# Cloud-Native Contrail Networking Overview

## SUMMARY

Learn about Cloud-Native Contrail Networking (CN2).

## IN THIS SECTION

- [Benefits of Cloud-Native Contrail Networking | 4](#)

**NOTE:** This section is intended to provide a brief overview of the Juniper Networks Cloud-Native Contrail Networking solution and might contain a description of features not supported in the Kubernetes distribution that you're using. See the Cloud-Native Contrail Networking Release Notes for information on features in the current release for your distribution.

Unless otherwise indicated, all references to Kubernetes in this Overview section are made generically and are not intended to single out a particular distribution.

In release 23.2, Cloud-Native Contrail Networking is supported on the following:

- [\(Upstream\) Kubernetes](#)
- [Red Hat Openshift](#)
- [Amazon EKS](#)
- [Rancher RKE2](#)

Contrail Networking is an SDN solution that automates the creation and management of virtualized networks to connect, isolate, and secure cloud workloads and services seamlessly across private and public clouds.

Cloud-Native Contrail Networking (CN2) brings this rich SDN feature set natively to Kubernetes as a networking platform and container network interface (CNI) plug-in.

Redesigned for cloud-native architectures, CN2 takes advantage of the benefits that Kubernetes offers, from simplified DevOps to turnkey scalability, all built on a highly available platform. These benefits include leveraging standard Kubernetes tools and practices to manage Contrail throughout its life cycle:

- Manage CN2 using standard Kubernetes and third-party tools.
- Scale CN2 by adding or removing nodes.
- Configure CN2 by using custom resource definitions (CRDs).

- Upgrade CN2 software by applying updated manifests.
- Uninstall CN2 by deleting Contrail namespaces and resources (where supported).

More than a CNI plug-in, CN2 is a networking platform that provides dynamic end-to-end virtual networking and security for cloud-native containerized and virtual machine (VM) workloads, across multi-cluster compute and storage environments, all from a central point of control. It supports hard multi-tenancy for single or multi-cluster environments shared across many tenants, teams, applications, or engineering phases, scaling to thousands of nodes.

The CN2 implementation consists of a set of Contrail controllers that reside on either Kubernetes control plane nodes or worker nodes depending on distribution. The Contrail controllers manage a distributed set of data planes implemented by a CNI plug-in and vRouter on every node. Integrating a full-fledged vRouter alongside the workloads provides CN2 the flexibility to support a wide range of networking requirements, from small single clusters to multi-cluster deployments, including:

- Full overlay networking including load balancing, security and multi-tenancy, elastic and resilient VPNs, and gateway services in single-cluster and multi-cluster deployments
- Highly available and resilient network controller overseeing all aspects of the network configuration and control planes
- Analytics services using telemetry and industry standard monitoring and presentation tools such as Prometheus and Grafana
- Support for both CRI-O and containerd runtimes
- Support for container and VM workloads (using kubevirt)
- Support for DPDK data plane acceleration

The Contrail controller automatically detects workload provisioning events such as a new workload being instantiated, network provisioning events such as a new virtual network being created, routing updates from internal and external sources, and unexpected network events such as link and node failures. The Contrail controller reports and logs these events where appropriate and reconfigures the vRouter data plane as necessary.

Although any single node can contain only one Contrail controller, a typical deployment contains multiple controllers running on multiple nodes. When there are multiple Contrail controllers, the controllers keep in synchronization by using iBGP to exchange routes. If a Contrail controller goes down, the Contrail controllers on the other nodes retain all database information and continue to provide the network control plane uninterrupted.

On the worker nodes where workloads reside, each vRouter establishes communications with two Contrail controllers, such that the vRouter can continue to receive instruction if any one controller goes down.

By natively supporting Kubernetes, the CN2 solution leverages the simplicity, flexibility, scalability, and availability inherent to the Kubernetes architecture, while supporting a rich SDN feature set that can meet the requirements of enterprises and service providers alike. Enterprises and service providers can now manage Contrail using simplified and familiar DevOps tools and processes without needing to learn a new life cycle management (LCM) paradigm.

## Benefits of Cloud-Native Contrail Networking

- Support a rich networking feature set for your overlay networks.
- Deploy a highly scalable and highly available SDN solution on both upstream and commercial Kubernetes distributions.
- Manage CN2 using familiar, industry-standard tools and practices.
- Optionally, use the CN2 Web UI to configure and monitor your network.
- Leverage the skill set of your existing DevOps engineers to quickly get CN2 up and running.
- Combine with Juniper Networks fabric devices and fabric management solutions or use your own fabric or third-party cloud networks.

## Terminology

Table 1: Terminology

Term	Meaning
Kubernetes control plane	The Kubernetes control plane is the collection of pods that manage containerized workloads on the worker nodes in a cluster.
Kubernetes control plane node	This is the virtual or physical machine that hosts the Kubernetes control plane, formerly known as a master node.
Server node	In Rancher terminology, a server node is a Kubernetes control plane node.

Table 1: Terminology (*Continued*)

Term	Meaning
Kubernetes node or worker node	Also called a worker node, a Kubernetes node is a virtual or physical machine that hosts containerized workloads in a cluster.  To reduce ambiguity, we refer to this strictly as a worker node in this document.
Agent node	In Rancher terminology, an agent node is a Kubernetes worker node.
Contrail compute node	This is equivalent to a worker node. It is the node where the Contrail vRouter is providing the data plane function.
Network control plane	The network control plane provides the core SDN capability. It uses BGP to interact with peers such as other controllers and gateway routers, and XMPP to interact with the data plane components.  CN2 supports a centralized network control plane architecture where the routing daemon runs centrally within the Contrail controller and learns and distributes routes from and to the data plane components.  This centralized architecture facilitates virtual network abstraction, orchestration, and automation.
Network configuration plane	The network configuration plane interacts with Kubernetes control plane components to manage all CN2 resources. You configure CN2 resources using custom resource definitions (CRDs).
Network data plane	The network data plane resides on all nodes and interacts with containerized workloads to send and receive network traffic. Its main component is the Contrail vRouter.
Contrail controller	This is the part of CN2 that provides the network configuration and network control plane functionality.  This name is purely conceptual – there is no corresponding Contrail controller object or entity in the UI.
Contrail controller node	This is the control plane node or worker node where the Contrail controller resides. In some Kubernetes distributions, the Contrail controller resides on control plane nodes. In other distributions, the Contrail controller resides on worker nodes.
Central cluster	In a multi-cluster deployment, this is the central Kubernetes cluster that houses the Contrail controller.

Table 1: Terminology (*Continued*)

Term	Meaning
Workload cluster	In a multi-cluster deployment, this is the distributed cluster that contains the workloads.

## CN2 Components

The CN2 architecture consists of pods that perform the network configuration plane and network control plane functions, and pods that perform the network data plane functions.

- The network configuration plane refers to the functionality that enables CN2 to manage its resources and interact with the rest of the Kubernetes control plane.
- The network control plane represents CN2's full-featured SDN capability. It uses BGP to communicate with other controllers and XMPP to communicate with the distributed data plane components on the worker nodes.
- The network data plane refers to the packet transmit and receive function on every node, especially on worker nodes where the workloads reside.

The pods that perform the configuration and control plane functions reside on Kubernetes control plane nodes. The pods that perform the data plane functions reside on both Kubernetes control plane nodes and Kubernetes worker nodes.

[Table 2 on page 7](#) describes the main CN2 components. Depending on configuration, there might be other components as well (not shown) that perform ancillary functions such as certificate management and status monitoring.

Table 2: CN2 Components

Pod Name		Where	Description
Configuration Plane <sup>1</sup>	contrail-k8s-apiserver	Control Plane Node	<p>This pod is an aggregated API server that is the entry point for managing all Contrail resources. It is registered with the regular kube-apiserver as an APIService. The regular kube-apiserver forwards all network-related requests to the contrail-k8s-apiserver for handling.</p> <p>There is one contrail-k8s-apiserver pod per Kubernetes control plane node.</p>
	contrail-k8s-controller	Control Plane Node	<p>This pod performs the Kubernetes control loop function to reconcile networking resources. It constantly monitors networking resources to make sure the actual state of a resource matches its intended state.</p> <p>There is one contrail-k8s-controller pod per Kubernetes control plane node.</p>
	contrail-k8s-kubemanager	Control Plane Node	<p>This pod is the interface between Kubernetes resources and Contrail resources. It watches the kube-apiserver for changes to regular Kubernetes resources such as service and namespace and acts on any changes that affect the networking resources.</p> <p>In a single-cluster deployment, there is one contrail-k8s-kubemanager pod per Kubernetes control plane node.</p> <p>In a multi-cluster deployment, there is additionally one contrail-k8s-kubemanager pod for every distributed workload cluster.</p>

Table 2: CN2 Components *(Continued)*

Pod Name		Where	Description
Control Plane <sup>1</sup>	contrail-control	Control Plane Node	<p>This pod passes configuration to the worker nodes and performs route learning and distribution. It watches the kube-apiserver for anything affecting the network control plane and then communicates with its BGP peers and/or vRouter agents (over XMPP) as appropriate.</p> <p>There is one contrail-control pod per Kubernetes control plane node.</p>
	contrail-vrouter-nodes	Worker Node	<p>This pod contains the vRouter agent and the vRouter itself.</p> <p>The vRouter agent acts on behalf of the local vRouter when interacting with the Contrail controller. There is one agent per node. The agent establishes XMPP sessions with two Contrail controllers to perform the following functions:</p> <ul style="list-style-type: none"> <li>• translates configuration from the control plane into objects that the vRouter understands</li> <li>• interfaces with the control plane for the management of routes</li> <li>• collects and exports statistics from the data plane</li> </ul> <p>The vRouter provides the packet send and receive function for the co-located pods and workloads. It provides the CNI plug-in functionality.</p>
	contrail-vrouter-masters	Control Plane Node	<p>This pod provides the same functionality as the contrail-vrouter-nodes pod, but resides on the control plane nodes.</p>

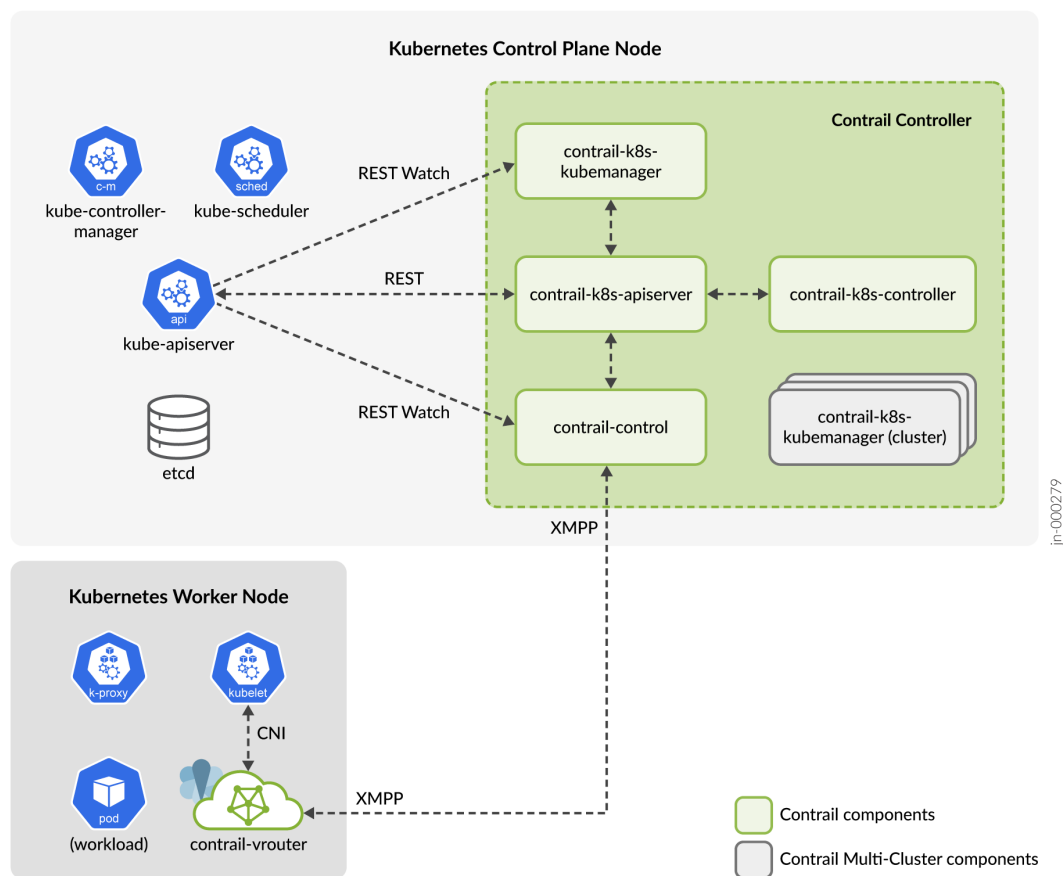

Table 2: CN2 Components *(Continued)*

Pod Name	Where	Description
<sup>1</sup> The components that make up the network configuration plane and the network control plane are collectively called the Contrail controller.		

Figure 1 on page 9 shows these components in the context of a Kubernetes cluster.

For clarity and to reduce clutter, the figures do not show the data plane pods on the node with the Contrail controller.

Figure 1: CN2 Components

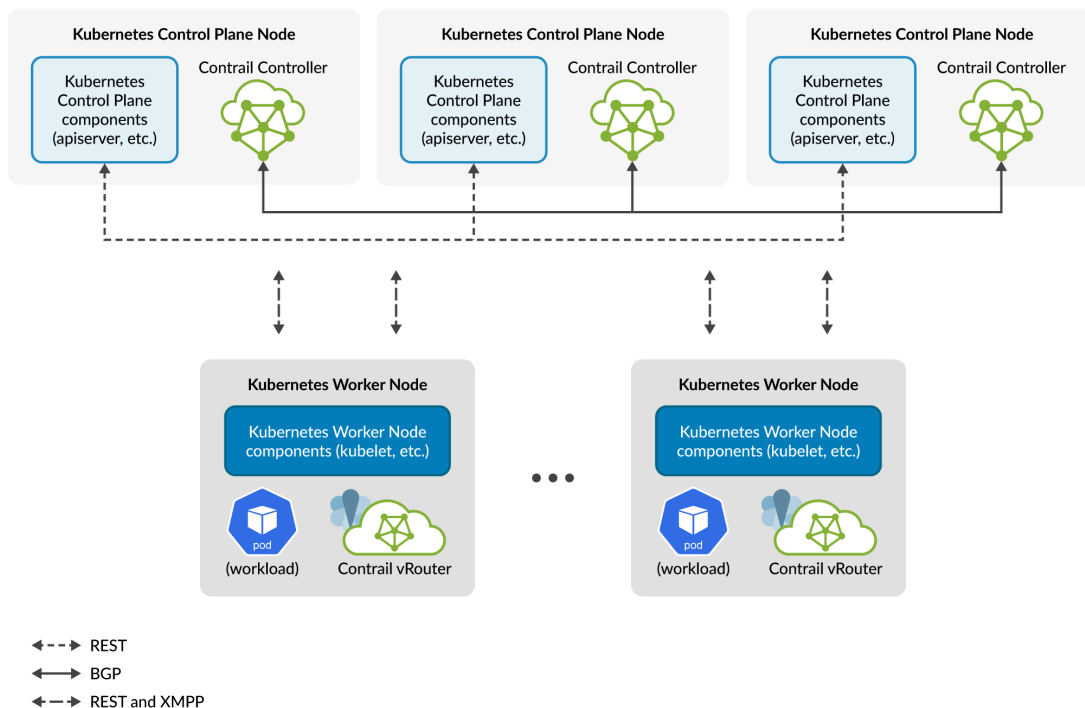

When running on upstream Kubernetes or Rancher RKE2, the Contrail controller stores all CN2 cluster data in the main Kubernetes etcd database by default. When running on OpenShift, the Contrail controller stores all CN2 cluster data in its own Contrail etcd database.

The kube-apiserver is the entry point for Kubernetes REST API calls for the cluster. It directs all networking requests to the contrail-k8s-apiserver, which is the entry point for Contrail API calls. The contrail-k8s-apiserver translates incoming networking requests into REST API calls to the respective CN2 objects. In some cases, these calls may result in the Contrail controller sending XMPP messages to the vRouter agent on one or more worker nodes or sending BGP messages (not shown) to other control plane nodes or external routers. These XMPP and BGP messages are sent outside of regular Kubernetes node-to-node communications.

The contrail-k8s-kubemanager (cluster) components are only present in multi-cluster deployments. For more information on the different types of deployment, see Deployment Models.

Figure 2 on page 10 shows a cluster with multiple Contrail controllers. These controllers reside on control plane nodes. The Kubernetes components communicate with each other using REST. The Contrail controllers exchange routes with each other using iBGP, outside of the regular Kubernetes REST interface. For redundancy, the vRouter agents on worker nodes always establish XMPP communications with two Contrail controllers.

**Figure 2: Multiple Contrail Controllers**

# Deployment Models

## SUMMARY

Learn about single cluster and multi-cluster CN2.

## IN THIS SECTION

- [Single Cluster Deployment | 11](#)
- [Multi-Cluster Deployment | 12](#)

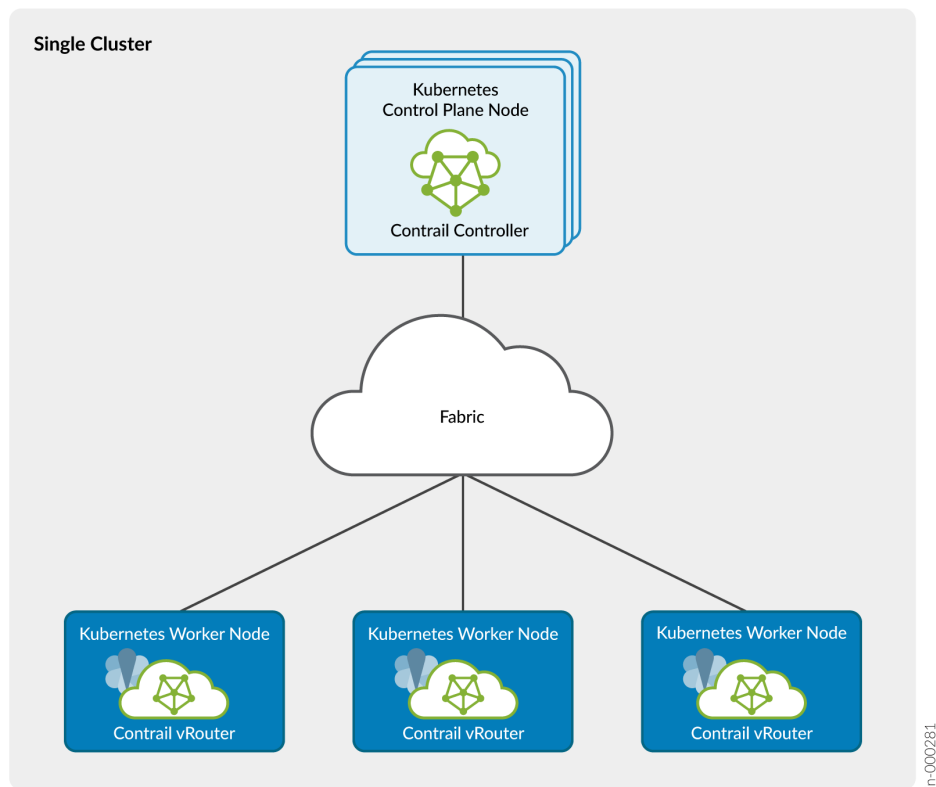

Cloud-Native Contrail Networking (CN2) is available both as an integrated networking platform in a single Kubernetes cluster and as a centralized networking platform to multiple distributed Kubernetes clusters. In both cases, Contrail works as an integrated component of your infrastructure by watching where workloads are instantiated and connecting those workloads to the appropriate overlay networks.

## Single Cluster Deployment

Cloud-Native Contrail Networking (CN2) is available as an integrated networking platform in a single Kubernetes cluster, watching where workloads are instantiated and connecting those workloads to the appropriate overlay networks.

In a single-cluster deployment ([Figure 3 on page 12](#)), the Contrail controller sits in the Kubernetes control plane and provides the network configuration and network control planes for the host cluster. The Contrail data plane components sit in all nodes and provide the packet send and receive function for the workloads.

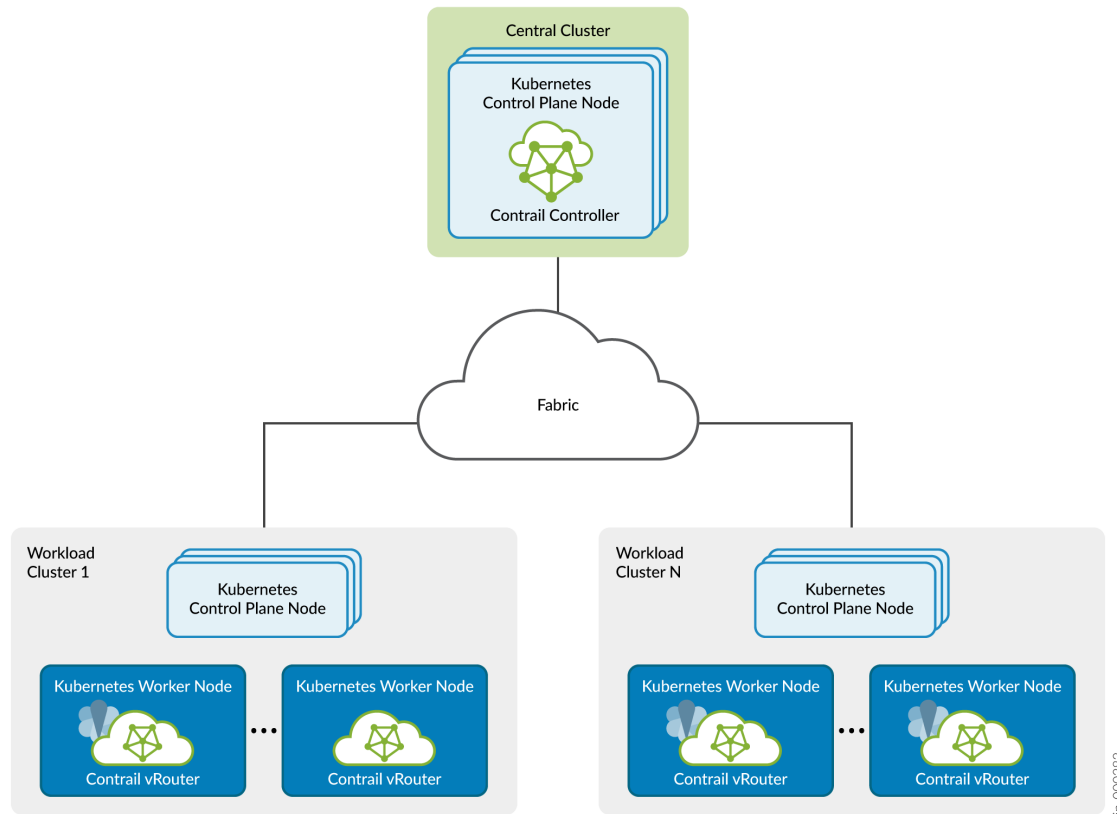

Figure 3: Single Cluster Deployment

## Multi-Cluster Deployment

In a multi-cluster deployment ([Figure 4 on page 13](#)), the Contrail controller resides in its own Kubernetes cluster and provides networking to other clusters. The Kubernetes cluster that the Contrail controller resides in is called the central cluster. The Kubernetes clusters that house the workloads are called the distributed workload clusters.

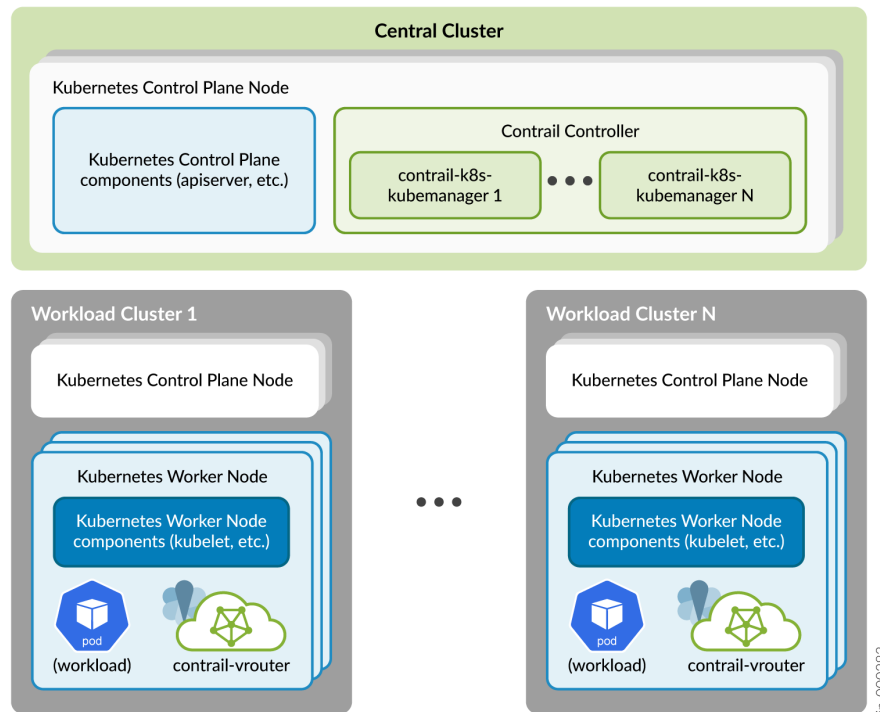

**Figure 4: Multi-Cluster Deployment**

Centralizing the network function in this way makes it not only easier to configure and manage, but also easier to apply consistent network policy and security.

[Figure 5 on page 14](#) provides more detail on this setup. The Contrail controller sits in the Kubernetes control plane of the central cluster and contains a kubemanager for each workload cluster that it serves. There are typically no worker nodes in the central cluster. Instead, the workloads reside in the worker nodes in the distributed workload clusters. The Contrail CNI plugin and vRouter sit in the worker nodes of the workload clusters. The Kubernetes control plane in the workload clusters do not contain any Contrail controller components.

Figure 5: Multi-Cluster Components

The multi-cluster Contrail controller differs from the single-cluster Contrail controller in two main ways:

- The multi-cluster Contrail controller has a **contrail-k8s-kubemanager** pod instantiated for each distributed workload cluster. As part of the procedure to connect a distributed workload cluster to the central cluster, you explicitly create and assign a **contrail-k8s-kubemanager** deployment that watches for changes to resources that affect its assigned workload cluster.
- The multi-cluster Contrail controller uses multi-cluster watch technology to detect changes in the distributed workload clusters.

The function of the multi-cluster **contrail-k8s-kubemanager** pod is identical to its single-cluster counterpart. It watches for changes to regular Kubernetes resources that affect its assigned cluster and acts on the changes accordingly.

All other Contrail components in a multi-cluster deployment behave in the same way as in a single-cluster deployment. The network control plane, for example, communicates with data plane components using XMPP, outside of regular Kubernetes REST channels. Because of this, the network control plane is indifferent to whether the data plane components that it communicates with reside in the same cluster or in different clusters. The only requirement is that the data plane components are reachable.

# System Requirements

Table 3: System Requirements for Upstream Kubernetes Installation with CN2

Machine	CPU	RAM	Storage	Notes
Control Plane Nodes <sup>1</sup>	8	32 GB	400 GB	Processor must support the AVX2 instruction set if running DPDK.
Worker Nodes <sup>2</sup>	4	16 GB	100 GB	Processor must support the AVX2 instruction set if running DPDK.
<p><sup>1</sup> Includes nodes in single clusters, central clusters, and distributed workload clusters.</p> <p><sup>2</sup> Based on workload requirements.</p>

# Overview

## IN THIS SECTION

- [Benefits of Upstream Kubernetes with Contrail | 17](#)

Upstream Kubernetes is an open source version of Kubernetes that is maintained by the Cloud Native Computing Foundation (CNCF). It consists of the core components that provide the infrastructure for container orchestration. It forms the basis for commercial Kubernetes distributions (in other words, it is 'upstream' of other distributions).

Upstream Kubernetes does not include any add-on components for monitoring and life-cycle managing your cluster. It's therefore targeted for organizations that have the ability to put together a usable orchestration solution by themselves. It's also good for users who want to quickly get a bare bones proof-of-concept installation up and running.

Upstream Kubernetes also does not include a CNI plug-in. After you install a fresh cluster, you'll need to install a CNI plug-in for that cluster. With CN2, you simply run the supplied Contrail deployer. The Contrail deployer runs in a container and behaves just like any other Kubernetes application. The deployer installs and provides life cycle management for CN2 components.

Once CN2 is installed, you manage it using kubectl and other standard Kubernetes tools. If you also install Contrail Analytics, you'll get Prometheus, Grafana, and other open source monitoring software installed automatically, with the added benefit that CN2 will work seamlessly with these latter applications with no further configuration necessary.

## Benefits of Upstream Kubernetes with Contrail

- Open source Kubernetes platform together with industry-leading CNI
- Install only what you need, fully customizable
- Ideal for roll-your-own and proof-of-concept installations
- Contrail deployer facilitates installation

# Before You Install

1. Set up an account with Juniper Networks so you can download CN2 manifests from the Juniper Networks download site (<https://support.juniper.net/support/downloads/?p=contrail-networking>) and access the container repository at <https://enterprise-hub.juniper.net>.
2. Set up the fabric network and connect your nodes to the fabric.  
The example networks used in this document are shown in the respective installation sections.
3. Download the Contrail Networking manifests ("[Manifests](#)" on page 37) and extract the tgz onto the host where you plan on running the installation. This host must be able to reach the cluster nodes.
4. Configure your repository login credentials in the downloaded manifests.  
Add your repository login credentials to the **contrail-manifests-k8s** and **contrail-tools** manifests. See "[Configure Repository Credentials](#)" on page 72 for one way to do this.
5. Configure the cluster nodes.
  - a. Install a fresh OS on all servers/VMs that you'll use as cluster nodes. Ensure the OS and kernel versions on the cluster nodes are on the list of supported OSes and kernels (see the *CN2 Tested Integrations* matrix at <https://www.juniper.net/documentation/us/en/software/cn-cloud-native/cn2-tested-integrations/cn-cloud-native-tested-integrations/concept/cn-cloud-native-tested-integrations.html>).
  - b. Configure the OS on each node minimally for the following:
    - static IP address and mask as per the example cluster you want to install (for example, 172.16.0.11/24 through 172.16.0.13/24 in our single cluster example) and gateway
    - access to one or more DNS servers

**NOTE:** If you're running **systemd-resolved** on Ubuntu, ensure that **/etc/resolv.conf** is linked to **/run/systemd/resolve/resolv.conf**, and not to **/run/systemd/resolve/stub-resolv.conf**.

```
ln -svf /run/systemd/resolve/resolv.conf /etc/resolv.conf
```

```
ls -l /etc/resolv.conf
```

```
lrwxrwxrwx 1 root root 32 May 23 19:15 /etc/resolv.conf -> /run/systemd/resolve/resolv.conf
```

<https://kubernetes.io/docs/tasks/administer-cluster/dns-debugging-resolution/#known-issues>

- SSH connectivity including root SSH access

- NTP (must be chrony)

The cluster nodes in our examples are running Ubuntu.

- If you're planning on running with a DPDK data plane, prepare each cluster node that is running DPDK.

For an example on how to do this, see ["Prepare a Cluster Node for DPDK" on page 75](#).

## 6. Install Contrail tools.

See ["Install Contrail Tools" on page 35](#).

## 7. Install contrailstatus on the machine where you plan on running kubectl. Contrailstatus is a kubectl plug-in you can use to query Contrail microservices and Contrail-specific resources.

The contrailstatus executable is packaged within the downloaded tools package. Extract and copy the **kubectl-contrailstatus** executable to **/usr/local/bin**.

If you're installing a multi-cluster, then repeat steps 3 to 7 for each cluster.

# Install Single Cluster Shared Network CN2

## SUMMARY

See examples on how to install single cluster CN2 in a deployment where Kubernetes traffic and CN2 traffic share the same network.

## IN THIS SECTION

- [Install Single Cluster Shared Network CN2 Running Kernel Mode Data Plane | 21](#)
- [Install Single Cluster Shared Network CN2 Running DPDK Data Plane | 23](#)

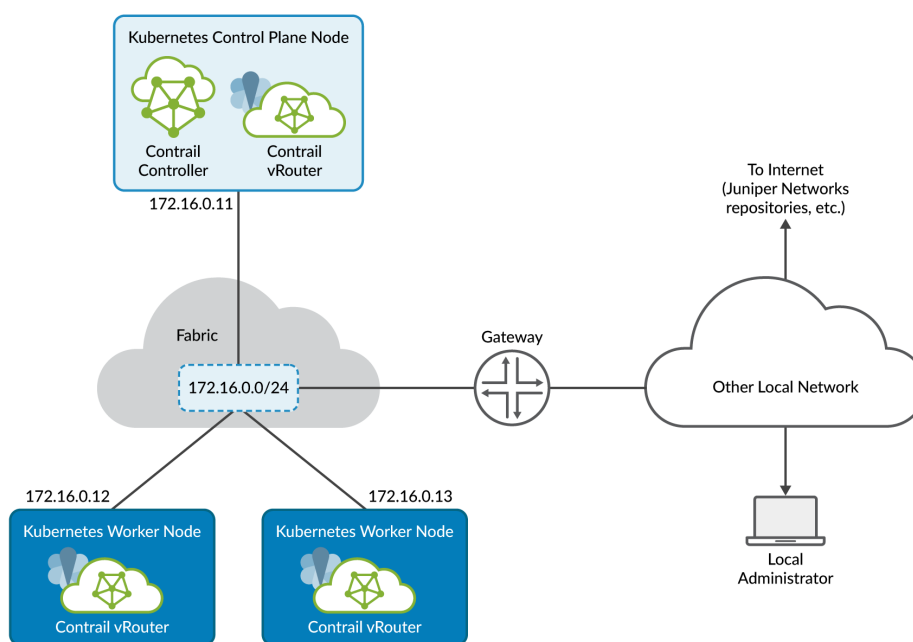

In a single cluster shared network deployment:

- CN2 is the networking platform and CNI plug-in for that cluster. The Contrail controller runs in the Kubernetes control plane, and the Contrail data plane components run on all nodes in the cluster.
- Kubernetes and CN2 traffic share a single network.

[Figure 6 on page 20](#) shows the cluster that you'll create if you follow the single cluster shared network example. The cluster consists of a single control plane node and two worker nodes.

All nodes shown can be VMs or bare metal servers.

Figure 6: Single Cluster Shared Network CN2

All communication between nodes in the cluster and between nodes and external sites takes place over the single 172.16.0.0/24 fabric virtual network. The fabric network provides the underlay over which the cluster runs.

The local administrator is shown attached to a separate network reachable through a gateway. This is typical of many installations where the local administrator manages the fabric and cluster from the corporate LAN. In the procedures that follow, we refer to the local administrator station as your local computer.

**NOTE:** Connecting all cluster nodes together is the data center fabric, which is shown in the example as a single subnet. In real installations, the data center fabric is a network of spine and leaf switches that provide the physical connectivity for the cluster.

In an Apstra-managed data center, this connectivity would be specified through the overlay virtual networks that you create across the underlying fabric switches.

The procedures in this section show basic examples of how you can use the provided manifests to create the specified CN2 deployment. You're not limited to the deployment described in this section nor are you limited to using the provided manifests. CN2 supports a wide range of deployments that are too numerous to cover in detail. Use the provided examples as a starting point to roll your own manifest tailored to your specific situation.

## Install Single Cluster Shared Network CN2 Running Kernel Mode Data Plane

Use this procedure to install CN2 in a single cluster shared network deployment running a kernel mode data plane.

The manifest that you will use in this example procedure is **single-cluster/single\_cluster\_deployer\_example.yaml**. The procedure assumes that you've placed this manifest into a **manifests** directory.

1. Create a Kubernetes cluster. You can follow the example procedure in ["Create a Kubernetes Cluster" on page 64](#) or you can use any other method. Create the cluster with the following characteristics:
  - Cluster has no CNI plug-in.
  - Disable Node Local DNS.
2. Apply the Contrail deployer manifest.

```
kubectl apply -f manifests/single_cluster_deployer_example.yaml
```

It may take a few minutes for the nodes and pods to come up.

3. Use standard kubectl commands to check on the deployment.
  - a. Show the status of the nodes.

```
kubectl get nodes
```

NAME	STATUS	ROLES	AGE	VERSION
k8s-cp0	Ready	control-plane,master	65m	v1.20.7
k8s-worker0	Ready	<none>	63m	v1.20.7
k8s-worker1	Ready	<none>	62m	v1.20.7

You can see that the nodes are now up. If the nodes are not up, wait a few minutes and check again.

- b. Show the status of the pods.

```
kubectl get pods -A -o wide
```

NAMESPACE	NAME	READY	STATUS	RESTARTS	AGE	IP	NODE	<trimmed>
contrail-deploy	contrail-k8s-deployer-747689445-7rx52	1/1	Running	0	44m	172.16.0.11	k8s-cp0	<none> <none>

kube-system	kube-controller-manager-k8s-cp0	1/1	Running	0	69m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	kube-proxy-k5mcp	1/1	Running	0	67m	172.16.0.13	k8s-worker1	<none>	<none>
kube-system	kube-proxy-sccjm	1/1	Running	0	67m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	kube-proxy-wqbt8	1/1	Running	1	67m	172.16.0.12	k8s-worker0	<none>	<none>
kube-system	kube-scheduler-k8s-cp0	1/1	Running	0	69m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	nginx-proxy-k8s-worker0	1/1	Running	0	67m	172.16.0.12	k8s-worker0	<none>	<none>
kube-system	nginx-proxy-k8s-worker1	1/1	Running	0	67m	172.16.0.13	k8s-worker1	<none>	<none>

All pods should now have a STATUS of Running. If not, wait a few minutes for the pods to come up.

- c. If some pods remain down, debug the deployment as you normally do. Use the `kubectl describe` command to see why a pod is not coming up. A common error is a network or firewall issue preventing the node from reaching the Juniper Networks repository.

Here is an example of a DNS problem.

Log in to each node having a problem and check name resolution for [enterprise-hub.juniper.net](https://enterprise-hub.juniper.net). For example:

```
ping enterprise-hub.juniper.net
ping: enterprise-hub.juniper.net: Temporary failure in name resolution
```

**NOTE:** Although [enterprise-hub.juniper.net](https://enterprise-hub.juniper.net) is not configured to respond to pings, we can use the ping command to check domain name resolution.

In this example, the domain name is not resolving. Check the domain name server configuration to make sure it's correct.

For example, in a Ubuntu system running **systemd resolved**, check that `/etc/resolv.conf` is linked to `/run/systemd/resolve/resolv.conf` as described in step 5 in "Before You Install" on page 18 and check that your DNS server is listed correctly in that file.

- d. If you run into a problem you can't solve or if you made a mistake during the installation, simply uninstall CN2 and start over. To uninstall CN2, see "Uninstall CN2" on page 54.

4. (Optional) Run postflight checks. See ["Run Preflight and Postflight Checks" on page 50](#).

## Install Single Cluster Shared Network CN2 Running DPDK Data Plane

Use this procedure to install CN2 in a single cluster shared network deployment running a DPDK data plane.

The manifest that you will use in this example procedure is **single-cluster/single\_cluster\_deployer\_example.yaml**. The procedure assumes that you've placed this manifest into a **manifests** directory.

1. Create a Kubernetes cluster. You can follow the example procedure in ["Create a Kubernetes Cluster" on page 64](#) or you can use any other method. Create the cluster with the following characteristics:

- Cluster has no CNI plug-in.
- Disable Node Local DNS.
- Enable multus version 0.3.1.

2. Specify the DPDK nodes.

For each node running DPDK, label it as follows:

```
kubectl label node <node-name> agent-mode=dpdk
```

By labeling the nodes in this way, CN2 will use the DPDK configuration specified in the manifest.

3. Apply the Contrail deployer manifest.

```
kubectl apply -f manifests/single_cluster_deployer_example.yaml
```

It may take a few minutes for the nodes and pods to come up.

4. Use standard kubectl commands to check on the deployment.

- a. Show the status of the nodes.

```
kubectl get nodes
```

NAME	STATUS	ROLES	AGE	VERSION
k8s-cp0	Ready	control-plane,master	65m	v1.20.7
k8s-worker0	Ready	<none>	63m	v1.20.7
k8s-worker1	Ready	<none>	62m	v1.20.7

You can see that the nodes are now up. If the nodes are not up, wait a few minutes and check again.

- b. Show the status of the pods.

```
kubectl get pods -A -o wide
```

NAMESPACE	NAME	READY	STATUS	RESTARTS	AGE	IP	NODE	<trimmed>	
contrail-deploy	contrail-k8s-deployer-747689445-7rx52	1/1	Running	0	44m	172.16.0.11	k8s-cp0	<none>	<none>

kube-system	kube-apiserver-k8s-cp0	1/1	Running	0	69m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	kube-controller-manager-k8s-cp0	1/1	Running	0	69m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	kube-proxy-k5mcp	1/1	Running	0	67m	172.16.0.13	k8s-worker1	<none>	<none>
kube-system	kube-proxy-sccjm	1/1	Running	0	67m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	kube-proxy-wqbt8	1/1	Running	1	67m	172.16.0.12	k8s-worker0	<none>	<none>
kube-system	kube-scheduler-k8s-cp0	1/1	Running	0	69m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	nginx-proxy-k8s-worker0	1/1	Running	0	67m	172.16.0.12	k8s-worker0	<none>	<none>
kube-system	nginx-proxy-k8s-worker1	1/1	Running	0	67m	172.16.0.13	k8s-worker1	<none>	<none>

All pods should now have a STATUS of Running. If not, wait a few minutes for the pods to come up.

- c. If some pods remain down, debug the deployment as you normally do. Use the `kubectl describe` command to see why a pod is not coming up. A common error is a network or firewall issue preventing the node from reaching the Juniper Networks repository.

Here is an example of a DNS problem.

Log in to each node having a problem and check name resolution for [enterprise-hub.juniper.net](https://enterprise-hub.juniper.net). For example:

```
ping enterprise-hub.juniper.net
ping: enterprise-hub.juniper.net: Temporary failure in name resolution
```

**NOTE:** Although enterprise-hub.juniper.net is not configured to respond to pings, we can use the ping command to check domain name resolution.

In this example, the domain name is not resolving. Check the domain name server configuration to make sure it's correct.

For example, in a Ubuntu system running **systemd resolved**, check that `/etc/resolv.conf` is linked to `/run/systemd/resolve/resolv.conf` as described in step 5 in ["Before You Install" on page 18](#) and check that your DNS server is listed correctly in that file.

- d. If you run into a problem you can't solve or if you made a mistake during the installation, simply uninstall CN2 and start over. To uninstall CN2, see ["Uninstall CN2" on page 54](#).
5. (Optional) Run postflight checks. See ["Run Preflight and Postflight Checks" on page 50](#).

## Install Single Cluster Multi-Network CN2

### SUMMARY

See examples on how to install single cluster CN2 in a deployment where Kubernetes traffic and CN2 traffic go over separate networks.

### IN THIS SECTION

- [Install Single Cluster Multi-Network CN2 Running Kernel Mode Data Plane | 27](#)
- [Install Single Cluster Multi-Network CN2 Running DPDK Data Plane | 29](#)

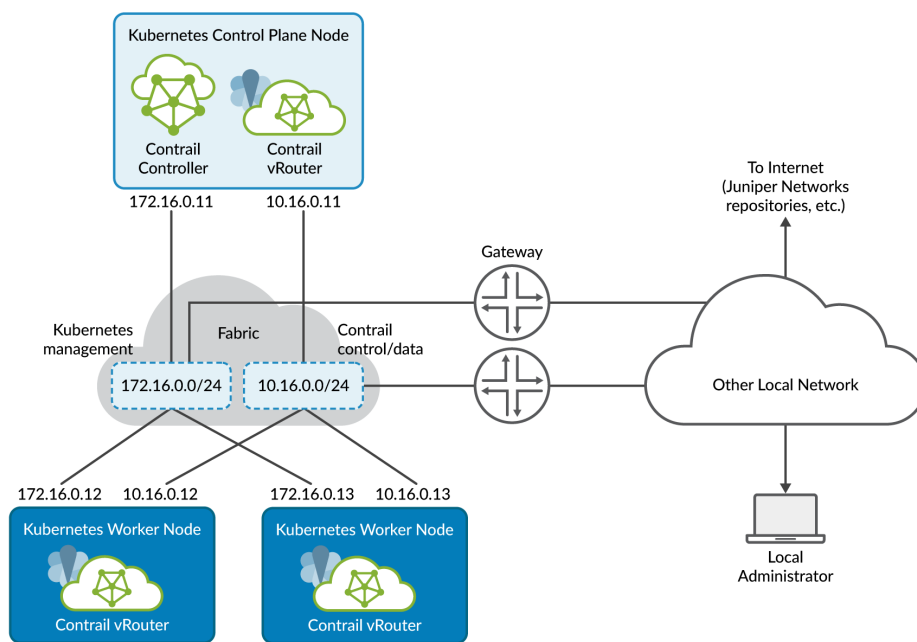

In a single cluster multi-network deployment:

- CN2 is the networking platform and CNI plug-in for that cluster. The Contrail controller runs in the Kubernetes control plane, and the Contrail data plane components run on all nodes in the cluster.
- Cluster traffic is separated onto two networks. The Kubernetes control plane traffic traverses one network while Contrail control and data traffic traverse the second network. It's also possible (but less common) to separate traffic onto more than two networks, but this is beyond the scope of these examples.

[Figure 7 on page 26](#) shows the cluster that you'll create if you follow this single cluster multi-network example. The cluster consists of a single control plane node, two worker nodes, and two subnets.

All nodes shown can be VMs or bare metal servers.

Figure 7: Single Cluster Multi-Network CN2

Kubernetes control plane traffic goes over the 172.16.0.0/24 fabric virtual network while Contrail control and data traffic go over the 10.16.0.0/24 fabric virtual network. The fabric networks provide the underlay over which the cluster runs.

The local administrator is shown attached to a separate network reachable through a gateway. This is typical of many installations where the local administrator manages the fabric and cluster from the corporate LAN. In the procedures that follow, we refer to the local administrator station as your local computer.

**NOTE:** Connecting all cluster nodes together is the data center fabric, which is shown in the example as two subnets. In real installations, the data center fabric is a network of spine and leaf switches that provide the physical connectivity for the cluster.

In an Apstra-managed data center, this connectivity would be specified through the overlay virtual networks that you create across the underlying fabric switches.

The procedures in this section show basic examples of how you can use the provided manifests to create the specified CN2 deployment. You're not limited to the deployment described in this section nor are you limited to using the provided manifests. CN2 supports a wide range of deployments that are too numerous to cover in detail. Use the provided examples as a starting point to roll your own manifest tailored to your specific situation.

## Install Single Cluster Multi-Network CN2 Running Kernel Mode Data Plane

Use this procedure to install CN2 in a single cluster multi-network deployment running a kernel mode data plane.

The manifest that you will use in this example procedure is **single-cluster/single\_cluster\_deployer\_example.yaml**. The procedure assumes that you've placed this manifest into a **manifests** directory.

1. Create a Kubernetes cluster. You can follow the example procedure in ["Create a Kubernetes Cluster" on page 64](#) or you can use any other method. Create the cluster with the following characteristics:
  - Cluster has no CNI plug-in.
  - Disable Node Local DNS.
2. Modify the **single\_cluster\_deployer\_example.yaml** to configure the Contrail control and data network.

You specify the Contrail network using a contrail-network-config ConfigMap. The **single\_cluster\_deployer\_example.yaml** manifest contains a commented example on how you can configure a contrail-network-config ConfigMap.

Either uncomment those lines and specify the appropriate subnet and gateway or copy and paste the following into the manifest.

```
---
apiVersion: v1
kind: ConfigMap
metadata:
  name: contrail-network-config
  namespace: contrail
data:
  networkConfig: |
    controlDataNetworks:
    - subnet: 10.16.0.0/24
      gateway: 10.16.0.254
```

The subnet and gateway you specify is the Contrail control and data network and gateway, which in our example is the 10.16.0.0/24 network.

### 3. Apply the Contrail deployer manifest.

```
kubectl apply -f manifests/single_cluster_deployer_example.yaml
```

It may take a few minutes for the nodes and pods to come up.

### 4. Use standard kubectl commands to check on the deployment.

#### a. Show the status of the nodes.

```
kubectl get nodes
```

NAME	STATUS	ROLES	AGE	VERSION
k8s-cp0	Ready	control-plane,master	65m	v1.20.7
k8s-worker0	Ready	<none>	63m	v1.20.7
k8s-worker1	Ready	<none>	62m	v1.20.7

You can see that the nodes are now up. If the nodes are not up, wait a few minutes and check again.

#### b. Show the status of the pods.

```
kubectl get pods -A -o wide
```

NAMESPACE	NAME	READY	STATUS	RESTARTS	AGE	IP	NODE	<trimmed>	
contrail-deploy	contrail-k8s-deployer-747689445-7rx52	1/1	Running	0	44m	172.16.0.11	k8s-cp0	<none>	<none>
contrail	contrail-control-0	2/2	Running	0	40m	172.16.0.11	k8s-cp0	<none>	<none>
contrail	contrail-k8s-apiserver-6b544788f4-mpk5d	1/1	Running	0	40m	172.16.0.11	k8s-cp0	<none>	<none>
contrail	contrail-k8s-controller-75b8d7b846-rvg7h	1/1	Running	2	40m	172.16.0.11	k8s-cp0	<none>	<none>
contrail	contrail-k8s-kubemanager-6c8b7bd5f5-mwdpj	1/1	Running	5	40m	172.16.0.11	k8s-cp0	<none>	<none>
contrail	contrail-vrouter-masters-pl4zf	3/3	Running	0	40m	172.16.0.11	k8s-cp0	<none>	<none>
contrail	contrail-vrouter-nodes-2tnqq	3/3	Running	0	40m	172.16.0.12	k8s-worker0	<none>	<none>
contrail	contrail-vrouter-nodes-66xnw	3/3	Running	0	40m	172.16.0.13	k8s-worker1	<none>	<none>
kube-system	coredns-657959df74-25sdx	1/1	Running	0	3m19s	10.233.64.2	k8s-cp0	<none>	<none>
kube-system	coredns-657959df74-rprzv	1/1	Running	0	66m	10.233.65.0	k8s-worker0	<none>	<none>
kube-system	dns-autoscaler-b5c786945-pcgsq	1/1	Running	0	66m	10.233.65.1	k8s-worker0	<none>	<none>
kube-system	kube-apiserver-k8s-cp0	1/1	Running	0	69m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	kube-controller-manager-k8s-cp0	1/1	Running	0	69m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	kube-proxy-k5mcp	1/1	Running	0	67m	172.16.0.13	k8s-worker1	<none>	<none>
kube-system	kube-proxy-sccjm	1/1	Running	0	67m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	kube-proxy-wqbt8	1/1	Running	1	67m	172.16.0.12	k8s-worker0	<none>	<none>
kube-system	kube-scheduler-k8s-cp0	1/1	Running	0	69m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	nginx-proxy-k8s-worker0	1/1	Running	0	67m	172.16.0.12	k8s-worker0	<none>	<none>
kube-system	nginx-proxy-k8s-worker1	1/1	Running	0	67m	172.16.0.13	k8s-worker1	<none>	<none>

All pods should now have a STATUS of Running. If not, wait a few minutes for the pods to come up.

- c. If some pods remain down, debug the deployment as you normally do. Use the `kubectl describe` command to see why a pod is not coming up. A common error is a network or firewall issue preventing the node from reaching the Juniper Networks repository.

Here is an example of a DNS problem.

Log in to each node having a problem and check name resolution for [enterprise-hub.juniper.net](https://enterprise-hub.juniper.net). For example:

```
ping enterprise-hub.juniper.net
ping: enterprise-hub.juniper.net: Temporary failure in name resolution
```

**NOTE:** Although [enterprise-hub.juniper.net](https://enterprise-hub.juniper.net) is not configured to respond to pings, we can use the `ping` command to check domain name resolution.

In this example, the domain name is not resolving. Check the domain name server configuration to make sure it's correct.

For example, in a Ubuntu system running **systemd resolved**, check that `/etc/resolv.conf` is linked to `/run/systemd/resolve/resolv.conf` as described in step 5 in ["Before You Install" on page 18](#) and check that your DNS server is listed correctly in that file.

- d. If you run into a problem you can't solve or if you made a mistake during the installation, simply uninstall CN2 and start over. To uninstall CN2, see ["Uninstall CN2" on page 54](#).
5. (Optional) Run postflight checks. See ["Run Preflight and Postflight Checks" on page 50](#).

## Install Single Cluster Multi-Network CN2 Running DPDK Data Plane

Use this procedure to install CN2 in a single cluster multi-network deployment running a DPDK data plane.

The manifest that you will use in this example procedure is **single-cluster/single\_cluster\_deployer\_example.yaml**. The procedure assumes that you've placed this manifest into a **manifests** directory.

1. Create a Kubernetes cluster. You can follow the example procedure in ["Create a Kubernetes Cluster" on page 64](#) or you can use any other method. Create the cluster with the following characteristics:
  - Cluster has no CNI plug-in.

- Disable Node Local DNS.
- Enable multus version 0.3.1.

2. Modify the **single\_cluster\_deployer\_example.yaml** to configure the Contrail control and data network.

You specify the Contrail network using a `contrail-network-config` ConfigMap. The **single\_cluster\_deployer\_example.yaml** manifest contains a commented example on how you can configure a `contrail-network-config` ConfigMap.

Either uncomment those lines and specify the appropriate subnet and gateway or copy and paste the following into the manifest.

```
---
apiVersion: v1
kind: ConfigMap
metadata:
  name: contrail-network-config
  namespace: contrail
data:
  networkConfig: |
    controlDataNetworks:
    - subnet: 10.16.0.0/24
      gateway: 10.16.0.254
```

The subnet and gateway you specify is the Contrail control and data network and gateway, which in our example is the 10.16.0.0/24 network.

3. Specify the DPDK nodes.

For each node running DPDK, label it as follows:

```
kubectl label node <node-name> agent-mode=dpdk
```

By labeling the nodes in this way, CN2 will use the DPDK configuration specified in the manifest.

4. Apply the Contrail deployer manifest.

```
kubectl apply -f manifests/single_cluster_deployer_example.yaml
```

It may take a few minutes for the nodes and pods to come up.

5. Use standard `kubectl` commands to check on the deployment.

- a. Show the status of the nodes.

```
kubectl get nodes
```

NAME	STATUS	ROLES	AGE	VERSION
k8s-cp0	Ready	control-plane,master	65m	v1.20.7
k8s-worker0	Ready	<none>	63m	v1.20.7
k8s-worker1	Ready	<none>	62m	v1.20.7

You can see that the nodes are now up. If the nodes are not up, wait a few minutes and check again.

- b. Show the status of the pods.

```
kubectl get pods -A -o wide
```

NAMESPACE	NAME	READY	STATUS	RESTARTS	AGE	IP	NODE	<trimmed>	
contrail-deploy	contrail-k8s-deployer-747689445-7rx52	1/1	Running	0	44m	172.16.0.11	k8s-cp0	<none>	<none>
contrail	contrail-control-0	2/2	Running	0	40m	172.16.0.11	k8s-cp0	<none>	<none>
contrail	contrail-k8s-apiserver-6b544788f4-mpk5d	1/1	Running	0	40m	172.16.0.11	k8s-cp0	<none>	<none>
contrail	contrail-k8s-controller-75b8d7b846-rvg7h	1/1	Running	2	40m	172.16.0.11	k8s-cp0	<none>	<none>
contrail	contrail-k8s-kubemanager-6c8b7bd5f5-mwdpj	1/1	Running	5	40m	172.16.0.11	k8s-cp0	<none>	<none>
contrail	contrail-vrouter-masters-pl4zf	3/3	Running	0	40m	172.16.0.11	k8s-cp0	<none>	<none>
contrail	contrail-vrouter-nodes-2tnqq	3/3	Running	0	40m	172.16.0.12	k8s-worker0	<none>	<none>
contrail	contrail-vrouter-nodes-66xnw	3/3	Running	0	40m	172.16.0.13	k8s-worker1	<none>	<none>
kube-system	coredns-657959df74-25sdx	1/1	Running	0	3m19s	10.233.64.2	k8s-cp0	<none>	<none>
kube-system	coredns-657959df74-rprzv	1/1	Running	0	66m	10.233.65.0	k8s-worker0	<none>	<none>
kube-system	dns-autoscaler-b5c786945-pcgsq	1/1	Running	0	66m	10.233.65.1	k8s-worker0	<none>	<none>
kube-system	kube-apiserver-k8s-cp0	1/1	Running	0	69m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	kube-controller-manager-k8s-cp0	1/1	Running	0	69m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	kube-proxy-k5mcp	1/1	Running	0	67m	172.16.0.13	k8s-worker1	<none>	<none>
kube-system	kube-proxy-sccjm	1/1	Running	0	67m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	kube-proxy-wqbt8	1/1	Running	1	67m	172.16.0.12	k8s-worker0	<none>	<none>
kube-system	kube-scheduler-k8s-cp0	1/1	Running	0	69m	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	nginx-proxy-k8s-worker0	1/1	Running	0	67m	172.16.0.12	k8s-worker0	<none>	<none>
kube-system	nginx-proxy-k8s-worker1	1/1	Running	0	67m	172.16.0.13	k8s-worker1	<none>	<none>

All pods should now have a STATUS of Running. If not, wait a few minutes for the pods to come up.

- c. If some pods remain down, debug the deployment as you normally do. Use the `kubectl describe` command to see why a pod is not coming up. A common error is a network or firewall issue preventing the node from reaching the Juniper Networks repository.

Here is an example of a DNS problem.

Log in to each node having a problem and check name resolution for [enterprise-hub.juniper.net](https://enterprise-hub.juniper.net). For example:

```
ping enterprise-hub.juniper.net
ping: enterprise-hub.juniper.net: Temporary failure in name resolution
```

**NOTE:** Although [enterprise-hub.juniper.net](https://enterprise-hub.juniper.net) is not configured to respond to pings, we can use the ping command to check domain name resolution.

In this example, the domain name is not resolving. Check the domain name server configuration to make sure it's correct.

For example, in a Ubuntu system running **systemd resolved**, check that `/etc/resolv.conf` is linked to `/run/systemd/resolve/resolv.conf` as described in step 5 in ["Before You Install" on page 18](#) and check that your DNS server is listed correctly in that file.

- d. If you run into a problem you can't solve or if you made a mistake during the installation, simply uninstall CN2 and start over. To uninstall CN2, see ["Uninstall CN2" on page 54](#).
6. (Optional) Run postflight checks. See ["Run Preflight and Postflight Checks" on page 50](#).

## Install Multi-Cluster Shared Network CN2

### SUMMARY

See examples on how to install multi-cluster CN2 in a deployment where Kubernetes traffic and CN2 traffic share the same network within each cluster.

### IN THIS SECTION

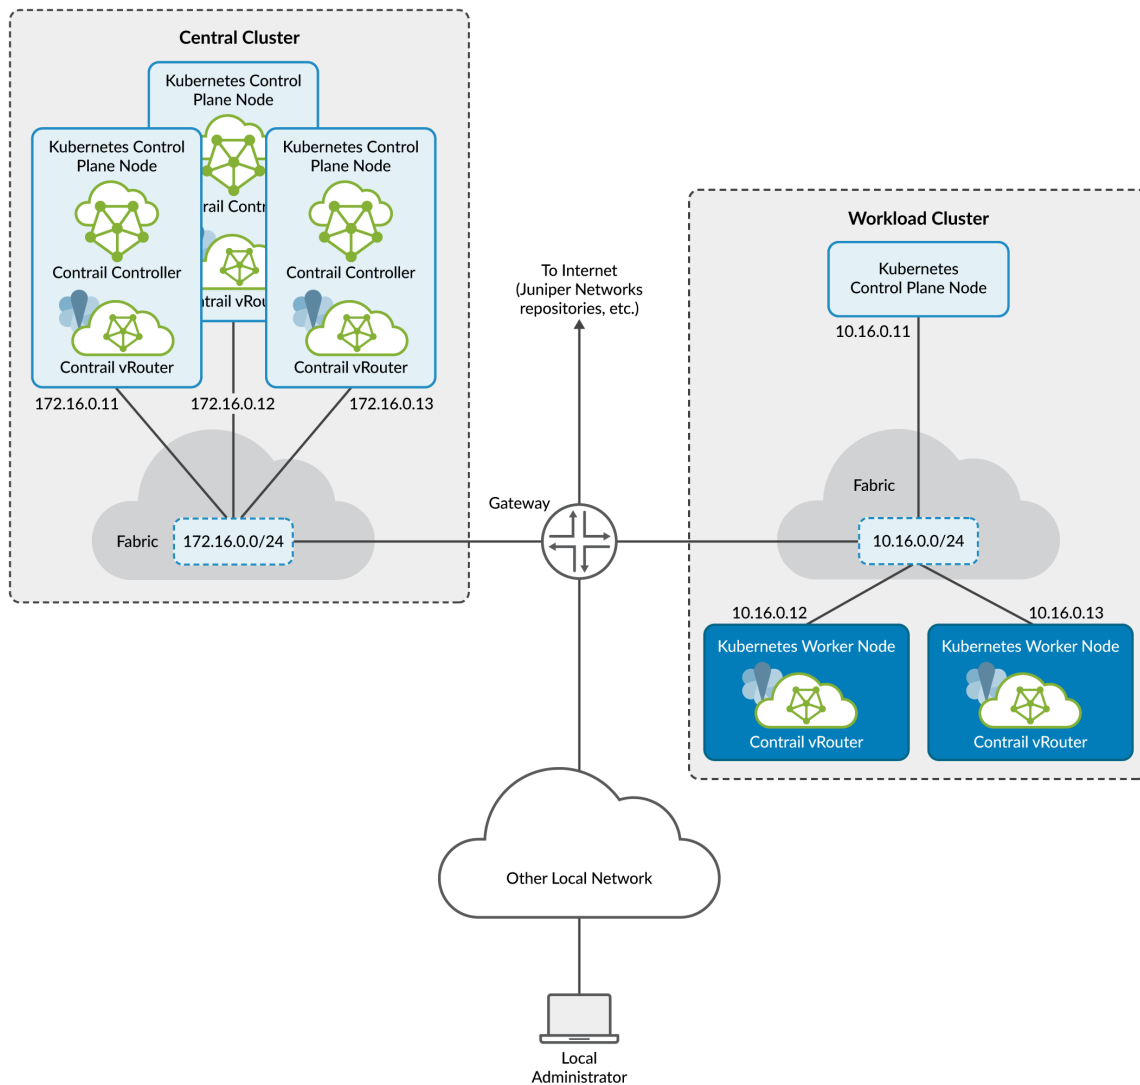

- [Install Multi-Cluster Shared Network CN2 | 34](#)

In a multi-cluster shared network deployment:

- CN2 is the central networking platform and CNI plug-in for multiple distributed workload clusters. The Contrail controller runs in the Kubernetes control plane in the central cluster, and the Contrail data plane components run on the worker nodes in the distributed workload clusters.
- Kubernetes and CN2 traffic within each cluster share a single network.

Figure 8 on page 33 shows the cluster you'll create if you follow the multi-cluster setup. The central cluster consists of 3 Kubernetes control plane nodes that run the Contrail controller. This centralized Contrail controller provides the networking for distributed workload clusters. In this example, there is one distributed cluster that consists of a single control plane node and two worker nodes. The worker nodes on the distributed workload cluster contain the Contrail data plane components.

**Figure 8: Multi-Cluster CN2**

The central cluster attaches to the 172.16.0.0/24 network while the distributed workload cluster attaches to the 10.16.0.0/24 network. A gateway sitting between the networks provides access to each other and external access for downloading images from Juniper Networks repositories.

The local administrator is shown attached to a separate network reachable through a gateway. This is typical of many installations where the local administrator manages the fabric and cluster from the corporate LAN. In the procedures that follow, we refer to the local administrator station as your local computer.

**NOTE:** Connecting all cluster nodes together is the data center fabric, which is simplified in the example into a single subnet per cluster. In real installations, the data center fabric is a network of spine and leaf switches that provide the physical connectivity for the cluster.

In an Apstra-managed data center, this connectivity would be specified through the overlay virtual networks that you create across the underlying fabric switches.

To install CN2 in a multi-cluster deployment, you first create the central cluster and then you attach the distributed workload clusters to the central cluster one by one. As with the single-cluster deployment, you'll start with a fresh cluster with no CNI plug-in installed and then you'll install CN2 on it.

The procedures in this section show basic examples of how you can use the provided manifests to create the specified CN2 deployment. You're not limited to the deployment described in this section nor are you limited to using the provided manifests. CN2 supports a wide range of deployments that are too numerous to cover in detail. Use the provided examples as a starting point to roll your own manifest for your specific situation.

## Install Multi-Cluster Shared Network CN2

Use this procedure to install CN2 in a multi-cluster shared network deployment running a kernel mode data plane.

The manifest that you will use in this example procedure is **multi-cluster/central\_cluster\_deployer\_example.yaml**. The procedure assumes that you've placed this manifest into a **manifests** directory.

### 1. Create the central cluster.

Follow the example procedure in ["Create a Kubernetes Cluster" on page 64](#) or you can use any other method. Create the cluster with the following characteristics:

- Cluster has no CNI plug-in.
- Disable Node Local DNS.

Tailor the procedure with the desired number of control plane and worker nodes accordingly.

### 2. Install CN2 on the central cluster.

- a. Apply the central cluster manifest (**central\_cluster\_deployer\_example.yaml**). This manifest creates the namespaces and other resources required by the central cluster. It also creates the contrail-k8s-deployer deployment, which deploys CN2 and provides life cycle management for the CN2 components.

```
user@central:~/contrail$ kubectl apply -f manifests/central_cluster_deployer_example.yaml
```

- b. Check that all pods are now up. This might take a few minutes.

```
kubectl get pods -A -o wide
```

You've now created the central cluster.

3. Follow ["Attach a Workload Cluster" on page 55](#) to create and attach a distributed workload cluster to the central cluster.
4. Repeat step 3 for every workload cluster you want to create and attach.
5. (Optional) Run postflight checks. See ["Run Preflight and Postflight Checks" on page 50](#).

**NOTE:** Run postflight checks from the central cluster only.

## Install Contrail Tools

### SUMMARY

Learn how to install tools that can help your CN2 installation go more smoothly.

### IN THIS SECTION

- [Install ContrailReadiness Controller | 36](#)

Contrail tools are implemented within the ContrailReadiness controller framework. The controller runs the tools and gathers and presents the results asynchronously on demand.

You'll need to set up the ContrailReadiness controller framework before you can run any tools. After the controller comes up, follow the procedure for the tool you would like to run.

- ["preflight checks" on page 50](#)
- ["postflight checks" on page 50](#)

- ["CN2 uninstall" on page 54](#)

## Install ContrailReadiness Controller

Use this procedure to install the ContrailReadiness controller. The ContrailReadiness controller is required before you can run any tools.

You can install the ContrailReadiness controller before or after you install CN2. Installing the controller before you install CN2 allows you to run preflight checks on the cluster.

1. Locate the **contrail-tools/contrail-readiness** directory from the downloaded CN2 Tools package.
2. If you haven't already done so, ensure you've populated the tools manifests with your repository login credentials. See ["Configure Repository Credentials" on page 72](#) for one way to do this.
3. Apply the ContrailReadiness custom resource definitions.

```
kubectl apply -f contrail-tools/contrail-readiness/crds
```

4. Create the ConfigMap from the deployer manifest that you plan to use or have used to install this cluster. Name the ConfigMap `deployer-yaml`.

```
kubectl create configmap deployer-yaml --from-file=<path_to_deployer_manifest>
```

where *<path\_to\_deployer\_manifest>* is the full path to the deployer manifest that you want to apply or have applied.

5. Patch the ConfigMap with the registry information.

```
kubectl patch configmap deployer-yaml --type merge -p '{"data":{"registry":"enterprise-hub.juniper.net/contrail-container-prod"}}'
```

6. Create the ContrailReadiness controller.

```
kubectl apply -f contrail-tools/contrail-readiness/contrail-readiness-controller.yaml
```

Check that the controller has come up.

```
kubectl get pods -n contrail-readiness
```

# Manifests

## SUMMARY

We provide sample manifests to make your installation easier. You can download these manifests from the Juniper Networks software download site or from GitHub.

## IN THIS SECTION

- [Manifests in Release 23.2 | 37](#)
- [Contrail Tools in Release 23.2 | 38](#)
- [Contrail Analytics in Release 23.2 | 39](#)

## Manifests in Release 23.2

The Manifests for Upstream Kubernetes package is available for download from the Juniper Networks software download site (<https://support.juniper.net/support/downloads/?p=contrail-networking>) or from github (<https://github.com/Juniper/contrail-networking/tree/main/releases/23.2>).

**NOTE:** The provided manifests might not be compatible between releases. Make sure you use the manifests for the release that you're running. In practice, this means that you should not modify the image tag in the supplied manifests.

If you're downloading from the Juniper Networks software download site, you'll need an account to download. If you don't have an account, contact your Juniper Networks sales representative to have one created for you. The package you download is called **contrail-manifests-k8s-23.2.0.157.tgz**.

The following table lists the single cluster manifests in that package.

**Table 4: Single Cluster Manifests for Upstream Kubernetes for Release 23.2**

Manifests	Description
k8s/single_cluster/ single_cluster_deployer_example.yaml	Contains the manifests to install Contrail in a single cluster.

The following table lists the manifests that are specific to setting up a multi-cluster.

Table 5: Multi-Cluster Manifests for Upstream Kubernetes for Release 23.2

Manifests	Description
k8s/multi-cluster/ central_cluster_deployer_example.yaml	Contrail deployer and necessary resources for the central cluster in a multi-cluster setup.
k8s/multi-cluster/ distributed_cluster_certmanager_example.yaml	Contrail cert-manager manifests for encrypting Contrail management and control plane communications.
k8s/multi-cluster/ distributed_cluster_deployer_example.yaml	Contrail deployer and necessary resources for distributed workload clusters in a multi-cluster setup.
k8s/multi-cluster/ distributed_cluster_vrouter_example.yaml	Contrail vRouter for the distributed workload clusters in a multi-cluster setup.

## Contrail Tools in Release 23.2

### IN THIS SECTION

- [Contrail Tools | 38](#)

## Contrail Tools

The optional Contrail Tools package is available for download from the Juniper Networks software download <https://support.juniper.net/support/downloads/?p=contrail-networking> site. Contrail tools are compatible with CN2 within the same release only.

You'll need an account to download. If you don't have an account, contact your Juniper Networks sales representative to have one created for you.

The release 23.2 package is called **contrail-tools-23.2.0.157.tgz**.

The following table lists tools that we provide.

**Table 6: Tools Manifests for Release 23.2**

Tools	Description
contrail-tools/contrail-readiness/contrail-readiness-controller.yaml	The ContrailReadiness controller that runs preflight and postflight checks
contrail-tools/contrail-readiness/contrail-readiness-preflight.yaml	ContrailReadiness preflight custom resource
contrail-tools/contrail-readiness/contrail-readiness-postflight.yaml	ContrailReadiness postflight custom resource
contrail-tools/contrail-readiness/contrail-readiness-uninstall.yaml	ContrailReadiness uninstall custom resource
contrail-tools/contrail-readiness/crds	ContrailReadiness custom resource definitions for the supported tools
contrail-tools/kubectl-contrailstatus- <release>.tar	The kubectl contrailstatus plug-in
contrail-tools/cn2_debug_infra- <release>.tar	The CN2 debug utility
contrail-tools/uninstall.tar.gz	Deprecated

## Contrail Analytics in Release 23.2

The optional Contrail Analytics package is available for download from the Juniper Networks software download <https://support.juniper.net/support/downloads/?p=contrail-networking> site. Select the Contrail Analytics package from the same release page that you select the Contrail Networking manifests. Contrail Analytics is compatible with Contrail Networking within the same release only.

You'll need an account to download. If you don't have an account, contact your Juniper Networks sales representative to have one created for you.

The release 23.2 package is called **contrail-analytics-23.2.0.157.tgz**.

To install Contrail Analytics, see the *Install Contrail Analytics and the CN2 Web UI* section.

# 3

CHAPTER

## Monitor

---

[Overview](#) | 41

[Install Contrail Analytics and the CN2 Web UI](#) | 41

[KubectI Contrailstatus](#) | 44

---

# Overview

You can monitor CN2 in the same way you monitor other Kubernetes components, using `kubectl` or other standard Kubernetes methods.

You can also install the optional Contrail Analytics package, which packages Prometheus, Grafana, Fluentd, and other popular open source software together with Contrail telemetry exporters to provide you with insight into the general health, performance, and traffic trends of the network. Included with Contrail Analytics is the CN2 Web UI, which you can use to monitor and configure CN2 components.

Additionally, we provide a `kubectl` plug-in that you can invoke to check the status of CN2 components from the command line. The `contrailstatus` plug-in allows you to query the CN2 configuration, control, and data plane components as well as BGP and XMPP relationships.

## Install Contrail Analytics and the CN2 Web UI

Use this procedure to install Contrail Analytics and the CN2 Web UI.

Contrail Analytics packages popular open source software such as Prometheus, Grafana, and Fluentd together with CN2 telemetry exporters to provide an industry-standard way for you to monitor and analyze your network and network infrastructure. Information collected includes logs, metrics, status' of various component, and flows.

Packaged with Contrail Analytics is the CN2 Web UI, which allows you to monitor and configure CN2 components.

When you install Contrail Analytics, all analytics components are preconfigured to work with each other.

You have the option of installing Contrail Analytics with a single instance of Prometheus or with HA Prometheus support. HA Prometheus for Contrail Analytics is a Tech Preview feature.

**NOTE:** We use Helm charts to install Contrail Analytics. Install Helm 3.0 or later on the host that you're using to install Contrail Analytics.

1. Locate the Contrail Analytics package that you downloaded.

```
contrail-analytics-<version>.tgz
```

2. To install Contrail Analytics with a single instance of Prometheus:

```
helm -n contrail-analytics install analytics contrail-analytics-<version>.tgz --create-namespace
```

The `--create-namespace` option creates the `contrail-analytics` namespace. You can omit this option if your cluster already has the `contrail-analytics` namespace defined.

Contrail Analytics is installed as a NodePort service. You can reach the service by specifying the IP address of any node running Contrail Analytics. By default, the port to use is 30443.

3. To install Contrail Analytics with HA Prometheus support (Tech Preview):

**NOTE:** This feature is classified as a Juniper CN2 Technology Preview feature. These features are "as is" and are for voluntary use. Juniper Support will attempt to resolve any issues that customers experience when using these features and create bug reports on behalf of support cases. However, Juniper may not provide comprehensive support services to Tech Preview features.

For additional information, refer to the ["Juniper CN2 Technology Previews \(Tech Previews\)" on page 80](#) or contact [Juniper Support](#).

- a. Extract the **thanos-values.yaml** file from the Contrail Analytics package.

```
tar --strip=1 -xzf contrail-analytics-<version>.tgz contrail-analytics/thanos-values.yaml
```

Contrail Analytics uses Thanos to provide high availability for Prometheus. Thanos is a set of open source components that integrate seamlessly with Prometheus to provide a highly available metric system.

- b. Install Contrail Analytics (referencing the **thanos-values.yaml**) file.

```
helm -n contrail-analytics install analytics contrail-analytics-<version>.tgz -f thanos-values.yaml --create-namespace
```

The `--create-namespace` option creates the `contrail-analytics` namespace. You can omit this option if your cluster already has the `contrail-analytics` namespace defined.

Contrail Analytics is installed as a NodePort service. You can reach the service by specifying the IP address of any node running Contrail Analytics. By default, the port to use is 30443.

4. Verify that the analytics components are installed and running.

```
helm -n contrail-analytics list
```

```
kubectl get pods -n contrail-analytics
```

5. After you install Contrail Analytics, you can access Grafana or the CN2 Web UI.

To access Grafana, point your browser to `https:// <node-IP-address>:30443/grafana/`. Be sure to include the trailing `/`. The default Grafana administrator username/password is `admin/prom-operator`.

To access the CN2 Web UI, point your browser to `https:// <node-IP-address>:30443`. The default CN2 Web UI username/password is `super/c0ntrail123`.

Change the default passwords after logging in.

**NOTE:** The CN2 Web UI is classified as a Juniper CN2 Technology Preview feature. These features are "as is" and are for voluntary use. Juniper Support will attempt to resolve any issues that customers experience when using these features and create bug reports on behalf of support cases. However, Juniper may not provide comprehensive support services to Tech Preview features.

For additional information, refer to the ["Juniper CN2 Technology Previews \(Tech Previews\)" on page 80](#) or contact [Juniper Support](#).

6. To uninstall Contrail Analytics:

```
helm -n contrail-analytics uninstall analytics
```

```
kubectl delete ns contrail-analytics
```

7. To upgrade Contrail Analytics:

```
helm -n contrail-analytics upgrade analytics contrail-analytics-<version>.tgz
```

or (for upgrading HA)

```
helm -n contrail-analytics upgrade analytics contrail-analytics-<version>.tgz -f thanos-values.yaml
```

# Kubectl Contrailstatus

## IN THIS SECTION

- [Syntax | 44](#)
- [Description | 44](#)
- [Options | 45](#)
- [Additional Information | 45](#)
- [Output Fields | 46](#)
- [Sample Output | 47](#)
- [Release Information | 48](#)

## Syntax

```
kubectl contrailstatus deployment --plane { config | control | data [--wide] }
kubectl contrailstatus resource { bgprouter [BGP | XMPP] | globalssystemconfig | routinginstance
| virtualnetwork [--wide] }
kubectl contrailstatus cresource all [detail]
kubectl contrailstatus configdump
kubectl contrailstatus --all [--wide]
kubectl contrailstatus version
```

## Description

This command displays the status' of various CN2 components. You can display the status' of the Configuration plane components, the Control plane components, the Data plane components, and the BGP routers and other resources.

## Options

<b>kubectl contrailstatus deployment --plane config</b>	Displays the status of the Configuration plane components: <ul style="list-style-type: none"> <li>• contrail-k8s-apiserver</li> <li>• contrail-k8s-controller</li> <li>• contrail-k8s-kubemanager</li> </ul>
<b>kubectl contrailstatus deployment --plane control</b>	Displays the status of the Control plane components: <ul style="list-style-type: none"> <li>• contrail-control</li> </ul>
<b>kubectl contrailstatus deployment --plane data</b>	Displays the status of the Data plane components: <ul style="list-style-type: none"> <li>• contrail-vrouter-masters</li> <li>• contrail-vrouter-nodes</li> </ul>
<b>kubectl contrailstatus resource bgprouter</b>	Displays the status' of the various BGP and XMPP neighbor relationships.
<b>kubectl contrailstatus resource globalsystemconfig</b>	Displays the status of the GlobalSystemConfig.
<b>kubectl contrailstatus resource routinginstance</b>	Displays the status' of the various RoutingInstances in CN2.
<b>kubectl contrailstatus resource virtualnetwork</b>	Displays the status' of the various VirtualNetworks in CN2.
<b>kubectl contrailstatus cresource all</b>	Displays all information about all resources (useful for displaying all information in a single command for debugging). If the detail option is used, the output is displayed in JSON format.
<b>kubectl contrailstatus configdump</b>	Lists the resources and their quantities.
<b>kubectl contrailstatus --all</b>	Displays the status' of the Configuration/Control/Data planes and the BGP and XMPP relationships.
<b>kubectl contrailstatus version</b>	Displays the versions of the various container images.

## Additional Information

The `--wide` qualifier displays more information (if available) on the queried component.

Use the `--help` qualifier to display the help at any point in the command.

This command looks for the kubeconfig file in the default `~/.kube/config` location. You can't use the `kubectrl --kubeconfig` option to specify the location of the kubeconfig file.

## Output Fields

Table 7 on page 46 lists some of the output fields for the `kubectrl contrailstatus` command.

**Table 7: kubectrl contrailstatus Output Fields**

Field Name	Field Description
NAME	The name of the pod or resource.
STATUS	The status of the pod or resource.
NODE	The name of the node on which the pod is running.
IP	The (machine) IP address of the node on which the pod is running.
MESSAGE	Not used.
LOCAL BGPROUTER	The name of the node on which the local BGP router is running.
NEIGHBOR BGPROUTER	The name of the node on which the neighbor BGP router is running.
ENCODING	Whether this connection is XMPP or BGP.
STATE	The state of this connection.
POD	The name of the pod on which the local BGP router is running.

## Sample Output

### kubectrl contrail-status --all

```
user@host> kubectrl contrail-status --all
```

NAME(CONFIG)	STATUS	NODE	IP	MESSAGE
contrail-k8s-apiserver-6d79c8598d-8lfnm	ok	ocp1	172.16.0.11

Manage Single Cluster CN2 | 50

Manage Multi-Cluster CN2 | 55

---

# Manage Single Cluster CN2

## SUMMARY

Learn how to perform life cycle management tasks in a single cluster installation or within a specific cluster in a multi-cluster installation.

## IN THIS SECTION

- [Overview | 50](#)
- [Run Preflight and Postflight Checks | 50](#)
- [Upgrade CN2 | 52](#)
- [Uninstall CN2 | 54](#)

## Overview

The way that you manage a Kubernetes cluster does not change when CN2 is the CNI plug-in. Once CN2 is installed, CN2 components work seamlessly with Kubernetes components to provide the networking infrastructure.

The Contrail controller is constantly watching and reacting to cluster events as they occur. When you add a new node, the Contrail data plane components are automatically deployed. When you delete a node, the Contrail controller automatically deletes networking resources associated with that node. CN2 works seamlessly with `kubectl` and other tools such as Prometheus and Grafana.

In addition to standard Kubernetes management tools, you can use tools and procedures that are specific to CN2. This section covers these tools and procedures.

## Run Preflight and Postflight Checks

Use this procedure to run preflight or postflight checks on all cluster nodes.

Preflight checks allow you to verify that your cluster nodes can support CN2. The checks test for resource capacity, kernel compability, network reachability, and other infrastructure requirements. You typically run preflight checks prior to installing CN2, but you can run these checks after installing CN2 as well.

Postflight checks allow you to verify that your CN2 installation is working properly. The checks test for status, pod-to-pod communication, API server reachability, and other basic functions. You run postflight checks after installing CN2.

Before you can run this procedure, ensure you've installed the ContrailReadiness controller. The ContrailReadiness controller provides the framework for preflight and postflight checks. See the *Install ContrailReadiness Controller* section.

1. Locate the **contrail-tools/contrail-readiness** directory from the downloaded CN2 Tools package.
2. If you haven't already done so, ensure you've populated the manifests with your repository login credentials. See ["Configure Repository Credentials" on page 72](#) for one way to do this.
3. To run the preflight checks:

```
kubectl apply -f contrail-tools/contrail-readiness/contrail-readiness-preflight.yaml
```

You typically run preflight checks after you create the cluster but before you install CN2.

**NOTE:** In a multi-cluster deployment, run preflight checks from the central cluster only.

4. To run the postflight checks:

```
kubectl apply -f contrail-tools/contrail-readiness/contrail-readiness-postflight.yaml
```

You run postflight checks after you install CN2.

**NOTE:** In a multi-cluster deployment, run postflight checks from the central cluster only.

5. Read the preflight and postflight check results as applicable.

```
kubectl get contrailreadiness preflight -o yaml
```

```
kubectl get contrailreadiness task preflight-kernel -o yaml
```

```
kubectl get contrailreadiness postflight -o yaml
```

```
kubectl get contrailreadiness task postflight-contrailresources -o yaml
```

Address any errors before proceeding.

**NOTE:** The preflight and postflight checks do not automatically rerun after you've fixed any errors. The output will continue to show errors even after you've fixed them.

## Upgrade CN2

Use this procedure to upgrade CN2.

The Contrail controller consists of Deployments and StatefulSets, which are configured for rolling updates. During the upgrade, the pods in each Deployment and StatefulSet are upgraded one at a time. The remaining pods in that Deployment or StatefulSet remain operational. This enables Contrail controller upgrades to be hitless.

The Contrail data plane consists of a DaemonSet with a single vRouter pod. During the upgrade procedure, this single pod is taken down and upgraded. Because of this, Contrail data plane upgrades are not hitless. If desired, migrate traffic off of the node being upgraded prior to performing the upgrade.

You upgrade CN2 software by porting the contents of your existing manifests to the new manifests, and then applying the new manifests. All CN2 manifests must reference the same software version.

**NOTE:** Before you upgrade, check to make sure that each node has at least one allocatable pod available. The upgrade procedure temporarily allocates an additional pod, which means that your

node cannot be running at maximum pod capacity when you perform the upgrade. You can check pod capacity on a node by using the `kubectl describe node` command.

1. Download the manifests for the new release.
2. Locate the (old) manifest(s) that you used to create the existing CN2 installation. In this procedure, we assume it's **single\_cluster\_deployer\_example.yaml**.
3. Port over any changes from the old manifest(s) to the new manifest(s).

The new manifests can contain constructs that are specific to the new release. Identify all changes that you've made to the old manifests and copy them over to the new manifests. This includes repository credentials, network configuration changes, and other customizations.

**NOTE:** If you have a large number of nodes, use node selectors to group your upgrades to a more manageable number.

4. Upgrade CN2.

```
kubectl apply -f manifests/single_cluster_deployer_example.yaml
```

The pods in each Deployment and Stateful set will upgrade one at a time. The vRouter DaemonSet will go down and come back up.

5. Use standard `kubectl` commands to check on the upgrade.

Check the status of the nodes.

```
kubectl get nodes
```

Check the status of the pods.

```
kubectl get pods -A -o wide
```

If some pods remain down, debug the installation as you normally do. Use the `kubectl describe` command to see why a pod is not coming up. A common error is a network or firewall issue preventing the node from reaching the Juniper Networks repository.

## Uninstall CN2

Use this procedure to uninstall CN2.

This tool removes the following:

- contrail namespace and resources that belong to that namespace
- contrail-system namespace and resources that belong to that namespace
- contrail-deploy namespace and resources that belong to that namespace
- default-global-vrouter-config and default-global-system-config

Before you can run this procedure, ensure you've installed the ContrailReadiness controller. The ContrailReadiness controller provides the framework for the uninstall task.

**NOTE:** Since there are interdependencies between CN2 components, don't try to delete CN2 components individually. The provided tool uninstalls CN2 components gracefully and in the proper sequence.

1. Locate the **contrail-tools/contrail-readiness** directory from the downloaded CN2 Tools package.
2. If you haven't already done so, ensure you've populated the manifests with your repository login credentials. See ["Configure Repository Credentials" on page 72](#) for one way to do this.
3. If you've installed Contrail Analytics, uninstall it now. The uninstall script does not uninstall resources in namespaces other than those listed above. To uninstall Contrail Analytics, see the *Install Contrail Analytics and the CN2 Web UI* section.
4. Delete any other resources and namespaces (for example, overlay networks) that you created after you installed CN2.
5. Uninstall CN2.

```
kubectl apply -f contrail-tools/contrail-readiness/contrail-readiness-uninstall.yaml
```

6. Query the uninstall results.

```
kubectl get contrailreadiness contrail-uninstall -o yaml
```

7. Finally, delete the contrail-readiness namespace.

```
kubectl delete ns contrail-readiness
```

# Manage Multi-Cluster CN2

## SUMMARY

Learn how to perform life cycle management tasks specific to a multi-cluster installation.

## IN THIS SECTION

- [Attach a Workload Cluster | 55](#)
- [Detach a Workload Cluster | 60](#)
- [Uninstall CN2 | 61](#)

This section covers tasks that are specific to a multi-cluster installation. If you want to perform management tasks in a specific cluster (such as adding and removing nodes within a cluster and upgrading a cluster) within the multi-cluster installation, then see ["Manage Single Cluster CN2" on page 50](#).

## Attach a Workload Cluster

Use this procedure to create and attach a distributed workload cluster (running a kernel mode data plane) to the central cluster. If you want to run a DPDK data plane, then extrapolate from the DPDK examples in this document.

The manifests that you will use in this example procedure are **multi-cluster/distributed\_cluster\_deployer\_example.yaml** and **multi-cluster/distributed\_cluster\_vrouter\_example.yaml**. The procedure assumes that you've placed these manifests into a **manifests** directory.

1. Prepare the distributed workload cluster as described in ["Before You Install" on page 18](#).
2. Create the distributed workload cluster.

Create a fresh cluster. You can follow the procedure in ["Create a Kubernetes Cluster" on page 64](#) or use your own methods to create a cluster. The cluster should have the following characteristics:

- Cluster has no CNI plug-in.
- Disable Node Local DNS.
- In a multi-cluster setup, you must configure different pod and service subnets on each cluster. These subnets must be unique within the entire multi-cluster.

- In a multi-cluster setup, you must configure different node names for nodes in each cluster. Node names must be unique across the entire multi-cluster.

3. Install CN2 components on the distributed workload cluster.

- a. On the workload cluster, copy the kubeconfig from the central cluster. We'll call this **central-cluster-kubeconfig** here.

```
scp user@central:~/.kube/config central-cluster-kubeconfig
```

- b. On the workload cluster, create the contrail-deploy namespace.

```
kubectl create ns contrail-deploy
```

- c. On the workload cluster, create a Kubernetes secret from the central cluster kubeconfig and name the secret **central-kubeconfig**.

**NOTE:** You must name the secret **central-kubeconfig**.

```
kubectl create secret generic central-kubeconfig -n contrail-deploy --from-file=kubeconfig=/root/contrail/central-cluster-kubeconfig
```

**NOTE:** You must specify the absolute path to the **central-cluster-kubeconfig** file.

- d. On the workload cluster, apply the deployer manifest. The deployer provides life cycle management for the CN2 components.

This manifest includes a reference to the **central-kubeconfig** secret you created in the previous substep.

```
kubectl apply -f manifests/distributed_cluster_deployer_example.yaml
```

- e. Check that the contrail-deployer has come up. This may take a few minutes.

```
kubectl get pods -n contrail-deploy
```

NAME	READY	STATUS	RESTARTS	AGE
contrail-k8s-deployer-6458859585-xhwx6	1/1	Running	0	6m

- f. On the workload cluster, apply the cert-manager manifest. The cert-manager provides encryption for all management and control plane connections.

```
kubectl apply -f manifests/distributed_cluster_certmanager_example.yaml
```

4. On the central cluster, attach the new workload cluster by creating a kubemanager for the new workload cluster.

- a. On the central cluster, copy the kubeconfig from the distributed workload cluster. We'll call this **workload-cluster-kubeconfig** here.

```
scp user@workload:~/.kube/config workload-cluster-kubeconfig
```

- b. On the central cluster, create a Kubernetes secret from the distributed workload cluster kubeconfig and choose a meaningful name for the secret (for example, **workload-kubeconfig**).

```
kubectl create secret generic workload-kubeconfig -n contrail --from-file=kubeconfig=/root/contrail/workload-cluster-kubeconfig
```

- c. Create the kubemanager manifest with the following content. Choose a meaningful name for the manifest (for example, **kubemanager-cluster1.yaml**).

```
apiVersion: configplane.juniper.net/v1alpha1
kind: Kubemanager
metadata:
  name: <CR name>
  namespace: contrail
spec:
  common:
    containers:
      - image: <contrail-image-repository>
```

```

    name: contrail-k8s-kubemanager
  podV4Subnet: <pod-v4-subnet-of-remote-cluster>
  serviceV4Subnet: <service-v4-subnet-of-remote-cluster>
  podV6Subnet: <pod-v6-subnet-of-remote-cluster>
  serviceV6Subnet: <service-v6-subnet-of-remote-cluster>
  clusterName: <worker-cluster-name>
  kubeconfigSecretName: <secret-name>
  enableNad: <true/false>
  listenerPort: <listener-port>
  constantRouteTargetNumber: <rt-number>

```

[Table 9 on page 58](#) explains the parameters that you need to set.

**Table 9: Kubemanager CRD**

Parameter	Meaning	Example
name	The name of the custom resource.	kubemanager-cluster1
image	The repository where you pull images	enterprise-hub.juniper.net/ contrail-container-prod/contrail- k8s-kubemanager:23.2.0.156
podV4Subnet	The IPv4 pod subnet that you configured earlier for the distributed workload cluster. This subnet must be unique within the entire multi-cluster.	10.234.64.0
serviceV4Subnet	The IPv4 service subnet that you configured earlier for the distributed workload cluster. This subnet must be unique within the entire multi-cluster.	10.234.0.0/18
podV6Subnet	The IPv6 pod subnet that you configured earlier for the distributed workload cluster. This subnet must be unique within the entire multi-cluster.	fd85:ee78:d8a6:8608::1:0000/1 12

Table 9: Kubemanager CRD *(Continued)*

Parameter	Meaning	Example
serviceV6Subnet	The IPv6 service subnet that you configured earlier for the distributed workload cluster. This subnet must be unique within the entire multi-cluster.	fd85:ee78:d8a6:8608::1000/116
clusterName	The name of the workload cluster.	workload-cluster
kubeconfigSecretName	The name of the secret containing the workload cluster kubeconfig token.	workload-kubeconfig
enableNad	True or false (to enable network address definition or not)	true
listenerPort	The port that the Contrail controller listens on for communications with this workload cluster. Set the port for the first workload cluster to 19446 and increment by 1 for each subsequent workload cluster.	19446
constantRouteTargetNumber	The route target for this workload cluster. Set the route target for the first workload cluster to 7699 and increment by 100 for each subsequent workload cluster.	7699

- d. On the central cluster, apply the kubemanager manifest you just created.

```
kubect1 apply -f manifests/kubemanager-cluster1.yaml
```

- e. On the central cluster, verify that you can see the workload cluster's namespaces.

```
kubectl get ns
```

The namespaces are in the following format: `<kubemanager-name> <workload-cluster-name> <namespace>`.  
For example:

```
kubemanager-workload1-workload-cluster-contrail
```

5. Finally, on the workload cluster, install the vRouter.

```
kubectl apply -f manifests/distributed_cluster_vrouter_example.yaml
```

After a few minutes, verify that all pods are up:

```
kubectl get pods -A
```

NAMESPACE	NAME	READY	STATUS	RESTARTS
cert-manager	cert-manager-7d6d9465db-mgbk4	1/1	Running	0
cert-manager	cert-manager-cainjector-6f567667c6-vm4	1/1	Running	0
cert-manager	cert-manager-webhook-f947d7c68-tlfx8	1/1	Running	0
contrail-deploy	contrail-k8s-deployer-6c88f6798f-jjx96	1/1	Running	3
contrail	contrail-vrouter-masters-phctx	3/3	Running	0
contrail	contrail-vrouter-nodes-xkkk8	3/3	Running	0
kube-system	coredns-657959df74-26jrk	1/1	Running	0
kube-system	dns-autoscaler-b5c786945-m4vtz	1/1	Running	0
kube-system	kube-apiserver-k8s-cp0	1/1	Running	0
kube-system	kube-controller-manager-k8s-cp0	1/1	Running	0
kube-system	kube-proxy-5rbp4	1/1	Running	0
kube-system	kube-proxy-kr95n	1/1	Running	0
kube-system	kube-scheduler-k8s-cp0	1/1	Running	0
kube-system	nginx-proxy-k8s-worker0	1/1	Running	0

You've now created and attached a distributed workload cluster to the central cluster.

## Detach a Workload Cluster

Use this procedure to detach a distributed workload cluster from the central cluster.

1. On the central cluster, delete the associated kubemanager.

```
kubectl delete kubemanager -n contrail <kubemanager-name>
```

2. On the distributed workload cluster that you're deleting, delete the vRouters.

```
kubectl delete vrouters -n contrail contrail-vrouter-masters
```

```
kubectl delete vrouters -n contrail contrail-vrouter-nodes
```

3. On the central cluster, delete the namespaces of the distributed workload cluster.  
List the namespaces and delete all namespaces associated with the distributed workload cluster.

```
kubectl get ns
```

```
kubectl delete ns <kubemanager-name>-<workload-cluster-name>-<namespace>
```

4. On the central cluster, delete the secret associated with the workload cluster that you're detaching.

```
kubectl delete secret <secret-name> -n contrail
```

where *<secret-name>* is the secret you created when you attached the workload cluster to the central cluster earlier. In our example, we called it **workload-kubeconfig**.

## Uninstall CN2

Use this procedure to uninstall CN2 from the central cluster and the workload clusters.

1. Follow the steps in ["Detach a Workload Cluster" on page 60](#) to detach the workload cluster that you want to delete.
2. Uninstall CN2 in the workload cluster.
  - a. Follow the steps in ["Uninstall CN2" on page 54](#) to uninstall CN2 in the workload cluster.  
Ignore any NotFound errors because those resources have already been deleted.

- b. On the workload cluster, verify that all resources related to default pod network namespace of the distributed workload cluster are gone, and verify that all resources related to the contrail namespace are gone.

```
kubect1 api-resources --verbs=list --namespaced -o name | xargs -n 1 kubect1 get --show-kind --ignore-not-found -n <default pod network namespace>
```

```
kubect1 api-resources --verbs=list --namespaced -o name | xargs -n 1 kubect1 get --show-kind --ignore-not-found -n contrail
```

If all you want to do is to uninstall CN2 from the workload cluster, then you're done. If you want to also uninstall CN2 from the central cluster, then proceed to the next step.

### 3. Uninstall CN2 in the central cluster.

- a. Follow the steps in ["Uninstall CN2" on page 54](#) to uninstall CN2 in the central cluster. Ignore any NotFound errors because those resources have already been deleted.
- b. On the central cluster, verify that all resources related to the contrail, contrail-system, and contrail-deploy namespaces are deleted.

```
kubect1 api-resources --verbs=list --namespaced -o name | xargs -n 1 kubect1 get --show-kind --ignore-not-found -n contrail
```

```
kubect1 api-resources --verbs=list --namespaced -o name | xargs -n 1 kubect1 get --show-kind --ignore-not-found -n contrail-system
```

```
kubect1 api-resources --verbs=list --namespaced -o name | xargs -n 1 kubect1 get --show-kind --ignore-not-found -n contrail-deploy
```

# Create a Kubernetes Cluster

Use this example procedure to create an upstream Kubernetes cluster.

**NOTE:** This procedure relates to the installation of third party software that is outside of our control. We provide this example to you purely for convenience. Although we make every effort to ensure its accuracy, we cannot guarantee that this example is up-to-date at all times.

There are multiple ways you can create a cluster. In this example, we'll use kubespray (version 2.20).

To make the steps easier to follow, we'll use a separate installer machine to perform the installation and to run kubectl and other tools.

For more information on creating a cluster, see the official Kubernetes documentation (<https://kubernetes.io/docs/home/>).

**NOTE:** The command line examples below don't show the directory paths. We leave it to you to apply these commands within your directory structure.

Before you start, make sure you've brought up the servers or VMs that you plan to use for the cluster nodes.

1. Install a fresh OS on the installer machine, configuring the OS minimally for the following:
  - static IP address and mask (for example, 172.16.0.10/24 for our single cluster) and gateway
  - access to one or more DNS servers
  - SSH connectivity including root SSH access
  - NTP

The installer machine used in our examples is a Ubuntu host attached to the cluster network.

2. From your local computer, SSH into the installer machine as the root user.
3. Install kubectl. In this example, we run kubectl on the installer machine. If you want to run kubectl on another machine (for example, your local computer), download and install kubectl on that machine instead.

- a. This downloads kubectl version 1.24.3:

```
curl -LO https://storage.googleapis.com/kubernetes-release/release/v1.24.3/bin/linux/  
amd64/kubectl
```

- b. Make the file executable and move it to a directory in your path (for example, `/usr/local/bin`).

```
chmod +x kubectl
```

```
sudo mv kubectl /usr/local/bin
```

4. Install the Python virtual environment for the Python version you're running. In this example, we're running Python 3.8.

```
python3 --version
```

```
apt install -y python3.8-venv
```

5. If you want to install Contrail Analytics, then install Helm 3.0 or later.  
For information on how to install Helm, see <https://helm.sh/docs/intro/install/>.
6. Configure SSH password-less root access from the installer machine to the control plane and worker nodes. This allows ansible to log in to these nodes when you run the playbook later.
  - a. Create an SSH key.

```
ssh-keygen
```

In this example, we store the SSH key in its default location `~/.ssh/id_rsa.pub`.

- b. Copy the key to the root user on the control plane and worker nodes. For example:

```
ssh-copy-id -i ~/.ssh/id_rsa.pub root@172.16.0.11
```

```
ssh-copy-id -i ~/.ssh/id_rsa.pub root@172.16.0.12
```

```
ssh-copy-id -i ~/.ssh/id_rsa.pub root@172.16.0.13
```

7. Clone the kubespray directory. In this example, we're cloning release 2.20.

For example:

```
git clone https://github.com/kubernetes-sigs/kubespray -b release-2.20
```

8. Install the required packages to run this version of kubespray. The required packages are listed in **kubespray/requirements.txt**. We'll install these packages inside a Python virtual environment.

- a. Set up the virtual environment.

```
cd kubespray
```

```
python3 -m venv env
```

```
source env/bin/activate
```

The virtual environment is indicated in the prompt by **env**.

- b. Install the required packages within the virtual environment.

```
pip3 install -r requirements.txt
```

**NOTE:** Perform subsequent steps in this virtual environment until the cluster is set up. This virtual environment ensures you're running the correct version of ansible for this version of kubespray.

9. Configure the pod and service subnets if desired.

The default subnets used by kubespray are defined in the **kubespray/roles/kubespray-defaults/defaults/main.yaml** file. Look for the following parameters in that file and change accordingly.

```
kube_service_addresses: 10.233.0.0/18
kube_pods_subnet: 10.233.64.0/18
kube_service_addresses_ipv6: fd85:ee78:d8a6:8607::1000/116
kube_pods_subnet_ipv6: fd85:ee78:d8a6:8607::1:0000/112
```

**NOTE:** If you're creating a multi-cluster CN2 setup, you must configure different pod and service subnets on each cluster. These subnets must be unique within the entire multi-cluster.

If you're following the multi-cluster example in this document, then leave the subnets on the central cluster at their defaults and configure the subnets on the workload cluster as follows:

```
kube_service_addresses: 10.234.0.0/18
kube_pods_subnet: 10.234.64.0/18
kube_service_addresses_ipv6: fd85:ee78:d8a6:8608::1000/116
kube_pods_subnet_ipv6: fd85:ee78:d8a6:8608::1:0000/112
```

10. If you're running DPDK in your cluster, then configure multus.

Multus is required when running DPDK.

a. Enable multus.

In **kubespray/roles/kubespray-defaults/defaults/main.yaml**, enable multus:

```
kube_network_plugin_multus: true
```

b. Set the multus version to 0.3.1, which is the version required for running DPDK. You set the version in two files.

In **kubespray/roles/network\_plugin/multus/defaults/main.yml**, configure the multus version:

```
multus_cni_version: "0.3.1"
```

In `kubespray/extra_playbooks/roles/network_plugin/multus/defaults/main.yml`, configure the multus version:

```
multus_cni_version: "0.3.1"
```

**11.** Create the inventory file for ansible to use. For example:

```
all:
  hosts:
    # list all nodes here
    k8s-cp0:
    # desired hostname
      ansible_host: 172.16.0.11
    k8s-worker0:
      ansible_host: 172.16.0.12
    k8s-worker1:
      ansible_host: 172.16.0.13
  vars:
    ansible_user: root
    artifacts_dir: /tmp/mycluster
    cluster_name: mycluster.contrail.lan
    container_manager: crio
    # container runtime
    download_container: false
    download_localhost: true
    download_run_once: true
    enable_dual_stack_networks: true
    enable_nodelocaldns: false
    etcd_deployment_type: host
    host_key_checking: false
    kube_network_plugin: cni
    kube_network_plugin_multus: false
    kube_version: v1.24.3
    kubeconfig_localhost: true
    kubectrl_localhost: true
    kubelet_deployment_type: host
    override_system_hostname: true
  kube-master:
    hosts:
    # hostname of control plane node (from hosts section)
    k8s-cp0:
  kube-node:
    hosts:
    # hostnames of worker nodes (from hosts section)
    k8s-worker0:
    k8s-worker1:
  etcd:
```

```

hosts:                                # hostname of control plane node (from hosts section)
  k8s-cp0:
k8s-cluster:
  children:
    kube-master:
    kube-node:

```

The host names (k8s-cp0, k8s-worker0, k8s-worker1) that you specify in the file are automatically configured on the node when the `override_system_hostname` parameter is set to `true`.

**NOTE:** If you're creating a multi-cluster CN2 setup, you must configure different node names for each node in the multi-cluster. Node names must be unique across the entire multi-cluster.

**NOTE:** If you're running DPDK, set `kube_network_plugin_multus: true`.

If you want to run with a different container runtime, change the `container_manager` value above.

Ensure `enable_nodelocaldns` is set to `false`.

If you want to run with a different number of control plane and worker nodes, adjust the inventory accordingly.

Place the inventory file outside of the kubespray directory hierarchy.

12. Check that ansible can SSH into the control plane and worker nodes based on the contents of the **inventory.yaml** file. In this example, the **inventory.yaml** file is in the `~/contrail` directory.

```
ansible -i inventory.yaml -m ping all
```

```

[WARNING]: Invalid characters were found in group names but not replaced, use -vvvv to see
details
k8s-cp0 | SUCCESS => {
  "ansible_facts": {
    "discovered_interpreter_python": "/usr/bin/python3"
  },
  "changed": false,
  "ping": "pong"
}

```

```
k8s-worker0 | SUCCESS => {ansi
  "ansible_facts": {
    "discovered_interpreter_python": "/usr/bin/python3"
  },
  "changed": false,
  "ping": "pong"
}
k8s-worker1 | SUCCESS => {ansi
  "ansible_facts": {
    "discovered_interpreter_python": "/usr/bin/python3"
  },
  "changed": false,
  "ping": "pong"
}
```

13. To create the cluster, run the playbook from the **kubespray** directory. Adjust the command below to reference the **inventory.yaml** within your directory structure.

```
ansible-playbook -i ../inventory.yaml cluster.yaml
```

This step can take an hour or more to complete, depending on the size of your cluster.

**NOTE:** You can safely ignore network and CNI warnings and errors because you haven't configured a CNI yet.

14. Optionally, deactivate the Python virtual environment. We've finished running ansible, so we no longer need the virtual environment.

```
deactivate
```

15. Copy the cluster's secure token to the default **~/.kube/config** location. The kubeconfig must be at that default location for CN2 tools to work.

You can find the secure token location from the **inventory.yaml** file. If you use the inventory file in this example, the token is in **/tmp/mycluster**.

```
mkdir ~/.kube
```

```
cp /tmp/mycluster/admin.conf ~/.kube/config
```

**NOTE:** If you have a kubeconfig that already holds tokens for existing clusters, then you'll need to merge rather than overwrite the `~/.kube/config` file.

**16.** Use standard kubectl commands to check on the health of the cluster.

a. Show the status of the nodes.

```
kubectl get nodes
```

NAME	STATUS	ROLES	AGE	VERSION
k8s-cp0	NotReady	control-plane,master	4m57s	v1.20.7
k8s-worker0	NotReady	<none>	3m17s	v1.20.7
k8s-worker1	NotReady	<none>	2m45s	v1.20.7

```
user@installer:~$ kubectl describe node k8s-cp0
```

```
<trimmed>
```

```
Conditions:
```

Type	Status	<trimmed>	Reason	Message
MemoryPressure	False		KubeletHasSufficientMemory	kubelet has sufficient memory available
DiskPressure	False		KubeletHasNoDiskPressure	kubelet has no disk pressure
PIDPressure	False		KubeletHasSufficientPID	kubelet has sufficient PID available
Ready	False		KubeletNotReady	runtime network not ready: NetworkReady=false

reason:NetworkPluginNotReady message:Network plugin returns error: No CNI configuration file in /etc/cni/net.d/. Has your network

```
Addresses:
<trimmed>
```

You can see that the nodes are not ready because there is no CNI plug-in. This is expected because you haven't installed CN2 yet.

b. Show the status of the pods.

```
kubectl get pods -A -o wide
```

NAMESPACE	NAME	READY	STATUS	RESTARTS	AGE	IP	NODE	<trimmed>
kube-system	coredns-657959df74-rprzv	0/1	Pending	0	6m44s	<none>	<none>	<none>
kube-system	dns-autoscaler-b5c786945	0/1	Pending	0	6m40s	<none>	<none>	<none>

kube-system	kube-apiserver-k8s-cp0	1/1	Running	0	9m27s	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	kube-controller-manager-	1/1	Running	0	9m27s	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	kube-proxy-k5mcp	1/1	Running	0	7m28s	172.16.0.13	k8s-worker1	<none>	<none>
kube-system	kube-proxy-sccjm	1/1	Running	0	7m28s	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	kube-proxy-wqbt8	1/1	Running	0	7m28s	172.16.0.12	k8s-worker0	<none>	<none>
kube-system	kube-scheduler-k8s-cp0	1/1	Running	0	9m27s	172.16.0.11	k8s-cp0	<none>	<none>
kube-system	nginx-proxy-k8s-worker0	1/1	Running	0	8m2s	172.16.0.12	k8s-worker0	<none>	<none>
kube-system	nginx-proxy-k8s-worker1	1/1	Running	0	7m30s	172.16.0.13	k8s-worker1	<none>	<none>

All pods should have a STATUS of Running except for the DNS pods. The DNS pods do not come up because there is no networking. This is what we expect.

You have successfully installed a new cluster. You can now proceed to install CN2 on this cluster.

## Configure Repository Credentials

Use this procedure to configure your repository login credentials in your manifests.

1. Install docker if you don't already have docker installed.
2. Log in to the Juniper Networks repository where you pull the container images.

```
docker login enterprise-hub.juniper.net
```

Enter your login credentials when prompted.

Once you've logged in, your credentials are automatically stored in `~/.docker/config.json`. (If you installed docker using snap, then the credentials are stored in the `~/snap/docker` directory hierarchy.)

3. Encode your credentials in base64 and store the resulting string.

```
ENCODED_CREDS=$(base64 -w 0 config.json)
```

Take a look at the encoded credentials.

```
echo $ENCODED_CREDS
```

4. Replace the credentials placeholder in the manifests with the encoded credentials.

The manifests have a `<base64-encoded-credential>` credentials placeholder. Simply replace the placeholder with the encoded credentials in all manifests.

```
sed -i s/'<base64-encoded-credential>'/${ENCODED_CREDS}/ *.yaml
```

Double check by searching for the encoded credentials in the manifests.

```
grep $ENCODED_CREDS *.yaml
```

You should see the encoded credentials in the manifests.

## RELATED DOCUMENTATION

| [https://www.juniper.net/documentation/en\\_US/day-one-books/topics/concept/secrets.html](https://www.juniper.net/documentation/en_US/day-one-books/topics/concept/secrets.html)

# Add a Cluster Node

Use this procedure to add a control plane or worker node to a cluster that you used kubespray to create.

We provide this example procedure purely for informational purposes. See Kubernetes documentation (<https://kubernetes.io/docs/home/>) for the official procedure.

1. Prepare the new node by following step 5 in "Before You Install" on page 18.
2. Add the node to the `inventory.yaml` file that you created in step 11 in "Create a Kubernetes Cluster" on page 64.
3. Verify that ansible can SSH into all the nodes.

```
ansible -i inventory.yaml -m ping all
```

4. Run the playbook from the **kubespray** directory. Adjust the command below to reference the **inventory.yaml** within your directory structure.

```
user@installer:~/contrail/kubespray$ ansible-playbook -i ../inventory.yaml cluster.yaml
```

CN2 automatically detects that you've add a new node and configures new networking components as necessary. You don't have to explicitly configure CN2 for the new node.

5. Use standard kubectl commands to check that the new node is now part of the cluster.

```
kubectl get nodes
```

```
kubectl get pods -A -o wide
```

## Delete a Cluster Node

Use this procedure to delete a node gracefully.

We provide this example procedure purely for informational purposes. See Kubernetes documentation (<https://kubernetes.io/docs/home/>) for the official procedure.

1. Drain the node.

```
kubectl drain <node> --ignore-daemonsets --delete-local-data
```

2. Ensure there are no jobs running or scheduled to run on that node.

```
kubectl get jobs -A
```

```
kubectl get cronjobs -A
```

```
kubectl get pods -A -o wide
```

3. Delete the node.

```
kubectl delete <node>
```

# Prepare a Cluster Node for DPDK

Use this example procedure to prepare a cluster node for DPDK.

We provide this example procedure purely for informational purposes. See DPDK documentation (<https://core.dpdk.org/doc/>) for the official procedure.

1. Enable Intel VT-d and SR-IOV in the BIOS.
2. Configure huge pages and enable IOMMU by editing `/etc/default/grub`. For example (for a huge page size of 1 GB):

```
GRUB_CMDLINE_LINUX_DEFAULT="default_hugepagesz=1G hugepagesz=1G hugepages=16 intel_iommu=on iommu=pt"
```

Update grub and reboot:

```
sudo update-grub
```

```
sudo reboot
```

3. Load the poll mode driver (PMD) kernel module according to the capabilities of your NIC.
  - If your NIC supports VFIO, then you might not need to do anything explicitly. Recent kernels include VFIO compiled in. If you need to load it:

```
sudo modprobe vfio-pci
```

- If your NIC only supports UIO:

```
sudo modprobe uio_pci_generic
```

**NOTE:** Some kernel versions do not automatically include `uio_pci_generic`. If you see a `Module uio_pci_generic not found error`, then install the module first (for example: `sudo apt install linux-modules-extra-5.4.0-xx-generic`) before loading the module.

# Back Up and Restore

## SUMMARY

Learn how to use `etcdctl` commands to back up and restore the etcd database.

## IN THIS SECTION

- [Back Up the Etcd Database | 76](#)
- [Restore the Etcd Database | 78](#)

We provide these example procedures purely for informational purposes. For more information on back up and restore, see the official Kubernetes documentation (<https://kubernetes.io/docs/tasks/administer-cluster/configure-upgrade-etcd/#backing-up-an-etcd-cluster> and <https://kubernetes.io/docs/tasks/administer-cluster/configure-upgrade-etcd/#restoring-an-etcd-cluster>).

## Back Up the Etcd Database

Use this example procedure to back up the etcd database.

1. SSH into one of the control plane nodes in the cluster.
2. Install `etcdctl` version 3.4.13 or later. `Etcdctl` is the command line tool for managing etcd.  
If the node already has `etcdctl` version 3.4.13 or later installed, then you can skip this step.

Otherwise, install `etcdctl`:

```
root@cp1:~# etcdctl version
Command 'etcdctl' not found
```

```
curl -L https://storage.googleapis.com/etcd/v3.5.0/etcd-v3.5.0-linux-amd64.tar.gz
```

In this example, we move the file to the `/tmp` directory.

```
mv etcd-v3.5.0-linux-amd64.tar.gz /tmp
```

Extract and copy the executable to **/usr/local/bin**.

```
mkdir -p /tmp/etcd-download
tar -xzf /tmp/etcd-v3.5.0-linux-amd64.tar.gz -C /tmp/etcd-download --strip-components=1
```

```
cp /tmp/etcd-download/etcdctl /usr/local/bin
```

Verify by querying the version.

```
root@cp1:~# etcdctl version
etcdctl version: 3.5.0
API version: 3.5
```

### 3. Set the required ETCDCTL env variables.

```
export ETCDCTL_CACERT=/etc/kubernetes/pki/etcd/ca.crt
export ETCDCTL_CERT=/etc/kubernetes/pki/etcd/server.crt
export ETCDCTL_KEY=/etc/kubernetes/pki/etcd/server.key
export ETCDCTL_API=3
```

These variables are used implicitly by the etcdctl commands. The file paths listed are the default file paths. You can obtain these file paths by issuing the `kubectl describe pod <etcd-pod>` command.

### 4. Set permissions on the certificate files.

```
chmod 777 /etc/kubernetes/pki/etcd/server.key
chmod 777 /etc/kubernetes/pki/etcd/ca.crt
```

### 5. Repeat step 1 to step 4 on all the control plane nodes.

### 6. Back up the etcd database.

SSH back into one of the control plane nodes and take a snapshot of the etcd database.

```
etcdctl snapshot save /tmp/etcdBackup.db --endpoints=https://127.0.0.1:2379
```

This takes a snapshot of the database and stores it in **/tmp/etcdBackup.db**.

### 7. Copy the snapshot off the node and store in a safe place.

## Restore the Etcd Database

Use this example procedure to restore the etcd database from a snapshot.

1. Restore the snapshot on all the control plane nodes.
  - a. SSH into one of the control plane nodes.
  - b. Copy the saved snapshot to **/tmp/etcdBackup.db** (for example).
  - c. Restore the backup.

```
etcdctl snapshot restore /tmp/etcdBackup.db \
--name=<cp1-etcd-pod> \
--initial-cluster=<cp1-etcd-pod>=https://<cp1-etcd-pod-ip>:2380,<cp2-etcd-pod>=https://
<cp2-etcd-pod-ip>:2380,<cp3-etcd-pod-name>=https://<cp3-etcd-pod-ip>:2380 \
--initial-advertise-peer-urls= https://<cp1-etcd-pod-ip>:2380
```

where *<cp1-etcd-pod>* is the name of the contrail-etcd pod that you're currently in and *<cp1-etcd-pod-ip>* is the IP address of that pod. The *<cp2-etcd-pod>* and *<cp3-etcd-pod>* refer to the other contrail-etcd pods. This creates a **<cp1-etcd-pod>.etcd** directory on the node.

- d. Repeat for the other control plane nodes, substituting the `--name` and `--initial-advertise-peer-urls` parameters with the respective pod name and IP address.
2. Stop the API server on all the control plane nodes.
  - a. SSH into one of the control plane nodes.
  - b. Stop the API server.

```
mkdir -p /tmp/k8s
```

```
mv /etc/kubernetes/manifests/*.yaml /tmp/k8s
```

- c. Repeat for the other control plane nodes.
3. Move the restored etcd snapshot to **/var/lib/etcd** on all the control plane nodes.
  - a. SSH into one of the control plane nodes.

- b. Move the restored etcd snapshot.

```
mv /var/lib/etcd/member /var/lib/etcd/member.bak
```

```
mv <restored-etcd-directory>/member /var/lib/etcd/
```

where *<restored-etcd-directory>* is the **.etcd** directory created in step [1](#).

- c. Repeat for the other control plane nodes.

#### 4. Restore the API server on all control plane nodes.

- a. SSH into one of the control plane nodes.
- b. Restore the API server.

```
mv /tmp/k8s/*.yaml /etc/kubernetes/manifests
```

- c. Repeat for the other control plane nodes.

#### 5. Restart the kubelet on all control plane nodes.

- a. SSH into one of the control plane nodes.
- b. Restart the kubelet.

```
systemctl stop kubelet
```

```
systemctl start kubelet
```

- c. Repeat for the other control plane nodes.

#### 6. Restart the kube-system apiserver and controller.

Delete all the kube-apiserver and kube-controller pods.

```
kubectl delete pod <kube-apiserver-xxx> -n kube-system
```

```
kubectl delete pod <kube-controller-xxx> -n kube-system
```

These pods will automatically restart.

7. Restart the contrail-system apiserver and controller.

Delete all the contrail-k8s-apiserver and contrail-k8s-controller pods.

```
kubectl delete pod <contrail-k8s-apiserver-xxx> -n contrail-system
```

```
kubectl delete pod <contrail-k8s-controller-xxx> -n contrail-system
```

These pods will automatically restart.

8. Restart the vrouters.

Delete all the contrail-vrouter-masters and contrail-vrouter-nodes pods.

```
kubectl delete pod <contrail-vrouter-masters-xxx> -n contrail
```

```
kubectl delete pod <contrail-vrouter-nodes-xxx> -n contrail
```

These pods will automatically restart.

9. Check that all pods are in running state.

```
kubectl get pods -n contrail-system
```

```
kubectl get pods -n contrail
```

## Juniper CN2 Technology Previews (Tech Previews)

Tech Previews enable you to test functionality and provide feedback during the development process of innovations that are not final production features. The goal of a Tech Preview is for the feature to gain wider exposure and potential full support in a future release. Customers are encouraged to provide feedback and functionality suggestions for a Technology Preview feature before it becomes fully supported.

Tech Previews may not be functionally complete, may have functional alterations in future releases, or may get dropped under changing markets or unexpected conditions, at Juniper's sole discretion. Juniper recommends that you use Tech Preview features in non-production environments only.

Juniper considers feedback to add and improve future iterations of the general availability of the innovations. Your feedback does not assert any intellectual property claim, and Juniper may implement your feedback without violating your or any other party's rights.

These features are "as is" and voluntary use. Juniper Support will attempt to resolve any issues that customers experience when using these features and create bug reports on behalf of support cases. However, Juniper may not provide comprehensive support services to Tech Preview features. Certain features may have reduced or modified security, accessibility, availability, and reliability standards relative to General Availability software. Tech Preview features are not eligible for P1/P2 JTAC cases, and should not be subject to existing SLAs or service agreements.

For additional details, please contact [Juniper Support](#) or your local account team.
