0/0/23 cost 1000
user@switch4# mstp interface ge-0/0/23 mode point-to-point
user@switch4# mstp interface ge-0/0/19 cost 1000
user@switch4# mstp interface ge-0/0/19 mode point-to-point
user@switch4# mstp msti 1 bridge-priority 16k
user@switch4# mstp msti 1 vlan [10 20]
user@switch4# mstp msti 2 bridge-priority 32k
user@switch4# mstp msti 2 vlan [30 40]
```

**Results** Check the results of the configuration:

```
user@switch4> show configuration
interfaces {
 ge-0/0/23 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members 10;
 members 20;
 members 30;
 members 40;
 }
 }
 }
 }
 ge-0/0/19 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members 10;
 members 20;
 members 30;
 members 40;
 }
 }
 }
 }
}
```

```

protocols {
 mstp {
 configuration-name region1;
 bridge-priority 16k;
 interface ge-0/0/23 {
 cost 1000;
 mode point-to-point;
 }
 interface ge-0/0/19 {
 cost 1000;
 mode point-to-point;
 }
 msti 1 {
 bridge-priority 16k;
 vlan [10 20];
 }
 msti 2 {
 bridge-priority 32k;
 vlan [30 40];
 }
 }
}
vlands {
 voice-vlan {
 vlan-id 10;
 }
 employee-vlan {
 vlan-id 20;
 }
 guest-vlan {
 vlan-id 30;
 }
 camera-vlan {
 vlan-id 40;
 }
}
}

```

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying MSTP Configuration on Switch 1 on page 2163](#)
- [Verifying MSTP Configuration on Switch 2 on page 2165](#)
- [Verifying MSTP Configuration on Switch 3 on page 2166](#)
- [Verifying MSTP Configuration on Switch 4 on page 2168](#)

### Verifying MSTP Configuration on Switch 1

**Purpose** Verify the MSTP configuration on Switch 1.

**Action** Issue the operational mode commands **show spanning-tree interface** and **show spanning-tree bridge**:

```
user@switch1> show spanning-tree interface
```

## Spanning tree interface parameters for instance 0

| Interface | Port ID | Designated<br>port ID | Designated<br>bridge ID | Port<br>Cost | State | Role |
|-----------|---------|-----------------------|-------------------------|--------------|-------|------|
| ge-0/0/9  | 128:490 | 128:490               | 16384.4c9614e9f841      | 1000         | BLK   | DIS  |
| ge-0/0/11 | 128:491 | 128:491               | 16384.4c9614e9f841      | 1000         | BLK   | DIS  |
| ge-0/0/13 | 128:492 | 128:492               | 16384.4c9614e9f841      | 1000         | BLK   | DIS  |

## Spanning tree interface parameters for instance 1

| Interface | Port ID | Designated<br>port ID | Designated<br>bridge ID | Port<br>Cost | State | Role |

**Meaning** The operational mode command **show spanning-tree interface** displays spanning-tree domain information such as the designated port and the port roles.

The operational mode command **show spanning-tree bridge** displays the spanning-tree domain information at either the bridge level or the interface level. If the optional interface name is omitted, all interfaces in the spanning-tree domain are displayed.

### Verifying MSTP Configuration on Switch 2

**Purpose** Verify the MSTP configuration on Switch 2.

**Action** Issue the operational mode commands **show spanning-tree interface** and **show spanning-tree bridge**:

```
user@switch2> show spanning-tree interface
```

Spanning tree interface parameters for instance 0

| Interface | Port ID | Designated<br>port ID | Designated<br>bridge ID | Port<br>Cost | State | Role |

```

**Meaning** The operational mode command **show spanning-tree interface** displays spanning-tree domain information such as the designated port and the port roles. The spanning-tree interface parameters for instance 2 show that both ports are designated ports, which means Switch 2 is the root bridge for this instance.

The operational mode command **show spanning-tree bridge** displays the spanning-tree domain information at either the bridge level or interface level. If the optional interface name is omitted, all interfaces in the spanning-tree domain are displayed.

### Verifying MSTP Configuration on Switch 3

**Purpose** Verify the MSTP configuration on Switch 3.

**Action** Issue the operational mode commands **show spanning-tree interface** and **show spanning-tree bridge**:

```
user@switch3> show spanning-tree interface
```

```
Spanning tree interface parameters for instance 0
```

| Interface | Port ID | Designated<br>port ID | Designated<br>bridge ID | Port<br>Cost | State | Role |

**Meaning** The operational mode command **show spanning-tree interface** displays spanning-tree domain information such as the designated port and the port roles. Switch 3 is the root bridge for instance 0, which is the CIST, as well as for instance 1. In both instances, all ports on Switch 3 are designated ports.

The operational mode command **show spanning-tree bridge** displays the spanning-tree domain information at either the bridge level or the interface level. If the optional interface name is omitted, all interfaces in the spanning-tree domain are displayed.

### Verifying MSTP Configuration on Switch 4

**Purpose** Verify the MSTP configuration on Switch 4.

**Action** Issue the operational mode commands **show spanning-tree interface** and **show spanning-tree bridge**:

```
user@switch4> show spanning-tree interface
```

```
Spanning tree interface parameters for instance 0
```

**Meaning** The operational mode command **show spanning-tree interface** displays spanning-tree domain information such as the designated port and the port roles.

The operational mode command **show spanning-tree bridge** displays the spanning-tree domain information at either the bridge level or the interface level. If the optional interface name is omitted, all interfaces in the spanning-tree domain are displayed.

## Configuring MSTP

You can configure the Multiple Spanning Tree Protocol (MSTP) under **[edit protocols]**.

To configure the Multiple Spanning Tree Protocol:

1. Enable MSTP as the version of spanning-tree protocol to be configured:

```
[edit]
user@switch# edit ... protocols mstp
```

2. Configure the interfaces that participate in the MSTP instance.

- Configure a specific interface:

- a. Enable MSTP on the specified interface:

```
[edit ... protocols mstp]
user@switch# edit interface interface-name
```

- b. Configure the interface priority:

```
[edit ... protocols mstp interface interface-name]
user@switch# set priority interface-priority
```

- c. (Optional) By default, the interface link cost is determined by the link speed. You can configure the interface link cost to control which bridge is the designated bridge and which port is the designated port:

```
[edit ... protocols mstp interface interface-name]
user@switch# set cost interface-link-cost
```

- d. Configure the interface link mode to identify point-to-point links:

```
[edit ... protocols mstp interface interface-name]
user@switch# set mode (p2p | shared)
```

Specify **p2p** if the link is point to point. Specify **shared** if the link is a shared media.

- e. (Optional) Configure the interface as an edge port:

```
[edit ... protocols mstp interface interface-name]
user@switch# set edge
```

Edge ports do not expect to receive bridge protocol data unit (BPDU) packets. If a BPDU packet is received for an edge port, the port becomes a nonedge port.

- f. (Optional) Disable MSTP on a specific interface:

```
[edit ... protocols mstp interface interface-name]
user@switch# set disable
```

- Enable MSTP on all the interfaces:

**NOTE:** You *cannot* disable MSTP on all the interfaces.

- a. Enable MSTP on all interfaces:

```
[edit ... protocols mstp]
user@switch# set interface all
```

You can also enable BPDU root protection for all spanning-tree protocol instances

on the interface. BPDU root protect ensures the port is the spanning-tree designated port. If the port receives superior BPDU packets, root protect moves this port to a root-prevented spanning-tree state. For configuration details, see *Checking the Status of Spanning-Tree Instance Interfaces*.

3. Configure the bridge priority

```
[edit ... protocols mstp]
user@switch# set bridge-priority bridge-priority
```

For more information, see *Bridge Priority for Election of Root Bridge and Designated Bridge*.

4. Configure hello BPDU timers.

a. Configure the maximum expected arrival time of hello BPDUs:

```
[edit ... protocols mstp]
user@switch# set max-age seconds
```

b. Configure the time interval at which the root bridge transmits configuration BPDUs:

```
[edit ... protocols mstp]
user@switch# set hello-time seconds
```

5. (Optional) By default, the bridge port remains in the listening and learning states for 15 seconds before transitioning to the forwarding state. You can specify a delay from 4 through 20 seconds instead:

```
[edit ... protocols mstp]
user@switch# set forward-delay seconds
```

6. Configure MSTP-specific options.

a. Configure the MSTP region configuration name:

```
[edit ... protocols mstp]
user@switch# set configuration-name configuration-name
```

b. Configure the MSTP revision level:

```
[edit ... protocols mstp]
user@switch# set revision-level revision-level
```

c. Configure the maximum number of hops a BPDU can be forwarded in the MSTP region:

```
[edit ... protocols mstp]
user@switch# set max-hops hops
```

## Understanding RSTP

---

Juniper Networks QFX Series products use Rapid Spanning Tree Protocol (RSTP) on the network side of the QFX Series to provide quicker convergence time than the base Spanning Tree Protocol (STP) does. RSTP identifies certain links as point to point. When a point-to-point link fails, the alternate link can transition to the forwarding state, which speeds up convergence.

Although STP provides basic loop prevention functionality, it does not provide fast network convergence when there are topology changes. The STP process to determine network state transitions is slower than the RSTP process because it is timer-based. A device must reinitialize every time a topology change occurs. The device must start in the listening state and transition to the learning state and eventually to a forwarding or blocking state. When default values are used for the maximum age (20 seconds) and forward delay (15 seconds), it takes 50 seconds for the device to converge. RSTP converges faster because it uses a handshake mechanism based on point-to-point links instead of the timer-based process used by STP.

For networks with virtual LANs (VLANs), you can use VLAN Spanning Tree Protocol (VSTP), which takes the paths of each VLAN into account when calculating routes. VSTP uses RSTP by default.

An RSTP domain running from the edge outward on a QFX Series product has the following components:

- A *root port*, which is the “best path” to the root device.
- A *designated port*, which indicates that the switch is the designated bridge for the other switch connecting to this port.
- An *alternate port*, which provides an alternate root port.
- A *backup port*, which provides an alternate designated port.

Port assignments change through messages exchanged throughout the domain. An RSTP device generates configuration messages once per hello time interval. If an RSTP device does not receive a configuration message from its neighbor after an interval of three hello times, it determines that the connection with the neighbor is lost. When a *root port* or a *designated port* fails on a device, the device generates a configuration message with the proposal bit set. Once its neighbor device receives this message, it verifies that this configuration message is valid for that port and starts a *synchronizing* operation to ensure that all of its ports are in sync with the new information.

Similar sets of messages propagate through the network, restoring the connectivity very quickly after a topology change (in a well-designed network that uses RSTP, network convergence can take as little as 0.5 seconds). If a device does not receive an agreement to a proposal message it has sent, it returns to the original IEEE 802.D convention.

RSTP was originally defined in the IEEE 802.1w draft specification and later incorporated into the IEEE 802.1D-2004 specification.

VSTP and RSTP can be configured at the same time. If you configure VSTP and RSTP at the same time and the switch has more than 253 VLANs, VSTP is configured only for the first 253 VLANs. For the remaining VLANs, only RSTP is configured. RSTP and VSTP are the only spanning-tree protocols that can be configured at the same time on the QFX Series.

## Example: Configuring Faster Convergence and Improved Network Stability with RSTP

**NOTE:** This example uses Junos OS for EX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Example: Faster Convergence and Improved Network Stability with RSTP on EX Series Switches*. For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 41](#).

EX Series switches use Rapid Spanning Tree Protocol (RSTP) by default to provide a loop-free topology.

When switches that support redundant Routing Engines use RSTP, it is important to keep RSTP synchronized on both Routing Engines so that no loss of service occurs after a Routing Engine switchover. Nonstop bridging protocol keeps Routing Engines synchronized.

This example describes how to configure RSTP and NSB on four EX Series switches:

- [Requirements on page 2173](#)
- [Overview and Topology on page 2174](#)
- [Configuring RSTP and Nonstop Bridging on Switch 1 on page 2176](#)
- [Configuring RSTP and Nonstop Bridging on Switch 2 on page 2179](#)
- [Configuring RSTP and Nonstop Bridging on Switch 3 on page 2182](#)
- [Configuring RSTP and Nonstop Bridging on Switch 4 on page 2185](#)
- [Verification on page 2188](#)

## Requirements

This example uses the following software and hardware components:

- Junos OS Release 15.1 or later or later for EX Series switches

- Four EX Series switches

Before you configure the switches for RSTP, be sure you have:

- Installed and connected the four switches. See the hardware documentation for your switch.
- Performed the initial software configuration on all switches. See *Connecting and Configuring an EX Series Switch (CLI Procedure)* or *Connecting and Configuring an EX Series Switch (J-Web Procedure)*.

## Overview and Topology

RSTP works by identifying certain links as point to point links and blocking other possible paths. When one of the point-to-point links fails, a designated alternate link transitions to the forwarding state and take over. Configuring nonstop bridging (NSB) on a switch with redundant Routing Engines keeps RSTP synchronized on both Routing Engines. This way, RSTP remains active immediately after a switchover because it is already synchronized to the backup Routing Engine. RSTP does not have to reconverge after a Routing Engine switchover when NSB is enabled because the neighbor devices do not detect an RSTP change on the switch. In this example, four EX Series switches are connected in the topology displayed in [Figure 25](#) to create a loop-free topology with NSB applied to switches with dual Routing Engines.

Figure 25: Network Topology for RSTP

[Table 189](#) shows the components of the topology for this example.

**NOTE:** You can configure RSTP only on physical interfaces, not on logical interfaces.

Table 189: Components of the Topology for Configuring RSTP

| Property               | Settings                                                                                                                                                                                                                                                                              |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Switch 1               | The following interfaces on Switch 1 are connected in this way: <ul style="list-style-type: none"><li>• <code>ge-0/0/9</code> is connected to Switch 2</li><li>• <code>ge-0/0/13</code> is connected to Switch 4</li><li>• <code>ge-0/0/11</code> is connected to Switch 3</li></ul>  |
| Switch 2               | The following interfaces on Switch 2 are connected in this way: <ul style="list-style-type: none"><li>• <code>ge-0/0/14</code> is connected to Switch 1</li><li>• <code>ge-0/0/18</code> is connected to Switch 3</li></ul>                                                           |
| Switch 3               | The following interfaces on Switch 3 are connected in this way: <ul style="list-style-type: none"><li>• <code>ge-0/0/26</code> is connected to Switch 1</li><li>• <code>ge-0/0/28</code> is connected to Switch 2</li><li>• <code>ge-0/0/24</code> is connected to Switch 4</li></ul> |
| Switch 4               | The following interfaces on Switch 4 are connected in this way: <ul style="list-style-type: none"><li>• <code>ge-0/0/19</code> is connected to Switch 1</li><li>• <code>ge-0/0/23</code> is connected to Switch 3</li></ul>                                                           |
| VLAN names and tag IDs | <code>voice-vlan</code> , tag 10<br><code>employee-vlan</code> , tag 20<br><code>guest-vlan</code> , tag 30<br><code>camera-vlan</code> , tag 40                                                                                                                                      |

This configuration example creates a loop-free topology between four EX Series switches using RSTP.

An RSTP topology contains ports that have specific roles:

- The *root port* is responsible for forwarding data to the root bridge.
- The *alternate port* is a standby port for the root port. When a root port goes down, the alternate port becomes the active root port.
- The *designated port* forwards data to the downstream network segment or device.
- The *backup port* is a backup port for the designated port. When a designated port goes down, the backup port becomes the active designated port and starts forwarding data.

**NOTE:** You also can create a loop-free topology between the aggregation layer and the distribution layer using redundant trunk links. For more information about configuring redundant trunk links, see [“Example: Configuring Redundant Trunk Links for Faster Recovery”](#) on page 2903.

## Configuring RSTP and Nonstop Bridging on Switch 1

**CLI Quick Configuration** To quickly configure RSTP and nonstop bridging on Switch 1, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans voice-vlan description "Voice VLAN"
set vlans voice-vlan vlan-id 10
set vlans employee-vlan description "Employee VLAN"
set vlans employee-vlan vlan-id 20
set vlans guest-vlan description "Guest VLAN"
set vlans guest-vlan vlan-id 30
set vlans camera-vlan description "Camera VLAN"
set vlans camera-vlan vlan-id 40
set interfaces ge-0/0/13 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/9 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/11 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/13 unit 0 family ethernet-switching interface-mode trunk
set interfaces ge-0/0/9 unit 0 family ethernet-switching interface-mode trunk
set interfaces ge-0/0/11 unit 0 family ethernet-switching interface-mode trunk
set protocols rstp bridge-priority 16k
set protocols rstp interface all cost 1000
set protocols rstp interface all mode point-to-point
```

If Switch 1 includes dual Routing Engines, configure NSB. To quickly configure nonstop bridging on Switch 1, copy the following commands and paste them into the switch terminal window:

```
set chassis redundancy graceful switchover
set system commit synchronize
set protocols layer2-control nonstop-bridging
```

**Step-by-Step Procedure** To configure RSTP and nonstop bridging on Switch 1:

1. Configure the VLANs **voice-vlan**, **employee-vlan**, **guest-vlan**, and **camera-vlan**:

```
[edit vlans]
user@switch1# set voice-vlan description "Voice VLAN"
user@switch1# set voice-vlan vlan-id 10
user@switch1# set employee-vlan description "Employee VLAN"
user@switch1# set employee-vlan vlan-id 20
user@switch1# set guest-vlan description "Guest VLAN"
user@switch1# set guest-vlan vlan-id 30
user@switch1# set camera-vlan description "Camera VLAN"
user@switch1# set camera-vlan vlan-id 40
```

2. Configure the VLANs on the interfaces, including support for the Ethernet switching protocol:

```
[edit interfaces]
user@switch1# set ge-0/0/13 unit 0 family ethernet-switching vlan members [10 20 30 40]
user@switch1# set ge-0/0/9 unit 0 family ethernet-switching vlan members [10 20 30 40]
```

```
user@switch1# set ge-0/0/11 unit 0 family ethernet-switching vlan members [10 20 30 40]
```

3. Configure the port mode for the interfaces:

```
[edit interfaces]
user@switch1# set ge-0/0/13 unit 0 family ethernet-switching interface-mode trunk
user@switch1# set ge-0/0/9 unit 0 family ethernet-switching interface-mode trunk
user@switch1# set ge-0/0/11 unit 0 family ethernet-switching interface-mode trunk
```

4. Configure RSTP on the switch:

```
[edit protocols]
user@switch1# rstp bridge-priority 16k
user@switch1# rstp interface all cost 1000
user@switch1# rstp interface all mode point-to-point
```

**Step-by-Step Procedure** If Switch 1 includes dual Routing Engines, configure nonstop bridging. To configure NSB on Switch 1:

1. Enable graceful Routing Engine switchover (GRES):

```
[edit chassis redundancy]
user@switch1# set graceful-switchover
```

2. Configure the switch to always synchronize configuration changes between the Routing Engines:

```
[edit system]
user@switch1# set commit synchronize
```

If you try to commit a configuration in which nonstop bridging is configured but synchronization of configuration changes is not configured, the configuration is not committed.

3. Enable nonstop bridging:

```
[edit protocols layer2-control]
user@switch1# set nonstop-bridging
```

**NOTE:** This process enables NSB for all NSB-supported Layer 2 protocols on the switch, including RSTP.

**Results** Check the results of the configuration:

```
user@switch1> show configuration
interfaces {
 ge-0/0/13 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members [10 20 30 40];
 }
 }
 }
 }
 ge-0/0/9 {
 unit 0 {
```

```
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members [10 20 30 40];
 }
 }
 }
}
ge-0/0/11 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members [10 20 30 40];
 }
 }
 }
}
}
protocols {
 layer2-control {
 nonstop-bridging;
 }
 rstp {
 bridge-priority 16k;
 interface ge-0/0/13 {
 cost 1000;
 mode point-to-point;
 }
 interface ge-0/0/9 {
 cost 1000;
 mode point-to-point;
 }
 interface ge-0/0/11 {
 cost 1000;
 mode point-to-point;
 }
 }
}
}
vllans {
 voice-vlan {
 vlan-id 10;
 }
 employee-vlan {
 vlan-id 20;
 }
 guest-vlan {
 vlan-id 30;
 }
 camera-vlan {
 vlan-id 40;
 }
}
}
system {
 commit synchronize;
}
```

```

}
chassis {
 redundancy {
 graceful-switchover;
 }
}

```

## Configuring RSTP and Nonstop Bridging on Switch 2

**CLI Quick Configuration** To quickly configure RSTP and nonstop bridging on Switch 2, copy the following commands and paste them into the switch terminal window:

```

[edit]
set vlans voice-vlan description "Voice VLAN"
set vlans voice-vlan vlan-id 10
set vlans employee-vlan description "Employee VLAN"
set vlans employee-vlan vlan-id 20
set vlans guest-vlan description "Guest VLAN"
set vlans guest-vlan vlan-id 30
set vlans camera-vlan description "Camera VLAN"
set vlans camera-vlan vlan-id 40
set interfaces ge-0/0/14 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/18 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/14 unit 0 family ethernet-switching interface-mode trunk
set interfaces ge-0/0/18 unit 0 family ethernet-switching interface-mode trunk
set protocols rstp bridge-priority 32k
set protocols rstp interface ge-0/0/14 cost 1000
set protocols rstp interface ge-0/0/14 mode point-to-point
set protocols rstp interface ge-0/0/18 cost 1000
set protocols rstp interface ge-0/0/18 mode point-to-point

```

**NOTE:** Starting with Junos OS Release 15.1 for EX Series and QFX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style, you can configure spanning tree parameters globally on all spanning tree interfaces. See [“Configuring RSTP \(CLI Procedure\)” on page 2190](#) for additional information.

If Switch 2 includes dual Routing Engines, configure NSB. To quickly configure nonstop bridging on Switch 2, copy the following commands and paste them into the switch terminal window:

```

set chassis redundancy graceful switchover
set system commit synchronize
set protocols layer2-control nonstop-bridging

```

**Step-by-Step  
Procedure**

To configure RSTP and nonstop bridging on Switch 2:

1. Configure the VLANs **voice-vlan**, **employee-vlan**, **guest-vlan**, and **camera-vlan**:

```
[edit vlans]
user@switch2# set voice-vlan description "Voice VLAN"
user@switch2# set voice-vlan vlan-id 10
user@switch2# set employee-vlan description "Employee VLAN"
user@switch2# set employee-vlan vlan-id 20
user@switch2# set guest-vlan description "Guest VLAN"
user@switch2# set guest-vlan vlan-id 30
user@switch2# set camera-vlan vlan-description "Camera VLAN"
user@switch2# set camera-vlan vlan-id 40
```

2. Configure the VLANs on the interfaces, including support for the Ethernet switching protocol:

```
[edit interfaces]
user@switch2# set ge-0/0/14 unit 0 family ethernet-switching vlan members [10 20 30 40]
user@switch2# set ge-0/0/18 unit 0 family ethernet-switching vlan members [10 20 30 40]
```

3. Configure the port mode for the interfaces:

```
[edit interfaces]
user@switch2# set ge-0/0/14 unit 0 family ethernet-switching interface-mode trunk
user@switch2# set ge-0/0/18 unit 0 family ethernet-switching interface-mode trunk
```

4. Configure RSTP on the switch:

```
[edit protocols]
user@switch2# rstp bridge-priority 32k
user@switch2# rstp interface ge-0/0/14 cost 1000
user@switch2# rstp interface ge-0/0/14 mode point-to-point
user@switch2# rstp interface ge-0/0/18 cost 1000
user@switch2# rstp interface ge-0/0/18 mode point-to-point
```

**Step-by-Step  
Procedure**

If Switch 2 includes dual Routing Engines, configure nonstop bridging. To configure NSB on Switch 2:

1. Enable graceful Routing Engine switchover (GRES):

```
[edit chassis redundancy]
user@switch2# set graceful-switchover
```

2. Configure the switch to always synchronize configuration changes between the Routing Engines:

```
[edit system]
user@switch2# set commit synchronize
```

If you try to commit a configuration in which nonstop bridging is configured but synchronization of configuration changes is not configured, the configuration is not committed.

3. Enable nonstop bridging:

```
[edit protocols layer2-control]
user@switch2# set nonstop-bridging
```

**NOTE:** This process enables NSB for all NSB-supported Layer 2 protocols on the switch, including RSTP.

**Results** Check the results of the configuration:

```

user@switch2> show configuration
interfaces {
 ge-0/0/14 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members [10 20 30 40];
 }
 }
 }
 }
 ge-0/0/18 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members [10 20 30 40];
 }
 }
 }
 }
}
protocols {
 layer2-control {
 nonstop-bridging;
 }
 rstp {
 bridge-priority 32k;
 interface ge-0/0/14 {
 cost 1000;
 mode point-to-point;
 }
 interface ge-0/0/18 {
 cost 1000;
 mode point-to-point;
 }
 }
}
vlands {
 voice-vlan {
 vlan-id 10;
 }
 employee-vlan {
 vlan-id 20;
 }
 guest-vlan {
 vlan-id 30;
 }
 camera-vlan {
 vlan-id 40;
 }
}

```

```
system {
 commit synchronize;
}
chassis {
 redundancy {
 graceful-switchover;
 }
}
```

## Configuring RSTP and Nonstop Bridging on Switch 3

**CLI Quick Configuration** To quickly configure RSTP and nonstop bridging on Switch 3, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans voice-vlan description "Voice VLAN"
set vlans voice-vlan vlan-id 10
set vlans employee-vlan description "Employee VLAN"
set vlans employee-vlan vlan-id 20
set vlans guest-vlan description "Guest VLAN"
set vlans guest-vlan vlan-id 30
set vlans camera-vlan description "Camera VLAN"
set vlans camera-vlan vlan-id 40
set interfaces ge-0/0/26 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/28 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/24 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/26 unit 0 family ethernet-switching interface-mode trunk
set interfaces ge-0/0/28 unit 0 family ethernet-switching interface-mode trunk
set interfaces ge-0/0/24 unit 0 family ethernet-switching interface-mode trunk
set protocols rstp bridge-priority 8k
set protocols rstp interface ge-0/0/26 cost 1000
set protocols rstp interface ge-0/0/26 mode point-to-point
set protocols rstp interface ge-0/0/28 cost 1000
set protocols rstp interface ge-0/0/28 mode point-to-point
set protocols rstp interface ge-0/0/24 cost 1000
set protocols rstp interface ge-0/0/24 mode point-to-point
```

If Switch 3 includes dual Routing Engines, configure NSB. To quickly configure nonstop bridging on Switch 3, copy the following commands and paste them into the switch terminal window:

```
set chassis redundancy graceful switchover
set system commit synchronize
set protocols layer2-control nonstop-bridging
```

**Step-by-Step Procedure** To configure RSTP and nonstop bridging on Switch 3:

1. Configure the VLANs **voice-vlan**, **employee-vlan**, **guest-vlan**, and **camera-vlan**:

```
[edit vlans]
user@switch3# set voice-vlan description "Voice VLAN"
user@switch3# set voice-vlan vlan-id 10
user@switch3# set employee-vlan description "Employee VLAN"
user@switch3# set employee-vlan vlan-id 20
user@switch3# set guest-vlan description "Guest VLAN"
user@switch3# set guest-vlan vlan-id 30
user@switch3# set camera-vlan description "Camera VLAN"
user@switch3# set camera-vlan vlan-id 40
```

2. Configure the VLANs on the interfaces, including support for the Ethernet switching protocol:

```
[edit interfaces]
user@switch3# set ge-0/0/26 unit 0 family ethernet-switching vlan members [10 20 30 40]
user@switch3# set ge-0/0/28 unit 0 family ethernet-switching vlan members [10 20 30 40]
user@switch3# set ge-0/0/24 unit 0 family ethernet-switching vlan members [10 20 30 40]
```

3. Configure the port mode for the interfaces:

```
[edit interfaces]
user@switch3# set ge-0/0/26 unit 0 family ethernet-switching interface-mode trunk
user@switch3# set ge-0/0/28 unit 0 family ethernet-switching interface-mode trunk
user@switch3# set ge-0/0/24 unit 0 family ethernet-switching interface-mode trunk
```

4. Configure RSTP on the switch:

```
[edit protocols]
user@switch3# rstp bridge-priority 8k
user@switch3# rstp interface ge-0/0/26 cost 1000
user@switch3# rstp interface ge-0/0/26 mode point-to-point
user@switch3# rstp interface ge-0/0/28 cost 1000
user@switch3# rstp interface ge-0/0/28 mode point-to-point
user@switch3# rstp interface ge-0/0/24 cost 1000
user@switch3# rstp interface ge-0/0/24 mode point-to-point
```

#### Step-by-Step Procedure

If Switch 3 includes dual Routing Engines, configure nonstop bridging. To configure NSB on Switch 3:

1. Enable graceful Routing Engine switchover (GRES):

```
[edit chassis redundancy]
user@switch3# set graceful-switchover
```

2. Configure the switch to always synchronize configuration changes between the Routing Engines:

```
[edit system]
user@switch3# set commit synchronize
```

If you try to commit a configuration in which nonstop bridging is configured but synchronization of configuration changes is not configured, the configuration is not committed.

3. Enable nonstop bridging:

```
[edit protocols layer2-control]
user@switch3# set nonstop-bridging
```

**NOTE:** This process enables NSB for all NSB-supported Layer 2 protocols on the switch, including RSTP.

**Results** Check the results of the configuration:

```
user@switch3> show configuration
interfaces {
 ge-0/0/26 {
 unit 0 {
 family ethernet-switching {
```

```
 interface-mode trunk;
 vlan {
 members [10 20 30 40];
 }
 }
}
ge-0/0/28 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members [10 20 30 40];
 }
 }
 }
}
ge-0/0/24 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members [10 20 30 40];
 }
 }
 }
}
}
}
protocols {
 layer2-control {
 nonstop-bridging;
 }
 rstp {
 bridge-priority 8k;
 interface ge-0/0/26 {
 cost 1000;
 mode point-to-point;
 }
 interface ge-0/0/28 {
 cost 1000;
 mode point-to-point;
 }
 interface ge-0/0/24 {
 cost 1000;
 mode point-to-point;
 }
 bridge-priority 8k;
 }
}
}
vlangs {
 voice-vlan {
 vlan-id 10;
 }
}
```

```

 }
 employee-vlan {
 vlan-id 20;
 }
 guest-vlan {
 vlan-id 30;
 }
 camera-vlan {
 vlan-id 40;
 }
}
system {
 commit synchronize;
}
chassis {
 redundancy {
 graceful-switchover;
 }
}

```

## Configuring RSTP and Nonstop Bridging on Switch 4

**CLI Quick Configuration** To quickly configure RSTP and nonstop bridging on Switch 4, copy the following commands and paste them into the switch terminal window:

```

[edit]
set vlans voice-vlan description "Voice VLAN"
set vlans voice-vlan vlan-id 10
set vlans employee-vlan description "Employee VLAN"
set vlans employee-vlan vlan-id 20
set vlans guest-vlan description "Guest VLAN"
set vlans guest-vlan vlan-id 30
set vlans camera-vlan description "Camera VLAN"
set vlans camera-vlan vlan-id 40
set interfaces ge-0/0/23 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/19 unit 0 family ethernet-switching vlan members [10 20 30 40]
set interfaces ge-0/0/23 unit 0 family ethernet-switching interface-mode trunk
set interfaces ge-0/0/19 unit 0 family ethernet-switching interface-mode trunk
set protocols rstp bridge-priority 16k
set protocols rstp interface ge-0/0/23 cost 1000
set protocols rstp interface ge-0/0/23 mode point-to-point
set protocols rstp interface ge-0/0/19 cost 1000
set protocols rstp interface ge-0/0/19 mode point-to-point

```

If Switch 4 includes dual Routing Engines, configure NSB. To quickly configure nonstop bridging on Switch 4, copy the following commands and paste them into the switch terminal window:

```

set chassis redundancy graceful switchover
set system commit synchronize
set protocols layer2-control nonstop-bridging

```

**Step-by-Step  
Procedure**

To configure RSTP and nonstop bridging on Switch 4:

1. Configure the VLANs **voice-vlan**, **employee-vlan**, **guest-vlan**, and **camera-vlan**:

```
[edit vlans]
user@switch4# set voice-vlan description "Voice VLAN"
user@switch4# set voice-vlan vlan-id 10
user@switch4# set employee-vlan description "Employee VLAN"
user@switch4# set employee-vlan vlan-id 20
user@switch4# set guest-vlan description "Guest VLAN"
user@switch4# set guest-vlan vlan-id 30
user@switch4# set camera-vlan description "Camera VLAN"
user@switch4# set camera-vlan vlan-id 40
```

2. Configure the VLANs on the interfaces, including support for the Ethernet switching protocol:

```
[edit interfaces]
user@switch4# set ge-0/0/23 unit 0 family ethernet-switching vlan members [10 20 30 40]
user@switch4# set ge-0/0/19 unit 0 family ethernet-switching vlan members [10 20 30 40]
```

3. Configure the port mode for the interfaces:

```
[edit interfaces]
user@switch4# set ge-0/0/23 unit 0 family ethernet-switching interface-mode trunk
user@switch4# set ge-0/0/19 unit 0 family ethernet-switching interface-mode trunk
```

4. Configure RSTP on the switch:

```
[edit protocols]
user@switch4# rstp bridge-priority 16k
user@switch4# rstp interface ge-0/0/23 cost 1000
user@switch4# rstp interface ge-0/0/23 mode point-to-point
user@switch4# rstp interface ge-0/0/19 cost 1000
user@switch4# rstp interface ge-0/0/19 mode point-to-point
```

**Step-by-Step  
Procedure**

If Switch 4 includes dual Routing Engines, configure nonstop bridging. To configure NSB on Switch 4:

1. Enable graceful Routing Engine switchover (GRES):

```
[edit chassis redundancy]
user@switch4# set graceful-switchover
```

2. Configure the switch to always synchronize configuration changes between the Routing Engines:

```
[edit system]
user@switch4# set commit synchronize
```

If you try to commit a configuration in which nonstop bridging is configured but synchronization of configuration changes is not configured, the configuration is not committed.

3. Enable nonstop bridging:

```
[edit protocols layer2-control]
user@switch4# set nonstop-bridging
```

**NOTE:** This process enables NSB for all NSB-supported Layer 2 protocols on the switch, including RSTP.

**Results** Check the results of the configuration:

```

user@switch4> show configuration
interfaces {
 ge-0/0/23 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members [10 20 30 40];
 }
 }
 }
 }
 ge-0/0/19 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members [10 20 30 40];
 }
 }
 }
 }
}
protocols {
 layer2-control {
 nonstop-bridging;
 }
 rstp {
 bridge-priority 16k;
 interface ge-0/0/23 {
 cost 1000;
 mode point-to-point;
 }
 interface ge-0/0/19 {
 cost 1000;
 mode point-to-point;
 }
 }
}
vlands {
 voice-vlan {
 vlan-id 10;
 }
 employee-vlan {
 vlan-id 20;
 }
 guest-vlan {
 vlan-id 30;
 }
 camera-vlan {
 vlan-id 40;
 }
}

```

```
system {
 commit synchronize;
}
chassis {
 redundancy {
 graceful-switchover;
 }
}
```

## Verification

To confirm that the configuration is working properly, perform these tasks on both Routing Engines:

- [Verifying RSTP Configuration on Switch 1 on page 2188](#)
- [Verifying RSTP Configuration on Switch 2 on page 2188](#)
- [Verifying RSTP Configuration on Switch 3 on page 2189](#)
- [Verifying RSTP Configuration on Switch 4 on page 2189](#)

### Verifying RSTP Configuration on Switch 1

**Purpose** Verify the RSTP configuration on Switch 1.

**Action** Use the operational mode command:

```
user@switch1> show spanning-tree interface
```

Spanning tree interface parameters for instance 0

| Interface | Port ID | Designated<br>port ID | Designated<br>bridge ID | Port<br>Cost | State | Role |
|-----------|---------|-----------------------|-------------------------|--------------|-------|------|
| ge-0/0/13 | 128:526 | 128:526               | 16384.0019e25040e0      | 1000         | BLK   | ALT  |
| ge-0/0/9  | 128:522 | 128:522               | 32768.0019e2503d20      | 1000         | BLK   | ALT  |
| ge-0/0/11 | 128:524 | 128:524               | 8192.0019e25051e0       | 1000         | FWD   | ROOT |

**Meaning** Refer to the topology in [Figure 25](#). The operational mode command **show spanning-tree interface** shows that **ge-0/0/13** is in a forwarding state. The other interfaces on Switch 1 are blocking.

### Verifying RSTP Configuration on Switch 2

**Purpose** Use this procedure to verify the RSTP configuration on both Switch 2 Routing Engines.

**Action** Use the operational mode command:

```
user@switch2> show spanning-tree interface
```

Spanning tree interface parameters for instance 0

| Interface | Port ID | Designated<br>port ID | Designated<br>bridge ID | Port<br>Cost | State | Role |
|-----------|---------|-----------------------|-------------------------|--------------|-------|------|
| ge-0/0/14 | 128:527 | 128:527               | 32768.0019e2503d20      | 1000         | FWD   | DESG |
| ge-0/0/18 | 128:529 | 128:529               | 8192.0019e25051e0       | 1000         | FWD   | ROOT |

**Meaning** Refer to the topology in [Figure 25](#). The operational mode command **show spanning-tree interface** shows that **ge-0/0/18** is in a forwarding state and is the root port.

### Verifying RSTP Configuration on Switch 3

**Purpose** Use this procedure to verify the RSTP configuration on both Switch 3 Routing Engines.

**Action** Use the operational mode commands:

```
user@switch3> show spanning-tree interface
```

Spanning tree interface parameters for instance 0

| Interface | Port ID | Designated<br>port ID | Designated<br>bridge ID | Port<br>Cost | State | Role |
|-----------|---------|-----------------------|-------------------------|--------------|-------|------|
| ge-0/0/26 | 128:539 | 128:539               | 8192.0019e25051e0       | 1000         | FWD   | DESG |
| ge-0/0/28 | 128:541 | 128:541               | 8192.0019e25051e0       | 1000         | FWD   | DESG |
| ge-0/0/24 | 128:537 | 128:537               | 8192.0019e25051e0       | 1000         | FWD   | DESG |

**Meaning** Refer to the topology in [Figure 25](#). The operational mode command **show spanning-tree interface** shows that no interface is the root interface.

### Verifying RSTP Configuration on Switch 4

**Purpose** Use this procedure to verify the RSTP configuration on both Switch 4 Routing Engines.

**Action** Use the operational mode commands:

```
user@switch4> show spanning-tree interface
Spanning tree interface parameters for instance 0
```

| Interface | Port ID | Designated<br>port ID | Designated<br>bridge ID | Port<br>Cost | State | Role |
|-----------|---------|-----------------------|-------------------------|--------------|-------|------|
| ge-0/0/23 | 128:536 | 128:536               | 8192.0019e25051e0       | 1000         | FWD   | ROOT |
| ge-0/0/19 | 128:532 | 128:532               | 16384.0019e25040e0      | 1000         | FWD   | DESC |

**Meaning** Refer to the topology in [Figure 25](#). The operational mode command **show spanning-tree interface** shows that interface **ge-0/0/23** is the root interface and forwarding.

- [Understanding RSTP for EX Series and QFX Series Switches](#)

## Configuring RSTP (CLI Procedure)

The default spanning-tree protocol for EX Series switches is Rapid Spanning Tree Protocol (RSTP). RSTP provides faster convergence times than the original Spanning Tree Protocol (STP). Because RSTP is configured by default, you only need to use this procedure if another spanning-tree protocol has been configured. In that case, you can reconfigure RSTP.

To enable RSTP:

1. Disable the other configured spanning-tree protocol (MSTP):

- To disable MSTP:

```
[edit protocols]
user@switch# set mstp disable
```

2. Configure RSTP

- To enable RSTP on a specific interface:

```
[edit protocols]
user@switch# set rstp interface interface-name
```

- To disable RSTP on a specific interface:

```
[edit protocols]
user@switch# set rstp interface interface-name disable
```

- To enable RSTP on a range of interfaces:

```
[edit protocols]
user@switch# set rstp interface interface-range-name
```

- To enable RSTP on all interfaces:

```
[edit protocols]
user@switch# set rstp interface all
```

## Understanding VSTP

VLAN Spanning Tree Protocol (VSTP) enables Juniper Networks switches to run one or more Spanning Tree Protocol (STP) or Rapid Spanning Tree Protocol (RSTP) instances for each VLAN on which VSTP is enabled. For networks with multiple VLANs, VSTP improves intelligent tree spanning by defining best paths within the VLANs instead of within the entire network.

You can configure VSTP for a maximum of 509 VLANs.

VSTP and RSTP can be configured at the same time. If you configure VSTP and RSTP at the same time and the switch has more than 253 VLANs, VSTP is configured only for the first 253 VLANs. For the remaining VLANs, only RSTP is configured. RSTP and VSTP are the only spanning-tree protocols that can be configured at the same time on a switch.

**NOTE:** We recommend that you enable VSTP on all VLANs that could receive VSTP bridge protocol data units (BPDUs).

- Related Documentation**
- [Example: Configuring VSTP on QFX Series Switches and EX4600 Switches on page 2191](#)
  - [Overview of Spanning-Tree Protocols on page 2148](#)
  - [Understanding RSTP on page 2172](#)
  - [Configuring VSTP \(CLI Procedure\) on page 2197](#)
  - [Configuring VLAN Spanning Tree Protocol](#)

## Example: Configuring VSTP on QFX Series Switches and EX4600 Switches

This example demonstrates configuring VSTP (VLAN Spanning Tree Protocol) on QFX Series switches and EX4600 switches. The default spanning-tree protocol on these switches is Rapid Spanning Tree Protocol (RSTP). VLAN Spanning Tree Protocol (VSTP) is an alternate protocol that allows switches to run one or more Spanning Tree Protocol (STP) or RSTP instances for each VLAN on which VSTP is enabled. For networks with multiple VLANs, VSTP improves network bandwidth utilization by load balancing traffic for each VLAN.

- [Requirements on page 2192](#)
- [Overview on page 2192](#)
- [Configuration on page 2193](#)

## Requirements

This example uses the following hardware and software components:

- QFX5100 switch (Note that any QFX Series switch or the EX4600 switch can be substituted.)
- Junos OS Release 13.2X51-D25 or later for the QFX Series or Junos OS Release 13.2X51-D25 or later for EX Series switches

Before you configure VSTP, be sure you have:

- Configured interfaces ge-0/0/3, ge-0/0/4, ge-0/0/8, ae0. For directions, see [“Configuring Gigabit and 10-Gigabit Ethernet Interfaces” on page 2826](#).
- Configured VLAN 200 with four interfaces. For directions, see [“Configuring VLANs” on page 2120](#).
- Configured VLAN 5 and VLAN 6 with three interfaces each. For directions, see [“Configuring VLANs” on page 2120](#).

## Overview

You can configure VSTP for an interface at the global level (for all configured VLANs) or for a specific VLAN.

NOTE:

- If you configure VSTP on an interface at both the global and the specific VLAN level, the interface configuration that is defined at the specific VLAN level overrides the interface configuration that is defined at the global level.
- If you specify VSTP to be configured on an interface that is not configured to belong to the VLAN (or VLANs), an error message is displayed.

For each VLAN configured with VSTP, a dedicated instance of a spanning tree is created. This approach is useful to optimize network usage in small networks with a limited number of VLANs.

In this example, you configure VSTP at the VLAN level for VLAN 200 and at the global level for VLAN 5 and VLAN 6.

NOTE: You can use Juniper Networks switches with VSTP and Cisco switches with PVST+ and Rapid-PVST+ in the same network. Cisco supports a proprietary Per-VLAN Spanning Tree (PVST) protocol, which maintains a separate spanning tree instance per each VLAN. One Spanning Tree per VLAN allows fine grain load balancing but requires more BPDU CPU processing as the number of VLANs increases. PVST runs on Cisco proprietary ISL trunks which is not supported by Juniper. Juniper switches only inter-operate with PVST+ and Rapid-PVST+.

## Topology

Table 190: Interfaces of the Topology for Configuring VSTP

| Interface | Description             |
|-----------|-------------------------|
| ge-0/0/3  | Promiscuous member port |
| ge-0/0/4  | Promiscuous member port |
| ge-0/0/8  | Promiscuous member port |
| ae0       | Promiscuous member port |

| VLAN ID | Description  |
|---------|--------------|
| 200     | Primary VLAN |
| 5       | Primary VLAN |
| 6       | Primary VLAN |

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set protocols vstp vlan 200 interface ge-0/0/3
set protocols vstp vlan 200 interface ge-0/0/4
set protocols vstp vlan 200 interface ge-0/0/8
set protocols vstp vlan 200 interface ae0
set protocols vstp interface ge-0/0/3
set protocols vstp interface ge-0/0/4
set protocols vstp interface ge-0/0/8
set protocols vstp vlan 5
set protocols vstp vlan 6
```

## Configuring

**Step-by-Step Procedure** To configure VSTP:

1. Enable VSTP on VLAN 200 using a single VLAN ID:
 

```
[edit protocols]
user@switch #set vstp vlan 200 interface ge-0/0/3
user@switch #set vstp vlan 200 interface ge-0/0/4
user@switch #set vstp vlan 200 interface ge-0/0/8
user@switch #set vstp vlan 200 interface ae0
```

**NOTE:** When you configure VSTP with the `set protocol vstp vlan all` command, VLAN ID 1 is not set; it is excluded so that the configuration is compatible with Cisco PVST+. If you want VLAN ID 1 to be included in the VSTP configuration on your switch, you must set it separately with the `set protocol vstp vlan 1` command.

**TIP:** You could also enable VSTP on a VLAN using a single VLAN name.

2. Enable VSTP on VLAN 5 and VLAN 6 at the VSTP global level:

```
[edit protocols]
user@switch #set vstp interface ge-0/0/3
user@switch #set vstp interface ge-0/0/4
user@switch #set vstp interface ge-0/0/8
user@switch #set vstp vlan 5
user@switch #set vstp vlan 6
```

**CAUTION:** Ensure that the interface is a member of all VLANs before you add the interface to the VSTP configuration. If the interface is not a member of all VLANs, this VSTP configuration will fail when you try to commit it.

## Verifying VSTP Configuration

**Purpose** View the spanning tree interface and bridge you just created.

**Action** To view a VSTP configuration, use the commands `show spanning-tree bridge` and `show spanning-tree interface`.

## Results

The results of this example are:

```
root@sw-16> show spanning-tree interface
```

Spanning tree interface parameters for VLAN 5

| Interface | Port ID<br>port ID | Designated<br>bridge ID | Designated<br>Cost | Port  | State | Role |
|-----------|--------------------|-------------------------|--------------------|-------|-------|------|
| ge-0/0/3  | 128:490            | 128:490                 | 32773.88e0f31f4040 | 20000 | FWD   | DESG |
| ge-0/0/4  | 128:491            | 128:490                 | 32773.88e0f31f4040 | 20000 | BLK   | BKUP |
| ge-0/0/8  | 128:492            | 128:492                 | 32773.88e0f31f4040 | 20000 | FWD   | DESG |

Spanning tree interface parameters for VLAN 6

| Interface | Port ID | Designated<br>port ID | Designated<br>bridge ID | Designated<br>Cost | Port  | State | Role |
|-----------|---------|-----------------------|-------------------------|--------------------|-------|-------|------|
| ge-0/0/3  | 128:490 | 128:490               | 128:490                 | 32774.88e0f31f4040 | 20000 | FWD   | DESG |
| ge-0/0/4  | 128:491 | 128:491               | 128:491                 | 32774.88e0f31f4040 | 20000 | FWD   | DESG |
| ge-0/0/8  | 128:492 | 128:492               | 128:492                 | 32774.88e0f31f4040 | 20000 | FWD   | DESG |

## Spanning tree interface parameters for VLAN 200

| Interface | Port ID | Designated<br>port ID | Designated<br>bridge ID | Designated<br>Cost | Port  | State | Role |
|-----------|---------|-----------------------|-------------------------|--------------------|-------|-------|------|

Documentation**

- *Understanding VSTP for EX Series Switches and QFX Series Switches*

## Configuring VSTP (CLI Procedure)

**NOTE:** This topic applies to Junos OS for EX Series and QFX switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Configuring VSTP (CLI Procedure)*. For ELS details, see “Getting Started with Enhanced Layer 2 Software” on page 41.

The default spanning-tree protocol for EX Series switches is Rapid Spanning Tree Protocol (RSTP). VLAN Spanning Tree Protocol (VSTP) is an alternate protocol that allows EX Series switches to run one or more Spanning Tree Protocol (STP) or RSTP instances for each VLAN on which VSTP is enabled. For networks with multiple VLANs, VSTP improves intelligent tree spanning by defining best paths within the VLANs instead of within the entire network.

**NOTE:** On EX Series (other than EX9200) and QFX switches running Junos OS that supports ELS—VSTP can support up to 510 VLANs. However, on EX9200 switches, VSTP can support only up to 253 VLANs.

You can configure VSTP at the global level:

- For all interfaces on the switch
- For all interfaces within all VLANs
- For all interfaces within a specified VLAN
- For all interfaces within a specified VLAN group

You can configure or disable VSTP for a specific interface:

- For a specific interface on the switch
- For a specific interface within all VLANs
- For a specific interface within a specified VLAN
- For a specific interface within a specified VLAN group

**NOTE:**

- If you configure VSTP on an interface at both the global and the specific VLAN level, the interface configuration that is defined at the specific VLAN level overrides the interface configuration that is defined at the global level.
- If you specify VSTP to be configured on an interface that is not configured to belong to the VLAN (or VLANs), an error message is displayed.

To configure VSTP:

- For all interfaces within any of the following scopes:

- For all interfaces on the switch:

```
[edit protocols vstp]
user@switch# set interface all
```

- For all interfaces within all VLANs:

```
[edit protocols vstp]
user@switch# set vlan all interface all
```

- For all interfaces within a specified VLAN:

```
[edit protocols vstp]
user@switch# set vlan (vlan-id |vlan-range |open-set-of-values) interface all interface
all
```

- For all interfaces within a specified VLAN group:

```
[edit protocols vstp]
user@switch# set vlan-group vlan-group-name vlan (vlan-id |vlan-range |open-set-of-values)
interface all
```

- On a specific interface within any of the following scopes:

- For a specific interface on the switch:

```
[edit protocols vstp]
user@switch# set interface interface-name
```

- For a specific interface within all VLANs:

```
[edit protocols vstp]
user@switch# set vlan all interface interface-name
```

**CAUTION:** Ensure that the interface is a member of all VLANs before you add the interface to the VSTP configuration. If the interface is not a member of all VLANs, this VSTP configuration will fail when you try to commit it.

---

- For a specific interface within a specified VLAN:

```
[edit protocols vstp]
user@switch# set vlan vlan-id-or-vlan-range interface interface-name
```

- For a specific interface within a specified VLAN group:

```
[edit protocols vstp]
user@switch# set vlan-group vlan-group-name vlan (vlan-id |vlan-range |open-set-of-values)
interface interface-name
```

## Understanding BPDU Protection for STP, RSTP, and MSTP

**NOTE:** Using the original CLI, you can disable BPDU protection on interfaces by issuing the `set ethernet-switching-options bpdu-block interface-name disable` command.

A Juniper Networks device Layer 2 loop prevention through Spanning Tree Protocol (STP), Rapid Spanning Tree Protocol (RSTP), VLAN Spanning Tree Protocol (VSTP), and Multiple Spanning Tree Protocol (MSTP). Bridge protocol data unit (BPDU) protection can help prevent STP misconfigurations that can lead to network outages.

A loop-free network is supported through the exchange of a special type of frame called a BPDU. Receipt of BPDUs on certain interfaces in an STP, RSTP, VSTP, or MSTP topology, however, can lead to network outages. Enable BPDU protection on those interfaces to prevent these outages.

Peer STP applications running on the device interfaces use BPDUs to communicate. Ultimately, the exchange of BPDUs determines which interfaces block traffic and which interfaces become root ports and forward traffic.

However, a user bridge application running on a device connected to the device can also generate BPDUs. If these BPDUs are picked up by STP applications running on the device, they can trigger STP miscalculations, and those miscalculations can lead to network outages.

Enable BPDU protection on device interfaces connected to user devices or on interfaces on which no BPDUs are expected, such as edge ports. If BPDUs are received on a protected interface, the interface is disabled and stops forwarding frames.

Not only can you configure BPDU protection on a device with a spanning tree, but also on a device without a spanning tree. This type of topology typically consists of a non-STP device connected to an STP device through a trunk interface.

To configure BPDU protection on a device with a spanning tree, include the **bpdu-block-on-edge** statement at the `[edit protocols (stp | mstp | rstp)]` hierarchy level. To configure BPDU protection on a device without a spanning tree, include the **bpdu-block** statement at the `[edit ethernet-switching-options interface interface-name]` hierarchy level.

If BPDUs are sent to an interface (indicating that the misconfiguration has been corrected), the interface can be unblocked in one of two ways:

- If the **disable-timeout** statement has been included in the BPDU configuration, the interface automatically returns to service after the timer expires.
- Use the `clear error bpdu interface` operational mode command.

Disabling the BPDU protection configuration does not unblock the interface.

## Example: Configuring BPDU Protection on Edge Interfaces to Prevent STP Miscalculations

---

EX Series and QFX Series switches provide Layer 2 loop prevention through Rapid Spanning Tree protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP). All spanning-tree protocols use a special type of frame called a bridge protocol data unit (BPDU) to communicate. Other devices—PC bridging applications, for example, also use BPDUs and generate their own BPDUs. These different BPDUs are not compatible. When BPDUs generated by spanning-tree protocols are transmitted to a device that uses another type of BPDU, they can cause problems on the device. Similarly, if switches within a spanning-tree topology receive BPDUs from other devices, network outages can occur because of STP miscalculations.

This example configures BPDU protection on an EX Series switch that uses RSTP. The upstream configuration is done on the edge interfaces, where outside BPDUs are often received from other devices:

- [Requirements on page 2200](#)
- [Overview and Topology on page 2200](#)
- [Configuration on page 2202](#)
- [Verification on page 2202](#)

### Requirements

This example uses the following software and hardware components:

- Two EX Series switches in an RSTP topology
- Junos OS Release 13.2X50-D10 or later or later for EX Series or QFX Series switches

Before you configure the interfaces on Switch 2 for BPDU protection, be sure you have:

- RSTP enabled on the switches.

**NOTE:** By default, RSTP is enabled on all EX Series switches.

---

### Overview and Topology

The switches, being in an RSTP topology, support a loop-free network through the exchange of BPDUs. Receipt of outside BPDUs in an RSTP or MSTP topology, however,

can lead to network outages by triggering an STP misconfiguration. To prevent such outages, enable BPDU protection on spanning tree interfaces that could receive outside BPDUs. If an outside BPDU is received on a BPDU-protected interface, the interface shuts down to prevent the outside BPDU from accessing the spanning tree interface.

Figure 26 shows the topology for this example. In this example, Switch 1 and Switch 2 are configured for RSTP and create a loop-free topology. The interfaces on Switch 2 are edge access ports—edge access ports frequently receive outside BPDUs generated by PC applications.

This example configures interface `ge-0/0/5` and interface `ge-0/0/6` as edge ports on Switch 2, and then configures BPDU protection on those ports. With BPDU protection enabled, these interfaces shut down when they encounter an outside BPDU sent by the PCs connected to Switch 2.

Figure 26: BPDU Protection Topology

Table 191 shows the components that will be configured for BPDU protection.

Table 191: Components of the Topology for Configuring BPDU Protection on EX Series Switches

| Property                      | Settings                                                                                                                                                              |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Switch 1 (Distribution Layer) | Switch 1 is connected to Switch 2 on a trunk interface.                                                                                                               |
| Switch 2 (Access Layer)       | Switch 2 has these access ports that require BPDU protection: <ul style="list-style-type: none"><li>• <code>ge-0/0/5</code></li><li>• <code>ge-0/0/6</code></li></ul> |

This configuration example uses RSTP topology. You also can configure BPDU protection for MSTP topologies at the `[edit protocols mstp]` hierarchy level.

## Configuration

To configure BPDU protection on two access interfaces:

### CLI Quick Configuration

Quickly configure RSTP on the two Switch 2 interfaces, and then configure BPDU protection on all edge ports on Switch 2 by copying the following commands and pasting them into the switch terminal window:

**NOTE:** This example configures BPDU protection on specific interfaces. However, starting with Junos OS Release 15.1 for EX Series and QFX Series switches with support for the Enhanced Layer 2 Software (ELS) configuration style, you can configure BPDU protection globally on all spanning tree interfaces. See [“Configuring BPDU Protection on Spanning Tree Interfaces” on page 2205](#) for additional information.

### Step-by-Step Procedure

[edit]

```
set protocols rstp interface ge-0/0/5 edge
set protocols rstp interface ge-0/0/6 edge
set protocols rstp bpdu-block-on-edge
```

To configure RSTP on the two Switch 2 interfaces, and then configure BPDU protection:

1. Configure RSTP on interface **ge-0/0/5** and interface **ge-0/0/6**, and configure them as edge ports:

```
[edit protocols rstp]
user@switch# set interface ge-0/0/5 edge
user@switch# set interface ge-0/0/6 edge
```

2. Configure BPDU protection on all edge ports on this switch:

```
[edit protocols rstp]
user@switch# set bpdu-block-on-edge
```

**Results** Check the results of the configuration:

```
user@switch> show configuration protocols rstp
interface ge-0/0/5 {
 edge;
}
interface ge-0/0/6 {
 edge;
}
bpdu-block-on-edge;
```

## Verification

To confirm that the configuration is working properly:

- [Displaying the Interface State Before BPDU Protection Is Triggered on page 2203](#)
- [Verifying That BPDU Protection Is Working Correctly on page 2203](#)

### Displaying the Interface State Before BPDU Protection Is Triggered

**Purpose** Before BPDUs can be received from PCs connected to interface **ge-0/0/5** and interface **ge-0/0/6**, confirm the interface state.

**Action** Use the operational mode command:

```
user@switch> show spanning-tree interface
```

Spanning tree interface parameters for instance 0

| Interface | Port ID | Designated<br>port ID | Designated<br>bridge ID | Port<br>Cost | State | Role |
|-----------|---------|-----------------------|-------------------------|--------------|-------|------|
| ge-0/0/0  | 128:513 | 128:513               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| ge-0/0/1  | 128:514 | 128:514               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| ge-0/0/2  | 128:515 | 128:515               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| ge-0/0/3  | 128:516 | 128:516               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| ge-0/0/4  | 128:517 | 128:517               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| ge-0/0/5  | 128:518 | 128:518               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| ge-0/0/6  | 128:519 | 128:519               | 32768.0019e2503f00      | 20000        | FWD   | DESG |

[output truncated]

**Meaning** The output from the operational mode command **show spanning-tree interface** shows that **ge-0/0/5** and interface **ge-0/0/6** are ports in a forwarding state.

### Verifying That BPDU Protection Is Working Correctly

**Purpose** In this example, the PCs connected to Switch 2 start sending BPDUs to interface **ge-0/0/5** and interface **ge-0/0/6**. Verify that BPDU protection is working on the interfaces.

**Action** Use the operational mode command:

```
user@switch> show spanning-tree interface
```

Spanning tree interface parameters for instance 0

| Interface                | Port ID | Designated<br>port ID | Designated<br>bridge ID | Port<br>Cost | State | Role |
|--------------------------|---------|-----------------------|-------------------------|--------------|-------|------|
| ge-0/0/0                 | 128:513 | 128:513               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| ge-0/0/1                 | 128:514 | 128:514               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| ge-0/0/2                 | 128:515 | 128:515               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| ge-0/0/3                 | 128:516 | 128:516               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| ge-0/0/4                 | 128:517 | 128:517               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| ge-0/0/5<br>(Bpdu-Incon) | 128:518 | 128:518               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| ge-0/0/6<br>(Bpdu-Incon) | 128:519 | 128:519               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| ge-0/0/7                 | 128:520 | 128:1                 | 16384.00aabbcc0348      | 20000        | FWD   | ROOT |
| ge-0/0/8                 | 128:521 | 128:521               | 32768.0019e2503f00      | 20000        | FWD   | DESG |

[output truncated]

**Meaning** When BPDUs are sent from the PCs to interface **ge-0/0/5** and interface **ge-0/0/6** on Switch 2, the output from the operational mode command **show spanning-tree interface**

shows that the interfaces have transitioned to a BPDU inconsistent state. The BPDU inconsistent state causes the interfaces to shut down.

Disabling the BPDU protection configuration on an interface does not automatically reenabling the interface. However, if the **disable-timeout (Spanning Trees)** statement has been included in the BPDU configuration, the interface does return to service after the timer expires. Otherwise, you must use the operational mode command **clear error bpdu** to unblock and reenabling the interface.

If the PCs connected to Switch 2 send BPDUs to the interfaces again, BPDU protection is triggered once more and the interfaces transition back to the BPDU inconsistent state, causing them to shut down. In such cases, you need to find and repair the misconfiguration on the PCs that is sending BPDUs to Switch 2.

## Configuring BPDU Protection on Spanning Tree Interfaces

**NOTE:** This topic applies to Junos OS for EX Series and QFX switches with support for the Enhanced Layer 2 Software (ELS) configuration style. For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 41](#).

You can configure BPDU protection to ignore BPDU received on interfaces where none should be expected. If a BPDU is received on a blocked interface, the interface is disabled and stops forwarding frames. By default, all BPDUs are accepted and processed on all interfaces.

To configure BPDU protection for spanning-tree instance interfaces:

- On a specific spanning-tree interface:

1. To enable BPDU protection on a specified spanning-tree interface:

```
[edit protocols layer2-control bpu-block]
user@switch# set interface (aex | (ge-fpc/pic/port | xe-fpc/pic/port)
```

If a BPDU is received on the interface, the system will disable the interface and stop forwarding frames out the interface until the bridging process is restarted.

2. (Optional) Configure the amount of time the system waits before *automatically* unblocking this interface after it has received a BPDU.

```
[edit protocols layer2-control bpu-block interface interface-name]
user@switch# set disable-timeout seconds
```

The range of the *seconds* option value is from 10 through 3600 seconds (one hour). A *seconds* option value of 0 is allowed, but this results in the default behavior (the interface is blocked until the interface is cleared).

- To disable BPDU protection for a specific spanning-tree interface

```
[edit protocols layer2-control bpu-block interface interface-name]
user@switch# set disable-timeout seconds
```

## Understanding Loop Protection for STP, RSTP, VSTP, and MSTP

---

A Juniper Networks device provides Layer 2 loop prevention through Spanning Tree Protocol (STP), Rapid Spanning Tree Protocol (RSTP), VLAN Spanning Tree Protocol (VSTP), and Multiple Spanning Tree Protocol (MSTP). Loop protection increases the efficiency of STP, RSTP, and MSTP by preventing ports from entering a forwarding state that would cause a loop to open in the network.

A loop-free network in spanning-tree topologies is supported through the exchange of a special type of frame called a bridge protocol data unit (BPDU). Peer STP applications running on the device interfaces use BPDUs to communicate. Ultimately, the exchange of BPDUs determines which interfaces block traffic (preventing loops) and which interfaces become root ports and forward traffic.

However, a blocking interface can mistakenly transition to the forwarding state if the interface stops receiving BPDUs from its designated port on the segment. Such a transition error can occur when there is a hardware error on the device or software configuration error between the device and its neighbor.

When loop protection is enabled, the spanning-tree topology detects root ports and blocked ports and ensures that both keep receiving BPDUs. If a loop-protection-enabled interface stops receiving BPDUs from its designated port, it reacts as it would react to a problem with the physical connection on this interface. It does not transition the interface to a forwarding state, but instead transitions it to a loop-inconsistent state. The interface recovers and it transitions back to the spanning-tree blocking state as soon as it receives a BPDU.

We recommend that you enable loop protection on all device interfaces that have a chance of becoming root or designated ports. Loop protection is most effective when enabled in the entire switched network. When you enable loop protection, you must configure at least one action (**alarm**, **block**, or both).

An interface can be configured for either loop protection or root protection, but not for both.

## Example: Configuring Loop Protection to Prevent Interfaces from Transitioning from Blocking to Forwarding in a Spanning Tree

The QFX Series products provide Layer 2 loop prevention through Spanning Tree Protocol (STP), Rapid Spanning Tree Protocol (RSTP), and Multiple Spanning Tree Protocol (MSTP). Loop protection increases the efficiency of STP, RSTP, and MSTP by preventing interfaces from moving into a forwarding state that would create a loop in the network.

This example describes how to configure loop protection for an interface for the QFX Series in an RSTP topology:

- [Requirements on page 2207](#)
- [Overview and Topology on page 2207](#)
- [Configuration on page 2209](#)
- [Verification on page 2209](#)

### Requirements

This example uses the following hardware and software components:

- Junos OS Release 11.1 or later for the QFX Series
- Three switches in an RSTP topology

**NOTE:** By default, RSTP is enabled for the QFX Series.

### Overview and Topology

A loop-free network in spanning-tree topologies is supported through the exchange of a special type of frame called a bridge protocol data unit (BPDU). Peer STP applications running on the switch interfaces use BPDUs to communicate. Ultimately, the exchange of BPDUs determines which interfaces block traffic (preventing loops) and which interfaces become root ports and forward traffic.

A blocking interface can transition to the forwarding state in error if the interface stops receiving BPDUs from its designated port on the segment. Such a transition error can occur when there is a hardware error on the switch or software configuration error between the switch and its neighbor. When this happens, a loop appears in the spanning tree. Loops in a Layer 2 topology cause broadcast, unicast, and multicast frames to continuously circle the looped network. As a switch processes a flood of frames in a looped network, its resources become depleted, and the ultimate result is a network outage.

**NOTE:** An interface can be configured for either loop protection or root protection, but not for both.

Three switches are displayed in Figure 27. In this example, they are configured for RSTP and create a loop-free topology. Interface **xe-0/0/6** is blocking traffic between Switch 3 and Switch 1; thus, traffic is forwarded through interface **xe-0/0/7** on Switch 2. BPDUs are being sent from the root bridge on Switch 1 to both of these interfaces.

This example shows how to configure loop protection on interface **xe-0/0/6** to prevent it from transitioning from a blocking state to a forwarding state and creating a loop in the spanning-tree topology.

Figure 27: Network Topology for Loop Protection

Table 192 shows the components that will be configured for loop protection.

Table 192: Topology for Configuring Loop Protection on the QFX Series

| Components | Settings                                                              |
|------------|-----------------------------------------------------------------------|
| Switch 1   | Switch 1 is the root bridge.                                          |
| Switch 2   | Switch 2 has the root port <b>xe-0/0/7</b> .                          |
| Switch 3   | Switch 3 is connected to Switch 1 through interface <b>xe-0/0/6</b> . |

A spanning-tree topology contains ports that have specific roles:

- The *root port* is responsible for forwarding data to the root bridge.
- The *alternate port* is a standby port for the root port. When a root port goes down, the alternate port becomes the active root port.
- The *designated port* forwards data to the downstream network segment or device.

This configuration example uses an RSTP topology. However, you can also configure loop protection for STP or MSTP topologies at the `[edit protocols (mstp | stp)]` hierarchy level.

## Configuration

|                                |                                                                                                                                                                                               |

| <b>CLI Quick Configuration</b> | To quickly configure loop protection on interface <b>xe-0/0/6</b> :<br><br>[edit]<br><b>set protocols rstp interface xe-0/0/6 bpdu-timeout-action block</b>                                   |
| <b>Step-by-Step Procedure</b>  | To configure loop protection:<br><br>1. Configure interface <b>xe-0/0/6</b> on Switch 3:<br><br>[edit protocols rstp]<br>user@switch# <b>set interface xe-0/0/6 bpdu-timeout-action block</b> |
| <b>Results</b>                 | Check the results of the configuration:<br><br>user@switch> <b>show configuration protocols rstp</b><br>interface xe-0/0/6.0 {<br>bpdu-timeout-action {<br>block;<br>}<br>}                   |

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Displaying the Interface State Before Loop Protection Is Triggered on page 2209](#)
- [Verifying That Loop Protection Is Working on an Interface on page 2210](#)

### Displaying the Interface State Before Loop Protection Is Triggered

|                |                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------|
| <b>Purpose</b> | Before loop protection is triggered on interface <b>xe-0/0/6</b> , confirm that the interface is blocked. |
|----------------|-----------------------------------------------------------------------------------------------------------|

**Action** Display the interface state and role before applying root protection:

```
user@switch> show spanning-tree interface
```

Spanning tree interface parameters for instance 0

| Interface  | Port ID | Designated<br>port ID | Designated<br>bridge ID | Port<br>Cost | State | Role |
|------------|---------|-----------------------|-------------------------|--------------|-------|------|
| xe-0/0/0.0 | 128:513 | 128:513               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| xe-0/0/1.0 | 128:514 | 128:514               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| xe-0/0/2.0 | 128:515 | 128:515               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| xe-0/0/3.0 | 128:516 | 128:516               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| xe-0/0/4.0 | 128:517 | 128:517               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| xe-0/0/5.0 | 128:518 | 128:518               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| xe-0/0/6.0 | 128:519 | 128:2                 | 16384.00aabbcc0348      | 20000        | BLK   | ALT  |

[output truncated]

**Meaning** The output from the operational mode command **show spanning-tree interface** shows that **xe-0/0/6.0** is the alternate port and is blocked.

### Verifying That Loop Protection Is Working on an Interface

**Purpose** Verify that the loop protection configuration on interface **xe-0/0/6**. RSTP has been disabled on interface **xe-0/0/4** on Switch 1. This stops BPDUs from being sent to interface **xe-0/0/6** and triggering loop protection on that interface.

**Action** Display the interface state and role after applying root protection:

```
user@switch> show spanning-tree interface
```

Spanning tree interface parameters for instance 0

| Interface  | Port ID | Designated<br>port ID | Designated<br>bridge ID | Port<br>Cost | State | Role |
|------------|---------|-----------------------|-------------------------|--------------|-------|------|
| xe-0/0/0.0 | 128:513 | 128:513               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| xe-0/0/1.0 | 128:514 | 128:514               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| xe-0/0/2.0 | 128:515 | 128:515               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| xe-0/0/3.0 | 128:516 | 128:516               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| xe-0/0/4.0 | 128:517 | 128:517               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| xe-0/0/5.0 | 128:518 | 128:518               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| xe-0/0/6.0 | 128:519 | 128:519               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |

(Loop-Incon)

[output truncated]

**Meaning** The operational mode command **show spanning-tree interface** shows that interface **xe-0/0/6.0** has detected that BPDUs are no longer being forwarded to it and has moved into a loop-inconsistent state. The loop-inconsistent state prevents the interface from transitioning to a forwarding state. The interface recovers and transitions back to its original state as soon as it receives BPDUs.

## Understanding Root Protection for STP, RSTP, VSTP, and MSTP

A Juniper Networks device provides Layer 2 loop prevention through Spanning Tree Protocol (STP), Rapid Spanning Tree Protocol (RSTP), VLAN Spanning Tree Protocol (VSTP), and Multiple Spanning Tree Protocol (MSTP). A loop-free network is supported through the exchange of a special type of frame called a bridge protocol data unit (BPDU). Peer STP applications running on the device interfaces use BPDUs to communicate. Ultimately, the exchange of BPDUs determines which interfaces block traffic and which interfaces become root ports and forward traffic.

You can also see BPDUs generated when you run a bridge application on a device attached to the device. This can interfere with root port election, which may sometimes lead to the wrong root port being elected through the above process. Root protection allows you to manually enforce the root bridge placement in the network.

Enable root protection on interfaces that should not receive higher-priority BPDUs from the root bridge and should not be elected as the root port. These interfaces become designated ports and are typically located on an administrative boundary. If the bridge receives more STP BPDUs on a port that has root protection enabled, that port transitions to a root-prevented STP state (inconsistency state), and the interface is blocked. This blocking prevents a bridge that should not be the root bridge from being elected the root bridge. After the bridge stops receiving more STP BPDUs on the interface with root protection, the interface returns to a listening state, followed by a learning state, and ultimately back to a forwarding state. Recovery back to the forwarding state is automatic.

When root protection is enabled on an interface, it is enabled for all the STP instances on that interface. The interface is blocked only for instances for which it receives more BPDUs. Otherwise, it participates in the spanning-tree topology.

An interface can be configured for either root protection or loop protection, but not for both.

## Example: Configuring Root Protection to Enforce Root Bridge Placement in Spanning Trees

---

QFX Series products provide Layer 2 loop prevention through Spanning Tree Protocol (STP), Rapid Spanning Tree Protocol (RSTP), and Multiple Spanning Tree Protocol (MSTP). Root protection increases the efficiency of STP, RSTP, and MSTP by allowing network administrators to enforce the root bridge placement in the network manually.

This example describes how to configure root protection on an interface for the QFX Series.

- [Requirements on page 2212](#)
- [Overview and Topology on page 2212](#)
- [Configuration on page 2214](#)
- [Verification on page 2215](#)

### Requirements

This example uses the following hardware and software components:

- Junos OS Release 11.1 or later for the QFX Series
- Four switches in an RSTP topology

Before you configure the interface for root protection, be sure you have:

- RSTP operating on the switches.

**NOTE:** By default, RSTP is enabled on the QFX Series.

---

### Overview and Topology

Peer STP applications running on switch interfaces exchange a special type of frame called a bridge protocol data unit (BPDU). Switches communicate interface information using BPDUs to create a loop-free topology that ultimately determines the root bridge and which interfaces block or forward traffic in the spanning tree.

You can also see BPDUs generated when you run a bridge application on a device attached to the switch. This can interfere with root port election, which may sometimes lead to the wrong root port being elected through the above process. Root protection allows you to manually enforce the root bridge placement in the network.

To prevent this from happening, enable root protection on interfaces that should not receive more BPDUs from the root bridge and should not be elected as the root port. These interfaces are typically located on an administrative boundary and are designated ports.

When root protection is enabled on an interface:

- The interface is blocked from becoming the root port.
- Root protection is enabled for all STP instances on that interface.
- The interface is blocked only for instances for which it receives more BPDUs. Otherwise, it participates in the spanning-tree topology.

**NOTE:** An interface can be configured for either root protection or loop protection, but not for both.

Four switches are displayed in Figure 28. In this example, they are configured for RSTP and create a loop-free topology. Interface `xe-0/0/7` on Switch 1 is a designated port on an administrative boundary. It connects to Switch 4. Switch 3 is the root bridge. Interface `xe-0/0/6` on Switch 1 is the root port.

This example shows how to configure root protection on interface `xe-0/0/7` to prevent it from transitioning to become the root port.

Figure 28: Network Topology for Root Protection

g040712

Table 193 shows the components that will be configured for root protection.

**Table 193: Topology for Configuring Root Protection on the QFX Series**

| Component | Settings                                                                                                                                                                                    |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Switch 1  | Switch 1 is connected to Switch 4 through interface <b>xe-0/0/7</b> .                                                                                                                       |
| Switch 2  | Switch 2 is connected to Switch 1 and Switch 3. Interface <b>xe-0/0/4</b> is the alternate port in the RSTP topology.                                                                       |
| Switch 3  | Switch 3 is the root bridge and is connected to Switch 1 and Switch 2.                                                                                                                      |
| Switch 4  | Switch 4 is connected to Switch 1. After loop protection is configured on interface <b>xe-0/0/7</b> , Switch 4 sends more BPDUs that trigger loop protection on interface <b>xe-0/0/7</b> . |

A spanning-tree topology contains ports that have specific roles:

- The *root port* is responsible for forwarding data to the root bridge.
- The *alternate port* is a standby port for the root port. When a root port goes down, the alternate port becomes the active root port.
- The *designated port* forwards data to the downstream network segment or device.

This configuration example uses an RSTP topology. However, you can also configure root protection for STP or MSTP topologies at the `[edit protocols (mstp | stp)]` hierarchy level.

## Configuration

**CLI Quick Configuration** To quickly configure root protection on interface **xe-0/0/7**, copy the following command and paste it into the switch terminal window:

```
[edit]
set protocols rstp interface xe-0/0/7 no-root-port
```

**Step-by-Step Procedure** To configure root protection:

1. Configure interface **xe-0/0/7**:
 

```
[edit protocols rstp]
user@switch#
set interface xe-0/0/7 no-root-port
```

**Results** Check the results of the configuration:

```
user@switch> show configuration protocols rstp
interface xe-0/0/7.0 {
 no-root-port;
}
```

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Displaying the Interface State Before Root Protection Is Triggered on page 2215](#)
- [Verifying That Root Protection Is Working on the Interface on page 2215](#)

### Displaying the Interface State Before Root Protection Is Triggered

**Purpose** Before root protection is triggered on interface **xe-0/0/7**, confirm the interface state.

**Action** Confirm the state of the interfaces before root protection is configured:

```
user@switch> show spanning-tree interface
```

Spanning tree interface parameters for instance 0

| Interface  | Port ID | Designated<br>port ID | Designated<br>bridge ID | Port<br>Cost | State | Role |
|------------|---------|-----------------------|-------------------------|--------------|-------|------|
| xe-0/0/0.0 | 128:513 | 128:513               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| xe-0/0/1.0 | 128:514 | 128:514               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| xe-0/0/2.0 | 128:515 | 128:515               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| xe-0/0/3.0 | 128:516 | 128:516               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| xe-0/0/4.0 | 128:517 | 128:517               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| xe-0/0/5.0 | 128:518 | 128:2                 | 16384.00aabbcc0348      | 20000        | BLK   | ALT  |
| xe-0/0/6.0 | 128:519 | 128:1                 | 16384.00aabbcc0348      | 20000        | FWD   | ROOT |
| xe-0/0/7.0 | 128:520 | 128:520               | 32768.0019e2503f00      | 20000        | FWD   | DESG |

[output truncated]

**Meaning** The output from the operational mode command **show spanning-tree interface** shows that **xe-0/0/7.0** is a designated port in a forwarding state.

### Verifying That Root Protection Is Working on the Interface

**Purpose** A configuration change takes place on Switch 4. A lower bridge priority on Switch 4 causes it to send more BPDUs to interface **xe-0/0/7**. Receipt of more BPDUs on interface **xe-0/0/7** triggers root protection. Verify that root protection is operating on interface **xe-0/0/7**.

**Action** Verify that root protection has been configured and is operating correctly:

```
user@switch> show spanning-tree interface
```

Spanning tree interface parameters for instance 0

| Interface  | Port ID | Designated<br>port ID | Designated<br>bridge ID | Port<br>Cost | State | Role |
|------------|---------|-----------------------|-------------------------|--------------|-------|------|
| xe-0/0/0.0 | 128:513 | 128:513               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| xe-0/0/1.0 | 128:514 | 128:514               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| xe-0/0/2.0 | 128:515 | 128:515               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |
| xe-0/0/3.0 | 128:516 | 128:516               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| xe-0/0/4.0 | 128:517 | 128:517               | 32768.0019e2503f00      | 20000        | FWD   | DESG |
| xe-0/0/5.0 | 128:518 | 128:2                 | 16384.00aabbcc0348      | 20000        | BLK   | ALT  |
| xe-0/0/6.0 | 128:519 | 128:1                 | 16384.00aabbcc0348      | 20000        | FWD   | ROOT |
| xe-0/0/7.0 | 128:520 | 128:520               | 32768.0019e2503f00      | 20000        | BLK   | DIS  |

(Root-Incon)  
[output truncated]

**Meaning** The operational mode command [show spanning-tree interface](#) shows that interface **xe-0/0/7.0** has transitioned to a loop inconsistent state. The loop inconsistent state blocks the interface and prevents it from becoming a candidate for the root port. When the root bridge no longer receives more STP BPDUs from the interface, the interface recovers and transitions back to a forwarding state. Recovery is automatic.

## Unblocking an Interface That Receives BPDUs in Error (CLI Procedure)

EX Series and QFX Series switches use bridge protocol data unit (BPDU) protection on interfaces to prevent them from receiving BPDUs that could trigger a spanning-tree misconfiguration. If BPDUs are received on a BPDU-protected interface, the interface either shuts down or transitions to a blocking state and stops forwarding frames. In the latter scenario, after the misconfiguration that triggered the BPDUs being sent to an interface is fixed in the topology, the interface can be unblocked and returned to service.

To unblock an interface and return it to service using the CLI:

- Automatically unblock an interface by configuring a timer that expires:

```
[edit protocols layer 2]
```

```
user@switch# set protocols layer2-control bpdv-block disable-timeout 30
```

All interfaces on the switch will be reenabled (unblocked) after the timer expires.

However, once an interface on the switch receives a new spanning-tree protocol BPDU, the interface returns to the blocked state.

- Manually unblock an interface using the operational mode command:

```
user@switch> clear error bpdv interface ge-0/0/6
```

This command will only reenable an interface but the BPDU configuration for the interface will continue to exist unless you remove the BPDU configuration explicitly.

## Understanding Q-in-Q Tunneling

---

**NOTE:** This topic applies to Junos OS switches with support for the Enhanced Layer 2 Software (ELS) configuration style. For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 41](#).

Q-in-Q tunneling enables service providers on Ethernet access networks to extend a Layer 2 Ethernet connection between two customer sites. Using Q-in-Q tunneling, providers can also segregate or bundle customer traffic into fewer VLANs or different VLANs by adding another layer of 802.1Q tags. Q-in-Q tunneling is useful when customers have overlapping VLAN IDs because customers' VLAN (C-VLAN) tags are prepended by the service-provider VLAN (S-VLAN) tag, which allows you to preserve each customers' VLAN IDs without conflict. The Juniper Networks Junos operating system (Junos OS) implementation of Q-in-Q tunneling supports the IEEE 802.1ad standard.

This topic describes:

- [How Q-in-Q Tunneling Works on page 2222](#)
- [How VLAN Translation Works on page 2222](#)
- [Sending and Receiving Untagged Packets on page 2222](#)
- [Disabling MAC Address Learning on page 2223](#)
- [Mapping C-VLANs to S-VLANs on page 2223](#)
- [Constraints for Q-in-Q Tunneling and VLAN Translation on page 2224](#)

## How Q-in-Q Tunneling Works

In Q-in-Q tunneling, as a packet travels from a C-VLAN to an S-VLAN, a service-provider-specific 802.1Q tag is added to the packet. This additional tag is used to segregate traffic into S-VLANs. The original customer 802.1Q tag of the packet is retained and is transmitted transparently, passing through the service provider's network. As the packet leaves the S-VLAN in the downstream direction, the additional 802.1Q tag is removed.

When Q-in-Q tunneling is enabled, trunk interfaces are assumed to be part of the service provider or data center network. Access interfaces are assumed to be customer-facing and accept both tagged and untagged frames. This topic refers to trunk interfaces as S-VLAN interfaces. This type of interface is also known as a network-to-network interface (NNI). The topic refers to access interfaces as C-VLAN interfaces. This type of interface is also known as a user-network interface (UNI).

---

### NOTE:

---

An interface can be a member of multiple S-VLANs. You can map one C-VLAN to one S-VLAN (1:1) or many C-VLANs to many S-VLANs (N:N). C-VLAN and S-VLAN tags are unique—for instance, you can have both a C-VLAN tag of 101 and an S-VLAN tag of 101. You can limit the set of accepted customer tags to a range of tags or to discrete values. Class-of-service (CoS) values of C-VLANs are unchanged in the downstream direction. You may copy ingress priority and CoS settings to the S-VLAN.

C-VLAN and S-VLAN interfaces accept priority-tagged packets without any configuration.

## How VLAN Translation Works

VLAN translation replaces an incoming C-VLAN tag with an S-VLAN tag instead of adding an additional tag. The C-VLAN tag is therefore lost, so a single-tagged packet is normally untagged when it leaves the S-VLAN (at the other end of the link). If an incoming packet has had Q-in-Q tunneling applied in advance, VLAN translation replaces the outer tag and the inner tag is retained when the packet leaves the S-VLAN at the other end of the link.

To configure VLAN translation, use the *mapping swap* statement at the **[edit vlans interface]** hierarchy level.

---

**NOTE:** You can configure VLAN translation on access ports only. You cannot configure it on trunk ports, and you cannot configure Q-in-Q tunneling on the same access port.

---

## Sending and Receiving Untagged Packets

To enable an interface to send and receive untagged packets, you must specify a native VLAN for a physical interface. When the interface receives an untagged packet, it adds

the VLAN ID of the native VLAN to the packet and sends the newly tagged packet to the mapped interface.

To specify a native VLAN, use the **native-vlan-id** statement at the **[edit interfaces interface-name]** hierarchy level. The native VLAN ID must match the C-VLAN or S-VLAN ID or be included in the VLAN ID list specified on the logical interface.

For example, on a logical interface for a C-VLAN interface, you might specify a C-VLAN ID list of 100-200. Then, on the C-VLAN physical interface, you could specify a native VLAN ID of 150. This configuration would work because the native VLAN of 150 is included in the C-VLAN ID list of 100-200.

We recommend configuring a native VLAN when using any of the approaches to map C-VLANs to S-VLANs. If you do not configure a native VLAN on an interface, untagged packets received by the interface are discarded. See the Mapping C-VLANs to S-VLANs section in this topic for information about the methods of mapping C-VLANs to S-VLANs.

## Disabling MAC Address Learning

In a Q-in-Q deployment, customer packets interfaces are transported without any changes to source and destination MAC addresses. You can disable MAC address learning at the global, interface, and VLAN levels:

- To disable learning globally, disable MAC address learning for the switch.
- To disable learning for an interface, disable MAC address learning for all VLANs of which the specified interface is a member.
- To disable learning for a VLAN, disable MAC address learning for a specified VLAN.

## Mapping C-VLANs to S-VLANs

There are three ways to map C-VLANs to S-VLANs:

- [All-in-One Bundling on page 2223](#)
- [Many-to-Many Bundling on page 2224](#)
- [Mapping a Specific Interface on page 2224](#)

If you configure multiple mapping methods, the switch gives priority to mapping a specific interface, then to many-to-many bundling, and last to all-in-one bundling. However, for a particular mapping method, setting up overlapping rules for the same C-VLAN is not supported.

### All-in-One Bundling

All-in-one bundling maps all packets from all C-VLAN interfaces to an S-VLAN.

The C-VLAN interface accepts untagged and single-tagged packets. An S-VLAN 802.1Q tag is then added to these packets, and the packets are sent to the S-VLAN interface, which accepts untagged, single-tagged, and double-tagged packets.

**NOTE:** The C-VLAN and S-VLAN interfaces accept untagged packets provided that the `native-vlan-id` statement is configured on these interfaces.

---

### Many-to-Many Bundling

Many-to-many bundling is used to specify which C-VLANs are mapped to which S-VLANs.

Use many-to-many bundling when you want a subset of the C-VLANs on the access switch to be part of multiple S-VLANs. With many-to-many bundling, the C-VLAN interfaces accept untagged and single-tagged packets. An S-VLAN 802.1Q tag is then added to these packets, and the packets are sent to the S-VLAN interfaces, which accept untagged, single-tagged, and double-tagged packets.

**NOTE:** The C-VLAN and S-VLAN interfaces accept untagged packets provided that the `native-vlan-id` statement is configured on these interfaces.

---

### Mapping a Specific Interface

Use specific interface mapping when you want to assign an S-VLAN to a specific C-VLAN on an interface. The configuration applies only to the specific interface, not to all access interfaces.

Specific interface mapping has two suboptions: **push** and **swap**. When traffic that is mapped to a specific interface is pushed, the packet retains its original tag as it moves from the C-VLAN to the S-VLAN and an additional S-VLAN tag is added to the packet. When traffic that is mapped to a specific interface is swapped, the incoming tag is replaced with a new VLAN tag. This is sometimes known as VLAN rewriting or VLAN translation.

Typically, this method is used to keep data from different customers separate or to provide individualized treatment of the packets on a certain interface. You might also use this method to map VLAN traffic from different customers to a single S-VLAN.

When using specific interface mapping, the C-VLAN interfaces accept untagged and single-tagged packets, while the S-VLAN interfaces accept untagged, single-tagged, and double-tagged packets.

**NOTE:** The C-VLAN and S-VLAN interfaces accept untagged packets provided that the `native-vlan-id` statement is configured on these interfaces.

---

## Constraints for Q-in-Q Tunneling and VLAN Translation

Be aware of the following constraints when configuring Q-in-Q tunneling and VLAN translation:

- With releases of Junos OS 13.2X51 previous to 13.2X51-D20, you cannot create a regular VLAN on an interface if you have created an S-VLAN or C-VLAN on that interface for Q-in-Q tunneling. This means that you cannot create an integrated routing and bridging (IRB) interface on that interface because regular VLANs are a required part of IRB configuration. With Junos OS 13.2X51-D25, you can create a regular VLAN on a trunk interface that has an S-VLAN, which means that you can also create an IRB interface on the trunk. In this case, the regular VLAN and S-VLAN on the same trunk interface cannot share the same VLAN ID. Junos OS 13.2X51-D25 does not allow you to create a regular VLAN on an access interface that has a C-VLAN.
- Most access port security features are not supported with Q-in-Q tunneling and VLAN translation.
- Configuring Q-in-Q tunneling and VLAN rewriting/VLAN translation on the same port is not supported.
- You can configure at most one VLAN rewrite/VLAN translation for a given VLAN and interface. For example, you can create no more than one translation for VLAN 100 on interface xe-0/0/0.
- The combined total of VLANs and rules for Q-in-Q tunneling and VLAN translation cannot exceed 6000. For example, you can configure and commit 4000 VLANs and 2000 rules for Q-in-Q tunneling and VLAN translation. However, you cannot configure 4000 VLANs and 2500 rules for Q-in-Q tunneling and VLAN translation. If you try to commit a configuration that exceeds the limit, you see CLI and syslog errors that inform you about the problem.
- MAC addresses are learned from S-VLANs, not C-VLANs.
- Broadcast, unknown unicast, and multicast traffic is forwarded to all members in the S-VLAN.
- The following features are not supported with Q-in-Q tunneling:
  - DHCP relay
  - Fibre Channel over Ethernet
  - IP Source Guard
- The following features are not supported with VLAN rewriting/VLAN translation:
  - Fibre Channel over Ethernet
  - Firewall filter applied to a port or VLAN in the output direction
  - Private VLANs
  - VLAN Spanning Tree Protocol
  - Reflective relay

## Configuring Q-in-Q Tunneling

---

Q-in-Q tunneling and VLAN translation allow service providers to create a Layer 2 Ethernet connection between two customer sites. Providers can segregate different customers' VLAN traffic on a link (for example, if the customers use overlapping VLAN IDs) or bundle different customer VLANs into a single service VLAN. Data centers can use Q-in-Q tunneling and VLAN translation to isolate customer traffic within a single site or to enable customer traffic flows between cloud data centers in different geographic locations.

Q-in-Q tunneling adds a service VLAN tag before the customer's 802.1Q VLAN tags. The Juniper Networks Junos operating system implementation of Q-in-Q tunneling supports the IEEE 802.1ad standard.

**NOTE:** This task uses a Junos OS release that supports the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Configuring Q-in-Q Tunneling*.

With releases of Junos OS 13.2X51 previous to 13.2X51-D20, you cannot create a regular VLAN on an interface if you have created an S-VLAN or C-VLAN on that interface for Q-in-Q tunneling. This means that you cannot create an integrated routing and bridging (IRB) interface on that interface because regular VLANs are a required part of IRB configuration. With Junos OS 13.2X51-D25, you can create a regular VLAN on a trunk interface that has an S-VLAN, which means that you can also create an IRB interface on the trunk. In this case, the regular VLAN and S-VLAN on the same trunk interface cannot share the same VLAN ID. Junos OS 13.2X51-D25 does not allow you to create a regular VLAN on an access interface that has a C-VLAN.

Before setting up Q-in-Q tunneling, make sure you have created and configured the necessary customer VLANs on the neighboring switches. See *Configuring VLANs*.

- [Using the Different Mapping Methods on page 2226](#)
- [Configuring All-in-One Bundling on page 2227](#)
- [Configuring Many-to-Many Bundling on page 2228](#)
- [Configuring a Specific Interface Mapping with VLAN ID Translation Option on page 2231](#)

### Using the Different Mapping Methods

Once you have created the required VLANs on the neighboring switches, configure Q-in-Q tunneling using one of the three methods to map customer VLANs (C-VLANs) to service-provider-defined service VLANs (S-VLANs):

- All-in-one bundling maps all packets from all C-VLAN interfaces to an S-VLAN. For information about how to use this method, see [“Configuring All-in-One Bundling” on page 2227](#).
- Use many-to-many bundling when you want a subset of the C-VLANs on the access switch to be part of multiple S-VLANs. For information about how to use this method, see [“Configuring Many-to-Many Bundling” on page 2228](#).

- Use specific interface mapping when you want to assign an S-VLAN to a specific C-VLAN on an interface. For information about how to use this method, see [“Configuring a Specific Interface Mapping with VLAN ID Translation Option”](#) on page 2231.

## Configuring All-in-One Bundling

You can configure Q-in-Q tunneling using the all-in-one bundling method, which forwards all packets that ingress on a C-VLAN interface to an S-VLAN. (Packets are forwarded to the S-VLAN regardless of whether they are tagged or untagged prior to ingress.) Using this approach saves you the effort of specifying a specific mapping for each C-VLAN.

First configure the S-VLAN and its interface:

1. Assign a logical interface (unit) to be a member of the S-VLAN.

```
[edit vlans vlan-name]
user@switch# interface interface-name.unit-number
```

**NOTE:** Do not use logical interface unit 0. You must later bind a VLAN tag ID to the unit you specify in this step, and you cannot bind a VLAN tag ID to unit 0. Also note that you do not create a VLAN ID for the S-VLAN. The ID is created automatically for the appropriate logical interface.

2. Enable the interface to transmit packets with two 802.1Q VLAN tags:

```
[edit interfaces interface-name]
user@switch# flexible-vlan-tagging
```

3. Enable extended VLAN bridge encapsulation on the interface:

```
[edit interfaces interface-name]
user@switch# encapsulation extended-vlan-bridge
```

4. Enable the S-VLAN interface to send and receive untagged packets:

```
[edit interfaces interface-name]
user@switch# native-vlan-id vlan-id
```

5. Bind the logical interface (unit) of the interface that you specified in step 1 to the automatically-created VLAN ID for the S-VLAN:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# vlan-id number
```

For example, the following configuration makes xe-0/0/0.10 a member of VLAN 10, enables Q-in-Q tunneling on interface xe-0/0/0, enables xe-0/0/0 to accept untagged packets, and binds the VLAN ID of S-VLAN v10 to a logical interface of xe-0/0/0.

```
set vlans v10 interface xe-0/0/0.10
set interfaces xe-0/0/0 flexible-vlan-tagging
set interfaces xe-0/0/0 native-vlan-id 10
set interfaces xe-0/0/0 encapsulation extended-vlan-bridge
set interfaces xe-0/0/0 unit 10 vlan-id 10
```

Now configure all-in-one bundling on a C-VLAN interface:

1. Assign a logical interface (unit) of the C-VLAN interface to be a member of the S-VLAN.

```
[edit vlans vlan-name]
user@switch# interface interface-name.unit-number
```

2. Enable the interface to transmit packets with 802.1Q VLAN tags :

```
[edit interfaces interface-name]
user@switch# flexible-vlan-tagging
```

3. Enable extended VLAN bridge encapsulation on the interface:

```
[edit interfaces interface-name]
user@switch# encapsulation extended-vlan-bridge
```

4. Enable the C-VLAN interface to send and receive untagged packets:

```
[edit interfaces interface-name]
user@switch# native-vlan-id vlan-id
```

5. Configure a logical interface to receive and forward any tagged packet whose VLAN ID tag matches the list of VLAN IDs you specify:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# vlan-id-list vlan-id-numbers
```

**WARNING:** On some EX and QFX Series switches, you can apply no more than eight VLAN identifier lists to a physical interface.

6. Configure the system to add an S-VLAN tag (outer tag) as packets travel from a C-VLAN interface to the S-VLAN:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# input-vlan-map push
```

7. Configure the system to remove the S-VLAN tag when packets are forwarded (internally) from the S-VLAN interface to the C-VLAN interface:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# output-vlan-map pop
```

For example, the following configuration makes xe-0/0/1.10 a member of S-VLAN v10, enables Q-in-Q tunneling, maps packets from C-VLANs 100 through 200 to S-VLAN 10, and enables xe-0/0/1 to accept untagged packets. If a packet originates in C-VLAN 100 and needs to be sent across the S-VLAN, a tag with VLAN ID 10 is added to the packet. When a packet is forwarded (internally) from the S-VLAN interface to interface xe-0/0/1, the tag with VLAN ID 10 is removed.

```
set vlans v10 interface xe-0/0/1.10
set interfaces xe-0/0/1 flexible-vlan-tagging
set interfaces xe-0/0/1 encapsulation extended-vlan-bridge
set interfaces xe-0/0/1 unit 10 vlan-id-list 100-200
set interfaces xe-0/0/1 native-vlan-id 150
set interfaces xe-0/0/1 unit 10 input-vlan-map push
set interfaces xe-0/0/1 unit 10 output-vlan-map pop
```

## Configuring Many-to-Many Bundling

You can configure Q-in-Q tunneling using the many-to-many bundling method, which maps packets from multiple C-VLANs to multiple S-VLANs. This method is convenient

for mapping a range of C-VLANs without having to specify each one individually. (You can also use this method to configure only one C-VLAN to be mapped to an S-VLAN.)

First configure the S-VLANs and assign them to an interface:

1. Assign a logical interface (unit) to be a member of one of the S-VLANs. Do not use logical interface unit 0.

```
[edit vlans vlan-name]
```

```
user@switch# interface interface-name.unit-number
```

**NOTE:** Note that you do not create a VLAN ID for the S-VLAN. The ID is created automatically for the appropriate logical interface.

2. Repeat step 1 for the other S-VLANs.
3. Enable the physical interface to transmit packets with two 802.1Q VLAN tags:

```
[edit interfaces interface-name]
```

```
user@switch# flexible-vlan-tagging
```

4. Enable extended VLAN bridge encapsulation on the interface:

```
[edit interfaces interface-name]
```

```
user@switch# encapsulation extended-vlan-bridge
```

5. Enable the S-VLAN interface to send and receive untagged packets:

```
[edit interfaces interface-name]
```

```
user@switch# native-vlan-id vlan-id
```

6. Bind one of the logical units of the interface to the VLAN ID for one of the S-VLANs.

```
[edit interfaces interface-name unit logical-unit-number]
```

```
user@switch# vlan-id number
```

7. Repeat step 6 to bind the automatically-created VLAN IDs for the other S-VLANs to the other logical units of the interface:

For example, the following configuration creates S-VLANs v10 and v30 and associates them with interface xe-0/0/0. It also enables Q-in-Q tunneling, enables xe-0/0/0 to accept untagged packets, and maps incoming C-VLAN packets to S-VLANs v10 and v30.

```
set vlans v10 interface xe-0/0/0.10
```

```
set vlans v30 interface xe-0/0/0.30
```

```
set interfaces xe-0/0/0 flexible-vlan-tagging
```

```
set interfaces xe-0/0/0 native-vlan-id 10
```

```
set interfaces xe-0/0/0 encapsulation extended-vlan-bridge
```

```
set interfaces xe-0/0/0 unit 10 vlan-id 10
```

```
set interfaces xe-0/0/0 unit 30 vlan-id 30
```

To configure the many-to-many bundling method on a C-VLAN interface, perform the following steps for each customer:

1. Assign a logical interface (unit) of one C-VLAN interface to be a member of one S-VLAN.

```
[edit vlans vlan-name]
```

```
user@switch# interface interface-name.unit-number
```

2. Repeat step 1 to assign another C-VLAN interface (physical interface) to be a member of another S-VLAN.

3. Enable the interface to transmit packets with 802.1Q VLAN tags:

```
[edit interfaces interface-name]
user@switch# flexible-vlan-tagging
```

4. Enable extended VLAN bridge encapsulation on the interface:

```
[edit interfaces interface-name]
user@switch# encapsulation extended-vlan-bridge
```

5. Enable the C-VLAN interface to send and receive untagged packets:

```
[edit interfaces interface-name]
user@switch# native-vlan-id vlan-id
```

6. For each physical interface, configure a logical interface (unit) to receive and forward any tagged packet whose VLAN ID tag matches the list of VLAN IDs you specify:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# vlan-id-list vlan-id-numbers
```

To configure only one C-VLAN to be mapped to an S-VLAN, specify only one VLAN ID after *vlan-id-list*.

**WARNING:** On some EX and QFX Series switches, you can apply no more than eight VLAN identifier list to a physical interface.

7. For each physical interface, configure the system to add an S-VLAN tag (outer tag) as packets travel from the C-VLAN interface to the S-VLAN:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# input-vlan-map push
```

8. For each physical interface, configure the system to remove the S-VLAN tag when packets are forwarded from the S-VLAN interface to the C-VLAN interface:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# output-vlan-map pop
```

For example, the following configuration makes xe-0/0/1.10 a member of S-VLAN v10, enables Q-in-Q tunneling, and maps packets from C-VLANs 10 through 20 to S-VLAN 10. The configuration for customer 2 makes xe-0/0/2.30 a member of S-VLAN v30, enables Q-in-Q tunneling, and maps packets from C-VLANs 30 through 40, 50 through 60, and 70 through 80 to S-VLAN 30. Both interfaces are configured to accept untagged packets.

If a packet originates in C-VLAN 10 and needs to be sent over the S-VLAN, a tag with a VLAN ID 10 is added to the packet. If a packet is forwarded internally from the S-VLAN interface to xe-0/0/1.10, the tag with VLAN ID 10 is removed. The same principles apply to the C-VLANs configured on interface xe-0/0/2.

**NOTE:** Notice that you can use the same tag value for an S-VLAN and C-VLAN. For example, the configuration for customer 1 maps C-VLAN ID 10 to S-VLAN ID 10. C-VLAN and S-VLAN tags use separate name spaces, so this configuration is allowed.

Configuration for customer 1:

```

set vlans v10 interface xe-0/0/1.10
set interfaces xe-0/0/1 flexible-vlan-tagging
set interfaces xe-0/0/1 encapsulation extended-vlan-bridge
set interfaces xe-0/0/1 unit 10 vlan-id-list 10-20
set interfaces xe-0/0/1 native-vlan-id 15
set interfaces xe-0/0/1 unit 10 input-vlan-map push
set interfaces xe-0/0/1 unit 10 output-vlan-map pop

```

Configuration for customer 2:

```

set vlans v30 interface xe-0/0/2.30
set interfaces xe-0/0/2 flexible-vlan-tagging
set interfaces xe-0/0/2 encapsulation extended-vlan-bridge
set interfaces xe-0/0/2 unit 30 vlan-id-list 30-40
set interfaces xe-0/0/2 unit 30 vlan-id-list 50-60
set interfaces xe-0/0/2 unit 30 vlan-id-list 70-80
set interfaces xe-0/0/2 native-vlan-id 75
set interfaces xe-0/0/2 unit 30 input-vlan-map push
set interfaces xe-0/0/2 unit 30 output-vlan-map pop

```

## Configuring a Specific Interface Mapping with VLAN ID Translation Option

You can configure Q-in-Q tunneling by mapping packets from a specified C-VLAN to a specified S-VLAN. In addition, you can configure the system to replace a C-VLAN tag with an S-VLAN tag or replace an S-VLAN tag with a C-VLAN tag (instead of double tagging). This is called VLAN translation or VLAN rewriting. VLAN translation is particularly useful if a service provider's Layer 2 network that connects a customer's sites does not support double tagged packets.

When you use VLAN translation, both ends of the link normally must be able to swap the tags appropriately. That is, both ends of the link must be configured to swap the C-VLAN tag for the S-VLAN tag and swap the S-VLAN tag for the C-VLAN tag so that traffic in both directions is tagged appropriately while in transit and after arrival.

First configure the S-VLAN and its interface:

1. Assign a logical interface to be a member of the S-VLAN. Do not use unit 0.

```
[edit vlans vlan-name]
```

```
user@switch# interface interface-name.unit-number
```

**NOTE:** Note that you do not create a VLAN ID for the S-VLAN. The ID is created automatically for the appropriate logical interface.

2. Enable the interface to transmit packets with 802.1Q VLAN tags:

```
[edit interfaces interface-name]
```

```
user@switch# flexible-vlan-tagging
```

3. Enable the S-VLAN interface to send and receive untagged packets:

```
[edit interfaces interface-name]
```

```
user@switch# native-vlan-id vlan-id
```

4. Enable extended VLAN bridge encapsulation on the interface:

```
[edit interfaces interface-name]
```

```
user@switch# encapsulation extended-vlan-bridge
```

5. Bind the logical interface (unit) of the interface that you specified earlier to the VLAN ID for the S-VLAN:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# vlan-id number
```

For example, the following configuration creates S-VLAN v200, makes xe-0/0/0.200 a member of that VLAN, enables Q-in-Q tunneling on interface xe-0/0/0, enables xe-0/0/0 to accept untagged packets, and binds a logical interface of xe-0/0/0 to the VLAN ID of VLAN v200.

```
set vlans v200 interface xe-0/0/0.200
set interfaces xe-0/0/0 flexible-vlan-tagging
set interfaces xe-0/0/0 native-vlan-id 10
set interfaces xe-0/0/0 encapsulation extended-vlan-bridge
set interfaces xe-0/0/0 unit 200 vlan-id 200
```

Now configure a specific interface mapping with optional VLAN ID translation on the C-VLAN interface:

1. Assign a logical interface of the C-VLAN interface to be a member of the S-VLAN.

```
[edit vlans vlan-name]
user@switch# interface interface-name.unit-number
```

2. Enable the interface to transmit packets with 802.1Q VLAN tags:

```
[edit interfaces interface-name]
user@switch# flexible-vlan-tagging
```

3. Enable the C-VLAN interface to send and receive untagged packets:

```
[edit interfaces interface-name]
user@switch# native-vlan-id vlan-id
```

4. Enable extended VLAN bridge encapsulation on the interface:

```
[edit interfaces interface-name]
user@switch# encapsulation extended-vlan-bridge
```

5. Configure a logical interface (unit) to receive and forward any tagged packet whose VLAN ID tag matches the VLAN IDs you specify:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# vlan-id number
```

6. Configure the system to remove the existing C-VLAN tag and replace it with the S-VLAN tag when packets ingress on the C-VLAN interface and are forwarded to the S-VLAN:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# input-vlan-map swap
```

7. Configure the system to remove the existing S-VLAN tag and replace it with the C-VLAN tag when packets are forwarded from the S-VLAN interface to the C-VLAN interface:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# output-vlan-map swap
```

8. To configure an S-VLAN and associate it with the appropriate C-VLAN interface:

```
[edit vlans vlan-name]
user@switch# interface interface-name
```

For example, the following configuration on C-VLAN interface xe-0/0/1 enables Q-in-Q tunneling, enables xe-0/0/1 to accept untagged packets, and maps incoming packets

from C-VLAN 150 to logical interface 200, which is a member of S-VLAN 200. Also, when packets egress from C-VLAN interface xe-0/0/1 and travel to the S-VLAN interface, the C-VLAN tag of 150 is removed and replaced with the S-VLAN tag of 200. When packets travel from the S-VLAN interface to the C-VLAN interface, the S-VLAN tag of 200 is removed and replaced with the C-VLAN tag of 150.

```
set vlans v200 interface xe-0/0/1.200
set interfaces xe-0/0/1 flexible-vlan-tagging
set interfaces xe-0/0/1 native-vlan-id 10
set interfaces xe-0/0/1 encapsulation extended-vlan-bridge
set interfaces xe-0/0/1 unit 200 vlan-id 150
set interfaces xe-0/0/1 unit 200 output-vlan-map swap
set interfaces xe-0/0/1 unit 200 input-vlan-map swap
```

**Related Documentation** • [Understanding Q-in-Q Tunneling on page 2221](#)

## Configuring All-in-One Bundling

You can configure Q-in-Q tunneling using the all-in-one bundling method, which forwards all packets that ingress on a C-VLAN interface to an S-VLAN. (Packets are forwarded to the S-VLAN regardless of whether they are tagged or untagged prior to ingress.) Using this approach saves you the effort of specifying a specific mapping for each C-VLAN.

First configure the S-VLAN and its interface:

1. Assign a logical interface (unit) to be a member of the S-VLAN.

```
[edit vlans vlan-name]
user@switch# interface interface-name.unit-number
```

**NOTE:** Do not use logical interface unit 0. You must later bind a VLAN tag ID to the unit you specify in this step, and you cannot bind a VLAN tag ID to unit 0. Also note that you do not create a VLAN ID for the S-VLAN. The ID is created automatically for the appropriate logical interface.

2. Enable the interface to transmit packets with two 802.1Q VLAN tags:

```
[edit interfaces interface-name]
user@switch# flexible-vlan-tagging
```

3. Enable extended VLAN bridge encapsulation on the interface:

```
[edit interfaces interface-name]
user@switch# encapsulation extended-vlan-bridge
```

4. Enable the S-VLAN interface to send and receive untagged packets:

```
[edit interfaces interface-name]
user@switch# native-vlan-id vlan-id
```

5. Bind the logical interface (unit) of the interface that you specified in step 1 to the automatically-created VLAN ID for the S-VLAN:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# vlan-id number
```

For example, the following configuration makes xe-0/0/0.10 a member of VLAN 10, enables Q-in-Q tunneling on interface xe-0/0/0, enables xe-0/0/0 to accept untagged packets, and binds the VLAN ID of S-VLAN v10 to a logical interface of xe-0/0/0.

```
set vlans v10 interface xe-0/0/0.10
set interfaces xe-0/0/0 flexible-vlan-tagging
set interfaces xe-0/0/0 native-vlan-id 10
set interfaces xe-0/0/0 encapsulation extended-vlan-bridge
set interfaces xe-0/0/0 unit 10 vlan-id 10
```

Now configure all-in-one bundling on a C-VLAN interface:

1. Assign a logical interface (unit) of the C-VLAN interface to be a member of the S-VLAN.

```
[edit vlans vlan-name]
user@switch# interface interface-name.unit-number
```

2. Enable the interface to transmit packets with 802.1Q VLAN tags :

```
[edit interfaces interface-name]
user@switch# flexible-vlan-tagging
```

3. Enable extended VLAN bridge encapsulation on the interface:

```
[edit interfaces interface-name]
user@switch# encapsulation extended-vlan-bridge
```

4. Enable the C-VLAN interface to send and receive untagged packets:

```
[edit interfaces interface-name]
user@switch# native-vlan-id vlan-id
```

5. Configure a logical interface to receive and forward any tagged packet whose VLAN ID tag matches the list of VLAN IDs you specify:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# vlan-id-list vlan-id-numbers
```

**WARNING:** On some EX and QFX Series switches, you can apply no more than eight VLAN identifier lists to a physical interface.

6. Configure the system to add an S-VLAN tag (outer tag) as packets travel from a C-VLAN interface to the S-VLAN:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# input-vlan-map push
```

7. Configure the system to remove the S-VLAN tag when packets are forwarded (internally) from the S-VLAN interface to the C-VLAN interface:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# output-vlan-map pop
```

For example, the following configuration makes xe-0/0/1.10 a member of S-VLAN v10, enables Q-in-Q tunneling, maps packets from C-VLANs 100 through 200 to S-VLAN 10, and enables xe-0/0/1 to accept untagged packets. If a packet originates in C-VLAN 100 and needs to be sent across the S-VLAN, a tag with VLAN ID 10 is added to the packet. When a packet is forwarded (internally) from the S-VLAN interface to interface xe-0/0/1, the tag with VLAN ID 10 is removed.

```
set vlans v10 interface xe-0/0/1.10
set interfaces xe-0/0/1 flexible-vlan-tagging
set interfaces xe-0/0/1 encapsulation extended-vlan-bridge
```

```

set interfaces xe-0/0/1 unit 10 vlan-id-list 100-200
set interfaces xe-0/0/1 native-vlan-id 150
set interfaces xe-0/0/1 unit 10 input-vlan-map push
set interfaces xe-0/0/1 unit 10 output-vlan-map pop

```

#### Related Documentation

- [Configuring Many-to-Many Bundling on page 2228](#)
- [Configuring a Specific Interface Mapping with VLAN ID Translation Option on page 2231](#)

## Configuring Many-to-Many Bundling

You can configure Q-in-Q tunneling using the many-to-many bundling method, which maps packets from multiple C-VLANs to multiple S-VLANs. This method is convenient for mapping a range of C-VLANs without having to specify each one individually. (You can also use this method to configure only one C-VLAN to be mapped to an S-VLAN.)

First configure the S-VLANs and assign them to an interface:

1. Assign a logical interface (unit) to be a member of one of the S-VLANs. Do not use logical interface unit 0.

[edit vlans *vlan-name*]

user@switch# **interface** *interface-name.unit-number*

**NOTE:** Note that you do not create a VLAN ID for the S-VLAN. The ID is created automatically for the appropriate logical interface.

2. Repeat step 1 for the other S-VLANs.
3. Enable the physical interface to transmit packets with two 802.1Q VLAN tags:

[edit interfaces *interface-name*]

user@switch# **flexible-vlan-tagging**

4. Enable extended VLAN bridge encapsulation on the interface:

[edit interfaces *interface-name*]

user@switch# **encapsulation extended-vlan-bridge**

5. Enable the S-VLAN interface to send and receive untagged packets:

[edit interfaces *interface-name*]

user@switch# **native-vlan-id** *vlan-id*

6. Bind one of the logical units of the interface to the VLAN ID for one of the S-VLANs.

[edit interfaces *interface-name* unit *logical-unit-number*]

user@switch# **vlan-id** *number*

7. Repeat step 6 to bind the automatically-created VLAN IDs for the other S-VLANs to the other logical units of the interface:

For example, the following configuration creates S-VLANs v10 and v30 and associates them with interface xe-0/0/0. It also enables Q-in-Q tunneling, enables xe-0/0/0 to accept untagged packets, and maps incoming C-VLAN packets to S-VLANs v10 and v30.

```

set vlans v10 interface xe-0/0/0.10

```

```

set vlans v30 interface xe-0/0/0.30
set interfaces xe-0/0/0 flexible-vlan-tagging
set interfaces xe-0/0/0 native-vlan-id 10
set interfaces xe-0/0/0 encapsulation extended-vlan-bridge
set interfaces xe-0/0/0 unit 10 vlan-id 10
set interfaces xe-0/0/0 unit 30 vlan-id 30

```

To configure the many-to-many bundling method on a C-VLAN interface, perform the following steps for each customer:

1. Assign a logical interface (unit) of one C-VLAN interface to be a member of one S-VLAN.

**[edit vlans *vlan-name*]**

```
user@switch# interface interface-name.unit-number
```

2. Repeat step 1 to assign another C-VLAN interface (physical interface) to be a member of another S-VLAN.

3. Enable the interface to transmit packets with 802.1Q VLAN tags:

**[edit interfaces *interface-name*]**

```
user@switch# flexible-vlan-tagging
```

4. Enable extended VLAN bridge encapsulation on the interface:

**[edit interfaces *interface-name*]**

```
user@switch# encapsulation extended-vlan-bridge
```

5. Enable the C-VLAN interface to send and receive untagged packets:

**[edit interfaces *interface-name*]**

```
user@switch# native-vlan-id vlan-id
```

6. For each physical interface, configure a logical interface (unit) to receive and forward any tagged packet whose VLAN ID tag matches the list of VLAN IDs you specify:

**[edit interfaces *interface-name* unit *logical-unit-number*]**

```
user@switch# vlan-id-list vlan-id-numbers
```

To configure only one C-VLAN to be mapped to an S-VLAN, specify only one VLAN ID after *vlan-id-list*.

**WARNING:** On some EX and QFX Series switches, you can apply no more than eight VLAN identifier list to a physical interface.

7. For each physical interface, configure the system to add an S-VLAN tag (outer tag) as packets travel from the C-VLAN interface to the S-VLAN:

**[edit interfaces *interface-name* unit *logical-unit-number*]**

```
user@switch# input-vlan-map push
```

8. For each physical interface, configure the system to remove the S-VLAN tag when packets are forwarded from the S-VLAN interface to the C-VLAN interface:

**[edit interfaces *interface-name* unit *logical-unit-number*]**

```
user@switch# output-vlan-map pop
```

For example, the following configuration makes xe-0/0/1.10 a member of S-VLAN v10, enables Q-in-Q tunneling, and maps packets from C-VLANs 10 through 20 to S-VLAN 10. The configuration for customer 2 makes xe-0/0/2.30 a member of S-VLAN v30, enables Q-in-Q tunneling, and maps packets from C-VLANs 30 through 40, 50 through

60, and 70 through 80 to S-VLAN 30. Both interfaces are configured to accept untagged packets.

If a packet originates in C-VLAN 10 and needs to be sent over the S-VLAN, a tag with a VLAN ID 10 is added to the packet. If a packet is forwarded internally from the S-VLAN interface to xe-0/0/1.10, the tag with VLAN ID 10 is removed. The same principles apply to the C-VLANs configured on interface xe-0/0/2.

**NOTE:** Notice that you can use the same tag value for an S-VLAN and C-VLAN. For example, the configuration for customer 1 maps C-VLAN ID 10 to S-VLAN ID 10. C-VLAN and S-VLAN tags use separate name spaces, so this configuration is allowed.

Configuration for customer 1:

```
set vlans v10 interface xe-0/0/1.10
set interfaces xe-0/0/1 flexible-vlan-tagging
set interfaces xe-0/0/1 encapsulation extended-vlan-bridge
set interfaces xe-0/0/1 unit 10 vlan-id-list 10-20
set interfaces xe-0/0/1 native-vlan-id 15
set interfaces xe-0/0/1 unit 10 input-vlan-map push
set interfaces xe-0/0/1 unit 10 output-vlan-map pop
```

Configuration for customer 2:

```
set vlans v30 interface xe-0/0/2.30
set interfaces xe-0/0/2 flexible-vlan-tagging
set interfaces xe-0/0/2 encapsulation extended-vlan-bridge
set interfaces xe-0/0/2 unit 30 vlan-id-list 30-40
set interfaces xe-0/0/2 unit 30 vlan-id-list 50-60
set interfaces xe-0/0/2 unit 30 vlan-id-list 70-80
set interfaces xe-0/0/2 native-vlan-id 75
set interfaces xe-0/0/2 unit 30 input-vlan-map push
set interfaces xe-0/0/2 unit 30 output-vlan-map pop
```

- [Configuring All-in-One Bundling on page 2227](#)
- [Configuring a Specific Interface Mapping with VLAN ID Translation Option on page 2231](#)

## Configuring a Specific Interface Mapping with VLAN ID Translation Option

You can configure Q-in-Q tunneling by mapping packets from a specified C-VLAN to a specified S-VLAN. In addition, you can configure the system to replace a C-VLAN tag with an S-VLAN tag or replace an S-VLAN tag with a C-VLAN tag (instead of double tagging). This is called VLAN translation or VLAN rewriting. VLAN translation is particularly useful if a service provider's Layer 2 network that connects a customer's sites does not support double tagged packets.

When you use VLAN translation, both ends of the link normally must be able to swap the tags appropriately. That is, both ends of the link must be configured to swap the

C-VLAN tag for the S-VLAN tag and swap the S-VLAN tag for the C-VLAN tag so that traffic in both directions is tagged appropriately while in transit and after arrival.

First configure the S-VLAN and its interface:

1. Assign a logical interface to be a member of the S-VLAN. Do not use unit 0.

```
[edit vlans vlan-name]
user@switch# interface interface-name.unit-number
```

**NOTE:** Note that you do not create a VLAN ID for the S-VLAN. The ID is created automatically for the appropriate logical interface.

2. Enable the interface to transmit packets with 802.1Q VLAN tags:

```
[edit interfaces interface-name]
user@switch# flexible-vlan-tagging
```

3. Enable the S-VLAN interface to send and receive untagged packets:

```
[edit interfaces interface-name]
user@switch# native-vlan-id vlan-id
```

4. Enable extended VLAN bridge encapsulation on the interface:

```
[edit interfaces interface-name]
user@switch# encapsulation extended-vlan-bridge
```

5. Bind the logical interface (unit) of the interface that you specified earlier to the VLAN ID for the S-VLAN:

```
[edit interfaces interface-name unit logical-unit-number]
user@switch# vlan-id number
```

For example, the following configuration creates S-VLAN v200, makes xe-0/0/0.200 a member of that VLAN, enables Q-in-Q tunneling on interface xe-0/0/0, enables xe-0/0/0 to accept untagged packets, and binds a logical interface of xe-0/0/0 to the VLAN ID of VLAN v200.

```
set vlans v200 interface xe-0/0/0.200
set interfaces xe-0/0/0 flexible-vlan-tagging
set interfaces xe-0/0/0 native-vlan-id 10
set interfaces xe-0/0/0 encapsulation extended-vlan-bridge
set interfaces xe-0/0/0 unit 200 vlan-id 200
```

Now configure a specific interface mapping with optional VLAN ID translation on the C-VLAN interface:

1. Assign a logical interface of the C-VLAN interface to be a member of the S-VLAN.

```
[edit vlans vlan-name]
user@switch# interface interface-name.unit-number
```

2. Enable the interface to transmit packets with 802.1Q VLAN tags:

```
[edit interfaces interface-name]
user@switch# flexible-vlan-tagging
```

3. Enable the C-VLAN interface to send and receive untagged packets:

```
[edit interfaces interface-name]
user@switch# native-vlan-id vlan-id
```

4. Enable extended VLAN bridge encapsulation on the interface:

```
[edit interfaces interface-name]
```

```
user@switch# encapsulation extended-vlan-bridge
```

5. Configure a logical interface (unit) to receive and forward any tagged packet whose VLAN ID tag matches the VLAN IDs you specify:

```
[edit interfaces interface-name unit logical-unit-number]
```

```
user@switch# vlan-id number
```

6. Configure the system to remove the existing C-VLAN tag and replace it with the S-VLAN tag when packets ingress on the C-VLAN interface and are forwarded to the S-VLAN:

```
[edit interfaces interface-name unit logical-unit-number]
```

```
user@switch# input-vlan-map swap
```

7. Configure the system to remove the existing S-VLAN tag and replace it with the C-VLAN tag when packets are forwarded from the S-VLAN interface to the C-VLAN interface:

```
[edit interfaces interface-name unit logical-unit-number]
```

```
user@switch# output-vlan-map swap
```

8. To configure an S-VLAN and associate it with the appropriate C-VLAN interface:

```
[edit vlans vlan-name]
```

```
user@switch# interface interface-name
```

For example, the following configuration on C-VLAN interface xe-0/0/1 enables Q-in-Q tunneling, enables xe-0/0/1 to accept untagged packets, and maps incoming packets from C-VLAN 150 to logical interface 200, which is a member of S-VLAN 200. Also, when packets egress from C-VLAN interface xe-0/0/1 and travel to the S-VLAN interface, the C-VLAN tag of 150 is removed and replaced with the S-VLAN tag of 200. When packets travel from the S-VLAN interface to the C-VLAN interface, the S-VLAN tag of 200 is removed and replaced with the C-VLAN tag of 150.

```
set vlans v200 interface xe-0/0/1.200
```

```
set interfaces xe-0/0/1 flexible-vlan-tagging
```

```
set interfaces xe-0/0/1 native-vlan-id 10
```

```
set interfaces xe-0/0/1 encapsulation extended-vlan-bridge
```

```
set interfaces xe-0/0/1 unit 200 vlan-id 150
```

```
set interfaces xe-0/0/1 unit 200 output-vlan-map swap
```

```
set interfaces xe-0/0/1 unit 200 input-vlan-map swap
```

## Understanding Proxy ARP

---

You can configure proxy Address Resolution Protocol (ARP) to enable the switch to respond to ARP queries for network addresses by offering its own Ethernet media access control (MAC) address. With proxy ARP enabled, the switch captures and routes traffic to the intended destination.

Proxy ARP is useful in situations where hosts are on different physical networks and you do not want to use subnet masking. Because ARP broadcasts are not propagated between hosts on different physical networks, hosts will not receive a response to their ARP request if the destination is on a different subnet. Enabling the switch to act as an ARP proxy allows the hosts to transparently communicate with each other through the switch. Proxy ARP can help hosts on a subnet reach remote subnets without your having to configure routing or a default gateway.

- [What Is ARP? on page 2243](#)
- [Proxy ARP Overview on page 2243](#)
- [Best Practices for Proxy ARP on page 2244](#)

## What Is ARP?

Ethernet LANs use ARP to map Ethernet MAC addresses to IP addresses. Each device maintains a cache containing a mapping of MAC addresses to IP addresses. The switch maintains this mapping in a cache that it consults when forwarding packets to network devices. If the ARP cache does not contain an entry for the destination device, the host (the DHCP client) broadcasts an ARP request for that device's address and stores the response in the cache.

## Proxy ARP Overview

When proxy ARP is enabled, if the switch receives an ARP request for which it has a route to the target (destination) IP address, the switch responds by sending a proxy ARP reply

packet containing its own MAC address. The host that sent the ARP request then sends its packets to the switch, which forwards them to the intended host.

**NOTE:** For security reasons, the source address in an ARP request must be on the same subnet as the interface on which the ARP request is received.

You can configure proxy ARP for each interface. You can also configure proxy ARP for a VLAN by using a routed VLAN interface (RVI).

Two modes of proxy ARP are supported: restricted and unrestricted. Both modes require that the switch have an active route to the destination address of the ARP request.

- **Restricted**—The switch responds to ARP requests in which the physical networks of the source and target are different and does not respond if the source and target IP addresses are on the same subnet. In this mode, hosts on the same subnet communicate without proxy ARP. We recommend that you use this mode on the switch.
- **Unrestricted**—The switch responds to all ARP requests for which it has a route to the destination. This is the default mode (because it is the default mode in Juniper Networks Junos operating system (Junos OS) configurations other than those on the switch). We recommend using restricted mode on the switch.

## Best Practices for Proxy ARP

We recommend these best practices for configuring proxy ARP on the switches:

- Set proxy ARP to restricted mode.
- Use restricted mode when configuring proxy ARP on RVIs.
- If you set proxy ARP to unrestricted, disable gratuitous ARP requests on each interface enabled for proxy ARP.

- Related Documentation**
- *Configuring Proxy ARP*
  - *proxy-arp*

## Configuring Proxy ARP (CLI Procedure)

**NOTE:** This task uses Junos OS for EX Series switches and QFX3500 and QFX3600 switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Configuring Proxy ARP (CLI Procedure)* or *Configuring Proxy ARP*. For ELS details, see “Getting Started with Enhanced Layer 2 Software” on page 41.

You can configure proxy Address Resolution Protocol (ARP) on your switch to enable the switch to respond to ARP queries for network addresses by offering its own media access control (MAC) address. With proxy ARP enabled, the switch captures and routes traffic to the intended destination.

To configure proxy ARP on a single interface:

```
[edit interfaces]
user@switch# set interface-name unit logical-unit-number proxy-arp (restricted |
unrestricted)
```

**BEST PRACTICE:** We recommend that you configure proxy ARP in restricted mode. In restricted mode, the switch does not act as a proxy if the source and target IP addresses are on the same subnet. If you decide to use unrestricted mode, disable gratuitous ARP requests on the interface to avoid a situation wherein the switch's response to a gratuitous ARP request appears to the host to be an indication of an IP conflict.

To configure proxy ARP on an integrated routing and bridging (IRB) interface:

```
[edit interfaces]
user@switch# set irb.logical-unit-number proxy-arp restricted
```

- Related Documentation**
- *Example: Configuring Proxy ARP on an EX Series Switch*
  - [Verifying That Proxy ARP Is Working Correctly on page 2245](#)
  - *Configuring Integrated Routing and Bridging Interfaces (CLI Procedure)*

## Verifying That Proxy ARP Is Working Correctly

**Purpose** Verify that the switch is sending proxy ARP messages.

**Action** List the system statistics for ARP:

```
user@switch> show system statistics arp
arp:
 90060 datagrams received
 34 ARP requests received
 610 ARP replies received
 2 resolution request received
 0 unrestricted proxy requests
 0 restricted proxy requests
```

```
0 received proxy requests
0 unrestricted proxy requests not proxied
0 restricted proxy requests not proxied
0 datagrams with bogus interface
0 datagrams with incorrect length
0 datagrams for non-IP protocol
0 datagrams with unsupported op code
0 datagrams with bad protocol address length
0 datagrams with bad hardware address length
0 datagrams with multicast source address
0 datagrams with multicast target address
0 datagrams with my own hardware address
0 datagrams for an address not on the interface
0 datagrams with a broadcast source address
294 datagrams with source address duplicate to mine
89113 datagrams which were not for me
0 packets discarded waiting for resolution
0 packets sent after waiting for resolution
309 ARP requests sent
35 ARP replies sent
0 requests for memory denied
0 requests dropped on entry
0 requests dropped during retry
0 requests dropped due to interface deletion
0 requests on unnumbered interfaces
0 new requests on unnumbered interfaces
0 replies for from unnumbered interfaces
0 requests on unnumbered interface with non-subnetted donor
0 replies from unnumbered interface with non-subnetted donor
```

**Meaning** The statistics show that two proxy ARP requests were received. The **unrestricted proxy requests not proxied** and **restricted proxy requests not proxied** fields indicate that all the unproxied ARP requests received have been proxied by the switch.

# Using Reflective Relay

- [Understanding Reflective Relay for Use with VEPA Technology on page 2249](#)
- [Configuring Reflective Relay on page 2250](#)
- [Example: Configuring Reflective Relay for Use with VEPA Technology on page 2251](#)

### Understanding Reflective Relay for Use with VEPA Technology

---

Virtual Ethernet Port Aggregator (VEPA) technology aggregates packets generated by virtual machines located on the same server and relays them to a physical switch. The physical switch then provides connectivity between the virtual machines located on the server, so the virtual machines do not communicate with one another. Offloading switching activities from a virtual switch to a physical switch reduces the computing overhead on the virtual servers and takes advantage of the security, filtering, and management features of the physical switch. Reflective relay, also known as “hairpin turn,” enables the physical switch to receive aggregated packets from the virtual machines hosted on the server through the VEPA on the downstream port and send those packets out the same downstream port from which the physical switch received them.

- [VEPA on page 2249](#)
- [Reflective Relay on page 2249](#)

### VEPA

Even though virtual machines are capable of sending packets directly to one another, it is more efficient to pass these aggregated packets from the VEPA to a physical switch. The switch can then send any packets destined for a virtual machine located on the same server to the VEPA.

### Reflective Relay

Reflective relay, also known as a “hairpin turn” or “hairpin mode,” returns aggregated packets to the VEPA by using the same downstream port that initially delivered the aggregated packets from the VEPA to the switch. Reflective relay must be configured on the interface located on the physical switch that receives aggregated packets, such as VEPA packets, because some of these packets might need to be sent back to the server if they are destined for another virtual machine on the same server.

Reflective relay only occurs in two situations:

- When the destination address of the packet was learned on that downstream port
- When the destination has not yet been learned

Reflective relay does not otherwise change the operation of the switch. If the interface to which the virtual machine is connected and the MAC address of the virtual machine packet are not yet included in the Ethernet switching table for the virtual machine's associated VLAN, an entry is added. If the source MAC address of an incoming packet under the respective VLAN is not yet present in the Ethernet switching table, the switch floods the packet on all the other ports that are members of the same VLAN, including the port on which the packet arrived.

Documentation**

- [Understanding Bridging and VLANs](#)
- [Understanding Bridging and VLANs on page 2089](#)

---

## Configuring Reflective Relay

Configure reflective relay when a switch port must return packets on a downstream port. For example, configure reflective relay when a switch port receives aggregated virtual machine packets from a technology such as virtual Ethernet port aggregator (VEPA). When these packets are passed through the switch, reflective relay allows the switch to send those packets back on the same interface that was used for delivery.

**NOTE:** This task uses Junos OS for QFX3500 and QFX3600 switches that supports the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Configuring Reflective Relay*.

Before you begin configuring reflective relay, ensure that you have:

- Configured packet aggregation on the server connected to the port. See your server documentation.
- Configured the port for all VLANs that could be included in aggregated packets..

To configure reflective relay:

1. Configure an Ethernet interface with an interface mode of **trunk**:

```
[edit]
user@switch# set interfaces interface-name unit number family family-type interface-mode
trunk
```

For example:

```
[edit]
user@switch# set interfaces xe-0/0/2 unit 0 family ethernet-switching interface-mode trunk
```

2. Configure the interface for reflective relay:

```
[edit]
user@switch# set interfaces interface-name unit number family family-type reflective-relay
```

For example:

```
[edit]
user@switch# set interfaces xe-0/0/2 unit 0 family ethernet-switching reflective-relay
```

3. Configure the interface for the VLANs that exist on the VM server:

```
[edit]
user@switch# set interfaces interface-name unit number family family-type vlan members
vlan-names
```

For example:

```
[edit]
user@switch# set interfaces xe-0/0/2 unit 0 family ethernet-switching vlan members
[VLAN_Purple VLAN_Orange VLAN_Blue]
```

### Example: Configuring Reflective Relay for Use with VEPA Technology

Reflective relay must be configured on a switch that receives virtual machine aggregated packets, such as Virtual Ethernet Port Aggregator (VEPA) packets, because some of these packets might be sent back to the server destined for another virtual machine on the same server. Reflective relay returns those packets to the original device using the same downstream port that delivered the packets to the switch.

**NOTE:** This example uses Junos OS for QFX3500 and QFX3600 switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Example: Configuring Reflective Relay for Use with VEPA Technology*. For ELS details, see [“Getting Started with Enhanced Layer 2 Software” on page 41](#).

This example shows how to configure a switch port interface to return packets sent by VEPA on the downstream interface back to the server using the same downstream interface:

- [Requirements on page 2252](#)
- [Overview and Topology on page 2252](#)
- [Configuration on page 2254](#)
- [Verification on page 2254](#)

## Requirements

This example uses the following hardware and software components:

- One QFX3500 switch
- One server
- Junos OS Release 12.1 or later for the QFX Series

Before you configure reflective relay on a switch port, be sure you have:

- Configured a server with six virtual machines, VM 1 through VM 6.
- Configured the server with three VLANs named VLAN\_Purple, VLAN\_Orange, and VLAN\_Blue and added two virtual machines to each VLAN.
- Configured the same three VLANs named VLAN\_Purple, VLAN\_Orange, and VLAN\_Blue on one interface.
- Installed and configured VEPA to aggregate the virtual machine packets.

## Overview and Topology

In this example, illustrated in [Figure 29](#), a switch is connected to one server that is hosting six virtual machines and is configured with a VEPA for aggregating packets. The server's six virtual machines are VM 1 through VM 6, and each virtual machine belongs to one of the three server VLANs, VLAN\_Purple, VLAN\_Orange, or VLAN\_Blue. Instead of the server directly passing packets between virtual machines, packets from any of the three VLANs that are destined for another one of the three VLANs are aggregated using VEPA technology and passed to the switch for processing. You must configure the switch port to accept these aggregated packets on the downstream interface and to return appropriate packets to the server on the same downstream interface after they are processed. [Figure 29](#) shows the topology for this example.

Figure 29: Reflective Relay Topology

g020996

In this example, you configure the physical Ethernet switch port interface for trunk interface mode and reflective relay. Configuring trunk port mode allows the interface to accept VLAN tagged packets. Configuring reflective relay allows the downstream port to return those packets on the same interface. [Table 194](#) shows the components used in this example.

Table 194: Components of the Topology for Configuring Reflective Relay

| Component        | Description                                                                                                                                             |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| QFX3500 switch   | Switch that supports reflective relay. For a list of switches that support this feature, see <i>QFX Series Software Features Overview</i> .             |
| <b>xe-0/0/2</b>  | Switch interface to the server.                                                                                                                         |
| Server           | Server with virtual machines and VEPA technology.                                                                                                       |
| Virtual machines | Six virtual machines located on the server: V1, V2, V3, V4, V5, and V6.                                                                                 |
| VLANs            | Three VLANs: VLAN_Purple, VLAN_Orange, and VLAN_Blue. Each VLAN has two virtual machine members.                                                        |
| VEPA             | Virtual Ethernet port aggregator that aggregates virtual machine packets on the server before the resulting single stream is transmitted to the switch. |

## Configuration

To configure reflective relay, perform these tasks:

- [Configuring Reflective Relay on the Port on page 2254](#)

---

### Configuring Reflective Relay on the Port

---

#### CLI Quick Configuration

To quickly configure reflective relay, copy the following commands and paste them into the switch window:

```
[edit]
set interfaces xe-0/0/2 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/2 unit 0 family ethernet-switching reflective-relay
set interfaces xe-0/0/2 unit 0 family ethernet-switching vlan members [VLAN_Blue VLAN_Orange
VLAN_Purple]
```

#### Step-by-Step Procedure

To configure reflective relay:

1. Configure the trunk interface mode on the interface:

```
[edit]
user@switch# set interfaces xe-0/0/2 unit 0 family ethernet-switching interface-mode
trunk
```

2. Configure reflective relay on the interface to allow it to both accept and send packets:

```
[edit]
user@switch# set interfaces xe-0/0/2 unit 0 family ethernet-switching reflective-relay
```

3. Configure the interface for the three VLANs on the server:

```
[edit]
user@switch# set interfaces xe-0/0/2 unit 0 family ethernet-switching vlan members
[VLAN_Purple VLAN_Orange VLAN_Blue]
```

#### Results

Check the results of the configuration:

```
[edit interfaces xe-0/0/2]
user@switch# show
unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 reflective-relay;
 vlan {
 members [VLAN_Purple VLAN_Orange VLAN_Blue];
 }
 }
}
```

## Verification

To confirm that reflective relay is enabled and working correctly, perform these tasks:

- [Verifying That Reflective Relay Is Enabled and Working Correctly on page 2254](#)

---

### Verifying That Reflective Relay Is Enabled and Working Correctly

---

#### Purpose

Verify that reflective relay is enabled and working correctly.

**Action** Use the `show ethernet-switching interfaces detail` command to display the reflective relay status:

```
user@switch> show ethernet-switching interfaces xe-0/0/2 detail
Interface: xe-0/0/2, Index: 66, State: down, Interface mode: Trunk
Reflective Relay Status: Enabled
Ether type for the interface: 0x8100
VLAN membership:
 VLAN_Purple, 802.1Q Tag: 450, tagged, unblocked
 VLAN_Orange, 802.1Q Tag: 460, tagged, unblocked
 VLAN_Blue, 802.1Q Tag: 470, tagged, unblocked
Number of MACs learned on IFL: 0
```

Confirm that reflective relay is working by sending a Layer 2 broadcast message from one virtual machine to another virtual machine located on the same VLAN. Check the switch to verify that the switch sends the packets back on the same interface on which they were received. One way to check this is to set up port mirroring on the switch interface, connect a traffic generator to the mirrored interface, and use the traffic generator to examine packets.

Alternatively, if you do not have a traffic generator available, you can send traffic between two virtual machines with FTP, Telnet, or SSH, while running the `tcpdump` utility on the receiver virtual machine port to capture reflected packets.

**Meaning** The reflective relay status is **Enabled**, meaning that interface `xe-0/0/2` is configured for the trunk interface mode, which accepts VLAN-tagged packets, and for reflective relay, which accepts and returns packets on the same interface.

When the traffic generator shows packets arriving at the switch and returning to the server on the same interface, reflective relay is working.

## east-interface

**Syntax**

```
east-interface {
 node-id mac-address;
 control-channel channel-name {
 vlan number;
 interface name interface-name
 }
 interface-none
 ring-protection-link-end;
}
```

**Hierarchy Level** [edit protocols protection-group **ethernet-ring** *ring-name*]

**Release Information** Statement introduced in Junos OS Release 9.4.  
Statement introduced in Junos OS Release 12.1 for EX Series switches.  
Statement introduced in Junos OS Release 14.153-D10 for QFX Series switches.

**Description** Define one of the two interface ports for Ethernet ring protection, the other being defined by the **west-interface** statement at the same hierarchy level. The interface must use the control channel's logical interface name. The control channel is a dedicated VLAN channel for the ring port.

EX Series switches do not use the node-id statement--the node ID is automatically configured on the switches using the MAC address.

**NOTE:** Always configure this port first, before configuring the **west-interface** statement.

**NOTE:** The Node ID is not configurable on EX Series switches. The node ID is automatically configured using the MAC address.

The statements are explained separately.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

## ethernet-ring

---

**Syntax**    ethernet-ring *ring-name* {  
              control-vlan (*vlan-id* | *vlan-name*);  
              data-channel {  
                  vlan *number*  
              }  
              east-interface {  
                  control-channel *channel-name* {  
                      vlan *number*;  
                      interface name *interface-name*  
                  }  
              }  
              guard-interval *number*;  
              node-id *mac-address*;  
              restore-interval *number*;  
              ring-protection-link-owner;  
              west-interface {  
                  control-channel *channel-name* {  
                      vlan *number*;  
                  }  
              }  
          }

**Hierarchy Level**    [edit protocols protection-group]

**Release Information**    Statement introduced in Junos OS Release 9.4.  
                              Statement introduced in Junos OS Release 12.1 for EX Series switches.  
                              Statement introduced in Junos OS Release 14.153-D10 for QFX Series switches.

**Description**    For Ethernet PICs on MX Series routers or for EX Series switches, , specify the Ethernet ring in an Ethernet ring protection switching configuration.

**Options**    *ring-name*—Name of the Ethernet protection ring.  
  
              The remaining statements are explained separately.

**Required Privilege Level**    interface—To view this statement in the configuration.  
                                  interface-control—To add this statement to the configuration.

| <b>Description</b>              | When a link goes down, the ring protection link (RPL) activates. When the downed link comes back up, the RPL link receives notification, restores the link, and waits for the restore interval before issuing another block on the same link. This configuration is a global configuration and applies to all Ethernet rings if the Ethernet ring does not have a more specific configuration for this value. If no parameter is configured at the protection group level, the global configuration of this parameter uses the default value. |
| <b>Options</b>                  | <i>number</i> —Guard timer interval, in milliseconds.<br><b>Range:</b> 10 through 2000 ms<br><b>Default:</b> 500 ms                                                                                                                                                                                                                                                                                                                                                                                                                           |

## west-interface

**Syntax**

```
west-interface {
 node-id mac-address;
 control-channel channel-name {
 vlan number;
 interface name interface-name
 }
 interface-name
 ring-protection-link-end;
 virtual-control-channel {
 west-interface name;
 east-interface name;
 }
}
```

**Hierarchy Level** [edit protocols protection-group **ethernet-ring** *ring-name*]

**Release Information** Statement introduced in Junos OS Release 9.5.  
Statement introduced in Junos OS Release 12.1 for EX Series switches.  
Statement introduced in Junos OS Release 14.153-D10 for QFX Series switches.

**Description** Define one of the two interface ports for Ethernet ring protection, the other being defined by the **east-interface** statement at the same hierarchy level. The interface must use the control channel's logical interface name. The control channel is a dedicated VLAN channel for the ring port.

**NOTE:** Always configure this port second, after configuring the **east-interface** statement.

The statements are explained separately.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

## [edit vlans] Configuration Statement Hierarchy on the QFX Series

---

This topic lists supported and unsupported configuration statements in the **[edit vlans]** hierarchy level on EX Series switches.

- *Supported* statements are those that you can use to configure some aspect of a software feature on the switch.
- *Unsupported* statements are those that appear in the command-line interface (CLI) on the switch, but that have no effect on switch operation if you configure them.

This topic lists:

- [Supported Statements in the \[edit vlans\] Hierarchy Level on page 2272](#)
- [Unsupported Statements in the \[edit vlans\] Hierarchy Level on page 2274](#)

### Supported Statements in the [edit vlans] Hierarchy Level

The following hierarchy shows the **[edit vlans]** configuration statements supported on one or more of the EX Series switches:

```
vlans {
 vlan-name {
 description text-description;
 domain-type bridge;
 forwarding-options {
 dhcp-security {
 arp-inspection;
 group group-name {
 interface interface-name {
 static-ip ip-address {
 mac mac-address;
 }
 }
 }
 overrides {
 no-option82;
 trusted;
 }
 }
 }
 ip-source-guard;
 no-dhcp-snooping;
 option-82 {
 circuit-id {
 prefix {
 host-name;
 logical-system-name;
 routing-instance-name;
 }
 }
 use-interface-description (device | logical);
 use-vlan-id;
 }
 remote-id {
 host-name;
 use-interface-description (device | logical);
 }
 }
}
```

```

 use-string string;
 }
 vendor-id {
 use-string string;
 }
}
filter {
 input filter-name;
 output filter-name;
}
flood {
 input filter-name;
}
}
l3-interface irb.logical-unit-number;
multicast-snooping-options {
 flood-groups [group-names];
 forwarding-cache {
 threshold {
 reuse threshold;
 suppress threshold;
 }
 }
 graceful-restart {
 disable;
 restart-duration duration;
 }
 host-outbound-traffic {
 dot1p bits;
 forwarding-class forwarding-class;
 }
 multichassis-lag-replicate-state;
 nexthop-hold-time time;
 options {
 syslog {
 level level;
 mark interval;
 upto level;
 }
 }
 traceoptions {
 file filename {
 files number;
 no-world-readable;
 size file-size;
 world-readable;
 }
 flag flag {
 disable;
 }
 }
}
switch-options {
 interface interface-name {
 interface-mac-limit limit {

```

```

 packet-action action;
 }
 static-mac mac-address;
}
interface-mac-limit limit {
 packet-action action;
}
mac-move-limit limit {
 packet-action action;
}
mac-table-size limit {
 packet-action drop;
}
no-mac-learning;
}
vlan-id number;
vlan-id-list [vlan-id | vlan-id-vlan-id];
}
}

```

### Unsupported Statements in the [edit vlans] Hierarchy Level

All statements in the **[edit vlans]** hierarchy level that are displayed in the command-line interface (CLI) on the switch are supported on the switch and operate as documented with the following exceptions:

**Table 195: Unsupported [edit vlans] Configuration Statements on EX Series Switches**

| Statement                                                                                         | Hierarchy Level |
|---------------------------------------------------------------------------------------------------|-----------------|
| <b>NOTE:</b> Variables, such as <i>filename</i> , are not shown in the statements or hierarchies. |                 |
| mcae-mac-synchronize                                                                              | [edit vlans]    |
| no-irb-layer-2-copy                                                                               | [edit vlans]    |

**Hierarchy Level** [edit forwarding-options],  
[edit vlans forwarding-options]

**Release Information** Statement introduced in Junos OS Release 11.3 for the QFX Series.

**Description** Configure extended Dynamic Host Configuration Protocol (DHCP) relay and DHCPv6 relay options on the switch and enable the switch to function as a DHCP relay agent. A DHCP relay agent forwards DHCP request and reply packets between a DHCP client and a DHCP server.

DHCP relay supports the attachment of dynamic profiles and also interacts with the local AAA Service Framework to use back-end authentication servers, such as RADIUS, to provide subscriber authentication. You can attach dynamic profiles and configure authentication support on a global basis or for a specific group of interfaces.

The extended DHCP and DHCPv6 relay agent options configured with the **dhcp-relay** and **dhcpv6** statements are incompatible with the DHCP/BOOTP relay agent options configured with the **bootp** statement. As a result, the extended DHCP or DHCPv6 relay agent and the DHCP/BOOTP relay agent cannot both be enabled on the router at the same time.

The remaining statements are explained separately.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

| <b>Description</b>         | Configure a limit to the number of MAC addresses that can be learned from a bridge domain, VLAN, virtual switch, or set of bridge domains or VLANs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**NOTE:** For multichassis link aggregation (MC-LAG) peers in active-active mode, configuring the `interface-mac-limit` statement or changing the `interface-mac-limit` configuration when traffic is flowing can cause the MAC entries to be out of synchronization between the two MC-LAG peers, which might result in flooding. To avoid flooding, you must either halt traffic forwarding and then configure the `interface-mac-limit` statement or use the `commit at` configuration statement to commit the changes at the same time in both the peer nodes.

Alternatively, if flooding does occur, you can clear the bridge MAC table on both the routers or switches by using the `clear bridge mac-table` command. Running this command ensures that the MAC entries are re-learned and in synchronization between both the peers.

**Default** For an access port, the default MAC limit is 1024 MAC addresses. For a trunk port, the default MAC limit is 8192 MAC addresses.

**Options** *limit*—Maximum number of MAC addresses learned from an interface.

**Range:** 1 through 524287 MAC addresses per interface

The remaining statement is explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

### Description

**NOTE:** This statement supports the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see [port-mode](#). For ELS details, see “[Getting Started with Enhanced Layer 2 Software](#)” on page 41.

(QFX Series 3500 and 3600 standalone switches)—Determine whether the logical interface accepts or discards packets based on VLAN tags. Specify the **trunk** option to accept packets with a VLAN ID that matches the list of VLAN IDs specified in the **vlan-id** or **vlan-id-list** statement, then forward the packet within the bridge domain or VLAN configured with the matching VLAN ID. Specify the **access** option to accept packets with no VLAN ID, then forward the packet within the bridge domain or VLAN configured with the VLAN ID that matches the VLAN ID specified in the **vlan-id** statement.

**NOTE:** On MX Series routers, if you want IGMP snooping to be functional for a bridge domain, then you should not configure **interface-mode** and **irb** for that bridge. Such a configuration commit succeeds, but IGMP snooping is not functional, and a message informing the same is displayed. For more information, see *Configuring a Trunk Interface on a Bridge Network*.

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Options</b> | <p><b>access</b>—Configure a logical interface to accept untagged packets. Specify the VLAN to which this interface belongs using the <b>vlan-id</b> statement.</p> <p><b>trunk</b>—Configure a single logical interface to accept packets tagged with any VLAN ID specified with the <b>vlan-id</b> or <b>vlan-id-list</b> statement.</p> <p><b>trunk inter-switch-link</b>—For a private VLAN, configure the InterSwitch Link protocol (ISL) on a trunk port of the primary VLAN in order to connect the switches composing the PVLAN to each other. You do not need to configure an ISL when a PVLAN is configured</p> |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

on a single switch. This configuration specifies whether the particular interface assumes the role of interswitch link for the PVLAN domains of which it is a member. This option is supported only on MX240, MX480, and MX960 routers in enhanced LAN mode.

|                                 |                                                                                                                                                                                                                                                                                                                                                                     |

## members

|                            |                                                                                               |
|----------------------------|-----------------------------------------------------------------------------------------------|
| <b>Syntax</b>              | <code>members [(all   <i>names</i>   <i>vlan-ids</i>)];</code>                                |
| <b>Hierarchy Level</b>     | [edit <a href="#">interfaces</a> <i>interface-name</i> unit 0 family ethernet-switching vlan] |
| <b>Release Information</b> | Statement introduced in Junos OS Release 11.1 for the QFX Series.                             |
| <b>Description</b>         | For trunk interfaces, configure the VLANs for which the interface can carry traffic.          |

**TIP:** To display a list of all configured VLANs on the system, including VLANs that are configured but not committed, type `?` after `vlan` or `vlands` in your configuration mode command line. Note that only one VLAN is displayed for a VLAN range.

**Options** `all`—Specify that this trunk interface be a member of all the VLANs that are configured on this switch. When a new VLAN is configured on the switch, this trunk interface automatically becomes a member of the VLAN.

**NOTE:** Each VLAN that is configured must have a specified VLAN ID when you attempt to commit the configuration; otherwise, the configuration commit fails. Also, `all` cannot be the name of a VLAN on the switch.

*names*—Names of one or more VLANs.

*vlan-ids*—Numeric identifiers of one or more VLANs.

**Required Privilege Level**  
`routing`—To view this statement in the configuration.  
`routing-control`—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b>              | <p>Configure the VLAN identifier to associate with untagged packets received on the interface. The logical interface on which untagged packets are received must be configured with the same VLAN ID as the native VLAN ID configured on the physical interface. To configure the logical interface, include the <b>vlan-id</b> statement (matching the <b>native-vlan-id</b> statement on the physical interface) at the [edit <a href="#">interfaces</a> <i>interface-name</i> unit <i>logical-unit-number</i>] hierarchy level.</p> <p>When the <b>native-vlan-id</b> statement is combined with the <a href="#">interface-mode</a> statement, untagged packets are accepted and forwarded within the bridge domain or VLAN that is configured with the matching VLAN ID.</p> <p>When the <b>native-vlan-id</b> statement is combined with the <a href="#">flexible-vlan-tagging</a> statement, untagged packets are accepted on the interfaces that are configured for Q-in-Q tunneling.</p> <p>.</p> |
| <b>Options</b>                  | <p><b>vlan-id</b>—Numeric identifier of the VLAN.</p> <p><b>Range:</b> 1 through 4094</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Release Information** Statement introduced in Junos OS Release 8.4.  
 Support for the **switch-options** statement added in Junos OS Release 9.2.  
 Support for top-level configuration for the **virtual-switch** type of routing instance added in Junos OS Release 9.2. In Junos OS Release 9.1 and earlier, the routing instances hierarchy supported this statement only for a VPLS instance or a bridge domain configured within a virtual switch.

Support for logical systems added in Junos OS Release 9.6.

[edit switch-options interface *interface-name* interface-mac-limit *limit*], [edit switch-options interface-mac-limit *limit*], [edit switch-options mac-table-size *limit*], [edit vlans *vlan-name* switch-options interface *interface-name* interface-mac-limit *limit*], [edit vlans *vlan-name* switch-options interface-mac-limit *limit*], and [edit vlans *vlan-name* switch-options mac-table-size *limit*] hierarchy levels introduced in Junos OS Release 12.3R2 for EX Series switches.

Support for EVPNs introduced in Junos OS Release 13.2 on MX Series 3D Universal Edge Routers.

Support at the [edit switch-options interface *interface-name* interface-mac-limit *limit*] hierarchy level and hierarchy levels under [edit vlans *vlan-name*] introduced in Junos OS Release 13.2X50-D10 for EX Series switches and Junos OS Release 13.2 for the QFX Series.

**Description** Specify the action taken when packets with new source MAC addresses are received after the MAC address limit is reached. If this statement is not configured, packets with new source MAC addresses are forwarded by default.

**Default**

**NOTE:** On a QFX Series Virtual Chassis, if you include the shutdown option at the [edit vlans *vlan-name* switch-options interface *interface-name* interface-mac-limit packet-action] hierarchy level and issue the commit operation, the system generates a commit error. The system does not generate an error if you include the shutdown option at the [edit switch-options interface *interface-name* interface-mac-limit packet-action] hierarchy level.

Disabled. The default is for packets for new source MAC addresses to be forwarded after the MAC address limit is reached.

**Options**

**drop**—Drop packets with new source MAC addresses, and do not learn the new source MAC addresses.

**drop-and-log**—(EX Series switches and QFX Series only) Drop packets with new source MAC addresses, and generate an alarm, an SNMP trap, or a system log entry.

**log**—(EX Series switches and QFX Series only) Hold packets with new source MAC addresses, and generate an alarm, an SNMP trap, or a system log entry.

**none**—(EX Series switches and QFX Series only) Forward packets with new source MAC addresses, and learn the new source MAC address.

**shutdown**—(EX Series switches and QFX Series only) Disable the specified interface, and generate an alarm, an SNMP trap, or a system log entry.

**Required Privilege Level**

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

| Release Information      | Statement introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Description              | <div> <b>NOTE:</b> This statement does not support the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that supports ELS, see <a href="#">interface-mode</a>. For ELS details, see “<a href="#">Getting Started with Enhanced Layer 2 Software</a>” on page 41.</div> <p>Configure whether an interface on the switch operates in access, tagged access, or trunk mode.</p>                                                                                                                                                                                                                                                         |
| Default                  | All switch interfaces are in access mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Options                  | <p><b>access</b>—Have the interface operate in access mode. In this mode, the interface can be in a single VLAN only. Access interfaces typically connect to network devices, such as PCs, printers, IP telephones, and IP cameras.</p> <p><b>tagged-access</b>—Have the interface operate in tagged-access mode. In this mode, the interface can be in multiple VLANs. Tagged access interfaces typically connect to network devices, such as PCs, printers, IP telephones, and IP cameras.</p> <p><b>trunk</b>—Have the interface operate in trunk mode. In this mode, the interface can be in multiple VLANs and can multiplex traffic between different VLANs. Trunk interfaces typically connect to other switches and to routers on the LAN.</p> |

| <b>Description</b>              | Configure an 802.1Q tag to apply to all traffic that originates on the VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Default</b>                  | <p>On a QFX3500 and QFX3500 switch, if you use the default factory configuration, all traffic originating on the VLAN is untagged and has a VLAN identifier of 1. The number zero is reserved for priority tagging and the number 4093 is also reserved.</p> <p>On a QFX5100 switch, if you use the default factory configuration, all traffic originating on the VLAN is untagged and has a VLAN identifier of 1. The number zero is reserved for priority tagging and the number 4093 is also reserved.</p>                                                                  |
|                                 | <div> <b>NOTE:</b> You can only create up to 4090 VLANs on a QFX5100 switch. If you create more than 4090 VLANs, the interfaces associated with the extra VLANs are not displayed in the <code>show vlans</code> command output. For example, if you create 4094 VLANs, the extra VLANs will not have interfaces associated with the VLANs. The order in which you configure the extra VLANs determines which interfaces are missing from the <code>show vlans</code> command output.</div> |

**Hierarchy Level** [edit]

**Release Information** Statement introduced in Junos OS Release 13.2 for the QFX Series.  
Statements for private VLANs and Q-in-Q tunneling introduced in Junos OS Release 12.1 for the QFX Series.

**Description** Configure VLAN properties on the QFX Series.

**Default** If you use the default factory configuration, all switch interfaces become part of the VLAN default.

**Options** *vlan-name*—Name of the VLAN. The name can contain letters, numbers, hyphens (-), and periods (.) and can be up to 255 characters long.

The remaining statements are described separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

In Junos OS Release 9.1 and earlier, the routing instances hierarchy supported this statement only for a VPLS instance or a bridge domain configured within a virtual switch.</p> <p>Support for logical systems added in Junos OS Release 9.6.</p> <p><b>[edit switch-options]</b> and <b>[edit vlans <i>vlan-name</i> switch-options]</b> hierarchy levels introduced in Junos OS Release 12.3R2 for EX Series switches.</p> <p>Support at the <b>[edit vlans <i>vlan-name</i> switch-options]</b> hierarchy level introduced in Junos OS Release 13.2 for the QFX Series.</p> |
| <b>Description</b>         | Modify the size of the MAC address table for the bridge domain or VLAN, a set of bridge domains or VLANs associated with a trunk port, or a virtual switch. The default is 5120 MAC addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**NOTE:** For multichassis link aggregation (MC-LAG) peers in active-active mode, configuring the **mac-table-size** statement or changing the **mac-table-size** configuration when traffic is flowing can cause the MAC entries to be out of synchronization between the two MC-LAG peers, which might result in flooding. To avoid flooding, you must either halt traffic forwarding and then configure the **mac-table-size** statement or use the **commit at** configuration statement to commit the changes at the same time in both the peer nodes.

Alternatively, if flooding does occur, you can clear the bridge MAC table on both the routers by using the **clear bridge mac-table** command. Running this command ensures that the MAC entries are re-learned and in synchronization between both the peers.

**Options** *limit*—Specify the maximum number of addresses in the MAC address table.  
**Range:** 16 through 1,048,575 MAC addresses  
**Default:** 5120 MAC addresses  
 There is no default MAC address limit for the **mac-table-size** statement at the **[edit switch-options]** hierarchy level. The number of MAC addresses that can be learned is only limited by the platform, 65,535 MAC addresses for EX Series switches and 1,048,575 MAC addresses for other devices.

The remaining statement is explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
 routing-control—To add this statement to the configuration.

## notification-interval

**Syntax** notification-interval *seconds*;

**Hierarchy Level** [edit ethernet-switching-options mac-notification]  
 [edit switch-options mac-notification]

**Release Information** Statement introduced in Junos OS Release 11.1 for the QFX Series.  
 Hierarchy level **[edit switch-options]** added in Junos OS Release 14.1X53-D10 for EX Series and QFX Series.

**Description** Configure the MAC notification interval for a switch.

The MAC notification interval is the amount of time the switch waits before sending learned or unlearned MAC address SNMP notifications to the network management server. For instance, if the MAC notification interval is set to 10, all of the MAC address addition and removal SNMP notifications are sent to the network management system every 10 seconds.

**Options** *seconds*—The MAC notification interval, in seconds.  
**Range:** 1 through 60  
**Default:** 30

**Required Privilege Level** routing—To view this statement in the configuration.  
 routing-control—To add this statement to the configuration.

| <b>Description</b>              | Configure link cost to control which bridge is the designated bridge and which port is the designated port. By default, the link cost is determined by the link speed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b>              | Configure link cost to control which bridge is the designated bridge and which port is the designated port. By default, the link cost is determined by the link speed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b>              | Configure interfaces as edge ports. Edge ports do not expect to receive BPDUs. If a BPDU is received, the port becomes a nonedge port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## msti

**Syntax** `msti msti-id {  
     bridge-priority priority;  
     vlan (vlan-id | vlan-range|open-set-of-values);  
     interface (interface-name | all) {  
         cost cost;  
         edge;  
         priority interface-priority;  
     }  
 }`

**Hierarchy Level** [edit protocols [mstp](#)],  
 [edit routing-instances *routing-instance-name* protocols mstp]

**Release Information** Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.  
 Statement updated in Junos OS Release 15.1 for EX Series switches to support configuration of spanning tree parameters globally on all interfaces.

**NOTE:** You cannot disable spanning tree parameters globally on all interfaces.

**Description** Configure the multiple spanning-tree instance (MSTI) identifier.

**Options** *msti-id*—MSTI instance identifier.  
**Range:** 1 through 4094

The remaining statements are explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
 routing-control—To add this statement to the configuration.

| <b>Description</b>              | Ensure the port is the spanning-tree designated port. If the port receives superior bridge protocol data unit (BPDU) packets, root protect moves this port to a root-prevented spanning-tree state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b>              | Use the interface priority to control which interface is elected as the root port. The interface priority must be set in increments of 16.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Hierarchy Level** [edit protocols]

**Release Information** Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches.  
Statement updated in Junos OS Release 15.1 for EX Series and QFX Series switches to support configuration of spanning tree parameters globally on all interfaces.

**NOTE:** You cannot disable spanning tree parameters globally on all interfaces.

**Description** Configure RSTP parameters.

**Options** The remaining statements are explained separately.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>         | Set protocol-level tracing options for spanning-tree protocols.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Default</b>             | The default STP protocol-level trace options are inherited from the global <b>traceoptions</b> statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Options</b>             | <p><b>disable</b>—(Optional) Disable the tracing operation. One use of this option is to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name in quotation marks. We recommend that you place STP tracing output in the file <code>/var/log/stp-log</code>.</p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file named <b>trace-file</b> reaches its maximum size, it is renamed <b>trace-file.0</b>, then <b>trace-file.1</b>, and so on, until the maximum number of trace files is reached. Then, the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you must also specify a maximum file size with the <b>size</b> option.</p> <p><b>Range:</b> 2 through 1000 files<br/> <b>Default:</b> 1 trace file only</p> <p><b>flag</b>—Tracing operation to perform. To specify more than one tracing operation, include multiple <b>flag</b> statements. The following are the STP-specific tracing options:</p> <ul style="list-style-type: none"> <li><b>all</b>—Trace all operations.</li> <li><b>all-failures</b>—Trace all failure conditions.</li> <li><b>bpdv</b>—Trace BPDU reception and transmission.</li> <li><b>bridge-detection-state-machine</b>—Trace the bridge detection state machine.</li> </ul> |

- **events**—Trace events of the protocol state machine.
- **port-information-state-machine**—Trace the port information state machine.
- **port-migration-state-machine**—Trace the port migration state machine.
- **port-receive-state-machine**—Trace the port receive state machine.
- **port-role-transit-state-machine**—Trace the port role transit state machine.
- **port-role-select-state-machine**—Trace the port role selection state machine.
- **port-state-transit-state-machine**—Trace the port state transit state machine.
- **port-transmit-state-machine**—Trace the port transmit state machine.
- **ppmd**—Trace the state and events for the ppm process.
- **state-machine-variables**—Trace when the state machine variables change.
- **timers**—Trace protocol timers.
- **topology-change-state-machine**—Trace the topology change state machine.

The following are the global tracing options:

- **all**—All tracing operations.
- **config-internal**—Trace configuration internals.
- **general**—Trace general events.
- **normal**—All normal events.

**Default:** If you do not specify this option, only unusual or abnormal operations are traced.

- **parse**—Trace configuration parsing.
- **policy**—Trace policy operations and actions.
- **regex-parse**—Trace regular-expression parsing.
- **route**—Trace routing table changes.
- **state**—Trace state transitions.
- **task**—Trace protocol task processing.
- **timer**—Trace protocol task timer processing.

**no-world-readable**—(Optional) Prevent any user from reading the log file.

**size size**—(Optional) Maximum size of each trace file, in kilobytes (KB) or megabytes (MB). When a trace file named **trace-file** reaches this size, it is renamed **trace-file.0**. When the **trace-file** again reaches its maximum size, **trace-file.0** is renamed **trace-file.1** and **trace-file** is renamed **trace-file.0**. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

If you specify a maximum file size, you must also specify a maximum number of trace files with the **files** option.

**Syntax:** **xk** to specify KB, **xm** to specify MB, or **xg** to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 1 MB

**world-readable**—(Optional) Allow any user to read the log file.

## vlan-group

**Syntax** `vlan-group group group-name {  
           vlan (vlan-id |vlan-group |all) {  
           }`

**Hierarchy Level**           [edit protocols **vstp**]

**Release Information**   Statement introduced in Junos OS Release 15.1 for EX Series switches.

**Description**           Configure VLAN group for Spanning Tree Protocol (VSTP). VSTP is used to prevent loops in Layer 2 networks on a per-VLAN basis.

**BEST PRACTICE:** Configure RSTP when you configure VSTP. RSTP overhead is minimal and this configuration ensures that a spanning-tree protocol is running on all VLANs on your switch, even when your switch is supporting more than the maximum number of allowed VSTP VLANs.

The remaining statements are explained separately.

**Required Privilege Level**   routing—To view this statement in the configuration.  
                                   routing-control—To add this statement to the configuration.

 }
 }
}
```

Hierarchy Level [edit protocols]

**Release Information** Statement introduced in Junos OS Release 13.2X50-D10 for EX Series switches. Statement updated in Junos OS Release 15.1 for EX Series switches to support configuration of spanning tree parameters globally on all interfaces.

NOTE: You cannot disable spanning tree parameters globally on all interfaces.

| <b>Description</b>         | <p>Configure mixed tagging support for untagged packets on a port for the following:</p> <ul style="list-style-type: none"><li>• M Series routers with Gigabit Ethernet IQ PICs with SFP and Gigabit Ethernet IQ2 PICs with SFP configured for 802.1Q flexible VLAN tagging</li><li>• MX Series routers with Gigabit Ethernet DPCs and MICs, Tri-Rate Ethernet DPCs and MICs, and 10-Gigabit Ethernet DPCs and MICs and MPCs configured for 802.1Q flexible VLAN tagging</li><li>• T4000 routers with 100-Gigabit Ethernet Type 5 PIC with CFP</li><li>• EX Series switches with Gigabit Ethernet, 10-Gigabit Ethernet, 40-Gigabit Ethernet, and aggregated Ethernet interfaces</li></ul> <p>When the <b>native-vlan-id</b> statement is included with the <b>flexible-vlan-tagging</b> statement, untagged packets are accepted on the same mixed VLAN-tagged port.</p> <div> <b>NOTE:</b> The logical interface on which untagged packets are received must be configured with the same VLAN ID as the native VLAN ID configured on the physical interface, otherwise the untagged packets are dropped.</div> <p>To configure the logical interface, include the <b>vlan-id</b> statement (matching the <b>native-vlan-id</b> statement on the physical interface) at the [edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i>] hierarchy level.</p> <p>When the <b>native-vlan-id</b> statement is included with the <b>interface-mode</b> statement, untagged packets are accepted and forwarded within the bridge domain or VLAN that is configured with the matching VLAN ID.</p> |
| <b>Default</b>             | By default, the untagged packets are dropped. That is, if you do not configure the <b>native-vlan-id</b> option, the untagged packets are dropped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Options</b>             | <b><i>number</i></b> —VLAN ID number.<br><b>Range:</b> (ACX Series routers and EX Series switches) 0 through 4094.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## output-vlan-map (Gigabit Ethernet IQ and 10-Gigabit Ethernet with SFPP)

**Syntax** `output-vlan-map {  
    (pop | pop-pop | pop-swap | push | push-push | swap | swap-push | swap-swap);  
    inner-tag-protocol-id tpid;  
    inner-vlan-id number;  
    tag-protocol-id tpid;  
    vlan-id number;  
}`

**Hierarchy Level** [edit interfaces *interface-name* unit *logical-unit-number*],  
[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

**Release Information** Statement introduced before Junos OS Release 7.4.  
**pop-pop**, **pop-swap**, **push-push**, **swap-push**, and **swap-swap** statements added in Junos OS Release 8.1.

**Description** For Gigabit Ethernet IQ and 10-Port 10-Gigabit Ethernet SFPP interfaces only, define the rewrite operation to be applied to outgoing frames on this logical interface.

The statements are explained separately.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

| <b>Description</b>              | <p> <b>NOTE:</b> On EX4300 switches, <code>push</code> is not supported at the <code>[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> output-vlan-map]</code> hierarchy level.</p> <p>Specify the VLAN rewrite operation to add a new VLAN tag to the top of the VLAN stack. An outer VLAN tag is pushed in front of the existing VLAN tag.</p> <p>You can use this statement on Gigabit Ethernet IQ and 10-Gigabit Ethernet IQ2 and IQ2-E interfaces; 10-Gigabit Ethernet LAN/WAN PIC; aggregated Ethernet interfaces using Gigabit Ethernet IQ interfaces; 100-Gigabit Ethernet Type 5 PIC with CFP; and Gigabit Ethernet, 10-Gigabit Ethernet, 40-Gigabit Ethernet, and aggregated Ethernet interfaces.</p> <p>If you include the <b>push</b> statement in the configuration, you must also include the <a href="#">pop</a> statement at the <code>[edit interfaces <i>interface-name</i> unit <i>logical-unit-number</i> output-vlan-map]</code> hierarchy level.</p> |
| <b>Required Privilege Level</b> | <p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b>              | <p>Specify the VLAN rewrite operation to replace a VLAN tag. The outer VLAN tag of the frame is overwritten with the user-specified VLAN tag information.</p> <p>On MX Series routers, you can enter this statement on Gigabit Ethernet IQ and 10-Gigabit Ethernet IQ2 and IQ2-E interfaces, 10-Gigabit Ethernet LAN/WAN PIC, aggregated Ethernet using Gigabit Ethernet IQ interfaces, and 100-Gigabit Ethernet Type 5 PIC with CFP. On EX Series switches, you can enter this statement on Gigabit Ethernet, 10-Gigabit Ethernet, 40-Gigabit Ethernet, and aggregated Ethernet interfaces.</p> |

| <b>Release Information</b> | Command introduced in Junos OS Release 9.3 for EX Series switches.<br>Command introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b>         | <div>  <p><b>NOTE:</b> On a QFabric system, using this command on an FCoE-enabled VLAN when FCoE sessions are active can cause traffic flooding and FCoE traffic drop. The FCoE sessions are not terminated and the traffic reconverges after a short period of time.</p> </div> <p>Clear learned entries, which are media access control (MAC) addresses, in the Ethernet switching table (also called the forwarding database table).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Options</b>             | <p><b>none</b>—Clear learned entries in the Ethernet switching table, except for persistent MAC addresses.</p> <p><b>interface <i>interface-name</i></b>—(Optional) Clear all learned MAC addresses for the specified interface from the Ethernet switching table.</p> <p><b>mac <i>mac-address</i></b>—(Optional) Clear the specified learned MAC address from the Ethernet switching table.</p> <p><b>management-vlan</b>—(Optional) Clear all MAC addresses learned for the management VLAN from the Ethernet switching table. Note that you do not specify a VLAN name because only one management VLAN exists.</p> <p><b>persistent-mac &lt;<i>interface</i>   <i>mac-address</i>&gt;</b>—(Optional) Clear all MAC addresses, including persistent MAC addresses. Use the <b>interface</b> option to clear all MAC addresses on an interface, or use the <b>mac-address</b> option to clear all entries for a specific MAC address.</p> <p>Use this command whenever you move a device in your network that has a persistent MAC address on the switch. If you move the device to another port on the switch and do not clear the persistent MAC address from the original port it was learned on, then the new port will not learn the MAC address and the device will not be able to connect. If the original port is down when you move the device, then the new port</p> |

will learn the MAC address and the device can connect—however, unless you cleared the MAC address on the original port, when the port comes back up, the system reinstalls the persistent MAC address in the forwarding table for that port. If this occurs, the address is removed from the new port and the device loses connectivity.

**vlan *vlan-name***—(Optional) Clear all MAC addresses learned for the specified VLAN from the Ethernet switching table.

| <b>untagged   tagged</b> | Specifies whether the interface forwards IEEE802.1Q-tagged or untagged traffic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | <b>detail</b>                                       |

## Sample Output

### show ethernet-switching interfaces

```
user@switch> show ethernet-switching interfaces
```

```

Interface State VLAN members Blocking
xe-0/0/0.0 up T1122 unblocked
xe-0/0/1.0 down default - MAC limit exceeded
xe-0/0/2.0 down default - MAC move limit exceeded
xe-0/0/3.0 down default - Storm control in effect
xe-0/0/4.0 down default unblocked
xe-0/0/5.0 down default unblocked
xe-0/0/6.0 down default unblocked
xe-0/0/7.0 down default unblocked
xe-0/0/8.0 down default unblocked
xe-0/0/9.0 up T111 unblocked
xe-0/0/10.0 down default unblocked
xe-0/0/11.0 down default unblocked
xe-0/0/12.0 down default unblocked
xe-0/0/13.0 down default unblocked
xe-0/0/14.0 down default unblocked
xe-0/0/15.0 down default unblocked
xe-0/0/16.0 down default unblocked
xe-0/0/17.0 down default unblocked
xe-0/0/18.0 down default unblocked
xe-0/0/19.0 up T111 unblocked
xe-0/1/0.0 down default unblocked
xe-0/1/1.0 down default unblocked
xe-0/1/2.0 down default unblocked
xe-0/1/3.0 down default unblocked

```

### show ethernet-switching interfaces summary

```
user@switch> show ethernet-switching interfaces summary
xe-0/0/0.0
xe-0/0/1.0
xe-0/0/2.0
xe-0/0/3.0
xe-0/0/8.0
xe-0/0/10.0
xe-0/0/11.0
```

### show ethernet-switching interfaces brief

```
user@switch> show ethernet-switching interfaces brief
Interface State VLAN members Blocking
xe-0/0/0.0 down default unblocked
xe-0/0/1.0 down employee-vlan unblocked
xe-0/0/2.0 down employee-vlan unblocked
xe-0/0/3.0 down employee-vlan unblocked
xe-0/0/8.0 down employee-vlan unblocked
xe-0/0/10.0 down default unblocked
xe-0/0/11.0 down employee-vlan unblocked
```

### show ethernet-switching interfaces detail

```
user@switch> show ethernet-switching interfaces detail
Interface: xe-0/0/0.0 Index: 65
State: down
VLANs:
 default untagged unblocked

Interface: xe-0/0/1.0 Index: 66
State: down
VLANs:
 employee-vlan untagged unblocked

Interface: xe-0/0/2.0 Index: 67
State: down
VLANs:
 employee-vlan untagged unblocked

Interface: xe-0/0/3.0 Index: 68
State: down
VLANs:
 employee-vlan untagged unblocked

Interface: xe-0/0/8.0 Index: 69
State: down
VLANs:
 employee-vlan untagged unblocked

Interface: xe-0/0/10.0 Index: 70
State: down
VLANs:
 default untagged unblocked

Interface: xe-0/0/11.0 Index: 71
State: down
VLANs:
 employee-vlan tagged unblocked
```

**show ethernet-switching interfaces interface-name**

```
user@switch> show ethernet-switching interfaces xe-0/0/0.0
Interface State VLAN members Blocking
xe-0/0/0.0 down default unblocked
```

## show ethernet-switching table

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |

Table 197: show ethernet-switching table Output Fields

| Field Name | Field Description | Level of Output |
|------------|-------------------|-----------------|
| VLAN       | Name of a VLAN.   | All levels      |

Table 197: show ethernet-switching table Output Fields (*continued*)

| Field Name         | Field Description                                                                                                                                                                                                                                                                                             | Level of Output          |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|
| <b>MAC address</b> | MAC address associated with the VLAN.                                                                                                                                                                                                                                                                         | All levels               |
| <b>Type</b>        | Type of MAC address: <ul style="list-style-type: none"> <li>• <b>static</b>—The MAC address is manually created.</li> <li>• <b>learn</b>—The MAC address is learned dynamically from a packet's source MAC address.</li> <li>• <b>flood</b>—The MAC address is unknown and flooded to all members.</li> </ul> | All levels               |
| <b>Age</b>         | Time remaining before the entry ages out and is removed from the Ethernet switching table.                                                                                                                                                                                                                    | All levels               |
| <b>Interfaces</b>  | Interface associated with learned MAC addresses or with the <b>All-members</b> option (flood entry).                                                                                                                                                                                                          | All levels               |
| <b>Learned</b>     | For learned entries, the time at which the entry was added to the Ethernet switching table.                                                                                                                                                                                                                   | <b>detail, extensive</b> |

## Sample Output

### show ethernet-switching table (Enhanced Layer 2 Software)

```
user@switch> show ethernet-switching table
MAC flags (S - static MAC, D - dynamic MAC, L - locally learned, P - Persistent
static
 SE - statistics enabled, NM - non configured MAC, R - remote PE MAC,
0 - ovsdb MAC)
```

```
Ethernet switching table : 2 entries, 2 learned
```

```
Routing instance : default-switch
```

| Vlan<br>name | MAC<br>address    | MAC<br>flags | Age | Logical<br>interface |
|--------------|-------------------|--------------|-----|----------------------|
| vlan1        | b0:c6:9a:ca:3c:01 | D            | -   | ae1.0                |
| vlan1        | b0:c6:9a:ca:3c:03 | D            | -   | ae1.0                |

```
MAC flags (S - static MAC, D - dynamic MAC, L - locally learned, P - Persistent
static
```

```
 SE - statistics enabled, NM - non configured MAC, R - remote PE MAC,
0 - ovsdb MAC)
```

```
Ethernet switching table : 2 entries, 2 learned
```

```
Routing instance : default-switch
```

| Vlan<br>name | MAC<br>address    | MAC<br>flags | Age | Logical<br>interface |
|--------------|-------------------|--------------|-----|----------------------|
| vlan10       | b0:c6:9a:ca:3c:01 | D            | -   | ae1.0                |
| vlan10       | b0:c6:9a:ca:3c:03 | D            | -   | ae1.0                |

MAC flags (S - static MAC, D - dynamic MAC, L - locally learned, P - Persistent static

SE - statistics enabled, NM - non configured MAC, R - remote PE MAC, O - ovsdb MAC)

Ethernet switching table : 2 entries, 2 learned

Routing instance : default-switch

| Vlan name | MAC address       | MAC flags | Age | Logical interface |
|-----------|-------------------|-----------|-----|-------------------|
| vlan2     | b0:c6:9a:ca:3c:01 | D         | -   | ae1.0             |
| vlan2     | b0:c6:9a:ca:3c:03 | D         | -   | ae1.0             |

MAC flags (S - static MAC, D - dynamic MAC, L - locally learned, P - Persistent static

SE - statistics enabled, NM - non configured MAC, R - remote PE MAC, O - ovsdb MAC)

Ethernet switching table : 2 entries, 2 learned

Routing instance : default-switch

| Vlan name | MAC address       | MAC flags | Age | Logical interface |
|-----------|-------------------|-----------|-----|-------------------|
| vlan3     | b0:c6:9a:ca:3c:01 | D         | -   | ae1.0             |
| vlan3     | b0:c6:9a:ca:3c:03 | D         | -   | ae1.0             |

MAC flags (S - static MAC, D - dynamic MAC, L - locally learned, P - Persistent static

SE - statistics enabled, NM - non configured MAC, R - remote PE MAC, O - ovsdb MAC)

Ethernet switching table : 2 entries, 2 learned

Routing instance : default-switch

| Vlan name | MAC address       | MAC flags | Age | Logical interface |
|-----------|-------------------|-----------|-----|-------------------|
| vlan4     | b0:c6:9a:ca:3c:01 | D         | -   | ae1.0             |
| vlan4     | b0:c6:9a:ca:3c:03 | D         | -   | ae1.0             |

### show ethernet-switching table

## show system statistics arp

```
user@switch> show system statistics arp
arp:
 90060 datagrams received
 34 ARP requests received
 610 ARP replies received
 0 resolution request received
 0 unrestricted proxy requests
 0 restricted proxy requests
 0 received proxy requests
 0 unrestricted proxy requests not proxied
 0 restricted proxy requests not proxied
 0 datagrams with bogus interface
 0 datagrams with incorrect length
 0 datagrams for non-IP protocol
 0 datagrams with unsupported op code
 0 datagrams with bad protocol address length
 0 datagrams with bad hardware address length
 0 datagrams with multicast source address
 0 datagrams with multicast target address
 0 datagrams with my own hardware address
 0 datagrams for an address not on the interface
 0 datagrams with a broadcast source address
 294 datagrams with source address duplicate to mine
 89113 datagrams which were not for me
 0 packets discarded waiting for resolution
 0 packets sent after waiting for resolution
 309 ARP requests sent
 35 ARP replies sent
 0 requests for memory denied
 0 requests dropped on entry
 0 requests dropped during retry
 0 requests dropped due to interface deletion
 0 requests on unnumbered interfaces
 0 new requests on unnumbered interfaces
 0 replies for from unnumbered interfaces
 0 requests on unnumbered interface with non-subnetted donor
 0 replies from unnumbered interface with non-subnetted donor
```

## show vlans

**Syntax** `show vlans`  
`<brief | detail | extensive>`  
`<dot1q-tunneling>`  
`<sort-by (tag | name)>`  
`<vlan-range-name>`

**Release Information** Command introduced in Junos OS Release 11.1 for the QFX Series.  
Option **dot1q-tunneling** added in Junos OS Release 12.1 for the QFX Series.

**Description** Display information about VLANs configured on bridged Ethernet interfaces. For interfaces configured to support a VoIP VLAN and a data VLAN, the **show vlans** command displays both tagged and untagged membership for those VLANs.

**NOTE:** When a series of VLANs is created using the `vlan-range` statement, such VLAN names are preceded and followed by a double underscore. For example, a series of VLANs using the VLAN range 1 through 3 and the base VLAN name `marketing` would be displayed as `__marketing_1__`, `__marketing_2__`, and `__marketing_3__`.

**NOTE:** To display an 802.1X supplicant successfully authenticated in multiple-suppliant mode with dynamic VLAN movement, use the `show vlans vlan-name extensive` operational mode command, where *vlan-name* is the dynamic VLAN.

**Options** **none**—Display information for all VLANs. VLAN information is displayed by VLAN name in ascending order.

**brief | detail | extensive**—(Optional) Display the specified level of output.

**sort-by (tag | name)**—(Optional) Display VLANs in ascending order of VLAN IDs or VLAN names.

**vlan-range-name**—(Optional) Display VLANs in ascending order of VLAN range names.

**Required Privilege Level** `view`

## CHAPTER 86

# MAC Address Operational Commands

- `show ethernet-switching mac-learning-log`
- `show ethernet-switching mac-notification`
- `show ethernet-switching statistics aging`
- `show ethernet-switching statistics mac-learning`

## show ethernet-switching mac-learning-log

|                                 |                                                                                                                                                                                           |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>                   | show ethernet-switching mac-learning-log                                                                                                                                                  |
| <b>Release Information</b>      | Command introduced in Junos OS Release 11.1 for the QFX Series.                                                                                                                           |
| <b>Description</b>              | Displays the event log of learned MAC addresses.                                                                                                                                          |
| <b>Required Privilege Level</b> | view                                                                                                                                                                                      |
| <b>Related Documentation</b>    | <ul style="list-style-type: none"> <li>• <a href="#">show ethernet-switching table on page 2386</a></li> <li>• <a href="#">show ethernet-switching interfaces on page 1998</a></li> </ul> |
| <b>List of Sample Output</b>    | <a href="#">show ethernet-switching mac-learning-log on page 2406</a>                                                                                                                     |
| <b>Output Fields</b>            | Table 199 lists the output fields for the <b>show ethernet-switching mac-learning-log</b> command. Output fields are listed in the approximate order in which they appear.                |

Table 199: show ethernet-switching mac-learning-log Output Fields

| Field Name            | Field Description                                                                                                                                                                                                                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Date and Time</b>  | Timestamp in UTC when the MAC operation occurred.                                                                                                                                                                                                                                             |
| <b>vlan_name</b>      | VLAN name. A value defined by the user for all user-configured VLANs. The name of the VLAN on which the MAC is learned.                                                                                                                                                                       |
| <b>MAC</b>            | Learned MAC address.                                                                                                                                                                                                                                                                          |
| <b>Event op</b>       | MAC address that are added, learned, deleted, changed or moved from one interface to another interface.                                                                                                                                                                                       |
| <b>Interface Name</b> | The name of the interface on which the MAC address is learned. When a MAC address is moved, there is another field with the name of the interface. The log displays the name of the interface from where the MAC address moved, and the name of the interface to where the MAC address moved. |
| <b>Flags</b>          | Displays the MAC address flags in which the MAC event occurred. This option is for debugging purposes.                                                                                                                                                                                        |

## Sample Output

### show ethernet-switching mac-learning-log

```

user@switch> show ethernet-switching mac-learning-log
Mon Jun 30 13:49:49 2014 vlan_name v11+11 mac 00:10:94:00:00:02 was learned on
ge-1/0/22.0 with flags: 0x2001f << MAC address that as dynamically learned
Mon Jun 30 13:50:29 2014 vlan_name v11+11 mac 00:10:94:00:00:02 was deleted from
ge-1/0/22.0 with flags: 0x1080 << MAC address that was deleted
Mon Jun 30 13:51:28 2014 vlan_name v11+11 mac 00:00:00:01:01:01 was added to
ge-1/0/22.0 with flags: 0x2013f << Static MAC address that was added
Mon Jun 30 13:51:46 2014 vlan_name v11+11 mac 00:00:00:01:01:01 was deleted from
ge-1/0/22.0 with flags: 0x1120 << delete of Static MAC address that was deleted

```

```
Mon Jun 30 13:52:03 2014 vlan_name v11+11 mac 00:10:94:00:00:02 was learned on
ge-1/0/22.0 with flags: 0x2001f << MAC address that was dynamically learned
Mon Jun 30 13:52:11 2014 vlan_name v11+11 mac 00:10:94:00:00:02 was moved from
ge-1/0/22.0 to ge-1/0/21.0 with flags: 0x2101f << MAC address that was moved
Mon Jun 30 13:54:24 2014 vlan_name v11+11 mac 00:10:94:00:00:02 was changed on
ge-1/0/21.0 with flags: 0x2113f << MAC address that changed from a dynamic
address to a static address
```

Table 201: show ethernet-switching statistics aging Output Fields

| Field Name                         | Field Description                                                                                                                                                                                                                                                                                                                                                                   | Level of Output |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Total age messages received</b> | Total number of aging messages received from the hardware.                                                                                                                                                                                                                                                                                                                          | All levels      |
| <b>Immediate aging</b>             | Aging message indicating that the entry should be removed immediately.                                                                                                                                                                                                                                                                                                              | All levels      |
| <b>MAC address seen</b>            | Aging message indicating that the MAC address has been detected by hardware and that the aging timer should be stopped.                                                                                                                                                                                                                                                             | All levels      |
| <b>MAC address not seen</b>        | Aging message indicating that the MAC address has not been detected by the hardware and that the aging timer should be started.                                                                                                                                                                                                                                                     | All levels      |
| <b>Error age messages</b>          | The received aging message contains the following errors: <ul style="list-style-type: none"> <li>• <b>Invalid VLAN</b>—The VLAN of the packet does not exist.</li> <li>• <b>No such entry</b>—The MAC address and VLAN pair provided by the aging message does not exist.</li> <li>• <b>Static entry</b>—An unsuccessful attempt was made to age out a static MAC entry.</li> </ul> | All levels      |

## Sample Output

### show ethernet-switching statistics aging

```
user@switch> show ethernet-switching statistics aging
```

```
Total age messages received: 0
```

```
Immediate aging: 0, MAC address seen: 0, MAC address not seen: 0
```

```
Error age messages: 0
```

```
Invalid VLAN: 0, No such entry: 0, Static entry: 0
```

## show ethernet-switching statistics mac-learning

## CHAPTER 87

# Spanning Tree Monitoring Commands

- clear error bpdu interface
- clear spanning-tree statistics
- show spanning-tree bridge
- show spanning-tree interface
- show spanning-tree mstp configuration
- show spanning-tree statistics

## clear error bpdu interface

---

|                                 |                                                                                                                                                                                                                                                    |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>                   | <code>clear error bpdu interface (all   <i>interface-name</i>)</code>                                                                                                                                                                              |
| <b>Release Information</b>      | Command introduced in Junos OS Release 9.4.<br>Command introduced in Junos OS Release 13.2X50-D10 for EX Series switches.<br>Command supports <b>all</b> option in Junos OS Release 15.1 for EX Series switches.                                   |
| <b>Description</b>              | Clear a bridge protocol data unit (BPDU) error condition caused by the detection of a possible bridging loop from Spanning Tree Protocol (STP) operation.                                                                                          |
| <b>Required Privilege Level</b> | clear                                                                                                                                                                                                                                              |
| <b>Related Documentation</b>    | <ul style="list-style-type: none"><li>• <a href="#">Configuring BPDU Protection on Spanning Tree Interfaces on page 2205</a></li><li>• <a href="#">Unblocking an Interface That Receives BPDUs in Error (CLI Procedure) on page 2217</a></li></ul> |
| <b>List of Sample Output</b>    | <a href="#">clear error bpdu interface on page 2418</a>                                                                                                                                                                                            |
| <b>Output Fields</b>            | When you enter this command, you are provided feedback on the status of your request.                                                                                                                                                              |

### Sample Output

#### clear error bpdu interface

```
user@switch> clear error bpdu interface ge-1/1/1
```

## clear spanning-tree statistics

|                                                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                         |

### Sample Output

#### clear stp statistics

```
user@host> clear stp statistics
```

## show spanning-tree bridge

**List of Syntax** [Syntax on page 2420](#)  
[Syntax \(QFX Series\) on page 2420](#)

**Syntax** `show spanning-tree bridge`  
`<brief | detail>`  
`<msti msti-id>`  
`<routing-instance routing-instance-name>`  
`<vlan-id vlan-id>`

**Syntax (QFX Series)** `show spanning-tree bridge`  
`<brief | detail>`  
`<msti msti-id>`  
`<vlan-id vlan-id>`

**Release Information** Command introduced in Junos OS Release 8.4.  
 Command introduced in Junos OS Release 11.1 for the QFX Series.

**Description** Display the configured or calculated Spanning Tree Protocol (STP) parameters.

**Options** **none**—(Optional) Display brief STP bridge information for all multiple spanning-tree instances (MSTIs).

**brief | detail**—(Optional) Display the specified level of output.

**msti *msti-id***—(Optional) Display STP bridge information for the specified MSTI.

**routing-instance *routing-instance-name***—(Optional) Display STP bridge information for the specified routing instance.

**vlan-id *vlan-id***—(Optional) Display STP bridge information for the specified VLAN.

**Required Privilege Level** view

**List of Sample Output** [show spanning-tree bridge routing-instance on page 2421](#)  
[show spanning-tree bridge msti on page 2422](#)  
[show spanning-tree bridge vlan-id \(MSTP\) on page 2423](#)  
[show spanning-tree bridge \(RSTP\) on page 2423](#)  
[show spanning-tree bridge vlan-id \(RSTP\) on page 2424](#)

**Output Fields** [Table 203](#) lists the output fields for the **show spanning-tree bridge** command. Output fields are listed in the approximate order in which they appear.

**Table 203: show spanning-tree bridge Output Fields**

| Field Name            | Field Description                                                  |
|-----------------------|--------------------------------------------------------------------|
| Routing instance name | Name of the routing instance under which the bridge is configured. |
| Enabled protocol      | Spanning Tree Protocol type enabled.                               |

Table 203: show spanning-tree bridge Output Fields (*continued*)

| Field Name                             | Field Description                                                                                                                               |
|----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Root ID</b>                         | Bridge ID of the elected spanning-tree root bridge. The bridge ID consists of a configurable bridge priority and the MAC address of the bridge. |
| <b>Root cost</b>                       | Calculated cost to reach the root bridge from the bridge where the command is entered.                                                          |
| <b>Root port</b>                       | Interface that is the current elected root port for this bridge.                                                                                |
| <b>CIST regional root</b>              | Bridge ID of the elected MSTP regional root bridge.                                                                                             |
| <b>CIST internal root cost</b>         | Calculated cost to reach the regional root bridge from the bridge where the command is entered.                                                 |
| <b>Hello time</b>                      | Configured number of seconds between transmissions of configuration BPDUs.                                                                      |
| <b>Maximum age</b>                     | Configured maximum expected arrival time of hello bridge protocol data units (BPDUs).                                                           |
| <b>Forward delay</b>                   | How long an STP bridge port remains in the listening and learning states before transitioning to the forwarding state.                          |
| <b>Hop count</b>                       | Configured maximum number of hops a BPDU can be forwarded in the MSTP region.                                                                   |
| <b>Message age</b>                     | Number of elapsed seconds since the most recent BPDU was received.                                                                              |
| <b>Number of topology changes</b>      | Total number of STP topology changes detected since the routing device last booted.                                                             |
| <b>Time since last topology change</b> | Number of elapsed seconds since the most recent topology change.                                                                                |
| <b>Bridge ID (Local)</b>               | Locally configured bridge ID. The bridge ID consists of a configurable bridge priority and the MAC address of the bridge.                       |
| <b>Extended system ID</b>              | System identifier.                                                                                                                              |
| <b>MSTI regional root</b>              | Bridge ID of the elected MSTP regional root bridge.                                                                                             |

## Sample Output

### show spanning-tree bridge routing-instance

```

user@host> show spanning-tree bridge routing-instance vs1 detail
STP bridge parameters
Routing instance name : vs1
Enabled protocol : MSTP

```

```
STP bridge parameters for CIST
 Root ID : 32768.00:13:c3:9e:c8:80
 Root cost : 0
 Root port : ge-10/2/0
 CIST regional root : 32768.00:13:c3:9e:c8:80
 CIST internal root cost : 22000
 Hello time : 2 seconds
 Maximum age : 20 seconds
 Forward delay : 15 seconds
 Hop count : 18
 Message age : 0
 Number of topology changes : 1
 Time since last topology change : 1191 seconds
 Local parameters
 Bridge ID : 32768.00:90:69:0b:7f:d1
 Extended system ID : 1

STP bridge parameters for MSTI 1
 MSTI regional root : 32769.00:13:c3:9e:c8:80
 Root cost : 22000
 Root port : ge-10/2/0
 Hello time : 2 seconds
 Maximum age : 20 seconds
 Forward delay : 15 seconds
 Hop count : 18
 Number of topology changes : 1
 Time since last topology change : 1191 seconds
 Local parameters
 Bridge ID : 32769.00:90:69:0b:7f:d1
 Extended system ID : 1

STP bridge parameters for MSTI 2
 MSTI regional root : 32770.00:13:c3:9e:c8:80
 Root cost : 22000
 Root port : ge-10/2/0
 Hello time : 2 seconds
 Maximum age : 20 seconds
 Forward delay : 15 seconds
 Hop count : 18
 Number of topology changes : 1
 Time since last topology change : 1191 seconds
 Local parameters
 Bridge ID : 32770.00:90:69:0b:7f:d1
 Extended system ID : 1
```

### show spanning-tree bridge msti

```
user@host> show spanning-tree bridge msti 1 routing-instance vs1 detail
STP bridge parameters
Routing instance name : vs1
Enabled protocol : MSTP

STP bridge parameters for MSTI 1
 MSTI regional root : 32769.00:13:c3:9e:c8:80
 Root cost : 22000
 Root port : xe-10/2/0
 Hello time : 2 seconds
 Maximum age : 20 seconds
 Forward delay : 15 seconds
 Hop count : 18
```

```

Number of topology changes : 1
Time since last topology change : 1191 seconds
Local parameters
 Bridge ID : 32769.00:90:69:0b:7f:d1
 Extended system ID : 1

```

### show spanning-tree bridge vlan-id (MSTP)

```
user@host> show spanning-tree bridge vlan-id 1101 routing-instance vs1 detail
```

```

STP bridge parameters
Routing instance name : vs1
Enabled protocol : MSTP

STP bridge parameters for CIST
Root ID : 32768.00:13:c3:9e:c8:80
Root cost : 0
Root port : xe-10/2/0
CIST regional root : 32768.00:13:c3:9e:c8:80
CIST internal root cost : 22000
Hello time : 2 seconds
Maximum age : 20 seconds
Forward delay : 15 seconds
Hop count : 18
Message age : 0
Number of topology changes : 0
Local parameters
 Bridge ID : 32768.00:90:69:0b:7f:d1
 Extended system ID : 1
 Hello time : 2 seconds
 Maximum age : 20 seconds
 Forward delay : 15 seconds
 Path cost method : 32 bit
 Maximum hop count : 20

```

### show spanning-tree bridge (RSTP)

```
user@host> show spanning-tree bridge
```

```

STP bridge parameters
Routing instance name : GLOBAL
Enabled protocol : RSTP
Root ID : 28672.00:90:69:0b:3f:d0
Hello time : 2 seconds
Maximum age : 20 seconds
Forward delay : 15 seconds
Message age : 0
Number of topology changes : 58
Time since last topology change : 14127 seconds
Local parameters
 Bridge ID : 28672.00:90:69:0b:3f:d0
 Extended system ID : 0

STP bridge parameters for bridge VLAN 10
Root ID : 28672.00:90:69:0b:3f:d0
Hello time : 2 seconds
Maximum age : 20 seconds
Forward delay : 15 seconds
Message age : 0
Number of topology changes : 58
Time since last topology change : 14127 seconds
Local parameters
 Bridge ID : 28672.00:90:69:0b:3f:d0

```

```
Extended system ID : 0

STP bridge parameters for bridge VLAN 20
Root ID : 28672.00:90:69:0b:3f:d0
Hello time : 2 seconds
Maximum age : 20 seconds
Forward delay : 15 seconds
Message age : 0
Number of topology changes : 58
Time since last topology change : 14127 seconds
Local parameters
 Bridge ID : 28672.00:90:69:0b:3f:d0
 Extended system ID : 0
```

#### show spanning-tree bridge vlan-id (RSTP)

```
user@host> show spanning-tree bridge vlan-id 10
STP bridge parameters
Routing instance name : GLOBAL
Enabled protocol : RSTP

STP bridge parameters for VLAN 10
Root ID : 28672.00:90:69:0b:3f:d0
Hello time : 2 seconds
Maximum age : 20 seconds
Forward delay : 15 seconds
Message age : 0
Number of topology changes : 58
Time since last topology change : 14127 seconds
Local parameters
 Bridge ID : 28672.00:90:69:0b:3f:d0
 Extended system ID : 0
```

## show spanning-tree interface

|                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Output Fields</b>                                  | Table 204 lists the output fields for the <b>show spanning-tree interface</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                   |

**Table 204: show spanning-tree Interface Output Fields**

| Field Name            | Field Description                                                             |
|-----------------------|-------------------------------------------------------------------------------|
| <b>Interface name</b> | Interface configured to participate in the STP, RSTP, VSTP, or MSTP instance. |

Table 204: show spanning-tree Interface Output Fields (*continued*)

| Field Name                  | Field Description                                                                                                                                                     |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Port ID</b>              | Logical interface identifier configured to participate in the MSTP or VSTP instance.                                                                                  |
| <b>Designated port ID</b>   | Port ID of the designated port for the LAN segment to which this interface is attached.                                                                               |
| <b>Designated bridge ID</b> | Bridge ID of the designated bridge for the LAN segment to which this interface is attached.                                                                           |
| <b>Port Cost</b>            | Configured cost for the interface.                                                                                                                                    |
| <b>Port State</b>           | STP port state: forwarding ( <b>FWD</b> ), blocking ( <b>BLK</b> ), listening, learning, or disabled.                                                                 |
| <b>Port Role</b>            | MSTP, VSTP, or RSTP port role: designated ( <b>DESG</b> ), backup ( <b>BKUP</b> ), alternate ( <b>ALT</b> ), ( <b>ROOT</b> ), or Root Prevented ( <b>Root-Prev</b> ). |
| <b>Link type</b>            | MSTP, VSTP, or RSTP link type. Shared or point-to-point (pt-pt) and edge or nonedge.                                                                                  |
| <b>Alternate</b>            | Identifies the interface as an MSTP, VSTP, or RSTP alternate root port ( <b>Yes</b> ) or nonalternate root port ( <b>No</b> ).                                        |
| <b>Boundary Port</b>        | Identifies the interface as an MSTP regional boundary port ( <b>Yes</b> ) or nonboundary port ( <b>No</b> ).                                                          |

## Sample Output

### show spanning-tree interface

```
user@host> show spanning-tree interface routing-instance vs1 detail
Spanning tree interface parameters for instance 0
```

## Understanding the Junos OS Implementation of OVSDB and VXLAN in a VMware NSX for Multi-Hypervisor Environment

Some Juniper Networks devices support Virtual Extensible LAN (VXLAN) and the Open vSwitch Database (OVSDB) management protocol. (See [“OVSDB Support on Juniper Networks Devices” on page 2446](#).) Support for VXLAN and OVSDB enables the Juniper Networks devices in a physical network to be integrated into a virtual network.

The implementation of VXLAN and OVSDB on Juniper Networks devices is supported in a VMware NSX for Multi-Hypervisor environment for the data center. [Table 207](#) outlines the components that compose this environment and products that are typically deployed for each component.

Table 207: NSX for Multi-Hypervisor Components and Related Products

| Component                       | Products                 |
|---------------------------------|--------------------------|
| Cloud management platform (CMP) | CloudStack               |
|                                 | OpenStack                |
|                                 | Custom CMP               |
| Network virtualization platform | NSX for Multi-Hypervisor |

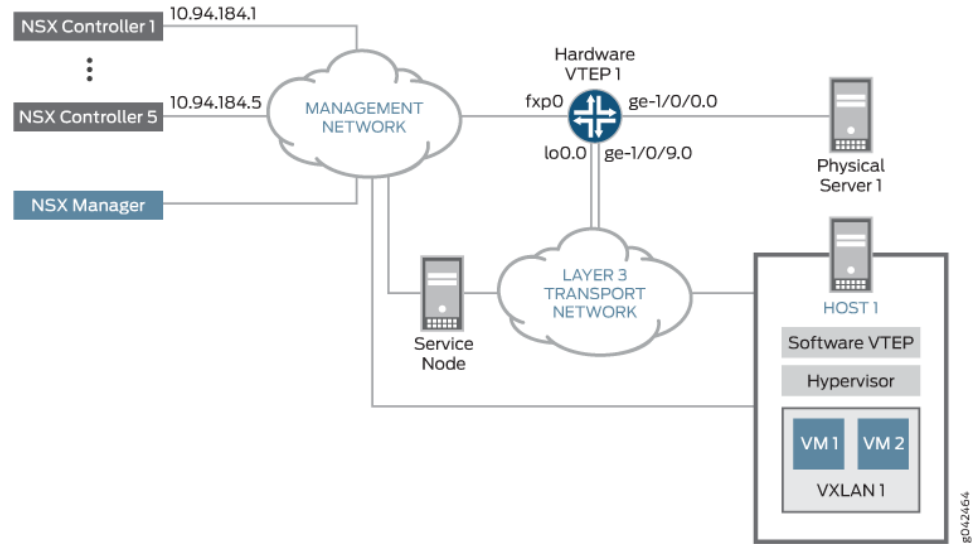

Figure 30 shows a high-level view of the NSX for Multi-Hypervisor platform architecture, while Figure 31 provides a more detailed representation of the components in the virtual and physical networks.

Figure 30: High-Level View of NSX for Multi-Hypervisor Architecture

**Figure 31: Integration of Juniper Networks Device into NSX for Multi-Hypervisor Environment**

In the data center topology shown in [Figure 31](#), the physical and virtual servers need to communicate. To facilitate this communication, a Juniper Networks device that supports VXLAN is strategically deployed so that it serves as a *gateway*, which is also known as a hardware virtual tunnel endpoint (VTEP), at the edge of the physical network. Working in conjunction with the software VTEP, which is deployed at the edge of the virtual network, the hardware VTEP encapsulates packets from resources on Physical Server 1 with a VXLAN header, and after the packets traverse the Layer 3 transport network, the software VTEP removes the VXLAN header from the packets and forwards the packets to the appropriate virtual machines (VMs). In essence, the encapsulation and de-encapsulation of packets by the hardware and software VTEPs enable the components in the physical and virtual networks to coexist without one needing to understand the workings of the other.

The same Juniper Networks device that acts as a hardware VTEP in [Figure 31](#) implements OVSDb, which enables this device to learn the MAC addresses of Physical Server 1 and other physical servers, and publish the addresses in the OVSDb schema, which was defined for physical devices. In the virtual network, one or more NSX controllers collect the MAC addresses of Host 1 and other virtual servers, and publish the addresses in the OVSDb schema. Using the OVSDb schema, components in the physical and virtual networks can exchange MAC addresses, as well as statistical information, enabling the components to learn about and reach each other in their respective networks.

## Understanding VXLANs

---

Virtual Extensible LAN protocol (VXLAN) technology allows networks to support more VLANs. According to the IEEE 802.1Q standard, traditional VLAN identifiers are 12 bits long—this naming limits networks to 4094 VLANs. The VXLAN protocol overcomes this limitation by using a longer logical network identifier that allows more VLANs and, therefore, more logical network isolation for large networks such as clouds that typically include many virtual machines.

- [How Does VXLAN Work? on page 2443](#)
- [VXLAN Implementation Methods on page 2443](#)
- [Using an MX Series Router or EX9200 Switch as a VTEP on page 2444](#)
- [Manual VXLANs Require PIM on page 2444](#)

### VXLAN Benefits

VXLAN technology allows you to segment your networks (as VLANs do), but it provides benefits that VLANs cannot. Here are the most important benefits of using VXLANs:

- You can theoretically create as many as 16 million VXLANs in an administrative domain (as opposed to 4094 VLANs on a Juniper Networks device).
  - MX Series routers and EX9200 switches support as many as 32,000 VXLANs, 32,000 multicast groups, and 8000 virtual tunnel endpoints (VTEPs). This means that VXLANs based on MX Series routers provide network segmentation at the scale required by cloud builders to support very large numbers of tenants.
  - QFX10000 Series switches support 4000 VXLANs and 2000 VTEPs.
- You can enable migration of virtual machines between servers that exist in separate Layer 2 domains by tunneling the traffic over Layer 3 networks. This functionality allows you to dynamically allocate resources within or between data centers without being constrained by Layer 2 boundaries or being forced to create large or geographically stretched Layer 2 domains.

Using VXLANs to create smaller Layer 2 domains that are connected over a Layer 3 network means that you do not need to use Spanning Tree Protocol (STP) to converge the topology but can use more-robust routing protocols in the Layer 3 network instead. In the absence of STP, none of your links are blocked, which means you can get full value from all the ports that you purchase. Using routing protocols to connect your Layer 2 domains also allows you to load-balance the traffic to ensure that you get the best use of your available bandwidth. Given the amount of east-west traffic that often flows within or between data centers, maximizing your network performance for that traffic is very important.

The video *Why Use an Overlay Network in a Data Center?* presents a brief overview of the advantages of using VXLANs.

Video: [Why Use an Overlay Network in a Data Center?](#)

## How Does VXLAN Work?

VXLAN is often described as an overlay technology because it allows you to stretch Layer 2 connections over an intervening Layer 3 network by encapsulating (tunneling) Ethernet frames in a VXLAN packet that includes IP addresses. Devices that support VXLANs are called virtual tunnel endpoints (VTEPs)—they can be end hosts or network switches or routers. VTEPs encapsulate VXLAN traffic and de-encapsulate that traffic when it leaves the VXLAN tunnel. To encapsulate an Ethernet frame, VTEPs add a number of fields, including the following:

- Outer media access control (MAC) destination address (MAC address of the tunnel endpoint VTEP)
- Outer MAC source address (MAC address of the tunnel source VTEP)
- Outer IP destination address (IP address of the tunnel endpoint VTEP)
- Outer IP source address (IP address of the tunnel source VTEP)
- Outer UDP header
- A VXLAN header that includes a 24-bit field—called the VXLAN network identifier (VNI)—that is used to uniquely identify the VXLAN. The VNI is similar to a VLAN ID, but having 24 bits allows you to create many more VXLANs than VLANs.

**NOTE:** Because VXLAN adds 50 to 54 bytes of additional header information to the original Ethernet frame, you might want to increase the MTU of the underlying network. In this case, configure the MTU of the physical interfaces that participate in the VXLAN network, not the MTU of the logical VTEP source interface, which is ignored.

Figure 32 shows the VXLAN packet format.

**Figure 32: VXLAN Packet Format**

## VXLAN Implementation Methods

Junos OS supports implementing VXLANs in the following environments:

- Without software-defined networking (SDN) controllers. VXLANs implemented in this type of environment are known as manual VXLANs.
- With SDN controllers. In this environment, SDN controllers use the Open vSwitch Database (OVSDB) management protocol to provide a means through which controllers (such as a VMware NSX or Juniper Contrail controller) and Juniper Networks devices that support OVSDB can communicate.

**NOTE:** If you want to implement VXLANs on a QFX10000 Series switch, you must use an SDN controller.

---

## Using an MX Series Router or EX9200 Switch as a VTEP

You can configure an MX Series router or EX9200 switch to act as a VTEP and perform all of the following roles:

- Act as a Layer 2 gateway between virtualized and nonvirtualized networks in the same data center or between data centers. For example, you can use an MX Series router to connect a network that uses VXLANs to one that uses VLANs.
- Act as a Layer 2 gateway between virtualized networks in the same or different data centers and allow virtual machines to move (VMotion) between those networks and data centers.
- Act as a Layer 3 gateway to route traffic between different VXLANs in the same data center.
- Act as a Layer 3 gateway to route traffic between different VXLANs in different data centers over a WAN or the Internet using standard routing protocols or virtual private LAN service (VPLS) tunnels.

**NOTE:** If you want an MX Series router or an EX9200 switch to be a VXLAN Layer 3 gateway, you must configure integrated routing and bridging (IRB) interfaces to connect the VXLANs, just as you do if you want to route traffic between VLANs.

---

## Manual VXLANs Require PIM

In an environment with a controller (such as a VMware NSX or Juniper Contrail controller), you can provision VXLANs on a Juniper Networks device. A controller also provides a control plane that VTEPs use to advertise their reachability and learn about the reachability of other VTEPs. You can also manually create VXLANs on Juniper Networks devices instead of using a controller. If you use this approach, you must also configure Protocol Independent Multicast (PIM) on the VTEPs so that they can create VXLAN tunnels between themselves.

You must also configure each VTEP in a given VXLAN to be a member of the same multicast group. (If possible, you should assign a different multicast group address to each VXLAN, though this is not required. Multiple VXLANs can share the same multicast

group.) The VTEPs can then forward ARP requests they receive from their connected hosts to the multicast group. The other VTEPs in the group de-encapsulate the VXLAN information, and (assuming they are members of the same VXLAN) they forward the ARP request to their connected hosts. When the target host receives the ARP request, it responds with its MAC address, and its VTEP forwards this ARP reply back to the source VTEP. Through this process, the VTEPs learn the IP addresses of the other VTEPs in the VXLAN and the MAC addresses of the hosts connected to the other VTEPs.

The multicast groups and trees are also used to forward broadcast, unknown unicast, and multicast (BUM) traffic between VTEPs. This prevents BUM traffic from being unnecessarily flooded outside the VXLAN.

**NOTE:** Multicast traffic that is forwarded through a VXLAN tunnel is sent only to the remote VTEPs in the VXLAN. That is, the encapsulating VTEP does not copy and send copies of the packets according to the multicast tree—it only forwards the received multicast packets to the remote VTEPs. The remote VTEPs de-encapsulate the encapsulated multicast packets and forward them to the appropriate Layer 2 interfaces. The remote VTEPs also do not copy and send copies of the packets according to the multicast tree.

## Understanding the OVSDb Protocol Running on Juniper Networks Devices

The Juniper Networks Junos OS implementation of the Open vSwitch Database (OVSDb) management protocol provides a means through which Juniper Networks devices that support OVSDb can communicate with software-defined networking (SDN) controllers. Juniper Networks devices exchange control and statistical information with the SDN controllers, thereby enabling virtual machine (VM) traffic from the entities in a virtualized network to be forwarded to entities in a physical network, and vice versa.

The Junos OS implementation of OVSDb includes an OVSDb server and an OVSDb client, both of which run on each Juniper Networks device that supports OVSDb.

The OVSDb server on a Juniper Networks device can communicate with an OVSDb client on an SDN controller. To establish a connection between a Juniper Networks device and an SDN controller, you must specify information about the SDN controller (IP address) and the connection (port over which the connection occurs and the communication protocol to be used) on each Juniper Networks device. After the configuration is successfully committed, the connection is established between the management port of the Juniper Networks device and the SDN controller port that you specify in the Junos OS configuration.

The OVSDb server stores and maintains an OVSDb database schema, which is defined for physical devices. This schema contains control and statistical information provided by the OVSDb client on the Juniper Networks devices and on SDN controllers. This

information is stored in various tables in the schema. The OVSDb client monitors the schema for additions, deletions, and modifications to this information, and the information is used for various purposes, such as learning the media access control (MAC) addresses of virtual hosts and physical servers.

The schema provides a means through which the Juniper Networks devices and the SDN controllers can exchange information. For example, the Juniper Networks devices capture MAC routes to entities in the physical network and push this information to a table in the schema so that SDN controllers with connections to these Juniper Networks devices can access the MAC routes. Conversely, SDN controllers capture MAC routes to entities in the virtualized network and push this information to a table in the schema so that Juniper Networks devices with connections to the SDN controllers can access the MAC routes.

Some of the OVSDb table names include the words *local* or *remote*, for example, *unicast MACs local table* and *unicast MACs remote table*. Information in *local* tables is learned by a Juniper Networks device that functions as a hardware virtual tunnel endpoint (VTEP), while information in *remote* tables is learned from other software or hardware VTEPs.

## OVSDb Support on Juniper Networks Devices

Table 208 lists the Juniper Networks devices that support the Open vSwitch Database (OVSDb) management protocol and the Junos OS releases in which OVSDb is supported.

The OVSDb software is included in the jsdn package. For some Juniper Networks devices, the jsdn package is included in the Junos OS software (jinstall) package. If the jsdn package is not included in the jinstall package for a particular device, a separate jsdn package must be installed on the device in addition to the jinstall package.

For each device and Junos OS release, the table outlines whether or not the jsdn package is included in the jinstall package. If the jsdn package is not included, the table also includes the name of the separate jsdn package.

**NOTE:** The separate jsdn package release number must be the same as the jinstall release number running on the device.

**Table 208: OVSDb Support on Juniper Networks Devices**

| Juniper Networks Device          | Junos OS Release | jsdn Package Included in jinstall Package? | Separate jsdn Package Name             |

## OVSDB Schema for Physical Devices

An Open vSwitch Database (OVSDB) server runs on a Juniper Networks device that supports the OVSDB management protocol. When this device is connected to one or more SDN controllers, the connections provide a means through which the Juniper Networks device and the SDN controllers can communicate.

Juniper Networks devices that support OVSDB and SDN controllers exchange control and statistical data. This data is stored in the OVSDB database schema defined for physical devices. The schema resides in the OVSDB server. The schema includes several tables. Juniper Networks devices and SDN controllers, both of which have OVSDB clients, can add rows to the tables as well as monitor the tables for the addition, deletion, and modification of rows.

For example, the OVSDB client on a Juniper Networks device and an SDN controller can collect MAC routes learned by entities in the physical or virtualized networks, respectively, and publish the routes to the appropriate table in the schema. By using the MAC routes and other information provided in the table, Juniper Networks devices in the physical network and entities in the virtualized network can determine where to forward virtual machine (VM) traffic.

Some of the OVSDB table names include the words *local* or *remote*—for example, the *unicast MACs local table* and the *unicast MACs remote table*. Information in *local* tables is learned by a Juniper Networks device that functions as a hardware virtual tunnel endpoint (VTEP), whereas information in *remote* tables is learned by other software or hardware VTEPs.

[Table 209](#) describes the tables in the schema, the physical or virtual entity that is the source of the data provided in the table, and the command that you can enter in the CLI of the Juniper Networks device to get similar information.

**Table 209: OVSDb Schema Tables**

| Table Name                       | Description                                                                                                                                                                                                                                                                                                          | Source of Information                                                                             | Command                                              |

## Understanding How Layer 2 BUM and Layer 3 Routed Multicast Traffic Are Handled with OVSDB

---

The Juniper Networks Junos OS implementation of the Open vSwitch Database (OVSDB) management protocol provides a means through which software-defined networking (SDN) controllers and Juniper Networks devices that support OVSDB can communicate.

This topic explains how a Juniper Networks device with Virtual Extensible LAN (VXLAN) and OVSDB management protocol capabilities handles the following types of traffic:

- (This scenario applies to all Juniper Networks devices that support VXLAN and OVSDB.) Layer 2 broadcast, unknown unicast, and multicast (BUM) traffic that originates in an OVSDB-managed VXLAN and is forwarded to interfaces within the same VXLAN.

**NOTE:** You must explicitly configure the replication of unknown unicast traffic in a Contrail environment.

- (This scenario applies only to MX Series routers and EX9200 switches that support VXLAN and OVSDB.) Layer 3 multicast traffic that is received by an integrated routing and bridging (IRB) in an OVSDB-managed VXLAN and is forwarded to interfaces in another OVSDB-managed VXLAN.

By default, Layer 2 BUM traffic that originates in an OVSDB-managed VXLAN is handled by one or more software virtual tunnel endpoints (VTEPs), service nodes, or top-of-rack service nodes (TSNs) in the same VXLAN. (This topic refers to the software VTEPs, service nodes, and TSNs collectively as *replicators*.) The table for remote multicast media access control (MAC) addresses in the OVSDB schema for physical devices contains only one entry that has the keyword **unknown-dst** as the MAC string and a list of replicators.

Given the previously described table entry, Layer 2 BUM traffic received on an interface in the OVSDB-managed VXLAN is forwarded to one of the replicators. The replicator to which a BUM packet is forwarded is determined by the Juniper Networks device on which the OVSDB-managed VXLAN is configured. On receiving the BUM packet, the entity replicates the packet and forwards the replicas to all interfaces within the VXLAN.

Instead of using replicators, you can optionally enable ingress node replication to handle Layer 2 BUM traffic on Juniper Networks devices that support OVSDB.

**NOTE:** For VXLAN-OVSDB, ingress node replication is supported on all Juniper Networks devices that support OVSDB except the QFX Series switches.

With ingress node replication enabled, on receiving a Layer 2 BUM packet on an interface in an OVSDB-managed VXLAN, the Juniper Networks device replicates the packet and then forwards the replicas to all software VTEPs included in the unicast MACs remote table in the OVSDB schema. The software VTEPs then forward the replicas to all virtual machines (VMs), except service VMs or nodes, on the same host.

.....

**NOTE:** When Juniper Networks devices replicate Layer 2 BUM packets to a large number of remote software VTEPs, the performance of the Juniper Networks devices can be impacted.

.....

On IRB interfaces that forward Layer 3 multicast traffic from one OVSDB-managed VXLAN to another, ingress node replication is automatically implemented. With ingress node replication, the Juniper Networks device replicates a Layer 3 multicast packet and then the IRB interface forwards the replicas to all hardware and software VTEPs, but not to service nodes, in the other OVSDB-managed VXLAN. For the routing of Layer 3 multicast traffic from one OVSDB-managed VXLAN to another, ingress node replication is the only option and does not need to be configured.

## OVSDb and VXLAN Configuration Workflows for VMware NSX Environment

---

The workflow that you use to configure Open vSwitch Database (OVSDb) and Virtual Extensible LAN (VXLAN) in a VMware NSX environment depends on the Juniper Networks device that you are configuring. This topic provides more information about the following workflows:

- [OVSDb and VXLAN Configuration Workflow for QFX Series Switches on page 2455](#)
- [OVSDb and VXLAN Configuration Workflow for MX Series Routers and EX9200 Switches on page 2457](#)

## OVSDb and VXLAN Configuration Workflow for QFX Series Switches

[Table 210](#) provides a high-level workflow of the tasks that you must perform to configure OVSDb and VXLAN on QFX Series switches. You must perform the tasks in [Table 210](#) for each Juniper Networks switch that you plan to deploy in an OVSDb environment. In

general, the successful completion of a task in this workflow depends on the successful completion of the previous task, so it is important to adhere to the task sequence provided in [Table 210](#).

**Table 210: OVSDB and VXLAN Configuration Workflow for QFX Series Switches**

| Sequence | Task                                                                                                                                                                                                                                                                                                                                                                  | For More Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| 5        | Configure a logical switch for each OVSDB-managed VXLAN that you plan to implement.                                                                                                                                                                                                                                                                                   | See the VMware documentation that accompanies NSX Manager or the NSX API.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 6        | <ul style="list-style-type: none"> <li>For each Juniper Network switch on which OVSDB-managed VXLANs and interfaces are configured, create a gateway.</li> <li>For each OVSDB-managed interface that you configure, create a gateway service.</li> <li>For each logical interface that you plan to implement for a VXLAN, configure a logical switch port.</li> </ul> | <p>For general information about configuring gateways, gateway services, and logical switch ports, see the VMware documentation that accompanies NSX Manager or the NSX API.</p> <p>For key NSX Manager configuration details that help you configure gateways, gateway services, and logical switch ports so they function properly with their physical counterparts, see <a href="#">“VMware NSX Configuration for Juniper Networks Devices Functioning as Virtual Tunnel Endpoints”</a> on page 2469.</p> |
| 7        | <p>Configure the loopback interface (lo0) on the Juniper Networks switch for VXLAN by entering the following configuration mode commands:</p> <ul style="list-style-type: none"> <li><b>set interfaces lo0 unit 0 family inet address <i>ip-address</i> primary</b></li> <li><b>set switch-options vtep-source-Interface lo0.0</b></li> </ul>                         | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

After you successfully complete task 6 in [Table 210](#), the Juniper Networks switch dynamically creates a VXLAN for each logical switch that you configured in task 5. The Juniper Networks switch also dynamically creates and associates interfaces with each VXLAN. The dynamically created interface configuration is based on the gateway service and logical switch ports that you configured in task 6. For more information, see [“Understanding Dynamically Configured VXLANs in an OVSDB Environment”](#) on page 2462.

For OVSDb-VXLAN scenarios in which Juniper Networks switches are commonly deployed, see the following topics:

- [Example: Setting Up a VXLAN Layer 2 Gateway and OVSDb Connections in a VMware NSX Environment \(Trunk Interfaces Supporting Untagged Packets\)](#) on page 2472
- [Example: Setting Up a VXLAN Layer 2 Gateway and OVSDb Connections Between Virtual and Physical Entities in a Data Center \(Using Trunk Interfaces\)](#) on page 2480

## OVSDb and VXLAN Configuration Workflow for MX Series Routers and EX9200 Switches

[Table 211](#) provides a high-level workflow of the tasks that you must perform to configure OVSDb and VXLAN on MX Series routers and EX9200 switches. You must perform the tasks in [Table 211](#) for each Juniper Networks device that you plan to deploy in an OVSDb environment. In general, the successful completion of a task in this workflow depends on the successful completion of the previous task, so it is important to adhere to the task sequence provided in [Table 211](#).

**Table 211: OVSDb and VXLAN Configuration Workflow for MX Series Routers and EX9200 Switches**

| Sequence | Task                                                                                                                                                                                                                                                                                                                       | For More Information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Understanding How to Set Up OVSDB Connections on a Juniper Networks Device

The Juniper Networks Junos OS implementation of the Open vSwitch Database (OVSDB) management protocol provides a means through which Juniper Networks devices that support OVSDB can communicate with software-defined networking (SDN) controllers. A Juniper Networks device exchanges control and statistical data with each SDN controller to which it is connected.

You can connect a Juniper Networks device to more than one SDN controller for redundancy.

In a VMware NSX environment, one cluster of NSX controllers typically includes three or five controllers. To implement the OVSDB management protocol on a Juniper Networks device, you must explicitly configure a connection to one SDN controller, using the Junos OS CLI. If the SDN controller to which you explicitly configure a connection is in a cluster, the controller pushes information about other controllers in the same cluster to the device, and the device establishes connections with the other controllers. However, you can also explicitly configure connections with the other controllers in the cluster, using the Junos OS CLI.

To implement the OVSDB management protocol on a Juniper Networks device in a Contrail environment, you must configure a connection to a Contrail controller, using the Junos OS CLI.

Connections to all SDN controllers are made on the management interface of the Juniper Networks device. To set up a connection between a Juniper Networks device and an SDN controller, you need to configure the following parameters on the Juniper Networks device:

- IP address of the SDN controller.
- The protocol that secures the connection. Secure Sockets Layer (SSL) is the supported protocol.

**NOTE:** The SSL connection requires a private key and certificates, which must be stored in the `/var/db/certs` directory of the Juniper Networks device. See [“Creating and Installing an SSL Key and Certificate on a Juniper Networks Device for Connection with SDN Controllers”](#) on page 2459.

- Number of the port over which the connection is made. The port number of the default port is 6632.

Optionally, you can configure the following connection timers on the Juniper Networks device:

- Inactivity probe duration—The maximum amount of time, in milliseconds, that the connection can be inactive before an inactivity probe is sent. The default value is 0 milliseconds, which means that an inactivity probe is never sent.
- Maximum backoff duration—If an attempt to connect to an SDN controller fails, the maximum amount of time, in milliseconds, before the device can make the next attempt. The default value is 1000 milliseconds.

## Creating and Installing an SSL Key and Certificate on a Juniper Networks Device for Connection with SDN Controllers

To secure a connection between a Juniper Networks device that supports the Open vSwitch Database (OVSDb) management protocol and one or more software-defined networking (SDN) controllers, the following Secure Sockets Layer (SSL) files must be present in the `/var/db/certs` directory on the device:

- `vtep-privkey.pem`
- `vtep-cert.pem`
- `ca-cert.pem`

You must create the `vtep-privkey.pem` and `vtep-cert.pem` files for the device and then install the two files in the `/var/db/certs` directory on the device.

Upon initial connection between a Juniper Networks device with OVSDb implemented and an SDN controller, the **ca-cert.pem** file is automatically generated and then installed in the **/var/db/certs** directory on the device.

**NOTE:** The situation at your particular site determines the possible methods that you can use to create the **vtep-privkey.pem** and **vtep-cert.pem** files and install them in the Juniper Networks device. Instead of providing procedures for all possible situations, this topic provides a procedure for one common scenario.

The procedure provided in this topic uses the OpenFlow public key infrastructure (PKI) management utility **ovs-pki** on a Linux computer to initialize a PKI and create the **vtep-privkey.pem** and **vtep-cert.pem** files. (If you have an existing PKI on your Linux computer, you can skip the step to initialize a new one.) By default, the utility initializes the PKI and places these files in the **/usr/local/share/openvswitch/pki** directory of the Linux computer.

To create and install an SSL key and certificate on a Juniper Networks device:

1. Initialize a PKI if one does not already exist on your Linux computer.

```
ovs-pki init
```

2. On the same Linux computer on which the PKI exists, create a new key and certificate for the Juniper Networks device.

```
ovs-pki req+sign vtep
```

3. Copy only the **vtep-privkey.pem** and **vtep-cert.pem** files from the Linux computer to the **/var/db/certs** directory on the Juniper Networks device.

## Setting Up OVSDB on Juniper Networks Devices That Support the Dynamic Configuration of VXLANs

To implement the Open vSwitch Database (OVSDB) management protocol on a Juniper Networks device, you must configure a connection between the Juniper Networks device and a software-defined networking (SDN) controller using the Junos OS CLI.

All SDN controller connections are made on the management interface of the Juniper Networks device. This connection is secured by using the Secure Sockets Layer (SSL) protocol. The default port number for the connection is 6632.

You must also specify that each physical interface that is connected to a physical server is managed by OVSDB. By performing this configuration, you essentially disable the Juniper Networks device from learning about other Juniper Networks devices that function as hardware virtual tunnel endpoints (VTEPs) and the MAC addresses learned by the hardware VTEPs. Instead, this configuration enables OVSDB to learn about these elements.

Before setting up OVSDB on a Juniper Networks device, you must do the following:

- Create an SSL private key and certificate, if they do not already exist, and install them in the `/var/db/certs` directory of the Juniper Networks device. See [“Creating and Installing an SSL Key and Certificate on a Juniper Networks Device for Connection with SDN Controllers”](#) on page 2459.

To set up OVSDB on a Juniper Networks device:

1. Specify the IP address of the SDN controller.
 

```
[edit protocols ovldb]
user@host# set controller ip-address
```
2. Specify SSL as the protocol that secures the connection between the Juniper Networks device and the SDN controller.
 

```
[edit protocols ovldb]
user@host# set controller ip-address protocol ssl
```
3. Set the number of the port over which the connection to the SDN controller is made.
 

```
[edit protocols ovldb]
user@host# set controller ip-address protocol ssl port number
```
4. (Optional) Specify (in milliseconds) how long the connection can be inactive before an inactivity probe is sent.
 

```
[edit protocols ovldb]
user@host# set controller ip-address inactivity-probe-duration milliseconds
```
5. (Optional) Specify (in milliseconds) how long the device must wait before it can try to connect to the SDN controller again if the previous attempt failed.
 

```
[edit protocols ovldb]
user@host# set controller ip-address maximum-backoff-duration milliseconds
```
6. (Optional) Repeat Steps 1 through 5 to configure a connection to an additional SDN controller in the NSX environment.
7. Specify that each physical interface that is connected to a physical server is managed by OVSDB.

```
[edit protocols ovssdb]
user@host# set interfaces interface-name
```

When specifying the *interface-name*, you do not need to include a logical unit number.

8. Complete the remaining configuration tasks, which are described in [“OVSSDB and VXLAN Configuration Workflows for VMware NSX Environment” on page 2455](#)).

## Understanding Dynamically Configured VXLANs in an OVSSDB Environment

---

**NOTE:** This topic applies only to QFX Series switches, which support the dynamic configuration of Open vSwitch Database (OVSSDB)-managed Virtual Extensible LANs (VXLANs). Although the configuration of OVSSDB-managed VXLANs is automated on these switches, there are tasks that you must perform before and after the dynamic configuration.

On all other Juniper Networks devices that support OVSSDB and VXLAN, you must manually configure OVSSDB-managed VXLANs using the Junos OS CLI. For more information about manually configuring OVSSDB-managed VXLANs, see [Configuring OVSSDB-Managed VXLANs](#).

The Juniper Networks Junos OS implementation of the OVSSDB management protocol provides a means through which Juniper Networks devices that support OVSSDB can communicate with software-defined networking (SDN) controllers. Support for OVSSDB enables the devices in a physical network to be integrated into a virtualized network.

In a Junos OS environment, the concept of an OVSSDB-managed Layer 2 broadcast domain in which data flows are limited to that domain is known as a *VXLAN*. The term used for the same concept in other OVSSDB environments depends on the environment:

- In an NSX environment, the same concept is known as a *logical switch*.
- In a Contrail environment, the same concept is known as a *virtual network*.

Understanding the terminology used in the different environments will help you to better understand the workflow associated with the dynamic configuration of OVSSDB-managed VXLANs, including tasks that you must perform before and after the dynamic configuration.

The following topics describe the dynamic configuration of OVSSDB-managed VXLANs:

- [Performing Tasks Before and After the Dynamic Configuration of OVSSDB-Managed VXLANs on page 2462](#)
- [What the Juniper Networks Switch Actually Creates Dynamically on page 2467](#)

### Performing Tasks Before and After the Dynamic Configuration of OVSSDB-Managed VXLANs

Although the configuration of OVSSDB-managed VXLANs is automated, there are some tasks that you must perform before and after the dynamic configuration. [Table 212](#) includes a sequentially ordered workflow of tasks and events for the dynamic configuration of OVSSDB-managed VXLANs in an NSX environment, while [Table 213](#) includes the

equivalent information for a Contrail environment. Your familiarity with these workflows will ensure that the dynamic configuration of OVSDB-managed VXLANs is properly implemented.

In [Table 212](#), the NSX controller and Juniper Networks switch handle the events described in workflow numbers 4, 6, and 7. You must perform the tasks described in workflow numbers 1, 2, 3, 5, and 8. If you perform a task in a different order than that outlined in [Table 212](#), the dynamic configuration might not work or the dynamically configured OVSDB-managed VXLAN might not become functional.

**Table 212: Workflow of Tasks and Events for the Dynamic Configuration of OVSDB-Managed VXLANs in an NSX Environment**

| Workflow Number | Task or Event                                                                                                                                       | How Task or Event Is Handled                                                                                                                                             | More Information About Task or Event                                                    |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| 1               | Enable the Juniper Networks switch to dynamically configure an OVSDB-managed VXLAN.                                                                 | You must manually enable this capability by entering the <b>set switch-options ovldb-managed</b> configuration mode command on the switch.                               | —                                                                                       |
| 2               | On the Juniper Networks switch, configure each physical interface that is connected to a physical server so that the interface is managed by OVSDB. | For each physical interface, you must manually enter the <b>set protocols ovldb interfaces interface-name</b> configuration mode command.                                | When entering the interface name, you do not need to include a logical unit number.     |
| 3               | For each OVSDB-managed VXLAN that you want to implement, configure a logical switch.                                                                | You must manually configure the logical switch by using NSX Manager or the NSX API. See the documentation that accompanies NSX Manager or the NSX API.                   | A universally unique identifier (UUID) for the logical switch is dynamically generated. |
| 4               | Relevant information about the logical switch is pushed to the Juniper Networks switch.                                                             | The NSX controller pushes relevant information to the logical switch table in the OVSDB schema for physical devices. This schema resides in the Juniper Networks switch. | —                                                                                       |

**Table 212: Workflow of Tasks and Events for the Dynamic Configuration of OVSDB-Managed VXLANs in an NSX Environment (*continued*)**

| Workflow Number | Task or Event                                                                                                                                                                                                                                                                                                                                                                                             | How Task or Event Is Handled                                                                                                                                                                                                                                                              | More Information About Task or Event                                                                                                                                                                                                                           |

See the documentation that accompanies NSX Manager or the NSX API. Also see <a href="#">“VMware NSX Configuration for Juniper Networks Devices Functioning as Virtual Tunnel Endpoints”</a> on page 2469. | –                                                                                                                                                                                                                                                              |
| 6               | Relevant information about the gateway service and logical switch port are pushed to the Juniper Networks switch.                                                                                                                                                                                                                                                                                         | The NSX controller pushes this information to the Juniper Networks switch.                                                                                                                                                                                                                | –                                                                                                                                                                                                                                                              |
| 7               | A corresponding VXLAN is dynamically created. Based on the gateway service and logical switch port configured in NSX Manager or the NSX API, one or more interfaces are also created and associated with the VXLAN.                                                                                                                                                                                       | The Juniper Networks switch dynamically creates the VXLAN and interface configuration.                                                                                                                                                                                                    | For the name of the VXLAN, the Juniper Networks switch uses the UUID of the logical switch.                                                                                                                                                                    |
| 8               | (Recommended) Verify that the logical switch, corresponding VXLAN, and associated interfaces are configured properly and are operational.                                                                                                                                                                                                                                                                 | You can enter the <b>show ovssdb logical-switch</b> operational mode command on the Juniper Networks switch. In the output, check the Flags field for the logical switches that you configured as described in workflow number 3 to ensure that it displays Created by both.              | If the output of the <b>show ovssdb logical-switch</b> operational mode command does not include the Created by both state, see <a href="#">“Troubleshooting a Nonoperational Logical Switch and Corresponding Junos OS OVSDB-Managed VXLAN”</a> on page 2507. |

In [Table 213](#), the Contrail controller and Juniper Networks switch handle the events described in workflow numbers 5, 8, and 9. You must perform all other tasks described in the table. If you perform a task in a different order than that outlined in [Table 213](#), the dynamic configuration might not work or the dynamically configured OVSDB-managed VXLAN might not become functional.

**NOTE:** Although you can perform the Contrail configurations outlined in [Table 213](#) in the Contrail Web user interface or in the Contrail REST API, [Table 213](#) only describes how to perform tasks in the Contrail Web user interface.

**Table 213: Workflow of Tasks and Events for the Dynamic Configuration of OVSDb-Managed VXLANs in a Contrail Environment**

| Workflow Number | Task or Event                                                                                                                                       | How Task or Event Is Handled                                                                                                                                                  | More Information About Task or Event                                                                             |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| 1               | On the Juniper Networks switch, configure a unique hostname for the switch.                                                                         | You must manually enter the <b>set system host-name</b> <i>host-name</i> configuration mode command on the switch.                                                            | If implementing a virtual chassis, be aware that all members of the virtual chassis must have the same hostname. |
| 2               | Enable the Juniper Networks switch to dynamically configure an OVSDb-managed VXLAN.                                                                 | You must manually enable this capability by entering the <b>set switch-options</b> <i>ovsdb-managed</i> configuration mode command on the switch.                             | —                                                                                                                |
| 3               | On the Juniper Networks switch, configure each physical interface that is connected to a physical server so that the interface is managed by OVSDb. | For each physical interface, you must manually enter the <b>set protocols ovsdb interfaces</b> <i>interface-name</i> configuration mode command.                              | When entering the interface name, you do not need to include a logical unit number.                              |
| 4               | For each OVSDb-managed VXLAN that you want to implement, configure a virtual network in the Contrail Web user interface.                            | You must manually configure the virtual network by navigating to Configure > Networking > Networks.<br><br>See <a href="#">Creating a Virtual Network</a> .                   | See <i>Contrail Configuration for Juniper Networks Devices That Function as Hardware VTEPs</i> .                 |
| 5               | Relevant information about the virtual network is pushed to the Juniper Networks switch.                                                            | The Contrail controller pushes relevant information to the logical switch table in the OVSDb schema for physical devices. This schema resides in the Juniper Networks switch. | —                                                                                                                |

Table 213: Workflow of Tasks and Events for the Dynamic Configuration of OVSDB-Managed VXLANs in a Contrail Environment (*continued*)

| Workflow Number | Task or Event                                                                                                                                                                                      | How Task or Event Is Handled                                                                                                                                                                                                                                                                                                       | More Information About Task or Event                                                                                                                                                                                                                           |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6               | For each interface that you plan to implement for a VXLAN, configure a logical interface.                                                                                                          | <p>In the Contrail Web user interface, you must manually configure the logical interface by navigating to Configure &gt; Physical Devices &gt; Interfaces.</p> <p>For information about configuring a logical interface, see <a href="#">Using TOR Switches and OVSDB to Extend the Contrail Cluster to Other Instances</a>.</p>   | See <i>Contrail Configuration for Juniper Networks Devices That Function as Hardware VTEPs</i> .                                                                                                                                                               |
| 7               | For each Juniper Networks switch that you deploy as a hardware VTEP, you create a physical router.                                                                                                 | <p>In the Contrail Web user interface, you must manually configure the physical router by navigating to Configure &gt; Physical Devices &gt; Physical Routers.</p> <p>For information about configuring a physical router, see <a href="#">Using TOR Switches and OVSDB to Extend the Contrail Cluster to Other Instances</a>.</p> | See <i>Contrail Configuration for Juniper Networks Devices That Function as Hardware VTEPs</i> .                                                                                                                                                               |
| 8               | Relevant information about the logical interfaces is pushed to the Juniper Networks switch.                                                                                                        | The Contrail controller pushes this information to the Juniper Networks switch.                                                                                                                                                                                                                                                    | —                                                                                                                                                                                                                                                              |
| 9               | A corresponding VXLAN is dynamically created. Based on the logical interface configured in the Contrail Web user interface, one or more interfaces are also created and associated with the VXLAN. | The Juniper Networks switch dynamically creates the VXLAN and interface configurations.                                                                                                                                                                                                                                            | For the name of the VXLAN, the Juniper Networks switch uses the prefix “Contrail-” and the UUID of the virtual network.                                                                                                                                        |
| 10              | (Recommended) Verify that the virtual network, corresponding VXLAN, and interfaces are configured properly and are operational.                                                                    | You can enter the <b>show ovssdb logical-switch</b> operational mode command on the Juniper Networks switch. In the output, check the Flags field for the virtual network that you configured as described in workflow number 4 to ensure that it displays Created by both.                                                        | If the output of the <b>show ovssdb logical-switch</b> operational mode command does not include the Created by both state, see <a href="#">“Troubleshooting a Nonoperational Logical Switch and Corresponding Junos OS OVSDB-Managed VXLAN”</a> on page 2507. |

## What the Juniper Networks Switch Actually Creates Dynamically

When a Juniper Networks switch creates a VXLAN, it sets up a configuration similar to the following sample:

```
set vlans 28805c1d-0122-495d-85df-19abd647d772 vxlan vni 100
```

Note the following meanings for this sample configuration:

- The name of the VXLAN is 28805c1d-0122-495d-85df-19abd647d772. The UUID of the logical switch, which was configured in NSX Manager or in the NSX API, is 28805c1d-0122-495d-85df-19abd647d772. For a VXLAN created in a Contrail environment, the name would be preceded by “Contrail-”.
- For the virtual network identifier (VNI), the Juniper Networks switch uses either the VNI specified in the logical switch configuration (NSX) or the VXLAN identifier specified in the virtual network configuration (Contrail). In this example, VNI 100 is used. If the Juniper Networks switch detects that VNI 100 is a duplicate of a VNI from a VXLAN configured by manually using the **set vlans *vlan-name* vxlan vni (1–16777214)** command in the Junos OS CLI, the switch deletes the manually configured VXLAN. Or, if the Juniper Networks switch detects that VNI 100 is specified in the dynamically configured VXLAN, but for some reason, the VNI is no longer in the equivalent logical switch or virtual network configuration, the Juniper Networks switch deletes VNI 100 from the VXLAN.

If you need to modify or delete an OVSDB-managed VXLAN that was dynamically configured by the Juniper Networks switch, you must modify or delete either the corresponding logical switch configuration (NSX), or the corresponding virtual network configuration (Contrail). After you modify or delete the configuration, the SDN controller pushes the update to the Juniper Networks switch, and the switch modifies or deletes its configuration accordingly.

Depending on either the gateway service and logical switch ports configuration (NSX), or the logical interface configuration (Contrail), the Juniper Networks switch dynamically creates and associates one or more interfaces with the VXLAN. The configuration generated by the switch depends on whether an interface must support untagged or tagged packets. The following sections provide information about the configuration that the switch dynamically generates for each interface:

- [Dynamic Association of a Trunk Interface Supporting Untagged Packets to a Dynamically Created VXLAN on page 2467](#)
- [Dynamic Association of a Trunk Interface Supporting Tagged Packets to a Dynamically Created VXLAN on page 2468](#)

### Dynamic Association of a Trunk Interface Supporting Untagged Packets to a Dynamically Created VXLAN

To determine the type of interface to create and associate with an OVSDB-managed VXLAN, the Juniper Networks switch uses the VLAN ID that you specified when configuring either the logical switch port (NSX), or the logical interface (Contrail). If you specified **0** as the VLAN ID, the switch dynamically configures a trunk interface that can handle

untagged packets. (If you specified a valid VLAN ID other than 0, the switch creates a trunk interface that handles tagged packets.)

After the SDN controller pushes either the NSX or Contrail configurations to the Juniper Networks switch, the switch dynamically creates a configuration similar to the following:

```
set interfaces ge-1/0/0 flexible-vlan-tagging
set interfaces ge-1/0/0 native-vlan-id 4094
set interfaces ge-1/0/0 encapsulation extended-vlan-bridge
set interfaces ge-1/0/0 unit 0 vlan-id 4094
set vlans 28805c1d-0122-495d-85df-19abd647d772 interface ge-1/0/0.0
```

This sample configuration sets up physical interface ge-1/0/0 as a trunk interface. It also configures a native VLAN with an ID of 4094 and specifies that logical interface ge-1/0/0.0 is a member of the native VLAN. As a result, logical interface ge-1/0/0.0 handles incoming untagged packets.

**NOTE:** We reserve VLAN ID 4094 for native VLANs in an OVSDb environment. As a result, when you create either a logical switch port (NSX) or a logical interface (Contrail), if you specify VLAN ID 4094, the Juniper Networks switch does not dynamically configure a corresponding interface. Also, a system log error message is generated.

Instead of dynamically configuring physical interface ge-1/0/0 as an access interface, which typically handles untagged packets, the Juniper Networks switch configures it as a trunk interface. The intent of this configuration is to support the division of physical interface ge-1/0/0 into multiple logical interfaces, some of which are associated with VXLANs that handle untagged packets and some of which are associated with VXLANs that handle tagged packets.

The sample configuration also creates logical interface ge-1/0/0.0 and associates this interface with VXLAN 28805c1d-0122-495d-85df-19abd647d772.

### **Dynamic Association of a Trunk Interface Supporting Tagged Packets to a Dynamically Created VXLAN**

---

In a network that is divided into multiple VXLANs, each VXLAN has a VLAN ID associated with it. Packets associated with a particular VXLAN include the corresponding tag. In this situation, the interface that connects the Juniper Networks switch to a physical server in an OVSDb environment is a trunk interface that handles only tagged packets.

To determine the type of interface to create and associate with an OVSDb-managed VXLAN, the Juniper Networks switch uses the VLAN ID that you specified when configuring either the logical switch port (NSX), or the logical interface (Contrail). If you specified a valid VLAN ID other than 0 in either configuration, the switch creates a trunk interface that can handle tagged packets. (If you specified 0 as the VLAN ID, the switch creates a trunk interface that handles untagged packets.)

After the SDN controller pushes the NSX or Contrail configuration to the Juniper Networks switch, the switch dynamically creates a configuration similar to the following:

```
set interfaces ge-1/0/0 flexible-vlan-tagging
set interfaces ge-1/0/0 encapsulation extended-vlan-bridge
set interfaces ge-1/0/0 unit 10 vlan-id 10
set vlans 28805c1d-0122-495d-85df-19abd647d772 interfaces ge-1/0/0.10
```

The sample configuration sets up physical interface ge-1/0/0 as a trunk interface. It also configures a VLAN with an ID of 10 and specifies that interface ge-1/0/0.10 is a member of the VLAN. With the configuration of VLAN 10, logical interface ge-1/0/0.10 accepts incoming packets with a VLAN tag of 10 and adds a tag of 100 to each packet. Adding a tag of 100 identifies the packets as received by the VXLAN 28805c1d-0122-495d-85df-19abd647d772, which has a VNI of 100. This configuration also associates the trunk interface with VXLAN 28805c1d-0122-495d-85df-19abd647d772.

## VMware NSX Configuration for Juniper Networks Devices Functioning as Virtual Tunnel Endpoints

---

When implementing the Open vSwitch Database (OVSDb) management protocol and Virtual Extensible LANs (VXLANs) on a Juniper Networks device, you must perform the following tasks in VMware NSX Manager or in the NSX API:

- For each Juniper Networks device on which OVSDb-managed VXLANs and physical interfaces are configured, you must create an NSX-equivalent entity, which is known as a *gateway*.
- For each OVSDb-managed physical interface that you configure on a Juniper Networks device, you must configure a gateway service—for example, a VTEP Layer 2 gateway service.
- For each logical interface that you want to implement for a VXLAN, you must configure a logical switch port.

The configurations described in this topic enable connectivity between physical servers in the physical network and virtual machines (VMs) in the virtual network.

This topic provides a high-level summary of the tasks that you must perform to create a gateway, gateway service, and logical switch ports. Although you can create these virtual entities either in NSX Manager or in the NSX API, this topic only describes how to perform the tasks in NSX Manager. Also, this topic does not include a complete procedure for each task. Rather, it includes key NSX Manager configuration details for ensuring the correct configuration of the virtual entities so that they function properly with the physical entities.

For complete information about performing the tasks described in this topic, see the documentation that accompanies NSX Manager.

This topic describes the following tasks:

- [Creating a Gateway on page 2470](#)
- [Creating a Gateway Service on page 2470](#)
- [Creating a Logical Switch Port on page 2471](#)

## Creating a Gateway

In NSX Manager, you must create a gateway for each Juniper Networks device on which OVSDB-managed VXLANs and physical interfaces are configured. [Table 214](#) provides a summary of key configuration fields in NSX Manager and how to configure them when creating a gateway.

**Table 214: Key Configurations to Create a Gateway in NSX Manager**

| NSX Manager Configuration Page or Dialog Box | NSX Manager Configuration Field | How to Configure                                                                       |
|----------------------------------------------|---------------------------------|----------------------------------------------------------------------------------------|
| Type                                         | Transport Node Type             | Select <b>Gateway</b> .                                                                |
| Properties                                   | VTEP Enabled                    | Select <b>VTEP Enabled</b> .                                                           |
| Credential                                   | Type                            | Select <b>Management Address</b> .                                                     |
| Credential                                   | Management Address              | Specify the management IP address of the Juniper Networks device.                      |
| Connections/Create Transport Connector       | Transport Type                  | Select <b>VXLAN</b> .                                                                  |
| Connections/Create Transport Connector       | Transport Zone UUID             | Select the UUID of an existing transport zone, or create a new transport zone.         |
| Connections/Create Transport Connector       | IP Address                      | Specify the IP address of the loopback interface (lo0) of the Juniper Networks device. |

## Creating a Gateway Service

In NSX Manager, you must create a gateway service for each OVSDB-managed physical interface that you configure on a Juniper Networks device. Creating a gateway service essentially does the following for each OVSDB-managed physical interface:

- Specifies a gateway service—for example, a VTEP Layer 2 gateway service.
- Binds the interface to a gateway that you created in [“Creating a Gateway” on page 2470](#).

Before you start this task, you must complete the following configurations:

- A gateway for the Juniper Networks device on which the OVSDB-managed physical interfaces are configured. See [“Creating a Gateway” on page 2470](#).

- The OVSDB-managed physical interfaces on the Juniper Networks device. For information about configuring OVSDB-managed physical interfaces on Juniper Networks devices, see [“Setting Up the OVSDB Protocol on Juniper Networks Devices that Support the Dynamic Configuration of VXLANs” on page 2461](#) or [Setting Up the OVSDB Protocol on Juniper Networks Devices that Support Manual Configuration of VXLANs](#).

[Table 215](#) provides a summary of key configuration fields in NSX Manager and how to configure them when creating a gateway service.

**Table 215: Key Configurations to Create a Gateway Service in NSX Manager**

| NSX Manager Configuration Page or Dialog Box | NSX Manager Configuration Field | How to Configure                                                                      |
|----------------------------------------------|---------------------------------|---------------------------------------------------------------------------------------|
| Type                                         | Gateway Service Type            | Select <b>VTEP L2 Gateway Service</b> .                                               |
| Transport Nodes/Edit Gateway                 | Transport Node                  | Select the gateway that you created for the Juniper Networks device.                  |
| Transport Nodes/Edit Gateway                 | Port ID                         | Select an OVSDB-managed physical interface configured on the Juniper Networks device. |

## Creating a Logical Switch Port

In NSX Manager, you must create a logical switch port for each logical interface that you plan to implement for a VXLAN. Creating the logical switch port essentially does the following for each logical interface:

- Binds the logical switch port to a logical switch that you created in NSX Manager or in the NSX API.
- Binds the logical interface to a gateway service that you configured in [“Creating a Gateway Service” on page 2470](#).

Before you start this task, you must complete the following configurations:

- A logical switch with which this logical port is associated. For information about configuring a logical switch, see the VMware documentation that accompanies NSX Manager or the NSX API.
- A gateway service that specifies the OVSDB-managed physical interface with which the logical interface is associated. See [“Creating a Gateway Service” on page 2470](#).

[Table 216](#) provides a summary of key configuration fields in NSX Manager and how to configure them when creating a logical switch port.

**Table 216: Key Configurations to Create a Logical Switch Port in NSX Manager**

| NSX Manager Configuration Page or Dialog Box | NSX Manager Configuration Field | How to Configure                     |
|----------------------------------------------|---------------------------------|--------------------------------------|
| Logical Switch                               | Logical Switch UUID             | Select the UUID of a logical switch. |

Table 216: Key Configurations to Create a Logical Switch Port in NSX Manager (*continued*)

| NSX Manager Configuration Page or Dialog Box | NSX Manager Configuration Field | How to Configure                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------------|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Attachment                                   | Attachment Type                 | Select <b>VTEP L2 Gateway</b> .                                                                                                                                                                                                                                                                                                                                                          |
| Attachment                                   | VTEP L2 Gateway Service UUID    | Select the UUID of a gateway service.                                                                                                                                                                                                                                                                                                                                                    |
| Attachment                                   | VLAN                            | <p>Select <b>0</b> to specify that the port handles untagged packets.</p> <p>Select <b>1</b> through <b>4000</b> to specify that the port handles tagged packets.</p> <p><b>NOTE:</b> VLAN ID 4094 is reserved for a native VLAN in an OVSDb environment. Specifying this VLAN ID results in an error message. Do not specify this VLAN ID or any VLAN ID not in the accepted range.</p> |

**Related Documentation** • [OVSDb and VXLAN Configuration Workflows for VMware NSX Environment on page 2455](#)

### Example: Setting Up a VXLAN Layer 2 Gateway and OVSDb Connections in a VMware NSX Environment (Trunk Interfaces Supporting Untagged Packets)

In a physical network, a Juniper Networks device that supports Virtual Extensible LAN (VXLAN) can function as a hardware virtual tunnel endpoint (VTEP). In this role, the Juniper Networks device encapsulates Layer 2 Ethernet frames received from software applications that run directly on a physical server in VXLAN packets. The VXLAN packets are tunneled over a Layer 3 transport network. Upon receipt of the VXLAN packets, software VTEPs in the virtual network de-encapsulate the packets and forward the packets to virtual machines (VMs).

In this VXLAN environment, you can also include VMware NSX controllers and implement the Open vSwitch Database (OVSDb) management protocol on the Juniper Networks device that functions as a hardware VTEP. The Junos OS implementation of OVSDb provides a means through which VMware NSX controllers and Juniper Networks devices can exchange MAC addresses of entities in the physical and virtual networks. This exchange of MAC addresses enables the Juniper Networks device that functions as a hardware VTEP to forward traffic to software VTEPs in the virtual network and software VTEPs in the virtual network to forward traffic to the Juniper Networks device in the physical network.

This example explains how to configure a QFX Series switch as a hardware VTEP, which serves as a Layer 2 gateway, and set up this device with an OVSDb connection to an NSX controller.

In this example, only one VXLAN is deployed. Given this scenario, the packets exchanged between an application running on a physical server and a VM in the VXLAN are untagged. As a result, the QFX Series switch automatically configures a logical trunk interface for

the connection between the physical server and the switch, as well as a native VLAN. The native VLAN enables the trunk interface to handle the untagged packets.

- [Requirements on page 2473](#)
- [Overview and Topology on page 2473](#)
- [Non-OVSDB and Non-VXLAN Configuration on page 2476](#)
- [OVSDB and VXLAN Configuration on page 2477](#)
- [Verification on page 2478](#)

## Requirements

This example includes the following hardware and software components:

- A physical server on which software applications directly run.
- A QFX10002 switch running Junos OS software 15.1X53-D30 or later.
- On the QFX Series switch, physical interface ge-1/0/0 provides a connection to physical server 1.
- A cluster of five NSX controllers. (In this example, you explicitly configure a connection with one NSX controller.)
- NSX Manager.
- A service node that handles the replication and forwarding of Layer 2 broadcast, unknown unicast, and multicast (BUM) traffic within the VXLAN used in this example.
- A host that includes VMs managed by a hypervisor, which includes a software VTEP.

Before you begin:

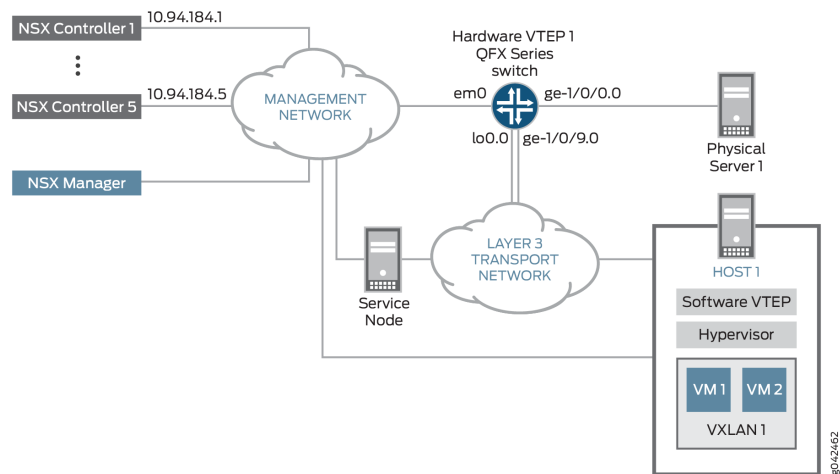

- Create an SSL private key and certificate, and install them in the `/var/db/certs` directory of the QFX Series switch. See [“Creating and Installing an SSL Key and Certificate on a Juniper Networks Device for Connection with SDN Controllers” on page 2459](#).
- Using NSX Manager, specify the IP address of the service node.

For information about using NSX Manager, see the documentation that accompanies these VMware products.

## Overview and Topology

[Figure 33](#) shows a topology in which a software application running directly on physical server 1 in the physical network needs to communicate with virtual machine VM1 in VXLAN 1 and vice versa.

Figure 33: VXLAN-OVSDB Layer 2 Gateway Topology

To establish communication between the software application on physical server 1 and VM 1 in VXLAN 1, a connection with an NSX controller is explicitly configured on the management interface of the QFX Series switch by using the Junos OS CLI.

Also, some entities in the VXLAN-OVSDB topology must be configured in both NSX Manager and on the QFX Series switch. [Table 217](#) provides a summary of the entities that must be configured and where they must be configured.

Table 217: NSX Manager and Junos OS Entities That Must Be Configured

| Entities                                                                      | What Must Be Configured in NSX Manager                                                                                                                                  | What Must Be Configured on a QFX Series Switch                                                                                             |
|-------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|

| QFX Series switch (hardware VTEP 1)                                           | Gateway                                                                                                                                                                 | —                                                                                                                                          |

In NSX Manager, a logical switch for VXLAN 1 is configured. In this configuration, a VXLAN network identifier (VNI) of 100 is specified. Also, the universally unique identifier (UUID) that NSX Manager assigns to the logical switch is 28805c1d-0122-495d-85df-19abd647d772. Based on this configuration, the QFX Series

switch automatically creates the following configuration for a Junos OS-equivalent VXLAN:

```
set vlans 28805c1d-0122-495d-85df-19abd647d772 vxlan vni 100
```

Based on the gateway service and logical switch port configuration (VLAN number 0) in NSX Manager, the QFX Series switch automatically creates the following configuration for a Junos OS-equivalent interface:

```
set interfaces ge-1/0/0 flexible-vlan-tagging
set interfaces ge-1/0/0 native-vlan-id 4094
set interfaces ge-1/0/0 encapsulation extended-vlan-bridge
set interfaces ge-1/0/0 unit 0 vlan-id 4094
set vlans 28805c1d-0122-495d-85df-19abd647d772 interface ge-1/0/0.0
```

This configuration sets physical interface ge-1/0/0 as a trunk interface. It also configures a native VLAN with an ID of 4094. The configuration creates logical interface ge-1/0/0.0 and specifies that it is a member of the native VLAN. As a result, logical interface ge-1/0/0.0 handles incoming untagged packets.

The configuration also associates logical interface ge-1/0/0.0 with VXLAN 28805c1d-0122-495d-85df-19abd647d772.

[Table 218](#) provides a summary of the VXLAN-OVSDB topology components that are configured on the QFX Series switch and the configuration settings for each component.

**Table 218: Components of the Topology for Setting Up a VXLAN Layer 2 Gateway and OVSDB Connections**

| Component                        | Setting                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NSX controller                   | IP address: 10.94.184.1                                                                                                                                                                                                                                                                                                                                                                                                            |
| OVSDB-managed physical interface | Interface name: ge-1/0/0<br>Native VLAN ID: 4094                                                                                                                                                                                                                                                                                                                                                                                   |
| Logical interface                | <p><b>NOTE:</b> The QFX Series switch automatically creates this logical interface configuration, which is based on the gateway service configuration and logical switch port configuration in NSX Manager. | Handling of Layer 2 BUM traffic in VXLAN 28805c1d-0122-495d-85df-19abd647d772 | <p>Service node</p> <p><b>NOTE:</b> By default, one or more service nodes handle Layer 2 BUM traffic within a VXLAN; therefore, no manual configuration is required.</p>                                                                                                                                 |

## Non-OVSDB and Non-VXLAN Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set interfaces ge-1/0/9 unit 0 family inet address 10.40.40.1/24
set routing-options static route 10.19.19.19/32 next-hop 10.40.40.2
set routing-options router-id 10.17.17.17
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface ge-1/0/9.0
```

**Step-by-Step Procedure** To configure the Layer 3 network over which the packets exchanged between the physical server and VMs are tunneled:

1. Configure the Layer 3 interface.
 

```
[edit interfaces]
user@switch# set ge-1/0/9 unit 0 family inet address 10.40.40.1/24
```
2. Set the routing options.
 

```
[edit routing-options]
user@switch# set static route 10.19.19.19/32 next-hop 10.40.40.2
user@switch# set router-id 10.17.17.17
```

3. Configure the routing protocol.

```
[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface ge-1/0/9.0
```

## OVSDb and VXLAN Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set switch-options ovbdb-managed
set protocols ovbdb controller 10.94.184.1
set protocols ovbdb interfaces ge-1/0/0
set protocols ovbdb traceoptions file ovbdb
set protocols ovbdb traceoptions file size 10m
set protocols ovbdb traceoptions flag all
set interfaces lo0 unit 0 family inet address 10.17.17.17/32 primary
set interfaces lo0 unit 0 family inet address 10.17.17.17/32 preferred
set switch-options vtep-source-interface lo0.0
```

**Step-by-Step Procedure** To configure the QFX Series switch as a hardware VTEP with an OVSDb connection to an NSX controller:

1. Enable the QFX Series switch to automatically configure OVSDb-managed VXLANs and associated interfaces.

```
[edit switch-options]
user@switch# ovbdb-managed
```

2. Explicitly configure a connection with an NSX controller.

```
[edit protocols]
user@switch# set ovbdb controller 10.94.184.1
```

3. Specify that the interface between hardware VTEP 1 and physical server 1 is managed by OVSDb.

```
[edit protocols]
user@switch# set ovbdb interfaces ge-1/0/0
```

4. Set up OVSDb tracing operations.

```
[edit protocols]
user@switch# set ovbdb traceoptions file ovbdb
user@switch# set ovbdb traceoptions file size 10m
user@switch# set ovbdb traceoptions flag all
```

5. Specify an IP address for the loopback interface. This IP address serves as the source IP address in the outer header of any VXLAN-encapsulated packet.

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 10.17.17.17/32 primary
user@switch# set lo0 unit 0 family inet address 10.17.17.17/32 preferred
```

6. Set the loopback interface as the interface that identifies hardware VTEP 1.

[edit switch-options]

user@switch# **set vtep-source-interface lo0.0**

7. In NSX Manager, configure a logical switch for VXLAN 1. See the VMware documentation that accompanies NSX Manager.
8. In NSX Manager, configure a gateway for the QFX Series switch, and configure a gateway service and logical switch port for the logical interface (ge-1/0/0.0). See [“VMware NSX Configuration for Juniper Networks Devices Functioning as Virtual Tunnel Endpoints”](#) on page 2469.

## Verification

Confirm that the configuration is working properly:

- [Verifying the Logical Switch Configuration on page 2478](#)
- [Verifying the MAC Address of VM 1 on page 2478](#)
- [Verifying the NSX Controller Connection on page 2479](#)
- [Verifying the OVSDb-Managed Interface on page 2479](#)

---

### Verifying the Logical Switch Configuration

**Purpose** Verify that the configuration of the logical switch with the UUID of 28805c1d-0122-495d-85df-19abd647d772 is present in the OVSDb schema for physical devices and that the Flags field of the **show ovssdb logical switch** output displays **Created by both**.

**Action** From operational mode, enter the **show ovssdb logical-switch** command.

```
user@switch> show ovssdb logical-switch
Logical switch information:
Logical Switch Name: 28805c1d-0122-495d-85df-19abd647d772
Flags: Created by both
VNI: 100
Num of Remote MAC: 1
Num of Local MAC: 0
```

**Meaning** The output verifies that the configuration for the logical switch is present. The **Created by both** state indicates that the logical switch was configured in NSX Manager, and that the QFX Series switch automatically created the corresponding VXLAN. In this state, the logical switch and the VXLAN are operational.

If the state of the logical switch is something other than **Created by both**, see [“Troubleshooting a Nonoperational Logical Switch and Corresponding Junos OS OVSDb-Managed VXLAN”](#) on page 2507.

---

### Verifying the MAC Address of VM 1

**Purpose** Verify that the MAC address of VM 1 is present in the OVSDb schema.

**Action** From operational mode, enter the **show ovssdb mac remote** command.

```
user@switch> show ovssdb mac remote
Logical Switch Name: 28805c1d-0122-495d-85df-19abd647d772
 Mac IP Encapsulation Vtep
 Address Address Address Address
a8:59:5e:f6:38:90 0.0.0.0 Vxlan over Ipv4 10.17.17.17
```

**Meaning** The output shows that the MAC address for VM 1 is present and is associated with the logical switch with the UUID of 28805c1d-0122-495d-85df-19abd647d772. Given that the MAC address is present, VM 1 is reachable through the QFX Series switch, which functions as a hardware VTEP.

### Verifying the NSX Controller Connection

**Purpose** Verify that the connection with the NSX controller is up.

**Action** From operational mode, enter the **show ovssdb controller** command to verify that the controller connection state is **up**.

```
user@switch> show ovssdb controller
VTEP controller information:
Controller IP address: 10.94.184.1
Controller protocol: ssl
Controller port: 6632
Controller connection: up
Controller seconds-since-connect: 542325
Controller seconds-since-disconnect: 542346
Controller connection status: active
```

**Meaning** The output shows that the connection state of the NSX controller is up, in addition to other information about the controller. The **up** state of the NSX controller indicates that OVSDb is enabled on the QFX Series switch.

### Verifying the OVSDb-Managed Interface

**Purpose** Verify that interface ge-1/0/0.0 is managed by OVSDb.

**Action** From operational mode, enter the **show ovssdb interface** command to verify that interface ge-1/0/0.0 is managed by OVSDb.

```
user@switch> show ovssdb interface
Interface VLAN ID Bridge-domain
ge-1/0/0 0 28805c1d-0122-495d-85df-19abd647d772
```

**Meaning** The output shows that interface ge-1/0/0 is managed by OVSDb. It also indicates that the interface is associated with VXLAN 28805c1d-0122-495d-85df-19abd647d772, which has a VLAN ID of 0.

## Example: Setting Up a VXLAN Layer 2 Gateway and OVSDB Connections in a VMware NSX Environment (Trunk Interfaces Supporting Tagged Packets)

---

In a physical network, a Juniper Networks device that supports Virtual Extensible LAN (VXLAN) can function as a hardware virtual tunnel endpoint (VTEP). In this role, the Juniper Networks device encapsulates Layer 2 Ethernet frames received from software applications that run directly on a physical server in VXLAN packets. The VXLAN packets are tunneled over a Layer 3 transport network. Upon receipt of the VXLAN packets, software VTEPs in the virtual network de-encapsulate the packets and forward the packets to virtual machines (VMs).

In this VXLAN environment, you can also include VMware NSX controllers and implement the Open vSwitch Database (OVSDB) management protocol on the Juniper Networks device that functions as a hardware VTEP. The Junos OS implementation of OVSDB provides a means through which VMware NSX controllers and Juniper Networks devices can exchange MAC addresses of entities in the physical and virtual networks. This exchange of MAC addresses enables the Juniper Networks device that functions as a hardware VTEP to forward traffic to software VTEPs in the virtual network and software VTEPs in the virtual network to forward traffic to the Juniper Networks device in the physical network.

This example explains how to configure a Juniper Networks device that supports VXLAN as a hardware VTEP. (The VTEP serves as a Layer 2 gateway.) This example also explains how to configure this device with an OVSDB connection to an NSX controller.

In this example, an application running directly on a physical server needs to communicate with a VM in a VXLAN, while another application on the physical server needs to communicate with VMs in another VXLAN. Therefore, the packets exchanged between the applications running on the physical server and the respective VMs with which they must communicate are tagged. As a result, a trunk interface is used for the connection between the physical server and the Juniper Networks device.

- [Requirements on page 2480](#)
- [Overview and Topology on page 2481](#)
- [Non-OVSDB and Non-VXLAN Configuration on page 2484](#)
- [OVSDB and VXLAN Configuration on page 2485](#)
- [Verification on page 2486](#)

### Requirements

This example includes the following hardware and software components:

- A physical server on which software applications directly run.
- A Juniper Networks switch that supports VXLAN and OVSDB. This switch can be a QFX10002 switch running Junos OS Release 15.1X53-D10 and later.
- On the Juniper Networks switch, physical interface ge-1/0/0 provides a connection to physical server 1.

- A cluster of five NSX controllers. (In this example, you explicitly configure a connection with one NSX controller.)
- NSX Manager.
- A service node that handles the replication and forwarding of Layer 2 broadcast, unknown unicast, and multicast (BUM) traffic within the VXLANs.
- Two hosts that include VMs. Each host is managed by a hypervisor, and each hypervisor includes a software VTEP.

Before you begin the configuration, you must perform the following tasks:

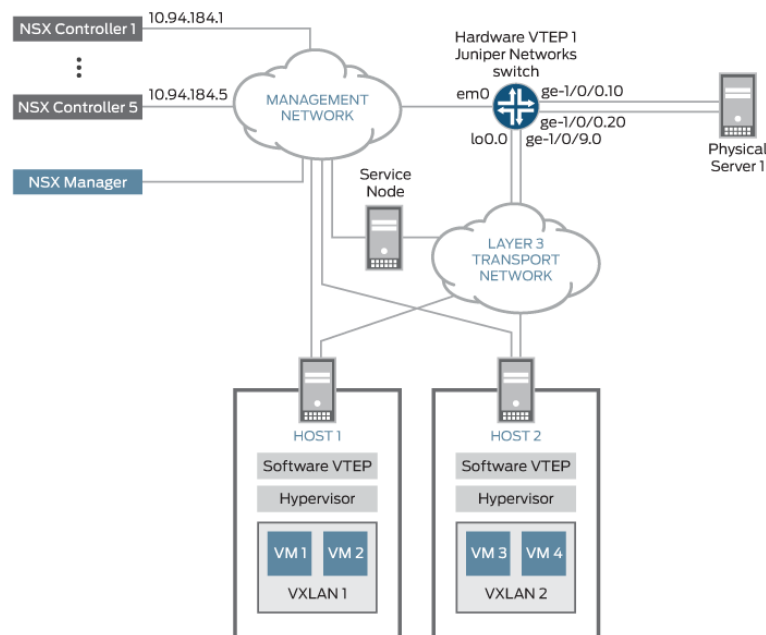

- Create an SSL private key and certificate, and install them in the `/var/db/certs` directory of the Juniper Networks switch. See [“Creating and Installing an SSL Key and Certificate on a Juniper Networks Device for Connection with SDN Controllers”](#) on page 2459.
- Using NSX Manager, specify the IP address of the service node.

For information about using NSX Manager, see the documentation that accompanies NSX Manager.

## Overview and Topology

Figure 33 shows a topology in which a software application running directly on physical server 1 in the physical network needs to communicate with virtual machine VM1 in VXLAN 1 and vice versa, and another software application on physical server 1 needs to communicate with virtual machines VM 3 and VM 4 in VXLAN 2 and vice versa.

Figure 34: VXLAN/OVSDB Layer 2 Gateway Topology

To establish communication between the software applications on physical server 1 and the VMs in VXLANs 1 and 2, some entities in the VXLAN-OVSDB topology must be configured in both NSX Manager and on the Juniper Networks switch. [Table 219](#) provides a summary of the entities that must be configured and where they must be configured.

**NOTE:** The term used for an entity configured in NSX Manager can differ from the term used for essentially the same entity configured on the Junos Network switch. To prevent confusion, [Table 219](#) shows the NSX Manager and Junos OS entities side-by-side.

**Table 219: NSX Manager and Junos OS Entities That Must Be Configured**

| Entities                                                                   | What Must Be Configured In NSX Manager                                                  | What Must Be Configured on Juniper Networks Switch                                        |
|----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|
| VXLAN 1                                                                    | Logical switch for VXLAN 1                                                              | VXLAN 1                                                                                   |
| VXLAN 2                                                                    | Logical switch for VXLAN 2                                                              | VXLAN 2                                                                                   |
|                                                                            |                                                                                         | <b>NOTE:</b> The Juniper Networks switch dynamically configures these VXLANs.             |
| Interface (ge-1/0/0) between physical server 1 and Juniper Networks switch | A gateway service. For gateway service type, select VTEP L2 gateway service.            | OVSDb management. Specify that interface ge-1/0/0 is managed by OVSDb.                    |
| One logical interface associated with VXLAN 1                              | One logical switch port for VXLAN 1. For this port, specify VLAN number 10.             | One logical interface (ge-1/0/0.10) for VXLAN 1                                           |
| One logical interface associated with VXLAN 2                              | One logical switch port for VXLAN 2. For this port, specify VLAN number 20.             | One logical interface (ge-1/0/0.20) for VXLAN 1                                           |
|                                                                            | <b>NOTE:</b> A VLAN number from 1 through 4000 indicates that the port is a trunk port. | <b>NOTE:</b> The Juniper Networks switch dynamically configures these logical interfaces. |
| Juniper Networks switch (hardware VTEP 1)                                  | Gateway                                                                                 | —                                                                                         |

Based on the configuration of the entities in NSX Manager as described in [Table 219](#), the Juniper Networks switch dynamically creates VXLANs 1 and 2 and their associated logical interfaces. [Table 220](#) provides the relevant NSX Manager configuration and the resulting VXLANs and associated logical interfaces that the Juniper Networks switch dynamically configures.

**Table 220: NSX Manager Configurations and Dynamic Configurations by Juniper Networks Switch**

| NSX Manager Configuration: Logical Switch and Logical Switch Port                                                                                               | VXLANs and Associated Logical Interfaces Dynamically Configured By Juniper Networks Switch                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Logical switch configuration:<br><br>UUID:<br>28805c1d-0122-495d-85df-19abd647d772<br><br>VNI: 100<br><br>Logical switch port configuration:<br><br>VLAN ID: 10 | For VXLAN 1:<br><br><b>set vlans 28805c1d-0122-495d-85df-19abd647d772 vxlan vni 100</b><br><br>For associated logical interface ge-1/0/0.10:<br><br><b>set interfaces ge-1/0/0 flexible-vlan-tagging</b><br><b>set interfaces ge-1/0/0 encapsulation extended-vlan-bridge</b><br><b>set interfaces ge-1/0/0 unit 10 vlan-id 10</b><br><b>set vlans 28805c1d-0122-495d-85df-19abd647d772 interfaces ge-1/0/0.10</b> |
| Logical switch configuration:<br><br>UUID: 9acc24b3-7b0a-4c2e-b572-3370c3e1acff<br><br>VNI: 200<br><br>Logical switch port configuration:<br><br>VLAN ID: 20    | For VXLAN 2:<br><br><b>set vlans 9acc24b3-7b0a-4c2e-b572-3370c3e1acff vxlan vni 200</b><br><br>For associated logical interface ge-1/0/0.20:<br><br><b>set interfaces ge-1/0/0 flexible-vlan-tagging</b><br><b>set interfaces ge-1/0/0 encapsulation extended-vlan-bridge</b><br><b>set interfaces ge-1/0/0 unit 20 vlan-id 20</b><br><b>set vlans 9acc24b3-7b0a-4c2e-b572-3370c3e1acff interfaces ge-1/0/0.20</b> |

For VXLANs 1 and 2, the Juniper Networks switch uses the UUIDs and VNI values that were provided for the corresponding logical switches.

In the logical switch port configurations in NSX Manager, VLAN ID values 10 and 20 and logical switch mappings are specified. As a result, the Juniper Networks switch creates logical interfaces ge-1/0/0.10 and ge-1/0/0.20, respectively. Both of these logical interfaces function as trunk interfaces. The Juniper Networks switch also maps the logical interfaces ge-1/0/0.10 and ge-1/0/0.20 to their respective VXLANs.

Based on the configurations generated by the Juniper Networks switch, the interface ge-1/0/0.10 accepts packets with a VLAN tag of 10 from VXLAN 1, and interface ge-1/0/0.20 accepts packets with a VLAN tag of 20 from VXLAN 2. On receiving packets from VXLAN 1, a VLAN tag of 100 is added to the packets, and a VLAN tag of 200 is added to packets from VXLAN 2. These tags are added to the respective packet streams to map the VLAN ID in a particular VXLAN to the corresponding VNI.

[Table 218](#) provides a summary of the components that are configured on the Juniper Networks switch. Unless noted, all configurations are performed manually in the Junos OS CLI.

**Table 221: Components for Two VXLAN Topologies Configured on a Juniper Networks Switch that Functions as a Hardware VTEP**

| Components     | Settings                |
|----------------|-------------------------|
| NSX controller | IP address: 10.94.184.1 |

**Table 221: Components for Two VXLAN Topologies Configured on a Juniper Networks Switch that Functions as a Hardware VTEP (*continued*)**

| Components                                                                                                                              | Settings                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OVSDB-managed interface                                                                                                                 | Interface name: ge-1/0/0                                                                                                                                                                                                                                                                                                                                                                                                           |
| VXLAN 1 and associated logical interface                                                                                                | <p><b>NOTE:</b> The Juniper Networks switch dynamically configures the VXLAN and associated logical interface, which are based on the logical switch and logical switch port configurations in NSX Manager. Therefore, no manual configuration is required.</p> <p>VXLAN name: 28805c1d-0122-495d-85df-19abd647d772</p> <p>VNI: 100</p> <p>Logical interface name: ge-1/0/0.10</p> <p>VLAN ID: 10</p> <p>Interface type: trunk</p> |
| VXLAN 2 and associated logical interface                                                                                                | <p><b>NOTE:</b> The Juniper Networks switch dynamically configures the VXLAN and associated interface, which are based on the logical switch and logical switch port configurations in NSX Manager. | OVSDB tracing operations                                                                                                                | <p>Filename: /var/log/ovsdb</p> <p>File size: 10 MB</p> <p>Flag: All</p>                                                                                                                                                                                                                                                                                                                                                           |
| Hardware VTEP source identifier                                                                                                         | <p>Source interface: loopback (lo0.0)</p> <p>Source IP address: 10.17.17.17/32</p>                                                                                                                                                                                                                                                                                                                                                 |
| Handling of Layer 2 BUM traffic within VXLAN 28805c1d-0122-495d-85df-19abd647d772 and within VXLAN 9acc24b3-7b0a-4c2e-b572-3370c3e1acff | <p>Service node</p> <p><b>NOTE:</b> By default, one or more service nodes handle Layer 2 BUM traffic in a VXLAN; therefore, no configuration is required.</p>                                                                                                                                                                                                                                                                      |

## Non-OVSDB and Non-VXLAN Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set interfaces ge-1/0/9 unit 0 family inet address 10.40.40.1/24
set routing-options static route 10.19.19.19/32 next-hop 10.40.40.2
set routing-options router-id 10.17.17.17
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface ge-1/0/9.0

```

**Step-by-Step Procedure** To configure the Layer 3 network over which the packets exchanged between physical server 1 and VM1 are tunneled:

1. Configure the Layer 3 interface.

```

[edit interfaces]
user@switch# set ge-1/0/9 unit 0 family inet address 10.40.40.1/24

```

2. Set the routing options.

```

[edit routing-options]
user@switch# set static route 10.19.19.19/32 next-hop 10.40.40.2
user@switch# set router-id 10.17.17.17

```

3. Configure the routing protocol.

```

[edit protocols]
user@switch# set ospf area 0.0.0.0 interface lo0.0
user@switch# set ospf area 0.0.0.0 interface ge-1/0/9.0

```

## OVSDb and VXLAN Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set switch-options ovssdb-managed
set protocols ovssdb controller 10.94.184.1
set protocols ovssdb interfaces ge-1/0/0
set protocols ovssdb traceoptions file ovssdb
set protocols ovssdb traceoptions file size 10m
set protocols ovssdb traceoptions flag all
set interfaces lo0 unit 0 family inet address 10.17.17.17/32 primary
set interfaces lo0 unit 0 family inet address 10.17.17.17/32 preferred
set switch-options vtep-source-interface lo0.0

```

**Step-by-Step Procedure** To configure the Juniper Networks switch as hardware VTEP 1 and with an OVSDb connection to an NSX controller:

1. Enable the Juniper Networks switch to dynamically configure OVSDb-managed VXLANs and associated interfaces.

```

[edit switch-options]
user@switch# set ovssdb-managed

```

2. Explicitly configure a connection with an NSX controller.

```

[edit protocols]
user@switch# set ovssdb controller 10.94.184.1

```

3. Specify that interface ge-1/0/0 is managed by OVSDB.

```
[edit protocols]
user@switch# set ovsdb interfaces ge-1/0/0
```

4. Set up OVSDB tracing operations.

```
[edit protocols]
user@switch# set ovsdb traceoptions file ovsdb
user@switch# set ovsdb traceoptions file size 10m
user@switch# set ovsdb traceoptions flag all
```

5. Specify an IP address for the loopback interface. This IP address serves as the source IP address in the outer header of any VXLAN-encapsulated packets.

```
[edit interfaces]
user@switch# set lo0 unit 0 family inet address 10.17.17.17/32 primary
user@switch# set lo0 unit 0 family inet address 10.17.17.17/32 preferred
```

6. Set the loopback interface as the interface that identifies hardware VTEP 1.

```
[edit switch-options]
user@switch# set vtep-source-interface lo0.0
```

7. In NSX Manager, configure a logical switch for VXLAN 1 and a logical switch for VXLAN 2. See the documentation that accompanies NSX Manager.
8. In NSX Manager, configure a gateway for the Juniper Networks switch, a gateway service for OVSDB-managed interface ge-1/0/0, and a logical switch port for logical interface ge-1/0/0.10, which is associated with VXLAN 1, and a logical switch port for logical interface ge-1/0/0.20, which is associated with VXLAN 2.

See “[VMware NSX Configuration for Juniper Networks Devices Functioning as Virtual Tunnel Endpoints](#)” on page 2469.

## Verification

Confirm that the configuration is working properly.

- [Verifying the Logical Switch Configuration on page 2486](#)
- [Verifying the MAC Addresses of VM 1, VM 3, and VM 4 on page 2487](#)
- [Verifying the NSX Controller Connection on page 2487](#)
- [Verifying the OVSDB-Managed Interface on page 2488](#)

---

### Verifying the Logical Switch Configuration

**Purpose** Verify that the configuration of logical switches with the UUIDs of 28805c1d-0122-495d-85df-19abd647d772 and 9acc24b3-7b0a-4c2e-b572-3370c3e1acff are present in the OVSDB schema for physical devices and that the Flags field of the **show ovsdb logical-switch** output is Created by both.

**Action** From operational mode, enter the **show ovssdb logical-switch** command.

```
user@switch> show ovssdb logical-switch
Logical switch information:
Logical Switch Name: 28805c1d-0122-495d-85df-19abd647d772
Flags: Created by both
VNI: 100
Num of Remote MAC: 1
Num of Local MAC: 0
Logical Switch Name: 9acc24b3-7b0a-4c2e-b572-3370c3e1acff
Flags: Created by both
VNI: 200
Num of Remote MAC: 2
Num of Local MAC: 0
```

**Meaning** The output verifies that the configuration for the logical switches is present. The **Created by both** state indicates that the logical switches were configured in NSX Manager, and that the Juniper Networks switch dynamically configured the corresponding VXLANs. In this state, the logical switches and VXLANs are operational.

If the state of the logical switches is something other than **Created by both**, see [“Troubleshooting a Nonoperational Logical Switch and Corresponding Junos OS OVSDB-Managed VXLAN” on page 2507](#).

### Verifying the MAC Addresses of VM 1, VM 3, and VM 4

**Purpose** Verify that the MAC addresses of VM1, VM 3, and VM 4 are present in the OVSDB schema.

**Action** From operational mode, enter the **show ovssdb mac remote** command.

```
user@switch> show ovssdb mac remote
Logical Switch Name: 28805c1d-0122-495d-85df-19abd647d772
 Mac IP Encapsulation Vtep
 Address Address
 a8:59:5e:f6:38:90 0.0.0.0 Vxlan over Ipv4 10.17.17.17
Logical Switch Name: 9acc24b3-7b0a-4c2e-b572-3370c3e1acff
 Mac IP Encapsulation Vtep
 Address Address
 00:23:9c:5e:a7:f0 0.0.0.0 Vxlan over Ipv4 10.17.17.17
 00:23:9c:5e:a7:f0 0.0.0.0 Vxlan over Ipv4 10.17.17.17
```

**Meaning** The output shows that the MAC addresses for VM 1, VM 3, and VM 4 are present and are associated with their respective logical switches. Given that the MAC addresses are present, VM 1, VM 3, and VM 4 are reachable through the Juniper Networks switch, which functions as a hardware VTEP.

### Verifying the NSX Controller Connection

**Purpose** Verify that the connection with the NSX controller is up.

**Action** From operational mode, enter the **show ovssdb controller** command to verify that the controller connection state is **up**.

```
user@switch> show ovssdb controller
VTEP controller information:
Controller IP address: 10.94.184.1
Controller protocol: ssl
Controller port: 6632
Controller connection: up
Controller seconds-since-connect: 542325
Controller seconds-since-disconnect: 542346
Controller connection status: active
```

**Meaning** The output shows that the connection state of the NSX controller is **up**, in addition to other information about the controller. By virtue of this connection being up, OVSSDB is enabled on the Juniper Networks switch.

---

### Verifying the OVSSDB-Managed Interface

---

**Purpose** Verify that interface ge-1/0/0 is managed by OVSSDB.

**Action** From operational mode, enter the **show ovssdb interface** command, and verify that logical interfaces ge-1/0/0.10 and ge-1/0/0.20 are managed by OVSSDB.

```
user@switch> show ovssdb interface
Interface VLAN ID Bridge-domain
ge-1/0/0 10 28805c1d-0122-495d-85df-19abd647d772
ge-1/0/0 20 9acc24b3-7b0a-4c2e-b572-3370c3e1acff
```

**Meaning** The output shows that logical interfaces **ge-1/0/0.10** and **ge-1/0/0.20** are managed by OVSSDB. It also indicates that interface **ge-1/0/0.10** is associated with VXLAN **28805c1d-0122-495d-85df-19abd647d772** and interface **ge-1/0/0.20** is associated with VXLAN **9acc24b3-7b0a-4c2e-b572-3370c3e1acff**.

---

## Verifying That a Logical Switch and Corresponding Junos OS OVSSDB-Managed VXLAN Are Working Properly

---

**Purpose** Verify the following:

- A logical switch, which is configured in an NSX environment, or a virtual network, which is configured in a Contrail environment, is learning MAC addresses in their respective environments.
- The corresponding OVSSDB-managed Virtual Extensible LAN (VXLAN), which is configured on a Juniper Networks device, is learning MAC addresses in the Junos OS environment.
- The logical switch or virtual network and OVSSDB-managed VXLAN are exchanging the MAC addresses learned in their respective environments so that virtual and physical servers can communicate.

**Action** To verify that a logical switch or virtual network and its corresponding OVSDb-managed VXLAN are learning and exchanging MAC addresses in their respective environments, enter the **show ovssdb logical-switch** operational mode command.

```
user@device> show ovssdb logical-switch
Logical switch information:
Logical Switch Name: 28805c1d-0122-495d-85df-19abd647d772
Flags: Created by both
VNI: 100
Num of Remote MAC: 1
Num of Local MAC: 0
```

**NOTE:** In the Open vSwitch Database (OVSDb) schema for physical devices, the logical switch table stores information about the Layer 2 broadcast domain that you configured in a VMware NSX or Contrail environment. In the NSX environment, the Layer 2 broadcast domain is known as a *logical switch*, while in the Contrail environment, the domain is known as a *virtual network*.

In the context of the **show ovssdb logical-switch** command, the term *logical switch* refers to the logical switch or virtual network that was configured in the NSX or Contrail environments, respectively, and the corresponding configuration that was pushed to the OVSDb schema.

**Meaning** The output in the Flags field (**Created by both**) indicates that the logical switch or virtual network and its corresponding OVSDb-managed VXLAN are both properly configured. In this state, the logical switch or virtual network and the VXLAN are learning and exchanging MAC addresses in their respective environments.

If the output in the Flags field displays a state other than **Created by both**, see [“Troubleshooting a Nonoperational Logical Switch and Corresponding Junos OS OVSDb-Managed VXLAN” on page 2507](#).

## VXLAN Constraints on QFX Series Switches

---

When configuring VXLANs on QFX switches, be aware of the constraints in the following list. In this list, “Layer 3 side” refers to a network-facing interface that performs VXLAN encapsulation and de-encapsulation, and “Layer 2 side” refers to a server-facing interface that is a member of a VLAN that is mapped to a VXLAN.

- You can use VXLANs on a Virtual Chassis or Virtual Chassis Fabric if all of the members are supported QFX switches. You cannot use VXLANs if any of the members is not a supported QFX switch.
- VXLAN configuration is supported only in the default routing instance.
- QFX switches cannot route traffic between different VXLANs.
- A physical interface cannot be a member of a VLAN and a VXLAN. That is, an interface that performs VXLAN encapsulation and de-encapsulation cannot also be a member of a VLAN. For example, if a VLAN that is mapped to a VXLAN is a member of trunk port xe-0/0/0, any other VLAN that is a member of xe-0/0/0 must also be assigned to a VXLAN.
- Multichassis link aggregation groups (MC-LAGS) are not supported with VXLAN.
- IP fragmentation and defragmentation are not supported on the Layer 3 side.
- The following features are not supported on the Layer 2 side:
  - STP (any variant)
  - IGMP snooping
  - Storm control

- Access port security features are not supported with VXLAN. For example, the following features are not supported:
  - DHCP snooping
  - Dynamic ARP inspection
  - MAC limiting and MAC move limiting
- See the following to determine whether ingress node replication is supported:
  - PIM used for control plane: ingress node replication is not supported.
  - Control plane provided by a SDN controller: ingress node replication is not supported.
  - EVPN-VXLAN: ingress node replication is supported.
- PIM-BIDIR and PIM-SSM are not supported with VXLANs.
- Class of service (CoS) features are not supported with VXLANs.
- If you configure a port-mirroring instance to mirror traffic egressing from an interface that performs VXLAN encapsulation, the source and destination MAC addresses of the mirrored packets are invalid. The original VXLAN traffic is not affected.

---

## Manually Configuring VXLANs on a QFX5100 Switch

---

Follow these steps to configure a QFX5100 switch to act as a VTEP. (If the switch is acting as a transit Layer 3 switch for downstream VTEPs, you do not need to perform these steps. No special configuration is needed in this case.)

- [Configuring a Source IP Address on page 2493](#)
- [Configuring PIM for VXLANs on page 2493](#)
- [Configuring VXLANs on page 2493](#)

## Configuring a Source IP Address

On a switch that will act as a VTEP, you must configure an IP address that will be used as the source address in the outer IP header of the VXLAN packet. This is the VXLAN tunnel source address.

1. Create a reachable IPv4 address on the loopback interface and configure it to be used as the tunnel source address:

```
[edit]
user@switch# set interfaces lo0.0 unit 0 family inet address ip-address
[edit]
user@switch# set switch-options vtep-interface-source lo0.0
```

## Configuring PIM for VXLANs

If you are not using a controller to create a VXLAN control plane, you must enable PIM on the switch so that the VTEP can use multicast groups to establish reachability with other VTEPs and forward BUM traffic.

1. Enable PIM on the interface that connects to the Layer 3 network. This is the interface the performs the VXLAN encapsulation and de-encapsulation.

```
[edit]
user@switch# set protocols pim interface interface-name
```

2. Configure the address of a PIM rendezvous point:

```
[edit]
user@switch# set protocols pim rp static address ip-address
```

## Configuring VXLANs

You configure VXLANs under the **vlan** stanza (which is why a QFX5100 switch supports 4K VLANs). You must also configure the server-facing interfaces to be VLAN members.

1. Create a VLAN to VXLAN mapping and assign a multicast group address to the VXLAN. All members of a VXLAN must use the same multicast group address:

```
[edit]
user@switch# set vlans name vlan-id ID vxlan vni ID multicast-group multicast-group-address
```

2. (Optional) Configure the switch to retain the original VLAN tag (in the inner Ethernet packet) after VXLAN encapsulation. By default, the original tag is dropped when the packet is encapsulated:

```
[edit]
user@switch# set vlans name vxlan encapsulate-inner-vlan
```

3. (Optional) Configure the switch to de-encapsulate and accept original VLAN tags in VXLAN packets. By default, the original tag is dropped when the packet is encapsulated:

```
[edit]
user@switch# set protocols l2-learning decapsulate-accept-inner-vlan
```

4. Configure server-facing interfaces to support multiple VLANs:

```
[edit]
user@switch# set interfaces interface unit unit family ethernet-switching interface-mode trunk
[edit]
```

```
user@switch# set interfaces interface unit unit family ethernet-switching vlan members all
```

You must create a VLAN to VXLAN mapping for each VLAN that will need Layer 2 connectivity over the Layer 3 network.

## Examples: Manually Configuring VXLANs on QFX Series Switches

These examples show how to configure VXLANs on QFX Series Switches for several use cases.

- [Example: Configuring a VXLAN Transit Switch on page 2494](#)
- [Example: Configuring a VXLAN Layer 2 Gateway on page 2496](#)

### Example: Configuring a VXLAN Transit Switch

If a QFX switch acts as a transit switch for downstream devices acting as VTEPs, you do not need to configure any VXLAN information on the QFX switch. You do need to configure PIM on the switch so that it can form the multicast tree required so that the VTEPs can establish reachability with each other.

- [Requirements on page 2494](#)
- [Overview on page 2494](#)
- [Configuring PIM on the Transit Switches on page 2495](#)

---

#### Requirements

This example uses the following hardware and software components:

- Two QFX5100 switches
- Junos OS 14.1X53-D10

---

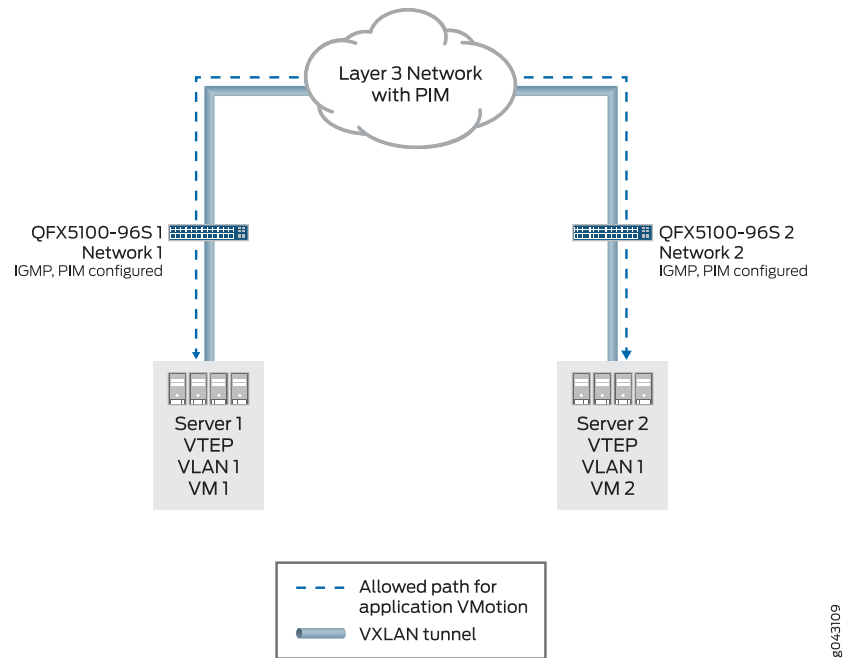

#### Overview

This example shows a simple use case in which QFX switches are connected to downstream servers acting as VTEPs and need to forward VXLAN packets between VM 1 on Server 1 and VM 2 on Server 2. Because this configuration allows Layer 2 connectivity between the VMs through the VXLAN tunnels, applications can VMotion between the VMs.

#### Topology

[Figure 35](#) shows a QFX 5100 switch configured to forward VXLAN packets for downstream VTEPs.

Figure 35: QFX5100 Acting as a VXLAN Transit Switch

### Configuring PIM on the Transit Switches

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set protocols pim interface all
set protocols pim rp static address ip-address
```

#### Step-by-Step Procedure

If you are not using a controller to create a VXLAN control plane, you must enable PIM on each switch so that the VTEP can use multicast groups to advertise its existence and to learn about other VTEPs. (Configuring PIM automatically enables IGMP.) You do not need to perform any VXLAN-specific configuration. Note that you also do not need to configure VLAN 1 or 2 on either switch.

1. Enable PIM:
 

```
[edit]
user@switch# set protocols pim interface all
```
2. Configure the address of a PIM rendezvous point:
 

```
[edit]
user@switch# set protocols pim rp static address ip-address
```

## Example: Configuring a VXLAN Layer 2 Gateway

If a QFX switch is connected to a downstream server that hosts a VM that needs Layer 2 connectivity with another VM that is reachable only through a Layer 3 network, you must configure the switch to act as a VTEP—that is, a Layer 2 gateway for downstream Layer 2 devices. You also need to configure PIM on the switch so that it can form the multicast tree required for reachability with other VTEPs and to allow BUM traffic to be forwarded between the VTEPs.

- [Requirements on page 2496](#)
- [Overview on page 2496](#)
- [Configuring the Switches on page 2497](#)
- [Verification on page 2500](#)

---

### Requirements

This example uses the following hardware and software components:

- Two QFX5100 switches
- Junos OS 14.1X53-D10

---

### Overview

This example shows a use case in which QFX switches are connected to downstream VTEPs and need to allow Layer 2 connectivity between VM 1 on Server 1 and VM 2 on Server 2 so that VMotion can occur between the VMs. The servers in this example can be in the same or different data centers—the only constraint is that there must be Layer 3 connectivity between the QFX switches. This allows your network to be very agile in response to demand for server usage or changes in bandwidth requirements.

Note that because the same VLAN exists in both Layer 2 domains and both switches encapsulate the VLAN traffic into the same VXLAN, you do not need a gateway for the VXLAN traffic in the Layer 3 network. The Layer 3 VXLAN packets are routed normally and no de-encapsulation or re-encapsulation is required..

### Topology

[Figure 36](#) shows a QFX 5100 switch configured to act as a VTEP.

Figure 36: QFX5100 Acting as a VTEP

8043108

### Configuring the Switches

#### CLI Quick Configuration

To quickly configure the QFX5100-96S 1 in this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

```
set interfaces lo0 unit 0 family inet address 10.1.1.1
set switch-options vtep-source-interface lo0.0
set protocols pim interface lo0.0
set protocols pim interface xe-0/0/0.0
set protocols pim rp static address 10.2.2.2
set vlans VLAN1 vlan-id 100 vxlan vni 100 multicast-group 224.2.2.2
set vlans VLAN1 vxlan encapsulate-inner-vlan
set vlans VLAN1 vxlan unreachable-vtep-aging-timer 600
set protocols l2-learning decapsulate-accept-inner-vlan
set interfaces xe-0/0/0 unit 0 family inet address 10.2.2.100/24
set interfaces xe-0/0/1 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/1 unit 0 family ethernet-switching vlan members all
```

The configuration for QFX5100-96S 2 is almost identical. The only changes a few of the addresses:

```
set interfaces lo0 unit 0 family inet address 10.1.1.2
set switch-options vtep-source-interface lo0.0
set protocols pim interface lo0.0
set protocols pim interface xe-0/0/0.0
set protocols pim rp static address 10.2.2.2
set vlans VLAN1 vlan-id 100 vxlan vni 100 multicast-group 224.2.2.2
set vlans VLAN1 vxlan encapsulate-inner-vlan
```

```

set vlans VLAN1 vxlan unreachable-vtep-aging-timer 600
set protocols l2-learning decapsulate-accept-inner-vlan
set interfaces xe-0/0/0 unit 0 family inet address 10.2.2.200/24
set interfaces xe-0/0/1 unit 0 family ethernet-switching interface-mode trunk
set interfaces xe-0/0/1 unit 0 family ethernet-switching vlan members all

```

**NOTE:** You must configure the same multicast group address for VLAN1 on both switches.

### Step-by-Step Procedure

Perform the following procedure on both switches to set up the example configuration. Note that you do not need to configure VLAN 1 or 2 on either switch.

1. Create a reachable IPv4 address on the loopback interface.

```

[edit]
user@switch# set interfaces lo0 unit 0 family inet address 10.1.1.1
For switch QFX5100-96S 2, use address 10.1.1.2.

```

2. Configure the loopback interface—and therefore, its associated address—to be used as the tunnel source address:

```

[edit]
user@switch# set switch-options vtep-source-interface lo0.0

```

3. Enable PIM on the loopback interface:

```

[edit]
user@switch# set protocols pim interface lo0.0

```

4. Enable PIM on the interface that connects to the Layer 3 network:

```

[edit]
user@switch# set protocols pim interface xe-0/0/0.0

```

5. Configure the address of a PIM rendezvous point:

```

[edit]
user@switch# set protocols pim rp static address 10.2.2.2

```

6. Create a VLAN, map it to a VXLAN, and assign a multicast group address to the VXLAN. All members of a VXLAN must use the same multicast group address:

```

[edit]
user@switch# set vlans VLAN1 vlan-id 100 vxlan vni 100 multicast-group 224.2.2.2

```

In this example, the **vlan-id** and **vni** are both set to 100. This is done only for simplicity and clarity. You do not need to set the **vlan-id** and **vni** to the same value.

7. (Optional) Configure the switch to retain the original VLAN tag (in the inner Ethernet packet) after VXLAN encapsulation. By default, the original tag is dropped when the packet is encapsulated:

```

[edit]
user@switch# set vlans VLAN1 vxlan encapsulate-inner-vlan

```

8. (Optional) Configure the system to age out the address for the remote VTEP (the other QFX5100 switch) if all the MAC addresses learned from that VTEP age out. The address for the remote VTEP expires the configured number of seconds after the last learned MAC address expires.

```

[edit]

```

```
user@switch# set vlans VLAN1 vxlan unreachable-vtep-aging-timer 600
```

(Optional) Configure the switch to de-encapsulate and accept original VLAN tags in VXLAN packets. By default, a preserved VLAN tag is dropped when the packet is de-encapsulated:

```
[edit]
```

```
user@switch# set protocols l2-learning decapsulate-accept-inner-vlan
```

9. Configure the interface that connects to the Layer 3 network:

```
[edit]
```

```
user@switch# set interfaces xe-0/0/0 unit 0 family inet address 10.2.2.100/24
```

For switch QFX5100-96S 2, use address 10.2.2.200.

10. Configure the server-facing interface to support multiple VLANs:

```
[edit]
```

```
user@switch# set interfaces xe-0/0/1 unit 0 family ethernet-switching interface-mode trunk
```

```
[edit]
```

```
user@switch# set interfaces xe-0/0/1 unit 0 family ethernet-switching vlan members all
```

**NOTE:** Because this example shows only one VLAN, this step is not required for the example. In a real-world configuration, however, it would be required in order to support multiple VMs connected to multiple VLANs. In this case you would also need to configure additional VLAN to VXLAN mappings.

### Results

From configuration mode, confirm your configuration by entering the following commands on QFX5100-96S 1. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@switch# show switch-options
```

```
 vtep-source-interface lo0.0;
```

```
user@switch# show vlans
```

```
VLAN1 {
 vlan-id 100;
 vxlan {
 vni 100;
 multicast-group 224.2.2.2;
 encapsulate-inner-vlan;
 }
}
```

```
user@switch# show interfaces
```

```
xe-0/0/0 {
 unit 0 {
 family inet {
 address 10.2.2.100/24;
 }
 }
}
```

```

}
xe-0/0/1 {
 unit 0 {
 family ethernet-switching {
 interface-mode trunk;
 vlan {
 members all;
 }
 }
 }
}
lo0 {
 unit 0 {
 family inet {
 address 10.1.1.1/32;
 }
 }
}

```

```
user@switch# show protocols pim
```

```

rp {
 static {
 address 10.2.2.2;
 }
}
interface xe-0/0/0.0

```

## Verification

Confirm that the configuration is working properly.

- [Verifying VXLAN Reachability on page 2500](#)
- [Verifying That the Local VTEP is Configured Correctly on page 2501](#)
- [Verifying MAC Learning from the Remote VTEP on page 2501](#)
- [Monitor the Remote Interface on page 2501](#)

### Verifying VXLAN Reachability

**Purpose** On QFX5100-96S 1, verify that there is connectivity with the remote VTEP (QFX5100-96S 2).

**Action** user@switch> show ethernet-switching vxlan-tunnel-end-point remote

| Logical System Name | Id          | SVTEP-IP | IFL   | L3-Idx |
|---------------------|-------------|----------|-------|--------|
| <default>           | 0           | 10.1.1.2 | lo0.0 | 0      |
| RVTEP-IP            | IFL-Idx     | NH-Id    |       |        |
| 10.1.1.2            | 559         | 1728     |       |        |
| VNID                | MC-Group-IP |          |       |        |
| 100                 | 224.2.2.2   |          |       |        |

**Meaning** The VTEP on QFX5100-96S 2 is reachable because its IP address (the address assigned to the loopback interface) appears in the output. The output also shows that the VXLAN (VNI 100) and corresponding multicast group are configured correctly on the remote VTEP.

***Verifying That the Local VTEP is Configured Correctly***

**Purpose** On QFX5100-96S 1, verify that the tunnel endpoint is correct..

**Action** user@switch> show ethernet-switching vxlan-tunnel-end-point source

|                     |    |               |       |             |
|---------------------|----|---------------|-------|-------------|
| Logical System Name | Id | SVTEP-IP      | IFL   | L3-Idx      |
| <default>           | 0  | 10.1.1.1      | lo0.0 | 0           |
| L2-RTT              |    | Bridge Domain | VNID  | MC-Group-IP |
| default-switch      |    | VLAN1+100     | 100   | 224.2.2.2   |

**Meaning** The VTEP on QFX5100-96S 1 shows the correct tunnel source IP address (assigned to the loopback interface), VLAN, and multicast group for the VXLAN.

***Verifying MAC Learning from the Remote VTEP***

**Purpose** On QFX5100-96S 1, verify that it is learning MAC addresses from the remote VTEP.

**Action** user@switch> show ethernet-switching table

MAC flags (S - static MAC, D - dynamic MAC, L - locally learned, P - Persistent static

SE - statistics enabled, NM - non configured MAC, R - remote PE MAC)

Ethernet switching table : 2 entries, 2 learned

Routing instance : default-switch

| Vlan name | MAC address       | MAC flags | Age | Logical interface |
|-----------|-------------------|-----------|-----|-------------------|
| VLAN1     | 00:00:00:ff:ff:ff | D         | -   | vtep.12345        |
| VLAN1     | 00:10:94:00:00:02 | D         | -   | xe-0/0/0.0        |

**Meaning** This shows the MAC addresses learned from the remote VTEP (in addition to those learned on the normal Layer 2 interfaces). It also shows the logical name of the remote VTEP interface (**vtep.12345** in the above output).

***Monitor the Remote Interface***

**Purpose** On QFX5100-96S 1, monitor traffic details for the remote VTEP interface.

**Action** user@switch> show interface vtep.12345 detail

```
M Flags: Up SNMP-Traps Encapsulation: ENET2
 VXLAN Endpoint Type: Remote, VXLAN Endpoint Address: 10.1.1.2, L2 Routing
Instance: default-switch, L3 Routing Instance: default
 Traffic statistics:
 Input bytes : 228851738624
 Output bytes : 0
 Input packets: 714162415
 Output packets: 0
 Local statistics:
 Input bytes : 0
 Output bytes : 0
 Input packets: 0
 Output packets: 0
 Transit statistics:
 Input bytes : 228851738624 0 bps
 Output bytes : 0 0 bps
 Input packets: 714162415 0 pps
 Output packets: 0 0 pps
 Protocol eth-switch, MTU: 1600, Generation: 277, Route table: 5
```

**Meaning** This shows traffic details for the remote VTEP interface. To get this information, you must supply the logical name of the remote VTEP interface (vtep.12345 in the above output), which you can learn by using the **show ethernet-switching table** command.

---

## Verifying That a Local VXLAN VTEP Is Configured Correctly

---

**Purpose** Verify that a local VTEP is correct..

**Action** user@switch> show ethernet-switching vxlan-tunnel-end-point source

| Logical System Name | Id            | SVTEP-IP | IFL   | L3-Idx      |
|---------------------|---------------|----------|-------|-------------|
| <default>           | 0             | 10.1.1.1 | 1o0.0 | 0           |
| L2-RTT              | Bridge Domain |          | VNID  | MC-Group-IP |
| default-switch      | VLAN1+100     |          | 100   | 232.1.1.1   |

**Meaning** The output should show the correct tunnel source IP address (loopback address), VLAN, and multicast group for the VXLAN.

**Related Documentation**

- [Understanding VXLANs on page 2442](#)

---

## Verifying MAC Learning from a Remote VTEP

---

**Purpose** Verify that a local VTEP is learning MAC addresses from a remote VTEP.

**Action** user@switch> show ethernet-switching table

MAC flags (S - static MAC, D - dynamic MAC, L - locally learned, P - Persistent static

SE - statistics enabled, NM - non configured MAC, R - remote PE MAC)

Ethernet switching table : 2 entries, 2 learned

Routing instance : default-switch

| Vlan<br>name | MAC<br>address    | MAC<br>flags | Age | Logical<br>interface |
|--------------|-------------------|--------------|-----|----------------------|
| VLAN1        | 00:00:00:ff:ff:ff | D            | -   | vtep.12345           |
| VLAN1        | 00:10:94:00:00:02 | D            | -   | xe-0/0/0.0           |

**Meaning** This shows the MAC addresses learned from the remote VTEP (in addition to those learned on the normal Layer 2 interfaces). It also shows the logical name of the remote VTEP interface (**vtep.12345** in the above output).

| <b>Problem</b>  | <p><b>Description:</b> The Flags field in the <code>show ovssdb logical-switch</code> operational mode command output is one of the following:</p> <ul style="list-style-type: none"><li>• <b>Created by Controller</b></li><li>• <b>Created by L2ALD</b></li><li>• <b>Tunnel key mismatch</b></li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Cause</b>    | <ul style="list-style-type: none"><li>• If the Flags field displays <b>Created by Controller</b>, a logical switch is configured in the NSX environment or a virtual network is configured in the Contrail environment. However, an equivalent VXLAN is not configured or is improperly configured on the Juniper Networks device.</li><li>• If the Flags field displays <b>Created by L2ALD</b>, a VXLAN is configured on the Juniper Networks device. However, an equivalent logical switch is not configured in the NSX environment or an equivalent virtual network is not configured in the Contrail environment.</li><li>• If the Flags field displays <b>Tunnel key mismatch</b>, the VXLAN network identifier (VNI) specified in the logical switch configuration or the VXLAN identifier specified in the virtual network configuration do not match the VNI in the equivalent VXLAN configuration.</li></ul> |
| <b>Solution</b> | <p>If the Flags field displays <b>Created by Controller</b>, take the following action:</p> <ul style="list-style-type: none"><li>• On a QFX Series switch, verify that the <code>set switch-options ovssdb-managed</code> configuration command was issued in the Junos OS CLI. Issuing this command and committing the configuration enable the Juniper Networks device to dynamically create OVSDb-managed VXLANs.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Another possible cause is that the L2ALD daemon has become nonfunctional. If this is the case, wait for a few seconds, reissue the **show ovsdb logical-switch** operational mode command, and recheck the setting of the Flags field.

Another possible cause is that the Juniper Networks device dynamically configured the VXLAN and its associated logical interface, but there is an error in the configuration of these entities themselves or in an entity that was committed in the same transaction. If there is an issue with one or more of the configurations in a transaction, all configurations in the transaction, even the ones that are correctly configured, remain uncommitted and in a queue until you troubleshoot and resolve the configuration issues. As a result, the Juniper Networks device was unable to commit all configurations in the transaction. For this situation, enter the **show ovsdb commit failures** operational mode command. In the output that is displayed, determine which configurations are erroneous. Issues that can cause commitment errors include but are not limited to the detection of the same VXLAN name or VXLAN network identifier (VNI) in a dynamically configured VXLAN and in a VXLAN that was previously configured using the Junos OS CLI. After resolving the errors, enter the **clear ovsdb commit failures** command to remove the transaction from the queue and then retry committing all configurations in the transaction.

- On all other Juniper Networks devices that support VXLAN and OVSDDB, determine whether a VXLAN equivalent to the logical switch configuration or virtual network configuration exists on the device. If the VXLAN is not configured, configure it using the procedure in *Configuring OVSDDB-Managed VXLANs*. If a VXLAN is configured, check the VXLAN name to make sure that it is the same as the universally unique identifier (UUID) of the logical switch (NSX) or virtual network (Contrail) configuration. Also, check the VNI to make sure that the value is the same as the value in the logical switch (NSX) or virtual network (Contrail) configuration.

If the Flags field displays **Created by L2ALD**, take the following action:

- On a QFX Series switch, two issues exist. First, despite the fact that the Juniper Networks device dynamically creates OVSDDB-managed VXLANs, this VXLAN was configured by using the Junos OS CLI. Second, a corresponding logical switch (NSX) or virtual network (Contrail) was not configured. To resolve both issues, configure a logical switch in the NSX environment or a virtual network in the Contrail environment. After the software-defined networking (SDN) controller pushes relevant logical switch or virtual network information to the Juniper Networks device, the device dynamically creates a corresponding VXLAN and deletes the VXLAN configured using the Junos OS CLI.
- On all other Juniper Networks devices that support VXLAN and OVSDDB, determine whether an equivalent logical switch is configured in the NSX environment or a virtual network is configured in the Contrail environment. If a logical switch or virtual network is not configured, configure one, keeping in mind that a UUID is automatically generated for the logical switch or virtual network and that this UUID must be used as the name of the VXLAN. That is, the VXLAN name must be reconfigured with the logical switch or virtual network UUID.

Another possibility is that the logical switch or virtual network configuration might exist, but the UUID of the entity might not match the VXLAN name. In the NSX or

Contrail environment, check for a logical switch or virtual network, respectively, that has the same configuration as the VXLAN but has a different UUID.

If the Flags field displays **Tunnel key mismatch**, take the following action:

- For a QFX Series switch, check the configuration of the VNI in the NSX environment or the VXLAN identifier in the Contrail environment to see whether it was changed after the Juniper Networks device dynamically created the equivalent VXLAN. If it was changed, update the VNI on the QFX Series switch using the Junos OS CLI.
- On all other Juniper Networks devices that support VXLAN and OVSDb, check the value of the VNI in the NSX environment or the VXLAN identifier in the Contrail environment and the Junos OS CLI. Change the incorrect value.

## Verifying VXLAN Reachability

**Purpose** On the local VTEP, verify that there is connectivity with the remote VTEP.

**Action** `user@switch> show ethernet-switching vxlan-tunnel-end-point remote`

| Logical System Name | Id          | SVTEP-IP | IFL   | L3-Idx |
|---------------------|-------------|----------|-------|--------|
| <default>           | 0           | 10.1.1.2 | 100.0 | 0      |
| RVTEP-IP            | IFL-Idx     | NH-Id    |       |        |
| 10.1.1.2            | 559         | 1728     |       |        |
| VNID                | MC-Group-IP |          |       |        |
| 100                 | 232.1.1.1   |          |       |        |

**Meaning** The remote VTEP is reachable because its IP address appears in the output. The output also shows that the VXLAN (VNI 100) and corresponding multicast group are configured correctly on the remote VTEP.

## Monitoring a Remote VTEP Interface

**Purpose** Monitor traffic details for a remote VTEP interface.

**Action** user@switch> show interface *logical-name* detail

```
M Flags: Up SNMP-Traps Encapsulation: ENET2
 VXLAN Endpoint Type: Remote, VXLAN Endpoint Address: 10.1.1.2, L2 Routing
Instance: default-switch, L3 Routing Instance: default
 Traffic statistics:
 Input bytes : 228851738624
 Output bytes : 0
 Input packets: 714162415
 Output packets: 0
 Local statistics:
 Input bytes : 0
 Output bytes : 0
 Input packets: 0
 Output packets: 0
 Transit statistics:
 Input bytes : 228851738624 0 bps
 Output bytes : 0 0 bps
 Input packets: 714162415 0 pps
 Output packets: 0 0 pps
 Protocol eth-switch, MTU: 1600, Generation: 277, Route table: 5
```

**Meaning** This shows traffic details for the remote VTEP interface. To get this information, you must supply the logical name of the remote VTEP interface (vtep.12345 in the above output), which you can learn by using the **show ethernet-switching table** command.

| <b>Description</b>              | <p>Configure a connection between a Juniper Networks device running the Open vSwitch Database (OVSDB) management protocol and a software-defined networking (SDN) controller. You can connect a Juniper Networks device to more than one SDN controller for redundancy.</p> <p>In a VMware NSX environment, one cluster of NSX controllers typically includes three or five controllers. To implement the OVSDB management protocol on a Juniper Networks device, you must explicitly configure a connection to one NSX controller, using the Junos OS CLI. If the NSX controller to which you explicitly configure a connection is in a cluster, the controller pushes information about other controllers in the same cluster to the device, and the device establishes connections with the other controllers. However, you can also explicitly configure connections with the other controllers in the cluster, using the Junos OS CLI.</p> <p>To implement the OVSDB management protocol on a Juniper Networks device in a Contrail environment, you must configure a connection to a Contrail controller, using the Junos OS CLI.</p> <p>Connections to all SDN controllers are made on the management interface of the Juniper Networks device.</p> |
| <b>Options</b>                  | <p><b>ip-address</b>—IPv4 address of the SDN controller.</p> <p>The remaining statements are explained separately.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## ovsdb

---

**Syntax**    ovsdb {  
              controller *ip-address* {  
                  inactivity-probe-duration *milliseconds*;  
                  maximum-backoff-duration *milliseconds*;  
              protocol *protocol* {  
                  port *number*;  
              }  
              }  
              interfaces *interface-name*;  
              traceoptions {  
                  file <*filename*> <files *number*> <match *regular-expression*> <no-world-readable |  
                    world-readable> <size *size*>;  
                  flag *flag*;  
                  no-remote-trace;  
              }  
              }

**Hierarchy Level**    [edit protocols]

**Release Information**    Statement introduced in Junos OS Release 14.1R2.  
                              Statement introduced in Junos OS Release 14.1X53-D10 for QFX Series switches.  
                              Statement introduced in Junos OS Release 14.2 for EX Series switches.

**Description**    Configure support for the Open vSwitch Database (OVSDb) management protocol on a Juniper Networks device.

                      The remaining statements are explained separately.

**Default**    The OVSDb management protocol is disabled on Juniper Networks devices.

**Required Privilege Level**    admin—To view this statement in the configuration.  
                                  admin-control—To add this statement to the configuration.

| <b>Description</b>              | <p>Disable a Juniper Networks device from learning about other Juniper Networks devices that function as hardware virtual tunnel endpoints (VTEPs) in a specified Virtual Extensible LAN (VXLAN) and the MAC addresses learned by the hardware VTEPs. Instead, the Juniper Networks device uses the Open vSwitch Database (OVSDb) management protocol to learn about the hardware VTEPs in the VXLAN and the media access control (MAC) addresses learned by the hardware VTEPs.</p> <p>The specified VXLAN must have a VXLAN network identifier (VNI) configured, using the <b>vni</b> statement in the [edit bridge-domains <i>bridge-domain-name</i> vxlan], [edit routing-instance <i>routing-instance-name</i> vxlan], or [edit vlans <i>vlan-name</i> vxlan] hierarchy.</p> <p>Also, for OVSDb-managed VXLANs, the multicast scheme described in “<a href="#">Understanding How Layer 2 BUM and Layer 3 Routed Multicast Traffic Are Handled with OVSDb</a>” on <a href="#">page 2450</a> is used. Therefore, specifying the <b>multicast-group</b> statement in the [edit bridge-domains <i>bridge-domain-name</i> vxlan], [edit routing-instances <i>routing-instance-name</i> vxlan], or [edit vlans <i>vlan-name</i> vxlan] hierarchy has no effect.</p> |
| <b>Required Privilege Level</b> | <p>admin—To view this statement in the configuration.</p> <p>admin-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b>         | Define tracing operations for the Open vSwitch Database (OVSDB) management protocol, which is supported on Juniper Networks devices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Default</b>             | If you do not include this statement, OVSDB-specific tracing operations are not performed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Options</b>             | <p><b>file <i>filename</i></b>—Name of file in which the system places the output of the tracing operations. By default, the system places all files in the <b>/var/log</b> directory.</p> <p><b>Default:</b> <b>/var/log/vgd</b></p> <p><b>files <i>number</i></b>—(Optional) Maximum number of trace files. When a trace file reaches the size specified by the <b>size</b> option, the filename is appended with 0 and compressed. For example, a trace file named <b>trace-file.gz</b> would be renamed <b>trace-file.0.gz</b>. When <b>trace-file.0.gz</b> reaches the specified size, it is renamed <b>trace-file.1.gz</b> and its contents are compressed to <b>trace-file.0.gz</b>. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.</p> <p>If you specify a maximum number of files, you also must specify a maximum file size with the <b>size</b> option and a filename.</p> <p><b>Range:</b> 2 through 1000 files</p> <p><b>Default:</b> 10 files</p> <p><b>flag <i>flag</i></b>—Tracing operation to perform. You can include one or more of the following flags:</p> <ul style="list-style-type: none"><li><b>all</b>—All OVSDB events.</li><li><b>configuration</b>—OVSDB configuration events.</li><li><b>core</b>—OVSDB core events.</li><li><b>function</b>—OVSDB function events.</li><li><b>interface</b>—OVSDB interface events.</li><li><b>l2-client</b>—OVSDB Layer 2 client events.</li></ul> |

**netconf-client**—(QFX Series switches only) Events for the dynamic configuration of Virtual Extensible LANs (VXLANs).

**ovs-client**—OVSDDB client events.

**match *regular-expression***—(Optional) Only log lines that match the regular expression.

**no-remote-trace**—(Optional) Disable tracing and logging operations that track normal operations, error conditions, and packets that are generated by or passed through the Juniper Networks device.

**no-world-readable**—Restrict access to the trace files to the owner.

**Default:** no-world-readable

**size *size***—(Optional) Maximum size of each trace file in bytes, kilobytes (KB), megabytes (MB), or gigabytes (GB). If you do not specify a unit, the default is bytes. If you specify a maximum file size, you also must specify a maximum number of trace files by using the **files** option and a filename by using the **file** option.

**Syntax:** *size* to specify bytes, *sizek* to specify KB, *sizem* to specify MB, or *sizeg* to specify GB.

**Range:** 10,240 through 1,073,741,824 bytes

**Default:** 128 KB

**world-readable**—Enable any user to access the trace files.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 14.1X53-D10.                                                                                                                                                                                                                                                                                                               |
| <b>Description</b>              | Configure the switch to preserve the original VLAN tag (in the inner Ethernet packet) when performing Virtual Extensible LAN (VXLAN) encapsulation.                                                                                                                                                                                                                 |
| <b>Default</b>                  | The original tag is dropped when the packet is encapsulated.                                                                                                                                                                                                                                                                                                        |

| <b>Description</b>              | <p>Disable a Juniper Networks device from learning about other Juniper Networks devices that function as hardware virtual tunnel endpoints (VTEPs) in a specified Virtual Extensible LAN (VXLAN) and the MAC addresses learned by the hardware VTEPs. Instead, the Juniper Networks device uses the Open vSwitch Database (OVSDB) management protocol to learn about the hardware VTEPs in the VXLAN and the media access control (MAC) addresses learned by the hardware VTEPs.</p> <p>The specified VXLAN must have a VXLAN network identifier (VNI) configured, using the <b>vni</b> statement in the [edit bridge-domains <i>bridge-domain-name</i> vxlan], [edit routing-instance <i>routing-instance-name</i> vxlan], or [edit vlans <i>vlan-name</i> vxlan] hierarchy.</p> <p>Also, for OVSDB-managed VXLANs, the multicast scheme described in “<a href="#">Understanding How Layer 2 BUM and Layer 3 Routed Multicast Traffic Are Handled with OVSDB</a>” on <a href="#">page 2450</a> is used. Therefore, specifying the <b>multicast-group</b> statement in the [edit bridge-domains <i>bridge-domain-name</i> vxlan], [edit routing-instances <i>routing-instance-name</i> vxlan], or [edit vlans <i>vlan-name</i> vxlan] hierarchy has no effect.</p> |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 14.1X53-D10.                                                                                                                                                                                                                                          |
| <b>Description</b>              | Configure the system to age out the address for the remote VTEP if all the MAC addresses learned from that virtual tunnel endpoint (VTEP) age out. The address for the remote VTEP expires the configured number of seconds after the last learned media access control (MAC) address expires. |

## CHAPTER 94

# OVSDDB Operational Commands

- `clear ovbdb commit failures`
- `show ovbdb commit failures`
- `show ovbdb controller`
- `show ovbdb interface`
- `show ovbdb logical-switch`
- `show ovbdb mac`
- `show ovbdb statistics interface`
- `show ovbdb virtual-tunnel-end-point`
- `show vpls mac-table`

## clear ovssdb commit failures

---

**Syntax**    `clear ovssdb commit failures`  
              `<transaction-id>`

**Release Information**    Command introduced in Junos OS Release 14.1X53-D26 for QFX Series switches.

**Description**    Remove a transaction from a queue maintained by a Juniper Networks switch that supports the Open vSwitch Database (OVSSDB) management protocol and Virtual Extensible LANs (VXLANs). The transaction includes OVSSDB-managed VXLANs and associated logical interfaces that the Juniper Networks switch dynamically configured and tried to commit but was unable to because of an issue with one or more of the configurations. In addition to removing the transaction, entering the **clear ovssdb commit failures** command causes the Juniper Networks switch to automatically retry committing all configurations in the transaction.

If there is an issue with one or more of the configurations in a transaction, this causes all configurations in the transaction, even the ones that are correctly configured, to remain uncommitted and in the queue until you troubleshoot and resolve the configuration issue(s).

You can display an erroneous transaction by entering the **show ovssdb commit failures** command. In the output that appears, you must determine which configuration(s) are erroneous and therefore prevent the Juniper Networks switch from committing the configurations in the transaction.

Issues that can cause commitment errors include but are not limited to the detection of the same VXLAN name or VXLAN network identifier (VNI) in a dynamically configured VXLAN and in a VXLAN that was previously configured using the Junos OS CLI.

To monitor for issues with dynamically configured OVSSDB-managed VXLANs and their associated interfaces, we recommend checking for system log messages and traceoptions files for OVSSDB.

After resolving the error(s), enter the **clear ovssdb commit failures** command to remove the transaction from the queue and retry committing all configurations in the transaction.

**NOTE:** While an erroneous transaction exists in the queue, the Juniper Networks switch cannot commit the dynamic configurations of additional VXLANs and their associated logical interfaces. The commitment of these VXLANs and logical interfaces remain in a pending state until all VXLAN and logical interface configurations in the erroneous transaction are resolved and successfully committed.

---

**Options**    **none**—Remove the transaction that currently appears in the **show ovssdb commit failures** command output, and retry committing all configurations in the transaction.

*transaction-id*—Remove the transaction with the specified numerical ID, and retry committing the configurations in the transaction.

**Required Privilege Level**    clear

## Sample Output

[clear ovldb commit failures](#)

```
user@host> clear ovldb commit failures
```

[clear ovldb commit failures \(Specific Transaction\)](#)

```
user@host> clear ovldb commit failures 1
```

## show ovssdb commit failures

---

**Syntax**    `show ovssdb commit failures`  
              `<transaction-id>`

**Release Information**    Command introduced in Junos OS Release 14.1X53-D26 for QFX Series switches.

**Description**    Display configurations of Open vSwitch Database (OVSSDB)-managed Virtual Extensible LANs (VXLANS) and associated logical interfaces that the Juniper Networks switch dynamically configured but was unable to commit.

For each OVSSDB-managed VXLAN and associated logical interface that you plan to implement in a Junos OS environment, you must configure equivalent entities in NSX Manager or in the NSX API for an NSX environment, or in the Contrail Web user interface for a Contrail environment. The software-defined networking (SDN) controller pushes these configurations to the connected Juniper Networks switch by way of the OVSSDB schema for physical devices. After the Juniper Networks switch receives these configurations, it dynamically configures a Junos OS-equivalent VXLAN and associated logical interface, and attempts to commit the configurations.

During the commitment of the dynamic configurations, If there is an issue with one or more of the configurations, all configurations in the transaction, even the ones that are correctly configured, remain uncommitted and are saved in a queue. All configurations in the transaction remain uncommitted and in the queue until you troubleshoot and resolve the configuration issues. After you resolve the configuration issues, you must use the [clear ovssdb commit failures](#) command to remove the transaction from the queue and retry committing the configurations.

**NOTE:** While an erroneous transaction exists in the queue, the Juniper Networks switch cannot commit the dynamic configurations of additional VXLANS and their associated logical interfaces. The commitment of these VXLANS and logical interfaces remain in a pending state until all VXLAN and logical interface configurations in the erroneous transaction are resolved and successfully committed.

---

Issues that can cause commitment errors include but are not limited to the detection of the same VXLAN name or VXLAN network identifier (VNI) in a dynamically configured VXLAN and in a VXLAN that was previously configured using the Junos OS CLI.

To monitor for issues with dynamically configured OVSSDB-managed VXLANS and their associated interfaces, we recommend checking for system log messages and traceoptions files for OVSSDB.

**Options**    **none**—Display information about an erroneous transaction.

**transaction-id**—Display information about the transaction with the specified numerical ID.

**Required Privilege Level** admin

Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                   |

**Table 223: show ovssdb controller Output Fields**

| Field Name                       | Field Description                                                                   |
|----------------------------------|-------------------------------------------------------------------------------------|
| Controller IP address            | IP address of the SDN controller to which the Juniper Networks device is connected. |
| Controller protocol              | Protocol used by the Juniper Networks device to initiate the connection.            |
| Controller port                  | Port to which the Juniper Networks device is connected.                             |
| Controller connection            | State of the connection with the SDN controller.                                    |
| Controller seconds-since-connect | Number of seconds since the connection with the SDN controller was established.     |

Table 223: show ovsdb controller Output Fields (*continued*)

| Field Name                          | Field Description                                                           |
|-------------------------------------|-----------------------------------------------------------------------------|
| Controller seconds-since-disconnect | Number of seconds since the connection with the SDN controller was dropped. |
| Controller connection status        | Status of the connection with the SDN controller.                           |

## Sample Output

### show ovsdb controller

```

user@host> show ovsdb controller
VTEP controller information:
Controller IP address: 10.168.66.189
Controller protocol: ssl
Controller port: 6632
Controller connection: up
Controller seconds-since-connect: 56290
Controller seconds-since-disconnect: 0
Controller connection status: active

Controller IP address: 10.168.181.54
Controller protocol: ssl
Controller port: 6632
Controller connection: up
Controller seconds-since-connect: 56292
Controller seconds-since-disconnect: 0
Controller connection status: active

Controller IP address: 10.168.182.45
Controller protocol: ssl
Controller port: 6632
Controller connection: up
Controller seconds-since-connect: 56292
Controller seconds-since-disconnect: 0
Controller connection status: active

```

### show ovsdb controller address

```

user@host> show ovsdb controller address 10.168.182.45
VTEP controller information:
Controller IP address: 192.168.182.45
Controller protocol: ssl
Controller port: 6632
Controller connection: up
Controller seconds-since-connect: 56347
Controller seconds-since-disconnect: 0
Controller connection status: active

```

## Sample Output

### show ovssdb interface

```
user@host> show ovssdb interface
```

| Interface   | VLAN ID | Bridge-domain |
|-------------|---------|---------------|
| ge-7/0/9.0  |         |               |
| ge-7/0/9.1  |         |               |
| irb.11      |         |               |
| irb.12      |         |               |
| irb.2       |         |               |
| irb.3       |         |               |
| xe-10/3/0.0 |         |               |
| xe-10/3/0.1 |         |               |

#### show ovbdb (Specific Interface)

```
user@host> show ovbdb interface ge-7/0/9.0
```

| Interface  | VLAN ID | Bridge-domain |
|------------|---------|---------------|
| ge-7/0/9.0 |         |               |

## show ovssdb logical-switch

---

**Syntax**    show ovssdb logical-switch  
              <logical-switch-name>

**Release Information**    Command introduced in Junos OS Release 14.1R2.  
                              Command introduced in Junos OS Release 14.1X53-D10 for QFX Series switches.  
                              Command introduced in Junos OS Release 14.2 for EX Series switches.

**Description**

**NOTE:** In the Open vSwitch Database (OVSSDB) schema for physical devices, the logical switch table stores information about the Layer 2 broadcast domain that you configured in a VMware NSX or Contrail environment. In the NSX environment, the Layer 2 broadcast domain is known as a *logical switch*, while in the Contrail environment, the domain is known as a *virtual network*.

In the context of the **show ovssdb logical-switch** command, the term *logical switch* refers to the logical switch or virtual network that was configured in the NSX or Contrail environments, respectively, and the corresponding configuration that was pushed to the OVSSDB schema.

Display information about logical switches and the corresponding Virtual Extensible LANs (VXLANs), which were configured on the Juniper Networks device.

In the command output, each logical switch is identified by a universally unique identifier (UUID), which in the context of this command, is also known as a logical switch name.

The **show ovssdb logical-switch** command displays the state of the logical switch (**Flags**), which can be one of the following:

**Created by Controller**—A logical switch is configured. However, a corresponding VXLAN is not yet configured. In this state, the logical switch and corresponding VXLAN are not yet operational.

**Created by L2ALD**—A VXLAN is configured. However, a corresponding logical switch is not yet configured. In this state, the logical switch and corresponding VXLAN are not yet operational.

**Created by both**—A logical switch and a corresponding VXLAN are configured. In this state, the logical switch and corresponding VXLAN are operational.

**Tunnel key mismatch**—The VNIs specified in the logical switch and corresponding VXLAN configurations do not match. In this state, the logical switch and corresponding VXLAN are not yet operational.

**Options**    **none**—Display information about all logical switches that are present in the OVSSDB schema for physical devices.

**logical-switch-name**—Display information about the specified logical switch.

**Required Privilege Level** admin

**Output Fields** [Table 225](#) lists the output fields for the **show ovssdb logical-switch** command. Output fields are listed in the approximate order in which they appear.

**Table 225: show ovssdb logical-switch Output Fields**

| Field Name          | Field Description                                                                                                                                                                          |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Logical Switch Name | UUID that is automatically generated and assigned to the logical switch. When you configure the corresponding VXLAN in the Junos OS CLI, you must specify the same UUID as the VXLAN name. |
| Flags               | State of the logical switch. For possible states, see the Description section of this topic.                                                                                               |
| VNI                 | VNI that is configured for the logical switch and corresponding VXLAN.                                                                                                                     |
| Num of Remote MAC   | The total number of remote media access control (MAC) addresses associated with the logical switch. These addresses are learned by software and hardware virtual tunnel endpoints (VTEPs). |
| Num of Local MAC    | The total number of local MAC addresses associated with the logical switch. <i>Local MAC addresses</i> are addresses learned on the local physical ports.                                  |

## Sample Output

### show ovssdb logical-switch

```
user@host> show ovssdb logical-switch
Logical switch information:
Logical Switch Name: 24a76aff-7e61-4520-a78d-3eca26ad7510
Flags: Created by both
VNI: 3
Num of Remote MAC: 13
Num of Local MAC: 12
Logical Switch Name: 9b4f880e-dac8-4612-a832-97ad9dec270f
Flags: Created by Controller
VNI: 50
Num of Remote MAC: 0
Num of Local MAC: 0
Logical Switch Name: bc0da2da-6c16-44bf-b655-442484294ded
Flags: Created by Controller
VNI: 51
Num of Remote MAC: 0
Num of Local MAC: 0
```

### show ovssdb logical-switch (Specific Logical Switch)

```
user@host> show ovssdb logical-switch 24a76aff-7e61-4520-a78d-3eca26ad7510
Logical switch information:
Logical Switch Name: 24a76aff-7e61-4520-a78d-3eca26ad7510
Flags: Created by both
VNI: 3
Num of Remote MAC: 13
Num of Local MAC: 12
```

## show ovssdb mac

**Syntax** show ovssdb mac  
 <address *mac-address*>  
 <local>  
 <logical-switch *logical-switch-uuid*>  
 <multicast>  
 <remote>  
 <unicast>

**Release Information** Command introduced in Junos OS Release 14.1R2.  
 Command introduced in Junos OS Release 14.1X53-D10 for QFX Series switches.  
 Command introduced in Junos OS Release 14.2 for EX Series switches.

**Description** Display media access control (MAC) addresses, as well as information about the media access control (MAC) addresses, learned by a Juniper Networks device that functions as a hardware virtual tunnel endpoint (VTEP). Using the Open vSwitch Database (OVSDb) management protocol, this hardware VTEP can learn about MAC addresses directly or from other software or hardware VTEPs. The MAC addresses learned directly by the hardware VTEP are known as *local addresses*, while the addresses learned from other software or hardware VTEPs are known as *remote addresses*.

**Options** Use one or more of the following options to display a more specific list of MAC addresses and information about the MAC addresses. For example, to display a list of local unicast MAC addresses, you can issue the **show ovssdb mac local unicast** command.

**none**—Display all MAC addresses, which includes all local, remote, unicast, and multicast addresses associated with all logical switches.

**address *mac-address***—Display the specified MAC address.

**count**—(All Juniper Networks devices that support OVSDb except EX9200 switches)  
 Display the number of MAC addresses learned by the Juniper Networks device. Using this option alone, the number includes all local, remote, unicast, and multicast MAC addresses associated with all logical switches in the logical switch table of the OVSDb schema for physical devices. You can use this option with one or more of the other options to display a more specific count of MAC addresses. For example, to display the number of local and remote unicast MAC addresses, you can issue the **show ovssdb mac count local remote unicast** command.

**local**—Display all local MAC addresses.

**logical-switch *logical-switch-uuid***—Display all MAC addresses associated with the specified logical switch in the logical switch table of the OVSDb schema for physical devices.

**multicast**—Display all multicast MAC addresses.

**remote**—Display all remote MAC addresses.

**unicast**—Display all unicast MAC addresses.

**Required Privilege Level** admin

**Output Fields** Table 226 lists the output fields for the **show ovssdb mac** command. Output fields are listed in the approximate order in which they appear.

**Table 226: show ovssdb mac Output Fields**

| Field Name          | Field Description                                                                                                                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Logical Switch Name | Universally unique identifier (UUID) of the logical switch.                                                                                                                                             |
| MAC Address         | MAC addresses of virtual machines (VMs).                                                                                                                                                                |
| IP Address          | IP address of VMs.<br><br><i>NOTE:</i> If the IP addresses of VMs are not published by the SDN controller, this field displays 0.0.0.0.                                                                 |
| Encapsulation       | Encapsulation type.                                                                                                                                                                                     |
| VTEP Address        | IP address of the hardware or software VTEP from which the MAC address was learned. Further, this VTEP can forward VM traffic to the associated host.                                                   |
| MAC Count           | <i>NOTE:</i> This field is supported by all Juniper Networks devices that support OVSDb except EX9200 switches.<br><br>Number of all or specified MAC addresses learned by the Juniper Networks device. |

| <b>Output Fields</b>            | <a href="#">Table 227</a> lists the output fields for the <b>show ovssdb statistics interface</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                        |

**Table 227: show ovssdb statistics interface Output Fields**

| Field Name      | Field Description                            |
|-----------------|----------------------------------------------|
| Num of rx pkts  | Number of packets received by the interface. |
| Num of tx pkts  | Number of packets sent by the interface.     |
| Num of rx bytes | Number of bytes received by the interface.   |
| Num of tx bytes | Number of bytes sent by the interface.       |

## Sample Output

### show ovssdb statistics interface

```

user@host> show ovssdb statistics interface
Interface Name: ge-7/0/9.0
Num of rx pkts: 945 Num of tx pkts: 113280890
Num of rx bytes: 56700 Num of tx bytes: 57531319540

```

|                             |                              |
|-----------------------------|------------------------------|
| Interface Name: ge-7/0/10.0 |                              |
| Num of rx pkts: 459         | Num of tx pkts: 473840856    |
| Num of rx bytes: 84747      | Num of tx bytes: 45830738532 |
| Interface Name: ge-7/0/11.0 |                              |
| Num of rx pkts: 305         | Num of tx pkts: 367483456    |
| Num of rx bytes: 98974      | Num of tx bytes: 33495468092 |

#### show ovsdb statistics interface (Specific Interface)

```
user@host> show ovsdb statistics interface ge-7/0/9.0
```

|                            |                              |

| <b>Output Fields</b>            | Table 229 describes the output fields for the <b>show vpls mac-table</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Table 229: show vpls mac-table Output fields

| Field Name              | Field Description                                                                                                                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Routing instance        | Name of the routing instance.                                                                                                                                                                                                                                                                      |
| Bridging domain         | Name of the bridging domain.                                                                                                                                                                                                                                                                       |
| MAC address             | MAC address or addresses learned on a logical interface.                                                                                                                                                                                                                                           |
| MAC flags               | Status of MAC address learning properties for each interface: <ul style="list-style-type: none"> <li>• <b>S</b>—Static MAC address configured.</li> <li>• <b>D</b>—Dynamic MAC address learned.</li> <li>• <b>SE</b>—MAC accounting is enabled.</li> <li>• <b>NM</b>—Nonconfigured MAC.</li> </ul> |
| Logical interface       | Name of the logical interface.                                                                                                                                                                                                                                                                     |
| MAC count               | Number of MAC addresses learned on a specific routing instance or interface.                                                                                                                                                                                                                       |
| Learning interface      | Logical interface or logical Label Switched Interface (LSI) the address is learned on.                                                                                                                                                                                                             |
| Base learning interface | Base learning interface of the MAC address. This field is introduced in Junos OS Release 14.2.                                                                                                                                                                                                     |
| Learn VLAN ID/VLAN      | VLAN ID of the routing instance or bridge domain in which the MAC address was learned.                                                                                                                                                                                                             |
| VXLAN ID/VXLAN          | VXLAN Network Identifier (VNI)                                                                                                                                                                                                                                                                     |
| Layer 2 flags           | Debugging flags signifying that the MAC address is present in various lists.                                                                                                                                                                                                                       |
| Epoch                   | Spanning Tree Protocol epoch number identifying when the MAC address was learned. Used for debugging.                                                                                                                                                                                              |
| Sequence number         | Sequence number assigned to this MAC address. Used for debugging.                                                                                                                                                                                                                                  |
| Learning mask           | Mask of Packet Forwarding Engines where this MAC address was learned. Used for debugging.                                                                                                                                                                                                          |
| IPC generation          | Creation time of the logical interface when this MAC address was learned. Used for debugging.                                                                                                                                                                                                      |

## Sample Output

### show vpls mac-table

```

user@host> show vpls mac-table
MAC flags (S -static MAC, D -dynamic MAC,
 SE -Statistics enabled, NM -Non configured MAC)

Routing instance : vpls_ldp1
VLAN : 223
 MAC MAC Logical
 address flags interface
 00:90:69:9c:1c:5d D ge-0/2/5.400

```

MAC flags (S -static MAC, D -dynamic MAC,  
SE -Statistics enabled, NM -Non configured MAC)

Routing instance : vpls\_red  
VLAN : 401

| MAC<br>address    | MAC<br>flags | Logical<br>interface |
|-------------------|--------------|----------------------|
| 00:00:aa:12:12:12 | D            | lsi.1051138          |
| 00:05:85:74:9f:f0 | D            | lsi.1051138          |

#### show vpls mac-table (with Layer 2 Services over GRE Interfaces)

user@host> show vpls mac-table  
MAC flags (S -static MAC, D -dynamic MAC, L -locally learned  
SE -Statistics enabled, NM -Non configured MAC, R -Remote PE MAC)

Routing instance : vpls\_4site:1000  
Bridging domain : \_\_vpls\_4site:1000\_\_, MAC

| address           | flags | MAC | Logical<br>interface |
|-------------------|-------|-----|----------------------|
| 00:01:01:00:01:f4 | D,SE  |     | ge-4/2/0.1000        |
| 00:02:01:33:01:f4 | D,SE  |     | lsi.1052004          |
| 00:03:00:32:01:f4 | D,SE  |     | lsi.1048840          |
| 00:04:00:14:01:f4 | D,SE  |     | lsi.1052005          |
| 00:02:01:33:02:f7 | D,SE  |     | gr-1/2/10.10         |

#### show vpls mac-table (with VXLAN enabled)

user@host> show vpls mac-table  
MAC flags (S -static MAC, D -dynamic MAC, L -locally learned  
SE -Statistics enabled, NM -Non configured MAC, R -Remote PE MAC)

Routing instance : vpls\_4site:1000  
Bridging domain : \_\_vpls\_4site:1000\_\_, VLAN : 4094,4093  
VXLAN: Id : 300, Multicast group: 226.1.1.3

| MAC<br>address    | MAC<br>flags | Logical<br>interface |
|-------------------|--------------|----------------------|
| 00:01:01:00:01:f4 | D,SE         | ge-4/2/0.1000        |
| 00:02:01:33:01:f4 | D,SE         | lsi.1052004          |
| 00:03:00:32:01:f4 | D,SE         | lsi.1048840          |
| 00:04:00:14:01:f4 | D,SE         | lsi.1052005          |
| 00:02:01:33:02:f7 | D,SE         | vtep.1052010         |
| 00:04:00:14:02:f7 | D,SE         | vtep.1052011         |

#### show vpls mac-table count

user@host> show vpls mac-table count  
0 MAC address learned in routing instance \_\_juniper\_private1\_\_

MAC address count per interface within routing instance:

| Logical interface | MAC count |
|-------------------|-----------|
| lc-0/0/0.32769    | 0         |
| lc-0/1/0.32769    | 0         |
| lc-0/2/0.32769    | 0         |
| lc-2/0/0.32769    | 0         |
| lc-0/3/0.32769    | 0         |
| lc-2/1/0.32769    | 0         |
| lc-9/0/0.32769    | 0         |
| lc-11/0/0.32769   | 0         |
| lc-2/2/0.32769    | 0         |
| lc-9/1/0.32769    | 0         |
| lc-11/1/0.32769   | 0         |

|                 |   |
|-----------------|---|
| 1c-2/3/0.32769  | 0 |
| 1c-9/2/0.32769  | 0 |
| 1c-11/2/0.32769 | 0 |
| 1c-11/3/0.32769 | 0 |
| 1c-9/3/0.32769  | 0 |

MAC address count per learn VLAN within routing instance:

| Learn VLAN ID | MAC count |
|---------------|-----------|
| 0             | 0         |

1 MAC address learned in routing instance vpls\_ldp1

MAC address count per interface within routing instance:

| Logical interface | MAC count |
|-------------------|-----------|
| lsi.1051137       | 0         |
| ge-0/2/5.400      | 1         |

MAC address count per learn VLAN within routing instance:

| Learn VLAN ID | MAC count |
|---------------|-----------|
| 0             | 1         |

1 MAC address learned in routing instance vpls\_red

MAC address count per interface within routing instance:

| Logical interface | MAC count |
|-------------------|-----------|
| ge-0/2/5.300      | 1         |

MAC address count per learn VLAN within routing instance:

| Learn VLAN ID | MAC count |
|---------------|-----------|
| 0             | 1         |

### show vpls mac-table detail

user@host> show vpls mac-table detail

MAC address: 00:90:69:9c:1c:5d

Routing instance: vpls\_ldp1

Learning interface: ge-0/2/5.400

Layer 2 flags: in\_ifd, in\_ifl, in\_vlan, kernel

Epoch: 0

Sequence number: 1

Learning mask: 0x1

IPC generation: 0

MAC address: 00:90:69:9c:1c:5d

Routing instance: vpls\_red

Learning interface: ge-0/2/5.300

Layer 2 flags: in\_ifd, in\_ifl, in\_vlan, kernel

Epoch: 0

Sequence number: 1

Learning mask: 0x1

IPC generation: 0

### show vpls mac-table extensive

user@host> show vpls mac-table extensive

MAC address: 00:10:00:01:00:00

Routing instance: vpls\_1

Bridging domain: \_\_vpls\_1\_\_, VLAN : NA

Learning interface: lsi.1049165

Base learning interface: lsi.1049165

Layer 2 flags: in\_hash, in\_ifd, in\_ifl, in\_vlan, in\_rtt, kernel, in\_ifbd

Epoch: 0

Sequence number: 1

Learning mask: 0x00000001

```
MAC address: 00:10:00:01:00:01
Routing instance: vpls_1
 Bridging domain: __vpls_1__, VLAN : NA
 Learning interface: lsi.1049165
 Base learning interface: lsi.1049165
 Layer 2 flags: in_hash,in_ifd,in_ifl,in_vlan,in_rtt,kernel,in_ifbd
 Epoch: 0 Sequence number: 1
 Learning mask: 0x00000001

MAC address: 00:10:00:01:00:02
Routing instance: vpls_1
 Bridging domain: __vpls_1__, VLAN : NA
 Learning interface: lsi.1049165
 Base learning interface: lsi.1049165
 Layer 2 flags: in_hash,in_ifd,in_ifl,in_vlan,in_rtt,kernel,in_ifbd
 Epoch: 0 Sequence number: 1
 Learning mask: 0x00000001

MAC address: 00:10:00:01:00:03
Routing instance: vpls_1
 Bridging domain: __vpls_1__, VLAN : NA
 Learning interface: lsi.1049165
 Base learning interface: lsi.1049165
 Layer 2 flags: in_hash,in_ifd,in_ifl,in_vlan,in_rtt,kernel,in_ifbd
 Epoch: 0 Sequence number: 1
 Learning mask: 0x00000001
```

## CHAPTER 95

# VXLAN Operational Commands

- `show bridge mac-table`
- `show vpls mac-table`

## show bridge mac-table

---

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Release Information</b>      | Command introduced in Junos OS Release 8.4.<br>Command introduced in Junos OS Release 15.1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b>              | (MX Series routers only) Display Layer 2 media access control (MAC) address information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Options</b>                  | <b>none</b> —Display all learned Layer 2 MAC address information.<br><br><b>brief   count   detail   extensive</b> —(Optional) Display the specified level of output.<br><br><b>bridge-domain (all   <i>bridge-domain-name</i>)</b> —(Optional) Display learned Layer 2 MAC addresses for all bridging domains or for the specified bridging domain.<br><br><b>global-count</b> —(Optional) Display the total number of learned Layer 2 MAC addresses on the system.<br><br><b>instance <i>instance-name</i></b> —(Optional) Display learned Layer 2 MAC addresses for the specified routing instance.<br><br><b>interface <i>interface-name</i></b> —(Optional) Display learned Layer 2 MAC addresses for the specified interface.<br><br><b>mac-address</b> —(Optional) Display the specified learned Layer 2 MAC address information.<br><br><b>vlan-id (all-vlan   <i>vlan-id</i>)</b> —(Optional) Display learned Layer 2 MAC addresses for all VLANs or for the specified VLAN. |
| <b>Additional Information</b>   | When Layer 2 protocol tunneling is enabled, the tunneling MAC address 01:00:0c:cd:cd:d0 is installed in the MAC table. When the Cisco Discovery Protocol (CDP), Spanning Tree Protocol (STP), or VLAN Trunk Protocol (VTP) is configured for Layer 2 protocol tunneling on an interface, the corresponding protocol MAC address is installed in the MAC table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Output Fields** Table 230 describes the output fields for the **show bridge mac-table** command. Output fields are listed in the approximate order in which they appear.

**Table 230: show bridge mac-table Output Fields**

| Field Name         | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Routing instance   | Name of the routing instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Bridging domain    | Name of the bridging domain.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| MAC address        | MAC address or addresses learned on a logical interface.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| MAC flags          | Status of MAC address learning properties for each interface: <ul style="list-style-type: none"> <li>• <b>S</b>—Static MAC address is configured.</li> <li>• <b>D</b>—Dynamic MAC address is configured.</li> <li>• <b>L</b>—Locally learned MAC address is configured.</li> <li>• <b>C</b>—Control MAC address is configured.</li> <li>• <b>SE</b>—MAC accounting is enabled.</li> <li>• <b>NM</b>—Non-configured MAC.</li> <li>• <b>R</b>—Remote PE MAC address is configured.</li> </ul> |
| Logical interface  | Name of the logical interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| MAC count          | Number of MAC addresses learned on the specific routing instance or interface.                                                                                                                                                                                                                                                                                                                                                                                                              |
| Learning interface | Name of the logical interface on which the MAC address was learned.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Learning VLAN      | VLAN ID of the routing instance or bridge domain in which the MAC address was learned.                                                                                                                                                                                                                                                                                                                                                                                                      |
| VXLAN ID/VXLAN     | VXLAN Network Identifier (VNI).                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Layer 2 flags      | Debugging flags signifying that the MAC address is present in various lists.                                                                                                                                                                                                                                                                                                                                                                                                                |
| Epoch              | Spanning Tree Protocol epoch number identifying when the MAC address was learned. Used for debugging.                                                                                                                                                                                                                                                                                                                                                                                       |
| Sequence number    | Sequence number assigned to this MAC address. Used for debugging.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Learning mask      | Mask of the Packet Forwarding Engines where this MAC address was learned. Used for debugging.                                                                                                                                                                                                                                                                                                                                                                                               |
| IPC generation     | Creation time of the logical interface when this MAC address was learned. Used for debugging.                                                                                                                                                                                                                                                                                                                                                                                               |

## Sample Output

### show bridge mac-table

```
user@host> show bridge mac-table
MAC flags (S -static MAC, D -dynamic MAC, L -locally learned, C -Control MAC
SE -Statistics enabled, NM -Non configured MAC, R -Remote PE MAC)

Routing instance : default-switch
Bridging domain : test1, VLAN : 1
 MAC MAC Logical NH RTR
 address flags interface Index ID
01:00:0c:cc:cc:cc S,NM NULL
01:00:0c:cc:cc:cd S,NM NULL
01:00:0c:cd:cd:d0 S,NM NULL

```

### show bridge mac-table count

```

user@host> show bridge mac-table count
2 MAC address learned in routing instance vs1 bridge domain vlan100

MAC address count per interface within routing instance:
Logical interface MAC count
ge-11/0/3.0 1
ge-11/1/4.100 0
ge-11/1/1.100 0
ge-11/1/0.100 0
xe-10/2/0.100 1
xe-10/0/0.100 0

MAC address count per learn VLAN within routing instance:
Learn VLAN ID MAC count
0 2

0 MAC address learned in routing instance vs1 bridge domain vlan200

MAC address count per interface within routing instance:
Logical interface MAC count
ge-11/1/0.200 0
ge-11/1/1.200 0
ge-11/1/4.200 0
xe-10/0/0.200 0
xe-10/2/0.200 0

MAC address count per learn VLAN within routing instance:
Learn VLAN ID MAC count
0 0

```

### show bridge mac-table detail

```

user@host> show bridge mac-table detail
MAC address: 00:00:00:19:1c:db
Routing instance: vs1
Bridging domain: vlan100
Learning interface: ge-11/0/3.0 Learning VLAN: 0
Layer 2 flags: in_ifd, in_ifl, in_vlan, kernel
Epoch: 4 Sequence number: 0
Learning mask: 0x800 IPC generation: 0

MAC address: 00:00:00:59:3a:2f
Routing instance: vs1
Bridging domain: vlan100
Learning interface: xe-10/2/0.100 Learning VLAN: 0
Layer 2 flags: in_ifd, in_ifl, in_vlan, kernel
Epoch: 7 Sequence number: 0
Learning mask: 0x400 IPC generation: 0

```

**show bridge mac-table instance pbb-evpn**

```
user@host> show bridge mac-table instance pbb-evpn
Routing instance : pbb-evpn
Bridging domain : isid-bd10000, ISID : 10000
MAC MAC Logical NH RTR
address flags interface Index ID

| <b>Output Fields</b>            | Table 229 describes the output fields for the <b>show vpls mac-table</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Table 231: show vpls mac-table Output fields

| Field Name              | Field Description                                                                                                                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Routing instance        | Name of the routing instance.                                                                                                                                                                                                                                                                      |
| Bridging domain         | Name of the bridging domain.                                                                                                                                                                                                                                                                       |
| MAC address             | MAC address or addresses learned on a logical interface.                                                                                                                                                                                                                                           |
| MAC flags               | Status of MAC address learning properties for each interface: <ul style="list-style-type: none"> <li>• <b>S</b>—Static MAC address configured.</li> <li>• <b>D</b>—Dynamic MAC address learned.</li> <li>• <b>SE</b>—MAC accounting is enabled.</li> <li>• <b>NM</b>—Nonconfigured MAC.</li> </ul> |
| Logical interface       | Name of the logical interface.                                                                                                                                                                                                                                                                     |
| MAC count               | Number of MAC addresses learned on a specific routing instance or interface.                                                                                                                                                                                                                       |
| Learning interface      | Logical interface or logical Label Switched Interface (LSI) the address is learned on.                                                                                                                                                                                                             |
| Base learning interface | Base learning interface of the MAC address. This field is introduced in Junos OS Release 14.2.                                                                                                                                                                                                     |
| Learn VLAN ID/VLAN      | VLAN ID of the routing instance or bridge domain in which the MAC address was learned.                                                                                                                                                                                                             |
| VXLAN ID/VXLAN          | VXLAN Network Identifier (VNI)                                                                                                                                                                                                                                                                     |
| Layer 2 flags           | Debugging flags signifying that the MAC address is present in various lists.                                                                                                                                                                                                                       |
| Epoch                   | Spanning Tree Protocol epoch number identifying when the MAC address was learned. Used for debugging.                                                                                                                                                                                              |
| Sequence number         | Sequence number assigned to this MAC address. Used for debugging.                                                                                                                                                                                                                                  |
| Learning mask           | Mask of Packet Forwarding Engines where this MAC address was learned. Used for debugging.                                                                                                                                                                                                          |
| IPC generation          | Creation time of the logical interface when this MAC address was learned. Used for debugging.                                                                                                                                                                                                      |

## Understanding Aggregated Ethernet Load Balancing

---

The link aggregation feature is used to bundle several physical aggregated Ethernet interfaces to form one logical interface. One or more links are aggregated to form a virtual link or link aggregation group (LAG). The MAC client treats this virtual link as if it were a single link. Link aggregation increases bandwidth, provides graceful degradation as failure occurs, and increases availability.

In addition to these benefits, an aggregated Ethernet bundle is enhanced to provide load-balancing capabilities that ensure that the link utilization among the member links of the aggregated Ethernet bundle are fully and efficiently utilized.

The load-balancing feature allows a device to divide incoming and outgoing traffic along multiple paths or interfaces in order to reduce congestion in the network. Load balancing improves the utilization of various network paths and provides more effective network bandwidth.

Typically, the applications that use load balancing include:

- Aggregated Interfaces (Layer 2)

Aggregated Interfaces (also called AE for aggregated Ethernet, and AS for aggregated SONET) are a Layer 2 mechanism for load-balancing across multiple interfaces between two devices. Because this is a Layer 2 load-balancing mechanism, all of the individual component links must be between the same two devices on each end. Junos OS supports a non-signaled (static) configuration for Ethernet and SONET, as well as the 802.3ad standardized LACP protocol for negotiation over Ethernet links.

- Equal-Cost Multipath (ECMP) (Layer 3)

By default, when there are multiple equal-cost paths to the same destination for the active route, Junos OS uses a hash algorithm to choose one of the next-hop addresses to install in the forwarding table. Whenever the set of next hops for a destination changes in any way, the next-hop address is rechosen using the hash algorithm. There is also an option that allows multiple next-hop addresses to be installed in the forwarding table, known as per-packet load balancing.

ECMP load balancing can be:

- Across BGP paths (BGP multipath)
- Within a BGP path, across multiple LSPs

In complex Ethernet topologies, traffic imbalances occur due to increased traffic flow, and load balancing becomes challenging for some of the following reasons:

- Incorrect load balancing by aggregate next hops
- Incorrect packet hash computation
- Insufficient variance in the packet flow
- Incorrect pattern selection

As a result of traffic imbalance, the load is not well distributed causing congestion in certain links, whereas some other links are not efficiently utilized.

To overcome these challenges, Junos OS provides the following solutions for resolving the genuine traffic imbalance on aggregated Ethernet bundles (IEEE 802.3ad).

- Adaptive Load Balancing

Adaptive load balancing uses a feedback mechanism to correct a genuine traffic imbalance. To correct the imbalance weights, the bandwidth and packet stream of links are adapted to achieve efficient traffic distribution across the links in an AE bundle.

To configure adaptive load balancing, include the **adaptive** statement at the **[edit interfaces aex aggregated-ether-options load-balance]** hierarchy level.

**NOTE:** Adaptive load balancing is not supported if the VLAN ID is configured on the aggregated Ethernet interface. This limitation affects the PTX Series Packet Transport Routers and QFX10000 switches only.

---

To configure the tolerance value as a percentage, include the **tolerance** optional keyword at the **[edit interfaces aex aggregated-ether-options load-balance adaptive]** hierarchy level.

To configure adaptive load balancing based on packets per second (instead of the default bits per second setting), include the **pps** optional keyword at the **[edit interfaces aex aggregated-ether-options load-balance adaptive]** hierarchy level.

To configure the scan interval for the hash value based on the sample rate for the last two seconds, include the **scan-interval** optional keyword at the **[edit interfaces aex aggregated-ether-options load-balance adaptive]** hierarchy level.

**NOTE:** The **pps** and **scan-interval** optional keywords are supported on PTX Series Packet Transport Routers only.

- Per-Packet Random Spray Load Balancing

When the adaptive load-balancing option fails, per-packet random spray load balancing serves as a last resort. It ensures that the members of an AE bundle are equally loaded without taking bandwidth into consideration. Per packet causes packet reordering and hence is recommended only if the applications absorb reordering. Per-packet random spray eliminates traffic imbalance that occurs as a result of software errors, except for packet hash.

To configure per-packet random spray load balancing, include the **per-packet** statement at the **[edit interfaces aex aggregated-ether-options load-balance]** hierarchy level.

**NOTE:** The Per-Packet option for load balancing is not supported on PTX Series Packet Transport Routers.

The aggregated Ethernet load-balancing solutions are mutually exclusive. When more than one of the load-balancing solutions is configured, the solution that is configured last overrides the previously configured one. You can verify the load-balancing solution being used by issuing the **show interfaces aex aggregated-ether-options load-balance** command.

## Configuring Adaptive Load Balancing

This topic describes how to configure adaptive load balancing. Adaptive load balancing maintains efficient utilization of member link bandwidth for an aggregated Ethernet (AE) bundle. Adaptive load balancing uses a feedback mechanism to correct traffic load imbalance by adjusting the bandwidth and packet streams on links within an AE bundle.

Before you begin:

- Configure a set of interfaces with a protocol family and IP address. These interfaces can make up the membership for the AE bundle.
- Create an AE bundle by configuring a set of router interfaces as aggregated Ethernet and with a specific AE group identifier.

To configure adaptive load balancing for an AE bundles:

1. Enable adaptive load balancing on the AE bundle:

```
[edit interfaces ae-x aggregated-ether-options load-balance]
user@router# set adaptive
```

2. Configure the scan interval value for adaptive load balancing on the AE bundle. The scan interval value determines the length of the traffic scan by multiplying the integer value with a 30-second time period:

```
[edit interfaces ae-x aggregated-ether-options load-balance adaptive]
user@router# set scan-interval multiplier
```

3. Configure the tolerance percentage value. The tolerance value determines the allowed deviation in the traffic rates among the members of the AE bundle before the router triggers an adaptive load balancing update:

```
[edit interfaces ae-x aggregated-ether-options load-balance adaptive]
user@router# set tolerance percentage
```

4. (Optional) Enable packet-per-second-based adaptive load balancing on the AE bundle:

```
[edit interfaces ae-x aggregated-ether-options load-balance adaptive]
user@router# set pps
```

## Graceful Restart Concepts

---

With routing protocols, any service interruption requires that an affected router recalculate adjacencies with neighboring routers, restore routing table entries, and update other protocol-specific information. An unprotected restart of a router can result in forwarding delays, route flapping, wait times stemming from protocol reconvergence, and even dropped packets. The main benefits of graceful restart are uninterrupted packet forwarding and temporary suppression of all routing protocol updates. Graceful restart enables a router to pass through intermediate convergence states that are hidden from the rest of the network.

Three main types of graceful restart are available on Juniper Networks routing platforms:

- Graceful restart for aggregate and static routes and for routing protocols—Provides protection for aggregate and static routes and for Border Gateway Protocol (BGP), End System-to-Intermediate System (ES-IS), Intermediate System-to-Intermediate System (IS-IS), Open Shortest Path First (OSPF), Routing Information Protocol (RIP), next-generation RIP (RIPng), and Protocol Independent Multicast (PIM) sparse mode routing protocols.
- Graceful restart for MPLS-related protocols—Provides protection for Label Distribution Protocol (LDP), Resource Reservation Protocol (RSVP), circuit cross-connect (CCC), and translational cross-connect (TCC). (Not supported on OCX Series switches.)
- Graceful restart for virtual private networks (VPNs)—Provides protection for Layer 2 and Layer 3 VPNs.

Graceful restart works similarly for routing protocols and MPLS protocols and combines components of these protocol types to enable graceful restart in VPNs. The main benefits of graceful restart are uninterrupted packet forwarding and temporary suppression of all routing protocol updates. Graceful restart thus enables a router to pass through intermediate convergence states that are hidden from the rest of the network.

Most graceful restart implementations define two types of routers—the restarting router and the helper router. The restarting router requires rapid restoration of forwarding state

information so it can resume the forwarding of network traffic. The helper router assists the restarting router in this process. Graceful restart configuration statements typically affect either the restarting router or the helper router.

## Configuring Routing Protocols Graceful Restart

This topic includes the following sections:

- [Enabling Graceful Restart on page 2580](#)
- [Configuring Graceful Restart Options for BGP on page 2581](#)
- [Configuring Graceful Restart Options for ES-IS on page 2582](#)
- [Configuring Graceful Restart Options for IS-IS on page 2582](#)
- [Configuring Graceful Restart Options for OSPF and OSPFv3 on page 2583](#)
- [Configuring Graceful Restart Options for RIP and RIPng on page 2585](#)
- [Configuring Graceful Restart Options for PIM Sparse Mode on page 2585](#)
- [Tracking Graceful Restart Events on page 2586](#)

### Enabling Graceful Restart

By default, graceful restart is disabled. To enable graceful restart, include the **graceful-restart** statement at the **[edit routing-instance *instance-name* routing-options]** or **[edit routing-options]** hierarchy level.

For example:

```
routing-options {
 graceful-restart;
}
```

To configure the duration of the graceful restart period, include the **restart-duration** at the **[edit routing-options graceful-restart]** hierarchy level.

**NOTE:** Helper mode (the ability to assist a neighboring router attempting a graceful restart) is enabled by default when you start the routing platform, even if graceful restart is not enabled. You can disable helper mode on a per-protocol basis.

```
[edit]
routing-options {
 graceful-restart {
 disable;
 restart-duration seconds;
 }
}
```

To disable graceful restart globally, include the **disable** statement at the **[edit routing-options graceful-restart]** hierarchy level.

When graceful restart is enabled for all routing protocols at the **[edit routing-options graceful-restart]** hierarchy level, you can disable graceful restart on a per-protocol basis.

**NOTE:** If you configure graceful restart after a BGP or LDP session has been established, the BGP or LDP session restarts and the peers negotiate graceful restart capabilities. Also, the BGP peer routing statistics are reset to zero.

## Configuring Graceful Restart Options for BGP

To configure the duration of the BGP graceful restart period, include the **restart-time** statement at the **[edit protocols bgp graceful-restart]** hierarchy level. To set the length of time the router waits to receive messages from restarting neighbors before declaring them down, include the **stale-routes-time** statement at the **[edit protocols bgp graceful-restart]** hierarchy level.

```
[edit]
protocols {
 bgp {
 graceful-restart {
 disable;
 restart-time seconds;
 stale-routes-time seconds;
 }
 }
}
routing-options {
 graceful-restart;
}
```

To disable BGP graceful restart capability for all BGP sessions, include the **disable** statement at the **[edit protocols bgp graceful-restart]** hierarchy level.

**NOTE:** To set BGP graceful restart properties or disable them for a group, include the desired statements at the `[edit protocols bgp group group-name graceful-restart]` hierarchy level.

To set BGP graceful restart properties or disable them for a specific neighbor in a group, include the desired statements at the `[edit protocols bgp group group-name neighbor ip-address graceful-restart]` hierarchy level.

**NOTE:** Configuring graceful restart for BGP resets the BGP peer routing statistics to zero. Also, existing BGP sessions restart, and the peers negotiate graceful restart capabilities.

## Configuring Graceful Restart Options for ES-IS

On J Series Services Routers, to configure the duration of the ES-IS graceful restart period, include the **restart-duration** statement at the `[edit protocols esis graceful-restart]` hierarchy level.

```
[edit]
protocols {
 esis {
 graceful-restart {
 disable;
 restart-duration seconds;
 }
 }
}
routing-options {
 graceful-restart;
}
```

To disable ES-IS graceful restart capability, include the **disable** statement at the `[edit protocols esis graceful-restart]` hierarchy level.

## Configuring Graceful Restart Options for IS-IS

To configure the duration of the IS-IS graceful restart period, include the **restart-duration** statement at the `[edit protocols isis graceful-restart]` hierarchy level.

```
[edit]
protocols {
 isis {
 graceful-restart {
 disable;
 helper-disable;
 restart-duration seconds;
 }
 }
}
routing-options {
 graceful-restart;
}
```

```
}
```

To disable IS-IS graceful restart helper capability, include the **helper-disable** statement at the **[edit protocols isis graceful-restart]** hierarchy level. To disable IS-IS graceful restart capability, include the **disable** statement at the **[edit protocols isis graceful-restart]** hierarchy level.

**NOTE:** If you configure Bidirectional Forwarding Detection (BFD) and graceful restart for IS-IS, graceful restart might not work as expected.

**NOTE:** If adjacencies between the Routing Engine and the neighboring peer 'helper' routers time out, graceful restart protocol extensions are unable to notify the peer 'helper' routers about the impending restart. Graceful restart can then stop and cause interruptions in traffic.

To ensure that these adjacencies are kept, change the hold-time for IS-IS protocols from the default of 27 seconds to a value higher than 40 seconds.

**NOTE:** You can also track graceful restart events with the **traceoptions** statement at the **[edit protocols isis]** hierarchy level. For more information, see [“Tracking Graceful Restart Events” on page 2586](#).

## Configuring Graceful Restart Options for OSPF and OSPFv3

To configure the duration of the OSPF/OSPFv3 graceful restart period, include the **restart-duration** statement at the **[edit protocols (ospf | ospfv3) graceful-restart]** hierarchy level. To specify the length of time for which the router notifies helper routers that it has completed graceful restart, include the **notify-duration** at the **[edit protocols (ospf | ospfv3) graceful-restart]** hierarchy level. Strict OSPF link-state advertisement (LSA) checking results in the termination of graceful restart by a helping router. To disable strict LSA checking, include the **no-strict-lsa-checking** statement at the **[edit protocols (ospf | ospfv3) graceful-restart]** hierarchy level.

```
[edit]
protocols {
 ospf | ospfv3 {
 graceful-restart {
 disable;
 helper-disable
 no-strict-lsa-checking;
 notify-duration seconds;
 restart-duration seconds;
 }
 }
}
routing-options {
 graceful-restart;
}
```

To disable OSPF/OSPFv3 graceful restart, include the **disable** statement at the **[edit protocols (ospf | ospfv3) graceful-restart]** hierarchy level.

Starting with Release 11.3, the Junos OS supports both the standard (based on RFC 3623, *Graceful OSPF Restart*) and the restart signaling-based (as specified in RFC 4811, RFC 4812, and RFC 4813) helper modes for OSPF version 2 graceful restart configurations. Both the standard and restart signaling-based helper modes are enabled by default. To disable the helper mode for OSPF version 2 graceful restart configurations, include the **helper-disable <both | restart-signaling | standard>** statement at the **[edit protocols ospf graceful-restart]** hierarchy level. Note that the last committed statement always takes precedence over the previous one.

```
[edit protocols ospf]
 graceful-restart {
 helper-disable <both | restart-signaling | standard>
 }
```

To reenable the helper mode, delete the **helper-disable** statement from the configuration by using the **delete protocols ospf graceful-restart helper-disable <restart-signaling | standard | both>** command. In this case also, the last executed command takes precedence over the previous ones.

**NOTE:**

Restart signaling-based helper mode is not supported for OSPFv3 configurations. To disable helper mode for OSPFv3 configurations, include the **helper-disable** statement at the **[edit protocols ospfv3 graceful-restart]** hierarchy level.

**TIP:** You can also track graceful restart events with the **traceoptions** statement at the **[edit protocols (ospf | ospfv3)]** hierarchy level. For more information, see [“Tracking Graceful Restart Events” on page 2586](#).

**NOTE:** You cannot enable OSPFv3 graceful restart between a routing platform running Junos OS Release 7.5 and earlier and a routing platform running Junos OS Release 7.6 or later. As a workaround, make sure both routing platforms use the same Junos OS version.

**NOTE:** If you configure BFD and graceful restart for OSPF, graceful restart might not work as expected.

---

## Configuring Graceful Restart Options for RIP and RIPng

To configure the duration of the RIP or RIPng graceful restart period, include the **restart-time** statement at the **[edit protocols (rip | ripng) graceful-restart]** hierarchy level.

```
[edit]
protocols {
 (rip | ripng) {
 graceful-restart {
 disable;
 restart-time seconds;
 }
 }
}
routing-options {
 graceful-restart;
}
```

To disable RIP or RIPng graceful restart capability, include the **disable** statement at the **[edit protocols (rip | ripng) graceful-restart]** hierarchy level.

## Configuring Graceful Restart Options for PIM Sparse Mode

PIM sparse mode continues to forward existing multicast packet streams during a graceful restart, but does not forward new streams until after the restart is complete. After a restart, the routing platform updates the forwarding state with any updates that were received from neighbors and occurred during the restart period. For example, the routing platform relearns the join and prune states of neighbors during the restart, but does not apply the changes to the forwarding table until after the restart.

PIM sparse mode-enabled routing platforms generate a unique 32-bit random number called a generation identifier. Generation identifiers are included by default in PIM hello messages, as specified in the IETF Internet draft *Protocol Independent Multicast - Sparse Mode (PIM-SM): Protocol Specification (Revised)*. When a routing platform receives PIM hellos containing generation identifiers on a point-to-point interface, Junos OS activates an algorithm that optimizes graceful restart.

Before PIM sparse mode graceful restart occurs, each routing platform creates a generation identifier and sends it to its multicast neighbors. If a PIM sparse mode-enabled routing platform restarts, it creates a new generation identifier and sends it to its neighbors. When a neighbor receives the new identifier, it resends multicast updates to the restarting router to allow it to exit graceful restart efficiently. The restart phase completes when either the PIM state becomes stable or when the restart interval timer expires.

If a routing platform does not support generation identifiers or if PIM is enabled on multipoint interfaces, the PIM sparse mode graceful restart algorithm does not activate, and a default restart timer is used as the restart mechanism.

To configure the duration of the PIM graceful restart period, include the **restart-duration** statement at the **[edit protocols pim graceful-restart]** hierarchy level:

```
[edit]
protocols {
```

```
pim {
 graceful-restart {
 disable;
 restart-duration seconds;
 }
}
routing-options {
 graceful-restart;
}
```

To disable PIM sparse mode graceful restart capability, include the **disable** statement at the **[edit protocols pim graceful-restart]** hierarchy level.

**NOTE:** Multicast forwarding can be interrupted in two ways. First, if the underlying routing protocol is unstable, multicast reverse-path-forwarding (RPF) checks can fail and cause an interruption. Second, because the forwarding table is not updated during the graceful restart period, new multicast streams are not forwarded until graceful restart is complete.

---

## Tracking Graceful Restart Events

To track the progress of a graceful restart event, you can configure graceful restart trace options flags for IS-IS and OSPF/OSPFv3. To configure graceful restart trace options, include the **graceful-restart** statement at the **[edit protocols *protocol* traceoptions flag]** hierarchy level:

```
[edit protocols]
isis {
 traceoptions {
 flag graceful-restart;
 }
}
(ospf | ospf3) {
 traceoptions {
 flag graceful-restart;
 }
}
```

## Nonstop Bridging Concepts

---

Nonstop bridging uses the same infrastructure as graceful Routing Engine switchover (GRES) to preserve interface and kernel information. However, nonstop bridging also saves Layer 2 Control Protocol (L2CP) information by running the Layer 2 Control Protocol process (l2cpd) on the backup Routing Engine.

**NOTE:** To use nonstop bridging, you must first enable graceful Routing Engine switchover on your routing (or switching) platform. For more information about graceful Routing Engine switchover, see [“Understanding Graceful Routing Engine Switchover” on page 2617](#).

[Figure 37](#) shows the system architecture of nonstop bridging and the process a routing (or switching) platform follows to prepare for a switchover.

**Figure 37: Nonstop Bridging Switchover Preparation Process**

The switchover preparation process for nonstop bridging follows these steps:

1. The master Routing Engine starts.
2. The routing platform processes on the master Routing Engine (such as the chassis process [chassisd] and the Layer 2 Control Protocol process [l2cpd]) start.
3. The Packet Forwarding Engine starts and connects to the master Routing Engine.
4. All state information is updated in the system.
5. The backup Routing Engine starts, including the chassis process (chassisd) and the Layer 2 Control Protocol process (l2cpd).
6. The system determines whether graceful Routing Engine switchover and nonstop bridging have been enabled.
7. The kernel synchronization process (ksyncd) synchronizes the backup Routing Engine with the master Routing Engine.
8. For supported protocols, state information is updated directly between the l2cpds on the master and backup Routing Engines.

Figure 38 shows the effects of a switchover on the routing platform.

Figure 38: Nonstop Bridging During a Switchover

The switchover process follows these steps:

1. When keepalives from the master Routing Engine are lost, the system switches over gracefully to the backup Routing Engine.
2. The Packet Forwarding Engine connects to the backup Routing Engine, which becomes the new master. Because the Layer 2 Control Protocol process (l2cpd) and chassis process (chassisd) are already running, these processes do not need to restart.
3. State information learned from the point of the switchover is updated in the system. Forwarding and bridging are continued during the switchover, resulting in minimal packet loss.

## Nonstop Bridging System Requirements

This topic contains the following sections:

- [Platform Support on page 2591](#)
- [Protocol Support on page 2592](#)

### Platform Support

Nonstop bridging is supported on MX Series 3D Universal Edge Routers. Your system must be running Junos OS Release 8.4 or later.

Nonstop bridging is supported on EX Series switches with redundant Routing Engines in a Virtual Chassis or in a Virtual Chassis Fabric.

Nonstop bridging is supported on QFX Series switches in a Virtual Chassis or in a Virtual Chassis Fabric.

For a list of the EX Series switches and Layer 2 protocols that support nonstop bridging, see *EX Series Switch Software Features Overview*.

**NOTE:** All Routing Engines configured for nonstop bridging must be running the same Junos OS release.

## Protocol Support

Nonstop bridging is supported for the following Layer 2 control protocols:

- Spanning Tree Protocol (STP)
- Rapid Spanning Tree Protocol (RSTP)
- Multiple Spanning Tree Protocol (MSTP)
- VLAN Spanning Tree Protocol (VSTP)

### Related Documentation

- [Configuring Nonstop Bridging](#)
- [Configuring Nonstop Bridging on Switches \(CLI Procedure\) on page 2593](#)

## Configuring Nonstop Bridging on Switches (CLI Procedure)

**NOTE:** This task uses switches with support for the Enhanced Layer 2 Software (ELS) configuration style. If your switch runs software that does not support ELS, see *Configuring Nonstop Bridging on EX Series Switches (CLI Procedure)*. For ELS details, see “Getting Started with Enhanced Layer 2 Software” on page 41.

You can configure nonstop bridging (NSB) to provide resilience for Layer 2 protocol sessions on a Juniper Networks EX Series switch with multiple Routing Engines or an EX Series or QFX Series switch in a Virtual Chassis or Virtual Chassis Fabric configuration. Limited support for NSB is also provided on QFX5100 and EX4600 standalone switches, but NSB is enabled *only* during an ISSU.

NSB operates by synchronizing all protocol information for NSB-supported Layer 2 protocols between the master and backup Routing Engines. If the switch has a Routing Engine switchover, the NSB-supported Layer 2 protocol sessions remain active because they are already synchronized on the backup Routing Engine. The Routing Engine switchover is transparent to neighbor devices, which do not detect any changes related to the Layer 2 protocol sessions. The neighboring devices and other devices on the network do not, therefore, have to resynchronize their Layer 2 protocol states to respond to the downtime on the switch—a process that adds network overhead and risks disrupting network performance—when a Routing Engine switchover occurs when NSB is enabled.

**NOTE:** If you are using a QFX5100 or EX4600 standalone switch and you want to use ISSU, configure Graceful Routing Engine switchover (GRES), NSB and nonstop active routing (NSR). You must configure NSB, GRES, and NSR in order to run ISSU. However, GRES, NSB and NSR are enabled *only* during the upgrade. During an ISSU, the Junos OS runs in two separate virtual machines (VMs)—one VM is in the master role acting as the master Routing Engine, and the other VM is in the backup role acting as the backup Routing Engine. The Junos OS is upgraded on the backup VM. After a successful software upgrade, the backup VM then becomes the master VM, and the original master VM is no longer needed and is shut down.

To configure NSB:

1. Enable graceful Routing Engine switchover (GRES):
 

```
[edit chassis redundancy]
user@switch# set graceful-switchover
```
2. Enable NSB:
 

```
[edit protocols layer2-control]
user@switch# set nonstop-bridging
```
3. Synchronize configuration changes between the Routing Engines:
 

```
[edit system]
```

user@switch# **set commit** [synchronize](#)

If you try to commit a configuration that includes NSB without including the **commit synchronize** statement, the commit fails.

**NOTE:** There is no requirement to start the two Routing Engines simultaneously. If the backup Routing Engine is not up when you use the **commit synchronize** statement, the candidate configuration is committed in the master Routing Engine. When the backup Routing Engine comes online, its configuration is automatically synchronized with that of the master.

**BEST PRACTICE:** After a graceful Routing Engine switchover, we recommend that you issue the clear interface statistics (*interface-name* | all) command to reset the cumulative values for local statistics on the new master Routing Engine.

## Nonstop Active Routing Concepts

---

Nonstop active routing (NSR) uses the same infrastructure as graceful Routing Engine switchover (GRES) to preserve interface and kernel information. However, NSR also saves routing protocol information by running the routing protocol process (rpd) on the backup Routing Engine. By saving this additional information, NSR is self-contained and does not rely on helper routers (or switches) to assist the routing platform in restoring routing protocol information. NSR is advantageous in networks in which neighbor routers (or switches) do not support graceful restart protocol extensions. As a result of this enhanced functionality, NSR is a natural replacement for graceful restart.

If you have NSR configured, it is never valid to issue the **restart routing** command in any form on the NSR master Routing Engine. Doing so results in a loss of protocol adjacencies and neighbors and a drop in traffic.

.....

**NOTE:** To use NSR, you must first enable GRES on your routing (or switching) platform. For more information about GRES, see [“Understanding Graceful Routing Engine Switchover” on page 2617](#).

.....

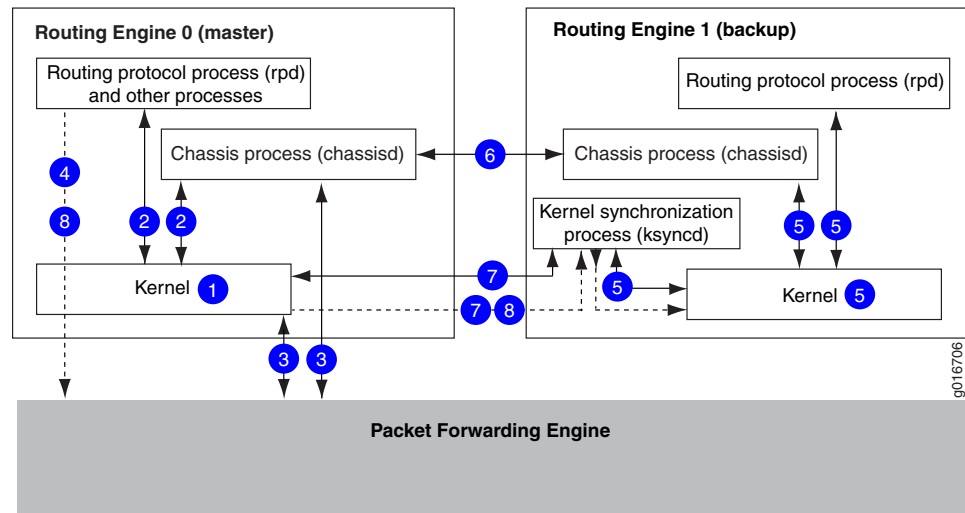

.....

**NOTE:** Due to its synchronization requirements and logic, NSR/GRES performance is limited by the slowest Routing Engine in the system.

.....

Figure 39 shows the system architecture of nonstop active routing and the process a routing (or switching) platform follows to prepare for a switchover.

**Figure 39: Nonstop Active Routing Switchover Preparation Process**

The switchover preparation process for NSR follows these steps:

1. The master Routing Engine starts.
2. The routing (or switching) platform processes on the master Routing Engine (such as the chassis process [chassisd] and the routing protocol process [rpd]) start.
3. The Packet Forwarding Engine starts and connects to the master Routing Engine.
4. All state information is updated in the system.
5. The backup Routing Engine starts, including the chassis process (chassisd) and the routing protocol process (rpd).
6. The system determines whether graceful Routing Engine switchover and nonstop active routing have been enabled.
7. The kernel synchronization process (ksyncd) synchronizes the backup Routing Engine with the master Routing Engine.
8. For supported protocols, state information is updated directly between the routing protocol processes on the master and backup Routing Engines.

Figure 40 shows the effects of a switchover on the routing platform.

Figure 40: Nonstop Active Routing During a Switchover

The switchover process follows these steps:

1. When keepalives from the master Routing Engine are lost, the system switches over gracefully to the backup Routing Engine.
2. The Packet Forwarding Engine connects to the backup Routing Engine, which becomes the new master. Because the routing protocol process (rpd) and chassis process (chassisd) are already running, these processes do not need to restart.
3. State information learned from the point of the switchover is updated in the system. Forwarding and routing are continued during the switchover, resulting in minimal packet loss.
4. Peer routers (or switches) continue to interact with the routing platform as if no change had occurred. Routing adjacencies and session state relying on underlying routing information are preserved and not reset.

**CAUTION:** We recommend that you do not restart the routing protocol process (rpd) on master Routing Engine after enabling NSR, as it disrupts the protocol adjacency/peering sessions, resulting in traffic loss.

## Nonstop Active Routing Platform and Switching Platform Support

Table 232 lists the platforms that support nonstop active routing (NSR).

**Table 232: Nonstop Active Routing Platform Support**

| Platform                            | Junos OS Release |
|-------------------------------------|------------------|
| M10i router                         | 8.4 or later     |
| M20 router                          | 8.4 or later     |
| M40e router                         | 8.4 or later     |
| M120 router                         | 9.0 or later     |
| M320 router                         | 8.4 or later     |
| MX Series routers                   | 9.0 or later     |
| PTX Series Packet Transport Routers | 12.1R4 or later  |

### NOTE:

Nonstop active routing (NSR) switchover on PTX series is supported only for the following MPLS and VPN protocols and applications using chained composite next hops:

- Labeled BGP
- Layer 2 VPNs excluding Layer 2 interworking (Layer 2 switching)
- Layer 3 VPNs
- LDP
- RSVP

Table 232: Nonstop Active Routing Platform Support (*continued*)

| Platform                                                                                                                                                                                                                                                                                                                                                                                          | Junos OS Release                                               |

**NOTE:** All Routing Engines configured for nonstop active routing must be running the same Junos OS release.

## Nonstop Active Routing Protocol and Feature Support

Table 233 lists the protocols that are supported by nonstop active routing.

**Table 233: Nonstop Active Routing Protocol and Feature Support**

| Protocol                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Junos OS Release                                                       |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|
| Aggregated Ethernet interfaces with Link Aggregation Control Protocol (LACP)                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 9.4 or later                                                           |

Table 233: Nonstop Active Routing Protocol and Feature Support (*continued*)

| Protocol | Junos OS Release |
|----------|------------------|
| VRRP     | 13.2 or later    |

**NOTE:** Layer 3 VPN support does not include dynamic GRE tunnels, multicast VPNs, or BGP flow routes.

**NOTE:** If you configure a protocol that is not supported by nonstop active routing, the protocol operates as usual. When a switchover occurs, the state information for the unsupported protocol is not preserved and must be refreshed using the normal recovery mechanisms inherent in the protocol.

**NOTE:** On routers that have logical systems configured on them, only the master logical system supports nonstop active routing.

**NOTE:** On EX9214 switches, the VRRP master state might change during graceful Routing Engine switchover, even when nonstop active routing is enabled.

## Nonstop Active Routing BFD Support

Nonstop active routing supports the Bidirectional Forwarding Detection (BFD) protocol, which uses the topology discovered by routing protocols to monitor neighbors. The BFD protocol is a simple hello mechanism that detects failures in a network. Because BFD is streamlined to be efficient at fast liveness detection, when it is used in conjunction with routing protocols, routing recovery times are improved. With nonstop active routing enabled, BFD session states are not restarted when a Routing Engine switchover occurs.

**NOTE:** BFD session states are saved only for clients using aggregate or static routes or for BGP, IS-IS, OSPF/OSPFv3, or PIM.

When a BFD session is distributed to the Packet Forwarding Engine, BFD packets continue to be sent during a Routing Engine switchover. If nondistributed BFD sessions are to be kept alive during a switchover, you must ensure that the session failure detection time is greater than the Routing Engine switchover time. The following BFD sessions are not distributed to the Packet Forwarding Engine: multihop sessions, tunnel-encapsulated sessions, and sessions over integrated routing and bridging (IRB) interfaces.

**NOTE:** BFD is an intensive protocol that consumes system resources. Specifying a minimum interval for BFD less than 100 ms for Routing Engine-based sessions and 10 ms for distributed BFD sessions can cause undesired BFD flapping. The minimum-interval configuration statement is a BFD liveness detection parameter.

Depending on your network environment, these additional recommendations might apply:

- For large-scale network deployments with a large number of BFD sessions, specify a minimum interval of 300 ms for Routing Engine-based sessions, and 100 ms for distributed BFD sessions.
- For very large-scale network deployments with a large number of BFD sessions, contact Juniper Networks customer support for more information.
- For BFD sessions to remain up during a Routing Engine switchover event when nonstop active routing is configured, specify a minimum interval of 10 seconds for Routing Engine-based sessions. For distributed BFD sessions with nonstop active routing configured, the minimum interval recommendations are unchanged and depend only on your network deployment.

## Nonstop Active Routing BGP Support

Nonstop active routing BGP support is subject to the following conditions:

- You must include the **path-selection external-router-ID** statement at the **[edit protocols bgp]** hierarchy level to ensure consistent path selection between the master and backup Routing Engines during and after the nonstop active routing switchover.
- You must include the **advertise-from-main-vpn-tables** statement at the **[edit protocols bgp]** hierarchy level to prevent BGP sessions from going down when route reflector (RR) or autonomous system border router (ASBR) functionality is enabled or disabled on a routing device that has VPN address families configured.
- BGP session uptime and downtime statistics are not synchronized between the primary and backup Routing Engines during Nonstop Active Routing and ISSU. The backup Routing Engine maintains its own session uptime based on the time when the backup first becomes aware of the established sessions. For example, if the backup Routing Engine is rebooted (or if you run **restart routing** on the backup Routing Engine), the backup's uptime is a short duration, because the backup has just learned about the established sessions. If the backup is operating when the BGP sessions first come up on the primary, the uptime on the primary and the uptime on the backup are almost the same duration. After a Routing Engine switchover, the new master continues from the time left on the standby Routing Engine.
- If the BGP peer in the master Routing Engine has negotiated address-family capabilities that are not supported for nonstop active routing, then the corresponding BGP neighbor state on the backup Routing Engine shows as idle. On switchover, the BGP session is reestablished from the new master Routing Engine.

Only the following address families are supported for nonstop active routing.

**NOTE:** Address families are supported only on the main instance of BGP. Only unicast is supported on VRF instances.

- inet unicast
  - inet labeled-unicast
  - inet multicast
  - inet6 labeled-unicast
  - inet6 multicast
  - inet6 unicast
  - route-target
  - l2vpn signaling
  - inet6-vpn unicast
  - inet-vpn unicast
  - inet-mdt
  - iso-vpn
- BGP route dampening does not work on the backup Routing Engine when nonstop active routing is enabled.

## Nonstop Active Routing Layer 2 Circuit and VPLS Support

Nonstop active routing supports Layer 2 circuit and VPLS on both LDP-based and RSVP-TE-based networks. Nonstop active routing support enables the backup Routing Engine to track the label advertised by Layer 2 circuit and VPLS on the primary Routing Engine, and to use the same label after the Routing Engine switchover.

in Junos OS Release 9.6 and later, nonstop active routing support is extended to the Layer 2 circuit and LDP-based VPLS pseudowire redundant configurations.

## Nonstop Active Routing PIM Support

Nonstop active routing supports Protocol Independent Multicast (PIM) with stateful replication on backup Routing Engines. State information replicated on the backup Routing Engine includes information about neighbor relationships, join and prune events, rendezvous point (RP) sets, synchronization between routes and next hops, multicast session states, and the forwarding state between the two Routing Engines.

**NOTE:** Nonstop active routing for PIM is supported for IPv4 on Junos OS Release 9.3 and later, and for IPv6 on Junos OS Release 10.4 and later. Starting with Release 11.1, Junos OS also supports nonstop active routing for PIM on devices that have both IPv4 and IPv6 configured on them.

To configure nonstop active routing for PIM, include the same statements in the configuration as for other protocols: the **nonstop-routing** statement at the **[edit routing-options]** hierarchy level and the **graceful-switchover** statement at the **[edit chassis redundancy]** hierarchy level. To trace PIM nonstop active routing events, include the **flag nsr-synchronization** statement at the **[edit protocols pim traceoptions]** hierarchy level.

**NOTE:** The **clear pim join**, **clear pim register**, and **clear pim statistics** operational mode commands are not supported on the backup Routing Engine when nonstop active routing is enabled.

Nonstop active routing support varies for different PIM features. The features fall into the following three categories: supported features, unsupported features, and incompatible features.

#### Supported features:

- Auto-RP

**NOTE:** Nonstop active routing PIM support on IPv6 does not support auto-RP because IPv6 does not support auto-RP.

- Bootstrap router (BSR)
- Static RPs
- Embedded RP on non-RP IPv6 routers
- Local RP

**NOTE:** RP set information synchronization is supported for local RP and BSR (on IPv4 and IPv6), autoRP (on IPv4), and embedded RP (on IPv6).

- BFD
- Dense mode
- Sparse mode
- Source-specific multicast (SSM)
- Draft Rosen multicast VPNs (MVPNs)

- Anycast RP (anycast RP set information synchronization and anycast RP register state synchronization on IPv4 and IPv6 configurations)
- Flow maps
- Unified ISSU
- Policy features such as neighbor policy, bootstrap router export and import policies, scope policy, flow maps, and reverse path forwarding (RPF) check policies
- Upstream assert synchronization
- PIM join load balancing

Starting with Release 12.2, Junos OS extends the nonstop active routing PIM support to draft Rosen MVPNs. Nonstop active routing PIM support for draft Rosen MVPNs enables nonstop active routing-enabled devices to preserve draft Rosen MPVN-related information—such as default and data multicast distribution tree (MDT) states—across switchovers. In releases earlier than 12.2, nonstop active routing PIM configuration was incompatible with draft Rosen MPVN configuration.

The backup Routing Engine sets up the default MDT based on the configuration and the information it receives from the master Routing Engine, and keeps updating the default MDT state information.

However, for data MDTs, the backup Routing Engine relies on the master Routing Engine to provide updates when data MDTs are created, updated, or deleted. The backup Routing Engine neither monitors data MDT flow rates nor triggers a data MDT switchover based on variations in flow rates. Similarly, the backup Routing Engine does not maintain the data MDT delay timer or timeout timer. It does not send MDT join TLV packets for the data MDTs until it takes over as the master Routing Engine. After the switchover, the new master Routing Engine starts sending MDT join TLV packets for each data MDT, and also resets the data MDT timers. Note that the expiration time for the timers might vary from the original values on the previous master Routing Engine.

Starting with Release 12.3, Junos OS extends the Protocol Independent Multicast (PIM) nonstop active routing support to IGMP-only interfaces.

In Junos OS releases earlier than 12.3, the PIM joins created on IGMP-only interfaces were not replicated on the backup Routing Engine. Thus, the corresponding multicast routes were marked as pruned (meaning discarded) on the backup Routing Engine. Because of this limitation, after a switchover, the new master Routing Engine had to wait for the IGMP module to come up and start receiving reports to create PIM joins and to install multicast routes. This caused traffic loss until the multicast joins and routes were reinstated.

However, in Junos OS Release 12.3 and later, the multicast joins on the IGMP-only interfaces are mapped to PIM states, and these states are replicated on the backup Routing Engine. If the corresponding PIM states are available on the backup, the multicast routes are marked as forwarding on the backup Routing Engine. This enables uninterrupted traffic flow after a switchover. This enhancement covers IGMPv2, IGMPv3, MLDv1, and MLDv2 reports and leaves.

**Unsupported features:** You can configure the following PIM features on a router along with nonstop active routing, but they function as if nonstop active routing is not enabled. In other words, during Routing Engine switchover and other outages, their state information is not preserved, and traffic loss is to be expected.

- Internet Group Management Protocol (IGMP) exclude mode
- IGMP snooping

Nonstop active routing is not supported for next-generation MVPNs with PIM provider tunnels. The commit operation fails if the configuration includes both nonstop active routing and next-generation MVPNs with PIM provider tunnels.

Junos OS provides a configuration statement that disables nonstop active routing for PIM only, so that you can activate incompatible PIM features and continue to use nonstop active routing for the other protocols on the router. Before activating an incompatible PIM feature, include the **nonstop-routing disable** statement at the **[edit protocols pim]** hierarchy level. Note that in this case, nonstop active routing is disabled for all PIM features, not just incompatible features.

## Nonstop Active Routing MSDP Support

Starting with Release 12.1, Junos OS extends nonstop active routing support to the Multicast Source Discovery Protocol (MSDP).

Nonstop active routing support for MSDP preserves the following MSDP-related information across the switchover:

- MSDP configuration and peer information
- MSDP peer socket information
- Source-active and related information

However, note that the following restrictions or limitations apply to nonstop active routing MSDP support:

- Because the backup Routing Engine learns the active source information by processing the source-active messages from the network, synchronizing of source active information between the master and backup Routing Engines might take up to 60 seconds. So, no planned switchover is allowed within 60 seconds of the initial replication of the sockets.
- Similarly, Junos OS does not support two planned switchovers within 240 seconds of each other.

Junos OS enables you to trace MSDP nonstop active routing events by including the **flag nsr-synchronization** statement at the **[edit protocols msdp traceoptions]** hierarchy level.

## Nonstop Active Routing Support for RSVP-TE LSPs

Junos OS extends nonstop active routing support to label-switching routers (LSRs) and Layer 2 Circuits that are part of an RSVP-TE LSP. Nonstop active routing support on LSRs ensures that the master to backup Routing Engine switchover on an LSR remains

transparent to the network neighbors and that the LSP information remains unaltered during and after the switchover.

You can use the **show rsvp version** command to view the nonstop active routing mode and state on an LSR. Similarly, you can use the **show mpls lsp** and **show rsvp session** commands on the standby Routing Engine to view the state recreated on the standby Routing Engine.

The Junos OS nonstop active routing feature is also supported on RSVP point-to-multipoint LSPs. Nonstop active routing support for RSVP point-to-multipoint egress and transit LSPs was added in Junos OS Release 11.4, and for ingress LSPs in Release 12.1. During the switchover, the LSP comes up on the backup Routing Engine that shares and synchronizes the state information with the master Routing Engine before and after the switchover. Nonstop active routing support for point-to-multipoint transit and egress LSPs ensures that the switchover remains transparent to the network neighbors, and preserves the LSP information across the switchover.

However, Junos OS nonstop active routing support for RSVP point-to-multipoint LSPs does not include support for dynamically created point-to-multipoint LSPs, such as VPLS.

Starting with Release 14.1, Junos OS extends nonstop active routing support to the next-generation multicast VPNs.

The **show rsvp session detail** command enables you to check the point-to-multipoint LSP remerge state information (**P2MP LSP re-merge**; possible values are **head**, **member**, and **none**).

However, Junos OS does not support nonstop active routing for the following features:

- Generalized Multiprotocol Label Switching (GMPLS) and LSP hierarchy
- Interdomain or loose-hop expansion LSPs
- BFD liveness detection

Nonstop active routing support for RSVP-TE LSPs is subject to the following limitations and restrictions:

- Detour LSPs are not maintained across a switchover and so, detour LSPs might fail to come back online after the switchover.
- Control plane statistics corresponding to the **show rsvp statistics** and **show rsvp interface detail | extensive** commands are not maintained across Routing Engine switchovers.
- Statistics from the backup Routing Engine are not reported for **show mpls lsp statistics** and **monitor mpls label-switched-path** commands. However, if a switchover occurs, the backup Routing Engine, after taking over as the master, starts reporting statistics. Note that the **clear statistics** command issued on the old master Routing Engine does not have any effect on the new master Routing Engine, which reports statistics, including any uncleared statistics.
- State timeouts might take additional time during nonstop active routing switchover. For example, if a switchover occurs after a neighbor has missed sending two hello

messages to the master, the new master Routing Engine waits for another three hello periods before timing out the neighbor.

- On the RSVP ingress router, if you configure auto-bandwidth functionality, the bandwidth adjustment timers are set in the new master after the switchover. This causes a one-time increase in the length of time required for the bandwidth adjustment after the switchover occurs.
- RSVP ingress LSPs that have BFD liveness detection enabled on them do not come up on the backup Routing Engine during the switchover. Such BFD-enabled LSPs have to be reestablished after the switchover.
- Backup LSPs —LSPs that are established between the point of local repair (PLR) and the merge point after a node or link failure—are not preserved during a Routing Engine switchover.
- When nonstop active routing is enabled, graceful restart is not supported. However, graceful restart helper mode is supported.

## Example: Configuring Nonstop Active Routing on Switches

Nonstop active routing (NSR) provides high availability for Routing Engines by enabling transparent switchover of the Routing Engines without necessitating restart of supported routing protocols. Both Routing Engines are fully active in processing protocol sessions, and so each can take over for the other. The switchover is transparent to neighbors.

This example describes how to configure nonstop active routing on switches with multiple Routing Engines or on an EX Series or a QFX series switch in a Virtual Chassis or Virtual Chassis Fabric configuration.

- [Requirements on page 2611](#)
- [Overview and Topology on page 2612](#)
- [Configuration on page 2612](#)
- [Verification on page 2613](#)
- [Troubleshooting on page 2613](#)

### Requirements

This example uses the following hardware and software components:

- An EX Series with multiple Routing Engines or on an EX Series or a QFX series switch in a Virtual Chassis or Virtual Chassis Fabric configuration
- Junos OS Release 10.4 or later for EX Series switches

- Junos OS Release 13.2X51-D20 or later for QFX Series switches

## Overview and Topology

Configure nonstop active routing on any EX Series with multiple Routing Engines or on an EX Series or a QFX series switch in a Virtual Chassis or Virtual Chassis Fabric configuration. Nonstop active routing is advantageous in networks where neighbor routing devices do not support graceful restart protocol extensions.

The topology used in this example consists of an EX8200 switch with redundant Routing Engines connected to neighbor routing devices that are not configured to support graceful restart of protocols.

## Configuration

### CLI Quick Configuration

To quickly configure nonstop active routing, copy the following commands and paste them into the switch terminal window:

```
[edit]
set chassis redundancy graceful-switchover
set routing-options nonstop-routing
set system commit synchronize
```

### Step-by-Step Procedure

To configure nonstop active routing on a switch:

1. Enable graceful Routing Engine switchover (GRES):  

```
[edit chassis redundancy]
user@switch# set graceful-switchover
```
2. Enable nonstop active routing (by default, nonstop active routing is disabled):  

```
[edit routing-options]
user@switch# set nonstop-routing
```
3. Synchronize configuration changes between the Routing Engines:  

```
[edit system]
user@switch# set commit synchronize
```

**NOTE:** If the backup Routing Engine is down when you issue the commit, a warning is displayed and the candidate configuration is committed in the master Routing Engine. When the backup Routing Engine comes up, its configuration is automatically synchronized with that of the master. If you subsequently insert or bring up a backup Routing Engine, it automatically synchronizes its configuration with the master Routing Engine configuration.

---

## Results

Check the results of the configuration:

```
[edit]
user@switch# show
chassis {
 redundancy {
 graceful-switchover;
 }
}
routing-options {
 nonstop-routing;
}
system {
 commit synchronize;
}
```

Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying That Nonstop Active Routing Is Working Correctly on the Switch on page 2613](#)

Verifying That Nonstop Active Routing Is Working Correctly on the Switch

**Purpose** Verify that nonstop active routing is enabled.

**Action** Issue the [show task replication](#) command:

```
user@switch# show task replication
Stateful Replication: Enabled
RE mode: Master

Protocol Synchronization Status

OSPF Complete
RIP Complete
PIM Complete
RSVP Complete
```

**Meaning** This output shows that nonstop active routing (Stateful Replication) is enabled on master routing engine. If nonstop routing is not enabled, instead of the output shown above:

- On the backup routing engine the following error message is displayed: “**error: the routing subsystem is not running.**”
- On the master routing engine, the following output is displayed if nonstop routing is not enabled:

```
Stateful Replication: Disabled
RE mode: Master
```

Troubleshooting

To troubleshoot nonstop active routing, perform these tasks:

- [Investigating Problems with Synchronization of Routing Engines When NSR Is Enabled on page 2614](#)

### Investigating Problems with Synchronization of Routing Engines When NSR Is Enabled

---

**Problem** A protocol loses connectivity with neighbors after a graceful Routing Engine switchover (GRES) occurs with nonstop active routing (NSR) enabled.

**Solution** Use trace options to help isolate the problem and gather troubleshooting information. Using the information gathered from trace options, you can confirm or eliminate the synchronization of the Routing Engines as the cause of the loss of connectivity for the protocol. See *Tracing Nonstop Active Routing Synchronization Events*.

## Understanding Graceful Routing Engine Switchover

---

This topic contains the following sections:

- [Graceful Routing Engine Switchover Concepts on page 2617](#)
- [Effects of a Routing Engine Switchover on page 2622](#)

### Graceful Routing Engine Switchover Concepts

The graceful Routing Engine switchover (GRES) feature in Junos OS enables a routing platform with redundant Routing Engines to continue forwarding packets, even if one Routing Engine fails. GRES preserves interface and kernel information. Traffic is not interrupted. However, GRES does not preserve the control plane.

**NOTE:** On T Series routers, TX Matrix routers, and TX Matrix Plus routers, the control plane is preserved in case of GRES with nonstop active routing (NSR), and nearly 75 percent of line rate worth of traffic per Packet Forwarding Engine remains uninterrupted during GRES.

Neighboring routers detect that the router has experienced a restart and react to the event in a manner prescribed by individual routing protocol specifications.

To preserve routing during a switchover, GRES must be combined with either:

- Graceful restart protocol extensions
- Nonstop active routing

Any updates to the master Routing Engine are replicated to the backup Routing Engine as soon as they occur.

**NOTE:** Due to its synchronization requirements and logic, NSR/GRES performance is limited by the slowest Routing Engine in the system.

Mastership switches to the backup Routing Engine if:

- The master Routing Engine kernel stops operating.
- The master Routing Engine experiences a hardware failure.
- The administrator initiates a manual switchover.

**NOTE:** To quickly restore or to preserve routing protocol state information during a switchover, GRES must be combined with either graceful restart or nonstop active routing, respectively. For more information about graceful restart, see [“Graceful Restart Concepts” on page 2579](#). For more information about nonstop active routing, see [“Nonstop Active Routing Concepts” on page 2597](#).

If the backup Routing Engine does not receive a keepalive from the master Routing Engine after 2 seconds (4 seconds on M20 routers), it determines that the master Routing Engine has failed and: takes mastership.

The Packet Forwarding Engine:

- Seamlessly disconnects from the old master Routing Engine
- Reconnects to the new master Routing Engine
- Does not reboot
- Does not interrupt traffic

The new master Routing Engine and the Packet Forwarding Engine then become synchronized. If the new master Routing Engine detects that the Packet Forwarding Engine state is not up to date, it resends state update messages.

**NOTE:** If adjacencies between the restarting router and the neighboring peer 'helper' routers time out, graceful restart protocol extensions are unable to notify the peer 'helper' routers about the impending restart. Graceful restart can then stop and cause interruptions in traffic.

To ensure that these adjacencies are kept, change the [hold-time](#) for IS-IS protocols from the default of 27 seconds to a value higher than 40 seconds.

**NOTE:** Successive Routing Engine switchover events must be a minimum of 240 seconds (4 minutes) apart after both Routing Engines have come up.

If the router or switch displays a warning message similar to **Standby Routing Engine is not ready for graceful switchover. Packet Forwarding Engines that are not ready for graceful switchover might be reset**. Do not attempt switchover. If you choose to proceed with switchover, only the Packet Forwarding Engines that were not ready for graceful switchover are reset. None of the FPCs should spontaneously restart. We recommend that you wait until the warning no longer appears and then proceed with the switchover.

**NOTE:** Starting from Junos OS Release 14.2, when you perform GRES on MX Series routers, you must execute the **clear synchronous-ethernet wait-to-restore** operational mode command on the new master Routing Engine to clear the wait-to-restore timer on it. This is because the **clear synchronous-ethernet wait-to-restore** operational mode command clears the wait-to-restore timer only on the local Routing Engine.

**NOTE:** In a routing matrix with TX Matrix Plus router with 3D SIBs, for successive Routing Engine switchover, events must be a minimum of 900 seconds (15 minutes) apart after both Routing Engines have come up.

GRES must be performed on one line-card chassis (LCC) (of a TX Matrix router with 3D SIBs) at a time to avoid synchronization issues.

**NOTE:**

- We do *not* recommend performing a commit operation on the backup Routing Engine when GRES is enabled on the router or switch.
- We do *not* recommend enabling GRES on the backup Routing Engine in *any* scenario.

Figure 41 shows the system architecture of graceful Routing Engine switchover and the process a routing platform follows to prepare for a switchover.

Figure 41: Preparing for a Graceful Routing Engine Switchover

**NOTE:** Check GRES readiness by executing both:

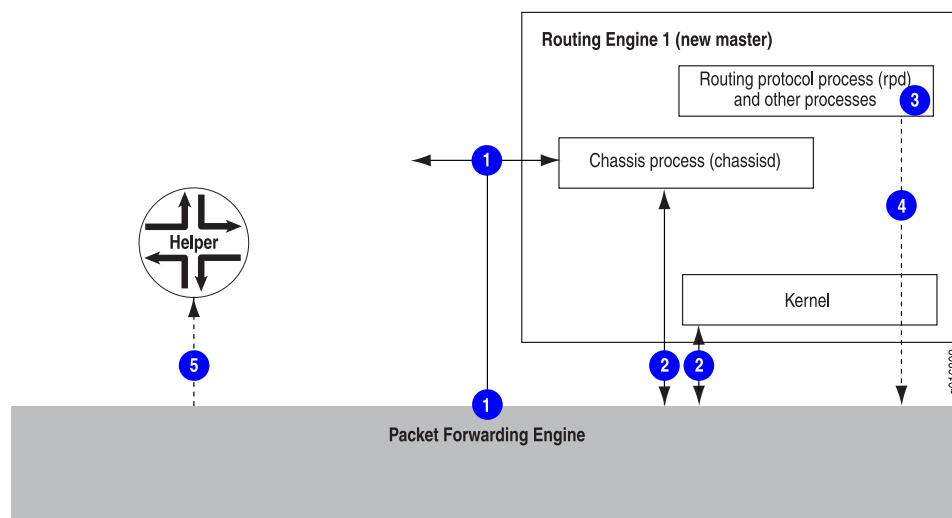

- The `request chassis routing-engine master switch check` command from the master Routing Engine
- The `show system switchover` command from the Backup Routing Engine

The switchover preparation process for GRES is as follows:

1. The master Routing Engine starts.
2. The routing platform processes (such as the chassis process [chassisd]) start.
3. The Packet Forwarding Engine starts and connects to the master Routing Engine.
4. All state information is updated in the system.
5. The backup Routing Engine starts.
6. The system determines whether GRES has been enabled.
7. The kernel synchronization process (ksyncd) synchronizes the backup Routing Engine with the master Routing Engine.
8. After ksyncd completes the synchronization, all state information and the forwarding table are updated.

Figure 42 shows the effects of a switchover on the routing (or switching) platform.

Figure 42: Graceful Routing Engine Switchover Process

When a switchover occurs, the switchover process is as follows:

1. When keepalives from the master Routing Engine are lost, the system switches over gracefully to the backup Routing Engine.
2. The Packet Forwarding Engine connects to the backup Routing Engine, which becomes the new master.
3. Routing platform processes that are not part of GRES (such as the routing protocol process [rpd]) restart.
4. State information learned from the point of the switchover is updated in the system.
5. If configured, graceful restart protocol extensions collect and restore routing information from neighboring peer *helper* routers.

**NOTE:** On T Series and M320 routers during GRES, the Switch Interface Boards (SIBs) are taken offline and restarted one by one. This is done to provide the Switch Processor Mezzanine Board (SPMB) that manages the SIB enough time to populate state information for its associated SIB. However, on a fully populated chassis where all FPCs are sending traffic at full line rate, there might be momentary packet loss during the switchover.

**NOTE:** When GRES is configured and the `restart chassis-control` command is executed on a TX Matrix Plus router with 3D SIBs, we cannot ascertain which Routing Engine becomes the master. This is because the `chassisd` process restarts with the execution of the `restart chassis-control` command. The `chassisd` process is responsible for maintaining and retaining mastership and when it is restarted, the new `chassisd` is processed based on the router or switch load. As a result, any one of the Routing Engines is made the master.

## Effects of a Routing Engine Switchover

Table 234 describes the effects of a Routing Engine switchover when different features are enabled:

- No high availability features
- Graceful Routing Engine switchover
- Graceful restart
- Nonstop active routing

**Table 234: Effects of a Routing Engine Switchover**

| Feature                                         | Benefits                                                                                                                                                                                                               | Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dual Routing Engines only (no features enabled) | <ul style="list-style-type: none"> <li>• When the switchover to the new master Routing Engine is complete, routing convergence takes place and traffic is resumed.</li> </ul>                                          | <ul style="list-style-type: none"> <li>• All physical interfaces are taken offline.</li> <li>• Packet Forwarding Engines restart.</li> <li>• The standby Routing Engine restarts the routing protocol process (rpd).</li> <li>• All hardware and interfaces are discovered by the new master Routing Engine.</li> <li>• The switchover takes several minutes.</li> <li>• All of the router's adjacencies are aware of the physical (interface alarms) and routing (topology) changes.</li> </ul> |
| GRES enabled                                    | <ul style="list-style-type: none"> <li>• During the switchover, interface and kernel information is preserved.</li> <li>• The switchover is faster because the Packet Forwarding Engines are not restarted.</li> </ul> | <ul style="list-style-type: none"> <li>• The new master Routing Engine restarts the routing protocol process (rpd).</li> <li>• All hardware and interfaces are acquired by a process that is similar to a warm restart.</li> <li>• All adjacencies are aware of the router's change in state.</li> </ul>                                                                                                                                                                                         |
| GRES <i>and</i> nonstop active routing enabled  | <ul style="list-style-type: none"> <li>• Traffic is not interrupted during the switchover.</li> <li>• Interface and kernel information are preserved.</li> </ul>                                                       | <ul style="list-style-type: none"> <li>• Unsupported protocols must be refreshed using the normal recovery mechanisms inherent in each protocol.</li> </ul>                                                                                                                                                                                                                                                                                                                                      |

Table 234: Effects of a Routing Engine Switchover (*continued*)

| Feature                           | Benefits                                                                                                                                                                                                                                                                                 | Considerations                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Graceful Routing Engine Switchover System Requirements

Graceful Routing Engine switchover is supported on all routing (or switching) platforms that contain dual Routing Engines. All Routing Engines configured for graceful Routing Engine switchover must run the same Junos OS release. Hardware and software support for graceful Routing Engine switchover is described in the following sections:

- [Graceful Routing Engine Switchover Platform Support on page 2623](#)
- [Graceful Routing Engine Switchover Feature Support on page 2624](#)
- [Graceful Routing Engine Switchover DPC Support on page 2626](#)
- [Graceful Routing Engine Switchover and Subscriber Access on page 2626](#)
- [Graceful Routing Engine Switchover PIC Support on page 2626](#)

## Graceful Routing Engine Switchover Platform Support

To enable graceful Routing Engine switchover, your system must meet these minimum requirements:

- M20 and M40e routers—Junos OS Release 5.7 or later
- M10i router—Junos OS Release 6.1 or later
- M320 router—Junos OS Release 6.2 or later
- T320 router, T640 router, and TX Matrix router—Junos OS Release 7.0 or later
- M120 router—Junos OS Release 8.2 or later
- MX960 router—Junos OS Release 8.3 or later
- MX480 router—Junos OS Release 8.4 or later (8.4R2 recommended)
- MX240 router—Junos OS Release 9.0 or later
- PTX5000 router—Junos OS Release 12.1X48 or later
- Standalone T1600 router—Junos OS Release 8.5 or later
- Standalone T4000 router—Junos OS Release 12.1R2 or later
- TX Matrix Plus router—Junos OS Release 9.6 or later
- TX Matrix Plus router with 3D SIBs—Junos Release 13.1 or later
- EX Series switches with dual Routing Engines or in a Virtual Chassis — Junos OS Release 9.2 or later for EX Series switches
- QFX Series switches in a Virtual Chassis —Junos OS Release 13.2 or later for the QFX Series
- EX Series or QFX Series switches in a Virtual Chassis Fabric —Junos OS Release 13.2X51-D20 or later for the EX Series and QFX Series switches

For more information about support for graceful Routing Engine switchover, see the sections that follow.

## Graceful Routing Engine Switchover Feature Support

Graceful Routing Engine switchover supports most Junos OS features in Release 5.7 and later. Particular Junos OS features require specific versions of Junos OS. See [Table 235](#).

**Table 235: Graceful Routing Engine Switchover Feature Support**

| Application                                                                                                  | Junos OS Release               |
|--------------------------------------------------------------------------------------------------------------|--------------------------------|
| Aggregated Ethernet interfaces with Link Aggregation Control Protocol (LACP) and aggregated SONET interfaces | 6.2                            |
| Asynchronous Transfer Mode (ATM) virtual circuits (VCs)                                                      | 6.2                            |
| Logical systems                                                                                              | 6.3                            |
| <b>NOTE:</b> In Junos OS Release 9.3 and later, the logical router feature is renamed to logical system.     |                                |
| Multicast                                                                                                    | 6.4 (7.0 for TX Matrix router) |

**Table 235: Graceful Routing Engine Switchover Feature Support (*continued*)**

| Application                                                                                                                                                                                            | Junos OS Release |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| Multilink Point-to-Point Protocol (MLPPP) and Multilink Frame Relay (MLFR)                                                                                                                             | 7.0              |
| Automatic Protection Switching (APS)—The current active interface (either the designated working or the designated protect interface) remains the active interface during a Routing Engine switchover. | 7.4              |
| Point-to-multipoint Multiprotocol Label Switching MPLS LSPs (transit only)                                                                                                                             | 7.4              |
| Compressed Real-Time Transport Protocol (CRTP)                                                                                                                                                         | 7.6              |
| Virtual private LAN service (VPLS)                                                                                                                                                                     | 8.2              |
| Ethernet Operation, Administration, and Management (OAM) as defined by IEEE 802.3ah                                                                                                                    | 8.5              |
| Extended DHCP relay agent                                                                                                                                                                              | 8.5              |
| Ethernet OAM as defined by IEEE 802.1ag                                                                                                                                                                | 9.0              |
| Packet Gateway Control Protocol (PGCP) process (pgcpd) on Multiservices 500 PICs on T640 routers.                                                                                                      | 9.0              |
| Subscriber access                                                                                                                                                                                      | 9.4              |
| Layer 2 Circuit and LDP-based VPLS pseudowire redundant configuration                                                                                                                                  | 9.6              |

The following constraints apply to graceful Routing Engine switchover feature support:

- When graceful Routing Engine switchover and aggregated Ethernet interfaces are configured in the same system, the aggregated Ethernet interfaces must not be configured for fast-polling LACP. When fast polling is configured, the LACP polls time out at the remote end during the Routing Engine mastership switchover. When LACP polling times out, the aggregated link and interface are disabled. The Routing Engine mastership change is fast enough that standard and slow LACP polling do not time out during the procedure. However, note that this restriction does not apply to MX Series Routers that are running Junos OS Release 9.4 or later and have distributed periodic packet management (PPM) enabled—which is the default configuration—on them. In such cases, you can configure graceful Routing Engine switchover and have aggregated Ethernet interfaces configured for fast-polling LACP on the same device.
- When a graceful Routing Engine switchover occurs, the VRRP state does not change. VRRP is supported by graceful Routing Engine switchover only in the case that PPM delegation is enabled (which the default).

## Graceful Routing Engine Switchover DPC Support

Graceful Routing Engine switchover supports all Dense Port Concentrators (DPCs) on the MX Series 3D Universal Edge Routers running the appropriate version of Junos OS as shown in “[Graceful Routing Engine Switchover Platform Support](#)” on page 2623. For more information about DPCs, see the *MX Series DPC Guide*.

## Graceful Routing Engine Switchover and Subscriber Access

Graceful Routing Engine switchover currently supports most of the features directly associated with dynamic DHCP and dynamic PPPoE subscriber access. Graceful Routing Engine switchover also supports the unified in-service software upgrade (ISSU) for the DHCP access model and the PPPoE access model used by subscriber access.

## Graceful Routing Engine Switchover PIC Support

Graceful Routing Engine switchover is supported on most PICs, except for the services PICs listed in this section. The PIC must be on a supported routing platform running the appropriate version of Junos OS. For information about FPC types, FPC/PIC compatibility, and the initial Junos OS Release in which an FPC supported a particular PIC, see the PIC guide for your router platform.

The following constraints apply to graceful Routing Engine switchover support for services PICs:

- You can include the **graceful-switchover** statement at the **[edit chassis redundancy]** hierarchy level on a router with Adaptive Services, Multiservices, and Tunnel Services PICs configured on it and successfully commit the configuration. However, all services on these PICs—except the Layer 2 service packages and extension-provider and SDK applications on Multiservices PICs—are reset during a switchover.
- Graceful Routing Engine switchover is not supported on any Monitoring Services PICs or Multilink Services PICs. If you include the **graceful-switchover** statement at the **[edit chassis redundancy]** hierarchy level on a router with either of these PIC types configured on it and issue the **commit** command, the commit fails.
- Graceful Routing Engine switchover is not supported on Multiservices 400 PICs configured for monitoring services applications. If you include the **graceful-switchover** statement, the commit fails.

**NOTE:** When an unsupported PIC is online, you cannot enable graceful Routing Engine switchover. If graceful Routing Engine switchover is already enabled, an unsupported PIC cannot come online.

## Configuring Graceful Routing Engine Switchover

---

This section contains the following topics:

- [Enabling Graceful Routing Engine Switchover on page 2627](#)
- [Configuring Graceful Routing Engine Switchover with Graceful Restart on page 2627](#)
- [Synchronizing the Routing Engine Configuration on page 2627](#)
- [Verifying Graceful Routing Engine Switchover Operation on page 2629](#)

### Enabling Graceful Routing Engine Switchover

By default, graceful Routing Engine switchover (GRES) is disabled. To configure GRES, include the **graceful-switchover** statement at the **[edit chassis redundancy]** hierarchy level.

```
[edit chassis redundancy]
graceful-switchover;
```

When you enable GRES, the command-line interface (CLI) indicates which Routing Engine you are using. For example:

```
{master} [edit]
user@host#
```

To disable GRES, delete the **graceful-switchover** statement from the **[edit chassis redundancy]** hierarchy level.

### Configuring Graceful Routing Engine Switchover with Graceful Restart

When using GRES with Graceful Restart, if adjacencies between the Routing Engine and the neighboring peer 'helper' routers time out, graceful restart protocol extensions are unable to notify the peer 'helper' routers about the impending restart. Graceful restart can then stop and cause interruptions in traffic.

To ensure that these adjacencies are kept, change the **hold-time** for IS-IS protocols from the default of 27 seconds to a value higher than 40 seconds.

### Synchronizing the Routing Engine Configuration

**NOTE:** A newly inserted backup Routing Engine automatically synchronizes its configuration with the master Routing Engine configuration.

When you configure GRES, you can bring the backup Routing Engine online after the master Routing Engine is already running. There is no requirement to start the two Routing Engines simultaneously.

Only when you enable the graceful Routing Engine switchover, you can copy the running Junos OS version of the master Routing Engine to the backup Routing Engine.

**NOTE:** If the system is in ISSU state, you cannot copy the running Junos OS version of the master Router Engine.

You can enable automatic synchronization of the master Routing Engine configuration with the backup Routing Engine by including the events CHASSISD\_SNMP\_TRAP7 statement at the [edit event-options policy *policy-name*] hierarchy level.

CHASSISD\_SNMP\_TRAP7 is a system event logging message that the chassis process (chassisd) generates a Simple Network Management Protocol (SNMP) trap with the seven indicated argument-value pairs. An example of an event script to trigger automatic synchronization of master to the backup Routing Engine is as follows:

```
[edit event-options]
policy UPGRADE-BACKUPRE {
 events CHASSISD_SNMP_TRAP7;
 attributes-match {
 CHASSISD_SNMP_TRAP7.value5 matches "Routing Engine";
 CHASSISD_SNMP_TRAP7.trap matches "Fru Online";
 CHASSISD_SNMP_TRAP7.argument5 matches jnxFruName;
 }
 then {
 event-script auto-image-upgrade.slax {
 arguments {
 trap "${$.trap}";
 value5 "${$.value5}";
 argument5 "${$.argument5}";
 }
 }
 }
 event-script {
 file auto-image-upgrade.slax;
 }
}
```

After receiving this event, the event policy on the master Router Engine is triggered and the image available in the */var/sw/pkg* path is pushed to the backup Router Engine upgrade. During script execution, the image is copied to the backup Routing Engine's */var/sw/pkg* path.

**NOTE:** If the image is not available in the */var/sw/pkg* path, the script is terminated with an appropriate syslog message.

If the Routing Engine is running at the Junos OS Release 13.2 or later, the Junos automation scripts is synchronized automatically.

After the master Router Engine is rebooted, the event script available at the */usr/libexec/scripts/event/auto-image-upgrade.slax* must be copied to the */var/db/scripts/event* path.

## Verifying Graceful Routing Engine Switchover Operation

To verify whether GRES is enabled on the backup Routing Engine, issue the **show system switchover** command. When the output of the command indicates that the **Graceful switchover** field is set to **On**, GRES is operational. The status of the kernel database and configuration database synchronization between Routing Engines is also provided. For example:

```
Graceful switchover: On
Configuration database: Ready
Kernel database: Ready
Peer state: Steady state
```

**NOTE:** You must issue the **show system switchover** command on the backup Routing Engine. This command is not supported on the master Routing Engine.

For more information about the **show system switchover** command, see the [CLI Explorer](#).

## Configuring Graceful Routing Engine Switchover in a Virtual Chassis (CLI Procedure)

In a Virtual Chassis, one member switch is assigned the master role and has the master Routing Engine. Another member switch is assigned the backup role and has the backup Routing Engine. Graceful Routing Engine switchover (GRES) enables the master and backup Routing Engines in a Virtual Chassis configuration to switch from the master to backup without interruption to packet forwarding. When you configure graceful Routing Engine switchover, the backup Routing Engine automatically synchronizes with the master Routing Engine to preserve kernel state information and the forwarding state.

To set up the Virtual Chassis configuration to use graceful Routing Engine switchover (GRES):

1. Set up a minimum of two switches in a Virtual Chassis configuration with mastership priority of 255:

```
[edit]
user@switch# set virtual-chassis member 0 mastership-priority 255
[edit]
```

```
user@switch# set virtual-chassis member 1 mastership-priority 255
```

2. Set up graceful Routing Engine switchover:

```
[edit]
```

```
user@switch# set chassis redundancy graceful-switchover
```

Commit the configuration.

**NOTE:** We recommend that you use the `commit synchronize` command to save any configuration changes that you make to a multimember Virtual Chassis.

## Resetting Local Statistics

When you enable graceful Routing Engine switchover, the master Routing Engine configuration is copied and loaded to the backup Routing Engine. User files, accounting information, and trace options information are not replicated to the backup Routing Engine.

When a graceful Routing Engine switchover occurs, local statistics such as process statistics and networking statistics are displayed as a cumulative value from the time the process first came online. Because processes on the master Routing Engine can start at different times from the processes on the backup Routing Engine, the statistics on the two Routing Engines for the same process might differ. After a graceful Routing Engine switchover, we recommend that you issue the **clear interface statistics (*interface-name* | all)** command to reset the cumulative values for local statistics. Forwarding statistics are not affected by graceful Routing Engine switchover.

For information about how to use the **clear** command to clear statistics and protocol database information, see the [CLI Explorer](#).

**NOTE:** The `clear firewall` command cannot be used to clear the Routing Engine filter counters on a backup Routing Engine that is enabled for graceful Routing Engine switchover.

## Understanding VRRP

---

Juniper Networks switches support the Virtual Router Redundancy Protocol (VRRP) and VRRPv3 (for IPv6). This topic covers:

- [Overview of VRRP on page 2633](#)
- [Sample VRRP Topology on page 2634](#)

## Overview of VRRP

Configuring end hosts on your network with static default routes minimizes configuration effort and complexity and reduces processing overhead on the end hosts. When hosts are configured with static routes, the failure of the default gateway normally results in a catastrophic event, isolating all hosts that are unable to detect available alternate paths to their gateway. Using Virtual Router Redundancy Protocol (VRRP) enables you to dynamically provide alternative gateways for end hosts if the primary gateway fails.

VRRP (defined in RFC 3768) provides dynamic failover of IP addresses from one router to another in the event of failure. You can implement VRRP to provide a highly available default path to a gateway without needing to configure dynamic routing or router discovery protocols on end hosts.

Switches configured with VRRP share a virtual IP address, which is the address you configure as the default route on the hosts. At any time, one of the switches is the VRRP master, meaning that it owns the virtual IP address and is the active default gateway. The other devices are backups. The switches dynamically assign master and backup roles based on priorities that you configure (**1 through 255**). If the master fails, the backup switch with the highest priority becomes the master within a few seconds. This is done without any interaction with the hosts.

In VRRP operation, the master sends advertisements to the backup switches at regular intervals. The default interval is 1 second. If the backup switches do not receive an advertisement for a set period, the backup with the highest priority takes over as master within a few seconds and begins forwarding packets. This is done without any interaction with the hosts.

**NOTE:** Priority 255 cannot be set for routed VLAN interfaces (RVIs).

---

You can configure two QFabric systems to participate in a VRRP configuration as if they were two standalone switches. One benefit of this configuration is if you use VMware's vMotion, virtual machines can transition between hosts connected to the QFabric systems without updating their default gateway information. For example, a virtual machine running on a host connected to a QFabric system in data center A can transition to a host connected to a QFabric system in data center B without needing to resolve a new gateway IP address and MAC address.

## Sample VRRP Topology

**Figure 43** illustrates a basic VRRP topology. In this example, switches A and B are running VRRP and share the virtual IP address 10.1.1.1. The default gateway for each of the clients is 10.1.1.1.

Figure 43: Basic VRRP Topology

The following illustrates basic VRRP behavior using [Figure 43](#) for reference:

1. When any of the servers wants to send traffic out of the LAN, it sends the traffic to the default gateway address of 10.1.1.1. This is a virtual IP address (VIP) owned by VRRP group 100. Because switch A is the master of the group, the VIP is associated with the “real” address 10.1.1.251 on switch A, and traffic from the servers is actually sent to this address. (Switch A is the master because it has been configured with a higher priority value.)
2. If there is a failure on switch A that prevents it from forwarding traffic to or from the servers—for example, if the interface connected to the LAN fails—switch B becomes the master and assumes ownership of the VIP. The servers continue to send traffic to the VIP, but because the VIP is now associated with the “real” address 10.1.1.252 on switch B (because of change of master), the traffic is sent to switch B instead of switch A.
3. If the problem that caused the failure on switch A is corrected, switch A becomes the master again and reasserts ownership of the VIP. In this case, the servers resume sending traffic to switch A.

Notice that no configuration changes are required on the servers for them to switch between sending traffic to switch A and switch B. When the VIP moves between 10.1.1.251 and 10.1.1.252, the change is detected by normal TCP-IP behavior and no configuration or intervention is required on the servers.

## Example: Configuring VRRP for Load Sharing

---

If you do not want to dedicate a switch to be a VRRP backup (and therefore leave it idle unless the master fails), you can create a load-sharing configuration in which each participating switch simultaneously acts as a master and a backup.

One reason to use a load-sharing (active-active) configuration is that you are more likely to actively monitor and maintain both switches and notice if a problem occurs on either of them. If you use a configuration in which one switch is only a backup (an active-backup configuration), you might be less likely to pay attention to the backup switch while it is idle. In the worst case, this could lead to the backup switch developing an undetected problem and not being able to perform adequately when a failover occurs.

- [Requirements on page 2636](#)
- [Overview and Topology on page 2636](#)
- [Configuring VRRP on Both Switches on page 2637](#)
- [Verification on page 2640](#)

### Requirements

This example uses the following hardware and software components:

- Two switches
- Junos OS Release 11.3 or later
- Static routing or a dynamic routing protocol enabled on both switches.

### Overview and Topology

This example uses two VRRP groups, each of which has its own virtual IP address. Devices on the LAN use one of these virtual IP addresses as their default gateway. If one of the switches fails, the other switch takes over for it. In the topology shown in [Figure 44](#), for example, Switch A is the master for VRRP group 100. If Switch A fails, Switch B takes over and forwards traffic that the end devices send to the default gateway address 10.1.1.1.

Figure 44: VRRP Load-Sharing Configuration

This example shows a simple configuration to illustrate the basic steps for configuring two switches running VRRP to back each other up. [Table 236](#) lists VRRP settings for each switch.

Table 236: Settings for VRRP Load-Sharing Example

| Switch A                                                                                                                                  | Switch B                                                                                                                                  |
|-------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| VRRP Group 100: <ul style="list-style-type: none"><li>Interface address: 10.1.1.251</li><li>VIP: 10.1.1.1</li><li>Priority: 250</li></ul> | VRRP Group 100: <ul style="list-style-type: none"><li>Interface address: 10.1.1.252</li><li>VIP: 10.1.1.1</li><li>Priority: 200</li></ul> |
| VRRP Group 200: <ul style="list-style-type: none"><li>Interface address: 10.1.1.251</li><li>VIP: 10.1.1.2</li><li>Priority: 200</li></ul> | VRRP Group 200: <ul style="list-style-type: none"><li>Interface address: 10.1.1.252</li><li>VIP: 10.1.1.2</li><li>Priority: 250</li></ul> |

In addition to configuring the two switches as shown, you must configure your end devices so that some of them use one of the virtual IP addresses as their default gateway and the remaining end devices use the other virtual IP address as their default gateway.

Note that if a failover occurs, the remaining switch might be unable to handle all of the traffic, depending on the demand.

Configuring VRRP on Both Switches

CLI Quick Configuration

Enter the following on Switch A:  
[edit]  
set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.251/24 vrrp-group 100 virtual-address 10.1.1.1  
set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.251/24 vrrp-group 100 priority 250

```
set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.251/24 vrrp-group 200 virtual-address 10.1.1.2
```

```
set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.251/24 vrrp-group 200 priority 200
```

Enter the following on Switch B:

```
[edit]
```

```
set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.252/24 vrrp-group 100 virtual-address 10.1.1.1
```

```
set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.252/24 vrrp-group 100 priority 200
```

```
set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.252/24 vrrp-group 200 virtual-address 10.1.1.2
```

```
set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.252/24 vrrp-group 200 priority 250
```

#### Step-by-Step Procedure

Configure the VRRP groups and priorities on Switch A:

1. Create VRRP group 100 on Switch A and configure the virtual IP address for the group:

```
[edit]
```

```
user@switch# set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.252/24 vrrp-group 100 virtual-address 10.1.1.1
```

2. Assign the VRRP priority for this interface in this group:

```
[edit]
```

```
user@switch# set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.251/24 vrrp-group 100 priority 250
```

3. Create VRRP group 200 on Switch A and configure the virtual IP address for the group:

```
[edit]
```

```
user@switch# set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.251/24 vrrp-group 200 virtual-address 10.1.1.2
```

4. Assign the VRRP priority for this interface in this group:

```
[edit]
```

```
user@switch# set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.251/24 vrrp-group 100 priority 200
```

#### Step-by-Step Procedure

Configure the VRRP groups and priorities on Switch B:

1. Create VRRP group 100 on Switch B and configure the virtual IP address for the group:

```
[edit]
```

```
user@switch# set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.252/24 vrrp-group 100 virtual-address 10.1.1.1
```

2. Assign the VRRP priority for this interface in this group:

```
[edit]
```

```
user@switch# set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.252/24 vrrp-group 100 priority 200
```

Switch A remains the master for group 100 because it has the highest priority for this group.

3. Create VRRP group 200 on Switch A and configure the virtual IP address for the group:

```
[edit]
```

```
user@switch# set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.252/24 vrrp-group 200 virtual-address 10.1.1.2
```

4. Assign the VRRP priority for this interface in this group:

```
[edit]
```

```
user@switch# set interfaces xe-0/0/0 unit 0 family inet address 10.1.1.251/24 vrrp-group 100 priority 250
```

Switch B becomes the master for group 200 because it has the highest priority for this group.

**Results** Display the results of the configuration on Switch A:

```
user@switch> show configuration
interfaces {
 xe-0/0/0 {
 unit 0 {
 family inet {
 address 10.1.1.251 {
 vrrp-group 100 {
 virtual address 10.1.1.1
 priority 250
 }
 }
 vrrp-group 200 {
 virtual address 10.1.1.2
 priority 200
 }
 }
 }
 }
}
```

Display the results of the configuration on Switch B:

```
user@switch> show configuration
interfaces {
 xe-0/0/0 {
 unit 0 {
 family inet {
 address 10.1.1.252 {
 vrrp-group 100 {
 virtual address 10.1.1.1
 priority 200
 }
 }
 vrrp-group 200 {
 virtual address 10.1.1.2
 priority 250
 }
 }
 }
 }
}
```

## Verification

- [Verifying that VRRP Is Working on Switch A on page 2640](#)
- [Verifying that VRRP Is Working on Switch B on page 2640](#)

### Verifying that VRRP Is Working on Switch A

**Purpose** Verify that VRRP is active on Switch A and that the master and backup roles are correct.

**Action** Use the following command to verify that VRRP is active on Switch A and that the switch is master for group 100 and backup for group 200.

```
user@switch> show vrrp
```

| Interface Address | State | Group | VR state | Timer                                  | Type |
|-------------------|-------|-------|----------|----------------------------------------|------|
| xe-0/0/0.0        | up    | 100   | master   | A .0327 lcl 10.1.1.251<br>vip 10.1.1.1 |      |
| xe-0/0/0.0        | up    | 200   | backup   | A .0327 lcl 10.1.1.251<br>vip 10.1.1.2 |      |

**Meaning** The **show vrrp** command displays fundamental information about the VRRP configuration. This output shows that both VRRP groups are active and that this switch has assumed the correct master and backup roles. The **lcl** address is the physical address of the interface and the **vip** address is the virtual address shared by both switches. The **Timer** value (**A .0327**) indicates the remaining time (in seconds) in which this switch expects to receive a VRRP advertisement from the other switch. If an advertisement for group 200 does not arrive before the timer expires, Switch A asserts itself as the master for this group.

### Verifying that VRRP Is Working on Switch B

**Purpose** Verify that VRRP is active on Switch B and that the master and backup roles are correct.

**Action** Use the following command to verify that VRRP is active on Switch B and that the switch is backup for group 100 and master for group 200.

```
user@switch> show vrrp
```

| Interface Address | State | Group | VR state | Timer                                  | Type |
|-------------------|-------|-------|----------|----------------------------------------|------|
| xe-0/0/0.0        | up    | 100   | backup   | A .0327 lcl 10.1.1.252<br>vip 10.1.1.1 |      |
| xe-0/0/0.0        | up    | 200   | master   | A .0327 lcl 10.1.1.252<br>vip 10.1.1.2 |      |

**Meaning** The **show vrrp** command displays fundamental information about the VRRP configuration. This output shows that both VRRP groups are active and that this switch has assumed the correct master and backup roles. The **lcl** address is the physical address of the interface and the **vip** address is the virtual address shared by both switches. The **Timer** value (**A .0327**) indicates the remaining time (in seconds) in which this switch expects to receive a VRRP advertisement from the other switch. If an advertisement for group 100 does not arrive before the timer expires, Switch B asserts itself as the master for this group.

- Related Documentation**
- [Understanding VRRP on page 2633](#)
  - [Configuring Basic VRRP Support for QFX on page 2641](#)

## Configuring Basic VRRP Support for QFX

To configure basic VRRP support, configure VRRP groups on interfaces by including the **vrrp-group** statement:

```
vrrp-group group-id {
 priority number;
 virtual-address [addresses];
}
```

An interface can be a member of multiple VRRP groups.

You can include this statement at the following hierarchy level:

- **[edit interfaces *interface-name* unit *logical-unit-number* family inet address *address*]**

For each interface, you must configure the following:

- Group identifier—Assign a value from 0 through 255. You must use the same identifier for each switch in the VRRP group.
- Priority—Assign a value from 1 through 255. The switch with the highest priority becomes the VRRP master. Assign different priorities to each switch in the VRRP group. If there are two or more switches with the same priority, the switch with the VRRP interface that has the highest IP address becomes the master.
- Virtual IP address—Normally, you configure only one address per group, but you can configure as many as eight addresses. Do not include a prefix length in a virtual IP address. The following considerations apply to configuring a virtual IP address:
  - You must configure the same address on all the switches in the VRRP group.
  - If you configure a virtual IP address to be the same as a physical interface address, the switch with that interface becomes the master for the group. You must configure the priority to be 255, and you must configure preemption by including the **preempt** statement.
  - If the virtual IP address is not the same as the physical interface address, you must ensure that the address does not appear anywhere else in the switch configuration. For example, verify that you do not use this address for another interface (including an aggregated Ethernet interface) or for a static ARP entry.

**NOTE:** If you enable MAC source address filtering on an interface, you must include the virtual MAC address in the list of source MAC addresses that you specify in the `source-address-filter` statement at the `[edit interfaces interface-name]` hierarchy. MAC addresses ranging from 00:00:5e:00:01:00 through 00:00:5e:00:01:ff are reserved for VRRP, as defined in RFC 3768. The VRRP group number must be the decimal equivalent of the last hexadecimal byte of the virtual MAC address.

---

**Related Documentation**

- [Understanding VRRP on page 2633](#)
- [Configuring the Startup Period for VRRP Operations on page 2643](#)
- [Configuring VRRP Authentication \(IPv4 Only\) on page 2642](#)

---

## Configuring VRRP Authentication (IPv4 Only)

---

VRRP (IPv4 only) protocol exchanges can be authenticated to guarantee that only trusted switches participate in a VRRP group. By default, VRRP authentication is disabled. You can configure one of the following authentication methods for a group, and each switch in the same group must use the same method:

- Simple authentication—Uses a text password included in the transmitted packet. The receiving switch uses an authentication key (password) to verify the packet.
- Message Digest 5 (MD5) algorithm—Adds an authentication header (AH) to the IP packet that encapsulates the VRRP packet. You create an authentication key that is used to create a hash of the packet, and the hash is stored in the AH. A receiving switch recalculates the hash on the incoming packet and compares the hashes. If they are identical, the packet is valid and is accepted. Otherwise the switch drops the incoming packet.

To enable authentication and specify an authentication method, include the **authentication-type** statement.

**authentication-type** *authentication*;

**authentication** can be **simple** or **md5**. The authentication type must be the same for all the switches in the VRRP group.

You can include this statement at the following hierarchy level:

- `[edit interfaces interface-name unit logical-unit-number family inet address address vrrp-group group-id]`

If you include the **authentication-type** statement, you can configure a key (password) on each interface by including the **authentication-key** statement:

**authentication-key** *key*;

**key** (the password) is an ASCII string. For simple authentication, it can be from 1 through 8 characters long. For MD5 authentication, it can be from 1 through 16 characters long. If you include spaces, enclose all characters in quotation marks (" ").

**NOTE:** The key must be the same for all switches in the VRRP group.

You can include this statement at the following hierarchy level:

- [edit interfaces *interface-name* unit *logical-unit-number* family inet address *address* vrrp-group *group-id*]

**Related Documentation**

- [Understanding VRRP on page 2633](#)
- [Configuring Basic VRRP Support for QFX on page 2641](#)

## Configuring the Startup Period for VRRP Operations

Configure the startup-silent period interval to avoid alarms caused by the delay or interruption of the incoming VRRP advertisement packets while an interface is coming online. The period starts when the state of a VRRP interface is changed from down to up. During this period, Master Down Events are ignored.

To configure the startup period for VRRP operations, include the **startup-silent-period** statement at the [edit protocols vrrp] hierarchy level:

```
[edit protocols vrrp]
 startup-silent-period seconds;
```

**Related Documentation**

- [Understanding VRRP on page 2633](#)
- [Configuring Basic VRRP Support for QFX on page 2641](#)
- [Example: Configuring VRRP for Load Sharing on page 2636](#)

## Configuring the Advertisement Interval for the VRRP Master

By default, the master switch sends VRRP advertisement packets every second to all members of the VRRP group. These packets indicate that the master switch is still operational. If the master switch fails or becomes unreachable, the backup switch with the highest priority value becomes the new master switch.

You can modify the advertisement interval in seconds or in milliseconds; the interval must be the same for all routing platforms in the VRRP group.

This topic contains the following sections:

- [Modifying the Advertisement Interval in Seconds on page 2644](#)
- [Modifying the Advertisement Interval in Milliseconds on page 2644](#)

## Modifying the Advertisement Interval in Seconds

To modify the time, in seconds, between the sending of VRRP advertisement packets, include the **advertise-interval** statement:

```
advertise-interval seconds;
```

The interval can be from 1 through 255 seconds.

You can include this statement at the following hierarchy level:

- [edit interfaces *interface-name* unit *logical-unit-number* family inet address *address* vrrp-group *group-id*]

## Modifying the Advertisement Interval in Milliseconds

To modify the time, in milliseconds, between the sending of VRRP advertisement packets, include the **fast-interval** statement:

```
fast-interval milliseconds;
```

The interval can be from 100 through 999 milliseconds.

You can include this statement at the following hierarchy level:

- [edit interfaces *interface-name* unit *logical-unit-number* family (inet | inet6) address *address* (vrrp-group | vrrp-inet6-group) *group-id*]

**NOTE:** Junos OS sets the advertisement interval to 0 in VRRP packets. When you configure VRRP with other vendors' equipment, the **fast-interval** statement works correctly only when the other equipment also has the advertisement interval set to 0 in the VRRP packet. Otherwise, Junos OS interprets other routers' settings as advertisement timer errors.

---

### Related Documentation

- [Understanding VRRP on page 2633](#)
- [Configuring Basic VRRP Support for QFX on page 2641](#)
- [Example: Configuring VRRP for Load Sharing on page 2636](#)

---

## Configuring VRRP Preemption and Hold Time

- [Configuring VRRP Preemption on page 2645](#)
- [Configuring the Preemption Hold Time on page 2645](#)
- [Overriding the Hold Time on page 2645](#)

## Configuring VRRP Preemption

By default, a higher-priority VRRP backup switch preempts a lower-priority master switch. To explicitly enable this behavior, include the following statement:

```
preempt;
```

To prohibit a higher-priority VRRP backup switch from preempting a lower-priority master switch, include the following statement on the lower-priority switch:

```
no-preempt;
```

You can include these statements at the following hierarchy level:

- [edit interfaces *interface-name* unit *logical-unit-number* family inet address *address* vrrp-group *group-id*]

## Configuring the Preemption Hold Time

You can also configure a preemption hold time, which is the number of seconds a higher-priority backup router that has just started up waits before preempting the master router. You might want to configure a hold time so that routing protocols or other Junos OS components converge before preemption occurs.

The hold time is applied only on startup. By default, the hold-time value is 0 seconds, meaning that preemption can occur immediately after the backup router starts up.

To modify the preemption hold-time value, configure the following statement:

```
hold-time seconds;
```

The hold time can be from 0 through 3600 seconds.

You can include this statement at the following hierarchy level:

- [edit interfaces *interface-name* unit *logical-unit-number* family inet address vrrp-group *group-id*] preempt

## Overriding the Hold Time

You can use the `asymmetric-hold-time` statement to configure a VRRP master to fail over to the backup immediately—without waiting for the preemption hold time to expire—when a tracked route goes down. Otherwise, the master waits for the hold time to expire before it initiates a failover when a tracked route goes down.

When the tracked route comes up again, the new backup (original master) router waits for the preemption hold time to expire before it reasserts mastership.

You can include this statement at the following hierarchy level:

- [edit protocols vrrp]

Related  
Documentation

- [Understanding VRRP on page 2633](#)

- [Configuring Basic VRRP Support for QFX on page 2641](#)
- [Example: Configuring VRRP for Load Sharing on page 2636](#)

## Configuring a Route to Be Tracked

---

A VRRP master can track a route and dynamically trigger a new master router election if the route becomes unreachable. To enable this behavior, you must configure a cost that will be subtracted from the priority of the master if the tracked route becomes unreachable. The new priority must be less than the priority of one of the backups so that the backup becomes the new master.

To configure a route to be tracked, include the following statements:

```
track {
 priority-hold-time seconds;
 route prefix/prefix-length routing-instance default priority-cost priority;
}
```

You can include these statements at the following hierarchy level:

- `[edit interfaces interface-name unit logical-unit-number family inet address address vrrp-group group-id]`

The **prefix** and **prefix-length** values specify the route to be tracked. The **priority-hold-time** statement is the minimum length of time that must elapse between priority changes. If the priority of the master changes because of a tracking event, the priority hold timer begins. If another tracking event or manual configuration change occurs while the timer is running, the new priority update is postponed until the timer expires. You might configure the **priority-hold-time** statement to prevent problems that could occur if there were multiple VRRP transitions in a short period of time.

The **priority-cost** option is the value to be subtracted from the VRRP priority when the tracked route goes down. The value can be 1 through 254. The sum of the costs for all tracked interfaces and routes must be less than or equal to the configured priority (so that subtracting all the costs results in a priority equal to or greater than 0).

### Related Documentation

- [Configuring Basic VRRP Support for QFX on page 2641](#)
- [Example: Configuring VRRP for Load Sharing on page 2636](#)
- [Configuring a Logical Interface to Be Tracked on page 2646](#)

## Configuring a Logical Interface to Be Tracked

---

VRRP can track whether a logical interface is up, down, or not present, and can change the priority of the switch based on the state of the interface, which might trigger a new master election. VRRP can also track the operational speed of a logical interface and update the priority of the switch when the speed crosses a configured threshold. For each VRRP group, you can track as many as 10 logical interfaces.

When interface tracking is enabled on a switch, you cannot assign the switch a priority of 255 to make it the master for the group.

To configure a logical interface to be tracked, include the following statements:

```
track {
 interface interface-name {
 bandwidth-threshold bits-per-second priority-cost priority;
 priority-cost priority;
 }
 priority-hold-time seconds;
}
```

You can include these statements at the following hierarchy level:

- [edit interfaces *interface-name* unit *logical-unit-number* family inet address *address* vrrp-group *group-id*]

The interface specified is the interface to be tracked for the VRRP group. The **priority-hold-time** statement is the minimum length of time that must elapse between priority changes. If the priority changes because of a tracking event, the priority hold timer begins. If another tracking event or manual configuration change occurs while the timer is running, the new priority update is postponed until the timer expires. You might configure the **priority-hold-time** statement to prevent problems that could occur if there were multiple VRRP transitions in a short period of time.

The **bandwidth-threshold** statement specifies a threshold for the tracked interface. If the bandwidth of the tracked interface drops below the threshold value, the system subtracts the bandwidth threshold **priority-cost** value from the VRRP priority for the switch. You can create as many as five **bandwidth-threshold** statements for each tracked interface.

The interface **priority-cost** statement is the value to be subtracted from the VRRP priority when the tracked route goes down. The value can be 1 through 254. The sum of the costs for all tracked interfaces and routes must be less than or equal to the configured priority (so that subtracting all the costs results in a priority equal to or greater than 0).

**WARNING:** On a QFabric system, do not apply interface tracking to a multichassis link aggregation group (MC-LAG) that includes an interface belonging to a network Node group device and an interface belonging to a server Node group device. If you do apply interface tracking to an MC-LAG configured in this way, a priority update will not occur if the state of the MC-LAG interface changes.

If you configure tracking for more than one interface, Junos OS subtracts the sum of the priority costs for the tracked interfaces from the VRRP priority if all the tracked interfaces fail. However, if you configure the interface **priority-cost** statement and the bandwidth threshold **priority-cost** statement, they are not added together. The switch uses only one priority cost for a tracked interface, as indicated in [Table 237](#):

Table 237: Interface State and Priority Cost Usage

| Tracked Interface State                                      | Priority Cost Usage                                        |
|--------------------------------------------------------------|------------------------------------------------------------|
| Down                                                         | <b>priority-cost</b> <i>priority</i>                       |
| Not down; media speed below one or more bandwidth thresholds | Priority-cost of the lowest applicable bandwidth threshold |

You must configure an interface priority cost only if you do not configure any bandwidth thresholds. If you do not configure an interface **priority-cost** value and the interface fails, Junos OS subtracts the bandwidth threshold **priority-cost** value of the lowest bandwidth threshold from the priority of the switch.

## Configuring a Backup to Accept Packets Destined for the Virtual IP Address

By default, a switch configured to be a VRRP backup but acting as the master does not process packets sent to the virtual IP address—that is, packets in which the destination address is the virtual IP address. To configure a backup switch to process packets sent to the virtual IP address while it is acting as the master, include the **accept-data** statement on the backup:

```
accept-data;
```

You can include this statement at the following hierarchy level:

- **[edit interfaces *interface-name* unit *logical-unit-number* family inet address *address* vrrp-group] *group-id***

To explicitly prohibit the backup from accepting packets destined for the virtual IP address while acting as master, include the **no-accept-data** statement:

```
no-accept-data;
```

If you include the **accept-data** statement, configure the connected hosts so that they:

- Process gratuitous ARP requests.
- Do not use packets other than ARP replies to update their ARP cache.

This statement is disabled by default. If you enable it, your configuration does not comply with RFC 3768.

To restrict incoming IP packets to ICMP only, you must configure firewall filters to accept only ICMP packets.

## Configuring Passive ARP Learning for VRRP Backups

By default, VRRP backup switches drop ARP requests for the MAC address of the VRRP IP. This means that backups do not learn the ARP mappings (IP address to MAC address mappings) for the hosts sending the requests. If it becomes the master, the configured backup must learn all the entries that were present in the ARP cache of the original master. In environments with many directly attached hosts, the number of ARP entries to learn can be very large. This can cause a significant delay while the backup transitions to the master state, during which traffic transmitted to some of the hosts might be dropped.

Passive ARP learning enables the ARP cache in the backup to learn approximately the same contents as the ARP cache in the master, thus preventing the problem of needing to learn many ARP entries quickly. To enable passive ARP learning, include the **passive-learning** statement at the **[edit system arp]** hierarchy level:

```
[edit system arp]
passive-learning;
```

We recommend setting passive learning on both the backup and master VRRP switches. Doing so prevents the need to manually configure a master that fails and becomes a backup. While a switch operates as the master, the passive learning configuration has no impact. The configuration takes effect only when a switch operates as a backup.

## Configuring the Silent Period

When the state of a VRRP interface changes from down to up, a silent period begins. During this period, any master down events are ignored. Configure the silent period interval to avoid problems that can be caused if incoming VRRP advertisement packets are delayed or interrupted while an interface starts up.

To configure the silent period, include the **startup-silent-period** statement at the **[edit protocols vrrp]** hierarchy level:

```
[edit protocols vrrp]
startup-silent-period seconds;
```

## Configuring Inheritance for a VRRP Group

---

Junos OS enables you to configure VRRP groups on the various subnets of a VLAN to inherit the state and configuration of one of the groups, which is known as the *active VRRP group*. By configuring inheritance, you can prevent VRRP groups other than the active group from sending out VRRP advertisements. When the **vrrp-inherit-from** configuration statement is included in the configuration, only the active VRRP group from which the other VRRP groups are inheriting the state sends out VRRP advertisements; the groups inheriting the state do not send any VRRP advertisements, because the state is maintained only on the group from which the state is inherited.

If the **vrrp-inherit-from** statement is not configured, each of the VRRP master groups in the various subnets on the VLAN sends out separate VRRP advertisements and adds to the traffic on the VLAN.

To configure inheritance for a VRRP group, include the **vrrp-inherit-from** statement at the **[edit interfaces *interface-name* unit *logical-unit-number* family inet address *address* *vrrp-group group-id*]**:

```
[edit interfaces interface-name unit logical-unit-number family inet address address
 vrrp-group group-id]
 vrrp-inherit-from vrrp-group;
```

When you configure a group to inherit a state from another group, note the following conditions:

- Both inheriting groups and active groups must be on the same physical interface and logical system. However, the groups need not necessarily be on the same VLAN or logical interface.
- Both inheriting groups and active groups must be on the same routing instances; however, this limitation does not apply for groups on the integrated routing and bridging (IRB) interfaces.

When you include the **vrrp-inherit-from** statement for a VRRP group, the VRRP group inherits the following parameters from the active group:

- **advertise-interval**
- **authentication-key**
- **authentication-type**
- **fast-interval**
- **preempt | no-preempt**
- **priority**
- **track interfaces**
- **track route**

However, you can configure the **accept-data | no-accept-data** statement for the group to specify whether the interface should accept packets destined for the virtual IP address.

---

## Troubleshooting VRRP

---

**Problem**    **Description:** If you configure multiple VRRP groups on an interface (using multiple VLANs), traffic for some of the groups might be briefly dropped if a failover occurs. This can happen because the new master must send gratuitous ARP replies for each VRRP group to update the ARP tables in the connected devices, and there is a short delay between each gratuitous ARP reply. Traffic sent by devices that have not yet received the gratuitous ARP reply is dropped (until the device receives the reply and learns the MAC address of the new master).

**Solution**    Configure a failover delay so that the new master delays sending gratuitous ARP replies for the period that you set. This allows the new master to send the ARP replies for all of the VRRP groups simultaneously.

| <b>Description</b>         | Disable graceful restart for BGP. Graceful restart allows a routing device undergoing a restart to inform its adjacent neighbors and peers of its condition.                                                                                                                                                                                                                                                                                                                                                                                                                       |

**NOTE:** When you disable graceful restart at one level in the configuration statement hierarchy, it is also disabled at lower levels in the same hierarchy. For example, if you disable graceful restart at the [edit protocols bgp **group** *group-name*] hierarchy level, it is disabled for all the peers in the group. Therefore, if you want to enable graceful restart for some peers in a group and disable it for others, enable graceful restart at the [edit protocols bgp **group** *group-name*] hierarchy level and disable graceful restart for each peer at the [edit protocols bgp **group** *group-name* **neighbor** *address*] hierarchy level.

| <b>Release Information</b> | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.<br>Statement introduced in Junos OS Release 12.1 for the QFX Series.<br>Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.                                                             |
| <b>Description</b>         | Configure graceful restart globally to enable the feature. You cannot enable graceful restart for specific protocols unless graceful restart is also enabled globally. You can, optionally, modify the global settings at the individual protocol level.                                                                               |

### NOTE:

- For VPNs, the `graceful-restart` statement allows a router whose VPN control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers.
  - For BGP, if you configure graceful restart after a BGP session has been established, the BGP session restarts and the peers negotiate graceful restart capabilities.
  - LDP sessions flap when `graceful-restart` configurations change.
-

| Description              | <p>Configure graceful restart for BGP. Graceful restart allows a routing device undergoing a restart to inform its adjacent neighbors and peers of its condition. Graceful restart is disabled by default. However, helper mode, the ability to assist a neighboring router attempting a graceful restart, is enabled by default.</p> <p>To configure the duration of the BGP graceful restart period, include the <b>restart-time</b> statement at the [edit protocols bgp graceful-restart] hierarchy level. To set the length of time the router waits to receive messages from restarting neighbors before declaring them down, include the <b>stale-routes-time</b> statement at the [edit protocols bgp graceful-restart] hierarchy level.</p> <div style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p> <b>NOTE:</b> If you configure graceful restart after a BGP session has been established, the BGP session restarts and the peers negotiate graceful restart capabilities.</p> </div> <p>Configure graceful restart globally at the [edit routing-options] or [edit routing-instances <i>instance-name</i> routing-options] hierarchy level to enable the feature. You cannot enable graceful restart for specific protocols unless graceful restart is also enabled globally. You can, optionally, modify the global settings at the individual protocol level.</p> <p>The remaining statements are explained separately.</p> |
| Required Privilege Level | <p>routing—To view this statement in the configuration.<br/>         routing-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b>         | Configure graceful restart for OSPF.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Options</b>             | <p><b>disable</b>—Disable graceful restart for OSPF.</p> <p><b>helper-disable (standard   restart-signaling   both)</b>—Disable helper mode for graceful restart. When helper mode is disabled, a device cannot help a neighboring device that is attempting to restart. Beginning with Junos OS Release 11.4, you can configure restart signaling-based helper mode for OSPFv2 graceful restart configurations. The <b>standard</b>, <b>restart-signaling</b>, and <b>both</b> options are only supported for OSPFv2. Specify <b>standard</b> to disable helper mode for standard graceful restart (based on RFC 3623). Specify <b>restart-signaling</b> to disable helper mode for restart signaling-based graceful restart (based on RFC 4811, RFC 4812, and RFC 4813). Specify <b>both</b> to disable helper mode for both standard and restart signaling-based graceful restart. The last committed statement takes precedence over the previously configured statement.</p> <p><b>Default:</b> Helper mode is enabled by default. For OSPFv2, both standard and restart-signaling based helper modes are enabled by default.</p> <p><b>no-strict-lsa-checking</b>—Disable strict OSPF link-state advertisement (LSA) checking to prevent the termination of graceful restart by a helping router. LSA checking is enabled by default.</p> |

**NOTE:** The **helper-disable** statement and the **no-strict-lsa-checking** statement cannot be configured at the same time. If you attempt to configure both statements at the same time, the routing device displays a warning message when you enter the **show protocols (ospf | ospf3)** command.

**notify-duration *seconds***—Estimated time needed to send out purged grace LSAs over all the interfaces.

**Range:** 1 through 3600 seconds

**Default:** 30 seconds

**restart-duration *seconds***—Estimated time needed to reacquire a full OSPF neighbor from each area.

**Range:** 1 through 3600 seconds

**Default:** 180 seconds

## restart-time (BGP Graceful Restart)

**Syntax** restart-time *seconds*;

**Hierarchy Level** [edit protocols (bgp | rip | ripng) [graceful-restart](#)],  
[edit logical-systems *logical-system-name* protocols (bgp | rip | ripng) [graceful-restart](#) ([Enabling Globally](#))],  
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols bgp [graceful-restart](#)],  
[edit routing-instances *routing-instance-name* protocols bgp [graceful-restart](#)]

**Release Information** Statement introduced in Junos OS Release 8.3.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Statement introduced in Junos OS Release 12.1 for the QFX Series.  
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

**Description** Configure the duration of the BGP, RIP, or next-generation RIP (RIPng) graceful restart period.

**Options** *seconds*—Length of time for the graceful restart period.  
**Range:** 1 through 600 seconds  
**Default:** Varies by protocol:

- BGP—120 seconds
- RIP and RIPng—60 seconds

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Hierarchy Level</b>     | [edit system commit]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Release Information</b> | Statement introduced in Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 10.4 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b>         | For devices with multiple Routing Engines only. Configure the <b>commit</b> command to automatically perform a <b>commit synchronize</b> action between dual Routing Engines within the same chassis. The Routing Engine on which you execute the <b>commit</b> command (the requesting Routing Engine) copies and loads its candidate configuration to the other (the responding) Routing Engine. Each Routing Engine then performs a syntax check on the candidate configuration file being committed. If no errors are found, the configuration is activated and becomes the current operational configuration on both Routing Engines. |

**NOTE:** If you configure the **commit synchronize** statement at the [edit system] hierarchy level and issue a **commit** in the master Routing Engine, the master configuration is automatically synchronized with the backup. However, if the backup Routing Engine is down when you issue the **commit**, the Junos OS displays a warning and commits the candidate configuration in the master Routing Engine. When the backup Routing Engine comes up, its configuration will automatically be synchronized with the master. A newly inserted backup Routing Engine automatically synchronizes its configuration with the master Routing Engine configuration.

**NOTE:** When you configure nonstop active routing (NSR), you must configure the **commit synchronize** statement. Otherwise, the **commit** operation fails.

On the TX Matrix router, synchronization only occurs between the Routing Engines within the same chassis. When synchronization is complete, the new configuration is then distributed to the Routing Engines on the T640 routers. That is, the master Routing Engine on the TX Matrix router distributes the configuration to the master Routing Engine on each T640 router. Likewise, the backup Routing Engine on the TX Matrix router distributes the configuration to the backup Routing Engine on each T640 router.

On the TX Matrix Plus router, synchronization only occurs between the Routing Engines within the switch-fabric chassis and when synchronization is complete, the new configuration is then distributed to the Routing Engines on the line-card chassis (LCC). That is, the master Routing Engine on the TX Matrix Plus router distributes the configuration to the master Routing Engine on each LCC. Likewise, the backup Routing Engine on the TX Matrix Plus router distributes the configuration to the backup Routing Engine on each LCC.

In EX Series Virtual Chassis configurations:

- On EX4200 switches in Virtual Chassis, synchronization occurs between the switch in the master role and the switch in the backup role.
- On EX8200 switches in a Virtual Chassis, synchronization occurs only between the master and backup XRE200 External Routing Engines.

**Options**    **and-quit**—(Optional) Quit configuration mode if the commit synchronization succeeds.

**at**—(Optional) Time at which to activate configuration changes.

**comment**—(Optional) Write a message to the commit log.

**force**—(Optional) Force a commit synchronization on the other Routing Engine (ignore warnings).

**scripts**—(Optional) Push scripts to the other Routing Engine.

**Required Privilege**    **system**—To view this statement in the configuration.

**Level**    **system-control**—To add this statement to the configuration.

| <b>Description</b>         | <p>Define tracing operations that track all routing protocol functionality in the routing device.</p> <p>To specify more than one tracing operation, include multiple <b>flag</b> statements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Default</b>             | If you do not include this statement, no global tracing operations are performed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Options</b>             | <p><b>Values:</b></p> <p><b>disable</b>—(Optional) Disable the tracing operation. You can use this option to disable a single operation when you have defined a broad group of tracing operations, such as <b>all</b>.</p> <p><b>file <i>filename</i></b>—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory <b>/var/log</b>. We recommend that you place global routing protocol tracing output in the file <b>routing-log</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**files *number***—(Optional) Maximum number of trace files. When a trace file named ***trace-file*** reaches its maximum size, it is renamed ***trace-file.0***, then ***trace-file.1***, and so on, until the maximum number of trace files is reached. Then, the oldest trace file is overwritten. Note that if you specify a maximum number of files, you also must specify a maximum file size with the **size** option.

**Range:** 2 through 1000 files

**Default:** 10 files

**flag *flag***—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements. These are the global routing protocol tracing options:

- **all**—All tracing operations
- **condition-manager**—Condition-manager events
- **config-internal**—Configuration internals
- **general**—All normal operations and routing table changes (a combination of the **normal** and **route** trace operations)
- **graceful-restart**—Graceful restart operations
- **normal**—All normal operations
- **nsr-packet**—Detailed trace information for BFD nonstop active routing only
- **nsr-synchronization**—Tracing operations for nonstop active routing
- **nsr-synchronization**—Nonstop active routing synchronization
- **parse**—Configuration parsing
- **policy**—Routing policy operations and actions
- **regex-parse**—Regular-expression parsing
- **route**—Routing table changes
- **state**—State transitions
- **task**—Interface transactions and processing
- **timer**—Timer usage

**no-world-readable**—(Optional) Prevent any user from reading the log file.

**size *size***—(Optional) Maximum size of each trace file, in kilobytes (KB), megabytes (MB), or gigabytes (GB). When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file.0***. When the ***trace-file*** again reaches its maximum size, ***trace-file.0*** is renamed ***trace-file.1*** and ***trace-file*** is renamed ***trace-file.0***. This renaming scheme continues until the maximum number of trace files is reached. Then, the oldest trace file is overwritten. Note that if you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option.

**Syntax:** ***xk*** to specify KB, ***xm*** to specify MB, or ***xg*** to specify GB

**Range:** 10 KB through the maximum file size supported on your system

**Default:** 128 KB

**world-readable**—(Optional) Allow any user to read the log file.

**Required Privilege** routing and trace—To view this statement in the configuration.  
**Level** routing-control and trace-control—To add this statement to the configuration.

**Related** • *Example: Tracing Global Routing Protocol Operations*

| <b>Description</b>              | <p>If you configure multiple VRRP groups on an interface (using multiple VLANs), traffic for some of the groups might be briefly dropped if a failover occurs. This can happen because the new master must send gratuitous ARP replies for each VRRP group to update the ARP tables in the connected devices, and there is a short delay between each gratuitous ARP reply. Traffic sent by devices that have not yet received the gratuitous ARP reply is dropped (until the device receives the reply and learns the MAC address of the new master).</p> <p>If you configure a failover delay, the new master delays sending gratuitous ARP replies for the period that you set. This allows the new master to send the ARP replies for all of the VRRP groups simultaneously.</p> |

| <b>Description</b>              | Configure a Virtual Router Redundancy Protocol (VRRP) router's priority cost for becoming the master default router. The router with the highest priority within the group becomes the master.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Options</b>                  | <b><i>priority</i></b> —The value subtracted from the configured VRRP priority when the tracked interface or route is down to force a new master router election. The sum of all the costs for all interfaces or routes that are tracked must be less than or equal to the configured priority of the VRRP group.<br><b>Range:</b> 1 through 254                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## traceoptions

---

**Syntax**    traceoptions {  
              file <filename> <files number> <match *regular-expression*> <microsecond-stamp>  
                  <size size> <world-readable | no-world-readable>;  
              flag *flag*;  
              no-remote-trace;  
              }

**Hierarchy Level**    [edit protocols vrrp]

**Release Information**    Statement introduced in Junos OS Release 11.3 for the QFX Series.  
                              Statement introduced in Junos OS Release 14.1x53-D20 for the OCX Series.

**Description**    Define tracing operations for the Virtual Router Redundancy Protocol (VRRP) process.

To specify more than one tracing operation, include multiple **flag** statements.

By default, VRRP logs the error, dcd configuration, and routing socket events in a file in the directory **/var/log**.

**NOTE:** The traceoptions statement is not supported on a QFabric system.

---

**Default**    If you do not include this statement, no VRRP-specific tracing operations are performed.

**Options**    **filename filename**—Name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**. By default, VRRP tracing output is placed in the file **vrrpd**.

**files number**—(Optional) Maximum number of trace files. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. When the maximum number is reached, the oldest trace file is overwritten.

**Range:** 0 through 4,294,967,296 files

**Default:** 3 files

If you specify a maximum number of files, you also must specify a maximum file size with the **size** option.

**flag flag**—Tracing operation to perform. To specify more than one tracing operation, include multiple **flag** statements. These are the VRRP-specific tracing options:

- **all**—All VRRP tracing operations
- **database**—Database changes
- **general**—General events

- **interfaces**—Interface changes
- **normal**—Normal events
- **packets**—Packets sent and received
- **state**—State transitions
- **timer**—Timer events

**match *regex***—(Optional) Refine the output to include only those lines that match the given regular expression.

**microsecond-stamp**—(Optional) Provide a timestamp with microsecond granularity.

**no-world-readable**—Restrict users from reading the log file.

**size *size***—(Optional) Maximum size of each trace file, in kilobytes, megabytes, or gigabytes. When a trace file named ***trace-file*** reaches this size, it is renamed ***trace-file.0***. When the ***trace-file*** again reaches its maximum size, ***trace-file.0*** is renamed ***trace-file.1*** and ***trace-file*** is renamed ***trace-file.0***. This renaming scheme continues until the maximum number of trace files is reached. Then the oldest trace file is overwritten.

**Syntax:** *xk* to specify KB, *xm* to specify MB, or *xg* to specify GB

**Range:** 10 KB through the maximum file size supported on your routing platform

**Default:** 1 MB

If you specify a maximum file size, you also must specify a maximum number of trace files with the **files** option.

**world-readable**—Allow users to read the log file.

| <b>Description</b>              | Configure the addresses of the virtual routers in a Virtual Router Redundancy Protocol (VRRP) IPv4 or IPv6 group. You can configure up to eight addresses.                                                                                                                                                                   |
| <b>Options</b>                  | <b><i>addresses</i></b> —Addresses of one or more virtual routers. Do not include a prefix length. If the address is the same as the interface's physical address, the interface becomes the master virtual router for the group.                                                                                            |
| <b>Required Privilege Level</b> | interface—To view this statement in the configuration.<br>interface-control—To add this statement to the configuration.                                                                                                                                                                                                      |

# Operational Mode Commands (Graceful Restart)

- [Verifying Graceful Restart Operation on page 2707](#)
- [show bgp neighbor](#)
- [show log](#)
- [show \(ospf | ospf3\) overview](#)

## Verifying Graceful Restart Operation

---

This topic contains the following sections:

- [Graceful Restart Operational Mode Commands on page 2707](#)
- [Verifying BGP Graceful Restart on page 2708](#)
- [Verifying IS-IS and OSPF Graceful Restart on page 2708](#)
- [Verifying CCC and TCC Graceful Restart on page 2709](#)

## Graceful Restart Operational Mode Commands

To verify proper operation of graceful restart, use the following commands:

- **show bgp neighbor** (for BGP graceful restart)
- **show log** (for IS-IS and OSPF/OSPFv3 graceful restart)
- **show (ospf | ospfv3) overview** (for OSPF/OSPFv3 graceful restart)
- **show rsvp neighbor detail** (for RSVP graceful restart—helper router)
- **show rsvp version** (for RSVP graceful restart—restarting router)
- **show ldp session detail** (for LDP graceful restart)
- **show connections** (for CCC and TCC graceful restart)
- **show route instance detail** (for Layer 3 VPN graceful restart and for any protocols using graceful restart in a routing instance)
- **show route protocol l2vpn** (for Layer 2 VPN graceful restart)

For more information about these commands and a description of their output fields, see the [CLI Explorer](#).

## Verifying BGP Graceful Restart

To view graceful restart information for BGP sessions, use the **show bgp neighbor** command:

```
user@PE1> show bgp neighbor 192.255.10.1
Peer: 192.255.10.1+179 AS 64595 Local: 192.255.5.1+1106 AS 64595
 Type: Internal State: Established Flags: <>
 Last State: OpenConfirm Last Event: RecvKeepAlive
 Last Error: None
 Export: [static]
 Options:<Preference LocalAddress HoldTime GracefulRestart Damping PeerAS Refresh>

 Local Address: 192.255.5.1 Holdtime: 90 Preference: 170
 IPsec SA Name: hope
 Number of flaps: 0
 Peer ID: 192.255.10.1 Local ID: 192.255.5.1 Active Holdtime: 90
 Keepalive Interval: 30
 NLRI for restart configured on peer: inet-unicast
 NLRI advertised by peer: inet-unicast
 NLRI for this session: inet-unicast
 Peer supports Refresh capability (2)
 Restart time configured on the peer: 180
 Stale routes from peer are kept for: 180
 Restart time requested by this peer: 300
 NLRI that peer supports restart for: inet-unicast
 NLRI that peer saved forwarding for: inet-unicast
 NLRI that restart is negotiated for: inet-unicast
 NLRI of received end-of-rib markers: inet-unicast
 NLRI of all end-of-rib markers sent: inet-unicast
 Table inet.0 Bit: 10000
 RIB State: restart is complete
 Send state: in sync
 Active prefixes: 0
 Received prefixes: 0
 Suppressed due to damping: 0
 Last traffic (seconds): Received 19 Sent 19 Checked 19
 Input messages: Total 2 Updates 1 Refreshes 0 Octets 42
 Output messages: Total 3 Updates 0 Refreshes 0 Octets 116
 Output Queue[0]: 0
```

## Verifying IS-IS and OSPF Graceful Restart

To view graceful restart information for IS-IS and OSPF, configure traceoptions (see [“Tracking Graceful Restart Events” on page 2586](#)).

Here is the output of a traceoptions log from an OSPF restarting router:

```
Oct 8 05:20:12 Restart mode - sending grace lsas
Oct 8 05:20:12 Restart mode - estimated restart duration timer triggered
Oct 8 05:20:13 Restart mode - Sending more grace lsas
```

Here is the output of a traceoptions log from an OSPF helper router:

```
Oct 8 05:20:14 Helper mode for neighbor 192.255.5.1
Oct 8 05:20:14 Received multiple grace lsa from 192.255.5.1
```

## Verifying CCC and TCC Graceful Restart

To view graceful restart information for CCC and TCC connections, use the **show connections** command. The following example assumes four remote interface CCC connections between CE1 and CE2:

```
user@PE1> show connections
CCC and TCC connections [Link Monitoring On]
Legend for status (St)
UN -- uninitialized
NP -- not present
WE -- wrong encapsulation
DS -- disabled
Dn -- down
-> -- only outbound conn is up
<- -- only inbound conn is up
Up -- operational
RmtDn -- remote CCC down
Restart -- restarting

Legend for connection types
if-sw: interface switching
rmt-if: remote interface switching
lsp-sw: LSP switching

Legend for circuit types
intf -- interface
tlsp -- transmit LSP
rlsp -- receive LSP
```

### CCC Graceful restart : Restarting

| Connection/Circuit | Type   | St      | Time last up | # Up trans |
|--------------------|--------|---------|--------------|------------|
| CE1-CE2-0          | rmt-if | Restart | -----        | 0          |
| fe-1/1/0.0         | intf   | Up      |              |            |
| PE1-PE2-0          | tlsp   | Up      |              |            |
| PE2-PE1-0          | rlsp   | Up      |              |            |
| CE1-CE2-1          | rmt-if | Restart | -----        | 0          |
| fe-1/1/0.1         | intf   | Up      |              |            |
| PE1-PE2-1          | tlsp   | Up      |              |            |

| Last error                                                     | <p>Last error that occurred in the BGP session:</p> <ul style="list-style-type: none"> <li>• <b>Cease</b>—An error occurred, such as a version mismatch, that caused the session to close.</li> <li>• <b>Finite State Machine Error</b>—In setting up the session, BGP received a message that it did not understand.</li> <li>• <b>Hold Time Expired</b>—The session's hold time expired.</li> <li>• <b>Message Header Error</b>—The header of a BGP message was malformed.</li> <li>• <b>Open Message Error</b>—A BGP open message contained an error.</li> <li>• <b>None</b>—No errors occurred in the BGP session.</li> <li>• <b>Update Message Error</b>—A BGP update message contained an error.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Export                                                         | Name of the export policy that is configured on the peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Import                                                         | Name of the import policy that is configured on the peer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Options                                                        | <p>Configured BGP options:</p> <ul style="list-style-type: none"> <li>• <b>AddressFamily</b>—Configured address family: <b>inet</b> or <b>inet-vpn</b>.</li> <li>• <b>AdvertiseBGPStatic</b>—Configured BGP static routes are advertised.</li> <li>• <b>AuthKeyChain</b>—Authentication key change is enabled.</li> <li>• <b>DropPathAttributes</b>—Certain path attributes are configured to be dropped from neighbor updates during inbound processing.</li> <li>• <b>GracefulRestart</b>—Graceful restart is configured.</li> <li>• <b>HoldTime</b>—Hold time configured with the <b>hold-time</b> statement. The hold time is three times the interval at which keepalive messages are sent.</li> <li>• <b>IgnorePathAttributes</b>—Certain path attributes are configured to be ignored in neighbor updates during inbound processing.</li> <li>• <b>Local Address</b>—Address configured with the <b>local-address</b> statement.</li> <li>• <b>LLGR</b>—BGP long-lived graceful restart capability is configured.</li> <li>• <b>LLGRHelperDisabled</b>—BGP long-lived graceful restart is completely disabled for a neighbor.</li> <li>• <b>Multihop</b>—Allow BGP connections to external peers that are not on a directly connected network.</li> <li>• <b>NLRI</b>—Configured MBGP state for the BGP group: <b>multicast</b>, <b>unicast</b>, or both if you have configured <b>nlri any</b>.</li> <li>• <b>Peer AS</b>—Configured peer autonomous system (AS).</li> <li>• <b>Preference</b>—Preference value configured with the <b>preference</b> statement.</li> <li>• <b>Refresh</b>—Configured to refresh automatically when the policy changes.</li> <li>• <b>Rib-group</b>—Configured routing table group.</li> </ul> |
| Path-attributes dropped                                        | Path attribute codes that are dropped from neighbor updates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Path-attributes ignored                                        | Path attribute codes that are ignored during neighbor updates.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Peer does not support LLGR Restarter or Receiver functionality | BGP neighbor does not support long-lived graceful restart (LLGR) restarter mode completely.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

Table 238: show bgp neighbor Output Fields (*continued*)

| Field Name                                         | Field Description                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Peer does not support LLGR Restarter functionality | BGP neighbor does not support long-lived graceful restart (LLGR) restarter mode for any family.                                                                                                                                                                                                                                                                                 |
| Authentication key change                          | (appears only if the <b>authentication-keychain</b> statement has been configured) Name of the authentication keychain enabled.                                                                                                                                                                                                                                                 |
| Authentication algorithm                           | (appears only if the <b>authentication-algorithm</b> statement has been configured) Type of authentication algorithm enabled: <b>hmac</b> or <b>md5</b> .                                                                                                                                                                                                                       |
| Address families configured                        | Names of configured address families for the VPN.                                                                                                                                                                                                                                                                                                                               |
| BGP-Static Advertisement Policy                    | Name of the bgp static policy that is configured on the peer.                                                                                                                                                                                                                                                                                                                   |
| Local Address                                      | Address of the local routing device.                                                                                                                                                                                                                                                                                                                                            |
| Remove-private options                             | Options associated with the <b>remove-private</b> statement.                                                                                                                                                                                                                                                                                                                    |
| Holdtime                                           | Hold time configured with the <b>hold-time</b> statement. The hold time is three times the interval at which keepalive messages are sent.                                                                                                                                                                                                                                       |
| Flags for NLRI inet-label-unicast                  | Flags related to labeled-unicast: <ul style="list-style-type: none"> <li>• <b>TrafficStatistics</b>—Collection of statistics for labeled-unicast traffic is enabled.</li> </ul>                                                                                                                                                                                                 |
| Traffic statistics                                 | Information about labeled-unicast traffic statistics: <ul style="list-style-type: none"> <li>• <b>Options</b>—Options configured for collecting statistics about labeled-unicast traffic.</li> <li>• <b>File</b>—Name and location of statistics log files.</li> <li>• <b>size</b>—Size of all the log files, in bytes.</li> <li>• <b>files</b>—Number of log files.</li> </ul> |
| Traffic Statistics Interval                        | Time between sample periods for labeled-unicast traffic statistics, in seconds.                                                                                                                                                                                                                                                                                                 |
| Preference                                         | Preference value configured with the <b>preference</b> statement.                                                                                                                                                                                                                                                                                                               |
| Outbound Timer                                     | Time for which the route is available in Junos OS routing table before it is exported to BGP. This field is displayed in the output only if the <b>out-delay</b> parameter is configured to a non-zero value.                                                                                                                                                                   |
| Number of flaps                                    | Number of times the BGP session has gone down and then come back up.                                                                                                                                                                                                                                                                                                            |
| Peer ID                                            | Router identifier of the peer.                                                                                                                                                                                                                                                                                                                                                  |
| Group index                                        | Index number for the BGP peer group. The index number differentiates between groups when a single BGP group is split because of different configuration options at the group and peer levels.                                                                                                                                                                                   |

Table 238: show bgp neighbor Output Fields (*continued*)

| Field Name                                                     | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Peer index                                                     | Index that is unique within the BGP group to which the peer belongs.                                                                                                                                                                                                                                                                                                                                                                                  |
| Local ID                                                       | Router identifier of the local routing device.                                                                                                                                                                                                                                                                                                                                                                                                        |
| Local Interface                                                | Name of the interface on the local routing device.                                                                                                                                                                                                                                                                                                                                                                                                    |
| Active holdtime                                                | Hold time that the local routing device negotiated with the peer.                                                                                                                                                                                                                                                                                                                                                                                     |
| Keepalive Interval                                             | Keepalive interval, in seconds.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| BFD                                                            | Status of BFD failure detection.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Local Address                                                  | Name of directly connected interface over which direct EBGp peering is established.                                                                                                                                                                                                                                                                                                                                                                   |
| NLRI and times for LLGR configured on peer                     | <p>Names of address families and stale time for BGP long-lived graceful restart configured on the BGP peer or neighbor.</p> <p>Times are displayed using the routing protocol daemon (rpd) %#OT format:</p> <p><b>&lt;weeks&gt;w&lt;days&gt;d &lt;hours&gt;:&lt;minutes&gt;:&lt;seconds&gt;</b></p> <p>Zero leading elements are omitted, for example, a value less than one week do not include the weeks.</p>                                       |
| NLRI and times that peer supports LLGR Restarter for           | <p>Names of address families and stale time that the BGP peer supports for restarter mode for BGP long-lived graceful restart.</p> <p>Times are displayed using the routing protocol daemon (rpd) %#OT format:</p> <p><b>&lt;weeks&gt;w&lt;days&gt;d &lt;hours&gt;:&lt;minutes&gt;:&lt;seconds&gt;</b></p> <p>Zero leading elements are omitted, for example, a value less than one week do not include the weeks.</p>                                |
| NLRI that peer saved LLGR forwarding for                       | Name of the address family for which the BGP peer saved BGP long-lived graceful restart forwarding.                                                                                                                                                                                                                                                                                                                                                   |
| Graceful Restart Details                                       | Amount of time that is remaining until LLGR expires and the time remaining on the GR stale timer, along with RIB details, are displayed while LLGR receiver mode is active (a peer that negotiated LLGR has disconnected and not yet reconnected)                                                                                                                                                                                                     |
| NLRI we are holding stale routes for                           | Names of address families (NLRIs) for which that stale routes are held or preserved when BGP graceful restart receiver mode is active for a neighbor.                                                                                                                                                                                                                                                                                                 |
| Time until end-of-rib is assumed for stale routes              | <p>Amount of time remaining on the stale timer until which end-of-RIB (EoR) markers are assumed when BGP graceful restart receiver mode is active for a neighbor.</p> <p>Time is displayed in Coordinated Universal Time (UTC) format (YYYY-MM-DD-HH:MM:SS). Note that the stale timer display ('Time until end-of-rib is assumed') is also present when a session is active, but the neighbor as not yet sent all of the end-of-rib indications.</p> |
| Time until stale routes are deleted or become long-lived stale | Amount of time up to which stale routes are deleted or become long-lived stale routes when BGP graceful restart receiver mode is active for a neighbor.                                                                                                                                                                                                                                                                                               |

Table 238: show bgp neighbor Output Fields (*continued*)

| Field Name                                    | Field Description                                                                                                                                                                                           |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NLRI for restart configured on peer           | Names of address families configured for restart.                                                                                                                                                           |
| NLRI advertised by peer                       | Address families supported by the peer: <b>unicast</b> or <b>multicast</b> .                                                                                                                                |
| NLRI for this session                         | Address families being used for this session.                                                                                                                                                               |
| Peer supports Refresh capability              | Remote peer's ability to send and request full route table readvertisement (route refresh capability). For more information, see RFC 2918, <i>Route Refresh Capability for BGP-4</i> .                      |
| Restart time configured on peer               | Configured time allowed for restart on the neighbor.                                                                                                                                                        |
| Stale routes from peer are kept for           | When graceful restart is negotiated, the maximum time allowed to hold routes from neighbors after the BGP session has gone down.                                                                            |
| Peer does not support Restarter functionality | Graceful restart restarter-mode is disabled on the peer.                                                                                                                                                    |
| Peer does not support Receiver functionality  | Graceful restart helper-mode is disabled on the peer.                                                                                                                                                       |
| Restart time requested by this peer           | Restart time requested by this neighbor during capability negotiation.                                                                                                                                      |
| Restart flag received from the peer           | When this field appears, the BGP speaker has restarted (Restarting), and this peer should not wait for the <b>end-of-rib</b> marker from the speaker before advertising routing information to the speaker. |
| NLRI that peer supports restart for           | Neighbor supports graceful restart for this address family.                                                                                                                                                 |
| NLRI peer can save forwarding state           | Neighbor supporting this address family saves all forwarding states.                                                                                                                                        |
| NLRI that peer saved forwarding for           | Neighbor saves all forwarding states for this address family.                                                                                                                                               |
| NLRI that restart is negotiated for           | Router supports graceful restart for this address family.                                                                                                                                                   |
| NLRI of received end-of-rib markers           | Address families for which end-of-routing-table markers are received from the neighbor.                                                                                                                     |
| NLRI of all end-of-rib markers sent           | Address families for which end-of-routing-table markers are sent to the neighbor.                                                                                                                           |
| Peer supports 4 byte AS extension (peer-as 1) | Peer understands 4-byte AS numbers in BGP messages. The peer is running Junos OS Release 9.1 or later.                                                                                                      |

Table 238: show bgp neighbor Output Fields (*continued*)

| Field Name                                                 | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NLRIs for which peer can receive multiple paths            | <p>Appears in the command output of the local router if the downstream peer is configured to receive multiple BGP routes to a single destination, instead of only receiving the active route.</p> <p>Possible value is <b>inet-unicast</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| NLRIs for which peer can send multiple paths: inet-unicast | <p>Appears in the command output of the local router if the upstream peer is configured to send multiple BGP routes to a single destination, instead of only sending the active route.</p> <p>Possible value is <b>inet-unicast</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Table <i>inet.number</i>                                   | <p>Information about the routing table:</p> <ul style="list-style-type: none"> <li>• <b>RIB State</b>—BGP is in the graceful restart process for this routing table: <b>restart is complete</b> or <b>restart in progress</b>.</li> <li>• <b>Bit</b>—Number that represents the entry in the routing table for this peer.</li> <li>• <b>Send state</b>—State of the BGP group: <b>in sync</b>, <b>not in sync</b>, or <b>not advertising</b>.</li> <li>• <b>Active prefixes</b>—Number of prefixes received from the peer that are active in the routing table.</li> <li>• <b>Received prefixes</b>—Total number of prefixes from the peer, both active and inactive, that are in the routing table.</li> <li>• <b>Accepted prefixes</b>—Total number of prefixes from the peer that have been accepted by a routing policy.</li> <li>• <b>Suppressed due to damping</b>—Number of routes currently inactive because of damping or other reasons. These routes do not appear in the forwarding table and are not exported by routing protocols.</li> </ul> |
| Last traffic (seconds)                                     | Last time any traffic was received from the peer or sent to the peer, and the last time the local routing device checked.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Input messages                                             | Messages that BGP has received from the receive socket buffer, showing the total number of messages, number of update messages, number of times a policy is changed and refreshed, and the buffer size in octets. The buffer size is 16 KB.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Output messages                                            | Messages that BGP has written to the transmit socket buffer, showing the total number of messages, number of update messages, number of times a policy is changed and refreshed, and the buffer size in octets. The buffer size is 16 KB.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Input dropped path attributes                              | <p>Information about dropped path attributes:</p> <ul style="list-style-type: none"> <li>• <b>Code</b>—Path attribute code.</li> <li>• <b>Count</b>—Path attribute count.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Input ignored path attributes                              | <p>Information about ignored path attributes:</p> <ul style="list-style-type: none"> <li>• <b>Code</b>—Path attribute code.</li> <li>• <b>Count</b>—Path attribute count.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 238: show bgp neighbor Output Fields (*continued*)

| Field Name                     | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Output queue</b>            | <p>Number of BGP packets that are queued to be transmitted to a particular neighbor for a particular routing table. Output queue <b>0</b> is for unicast NLRIs, and queue <b>1</b> is for multicast NLRIs.</p> <p>It also specifies the routing table name and the NLRI that the table was advertised through, in the format <b>(routing table name, NLRI)</b>.</p> <p><b>NOTE:</b> The output queue of routing tables that are not advertised, will only show up at <b>extensive</b> output level.</p> |
| <b>Trace options</b>           | Configured tracing of BGP protocol packets and operations.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Trace file</b>              | Name of the file to receive the output of the tracing operation.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Filter Updates rcv</b>      | <p>(<b>orf</b> option only) Number of outbound-route filters received for each configured address family.</p> <p><b>NOTE:</b> The counter is cumulative. For example, the counter is increased after the remote peer either resends or clears the outbound route filtering prefix list.</p>                                                                                                                                                                                                             |
| <b>Immediate</b>               | <p>(<b>orf</b> option only) Number of route updates received with the immediate flag set. The immediate flag indicates that the BGP peer should readvertise the updated routes.</p> <p><b>NOTE:</b> The counter is cumulative. For example, the counter is increased after the remote peer either resends or clears the outbound route filtering prefix list.</p>                                                                                                                                       |
| <b>Filter</b>                  | ( <b>orf</b> option only) Type of prefix filter received: <b>prefix-based</b> or <b>extended-community</b> .                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Received filter entries</b> | ( <b>orf</b> option only) List of received filters displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>seq</b>                     | ( <b>orf</b> option only) Numerical order assigned to this prefix entry among all the received outbound route filter prefix entries.                                                                                                                                                                                                                                                                                                                                                                    |
| <b>prefix</b>                  | ( <b>orf</b> option only) Address for the prefix entry that matches the filter.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>minlength</b>               | ( <b>orf</b> option only) Minimum prefix length, in bits, required to match this prefix.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>maxlength</b>               | ( <b>orf</b> option only) Maximum prefix length, in bits, required to match this prefix.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>match</b>                   | ( <b>orf</b> option only) For this prefix match, whether to <b>permit</b> or <b>deny</b> route updates.                                                                                                                                                                                                                                                                                                                                                                                                 |

## Sample Output

| <b>Description</b>                        | List log files, display log file contents, or display information about users who have logged in to the router or switch.                                                                                                                                                                                                                                                                                    |

**NOTE:** On MX Series routers, modifying a configuration to replace a service interface with another service interface is treated as a catastrophic event. When you modify a configuration, the entire configuration associated with the service interface—including NAT pools, rules, and service sets—is deleted and then re-created for the newly specified service interface. If there are active sessions associated with the service interface that is being replaced, these sessions are deleted and the NAT pools are then released, which leads to the generation of the NAT\_POOL\_RELEASE system log messages. However, because NAT pools are already deleted as a result of the catastrophic configuration change and no longer exist, the NAT\_POOL\_RELEASE system log messages are not generated for the changed configuration.

**Options** none—List all log files.

**<all-lcc | lcc *number* | scc>**—(Routing matrix only) (Optional) Display logging information about all T640 routers (or line-card chassis) or a specific T640 router (replace *number* with a value from 0 through 3) connected to a TX Matrix router. Or, display logging information about the TX Matrix router (or switch-card chassis).

**device-type**—(QFabric system only) (Optional) Display log messages for only one of the following device types:

- **director-device**—Display logs for Director devices.
- **infrastructure-device**—Display logs for the logical components of the QFabric system infrastructure, including the diagnostic Routing Engine, fabric control Routing Engine, fabric manager Routing Engine, and the default network Node group and its backup (NW-NG-0 and NW-NG-0-backup).
- **interconnect-device**—Display logs for Interconnect devices.
- **node-device**—Display logs for Node devices.

**NOTE:** If you specify the **device-type** optional parameter, you must also specify either the **device-id** or **device-alias** optional parameter.

**(device-id | device-alias)**—If a device type is specified, display logs for a device of that type. Specify either the device ID or the device alias (if configured).

**filename**—(Optional) Display the log messages in the specified log file. For the routing matrix, the filename must include the chassis information.

**user <username>**—(Optional) Display logging information about users who have recently logged in to the router or switch. If you include **username**, display logging information about the specified user.

**Required Privilege Level** trace

| <b>Output Fields</b>                            | Table 239 lists the output fields for the <b>show ospf overview</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Table 239: show ospf overview Output Fields

| Field name                       | Field Description                                                                                                                                                                        | Level of Output |
|----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| <b>Instance</b>                  | OSPF routing instance.                                                                                                                                                                   | All levels      |
| <b>Router ID</b>                 | Router ID of the routing device.                                                                                                                                                         | All levels      |
| <b>Route table index</b>         | Route table index.                                                                                                                                                                       | All levels      |
| <b>Configured overload</b>       | Overload capability is enabled. If the overload timer is also configured, display the time that remains before it is set to expire. This field is not displayed after the timer expires. | All levels      |
| <b>Topology</b>                  | Topology identifier.                                                                                                                                                                     | All levels      |
| <b>Prefix export count</b>       | Number of prefixes exported into OSPF.                                                                                                                                                   | All levels      |
| <b>Full SPF runs</b>             | Number of complete Shortest Path First calculations.                                                                                                                                     | All levels      |
| <b>SPF delay</b>                 | Delay before performing consecutive Shortest Path First calculations.                                                                                                                    | All levels      |
| <b>SPF holddown</b>              | Delay before performing additional Shortest Path First (SPF) calculations after the maximum number of consecutive SPF calculations is reached.                                           | All levels      |
| <b>SPF rapid runs</b>            | Maximum number of Shortest Path First calculations that can be performed in succession before the hold-down timer begins.                                                                | All levels      |
| <b>LSA refresh time</b>          | Refresh period for link-state advertisement (in minutes).                                                                                                                                | All levels      |
| <b>Database protection state</b> | Current state of database protection.                                                                                                                                                    | All levels      |
| <b>Warning threshold</b>         | Threshold at which a warning message is logged (percentage of maximum LSA count).                                                                                                        | All levels      |
| <b>Non self-generated LSAs</b>   | Number of LSAs whose router ID is not equal to the local router ID: <b>Current</b> , <b>Warning</b> (threshold), and <b>Allowed</b> .                                                    | All levels      |
| <b>Ignore time</b>               | How long the database has been in the ignore state.                                                                                                                                      | All levels      |
| <b>Reset time</b>                | How long the database must stay out of the ignore or isolated state before it returns to normal operations.                                                                              | All levels      |
| <b>Ignore count</b>              | Number of times the database has been in the ignore state: <b>Current</b> and <b>Allowed</b> .                                                                                           | All levels      |
| <b>Restart</b>                   | Graceful restart capability: <b>enabled</b> or <b>disabled</b> .                                                                                                                         | All levels      |
| <b>Restart duration</b>          | Time period for complete reacquisition of OSPF neighbors.                                                                                                                                | All levels      |
| <b>Restart grace period</b>      | Time period for which the neighbors should consider the restarting routing device as part of the topology.                                                                               | All levels      |

Table 239: show ospf overview Output Fields (*continued*)

| Field name                    | Field Description                                                                                                                                    | Level of Output  |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| Graceful restart helper mode  | (OSPFv2) Standard graceful restart helper capability (based on RFC 3623): <b>enabled</b> or <b>disabled</b> .                                        | All levels       |
| Restart-signaling helper mode | (OSPFv2) Restart signaling-based graceful restart helper capability (based on RFC 4811, RFC 4812, and RFC 4813): <b>enabled</b> or <b>disabled</b> . | All levels       |
| Helper mode                   | (OSPFv3) Graceful restart helper capability: <b>enabled</b> or <b>disabled</b> .                                                                     | All levels       |
| Trace options                 | OSPF-specific trace options.                                                                                                                         | <b>extensive</b> |
| Trace file                    | Name of the file to receive the output of the tracing operation.                                                                                     | <b>extensive</b> |
| Area                          | Area number. Area 0.0.0.0 is the backbone area.                                                                                                      | All levels       |
| Stub type                     | Stub type of area: <b>Normal Stub</b> , <b>Not Stub</b> , or <b>Not so Stubby Stub</b> .                                                             | All levels       |
| Authentication Type           | Type of authentication: <b>None</b> , <b>Password</b> , or <b>MD5</b> .                                                                              | All levels       |
| Area border routers           | Number of area border routers.                                                                                                                       | All levels       |
| Neighbors                     | Number of autonomous system boundary routers.                                                                                                        | All levels       |

## Sample Output

### show ospf overview

```

user@host> show ospf overview
Instance: master
 Router ID: 10.255.245.6
 Route table index: 0
 Configured overload, expires in 118 seconds
 LSA refresh time: 50 minutes
Restart: Enabled
 Restart duration: 20 sec
 Restart grace period: 40 sec
 Helper mode: enabled
Area: 0.0.0.0

| <b>Release Information</b>            | Command introduced before Junos OS Release 7.4.<br>Command introduced in Junos OS Release 9.0 for EX Series switches.<br>sfc option introduced for the TX Matrix Plus router in Junos OS Release 9.6.<br>Command introduced in Junos OS Release 13.2X51-D20 for QFX Series switches. |
| <b>Description</b>                    | Display whether graceful Routing Engine switchover is configured, the state of the kernel replication (ready or synchronizing), any replication errors, and whether the primary and standby Routing Engines are using compatible versions of the kernel database.                    |

**NOTE:** Issue the `show system switchover` command *only* on the backup Routing Engine. This command is *not* supported on the master Routing Engine, because the kernel-replication process daemon does not run on the master Routing Engine. This process runs only on the backup Routing Engine.

Beginning Junos OS Release 9.6, the `show system switchover` command has been deprecated on the master Routing Engine on all routers other than a TX Matrix (switch-card chassis) or a TX Matrix Plus (switch-fabric chassis) router.

However, in a routing matrix, if you issue the `show system switchover` command on the master Routing Engine of the TX Matrix router (or switch-card chassis), the CLI displays graceful switchover information for the master Routing Engine of the T640 routers (or line-card chassis) in the routing matrix. Likewise, if you issue the `show system switchover` command on the master Routing Engine of a TX Matrix Plus router (or switch-fabric chassis), the CLI displays output for the master Routing Engine of T1600 or T4000 routers in the routing matrix.

---

**Options** **all-chassis**—(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router, display graceful Routing Engine switchover information for all Routing Engines on the TX Matrix router and the T640 routers configured in the routing matrix. On a TX Matrix Plus router, display graceful Routing Engine switchover information for all Routing Engines on the TX Matrix Plus router and the T1600 or T4000 routers configured in the routing matrix.

**all-lcc**—(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router, display graceful Routing Engine switchover information for all T640 routers (or line-card chassis) connected to the TX Matrix router. On a TX Matrix Plus router, display graceful Routing Engine switchover information for all connected T1600 or T4000 LCCs.

Note that in this instance, packets get dropped. The LCCs perform GRES on their own chassis (GRES cannot be handled by one particular chassis for the entire router) and synchronization is not possible as the LCC plane bringup time varies for each LCC. Therefore, when there is traffic on these planes, there may be a traffic drop.

**all-members**—(MX Series routers only) (Optional) Display graceful Routing Engine switchover information for all Routing Engines on all members of the Virtual Chassis configuration.

**lcc *number***—(TX Matrix routers and TX Matrix Plus routers only) (Optional) On a TX Matrix router, display graceful Routing Engine switchover information for a specific T640 router connected to the TX Matrix router. On a TX Matrix Plus router, display graceful Routing Engine switchover information for a specific router connected to the TX Matrix Plus router.

Replace *number* with the following values depending on the LCC configuration:

- 0 through 3, when T640 routers are connected to a TX Matrix router in a routing matrix.
- 0 through 3, when T1600 routers are connected to a TX Matrix Plus router in a routing matrix.
- 0 through 7, when T1600 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.
- 0, 2, 4, or 6, when T4000 routers are connected to a TX Matrix Plus router with 3D SIBs in a routing matrix.

**local**—(MX Series routers only) (Optional) Display graceful Routing Engines switchover information for all Routing Engines on the local Virtual Chassis member.

**member *member-id***—(MX Series routers only) (Optional) Display graceful Routing Engine switchover information for all Routing Engines on the specified member of the Virtual Chassis configuration. Replace *member-id* with a value of 0 or 1.

**scc**—(TX Matrix router only) (Optional) Display graceful Routing Engine switchover information for the TX Matrix router (or switch-card chassis).

**sfc**—(TX Matrix Plus routers only) (Optional) Display graceful Routing Engine switchover information for the TX Matrix Plus router.

**Additional Information** If you issue the **show system switchover** command on a TX Matrix backup Routing Engine, the command is broadcast to all the T640 backup Routing Engines that are connected to it.

Likewise, if you issue the **show system switchover** command on a TX Matrix Plus backup Routing Engine, the command is broadcast to all the T1600 or T4000 backup Routing Engines that are connected to it.

If you issue the **show system switchover** command on the active Routing Engine in the master router of an MX Series Virtual Chassis, the router displays a message that this command is not applicable on this member of the Virtual Chassis.

Not ready for mastership switch, try after xxx secs.</b></li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                |

## Sample Output

### show system switchover (Backup Routing Engine - Ready)

```
user@host> show system switchover
Graceful switchover: On
Configuration database: Ready
Kernel database: Ready
Peer state: Steady State
Switchover Ready
```

### show system switchover (Backup Routing Engine - Not Ready)

```
user@host> show system switchover
Graceful switchover: On
Configuration database: Ready
Kernel database: Ready
Peer state: Steady State
```

```
error: Command aborted. Not ready for mastership switch, try after 174 secs.
```

### show system switchover (MX Virtual Chassis)

```
{master:member1-re1}
user@host> show system switchover
member0:

Graceful switchover: On
Configuration database: Ready
Kernel database: Ready
Switchover Ready
```

member1:

-----  
Command is not applicable on this member of the virtual-chassis

#### show system switchover (Routing Matrix and Routing Matrix Plus) - Master Ready

```
user@host> show system switchover
lcc0-re1:
```

-----  
Multichassis replication: On  
Configuration database: Ready  
Kernel database: Ready  
Peer state: Steady State  
Switchover Ready

lcc2-re0:

-----  
Multichassis replication: On  
Configuration database: Ready  
Kernel database: Ready  
Peer state: Steady State  
Switchover Ready

#### show system switchover (Routing Matrix and Routing Matrix Plus) - Master Not Ready

```
user@host> show system switchover
lcc0-re1:
```

-----  
Multichassis replication: On  
Configuration database: Ready  
Kernel database: Ready  
Peer state: Steady State  
Switchover Ready

lcc2-re1:

-----  
Multichassis replication: On  
Configuration database: Ready  
Kernel database: Ready  
Peer state: Steady State  
error: Command aborted. Not ready for mastership switch, try after 228 secs.

#### show system switchover (Routing Matrix and Routing Matrix Plus) - Backup Ready

```
user@host> show system switchover
scc-re0:
```

-----  
Graceful switchover: On  
Configuration database: Ready  
Kernel database: Ready  
Switchover Ready

lcc0-re0:

-----  
Graceful switchover: On  
Configuration database: Ready  
Kernel database: Ready  
Switchover Ready

lcc2-re1:

```
Graceful switchover: On
Configuration database: Ready
Kernel database: Ready
Switchover Ready
```

#### show system switchover (Routing Matrix and Routing Matrix Plus) - Backup Not Ready

```
user@host> show system switchover
scc-re0:

Graceful switchover: On
Configuration database: Ready
Kernel database: Ready
error: Command aborted. Not ready for mastership switch, try after 223 secs.

lcc0-re0:

Graceful switchover: On
Configuration database: Ready
Kernel database: Ready
Switchover Ready

lcc2-re1:

Graceful switchover: On
Configuration database: Ready
Kernel database: Ready
Switchover Ready
```

#### show system switchover all-lcc (Routing Matrix and Routing Matrix Plus)

```
user@host> show system switchover all-lcc

lcc0-re0:

Multichassis replication: On
Configuration database: Ready
Kernel database: Ready
Peer state: Steady State
lcc2-re0:

Multichassis replication: On
Configuration database: Ready
Kernel database: Ready
Peer state: Steady State
```

## show task replication

| <b>List of Sample Output</b>    | <a href="#">show task replication (Issued on the Master Routing Engine) on page 2744</a><br><a href="#">show task replication (Issued on the Backup Routing Engine) on page 2745</a>                                                                                                   |
| <b>Output Fields</b>            | Table 241 lists the output fields for the <b>show task replication</b> command. Output fields are listed in the approximate order in which they appear.                                                                                                                                |

**Table 241: show task replication Output Fields**

| Field Name                    | Field Description                                                                                                                                                   |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Stateful replication</b>   | Displays whether or not graceful Routing Engine switchover is configured. The status can be <b>Enabled</b> or <b>Disabled</b> .                                     |
| <b>RE mode</b>                | Displays the Routing Engine on which the command is issued: <b>Master</b> , <b>Backup</b> , or <b>Not applicable</b> (when the router has only one Routing Engine). |
| <b>Protocol</b>               | Protocols that are supported by nonstop active routing.                                                                                                             |
| <b>Synchronization Status</b> | Nonstop active routing synchronization status for the supported protocols. States are <b>NotStarted</b> , <b>InProgress</b> , and <b>Complete</b> .                 |

## Sample Output

### show task replication (Issued on the Master Routing Engine)

```

user@host> show task replication
 Stateful Replication: Enabled
 RE mode: Master

 Protocol Synchronization Status

 OSPF NotStarted
 BGP Complete
 IS-IS NotStarted

```

|     |          |
|-----|----------|
| LDP | Complete |
| PIM | Complete |

#### show task replication (Issued on the Backup Routing Engine)

```
user@host> show task replication
Stateful Replication: Enabled
RE mode: Backup
```

## CHAPTER 109

# Operational Mode Command (Nonstop Routing)

- `show task replication`

Table 243: show vrrp Output Fields (*continued*)

| Field Name                  | Field Description                                                                                                                                                                                                                                                                                              | Level of Output   |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|
| Master router               | IP address of the interface that is acting as the master. If the VRRP interface is down, the output is <b>N/A</b> .                                                                                                                                                                                            | detail, extensive |
| Virtual router uptime       | Time that the virtual router has been up.                                                                                                                                                                                                                                                                      | detail, extensive |
| Master router uptime        | Time that the master router has been up.                                                                                                                                                                                                                                                                       | detail, extensive |
| Virtual MAC                 | MAC address associated with the virtual IP address.                                                                                                                                                                                                                                                            | detail, extensive |
| Tracking                    | Whether tracking is <b>enabled</b> or <b>disabled</b> .                                                                                                                                                                                                                                                        | detail, extensive |
| Current priority            | Current operational priority for being the VRRP master.                                                                                                                                                                                                                                                        | detail, extensive |
| Configured priority         | Configured base priority for being the VRRP master.                                                                                                                                                                                                                                                            | detail, extensive |
| Priority hold-time          | Minimum time interval, in seconds, between successive changes to the current priority. <b>Disabled</b> indicates no minimum interval.                                                                                                                                                                          | detail, extensive |
| Remaining-time              | ( <b>track</b> option only) Displays the time remaining in the priority hold-time interval.                                                                                                                                                                                                                    | detail            |
| Interface tracking          | Whether interface tracking is enabled or disabled. When enabled, the output also displays the number of tracked interfaces.                                                                                                                                                                                    | detail extensive  |
| Interface/Tracked interface | Name of the tracked interface.                                                                                                                                                                                                                                                                                 | detail extensive  |
| Int state/Interface state   | Current operational state of the tracked interface: <b>up</b> or <b>down</b> .                                                                                                                                                                                                                                 | detail, extensive |
| Int speed/Speed             | Current operational speed, in bits per second, of the tracked interface.                                                                                                                                                                                                                                       | detail, extensive |
| Incurred priority cost      | Operational priority cost incurred due to the state and speed of this tracked interface. This cost is applied to the configured priority to obtain the current priority.                                                                                                                                       | detail, extensive |
| Threshold                   | Speed below which the corresponding priority cost is incurred. In other words, when the speed of the interface drops below the threshold speed, the corresponding priority cost is incurred.<br><br>An entry of <b>down</b> means that the corresponding priority cost is incurred when the interface is down. | detail, extensive |
| Route tracking              | Whether route tracking is enabled or disabled. When enabled, the output also displays the number of tracked routes.                                                                                                                                                                                            | detail, extensive |
| Route count                 | The number of routes being tracked.                                                                                                                                                                                                                                                                            | detail, extensive |

Table 243: show vrrp Output Fields (*continued*)

| Field Name                               | Field Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Level of Output          |

## Understanding Ethernet OAM Link Fault Management for an EX Series Switch

---

Juniper Networks Junos operating system (Junos OS) for Juniper Networks EX Series Ethernet Switches allows the Ethernet interfaces on these switches to support the IEEE 802.3ah standard for the Operation, Administration, and Maintenance (OAM) of Ethernet in access networks. The standard defines OAM link fault management (LFM). You can configure IEEE 802.3ah OAM LFM on point-to-point Ethernet links that are connected either directly or through Ethernet repeaters. The IEEE 802.3ah standard meets the requirement for OAM capabilities even as Ethernet moves from being solely an enterprise technology to a WAN and access technology, and the standard remains backward-compatible with existing Ethernet technology.

Ethernet OAM provides the tools that network management software and network managers can use to determine how a network of Ethernet links is functioning. Ethernet OAM should:

- Rely only on the media access control (MAC) address or virtual LAN identifier for troubleshooting.
- Work independently of the actual Ethernet transport and function over physical Ethernet ports or a virtual service such as pseudowire.
- Isolate faults over a flat (or single operator) network architecture or nested or hierarchical (or multiprovider) networks.

The following OAM LFM features are supported on EX Series switches:

- Discovery and Link Monitoring

The discovery process is triggered automatically when OAM is enabled on the interface. The discovery process permits Ethernet interfaces to discover and monitor the peer

on the link if it also supports the IEEE 802.3ah standard. You can specify the discovery mode used for IEEE 802.3ah OAM support. In active mode, the interface discovers and monitors the peer on the link if the peer also supports IEEE 802.3ah OAM functionality. In passive mode, the peer initiates the discovery process. After the discovery process has been initiated, both sides participate in discovery. The switch performs link monitoring by sending periodic OAM protocol data units (PDUs) to advertise OAM mode, configuration, and capabilities.

You can specify the number of OAM PDUs that an interface can miss before the link between peers is considered down.

- Remote Fault Detection

Remote fault detection uses flags and events. Flags are used to convey the following: Link Fault means a loss of signal, Dying Gasp means an unrecoverable condition such as a power failure, and Critical Event means an unspecified vendor-specific critical event. You can specify the periodic OAM PDU sending interval for fault detection. The EX Series switch uses the Event Notification OAM PDU to notify the remote OAM device when a problem is detected. You can specify the action to be taken by the system when the configured link-fault event occurs.

- Remote Loopback Mode

Remote loopback mode ensures link quality between the switch and a remote peer during installation or troubleshooting. In this mode, when the interface receives a frame that is not an OAM PDU or a pause frame, it sends it back on the same interface on which it was received. The link appears to be in the active state. You can use the returned loopback acknowledgement to test delay, jitter, and throughput.

Junos OS can place a remote DTE into loopback mode (if remote loopback mode is supported by the remote DTE). When you place a remote DTE into loopback mode, the interface receives the remote loopback request and puts the interface into remote loopback mode. When the interface is in remote loopback mode, all frames except OAM PDUs are looped back without any changes made to the frames. OAM PDUs continue to be sent and processed.

- [Example: Configuring Ethernet OAM Link Fault Management on EX Series Switches on page 2770](#)

---

## Configuring Ethernet OAM Link Fault Management (CLI Procedure)

Ethernet OAM link fault management (LFM) can be used for physical link-level fault detection and management. The IEEE 802.3ah LFM works across point-to-point Ethernet links either directly or through repeaters.

To configure Ethernet OAM LFM using the CLI:

1. Enable IEEE 802.3ah OAM support on an interface:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name
```

**NOTE:** You can configure Ethernet OAM LFM on aggregated interfaces.

**NOTE:** The remaining steps are optional. You can choose which of these features to configure for Ethernet OAM LFM on your switch.

2. Specify whether the interface or the peer initiates the discovery process by configuring the link discovery mode to **active** or **passive** (**active** = interface initiates; **passive** = peer initiates):

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name link-discovery active
```

3. Configure a periodic OAM PDU-sending interval (in milliseconds) for fault detection:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name pdu-interval interval
```

4. Specify the number of OAM PDUs that an interface can miss before the link between peers is considered down:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name pdu-threshold threshold-value
```

5. Configure event threshold values on an interface for the local errors that trigger the sending of link event TLVs:

- Set the threshold value (in seconds) for sending frame-error events or taking the action specified in the action profile:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name event-thresholds frame-error count
```

- Set the threshold value (in seconds) for sending frame-period events or taking the action specified in the action profile:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name event-thresholds frame-period count
```

- Set the threshold value (in seconds) for sending frame-period-summary events or taking the action specified in the action profile:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name event-thresholds frame-period-summary count
```

- Set the threshold value (in seconds) for sending symbol-period events or taking the action specified in the action profile:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name event-thresholds symbol-period count
```

**NOTE:** You can disable the sending of link event TLVs.

To disable the sending of link event TLVs:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name negotiation-options no-allow-link-events
```

6. Create an action profile to define event fault flags and thresholds to be taken when the link fault event occurs. Then apply the action profile to one or more interfaces. (You can also apply multiple action profiles to a single interface.)

- a. Name the action profile:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set action-profile profile-name
```

- b. Specify actions to be taken by the system when the link fault event occurs:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set action-profile profile-name action syslog
user@switch# set action-profile profile-name action link-down
```

- c. Specify events for the action profile:

```
[edit protocols oam ethernet link-fault-management]
user@switch# set action-profile profile-name event link-adjacency-loss
```

**NOTE:** For each action profile, you must specify at least one link event and one action. The actions are taken only when all of the events in the action profile are true. If more than one action is specified, all actions are executed. You can set a low threshold for a specific action such as logging the error and set a high threshold for another action such as system logging.

7. Set a remote interface into loopback mode so that all frames except OAM PDUs are looped back without any changes made to the frames. Set the remote DTE in loopback mode (the remote DTE must support remote-loopback mode) and then enable remote loopback support for the local interface.

```
[edit protocols oam ethernet link-fault-management]
user@switch# set interface interface-name remote-loopback
user@switch# set interface interface-name negotiation-options allow-remote-loopback
```

## Example: Configuring Ethernet OAM Link Fault Management on EX Series Switches

---

Junos OS for EX Series switches allows the Ethernet interfaces on these switches to support the IEEE 802.3ah standard for the Operation, Administration, and Maintenance (OAM) of Ethernet in access networks. The standard defines OAM link fault management (LFM). You can configure IEEE 802.3ah OAM LFM on point-to-point Ethernet links that are connected either directly or through Ethernet repeaters.

This example describes how to enable and configure OAM LFM on a Gigabit Ethernet interface:

- [Requirements on page 2771](#)
- [Overview and Topology on page 2771](#)
- [Configuring Ethernet OAM Link Fault Management on Switch 1 on page 2771](#)
- [Configuring Ethernet OAM Link Fault Management on Switch 2 on page 2772](#)
- [Verification on page 2773](#)

## Requirements

This example uses the following hardware and software components:

- Junos OS Release 9.4 or later for EX Series switches
- Two EX3200 or EX4200 switches connected directly

## Overview and Topology

Junos OS for EX Series switches allows the Ethernet interfaces on these switches to support the IEEE 802.3ah standard for the Operation, Administration, and Maintenance (OAM) of Ethernet in access networks. The standard defines OAM link fault management (LFM). You can configure IEEE 802.3ah OAM LFM on point-to-point Ethernet links that are connected either directly or through Ethernet repeaters.

This example uses two EX4200 switches connected directly. Before you begin configuring Ethernet OAM LFM on two switches, connect the two switches directly through a trunk interface.

## Configuring Ethernet OAM Link Fault Management on Switch 1

**CLI Quick Configuration** To quickly configure Ethernet OAM LFM, copy the following commands and paste them into the switch terminal window:

```
[edit protocols oam ethernet link-fault-management]
set interface ge-0/0/0
set interface ge-0/0/0 link-discovery active
set interface ge-0/0/0 pdu-interval 800
set interface ge-0/0/0 remote-loopback
```

**Step-by-Step Procedure** To configure Ethernet OAM LFM on switch 1:

1. Enable IEEE 802.3ah OAM support on an interface:
 

```
[edit protocols oam ethernet link-fault-management]
user@switch1# set interface (OAM LFM) ge-0/0/0
```
2. Specify that the interface initiates the discovery process by configuring the link discovery mode to **active**:
 

```
[edit protocols oam ethernet link-fault-management]
user@switch1# set interface ge-0/0/0 link-discovery active
```
3. Set the periodic OAM PDU-sending interval (in milliseconds) to 800 on switch 1:
 

```
[edit protocols oam ethernet link-fault-management]
user@switch1# set interface pdu-interval 800
```

4. Set a remote interface into loopback mode so that all frames except OAM PDUs are looped back without any changes made to the frames. Ensure that the remote DTE supports remote loopback mode. To set the remote DTE in loopback mode

```
[edit protocols oam ethernet link-fault-management]
user@switch1# set interface ge-0/0/0.0 remote-loopback
```

## Results

---

Check the results of the configuration:

```
[edit]
user@switch1# show

protocols {
 oam {
 ethernet {
 link-fault-management {
 interface ge-0/0/0 {
 pdu-interval 800;
 link-discovery active;
 remote-loopback;
 }
 }
 }
 }
}
```

## Configuring Ethernet OAM Link Fault Management on Switch 2

**CLI Quick Configuration** To quickly configure Ethernet OAM LFM on switch 2, copy the following commands and paste them into the switch terminal window:

```
[edit protocols oam ethernet link-fault-management]
set interface ge-0/0/1
set interface ge-0/0/1 negotiation-options allow-remote-loopback
```

**Step-by-Step Procedure** To configure Ethernet OAM LFM on switch 2:

1. Enable OAM on the peer interface on switch 2:

```
[edit protocols oam ethernet link-fault-management]
user@switch2# set interface ge-0/0/1
```

2. Enable remote loopback support for the local interface:

```
[edit protocols oam ethernet link-fault-management]
user@switch2# set interface ge-0/0/1 negotiation-options allow-remote-loopback
```

**Results** Check the results of the configuration:

```
[edit]
user@switch2# show

protocols {
 oam {
 ethernet {
 link-fault-management {
 interface ge-0/0/1 {
 negotiation-options {
```

```

 allow-remote-loopback;
 }
}
}
}
}

```

## Verification

### Verifying That OAM LFM Has Been Configured Properly

- Purpose** Verify that OAM LFM has been configured properly.
- Action** Use the `show oam ethernet link-fault-management` command:
- ```
user@switch1#show oam ethernet link-fault-management
```

Sample Output

```

Interface: ge-0/0/0.0
Status: Running, Discovery state: Send Any
Peer address: 00:19:e2:50:3b:e1
Flags:Remote-Stable Remote-State-Valid Local-Stable 0x50
Remote entity information:
Remote MUX action: forwarding, Remote parser action: forwarding
Discovery mode: active, Unidirectional mode: unsupported
Remote loopback mode: supported, Link events: supported
Variable requests: unsupported

```

- Meaning** When the output displays the MAC address and the discover state is **Send Any**, it means that OAM LFM has been configured properly.

Generic Routing Encapsulation (GRE)

- [Understanding GRE on page 2777](#)

CHAPTER 112

Understanding GRE

- [Understanding Generic Routing Encapsulation on page 2777](#)
- [Configuring Generic Routing Encapsulation Tunneling on page 2780](#)
- [Verifying That Generic Routing Encapsulation Tunneling Is Working Correctly on page 2781](#)

Understanding Generic Routing Encapsulation

Generic routing encapsulation (GRE) provides a private, secure path for transporting packets through an otherwise public network by encapsulating (or tunneling) the packets.

This topic describes:

- [Overview of GRE on page 2777](#)
- [GRE Tunneling on page 2778](#)
- [Using a Firewall Filter to De-encapsulate GRE Traffic on a QFX5100 and OCX Series Switches on page 2779](#)
- [Configuration Limitations on page 2780](#)

Overview of GRE

GRE encapsulates data packets and redirects them to a device that de-encapsulates them and routes them to their final destination. This allows the source and destination switches to operate as if they have a virtual point-to-point connection with each other (because the outer header applied by GRE is transparent to the encapsulated payload packet). For example, GRE tunnels allow routing protocols such as RIP and OSPF to forward data packets from one switch to another switch across the Internet. In addition, GRE tunnels can encapsulate multicast data streams for transmission over the Internet.

GRE is described in RFC 2784 (obsoletes earlier RFCs 1701 and 1702). The switches support RFC 2784, but not completely. (For a list of limitations, see [“Configuration Limitations” on page 2780.](#))

As a *tunnel source router*, the switch encapsulates a payload packet for transport through the tunnel to a destination network. The payload packet is first encapsulated in a GRE packet, and then the GRE packet is encapsulated in a delivery protocol. The switch performing the role of a *tunnel remote router* extracts the tunneled packet and forwards the packet to its destination. Note that you can use one firewall term to terminate many GRE tunnels on a QFX5100 switch.

GRE Tunneling

Data is routed by the system to the GRE endpoint over routes established in the route table. (These routes can be statically configured or dynamically learned by routing protocols such as RIP or OSPF.) When a data packet is received by the GRE endpoint, it is de-encapsulated and routed again to its destination address.

GRE tunnels are *stateless*—that is, the endpoint of the tunnel contains no information about the state or availability of the remote tunnel endpoint. Therefore, the switch operating as a tunnel source router cannot change the state of the GRE tunnel interface to down if the remote endpoint is unreachable.

For details about GRE tunneling, see:

- [Encapsulation and De-Encapsulation on the Switch on page 2778](#)
- [Number of Source and Destination Tunnels Allowed on a Switch on page 2778](#)
- [Class of Service on GRE Tunnels on page 2779](#)
- [Applying Firewall Filters to GRE Traffic on page 2779](#)

Encapsulation and De-Encapsulation on the Switch

Encapsulation—A switch operating as a tunnel source router encapsulates and forwards GRE packets as follows:

1. When a switch receives a data packet (payload) to be tunneled, it sends the packet to the tunnel interface.
2. The tunnel interface encapsulates the data in a GRE packet and adds an outer IP header.
3. The IP packet is forwarded on the basis of the destination address in the outer IP header.

De-encapsulation—A switch operating as a tunnel remote router handles GRE packets as follows:

1. When the destination switch receives the IP packet from the tunnel interface, the outer IP header and GRE header are removed.
2. The packet is routed based on the inner IP header.

Number of Source and Destination Tunnels Allowed on a Switch

QFX5100 and OCX Series switches support as many as 512 GRE tunnels, including tunnels created with a firewall filter. That is, you can create a total of 512 GRE tunnels, regardless of which method you use.

EX switches support as many as 500 GRE tunnels between switches transmitting IPv4 or IPv6 payload packets over GRE. If a passenger protocol in addition to IPv4 and IPv6 is used, you can configure up to 333 GRE tunnels between the switches.

An EX switch can have a maximum of 20 tunnel source IP addresses configured, and each tunnel source IP can be configured with up to 20 destination IP addresses on a second switch. As a result, the two connected switches can have a maximum of 400 GRE tunnels. If the first switch is also connected to a third switch, the possible maximum number of tunnels is 500.

Class of Service on GRE Tunnels

When a network experiences congestion and delay, some packets might be dropped. Junos OS class of service (CoS) divides traffic into classes to which you can apply different levels of throughput and packet loss when congestion occurs and thereby set rules for packet loss. For details about CoS, see [Junos OS CoS for EX Series Switches Overview](#).

The following CoS components are available on a switch operating as a GRE tunnel source router or GRE tunnel remote router:

- At the GRE tunnel source—On a switch operating as a tunnel source router, you can apply CoS classifiers on an *ingress port* or on a *GRE port*, with the following results on CoS component support on tunneled packets:
 - Schedulers only—Based on the CoS classification on the ingress port, you can apply CoS schedulers on a GRE port of the switch to define output queues and control the transmission of packets through the tunnel after GRE encapsulation. However, you cannot apply CoS rewrite rules to these packets.
 - Schedulers and rewrite rules—Depending on the CoS classification on the GRE port, you can apply both schedulers and rewrite rules to the encapsulated packets transmitted through the tunnel.
- At the GRE tunnel endpoint—When the switch is a tunnel remote router, you can apply CoS classifiers on the GRE port and schedulers and rewrite rules on the egress port to control the transmission of a de-encapsulated GRE packet out from the egress port.

Applying Firewall Filters to GRE Traffic

Firewall filters provide rules that define whether to permit, deny, or forward packets that are transiting an interface on a switch. (For details, see [Firewall Filters for EX Series Switches Overview](#).) Because of the encapsulation and de-encapsulation performed by GRE, you are constrained as to where you can apply a firewall filter to filter tunneled packets and which header will be affected. [Table 244](#) identifies these constraints.

Table 244: Firewall Filter Application Points for Tunneled Packets

Endpoint Type	Ingress Interface	Egress Interface
Source (encapsulating)	inner header	outer header
Remote (de-encapsulating)	Cannot filter packets on ingress interface	inner header

Using a Firewall Filter to De-encapsulate GRE Traffic on a QFX5100 and OCX Series Switches

You can also use a firewall filter to de-encapsulate GRE traffic on switches. This feature provides significant benefits in terms of scalability, performance, and flexibility because

you don't need to create a tunnel interface to perform the de-encapsulation. For example, you can terminate many tunnels from multiple source IP addresses with one firewall term. See *Configuring a Firewall Filter to De-encapsulate GRE Traffic on a QFX5100 Switch* for information about how to configure a firewall filter for this purpose.

Configuration Limitations

Table 245 lists features that are not supported with GRE.

Table 245: Features Not Supported with GRE

EX Switches	QFX Switches
MPLS over GRE tunnels	MPLS over GRE tunnels
GRE keepalives	GRE keepalives
GRE keys, payload packet fragmentation, and sequence numbers for fragmented packets	GRE keys, payload packet fragmentation, and sequence numbers for fragmented packets
BGP dynamic tunnels	BGP dynamic tunnels
Outer IP address must be IPv4	Outer IP address must be IPv4
Virtual routing instances	
Bidirectional Forwarding Detection (BFD) protocol over GRE distributed mode	
OSPF limitation—Enabling OSPF on a GRE interface creates two equal-cost routes to the destination: one through the Ethernet network or uplink interface and the other through the tunnel interface. If data is routed through the tunnel interface, the tunnel might fail. To keep the interface operational, we recommend that you use a static route, disable OSPF on the tunnel interface, or configure the peer not to advertise the tunnel destination over the tunnel interface.	

- Related Documentation**
- [Configuring Generic Routing Encapsulation Tunneling \(CLI Procedure\)](#)
 - [Configuring Generic Routing Encapsulation Tunneling on page 2780](#)
 - [Configuring a Firewall Filter to De-encapsulate GRE Traffic on a QFX5100 Switch](#)

Configuring Generic Routing Encapsulation Tunneling

Generic routing encapsulation (GRE) provides a private, secure path for transporting packets through an otherwise public network by encapsulating (or tunneling) the packets. GRE tunneling is accomplished through tunnel endpoints that encapsulate or de-encapsulate traffic.

You can also use a firewall filter to de-encapsulate GRE traffic on QFX5100 and OCX Series switches. This feature provides significant benefits in terms of scalability, performance, and flexibility because you don't need to create a tunnel interface to perform the de-encapsulation. For example, you can terminate many tunnels from multiple source

IP addresses with one firewall term. For more information on this feature, see *Configuring a Firewall Filter to De-encapsulate GRE Traffic on a QFX5100 Switch*.

This topic describes:

1. [Configuring a GRE Tunnel on page 2781](#)

Configuring a GRE Tunnel

To configure a GRE tunnel interface:

1. Create a GRE interface with a unit number and address:

```
[edit interfaces]
user@switch# set gr-0/0/0 unit number family inet address
```

NOTE: The base name of the interface must be `gr-0/0/0`.

This is a pseudo interface, and the address you specify can be any IP address. The routing table must specify `gr-0/0/0.x` as the outgoing interface for any packets that will be tunneled.

If you configure a GRE interface on a QFX5100 switch that is a member of a Virtual Chassis and later change the Virtual Chassis member number of the switch, the name of the GRE interface does not change in any way (because it is a pseudo interface). For example, if you change the member number from `0` to `5`, the GRE interface name does *not* change from `gr-0/0/0.x` to `gr-5/0/0.x`.

2. Specify the tunnel source address for the logical interface:

```
[edit interfaces]
user@switch# set gr-0/0/0 unit number tunnel (Legacy Switches) source
source-address
```

3. Specify the destination address:

```
[edit interfaces]
user@switch# set gr-0/0/0 unit number tunnel (Legacy Switches) destination
destination-address
```

The destination address must be reachable through static or dynamic routing. If you use static routing, you must get the destination MAC address (for example, by using `ping`) before user traffic can be forwarded through the tunnel.

Related Documentation

- [Verifying That Generic Routing Encapsulation Tunneling Is Working Correctly on page 2781](#)
- [Understanding Generic Routing Encapsulation on page 2777](#)
- [Configuring a Firewall Filter to De-encapsulate GRE Traffic on a QFX5100 Switch](#)

Verifying That Generic Routing Encapsulation Tunneling Is Working Correctly

Purpose Verify that the generic routing encapsulation (GRE) interface is sending tunneled traffic.

Action Display status information about the specified GRE interface by using the command [show interfaces](#).

```
user@switch> show interfaces gr-0/0/0.0
Physical interface: gr-0/0/0, Enabled, Physical link is Up
Interface index: 132, SNMP ifIndex: 26
  Type: GRE, Link-level type: GRE, MTU: Unlimited, Speed: 800mbps
  Device flags   : Present Running
  Interface flags: Point-To-Point SNMP-Traps
  Input rate     : 0 bps (0 pps)
  Output rate    : 0 bps (0 pps)

Logical interface gr-0/0/0.0 (Index 68) (SNMP ifIndex 47)
  Flags: Point-To-Point SNMP-Traps 16384
  IP-Header 1.1.1.2:1.1.1.1:47:df:64:0000000000000000 Encapsulation: GRE-NULL
  Input packets : 0
  Output packets: 0
  Protocol inet, MTU: 1476
    Flags: None
    Addresses, Flags: Is-Primary
      Local: 1.10.1.1
```

Meaning The output indicates that the GRE interface gr-0/0/0 is up. The output displays the name of the physical interface and the traffic statistics for this interface---the number of and the rate at which input and output bytes and packets are received and transmitted on the physical interface.

Interfaces Overview

Juniper Networks devices have two types of interfaces: network interfaces and special interfaces. This topic provides brief information about these interfaces. For additional information, see the *Junos OS Network Interfaces Library for Routing Devices*.

- [Network Interfaces on page 2785](#)
- [Special Interfaces on page 2786](#)

Network Interfaces

Network interfaces connect to the network and carry network traffic. [Table 246](#) lists the types of network interfaces supported.

Table 246: Network Interface Types and Purposes

Type	Purpose
Aggregated Ethernet interfaces	You can group Ethernet interfaces at the physical layer to form a single link-layer interface, also known as a <i>link aggregation group (LAG)</i> or <i>bundle</i> . These aggregated Ethernet interfaces help to balance traffic and increase the uplink bandwidth.

Table 246: Network Interface Types and Purposes (*continued*)

Type	Purpose
Channelized Interfaces	<p>Depending on the device and software package, 40-Gbps QSFP+ ports can be configured to operate as the following types of interfaces:</p> <ul style="list-style-type: none"> • 10-Gigabit Ethernet interfaces (<i>xe</i>) • 40-Gigabit Ethernet interfaces (<i>et</i> and <i>xle</i>) • 40-Gigabit data plane uplink interfaces (<i>fte</i>) <p>When an <i>et</i> port is channelized to four <i>xe</i> ports, a colon is used to signify the four separate channels. For example, on a QFX3500 standalone switch with port 2 on PIC 1 configured as four 10-Gigabit Ethernet ports, the interface names are <i>xe-0/1/2:0</i>, <i>xe-0/1/2:1</i>, <i>xe-0/1/2:2</i>, and <i>xe-0/1/2:3</i>.</p> <p>NOTE: You cannot configure channelized interfaces to operate as Virtual Chassis ports.</p>
Ethernet Interfaces	You can configure Gigabit Ethernet, 10-Gigabit Ethernet, 40-Gigabit Ethernet interfaces to connect to other servers, storage, and switches. You can configure 40-Gigabit data plane uplink ports to connect a Node device to an Interconnect devices as well as for Virtual Chassis ports (VCPs).
Fibre Channel interfaces	You can use Fibre Channel interfaces to connect the switch to a Fibre Channel over Ethernet (FCoE) forwarder or a Fibre Channel switch in a storage area network (SAN). You can configure Fibre Channel interfaces only on ports 0 through 5 and 42 through 47 on QFX3500 devices. Fibre Channel interfaces do not forward Ethernet traffic.
LAN access interfaces	You can use these interfaces to connect to other servers, storage, and switches. When you power on a QFX Series product and use the factory-default configuration, the software automatically configures interfaces in access mode for each of the network ports.
Multichassis aggregated Ethernet (MC-AE) interfaces	You can group a LAG on one standalone switch with a LAG on another standalone switch to create a MC-AE. The MC-AE provides load balancing and redundancy across the two standalone switches.
Tagged-access mode interfaces	You can use tagged-access interfaces to connect a switch to an access layer device. Tagged-access interfaces can accept VLAN-tagged packets from multiple VLANs.
Trunk interfaces	You can use trunk interfaces to connect to other switches or routers. To use a port for this type of connection, you must explicitly configure the port interface for trunk mode. The interfaces from the switches or routers must also be configured for trunk mode. In this mode, the interface can be in multiple VLANs and accept tagged packets from multiple devices. Trunk interfaces typically connect to other switches and to routers on the LAN.
Virtual Chassis ports (VCPs)	You can use Virtual Chassis ports to send and receive Virtual Chassis Control Protocol (VCCP) traffic, and to create, monitor, and maintain the Virtual Chassis. On QFX3500, QFX3600, QFX5100, and EX4600 standalone switches, you can configure 40-Gigabit Ethernet QSFP+ uplink ports (non-channelized) or fixed SFP+ 10-Gigabit Ethernet ports as VCPs by issuing the request virtual-chassis-vc-port-set CLI command.

Special Interfaces

Table 247 lists the types of special interfaces supported.

Table 247: Special Interface Types and Purposes

Type	Purpose
Console port	Each device has a serial console port, labeled CON or CONSOLE , for connecting tty-type terminals to the switch. The console port does not have a physical address or IP address associated with it. However, it is an interface in the sense that it provides access to the switch.
Loopback interface	A software-only virtual interface that is always up. The loopback interface provides a stable and consistent interface and IP address on the switch.
Management interface	<p>The management Ethernet interface provides an out-of-band method for connecting to a standalone switch and QFabric system.</p> <p>NOTE: On OCX Series switches, the em0 management interface always has the status up in show command outputs, even if the physical port is empty. The me0 interface is a virtual interface between Junos and the host operating system, therefore its status is independent from the status of the physical port.</p>
Routed VLAN interfaces (RVI and IRB interfaces)	<p>Layer 3 routed VLAN interfaces (called RVI in the original CLI, and called IRB in Enhanced Layer 2 Software) route traffic from one broadcast domain to another and perform other Layer 3 functions such as traffic engineering. These functions are typically performed by a router interface in a traditional network.</p> <p>The RVI or IRB functions as a logical router, eliminating the need for having both a switch and a router. The RVI or IRB must be configured as part of a broadcast domain or virtual private LAN service (VPLS) routing instance for Layer 3 traffic to be routed out of it.</p>

Understanding Interface Naming Conventions

The QFX Series and the EX4600 device uses a naming convention for defining the interfaces that is similar to that of other platforms running under Juniper Networks Junos OS. This topic provides brief information about the naming conventions used for interfaces on the QFX Series and on EX4600 switches.

This topic describes:

- [Physical Part of an Interface Name on page 2788](#)
- [Logical Part of an Interface Name on a Switch Running QFabric Software Package on page 2794](#)
- [Logical Part of a Channelized Interface Name on a Switch Running Enhanced Layer 2 Software on page 2795](#)
- [Wildcard Characters in Interface Names on page 2795](#)

Physical Part of an Interface Name

Interfaces in Junos OS are specified as follows:

device-name:type-fpc/pic/port

The convention is as follows:

- *device-name*—(QFabric systems only) The *device-name* is either the serial number or the alias of the QFabric system component, such as a Node device, Interconnect device, or QFabric infrastructure. The name can contain a maximum of 128 characters and cannot contain any colons.
- *type*—The QFX Series and EX4600 device interfaces use the following media types:
 - **fc**—Fibre Channel interface
 - **ge**—Gigabit Ethernet interface
 - **xe**—10-Gigabit Ethernet interface
 - **xle**—40-Gigabit Ethernet interface (QFX3500, QFX3600, and QFX5100 switches running a QFabric software package)
 - **et**—40-Gigabit Ethernet interface (QFX3500, QFX3600, QFX5100, QFX10000, and EX4600 switches running Enhanced Layer 2 Software)
 - **fte**—40-Gigabit data plane uplink interface (QFX3500, QFX3600, and QFX5100 switches running a QFabric software package)
 - **me**—Management interface
 - **em**—Management interface on QFX5100 and EX4600 switches.
- *fpc*—Flexible PIC Concentrator. QFX Series interfaces use the following convention for the FPC number in interface names:
 - On QFX3500, QFX3600, QFX5100 devices running a QFabric software package, and QFX10002 switches, the FPC number is always **0**.

The FPC number indicates the slot number of the line card that contains the physical interface.

- On QFX3500, QFX3600, QFX5100, EX4600, and QFX10002 switches running Enhanced Layer 2 Software, the member ID of a member in a Virtual Chassis determines the FPC number.

NOTE: Every member in a Virtual Chassis must have a unique member ID, otherwise the Virtual Chassis will not be created.

- On standalone QFX5100, EX4600, and QFX10002 switches, the FPC number is always **0**.
- *pic*—QFX Series and EX4600 device interfaces use the following convention for the PIC (Physical Interface Card) number in interface names:

- On a QFX3500 switch running a QFabric software package, PIC 0 can support 48 ports, PIC 1 can support 16 10-Gigabit Ethernet ports, and PIC 2 can support 4 40-Gigabit Ethernet ports.
- On a QFX3500 switch running Enhanced Layer 2 software, PIC 0 can support 48 ports, and PIC 1 can support 16 10-Gigabit Ethernet ports, and 4 40-Gigabit Ethernet ports.
- On a QFX3500 Node device running a QFabric software package, PIC 0 can support 48 ports and PIC 1 can support four 40-Gigabit data plane uplink ports.
- On a QFX3600 switch running a QFabric software package, PIC 0 can support 64 10-Gigabit Ethernet ports, and PIC 1 can support 16 40-Gigabit Ethernet ports.
- On a QFX3600 switch running Enhanced Layer 2 software, PIC 0 can support 64 10-Gigabit Ethernet ports and can also support 16 40-Gigabit Ethernet ports.
- On a QFX3600 Node device running a QFabric software package, PIC 0 can support 56 10-Gigabit Ethernet ports, and PIC 1 can support 8 40-Gigabit data plane uplink ports, and up to 14 40-Gigabit Ethernet ports.
- On a QFX5100-48S switch running Enhanced Layer 2 software, PIC 0 provides six 40-Gbps QSFP+ ports and 48 10-Gigabit Ethernet interfaces.
- On an EX4600 device running Enhanced Layer 2 software, PIC 0 provides 4 40-Gbps QSFP+ ports and 24 10-Gigabit Ethernet interfaces. There are two expansion bays (PIC 1 and PIC 2), and you can insert QFX-EM-4Q expansion modules and EX4600-EM-8F expansion modules. The QFX-EM-4Q expansion module provide 4 40-Gbps QSFP+ ports. The EX4600-EM-8F expansion module provides 8 40-Gbps QSFP+ ports. You can insert any combination of expansion modules. For example, you can insert two EX4600-EM-8F expansion modules, two QFX-EM-4Q expansion modules, or one of each.
- On a QFX5100-48S switch running a QFabric software package, PIC 1 provides six 40-Gbps QSFP+ ports, and PIC 0 provides 48 10-Gigabit Ethernet interfaces.
- On a QFX5100-24Q switch running Enhanced Layer 2 software, PIC 0 provides 24 40-Gbps QSFP+ ports. PIC 1 and PIC 2 can each contain a QFX-EM-4Q expansion module, and each expansion module provides 4 40-Gbps QSFP+ ports
- On a QFX5100-96S switch running Enhanced Layer 2 software, PIC 0 provides 96 10-Gigabit Ethernet interfaces and 8 40-Gbps QSFP+ ports .
- On a QFX10002-36Q switch running Enhanced Layer 2 software, PIC 0 provides 144 10-Gigabit Ethernet interfaces, and 36 40-Gbps QSFP+ ports, and 12 100-Gigabit Ethernet interfaces.
- On a QFX10002-72Q switch running Enhanced Layer 2 software, PIC 0 provides 288 10-Gigabit Ethernet interfaces, and 72 40-Gbps QSFP+ ports, and 24 100-Gigabit Ethernet interfaces.
- On a QFX10008 switch running Enhanced Layer 2 software, PIC 0 provides one-thousand, one-hundred fifty two 10-Gigabit Ethernet interfaces, two-hundred

eighty-eight 40-Gbps QSFP+ ports, or two-hundred forty 10-Gigabit Ethernet interfaces.

- *port*—Interfaces use the following convention for port numbers:

- On a QFX3500 switch running a QFabric software package, there are 48 network access ports (10-Gigabit Ethernet) labeled 0 through 47 on PIC 0 and, 16 network access ports labeled 0 through 15 on PIC 1, and four 40-Gbps QSFP+ ports labeled Q0 through Q3 on PIC 2. You can use the QSFP+ ports to connect the Node device to Interconnect devices.

By default, the 40-Gbps QSFP+ ports are configured to operate as 10-Gigabit Ethernet ports. You can use QSFP+ to four SFP+ copper breakout cables to connect the 10-Gigabit Ethernet ports to other servers, storage, and switches. Optionally, you can choose to configure the QSFP+ ports as 40-Gigabit Ethernet ports (see *Configuring the QSFP+ Port Type on QFX3500 Standalone Switches*).

- On a QFX3500 switch running Enhanced Layer 2 software, there are 48 network access ports labeled 0 through 47 on PIC 0 and 4 40-Gbps QSFP+ ports labeled Q0 through Q3 on PIC 1. See [“Channelizing Interfaces” on page 2835](#) for information on how to configure and channelize the 40-Gbps QSFP+ ports.
- On a QFX3600 switch running a QFabric software package, there are 64 network access ports (10-Gigabit Ethernet) labeled Q0 through Q15 on PIC 0, and there are 16 network access ports (40-Gigabit Ethernet) labeled Q0 through Q15 on PIC 1.

By default, all the QSFP+ ports are configured to operate as 40-Gigabit Ethernet ports. Optionally, you can choose to configure the QSFP+ ports as 10-Gigabit Ethernet ports (see *Configuring the Port Type on QFX3600 Standalone Switches*) and use QSFP+ to four SFP+ copper breakout cables to connect the 10-Gigabit Ethernet ports to other servers, storage, and switches.

- On a QFX3600 Node device running a QFabric software package, PIC 0 can support up to 56 10-Gigabit Ethernet ports labeled Q2 through Q15, and PIC 1 can support up to 8 40-Gigabit data plane uplink ports labeled Q0 through Q7, and up to 14 40-Gigabit Ethernet ports labeled Q2 through Q15.

On a QFX3600 Node device, by default, four 40-Gbps QSFP+ ports (labeled Q0 through Q3) are configured for uplink connections between your Node device and your Interconnect devices, and twelve 40-Gbps QSFP+ ports (labeled Q4 through Q15) use QSFP+ to four SFP+ copper breakout cables to support up to 48 10-Gigabit Ethernet ports for connections to either endpoint systems (such as servers and storage devices) or external networks. Optionally, you can choose to configure the first eight ports (Q0 through Q7) for uplink connections between your Node device and your Interconnect devices, and ports Q2 through Q15 for 10-Gigabit Ethernet or 40-Gigabit Ethernet connections to either endpoint systems or external networks (see *Configuring the Port Type on QFX3600 Node Devices*).

- On a QFX3600 switch running Enhanced Layer 2 software, PIC 0 can support 64 network access ports (10-Gigabit Ethernet ports) labeled Q0 through Q15 and 16 40-Gigabit Ethernet ports labeled Q0 through Q15. See [“Channelizing Interfaces” on page 2835](#) for information on how to configure and channelize the 40-Gbps QSFP+ ports.

- On a QFX5100-48S switch running Enhanced Layer 2 software, PIC 0 can support 48 network access ports (10-Gigabit Ethernet ports) labeled 0 through 47 and 6 40-Gbps QSFP+ ports labeled 48 through 53. See [“Channelizing Interfaces” on page 2835](#) for information on how to configure and channelize the 40-Gbps QSFP+ ports.
- On an EX4600 switch running Enhanced Layer 2 software, PIC 0 can support 24 network access ports (10-Gigabit Ethernet ports) labeled 0 through 23 and 4 40-Gbps QSFP+ ports labeled 24 through 27. There are two expansion bays (PIC 1 and PIC 2), and you can insert QFX-EM-4Q expansion modules and EX4600-EM-8F expansion modules. The QFX-EM-4Q expansion module provide 4 40-Gbps QSFP+ ports. The EX4600-EM-8F expansion module provides 8 40-Gbps QSFP+ ports. You can insert any combination of expansion modules. For example, you can insert two EX4600-EM-8F expansion modules, two QFX-EM-4Q expansion modules, or one of each. See [“Channelizing Interfaces” on page 2835](#) for information on how to configure and channelize the 40-Gbps QSFP+ ports.
- On a QFX5100-48S switch running a QFabric software package, PIC 0 can support 48 network access ports (10-Gigabit Ethernet ports) labeled 0 through 47, and PIC 1 can support 6 40-Gbps QSFP+ ports labeled 0 through 5. See *Configuring the QSFP+ Port Type on QFX5100 Switches* for information on how to configure the port mode of 40-Gbps QSFP+ ports.
- On a QFX5100-24Q switch running Enhanced Layer 2 software, PIC 0 can support 24 40-Gbps QSFP+ ports labeled 0 through 23. PIC 1 and PIC 2 each support 4 40-Gbps QSFP+ port, for a total of eight 40-Gbps QSFP+ ports. See [“Channelizing Interfaces” on page 2835](#) for information on how to configure and channelize the 40-Gbps QSFP+ ports.

NOTE: You cannot channelize the 40-Gbps QSFP+ ports provided in the two QFX-EM-4Q expansion modules. Also, even though there is a total of 128 physical ports, only 104 logical ports can be channelized.

You can configure different system modes to achieve varying levels of port density on the QFX5100-24Q and QFX5100-96S switches. Depending on the system mode you configure, there are restrictions on which ports you can channelize. If you channelize ports that are restricted, the configuration is ignored. See *Configuring the System Mode* for information on how to configure the system mode.

- On a QFX5100-96S switch running Enhanced Layer 2 software, PIC 0 can support 96 10-Gigabit Ethernet ports labeled 0 through 95, and 8 40-Gbps QSFP+ ports labeled 96 through 103. See [“Channelizing Interfaces” on page 2835](#) for information on how to configure and channelize the 40-Gbps QSFP+ ports.

NOTE: You can only channelize the 40-Gbps QSFP+ ports provided in ports 96 and 100, because only 104 logical ports can be channelized.

You can configure different system modes to achieve varying levels of port density on the QFX5100-24Q and QFX5100-96S switches. Depending on the system mode

you configure, there are restrictions on which ports you can channelize. If you channelize ports that are restricted, the configuration is ignored. See *Configuring the System Mode* for information on how to configure the system mode.

- On a QFX10002-36Q switch running Enhanced Layer 2 software, there are 36 quad small-form factor pluggable plus (QSFP+) ports that support 40-Gigabit Ethernet optical transceivers. Out of these 36 ports, 12 ports are QSFP28 capable, which are dual speed 40- or 100-Gigabit Ethernet optical transceivers.

Each QSFP28 socket can be configured to support:

- 100-Gigabit Ethernet using 28-Gbps QSFP28 optical transceivers. When a QSFP28 transceiver is inserted into the ports marked with a fine black line underneath the socket and the port is configured for 100-Gigabit Ethernet, the two adjacent ports are disabled and the QSFP28 is enabled for 100-Gigabit Ethernet.
- 40-Gigabit Ethernet using QSFP+ optical transceivers.
- 10-Gigabit Ethernet using breakout cables. When configured for channelization, a breakout cable converts the 40-Gigabit Ethernet port into 4 independent 10-Gigabit Ethernet ports.

Any of the 36 ports 0 through 35 can be configured as either uplink or access ports. See [“Channelizing Interfaces” on page 2835](#) for information on how to configure and channelize the 40-Gbps QSFP+ ports.

Each of the 12 QSFP28 ports support:

- 100-Gigabit Ethernet QSFP28 transceivers
- 40-Gigabit Ethernet QSFP+ transceivers

Each of the 36 QSFP+ ports support:

- 40-Gigabit Ethernet QSFP+ transceivers
- Access ports
- On a QFX10002-72Q switch running Enhanced Layer 2 software, there are 72 quad small-form factor pluggable plus (QSFP+) ports that support 40-Gigabit Ethernet optical transceivers. Out of these 72 ports, 24 ports are QSFP28 capable, which are dual speed 40- or 100-Gigabit Ethernet optical transceivers.

Each QSFP28 socket can be configured to support:

- 100-Gigabit Ethernet using 28-Gbps QSFP28 optical transceivers. When a QSFP28 transceiver is inserted into the ports marked with a fine black line underneath the socket and the port is configured for 100-Gigabit Ethernet, the two adjacent ports are disabled and the QSFP28 is enabled for 100-Gigabit Ethernet.
- 40-Gigabit Ethernet using QSFP+ optical transceivers.
- 10-Gigabit Ethernet using breakout cables. When configured for channelization, a breakout cable converts the 40-Gigabit Ethernet port into 4 independent 10-Gigabit Ethernet ports.

Any of the 72 ports 0 through 71 can be configured as either uplink or access ports. See [“Channelizing Interfaces” on page 2835](#) for information on how to configure and channelize the 40-Gbps QSFP+ ports.

Each of the 24 QSFP28 ports support:

- 100-Gigabit Ethernet QSFP28 transceivers

Each of the 72 QSFP+ ports support:

- 40-Gigabit Ethernet QSFP+ transceivers

Each of the 36 QSFP+ ports support:

- 40-Gigabit Ethernet QSFP+ transceivers
- Access ports
- Uplink ports
- On a QFX10008 switch running Enhanced Layer 2 software, there are two line cards available:
 - QFX10000-36Q, a 36-port 40-Gigabit Ethernet quad small form-factor pluggable plus transceiver (QSFP+) or 12-port 100GbE QSFP28 line card
 - QFX10000-30C, a 30-port 100-Gigabit or 40-Gigabit Ethernet QSFP28 line card

The QFX10000-36Q line cards supports

- 36 quad small form-factor pluggable plus (QSFP+) ports that support 40-Gigabit Ethernet optical transceivers. Out of these 36 ports, 12 ports are QSFP28 capable. The QSFP+ ports are dual speed and can support either 40-Gigabit or 100-Gigabit Ethernet optical transceivers. The line card can support 10-Gigabit Ethernet by channelizing the 40-Gigabit ports. Channelization is supported on fiber break-out cable using standard structured cabling techniques.
- Each QSFP28 socket can be configured to support:
 - 100-Gigabit Ethernet using QSFP28 optical transceivers. When a QSFP28 transceiver is inserted into the ports marked with a fine black line underneath the socket and the port is configured for 100-Gigabit Ethernet, the two adjacent ports are disabled and the QSFP28 socket is enabled for 100-Gigabit Ethernet.
 - 40-Gigabit Ethernet using QSFP+ optical transceivers.
 - 10-Gigabit Ethernet using breakout cabling and attached optical transceivers. When configured for channelization, the system converts the 40-Gigabit Ethernet port into 4 independent 10-Gigabit Ethernet ports.

Any of the 36 ports 0 through 35 can be configured as either uplink or access ports. See [“Channelizing Interfaces” on page 2835](#) for information on how to configure and channelize the 40-Gbps QSFP+ ports.

- Each of the 12 QSFP28 ports supports:
 - 100-Gigabit Ethernet QSFP28 transceivers

- 40-Gigabit Ethernet QSFP+ transceivers
- Each of the 12 QSFP28 ports supports:
 - 100-Gigabit Ethernet QSFP28 transceivers
 - 40-Gigabit Ethernet QSFP+ transceivers

Each of the 36 QSFP+ ports support:

- 40-Gigabit Ethernet QSFP+ transceivers
- Access ports
- Uplink ports

The QFX10000-30C line cards supports

- Thirty 28-Gbps QSFP+ Pluggable Solution (QSFP28) cages that support either 40-Gigabit Ethernet or 100-Gigabit Ethernet optical transceivers. The QFX10000-30C ports auto detect the type of transceiver installed and set the configuration to the appropriate speed.
- Each QSFP28 socket can be configured to support:
 - 100-Gigabit Ethernet using QSFP28 optical transceivers. When a QSFP28 transceiver is inserted into the ports marked with a fine black line underneath the socket and the port is configured for 100-Gigabit Ethernet, the two adjacent ports are disabled and the QSFP28 socket is enabled for 100-Gigabit Ethernet.
 - 40-Gigabit Ethernet using QSFP+ optical transceivers.

See [“Channelizing Interfaces” on page 2835](#) for information on how to configure and channelize the 40-Gbps QSFP+ ports.

- Each of the 30 QSFP28 ports supports:
 - 100-Gigabit Ethernet QSFP28 transceivers
 - 40-Gigabit Ethernet QSFP+ transceivers
 - Access ports
 - Uplink ports

Logical Part of an Interface Name on a Switch Running QFabric Software Package

The logical unit part of the interface name corresponds to the logical unit number, which can be a number from 0 through 16384. In the virtual part of the name, a period (.) separates the port and logical unit numbers: *device-name* (QFabric systems only): *type-fpc/pic/port.logical-unit-number*. For example, if you issue the **show ethernet-switching interfaces** command on a system with a default VLAN, the resulting display shows the logical interfaces associated with the VLAN:

Interface	State	VLAN members	Blocking
node-device1:xe-0/0/1.0	down	remote-analyzer	unblocked

```
node-device1:xe-0/0/2.0  down    default  unblocked
node-device1:xe-0/0/3.0  down    default  unblocked
```

When you configure aggregated Ethernet interfaces, you configure a logical interface, which is called a *bundle* or a *LAG*. Each LAG can include up to eight Ethernet interfaces, depending on the switch model.

Logical Part of a Channelized Interface Name on a Switch Running Enhanced Layer 2 Software

Channelizing enables you to configure four 10-Gigabit Ethernet interfaces from a 40-Gigabit Ethernet QSFP+ interface. By default, a 40-Gigabit Ethernet QSFP+ interface is named *et-fpc/pic/port*. The resulting 10-Gigabit Ethernet interfaces appear in the following format: *xe-fpc/pic/port:channel*, where channel can be a value of 0 through 3.

For example, if an *et* interface named **et-0/0/3** is channelized to four 10-Gigabit Ethernet interfaces, the resulting 10-Gigabit Ethernet interface names will be **xe-0/0/3:0**, **xe-0/0/3:1**, **xe-0/0/3:2**, and **xe-0/0/3:3**:

Interface	Admin	Link	Proto	Local	Remote
xe-0/0/3:0	up	down			
xe-0/0/3:1	up	down			
xe-0/0/3:2	up	down			
xe-0/0/3:3	up	down			

Wildcard Characters in Interface Names

In the **show interfaces** and **clear interfaces** commands, you can use wildcard characters in the *interface-name* option to specify groups of interface names without having to type each name individually. You must enclose all wildcard characters except the asterisk (*) in quotation marks (" ").

Understanding Interface Ranges

You can use the interface ranges to group interfaces of the same type that share a common configuration profile. This helps reduce the time and effort in configuring interfaces. The configurations common to all the interfaces can be included in the interface range definition.

The interface range definition contains the name of the interface range defined, the names of the individual member interfaces that do not fall in a series of interfaces, a range of interfaces defined in the member range, and the configuration statements common to all the interfaces. An interface range defined with member ranges and individual members but without any common configurations is also a valid definition.

NOTE: The interface range definition is supported only for Gigabit Ethernet, 10-Gigabit Ethernet, and Fibre Channel interfaces. OCX Series switches do not support Fibre Channel interfaces.

The common configurations defined in the interface range will be overridden by the local configuration.

The defined interface ranges can be used at places where the **interface** statement is used in the following configuration hierarchies:

NOTE: These statements are not supported on OCX Series switches:

- **protocols isis interface**
- **protocols sflow interfaces**

Understanding Management Interfaces

You use management interfaces to access devices remotely. Typically, a management interface is not connected to the in-band network, but is connected to a device in the internal network. Through a management interface, you can access the device over the network using utilities such as **ssh** and **telnet** and configure it from anywhere, regardless of its physical location. As a security feature, users cannot log in as **root** through a management interface. To access the device as **root**, you must use the console port. You can also use **root** to log in using SSH.

NOTE: Before you can use management interfaces, you must configure the logical interfaces with valid IP addresses. Juniper Networks does not support configuring two management interfaces in the same subnet.

Management interface port ranges vary based on device type:

- QFX3500 devices:

The valid port range for a management interface (**me**) on a QFX3500 device is between 0 and 6, with a total of seven available ports. On a QFX3500 standalone switch, however, you can only configure **me0** and **me1** as management interfaces. The management interfaces are labeled **C0** and **C1**, and they correspond to **me0** and **me1**. On a QFX3500 Node device, the RJ-45 management interfaces and SFP management interfaces correspond to **me5** and **me6**.

- QFX3600 devices:

There are two RJ-45 management interfaces (labeled **C0** and **C1**) and two SFP management interfaces (labeled **C0S** and **C1S**). On a QFX3600 standalone switch, the RJ-45 management interfaces and SFP management interfaces correspond to **me0** and **me1**. On a QFX3600 Node device, the RJ-45 management interfaces and SFP management interfaces correspond to **me5** and **me6**. Each pair of management interfaces correspond to one Ethernet interface—for example, both RJ-45 management interfaces (labeled **C0** and **C0s**) can correspond to **me0**, and both SFP management interfaces (labeled **C1** and **C1S**) can correspond to **me1**. By default, both RJ-45 management interfaces are active. If you insert an SFP interface into the SFP management port (**C0S**, for example), the SFP interface would become the active management interface, and the corresponding RJ-45 management interface (**C0**) is disabled.

NOTE: On a QFX3600 device, you can use either the RJ-45 or the SFP management interfaces, but not both at the same time.

- On QFX5100, QFX5200, and EX4600 switches, there is one RJ-45 management interface (labeled **C0** and one SFP management interface (labeled **C1**), and they correspond to **em0** and **em1**. You can use both management interfaces simultaneously.
- On QFX10002 and QFX10008 switches, there is one RJ-45 management interface (labeled **MGMT** and one SFP management interface (labeled **MGMT**), and they correspond to **em0** and **em1**. Although the CLI permits you to configure two management Ethernet interfaces within the same subnet, only one interface is usable and supported.
- On OCX Series switches:

There is one RJ-45 management interface (labeled **MGMT**), which corresponds to **em0**. The **em0** interface always has the status **up** in show command outputs, even if the physical port is empty. The **me0** interface is a virtual interface between Junos and

the host operating system, therefore its status is independent from the status of the physical port.

- QFabric system:

On a QFabric system, there are management interfaces on the Node devices, Interconnect devices, and Director devices. However, you cannot access the management interfaces on the Node devices or Interconnect devices directly. You can only manage and configure these devices using the Director device. You can connect to the management interface over the network using utilities such as SSH.

Related Documentation • [Interfaces Overview on page 2785](#)

Understanding Port Ranges and System Modes

QFX Series devices and EX4600 switches can support different port ranges depending on the device, media type of the interface, the software that is running on the device, and the system mode.

This topic describes:

- [Port Ranges for Different Media Types on page 2798](#)
- [Supported System Modes on page 2822](#)

Port Ranges for Different Media Types

The following media types support the following port ranges:

- On a QFX3500 device:
 - The valid port range for a Fibre Channel (fc) interface is **0** through **5** and **42** through **47** on PIC **0**, with a total of 12 available Fibre Channel ports.

NOTE: Fibre Channel ports are not supported on QFX3500, QFX3600, and QFX5100 switches running Enhanced Layer 2 software.

- The valid port range for a Gigabit Ethernet (ge) interface is **6** through **41** on PIC **0** because the ports between **0** and **5** and **42** and **47** are reserved as Fibre Channel ports. The total number of available Gigabit Ethernet ports is 36, because 12 of the remaining 48 ports are reserved for Fibre Channel and 10-Gigabit Ethernet interfaces. Fibre Channel ports cannot be configured as Gigabit Ethernet ports.
- The valid port range for a 10-Gigabit Ethernet (xe) interface is **0** through **47** on PIC **0**. The valid port range for a 10-Gigabit Ethernet (xe) interface is **0** through **15** on PIC **1**. The total number of available 10-Gigabit Ethernet ports is 64.

- The valid port range for a 40-Gigabit data plane uplink interface is **0** through **3** on PIC 1
- The valid port range for a 40-Gigabit Ethernet interface is **0** through **3** on PIC 2. There are four available ports.
- On a QFX3600 Node device:
 - The valid port range for a 10-Gigabit Ethernet interface is **8** through **63** on PIC 0. There are 56 available ports.
 - The valid port range for a 40-Gigabit Ethernet interface is **2** through **15** on PIC 1. There are 14 available ports.
 - The valid port range for a 40-Gigabit data plane uplink interface is **0** through **7** on PIC 1. There are eight available ports.

See [Table 250](#) for physical port to logical port mappings.

- On a QFX3600 switch running Enhanced Layer 2 Software:
 - The valid port range for a 10-Gigabit Ethernet interface is **0** through **63** on PIC 0. There are 64 available ports.
 - The valid port range for a 40-Gigabit Ethernet interface is **0** through **15** on PIC 0. There are 16 available ports.

See [Table 251](#) for physical port to logical port mappings.

- On QFX5100-48S and QFX5100-48T switches running Enhanced Layer 2 Software:
 - The valid port range for a 10-Gigabit Ethernet interface is **0** through **47** on PIC 0. There are 48 available ports. When you channelize the 6 40-Gbps QSFP+ ports on **0** through **5** on PIC 1, there are 72 available ports.

NOTE: On PIC 1, ports 0 and 1 are reserved for fte ports. You cannot convert these fte ports to xe or xle ports.

- The valid port range for a 40-Gbps QSFP+ port is **0** through **5** on PIC 1. There are six available ports.

See [Table 253](#) for physical port to logical port mappings.

- On EX4600 switches running Enhanced Layer 2 Software:
 - The valid port range for a 10-Gigabit Ethernet interface is **0** through **23** on PIC 0. There are 24 available ports. When you channelize the 4 40-Gbps QSFP+ ports on **24** through **27** on PIC 0. There are 40 available ports.

See [Table 253](#) for physical port to logical port mappings.

- On QFX5100-48S and QFX5100-48T switches running a QFabric software package:
 - The valid port range for a 10-Gigabit Ethernet interface is **0** through **47** on PIC 0. There are 48 available ports.

- The valid port range for a 40-Gbps QSFP+ port is 0 through 5 on PIC 1. There are six available ports.

NOTE: On PIC 1, ports 0 and 1 are reserved for fte ports. You cannot convert these fte ports to xe or xle ports.

See [Table 254](#) for physical port to logical port mappings.

- For QFX5100-24Q and QFX5100-96S switches running Enhanced Layer 2 Software, see [Table 255](#) for physical port to logical port mappings for different system modes.

Table 248: Valid Port Ranges on QFX3500 Switches Running QFabric Software Package

Port Number	Fibre Channel Interfaces (On PIC 0)	Gigabit Ethernet Interfaces (On PIC 0)	10-Gigabit Ethernet Interfaces (On PIC 0 and 1)	40-Gigabit Data Plane Uplink Interfaces (On PIC 1)	40-Gigabit Ethernet Interfaces (On PIC 2)
