## Changing CoS Services Overview

---

This topic describes how to provide CoS when subscribers dynamically upgrade or downgrade services in an access environment.

You can configure your network with an *access profile* that provides all subscribers with default CoS parameters when they log in. For example, all subscribers can receive a basic data service. By configuring the access profile with Junos OS predefined variables for RADIUS-provided CoS parameters, you also enable the service to be activated for those subscribers at login.

To enable subscribers to activate a service or upgrade to different services through RADIUS change-of-authorization (CoA) messages after login, configure a *service profile* that includes user-defined variables.

### Types of CoS Variables Used in a Service Profile

You can configure variables for the following CoS parameters in a service profile:

- Shaping rate
- Delay buffer rate
- Guaranteed rate
- Scheduler map

For each CoS parameter, you must associate a RADIUS vendor ID. For each vendor ID, you must assign an attribute number and a tag. The tag is used to differentiate between values for different CoS variables when you specify the same attribute number for those variables. These values are matched with the values supplied by RADIUS during subscriber authentication. All of the values in the dynamic profile must be defined in RADIUS or none of the values are passed.

Optionally, you can configure default values for each parameter. Configuring default values is beneficial if you do not configure RADIUS to enable service changes. During service changes, RADIUS takes precedence over the default value that is configured.

### Static and Dynamic CoS Configurations

Depending on how you configure CoS parameters in the access and service profiles, certain CoS parameters are replaced or merged when subscribers change or activate new services.

Static configuration is when you configure the scheduler map and schedulers in the static **[edit class-of-service]** hierarchy and reference the scheduler map in the dynamic profile. Dynamic configuration is when you configure the scheduler map and schedulers within the dynamic profile.

The CoS configuration also depends on whether you have enabled multiple subscribers on the same logical interface using the **aggregate-clients** statements in the dynamic profile referenced by DHCP. When you specify the **aggregate-clients replace** statement, the scheduler map names are replaced. In both cases, if the length of the scheduler map

name exceeds 128 characters, subscribers cannot log in. When you specify the **aggregate-clients merge** statement, the scheduler map names specified in the dynamic profile are appended.

**BEST PRACTICE:** To improve CoS performance in IPv4, IPv6, and dual-stack networks, we recommend that you use the **aggregate-clients replace** statement rather than the **aggregate-clients merge** statement.

## Scenarios for Static and Dynamic Configuration of CoS Parameters

Table 78 on page 940 lists the scenarios for static and dynamic configuration of CoS parameters in access profiles and service profiles at subscriber login. The table also lists the behavior for each configuration for service activation and service modification using RADIUS CoA messages.

Table 78: CoS Services and Variables

Scenario	Static CoS Configuration (Single Subscriber)	Dynamic CoS Configuration (Single Subscriber)	Dynamic CoS Configuration (Multiple Subscribers Enabled on a Logical Interface with the aggregate-clients merge Statement)	Dynamic CoS Configuration (Multiple Subscribers Enabled on a Logical Interface with the aggregate-clients replace Statement)
Subscriber login	<ul style="list-style-type: none"> <li>Configure RADIUS values or default values for all parameters in access profile</li> <li>Configure scheduler map in <b>edit class-of-service</b> hierarchy and reference in access profile</li> </ul>	<ul style="list-style-type: none"> <li>Configure RADIUS values or default values for all parameters in access profile</li> <li>Configure scheduler map and schedulers in access profile</li> </ul>	<ul style="list-style-type: none"> <li>Configure RADIUS values or default values for all parameters in access profile</li> <li>Configure scheduler map and schedulers in access profile</li> </ul>	<ul style="list-style-type: none"> <li>Configure RADIUS values or default values for all parameters in access profile</li> <li>Configure scheduler map and schedulers in access profile</li> </ul>
RADIUS CoA for service or variable change	Replaces the following parameters: <ul style="list-style-type: none"> <li>Delay buffer rate</li> <li>Guaranteed rate</li> <li>Scheduler map</li> <li>Shaping rate</li> </ul>	Replaces the following parameters: <ul style="list-style-type: none"> <li>Delay buffer rate</li> <li>Guaranteed rate</li> <li>Shaping rate</li> <li>Scheduler map</li> </ul>	Combines the values of the following parameters to their maximum scalar value: <ul style="list-style-type: none"> <li>Delay buffer rate</li> <li>Guaranteed rate</li> <li>Shaping rate</li> </ul> Appends the scheduler map parameter	Replaces the following parameters: <ul style="list-style-type: none"> <li>Delay buffer rate</li> <li>Guaranteed rate</li> <li>Shaping rate</li> <li>Scheduler map</li> </ul>

Table 78: CoS Services and Variables (*continued*)

Scenario	Static CoS Configuration (Single Subscriber)	Dynamic CoS Configuration (Single Subscriber)	Dynamic CoS Configuration (Multiple Subscribers Enabled on a Logical Interface with the aggregate-clients merge Statement)	Dynamic CoS Configuration (Multiple Subscribers Enabled on a Logical Interface with the aggregate-clients replace Statement)
RADIUS CoA for service activation	<p>Does not merge queues</p> <p><b>NOTE:</b>In this case, use a similar configuration to the access profile, including the same name for the traffic-control-profile. During service activation, this configuration replaces the original configuration in the access profile.</p>	<p>Merge queues if the queue specified in the service profile is not already in use for the subscriber</p> <p><b>NOTE:</b> Do not instantiate a CoA request using a service dynamic profile that is already in use on the same logical interface.</p>	<p>Merge queues if the queue specified in the service profile is not already in use for the subscriber</p> <p><b>NOTE:</b> Do not instantiate a CoA request using a service dynamic profile that is already in use on the same logical interface.</p>	<p>Merge queues if the queue specified in the service profile is not already in use for the subscriber</p> <p><b>NOTE:</b> Do not instantiate a CoA request using a service dynamic profile that is already in use on the same logical interface.</p>

## CoS Traffic Shaping Attributes for Dynamic Interface Sets and Member Subscriber Sessions Overview

---

To control bandwidth at a household level in a subscriber access network, you can apply RADIUS dynamic class of service (CoS) traffic-shaping attributes to a dynamic interface set and its member subscriber sessions when the subscriber sessions are authenticated. (The dynamic interface set itself does not go through the authentication process.)

A *household* is represented by either a dynamic interface set or a dynamic agent-circuit-identifier (ACI) interface set from which the subscriber sessions originate. For this feature, dynamic interface sets and dynamic ACI interface sets are mapped to Level 2 of the Junos OS CoS scheduler hierarchy, which enables you to use CoS traffic-shaping to shape the bandwidth at the household (interface set) level.

The *subscriber sessions*, also referred to as *subscriber interfaces* or *client sessions*, can be dynamic VLAN, PPPoE, or IP demultiplexing (IP demux) subscriber interfaces. The subscriber interfaces are mapped to Level 3 of the Junos OS CoS scheduler hierarchy.

- [Supported Network Configurations on page 942](#)
- [Traffic-Control Profiles in Subscriber Interface Dynamic Profiles on page 942](#)
- [CoS Traffic Shaping Predefined Variables for Dynamic Interface Sets and Member Subscriber Sessions on page 943](#)

### Supported Network Configurations

Applying RADIUS dynamic CoS traffic-shaping attributes to a dynamic interface set and its member subscriber sessions is supported for the following network configurations:

- Dynamic IP demux subscriber interfaces (for DHCP subscribers) over either a dynamic interface set or a dynamic ACI interface set
- Dynamic PPPoE subscriber interfaces over either a dynamic interface set or a dynamic ACI interface set

### Traffic-Control Profiles in Subscriber Interface Dynamic Profiles

To apply dynamic CoS traffic-shaping attributes to a dynamic interface set and its member subscriber sessions, you must define and attach the traffic-control profiles for *both* the dynamic interface set and the dynamic subscriber sessions within the dynamic profile for the subscriber interface.

At the **[edit dynamic-profiles profile-name class-of-service traffic-control-profiles]** hierarchy level in the dynamic profile, configure both of the following:

- Traffic-control profile for the dynamic VLAN, PPPoE, or IP demux subscriber interfaces
- Traffic-control profile for the dynamic interface set or dynamic ACI interface set to which the subscriber interfaces belong

RADIUS tag values for the Junos OS CoS traffic shaping predefined variables used in both traffic-control profiles must be in the 100s range, as described in [“CoS Traffic Shaping Predefined Variables for Dynamic Interface Sets” on page 951](#).

At the `[edit dynamic-profiles profile-name interfaces]` hierarchy level in the dynamic profile, use the `output-traffic-control-profile` statement to apply the traffic-control profiles to the dynamic subscriber interface and the dynamic interface set or dynamic ACI interface set.

## CoS Traffic Shaping Predefined Variables for Dynamic Interface Sets and Member Subscriber Sessions

The set of `$junos-cos-parameter` predefined dynamic variables has been duplicated and assigned a RADIUS tag value in the 100s range for use with this feature. The RADIUS tag value is the only difference between the existing CoS traffic-shaping predefined dynamic variables and the predefined dynamic variables that you must use with this feature.

Both RADIUS instances of the `$junos-cos-parameter` predefined dynamic variables are available, but you must use the dynamic variables with tag values in the 100s range to apply CoS traffic-shaping attributes to both the dynamic interface set and member subscriber sessions in a subscriber interface dynamic profile.

For example, the existing `$junos-cos-shaping-rate` predefined variable is assigned RADIUS vendor ID 4874, attribute number 108, and tag value 2. To apply CoS traffic-shaping attributes to the dynamic interface set and its member subscriber sessions, you must instead use the `$junos-cos-shaping-rate` predefined variable that is assigned RADIUS vendor ID 4874, attribute number 108, and tag value 102.

**NOTE:** Do not configure a combination of `$junos-cos-parameter` predefined dynamic variables with RADIUS tag values in the 100s range and `$junos-cos-parameter` predefined dynamic variables with tag values not in the 100s range in the same traffic-control profile. If you do so, the subscriber authentication process fails.

## Guidelines for Configuring CoS Traffic Shaping Attributes for Dynamic Interface Sets and Member Subscriber Sessions

---

Observe the following guidelines when you apply dynamic CoS traffic-shaping attributes to a dynamic interface set or a dynamic ACI interface set and its member subscriber sessions. For complete information about the Junos OS CoS traffic-shaping predefined dynamic variables and RADIUS tag values used with this feature, see [“CoS Traffic Shaping Predefined Variables for Dynamic Interface Sets” on page 951](#).

- This feature is supported only for dynamically configured and instantiated subscriber interfaces.
- Do not configure a combination of **\$junos-cos-parameter** predefined dynamic variables with RADIUS tag values in the 100s range and **\$junos-cos-parameter** predefined dynamic variables with tag values not in the 100s range in the same traffic-control profile. If you do so, the subscriber authentication process fails.
- Use the **\$junos-cos-adjust-minimum** predefined variable (tag 109) only in traffic-control profiles for dynamic subscriber interfaces. Using this variable in a traffic-control profile for a dynamic interface set or dynamic ACI interface set has no effect.
- Do not configure the **\$junos-cos-excess-rate-high** predefined variable (tag 110) when the **\$junos-cos-excess-rate** predefined variable (tag 105) is configured, and vice-versa.
- Do not configure the **\$junos-cos-excess-rate-low** predefined variable (tag 111) when the **\$junos-cos-excess-rate** predefined variable (tag 105) is configured, and vice-versa.
- Do not configure the **\$junos-cos-byte-adjust-frame** predefined variable (tag 114) when the **\$junos-cos-byte-adjust** predefined variable (tag 108) is configured, and vice-versa.
- Do not configure the **\$junos-cos-byte-adjust-cell** predefined variable (tag 115) when the **\$junos-cos-byte-adjust** predefined variable (tag 108) is configured, and vice-versa.
- Use the per-priority **\$junos-cos-shaping-rate-parameter** predefined variables (tags 116 through 125) only in traffic-control profiles for dynamic interface sets or dynamic ACI interface sets. Using these variables in traffic-control profiles for a dynamic logical subscriber interface causes the subscriber session to fail.

## Configuring Initial CoS Parameters Dynamically Obtained from RADIUS

---

You can configure a subscriber interface so that subscribers receive initial CoS parameters that the router obtains from the RADIUS authentication server when subscribers log in using that logical interface on the router.

1. Configure external RADIUS server VSAs with values that you expect subscribers to log in with.
  - To configure a RADIUS authentication server to include CoS traffic-shaping parameters in authentication grants on certain subscriber interfaces, configure Juniper Networks VSA 26–108.
  - To configure a RADIUS authentication server to include CoS scheduling and queuing parameters in authentication grants a certain subscriber interfaces, configure Juniper Networks VSA 28–146.

See [“Configuring Router or Switch Interaction with RADIUS Servers” on page 23](#) and [“Configuring RADIUS Server Parameters for Subscriber Access” on page 35](#).

2. Configure a subscriber interface that supports hierarchical CoS.
  - For static VLAN interfaces, see [“Configuring Static Subscriber Interfaces in Dynamic Profiles” on page 723](#).
  - For static VLAN interfaces over aggregated Ethernet, see [“Configuring a Static or Dynamic VLAN Subscriber Interface over Aggregated Ethernet” on page 782](#).
  - For static IP demux interface sets, see [“Configuring Dynamic Subscriber Interfaces Using IP Demux Interfaces in Dynamic Profiles” on page 729](#).
  - For dynamic IP demux interface sets, see [“Configuring a Subscriber Interface Using a Set of Static IP Demux Interfaces” on page 727](#)

3. Associate a traffic control profile with the interface.

See [“Applying Traffic Shaping and Scheduling to a Subscriber Interface in a Dynamic Profile”](#) on page 927.

4. Configuring initial traffic-shaping parameters to be obtained from RADIUS.

See [“Configuring Dynamic Traffic Shaping and Scheduling Parameters in a Dynamic Profile”](#) on page 920.

5. Configure forwarding classes and scheduler maps statically.

See [Configuring Forwarding Classes and Configuring Scheduler Maps](#).

6. Configure a scheduler to specify initial scheduling and queuing parameters to be dynamically obtained from RADIUS when a subscriber logs in.

See [“Configuring Dynamic Schedulers with Variables in a Dynamic Profile”](#) on page 923.

## Configuring User-Defined CoS Variables in a Dynamic Service Profile

You can configure user-defined variables in the dynamic service profile for traffic scheduling and shaping parameters.

You can use variables in a dynamic service profile in two ways:

- To enable subscribers to upgrade or downgrade services after login using a RADIUS change of authorization (CoA), configure user-defined variables for CoS parameters as RADIUS attributes.
- To provide subscribers with default values for CoS parameters, configure user-defined variables for CoS parameters with static default values. If you have configured values to be supplied by a RADIUS CoA, subscribers can receive the previously configured default value when deactivating a service.

You activate the variables by referencing them in the traffic control profile configured in the dynamic service profile.

To configure user-defined variables for CoS in a dynamic profile:

1. Specify that you want to configure variables in the dynamic profile.

```
[edit dynamic-profiles residential-silver variables]
```

2. Do one of the following to configure variables for the shaping rate:

- Enable RADIUS to modify the shaping rate based on service changes.

- a. Configure the attribute:

```
[edit dynamic-profiles residential-silver variables]
user@host# set srate radius vendor-id 4874 attribute 108
```

- b. Configure the tag:

```
[edit dynamic-profiles residential-silver variables]
user@host# set srate radius vendor-id 4874 tag 2
```

**NOTE:** You can configure user-defined values for RADIUS tags that are different than the values that are required in access profiles with predefined variables. For example, in a dynamic service profile, you can assign the shaping rate with a tag of 1 rather than 2, which is required for the \$junos-shaping-rate variable. When you configure user-defined values, the VSA that is sent from RADIUS must share the same definition.

- Configure a default value for the shaping rate.

```
[edit dynamic-profiles residential-silver variables]
user@host# set srate default-value 10m
```

3. Do one of the following to configure variables for the guaranteed rate:

- Enable RADIUS to modify the guaranteed rate based on service changes.

- a. Configure the attribute.

```
[edit dynamic-profiles residential-silver variables]
user@host# set grate radius vendor-id 4874 attribute 108
```

- b. Configure the tag.

```
[edit dynamic-profiles residential-silver variables]
user@host# set grate radius vendor-id 4874 tag 3
```

- Configure a default value for the guaranteed rate.

```
[edit dynamic-profiles residential-silver variables]
user@host# set grate default-value 5m
```

4. Do one of the following to configure variables for the delay buffer rate:

- Enable RADIUS to modify the delay buffer rate based on service changes.

- a. Configure the attribute.

```
[edit dynamic-profiles residential-silver variables]
user@host# set dbrate radius vendor-id 4874 attribute 108
```

- b. Configure the tag.

```
[edit dynamic-profiles residential-silver variables]
user@host# set dbrate radius vendor-id 4874 tag 4
```

- Configure a default value for the delay buffer rate.

```
[edit dynamic-profiles residential-silver variables]
user@host# set dbrate default-value 10m
```

- 5. Do one of the following to configure variables for the scheduler map:

- Enable RADIUS to modify the scheduler map based on service changes.

- a. Configure the attribute.

```
[edit dynamic-profiles residential-silver variables]
user@host# set smap radius vendor-id 4874 attribute 108
```

- b. Configure the tag.

```
[edit dynamic-profiles residential-silver variables]
user@host# set smap radius vendor-id 4874 tag 1
```

- Configure a default value for the scheduler map.

```
[edit dynamic-profiles residential-silver variables]
user@host# set smap default-value triple-play
```

- 6. Configure the variables for the CoS parameters in the traffic control profile.

Either the shaping rate or the guaranteed rate is required in the traffic control profile.

- a. Specify that you want to configure CoS parameters in the dynamic profile.

```
user@host# edit dynamic-profiles residential-silver class-of-service
traffic-control-profiles tcp1
```

- b. Configure the scheduler map variable.

```
[edit dynamic-profiles residential-silver class-of-service traffic-control-profiles
tcp1]
user@host# set scheduler-map "$smap"
```

- c. Configure the shaping rate variable.

```
[edit dynamic-profiles residential-silver class-of-service traffic-control-profiles
tcp1]
user@host# set shaping-rate "$srate"
```

- d. Configure the guaranteed rate variable.

```
[edit dynamic-profiles residential-silver class-of-service traffic-control-profiles
tcp1]
user@host# set guaranteed-rate "$grate"
```

- e. Configure the delay buffer rate variable.

```
[edit dynamic-profiles residential-silver class-of-service traffic-control-profiles
tcp1]
user@host# set delay-buffer-rate "$dbrate"
```

  - [Changing CoS Services Overview on page 939](#)

## Applying CoS Traffic-Shaping Attributes to Dynamic Interface Sets and Member Subscriber Sessions

To control bandwidth at a household level in a subscriber access network, you can apply RADIUS dynamic class of service (CoS) traffic-shaping attributes to a dynamic interface set or agent-circuit-identifier (ACI) interface set and its member subscriber sessions when the member sessions are authenticated. The dynamic interface set or ACI interface set represents the *household* from which the subscriber sessions originate. The *subscriber sessions*, also referred to as *client sessions* or *subscriber interfaces*, can be dynamic VLAN, PPPoE, or IP demultiplexing (IP demux, for DHCP) subscriber interfaces.

To apply RADIUS dynamic CoS traffic-shaping attributes to both the dynamic interface set and its member subscriber sessions, you must configure two traffic-control profiles in the dynamic profile for the subscriber interface: one traffic-control profile for the “parent” dynamic interface set, and a second traffic-control profile for the dynamic subscriber interfaces. RADIUS tag values for the Junos OS CoS traffic shaping predefined variables used in both traffic-control profiles must be in the 100s range.

Before you begin:

- Create a dynamic profile that defines the VLAN, PPPoE, or IP demux logical subscriber interface.

See the following topics:

- [Configuring a Basic Dynamic Profile on page 633](#)
- [Configuring VLAN Dynamic Profiles on page 673](#)
- [Configuring Dynamic PPPoE Subscriber Interfaces Using Dynamic Profiles on page 857](#)
- [Configuring Dynamic Subscriber Interfaces Using IP Demux Interfaces in Dynamic Profiles on page 729](#)

To apply dynamic CoS traffic-shaping attributes to a dynamic ACI or non-ACI interface set and its member subscriber sessions in a dynamic profile for the subscriber interface:

1. Configure two traffic-control profiles at the **[edit dynamic-profiles *profile-name* class-of-service traffic-control profiles]** hierarchy level:
  - Traffic-control profile for the VLAN, PPPoE, or IP demux dynamic subscriber interfaces
  - Traffic-control profile for the dynamic interface set or dynamic ACI interface set to which the subscriber interfaces belong
2. In the traffic-control profiles configured for the dynamic interface set and the subscriber interfaces, reference Junos OS CoS traffic-shaping predefined variables with RADIUS tag values in the 100s range.

See [“CoS Traffic Shaping Predefined Variables for Dynamic Interface Sets”](#) on page 951 for a complete list of the Junos OS predefined variables and RADIUS tag values that you must use in the traffic-control profiles for the dynamic subscriber interfaces and the dynamic interface set.

3. At the **[edit dynamic-profiles *profile-name* interfaces]** hierarchy level, use the **output-traffic-control-profile** statement to apply the traffic-control profiles to the dynamic subscriber interface and the dynamic interface set or dynamic ACI interface set.

#### Example: Dynamic PPPoE Subscriber Interface over Dynamic ACI Interface Set

The following example shows a dynamic profile named `pppoe-subscriber` that configures a dynamic PPPoE (**pp0**) subscriber interface over a dynamic ACI interface set.

The **traffic-control-profiles** stanza defines two traffic-control profiles: `tcp-pppoe-session` for the dynamic PPPoE subscriber interface, and `tcp-parent-aci-set` for the dynamic “parent” ACI interface set. The `$junos-cos-shaping-rate` predefined variable included in each of these traffic-control profiles is assigned RADIUS vendor ID 4874, attribute number 108, and tag value 102. The `$junos-cos-shaping-mode` variable is assigned RADIUS vendor ID 4874, attribute number 108, and tag value 107.

The **interfaces** stanza applies output traffic-control profile `tcp-pppoe-session` to the dynamic PPPoE (**pp0**) subscriber interface, and output traffic-control profile `tcp-parent-aci-set` to the dynamic ACI interface set.

```
[edit dynamic-profiles]
pppoe-subscriber {
  interfaces {
    interface-set "$junos-interface-set-name" {
      interface pp0 {
        unit "$junos-interface-unit";
      }
    }
    pp0 {
      unit "$junos-interface-unit" {
        ppp-options {
          pap;
        }
        pppoe-options {
          underlying-interface "$junos-underlying-interface";
          server;
        }
        no-keepalives;
        family inet {
          unnumbered-address lo0.0;
        }
      }
    }
  }
}
class-of-service {
```

```

traffic-control-profiles {
  tcp-pppoe-session {
    scheduler-map smap-1;
    shaping-rate $junos-cos-shaping-rate;
    overhead-accounting $junos-cos-shaping-mode frame-mode-bytes -4
    cell-mode-bytes 12;
  }
  tcp-parent-aci-set {
    shaping-rate $junos-cos-shaping-rate;
    overhead-accounting $junos-cos-shaping-mode frame-mode-bytes -4
    cell-mode-bytes 12;
  }
}
interfaces {
  pp0 {
    unit "$junos-interface-unit" {
      output-traffic-control-profile tcp-pppoe-session;
    }
  }
  interface-set $junos-interface-set-name {
    output-traffic-control-profile tcp-parent-aci-set;
  }
}
}
}
}

```

## CoS Traffic Shaping Predefined Variables for Dynamic Interface Sets

To control bandwidth at a household level in a subscriber access network, you can apply RADIUS CoS traffic-shaping attributes to a dynamic interface set and its member subscriber sessions when the member sessions are authenticated. The dynamic interface set, which represents the household level in a subscriber access network, can be either a dynamic agent-circuit-identifier (ACI) interface set or a non-ACI-based dynamic interface set. The subscriber sessions belonging to the interface set can be dynamic VLAN, DHCP, or PPPoE subscriber interfaces.

To apply RADIUS CoS traffic-shaping attributes to both the dynamic interface set and its member subscriber sessions, you must configure two traffic-control profiles in the dynamic profile for the subscriber interface: one traffic-control profile for the “parent” dynamic interface set, and a second traffic-control profile for the dynamic subscriber interfaces. RADIUS tag values for the Junos OS CoS traffic-shaping predefined variables used in these traffic-control-profiles must be in the 100s range, as described in [Table 79 on page 952](#).

To accommodate this feature, the set of existing **\$junos-cos-parameter** predefined dynamic variables for traffic shaping have been duplicated and assigned a tag value in the 100s range, as listed in [Table 79 on page 952](#). The tag value is the only difference between the existing predefined dynamic variables and the predefined dynamic variables that you must use with this feature.

For example, the existing **\$junos-cos-shaping-rate** predefined variable is assigned RADIUS vendor ID 4874, attribute number 108, and tag value 2. To apply RADIUS CoS traffic-shaping attributes to the dynamic interface set and its member subscriber sessions, you must instead use the **\$junos-cos-shaping-rate** predefined variable that is assigned RADIUS vendor ID 4874, attribute number 108, and tag value 102.

[Table 79 on page 952](#) describes the Junos OS predefined dynamic variables and RADIUS tag values that you can use in a dynamic profile to apply RADIUS CoS traffic-shaping attributes to the dynamic interface set and its member subscriber sessions. The table lists the predefined dynamic variables in ascending order by tag value.

**NOTE:** All of the predefined variables listed in [Table 79 on page 952](#) use RADIUS vendor ID 4874 and RADIUS attribute value 108.

**Table 79: Junos OS CoS Traffic Shaping Predefined Variables for Dynamic Interface Sets**

Predefined Variable	RADIUS Tag Value	Description
\$junos-cos-scheduler-map	101	Scheduler-map name configured in a traffic-control profile in a dynamic profile.
\$junos-cos-shaping-rate	102	Shaping rate configured in a traffic-control profile in a dynamic profile. Represents the maximum bandwidth of a CoS scheduler node.
\$junos-cos-guaranteed-rate	103	Guaranteed rate configured in a traffic-control profile in a dynamic profile. Represents the minimum bandwidth of a CoS scheduler node.
\$junos-cos-delay-buffer-rate	104	Delay-buffer rate configured in a traffic-control profile in a dynamic profile.

**Table 79: Junos OS CoS Traffic Shaping Predefined Variables for Dynamic Interface Sets** (*continued*)

Predefined Variable	RADIUS Tag Value	Description
\$junos-cos-excess-rate	105	<p>Excess rate configured in a traffic-control profile in a dynamic profile; scheduler weighting when operating in the excess region between the guaranteed rate and the shaping rate.</p> <p><b>NOTE:</b> Do not configure the \$junos-cos-excess-rate variable when either the \$junos-cos-excess-rate-high variable or the \$junos-cos-excess-rate-low variable is configured.</p>
\$junos-cos-traffic-control-profile	106	Traffic-control profile configured in a dynamic profile for subscriber access.
\$junos-cos-shaping-mode	107	Overhead-accounting mode configured in a traffic-control profile in a dynamic profile to shape downstream ATM traffic based on either frames (frame-mode) or cells (cell-mode).
\$junos-cos-byte-adjust	108	<p>Byte adjustment value for the cell or frame shaping mode configured in a traffic-control profile in a dynamic profile.</p> <p><b>NOTE:</b> Do not configure the \$junos-cos-byte-adjust variable when either the \$junos-cos-byte-adjust-frame variable or the \$junos-cos-byte-adjust-cell variable is configured.</p>
\$junos-cos-adjust-minimum	109	Minimum adjusted shaping rate configured in a traffic-control profile for a dynamic subscriber interface. Specifying this variable in a traffic-control profile for a dynamic interface set has no effect.

**Table 79: Junos OS CoS Traffic Shaping Predefined Variables for Dynamic Interface Sets** (*continued*)

Predefined Variable	RADIUS Tag Value	Description
\$junos-cos-excess-rate-high	110	Shaping rate configured for excess high-priority traffic in a traffic-control profile in a dynamic profile.  <b>NOTE:</b> Do not configure the \$junos-cos-excess-rate-high variable when the \$junos-cos-excess-rate variable is configured.
\$junos-cos-excess-rate-low	111	Shaping rate configured for excess low-priority traffic in a traffic-control profile in a dynamic profile.  <b>NOTE:</b> Do not configure the \$junos-cos-excess-rate-low variable when the \$junos-cos-excess-rate variable is configured.
\$junos-cos-shaping-rate-burst	112	Burst size for the shaping rate configured in a traffic-control profile in a dynamic profile.
\$junos-cos-guaranteed-rate-burst	113	Burst size for the guaranteed rate configured in a traffic-control profile in a dynamic profile.
\$junos-cos-byte-adjust-frame	114	Overhead bytes when downstream ATM traffic is in frame-mode.  <b>NOTE:</b> Do not configure the \$junos-cos-byte-adjust-frame variable when the \$junos-cos-byte-adjust variable is configured.
\$junos-cos-byte-adjust-cell	115	Overhead bytes when downstream ATM traffic is in cell-mode.  <b>NOTE:</b> Do not configure the \$junos-cos-byte-adjust-cell variable when the \$junos-cos-byte-adjust variable is configured.

**Table 79: Junos OS CoS Traffic Shaping Predefined Variables for Dynamic Interface Sets** *(continued)*

Predefined Variable	RADIUS Tag Value	Description
\$junos-cos-shaping-rate-priority-high	116	Shaping rate configured for high-priority traffic in a traffic-control profile for a dynamic interface set or dynamic ACI interface set at a household level. Specifying this variable in a traffic-control profile for a dynamic subscriber interface is prohibited.
\$junos-cos-shaping-rate-priority-high-burst	117	Shaping rate burst size configured for high-priority traffic in a traffic-control profile for a dynamic interface set or dynamic ACI interface set at a household level. Specifying this variable in a traffic-control profile for a dynamic subscriber interface is prohibited.
\$junos-cos-shaping-rate-priority-medium	118	Shaping rate configured for medium-priority traffic in a traffic-control profile for a dynamic interface set or dynamic ACI interface set at a household level. Specifying this variable in a traffic-control profile for a dynamic subscriber interface is prohibited.
\$junos-cos-shaping-rate-priority-medium-burst	119	Shaping rate burst size configured for medium-priority traffic in a traffic-control profile for a dynamic interface set or dynamic ACI interface set at a household level. Specifying this variable in a traffic-control profile for a dynamic subscriber interface is prohibited.
\$junos-cos-shaping-rate-priority-low	120	Shaping rate configured for low-priority traffic in a traffic-control profile for a dynamic interface set or dynamic ACI interface set at a household level. Specifying this variable in a traffic-control profile for a dynamic subscriber interface is prohibited.

**Table 79: Junos OS CoS Traffic Shaping Predefined Variables for Dynamic Interface Sets *(continued)***

Predefined Variable	RADIUS Tag Value	Description
\$junos-cos-shaping-rate-priority-low-burst	121	Shaping rate burst size configured for low-priority traffic in a traffic-control profile for a dynamic interface set or dynamic ACI interface set at a household level. Specifying this variable in a traffic-control profile for a dynamic subscriber interface is prohibited.
\$junos-cos-shaping-rate-excess-high	122	Shaping rate configured for excess high-priority traffic in a traffic-control profile for a dynamic interface set or dynamic ACI interface set at a household level. Specifying this variable in a traffic-control profile for a dynamic subscriber interface is prohibited.
\$junos-cos-shaping-rate-excess-high-burst	123	Shaping rate burst size configured for excess high-priority traffic in a traffic-control profile for a dynamic interface set or dynamic ACI interface set at a household level. Specifying this variable in a traffic-control profile for a dynamic subscriber interface is prohibited.
\$junos-cos-shaping-rate-excess-low	124	Shaping rate configured for excess low-priority traffic in a traffic-control profile for a dynamic interface set or dynamic ACI interface set at a household level. Specifying this variable in a traffic-control profile for a dynamic subscriber interface is prohibited.
\$junos-cos-shaping-rate-excess-low-burst	125	Shaping rate burst size configured for excess low-priority traffic in a traffic-control profile for a dynamic interface set or dynamic ACI interface set at a household level. Specifying this variable in a traffic-control profile for a dynamic subscriber interface is prohibited.

## CoS for Aggregated Ethernet Subscriber Interfaces Overview

---

You can apply static or dynamic hierarchical CoS to a scheduler node at the aggregated Ethernet logical interface, its underlying physical interface, or an interface set.

- [Guidelines for Configuring CoS for Aggregated Ethernet Subscribers on page 959](#)

## Guidelines for Configuring CoS for Aggregated Ethernet Subscribers

When you configure CoS for aggregated Ethernet interfaces, consider the following guidelines:

- Configure the aggregated Ethernet logical interface over two physical interfaces capable of performing hierarchical scheduling.
- For VLAN subscriber interfaces over aggregated Ethernet, you must enable link protection on the aggregated Ethernet interface for hierarchical CoS to operate.
- Link protection is not required for IP or demux subscriber interfaces over aggregated Ethernet. We recommend that you enable targeted distribution on the demux interface to provide accurate hierarchical scheduling for these links.
- Keep the following guidelines in mind when configuring interface sets of aggregated Ethernet interfaces:
  - Sets of aggregated Ethernet interfaces are supported on MPC/MIC interfaces on MX Series routers only.
  - The supported logical interfaces for aggregated Ethernet in an interface set include VLAN demux interfaces, IP demux interfaces, and PPPoE logical interfaces over VLAN demux interfaces.

- The link membership list and scheduler mode of the interface set are inherited from the underlying aggregated Ethernet interface over which the interface set is configured.
- When an aggregated Ethernet interface operates in link protection mode, or if the scheduler mode is configured to replicate member links, the scheduling parameters of the interface set are copied to each of the member links.
- If the scheduler mode of the aggregated Ethernet interface is set to scale member links, the scheduling parameters are scaled based on the number of active member links and applied to each of the aggregated interface member links.

---

## CoS for PPPoE Subscriber Interfaces Overview

---

You can configure CoS functionality for static and dynamic PPPoE subscriber interfaces configured on Gigabit Ethernet Intelligent Queuing 2 (IQ2) and Ethernet Enhanced IQ2 (IQ2E) PICs on the M120 and M320 routers, and on MPCs on the MX Series 3D Universal Edge Router.

For all supported hardware platforms, you can attach an output traffic control profile that contains basic shaping and scheduling properties directly to a PPPoE interface. In this type of scenario, you can use each PPPoE interface to represent a household and shape all of the household traffic to an aggregate rate. Each forwarding class is mapped to a queue, and represents one type of services provided to a household customer.

Both the IQ2E PIC and MPC support hierarchical scheduling functionality that is not available on the IQ2 PIC. To shape customer or DSLAM traffic at different levels of the PPPoE interface hierarchy, you can attach traffic control profiles to interface sets that contain PPPoE members.

MPCs support subscriber interfaces with PPPoE encapsulation over aggregated Ethernet interfaces. These PPPoE subscriber interfaces are configured over VLAN demux interfaces, which are also configured over Aggregated Ethernet interfaces.

You can configure 802.3ad link aggregation group (LAG) stateful port and dense port concentrator (DPC) redundancy. This provides targeted distribution of non-replicated (stacked) PPPoE or IP demux links over VLAN demux links, which in turn are over an

aggregated Ethernet (AE) logical interface. Service providers with PPPoE or IP demux interfaces for CoS configurations can provide DPC and port redundancy to subscribers.

**NOTE:** For static PPPoE underlying logical interfaces, use PPPoE interface sets.

## CoS for L2TP LAC Subscriber Interfaces Overview

You can apply CoS to the Layer 2 Tunnel Protocol (L2TP) access concentrator (LAC) component.

In Layer 2 Tunnel Protocol (L2TP) configurations, IP and L2TP headers are added to packets arriving at a PPP subscriber interface on the L2TP access concentrator (LAC) before being tunneled to the L2TP network server (LNS). You can manage the IP header by configuring classifiers and rewrite-rules that transfer the ToS (Type of Service) value or the 802.1p value from the *inner* IP header to the *outer* IP header of the L2TP packet.

[Figure 21 on page 961](#) shows the classifier and rewrite rules that you can configure from the LAC to the LNS, and from the LNS to the LAC.

**Figure 21: CoS Configuration for L2TP LAC Topology**

- [Traffic from LAC to LNS on page 962](#)
- [LAC Tunnels: Traffic from LNS to LAC on page 962](#)

## Traffic from LAC to LNS

To set the ToS value or the 802.1p value on the inner IP header, you can configure both fixed and behavior aggregate (BA) classifiers for subscribers at Layer 2 or Layer 3 of the network.

[Table 80 on page 962](#) lists the configuration options for applying classifiers to a subscriber interface on an ingress LAC tunnel.

**Table 80: Ingress LAC Tunnel Classifier Options**

Classifier	Subscriber Interface
Fixed	Either of the following: <ul style="list-style-type: none"> <li>• PPP interface</li> <li>• Underlying VLAN interface</li> </ul>
Layer 2	Either of the following: <ul style="list-style-type: none"> <li>• PPP interface</li> <li>• Underlying VLAN interface</li> </ul>
Layer 3	Family of PPP interfaces

You cannot configure a Layer 2 and fixed classifier together.

The behavior of the Layer 2 and Layer 3 classifiers depends on the configuration. For example, a Layer 3 classifier for a family of PPP interfaces overrides a Layer 2 classifier configured at the PPP interface, except for the unknown packets and control packets.

If you do not configure a classifier for Layer 2, the system applies the default Layer 3 classifier so that tunneled and terminated subscribers have the same behavior. To prevent unknown packets and control packets from being discarded, the system assigns them to the best-effort forwarding class.

For egress tunnels, you configure rewrite rules at the PPP interface to set the ToS or 802.1p value of the outer IP header. Rewrite rules are applied accordingly to the forwarding class, packet loss priority (PLP), and code point.

## LAC Tunnels: Traffic from LNS to LAC

On a LAC, mapping the inner IP header to the outer IP header of the L2TP packet depends on the classifier and rewrite-rule configurations. For example, [Table 81 on page 963](#) lists the values for the classifier and rewrite rules for a VLAN interface. For assured forwarding, the inner 802.1p value (**ob001**) is classified with the assured-forwarding class and low loss priority at the ingress interface. Based on the assured-forwarding class and low loss priority in the rewrite rule, the ToS value in the outer IP header is set to **ob001**.

Table 81: Sample Result

Inner .Ip Value	Forwarding Class	Loss Priority	Code Point	Outer ToS Value
ob000	best-effort	low	000	ob000
ob001	assured-forwarding	low	001	ob001
ob101	expedited-forwarding	low	101	ob101
ob111	network-control	low	11	ob111

- [Configuring Dynamic CoS for an L2TP LAC Tunnel on page 971](#)

## CoS for L2TP LNS Inline Services Overview

You can apply hierarchical scheduling and per-session shaping to Layer 2 Tunnel Protocol (L2TP) network server (LNS) inline services using a static or dynamic CoS configuration.

This feature is supported on MIC and MPC interfaces on MX240, MX480, and MX960 routers.

- [Guidelines for Applying CoS to the LNS on page 963](#)
- [Hardware Requirements for Inline Services on the LNS on page 964](#)

### Guidelines for Applying CoS to the LNS

In L2TP configurations, IP, UDP, and L2TP headers are added to packets arriving at a PPP subscriber interface on the L2TP access concentrator (LAC) before being tunneled to the LNS.

When a service interface is configured for an L2TP LNS session, it has an *inner* IP header and an outer IP header. You can configure CoS for an LNS session that corresponds to the inner IP header only. The *outer* IP header is used for L2TP tunnel processing only.

However, we recommend that you configure classifiers and rewrite-rules to transfer the ToS (type of service) value from the inner IP header to the outer IP header of the L2TP packet.

[Figure 22 on page 964](#) shows the classifier and rewrite rules that you can configure on an LNS inline service.

Figure 22: Processing of CoS Parameters in an L2TP LNS Inline Service

By default, the shaping calculation on the service interface includes the L2TP encapsulation. If necessary, you can configure additional adjustments for downstream ATM traffic from the LAC or differences in Layer 2 protocols.

### Hardware Requirements for Inline Services on the LNS

Hierarchical scheduling for L2TP LNS inline services is supported on MIC and MPC interfaces only. The services that you can configure depend on the hardware combination. [Table 82 on page 964](#) lists the supported inline services and peer interfaces for each MIC and MPC combination.

Table 82: Hardware Requirements for L2TP LNS Inline Services

MPC Module	Inline Service Support—With Per-Session Shaping	Inline Service Support—Without Per-Session Shaping
MX-MPC1-3D	No	Yes
MX-MPC2-3D		
MX-MPC1-3D-Q	Yes	Yes
MX-MPC2-3D-Q		
MX-MPC2-3D-EQ		
MPC-3D-16XGE-SFPP	No	No

## CoS for Interface Sets of Subscribers Overview

Interface sets enable service providers to group logical interfaces so they can apply CoS parameters to all of the traffic in the group.

Interface sets are beneficial for various scenarios in a subscriber access network. For example, you can use an interface set to configure a local loop with a small number of subscribers. Interface sets are also useful for grouping a large number of subscribers into a particular service class or for defining traffic engineering aggregates for DSLAMs.

- [Guidelines for Configuring Dynamic Interface Sets in a Subscriber Access Network](#) on page 965

### Guidelines for Configuring Dynamic Interface Sets in a Subscriber Access Network

Interface sets enable service providers to group logical interfaces so they can apply CoS parameters to all of the traffic in the group.

Interface sets are beneficial for various scenarios in a subscriber access network. For example, you can use an interface set to configure a local loop with a small number of subscribers. Interface sets are also useful for grouping a large number of subscribers into a particular service class or for defining traffic engineering aggregates for DSLAMs.

When configuring interface sets for subscriber access, keep the following guidelines in mind:

- You can configure interface sets of VLAN demux, PPPoE, or demux interfaces over aggregated Ethernet interfaces.
- An interface can only belong to one interface set. If you try to add the same interface to different interface sets, the commit operation fails.
- You configure the interface set and the traffic scheduling and shaping parameters in a dynamic profile. However, you must apply the traffic-control profile to the interface set in the static **[edit class-of-service]** hierarchy.

**NOTE:** This rule applies to all interface sets except ACI sets.

- The **\$junos-interface-set-name** predefined variable is available only for RADIUS Accept messages; change of authorization (CoA) requests are not supported.
- The **\$junos-svlan-interface-set-name** predefined variable locally generates an interface set name for use by dual-tagged VLAN interfaces based on the outer tag of the dual-tagged VLAN. The format of the generated variable is **physical\_interface\_name - outer\_VLAN\_tag**. For example, an aggregated Ethernet interface “ae0,” with a dual-tagged VLAN interface that has an outer tag of “111,” results in a **\$junos-svlan-interface-set-name** dynamic variable of “ae0-111”. Similarly, a non-aggregated Ethernet interface of ge-1/1/0, with the same dual-tagged VLAN interface that has an outer tag of “111,” results in a **\$junos-svlan-interface-set-name** dynamic variable of “ge-1/1/0-111”.

- The **\$junos-tagged-vlan-interface-set-name** predefined variable locally generates an interface set name used for grouping logical interfaces stacked over logical stacked VLAN demux interfaces for either a 1:1 (dual-tagged; individual client) VLAN or N:1 (single tagged; service) VLAN. The format of the generated variable differs with VLAN type as follows:
  - Dual-tagged (client) VLAN—***physical\_interface\_name - outer\_VLAN\_tag - inner\_VLAN\_tag***. For example, an aggregated Ethernet interface “ae0,” with a dual-tagged VLAN interface that has an outer tag of “111” and an inner tag of “200,” results in a **\$junos-tagged-vlan-interface-set-name** dynamic variable of “ae0-200-111”. Similarly, a non-aggregated Ethernet interface of ge-1/1/0, with the same dual-tagged VLAN interface that has an outer tag of “111” and an inner tag of “200,” results in a **\$junos-tagged-vlan-interface-set-name** dynamic variable of “ge-1/1/0-200-111”.
  - Single tagged (service) VLAN—***physical\_interface\_name - VLAN\_tag***. For example, an aggregated Ethernet interface “ae0,” with an N:1 VLAN using the single tag of “200,” results in a **\$junos-tagged-vlan-interface-set-name** dynamic variable of “ae0-200”. Similarly, a non-aggregated Ethernet interface of ge-1/1/0, with the same N:1 VLAN using the single tag of “200,” results in a **\$junos-tagged-vlan-interface-set-name** dynamic variable of “ge-1/1/0-200”.
- All dynamic demux, dual-tagged VLAN logical interfaces with the same outer VLAN tag and physical interface are assigned to the same interface set and all CoS values provisioned with the dynamic profile are applied to the interfaces that are part of the set.
- The interface set name must be explicitly referenced in the CoS configuration as part of the static configuration outside of the dynamic profile. The CoS configuration is static and the interface set name must be statically referenced.

**NOTE:** This rule applies to all interface sets except ACI sets.

---

- RADIUS can return an *access-accept* message under certain conditions. A configured RADIUS VSA for the interface set name takes precedence over the locally generated variable on the router. This means that if the interface-set-name VSA is configured on RADIUS, the router continues to use this variable instead of the locally generated value from the dynamic variable.
- Sets of aggregated Ethernet interfaces are supported on MPC/MIC interfaces on MX Series routers only.
- The supported interface stacks for aggregated Ethernet in an interface set include VLAN demux interfaces, IP demux interfaces, and PPPoE logical interfaces over VLAN demux interfaces.
- The link membership list and scheduler mode of the interface set are inherited from the underlying aggregated Ethernet interface over which the interface set is configured.

- When an aggregated Ethernet interface operates in link protection mode, or if the scheduler mode is configured to replicate member links, the scheduling parameters of the interface set are copied to each of the member links.
- If the scheduler mode of the aggregated Ethernet interface is set to scale member links, the scheduling parameters are scaled based on the number of active member links and applied to each of the aggregated interface member links.

## Configuring Hierarchical CoS for a Subscriber Interface of Aggregated Ethernet Links

You can enable hierarchical CoS on a subscriber interface with an underlying aggregated Ethernet interface.

Before you begin, configure the subscriber interface with aggregated Ethernet.

- To configure a VLAN interface over aggregated Ethernet with link protection, see [“Configuring a Static or Dynamic VLAN Subscriber Interface over Aggregated Ethernet” on page 782](#) and [Configuring Link Protection for Aggregated Ethernet Interfaces](#).
- To configure a demux subscriber interface:

For static and dynamic IP demux interfaces, see [“Configuring a Static or Dynamic IP Demux Subscriber Interface over Aggregated Ethernet” on page 783](#).

For static and dynamic VLAN demux interfaces, see [“Configuring a Static or Dynamic VLAN Demux Subscriber Interface over Aggregated Ethernet” on page 784](#).

**BEST PRACTICE:** Link protection is not required for IP or demux subscriber interfaces. We recommend that you enable targeted distribution on the demux interface to provide accurate hierarchical scheduling for these links. See [“Providing Accurate Scheduling for a Demux Subscriber Interface of Aggregated Ethernet Links” on page 1041](#).

To configure hierarchical CoS on the link aggregation (LAG) bundle:

1. Specify that you want to access the LAG bundle.

```
user@host# edit interfaces aex
```

2. Configure the link aggregation (LAG) bundle with hierarchical scheduler mode.

```
[edit interfaces aex]  
user@host# set hierarchical-scheduler
```

You can then attach static or dynamic traffic shaping and scheduling parameters at the aggregated Ethernet logical interface or its underlying physical interface. See:

- [Configuring Traffic Scheduling and Shaping for Subscriber Access on page 919](#)
- [Configuring Schedulers in a Dynamic Profile for Subscriber Access on page 921](#)
- [Applying Traffic Shaping and Scheduling to a Subscriber Interface in a Dynamic Profile on page 927](#)

**Related  
Documentation**

---

## Configuring Hierarchical CoS on a Static PPPoE Subscriber Interface

---

You can configure hierarchical CoS on a static PPPoE subscriber interface.

Before you begin:

- Configure the static PPPoE subscriber interface.

See [Configuring PPPoE](#).

To configure hierarchical CoS on a static PPPoE subscriber interface:

1. Specify the PPPoE interface that you want to configure.

```
user@host# edit interfaces pppoe-interface-name
```

2. Configure the hierarchical scheduler for the interface.

```
[edit interfaces interface-name]  
user@host# set hierarchical-scheduler
```

3. (Optional) Group the PPPoE interfaces in an interface set.

```
[edit]  
user@host# edit interfaces interface-set interface-set-name
```

You can now configure static traffic and scheduling parameters for each traffic-control profile, and attach each traffic-control profile to the PPPoE interface or the PPPoE interface set. For more information, see the [Junos OS Class of Service Configuration Guide](#).

- Related Documentation**
- For hardware requirements and configuration guidelines, see [Guidelines for Configuring Dynamic CoS for Subscriber Access on page 906](#)
  - [CoS for PPPoE Subscriber Interfaces Overview on page 960](#)
  - [Example: Configuring Hierarchical Scheduling and Queuing for a Static PPPoE Subscriber Interface on page 991](#)
  - [Example: Configuring Hierarchical Scheduling and Queuing for an Underlying Static PPPoE Subscriber Interface on page 993](#)
  - [Example: Configuring Hierarchical Scheduling and Queuing for an Interface Set of Static PPPoE Subscriber Interfaces on page 995](#)
  - [Verifying the Scheduling and Shaping Configuration for Subscriber Access on page 934](#)

## Configuring Dynamic CoS for an L2TP LAC Tunnel

In L2TP configurations, IP and L2TP headers are added to packets arriving at a PPP subscriber interface on the LAC before being tunneled to the L2TP network server (LNS).

Classifiers and rewrite rules enable you to properly transfer the ToS (Type of Service) value or the 802.1p value from the inner IP header to the outer IP header of the L2TP packet.

Before you begin, configure the L2TP LAC. See “[Configuring an L2TP LAC](#)” on page 374.

To manage the IP header values for a LAC tunnel:

1. Configure the classifier for the inner tunnel.
  - a. Define the fixed or behavior aggregate (BA) classifier.
    - To configure a fixed classifier:
 

```
[edit class-of-service interfaces interface-name unit logical-unit-number]
user@host# set forwarding-class class-name
```
    - To configure a BA classifier:
 

```
[edit class-of-service]
user@host# set classifiers (ieee-802.1 | inet-precedence) classifier-name
forwarding-class class-name loss-priority level code-points [ aliases ] [
bit-patterns]
```
  - b. Apply the classifier to the Layer 2 interface or Layer 3 interface. For Layer 2, you can apply the classifier at the PPP interface or an underlying VLAN interface. For Layer 3, you can apply classifiers to a family of PPP interfaces.
    - To apply the classifier for the IEEE 802.1p value:
 

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name
unit logical-unit-number classifiers]
user@host# set ieee-802.1 (classifier-name | default) vlan-tag (inner | outer)
```
    - To apply the classifier for the ToS value:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name
  unit logical-unit-number classifiers]
user@host# set inet-precedence (classifier-name | default)
```

2. Configure the rewrite rule for the egress tunnel.

- a. Configure the rewrite rule with the forwarding class and the loss priority value.

```
[edit class-of-service]
user@host# set rewrite-rules (ieee-802.1 | inet-precedence) rewrite-name
  forwarding-class class-name loss-priority level code-point (alias | bits)
```

- b. Apply the rewrite rule to the PPP interface for which the L2TP tunnel is configured.

- To apply the rewrite-rule for the IEEE 802.1p value:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name
  unit logical-unit-number rewrite-rules]
user@host# set ieee-802.1 (rewrite-name | default) vlan-tag (outer |
  outer-and-inner)
```

- To apply the rewrite rule for the ToS value:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name
  unit logical-unit-number rewrite-rules]
user@host# set inet-precedence (rewrite-name | default)
```

## Configuring Dynamic CoS for an L2TP LNS Inline Service

You can configure hierarchical scheduling for an L2TP LNS inline service and manage the IP header values using rewrite rules and classifiers.

Before you begin, configure the L2TP LNS inline service interface. See [“Configuring an L2TP LNS with Inline Service Interfaces” on page 384](#).

To configure CoS for an L2TP LNS inline service in a dynamic profile:

1. Configure the hierarchical scheduler for the service interface (si) interface.

```
[edit interfaces si-fpc/port/pic ]
user@host# set hierarchical-scheduler maximum-hierarchy-levels 2
```

**BEST PRACTICE:** To enable Level 3 nodes in the LNS scheduler hierarchy and to provide better scaling, we recommend that you also specify a maximum of two hierarchy levels.

2. Configure the LNS to reflect the IP ToS value in the inner IP header to the outer IP header.

```
[edit services l2tp tunnel-group name]
user@host# set tos-reflect
```

## 3. Configure the classifier for egress traffic from the LAC.

## a. Define the fixed or behavior aggregate (BA) classifier.

- To configure a fixed classifier:

```
[edit class-of-service interfaces interface-name unit logical-unit-number]
user@host# set forwarding-class class-name
```

- To configure a BA classifier:

```
[edit class-of-service]
user@host# set classifiers (dscp | dscp-ipv6 | inet-precedence) classifier-name
forwarding-class class-name loss-priority level code-points [ aliases ] [
bit-patterns]
```

## b. Apply the classifier to the service interface.

- To apply the classifier for the DSCP or DSCP IPv6 value:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name
unit logical-unit-number classifiers]
user@host# set dscp (classifier-name | default)
user@host# set dscp-ipv6 (classifier-name | default)
```

- To apply the classifier for the ToS value:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name
unit logical-unit-number classifiers]
user@host# set inet-precedence (classifier-name | default)
```

## 4. Configure and apply a rewrite-rule to ingress traffic to the LAC:

## a. Configure the rewrite rule with the forwarding class and the loss priority value.

```
[edit class-of-service]
user@host# set rewrite-rules (dscp | dscp-ipv6 | inet-precedence) rewrite-name
forwarding-class class-name loss-priority level code-point (alias | bits)
```

## b. Apply the rewrite rule to the service interface.

- To apply the rewrite rule for the DSCP or DSCP IPv6 value:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name
unit logical-unit-number rewrite-rules]
user@host# set dscp (rewrite-name | default)
user@host# set dscp-ipv6 (rewrite-name | default)
```

- To apply the rewrite rule for the ToS value:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name
unit logical-unit-number rewrite-rules]
user@host# set inet-precedence (rewrite-name | default)
```

## 5. (Optional) Configure additional adjustments for downstream ATM traffic.

By default, the shaping calculation on the service interface includes the L2TP encapsulation. If necessary, you can configure additional adjustments for downstream ATM traffic from the LAC or differences in Layer 2 protocols.

```
[edit dynamic-profiles profile-name class-of-service traffic-control-profiles profile-name]
```

```
user@host# set overhead-accounting (frame-mode | cell-mode |  
$junos-cos-shaping-mode) <bytes (byte-value | $junos-cos-byte-adjust)
```

6. Apply the traffic-control profile.

```
[edit dynamic-profiles profile-name class-of-service interfaces  
$junos-interface-ifd-name unit $junos-interface-unit]  
user@host# set output-traffic-control-profile profile-name
```

## Configuring an Interface Set of Subscribers in a Dynamic Profile

---

Interface sets enable you to provide hierarchical scheduling to a group of subscriber interfaces.

Before you begin, configure the subscriber interfaces that you intend to include in the interface set.

- For static VLAN interfaces, see “[Configuring Static Subscriber Interfaces in Dynamic Profiles](#)” on page 723.
- For dynamic VLAN interfaces, see “[Configuring a Static or Dynamic VLAN Subscriber Interface over Aggregated Ethernet](#)” on page 782.
- For dynamic IP demux interfaces, see “[Configuring Dynamic Subscriber Interfaces Using IP Demux Interfaces in Dynamic Profiles](#)” on page 729 and “[Configuring a Static or Dynamic IP Demux Subscriber Interface over Aggregated Ethernet](#)” on page 783.
- For dynamic VLAN demux interfaces, see “[Configuring Dynamic Subscriber Interfaces Using VLAN Demux Interfaces in Dynamic Profiles](#)” on page 730.
- For dynamic PPPoE interfaces, see “[Configuring Dynamic PPPoE Subscriber Interfaces Using Dynamic Profiles](#)” on page 857.
- For aggregated Ethernet interfaces, see “[Configuring Hierarchical CoS for a Subscriber Interface of Aggregated Ethernet Links](#)” on page 969

To configure an interface set of subscriber interfaces:

1. Configure the interface set in the dynamic profile.

```
[edit dynamic-profiles profile-name interfaces]  
user@host# edit interface-set interface-set-name
```

Replacing the *interface-set-name* variable with the *\$junos-interface-set-name*, *\$junos-svlan-interface-set-name*, or *\$junos-tagged-vlan-interface-set-name* predefined variable. The interface set is created dynamically when the subscriber logs in.

2. Include the interfaces within the dynamic interface-set.

```
[edit dynamic-profiles profile-name interfaces interface-set $junos-interface-set-name]
user@host# set interface interface-name unit logical-unit-number
```

3. Apply traffic shaping and queuing parameters to the interface set.

**TIP:** You must configure the interface set in the static [edit class-of-service] hierarchy, not in the [edit dynamic-profiles] hierarchy.

```
[edit class-of-service interfaces]
user@host# edit interface-set interface-set-name
[edit class-of-service interfaces interface-set interface-set-name]
user@host# set output-traffic-control-profile profile-name
```

## Example: Configuring Static Hierarchical Scheduling and Queuing for Subscriber Access

This example shows you how to configure CoS for a subscriber in a dynamic profile. The CoS parameters configure a best-effort, data service for subscribers.

1. Configure the static CoS parameters in the **[edit class-of-service]** hierarchy.

You must configure the scheduler maps in this hierarchy; it will get referenced in the dynamic profile.

```
class-of-service {
  forwarding-classes {
    queue 0 best-effort;
    queue 1 expedited-forwarding;
```

```
    queue 3 network-control;
    queue 2 assured-forwarding;
  }
  scheduler-maps {
    data_smap {
      forwarding-class best-effort scheduler be_sch;
    }
  }
  schedulers {
    be_sch {
      transmit-rate percent 10;
      buffer-size remainder;
      priority low;
    }
  }
}
```

2. Configure the subscriber interface in the **[edit interfaces]** hierarchy. Enable hierarchical scheduling for the interface.

```
interfaces {
  ge-2/2/0 {
    hierarchical-scheduler;
    vlan-tagging;
    unit 100 {
      vlan-id 100;
      family inet {
        unnumbered-address lo0.0 preferred-source-address 100.0.0.1;
      }
    }
  }
}
```

3. Configure CoS in the dynamic profile.

```
dynamic-profiles {
  data-service {
    interfaces {
      "$junos-interface-ifd-name" {
        unit "$junos-underlying-interface-unit" {
          family inet;
        }
      }
    }
  }
  class-of-service {
    traffic-control-profiles {
      tcp1 {
        scheduler-map data_smap;
        shaping-rate 50k;
        guaranteed-rate 10k;
      }
    }
    interfaces {
      "$junos-interface-ifd-name" {
        unit "$junos-underlying-interface-unit" {
          output-traffic-control-profile tcp1;
        }
      }
    }
  }
}
```

```

    }
  }
}

```

## Example: Configuring Dynamic Hierarchical Scheduling and Queuing for Subscriber Access

In this example, subscribers are provided with a data and voice service defined in an access profile when they initially log in. The RADIUS administrator supplies the initial values on the RADIUS server, and the service activation is performed at subscriber login.

After the initial login, the subscriber adds an assured forwarding service that is not defined in the original access profile. A service profile is used to configure the schedulers and a RADIUS CoA activates the service. The queues defined for the schedulers in the initial scheduler map and the new scheduler map are merged.

In addition, the values for the initial data and voice service are upgraded by the RADIUS administrator through a separate RADIUS CoA message.

To configure the initial service and enable the activation through a RADIUS CoA:

1. Configure the access profile for the service activation.
  - a. Configure the VLAN interface for the access profile.

```

[edit]
dynamic-profiles access-profile {
  interfaces {
    $junos-interface-ifd-name {
      unit $junos-underlying-interface-unit {
        family inet;
      }
    }
  }
}

```

- b. Configure the class of service parameters in the access profile. In this example, you configure Junos OS predefined variables that provide the initial scheduler name and scheduler parameters obtained from the RADIUS authentication server when the subscriber logs in.

Include the configurations for the interfaces, schedulers, and the scheduler maps.

```

[edit]
dynamic-profiles access-profile {
  class-of-service {
    traffic-control-profiles {
      tcp1 {

```

```

        scheduler-map $junos-cos-scheduler-map;
        shaping-rate $junos-cos-shaping-rate;
        guaranteed-rate $junos-cos-guaranteed-rate;
        delay-buffer-rate $junos-cos-delay-buffer-rate;
    }
}
interfaces {
    $junos-interface-ifd-name {
        unit "$junos-underlying-interface-unit" {
            classifiers {
                ieee-802.1 l2_classifier;
            }
            rewrite-rules {
                ieee-802.1 l2_rewrite;
            }
            output-traffic-control-profile tcp1;
        }
    }
}
schedulers {
    $junos-cos-scheduler {
        buffer-size percent $junos-cos-scheduler-bs;
        priority $junos-cos-scheduler-pri;
        transmit-rate percent $junos-cos-scheduler-tx;
        drop-profile-map loss-priority low protocol any $junos-cos-scheduler-low;
        drop-profile-map loss-priority medium-low protocol any
            $junos-cos-scheduler-medium-low;
        drop-profile-map loss-priority medium-high protocol any
            $junos-cos-scheduler-medium-high;
        drop-profile-map loss-priority high protocol any $junos-cos-scheduler-high;
    }
}
scheduler-maps {
    data_voice_smap {
        forwarding-class be scheduler be_sch;
        forwarding-class ef scheduler ef_sch;
    }
}
}
}

```

Table 83 on page 980 lists the initial values defined by the RADIUS administrator for the scheduler map and shaping rates.

**Table 83: Initial Scheduler Map and Shaping Values at Subscriber Login**

Predefined Variable	RADIUS Tag	Value
\$junos-cos-scheduler-map	T01	data_voice_smap
\$junos-cos-shaping-rate	T02	6m
\$junos-cos-guaranteed-rate	T03	4m
\$junos-cos-delay-buffer-rate	T04	4m

[Table 84 on page 981](#) lists the initial values defined by the RADIUS administrator for the voice (expedited forwarding) scheduler.

**Table 84: Initial CoS Values for the Voice Scheduler at Subscriber Login**

Predefined Variable	Tag	Value

2. Configure the classifiers, drop profiles, forwarding classes, and rewrite rules in the static **[edit class-of-service]** hierarchy.

```
[edit]
class-of-service {
  classifiers {
```

```
dscp dscp_classifier {
  forwarding-class be {
    loss-priority low code-points 000000;
  }
  forwarding-class af {
    loss-priority medium-low code-points 000001;
  }
}
ieee-802.1 l2_classifier {
  forwarding-class be {
    loss-priority medium-low code-points 000;
  }
  forwarding-class ef {
    loss-priority medium-low code-points 100;
  }
  forwarding-class af {
    loss-priority medium-low code-points 010;
  }
}
}
drop-profiles {
  d0 {
    fill-level 25 drop-probability 100;
    fill-level 0 drop-probability 0;
  }
  d1 {
    fill-level 50 drop-probability 100;
    fill-level 0 drop-probability 0;
  }
  d2 {
    fill-level 75 drop-probability 100;
    fill-level 0 drop-probability 0;
  }
  d3 {
    fill-level 0 drop-probability 0;
    fill-level 100 drop-probability 100;
  }
}
forwarding-classes {
  queue 0 be;
  queue 1 ef;
  queue 2 af;
  queue 3 nc;
}
interfaces {
  ge-1/2/9 {
    shaping-rate 100m;
  }
}
rewrite-rules {
  ieee-802.1 l2_rewrite {
    forwarding-class be {
      loss-priority medium-low code-point 000;
    }
    forwarding-class ef {
      loss-priority medium-low code-point 001;
    }
  }
}
```

```

    }
    forwarding-class af {
        loss-priority medium-low code-point 100;
    }
}
dscp l2_rewrite {
    forwarding-class be {
        loss-priority medium-low code-points 000;
    }
    forwarding-class ef {
        loss-priority medium-low code-points 001;
    }
    forwarding-class af {
        loss-priority medium-low code-points 001;
    }
}
}
}

```

3. Configure the service profile enable RADIUS to activate the video service after login. The video service corresponds to assured forwarding PHB.

In this example, you configure Junos OS predefined variables that provide the initial scheduler name and scheduler parameters obtained from the RADIUS authentication server when the subscriber logs in.

```

[edit]
dynamic-profiles service-af {
    variables {
        af_fc default-value video;
        af_sch default-value af_sch;
        sch-drop-any default-value all;
        sch-pri-2 default-value strict-high;
        sch-bs-2 default-value 40;
        sch-tx-2 default-value 3m;
        smap default-value any
    }
    class-of-service {
        scheduler-maps {
            "$smap" {
                forwarding-class "$af_fc" scheduler "$af_sch";
            }
        }
        schedulers {
            "$af_sch" {
                transmit-rate percent "$sch-tx-2";
                buffer-size percent "$sch-bs-2";
                priority "$sch-pri-2";
                drop-profile-map loss-priority any protocol any drop-profile "$sch-drop-any";
            }
        }
    }
}
}

```

After the three services are activated, subscribers receive upgraded values for the data and voice service when RADIUS sends a change of authorization (CoA). In this case, the CoS parameters are replaced, because multiple subscribers were not enabled on the logical interface.

Table 86 on page 984 lists the upgraded values defined by the RADIUS administrator.

**Table 86: Upgraded CoS Values for the Video Service**

Variable	RADIUS Tag	Value
junos-cos-scheduler-map	T01	data_voice_smap
junos-cos-shaping-rate	T02	14m
junos-cos-guaranteed-rate	T03	13m
junos-cos-delay-buffer-rate	T04	12m

Table 87 on page 984 lists the values defined by the RADIUS administrator for the video (assured forwarding) scheduler.

**Table 87: Upgraded CoS Values for the Video Scheduler**

Predefined Variable	Tag	Value
\$junos-cos-scheduler	—	af_sch
\$junos-cos-scheduler-tx	T01	10
\$junos-cos-scheduler-bs	T02	10
\$junos-cos-scheduler-pri	T03	medium
\$junos-cos-scheduler-dropfile-low	T04	d3
\$junos-cos-scheduler-dropfile-medium-low	T05	d2
\$junos-cos-scheduler-dropfile-medium-high	T06	d1
\$junos-cos-scheduler-dropfile-high	T07	d0

Table 88 on page 984 lists the values defined by the RADIUS administrator for the expedited forwarding scheduler in the CoA message. The values are the same as the initial service.

**Table 88: Initial CoS Values for the Expedited Forwarding Scheduler at Subscriber Login**

Predefined Variable	Tag	Value
\$junos-cos-scheduler	—	ef_sch
\$junos-cos-scheduler-tx	T01	10
\$junos-cos-scheduler-bs	T02	10

**Table 88: Initial CoS Values for the Expedited Forwarding Scheduler at Subscriber Login (*continued*)**

- [Guidelines for Configuring Dynamic CoS for Subscriber Access on page 906](#)

## Example: Configuring Initial CoS Parameters Dynamically Obtained from RADIUS

The following configuration is an example of a client dynamic profile in which initial CoS parameters are dynamically obtained from the RADIUS server when a subscriber authenticates over the interface to which the dynamic profile is applied.

For this example, assume that the RADIUS authentication server has been configured with traffic-shaping parameters (at Juniper Networks VSA 26-108) and CoS scheduling and queuing parameters (at Juniper Networks VSA 26-146).

The subscriber interface is a single-unit static gigabit Ethernet VLAN interface on an EQ DPC port:

```
[edit]
interfaces {
  ge-9/0/3 {
    hierarchical-scheduler;
    vlan-tagging;
    unit 100 {
      vlan-id 100;
      family inet {
        address 192.168.32.2/24;
      }
    }
  }
}
```

The client dynamic profile **residential\_silver** attaches the traffic-control profile **tcp\_1** to the subscriber interface that is defined in the dynamic profile using the **\$junos-interface-ifd-name** predefined variable.

```
[edit]
dynamic-profiles {
  residential_silver {
    interfaces {
      "$junos-interface-ifd-name" {
        unit "$junos-underlying-interface-unit" {
          family inet;
        }
      }
    }
    class-of-service {
      interfaces {
        "$junos-interface-ifd-name" {
          unit "$junos-underlying-interface-unit" {
            output-traffic-control-profile tcp_1;
          }
        }
      }
    }
  }
}
```

The traffic-control profile **tcp\_1**, references Junos OS predefined variables to obtain a scheduler-map name and traffic-shaping parameter values from RADIUS when a subscriber logs in. For this example, assume that the RADIUS server replaces the Junos OS predefined variable **\$junos-cos-scheduler-map** scheduler-map name **business\_smap\_1**. The scheduler map **business\_smap\_1** is configured in the client dynamic profile:

```
[edit]
dynamic-profiles {
  residential_silver {
    class-of-service {
```

```

traffic-control-profiles {
  tcp_1 {
    scheduler-map "$junos-cos-scheduler-map"; # 'business_smap_1'
    shaping-rate "$junos-cos-shaping-rate";
    guaranteed-rate "$junos-cos-guaranteed-rate";
    delay-buffer-rate "$junos-cos-delay-buffer-rate";
  }
}
scheduler-maps {
  business_smap_1 {
    forwarding-class best-effort scheduler be_sched;
    forwarding-class ef scheduler home_sched
  }
}
}
}

```

A scheduler definition references Junos OS predefined variables to obtain scheduler configurations from RADIUS when a subscriber logs in. For this example, assume that the RADIUS server provides scheduler configurations for schedulers named **be\_sched** and **home\_sched**, which are included in the scheduler map **business\_smap\_1**:

```

[edit]
dynamic-profiles {
  residential_silver {
    class-of-service {
      schedulers {
        "$junos-cos-scheduler" { # 'be_sched' and 'home_sched'
          transmit-rate "$junos-cos-scheduler-tx";
          buffer-size "$junos-cos-scheduler-bs";
          priority "$junos-cos-scheduler-pri";
          drop-profile-map loss-priority low protocol any drop-profile
            "$junos-cos-scheduler-dropfile-low";
          drop-profile-map loss-priority medium-low protocol any drop-profile
            "$junos-cos-scheduler-dropfile-medium-low";
          drop-profile-map loss-priority medium-high protocol any drop-profile
            "$junos-cos-scheduler-dropfile-medium-high";
          drop-profile-map loss-priority high protocol any drop-profile
            "$junos-cos-scheduler-dropfile-high";
        }
      }
    }
  }
}

```

Static configurations for CoS consist of configurations for the forwarding classes used in the scheduler map **business\_smap\_1** and configurations for drop-profile names provided by RADIUS for as part of the scheduler configurations provided (for **be\_sched** and **home\_sched**) when a subscriber logs in:

```

[edit]
class-of-service {
  forwarding-classes {
    queue 0 best-effort;
    queue 1 ef;
  }
}

```

```
drop-profiles {  
    ...configurations_for_drop_profile_names_provided_by_RADIUS...  
}  
}  
}
```

## Example: Providing Unique Rate Configurations for Schedulers in a Dynamic Profile

Combining static and dynamic schedulers in a dynamic profile enables you to provide subscribers with services that have unique scheduler definitions.

In this example, the network administrator configures the data service with a **transmit-rate** that is rate controlled using the **\$junos-cos-scheduler-tx** predefined variable. RADIUS dynamically supplies the percentage value for the transmission rate that is specified in the RADIUS VSA to the data scheduler when the subscriber logs in.

For the best-effort service, the network administrator assigns the remaining transmission rate that is available.

```
schedulers {  
  data-scheduler {  
    transmit-rate percent rate-limit $junos-cos-scheduler-tx;  
    buffer-size percent $junos-cos-scheduler-bs;  
    priority $junos-cos-scheduler-pri;  
    drop-profile-map loss-priority low protocol any drop-profile d0;  
    drop-profile-map loss-priority medium-low protocol any drop-profile d1;  
    drop-profile-map loss-priority medium-high protocol any drop-profile d2;  
    drop-profile-map loss-priority high protocol any drop-profile d3;  
    drop-profile-map loss-priority any protocol any drop-profile all;  
  }  
  best-effort-scheduler {  
    transmit-rate remainder;  
    buffer-size percent $junos-cos-scheduler-bs;  
    priority medium-high;  
    drop-profile-map loss-priority low protocol any drop-profile  
      $junos-cos-scheduler-dropfile-low;  
    drop-profile-map loss-priority medium-low protocol any drop-profile d1;  
    drop-profile-map loss-priority medium-high protocol any drop-profile  
      $junos-cos-scheduler-dropfile-medium-high;  
    drop-profile-map loss-priority high protocol any drop-profile d3;  
    drop-profile-map loss-priority any protocol any drop-profile  
      $junos-cos-scheduler-dropfile-any;  }  
}
```

```
}
```

## Example: Configuring Aggregate Scheduling of Queues for Residential Subscribers on Static IP Demux Interfaces

In this example, scheduling is configured for a residential subscriber. Each forwarding class represents a multiplay service (voice, video, and data), and is equivalent to a queue.

An interface set of IP demux interfaces represents a DSLAM, and provides shaping of subscribers services to a DSLAM aggregate rate.

```
[edit]
interfaces {
  interface-set demux-set {
    interface demux0 {

## Example: Configuring Hierarchical Scheduling and Queuing for a Static PPPoE Subscriber Interface

In this example, the network administrator defines hierarchical queuing and scheduler parameters by configuring traffic control profile and binding it directly to a PPPoE subscriber interface.

This configuration is supported on the IQ2E PIC.

To use this configuration in a broadband access network, each forwarding class can represent one type of services provided to a household customer and is mapped to a queue. Each PPPoE interface represents a household and provides shaping of all household traffic to an aggregate rate. All of the PPPoE interfaces on the physical interfaces are shaped to the underlying physical interface rate.

[Table 90 on page 991](#) lists the scheduler and queue mapping for this configuration.

**Table 90: Scheduler Per Logical Interface Mapping**

Level	Type	Mapping
4	Queue	PPPoE interface
3	Scheduler	PPPoE interface
2	Scheduler	—
1	Scheduler	Underlying physical interface

```

interfaces {
  ge-3/0/3 {
    hierarchical-scheduler;

## Example: Configuring a Dynamic Interface Set of VLAN Subscribers

---

- [Requirements on page 998](#)
- [Overview on page 998](#)
- [Configuring the Dynamic VLANs on page 998](#)
- [Configuring Dynamic Traffic Scheduling and Shaping on page 1000](#)
- [Configuring the Interface Set in the Dynamic Profile on page 1003](#)
- [Configuring DHCP Access on page 1004](#)
- [Configuring RADIUS Authentication on page 1006](#)
- [Verification on page 1010](#)

### Requirements

This example uses the following software and hardware components:

- Junos OS Release 10.4
- MX Series Router with MPCs

### Overview

In this example, the network administrator groups dynamic VLAN interfaces in an interface set. The interface set is configured in a dynamic profile, and enables hierarchical scheduling for the VLAN interfaces for a multiplay service.

DHCP is used as the access method, and RADIUS is used as the authentication method for the interfaces associated with the interface set.

### Configuring the Dynamic VLANs

- CLI Quick Configuration** To quickly configure the dynamic VLANs, copy the following commands and paste them into the router terminal window:

```
[edit]
edit dynamic-profiles vlan-prof
edit interfaces $junos-interface-ifd-name unit $junos-interface-unit
set vlan-id $junos-vlan-id
set demux-source inet
set family inet unnumbered-address lo0.0 preferred-source-address 100.20.32.2
top
edit interfaces ge-1/0/0
set hierarchical-scheduler
set vlan-tagging
edit auto-configure vlan-ranges dynamic-profile vlan-prof
set ranges any
set accept inet
```

```
top
set interfaces lo0 unit 0 family inet address 100.20.32.2/32
```

### Configuring the Dynamic Profile for the Autoconfigured VLANs

**Step-by-Step Procedure** In this section, you create a dynamic profile for the VLAN IDs to be automatically assigned when subscribers log in.

To configure the dynamic profile for the VLANs:

1. Configure the dynamic profile.  

```
[edit]
user@host#edit dynamic-profile vlan-prof
```
2. Configure the interfaces.  

```
[edit dynamic-profiles vlan-prof]
user@host#edit interfaces $junos-interface-ifd-name unit $junos-interface-unit
```
3. Add the VLAN ID variable.  

```
[edit dynamic-profiles vlan-prof interfaces $junos-interface-ifd-name unit
$junos-interface-unit]
user@host#set vlan-id $junos-vlan-id
```
4. Configure the demux source as IPv4.  

```
[edit dynamic-profiles vlan-prof interfaces $junos-interface-ifd-name unit
$junos-interface-unit]
user@host#set demux-source inet
```
5. Configure the family.  

```
[edit dynamic-profiles vlan-prof interfaces $junos-interface-ifd-name unit
$junos-interface-unit]
user@host#set family inet unnumbered-address lo0.0 preferred-source-address
100.20.32.2
```

### Configuring the VLAN Interfaces

**Step-by-Step Procedure** To configure the VLAN interfaces:

1. Create the VLAN interface.  

```
[edit]
user@host# edit interfaces ge-1/0/0
```
2. Enable hierarchical scheduling.  

```
[edit interfaces ge-1/0/0]
user@host# set hierarchical-scheduler
```
3. Configure VLAN tagging.  

```
[edit interfaces ge-1/0/0]
user@host# set vlan-tagging
```
4. Configure auto-configuration for the dynamic profile.  

```
[edit interfaces ge-1/0/0]
```

```
user@host# edit auto-configure vlan-ranges dynamic-profile vlan-prof
```

5. Configure any VLAN ID range.

```
[edit interfaces ge-1/0/0 auto-configure vlan-ranges dynamic-profile vlan-prof]  
user@host# set ranges any
```

6. Specify IPv4 traffic for the VLAN.

```
[edit interfaces ge-1/0/0 auto-configure vlan-ranges dynamic-profile vlan-prof]  
user@host# set accept inet
```

---

### Configuring the Loopback Interface

#### Step-by-Step Procedure

To configure the loopback interface:

1. Create the loopback interface.

```
[edit]  
user@host# edit interfaces lo0
```

2. Configure the unit and the family.

```
[edit interfaces lo0]  
user@host# set unit 0 family inet address 100.20.32.2/32
```

### Configuring Dynamic Traffic Scheduling and Shaping

#### CLI Quick Configuration

To quickly configure the traffic scheduling and shaping parameters, copy the following commands and paste them into the router terminal window:

```
[edit]  
edit dynamic-profiles multiplay class-of-service schedulers be_sch  
set transmit-rate percent 12  
set buffer-size percent 12  
set priority low  
up  
edit ef_sch  
set transmit-rate percent 12  
set buffer-size percent 12  
set priority low  
up  
edit af_sch  
set transmit-rate percent 12  
set buffer-size percent 12  
set priority low  
up  
edit nc_sch  
set transmit-rate percent 12  
set buffer-size percent 12  
set priority low  
up  
edit voice_sch  
set transmit-rate percent 12  
set buffer-size percent 12  
set priority low  
up
```

```

edit video_sch
set transmit-rate percent 12
set buffer-size percent 12
set priority low
up
edit game_sch
set transmit-rate percent 12
set buffer-size percent 12
set priority low
up
edit data_sch
set transmit-rate percent 12
set buffer-size percent 12
set priority low
up 2
edit scheduler-maps all_smap
set forwarding-class be scheduler be_sch
set forwarding-class ef scheduler ef_sch
set forwarding-class af scheduler af_sch
set forwarding-class nc scheduler nc_sch
set forwarding-class voice scheduler voice_sch
set forwarding-class video scheduler video_sch
set forwarding-class game scheduler game_sch
set forwarding-class data scheduler data_sch
up 2
edit traffic-control-profiles multiplay
set scheduler-map all_smap
set shaping-rate 100m
set guaranteed-rate 20m

```

### Configuring the Schedulers in the Dynamic Profile

#### Step-by-Step Procedure

In this section, you create a dynamic profile for the multiplay service and configure scheduling and shaping.

To configure the schedulers:

1. Create the **multiplay** dynamic profile.  

```

[edit]
user@host# edit dynamic-profiles multiplay class-of-service schedulers

```
2. Configure the best effort scheduler.  

```

[edit dynamic-profiles multiplay class-of-service schedulers]
user@host# edit be_sch
user@host# set transmit-rate percent 12
user@host# set buffer-size percent 12
user@host# set priority low

```
3. Configure the expedited forwarding scheduler.  

```

[edit dynamic-profiles multiplay class-of-service schedulers]
user@host# edit ef_sch
user@host# set transmit-rate percent 12
user@host# set buffer-size percent 12
user@host# set priority low

```

4. Configure the assured forwarding scheduler.  

```
[edit dynamic-profiles multiplay class-of-service schedulers]
user@host# edit af_sch
user@host# set transmit-rate percent 12
user@host# set buffer-size percent 12
user@host# set priority low
```
5. Configure the network control scheduler.  

```
[edit dynamic-profiles multiplay class-of-service schedulers]
user@host# edit nc_sch
user@host# set transmit-rate percent 12
user@host# set buffer-size percent 12
user@host# set priority low
```
6. Configure the voice scheduler.  

```
[edit dynamic-profiles multiplay class-of-service schedulers]
user@host# edit voice_sch
user@host# set transmit-rate percent 12
user@host# set buffer-size percent 12
user@host# set priority low
```
7. Configure the video scheduler.  

```
[edit dynamic-profiles multiplay class-of-service schedulers]
user@host# edit video_sch
user@host# set transmit-rate percent 12
user@host# set buffer-size percent 12
user@host# set priority low
```
8. Configure the gaming scheduler.  

```
[edit dynamic-profiles multiplay class-of-service schedulers]
user@host# edit game_sch
user@host# set transmit-rate percent 12
user@host# set buffer-size percent 12
user@host# set priority low
```
9. Configure the data scheduler.  

```
[edit dynamic-profiles multiplay class-of-service schedulers]
user@host# edit data_sch
user@host# set transmit-rate percent 12
user@host# set buffer-size percent 12
user@host# set priority low
```

---

### Configuring the Scheduler Map in the Dynamic Profile

#### Step-by-Step Procedure

To configure the scheduler map:

1. Configure the scheduler map for all of the services.  

```
[edit dynamic-profiles multiplay class-of-service]
user@host# edit scheduler-maps all_smap
```
2. Configure the forwarding classes for each service in the scheduler map.  

```
[edit dynamic-profiles multiplay class-of-service scheduler-maps all_smap]
```

```

user@host# set forwarding-class be scheduler be_sch
user@host# set forwarding-class ef scheduler ef_sch
user@host# set forwarding-class af scheduler af_sch
user@host# set forwarding-class nc scheduler nc_sch
user@host# set forwarding-class voice scheduler voice_sch
user@host# set forwarding-class video scheduler video_sch
user@host# set forwarding-class game scheduler game_sch
user@host# set forwarding-class data scheduler data_sch

```

### Configuring the Traffic-Control Profile in the Dynamic Profile

#### Step-by-Step Procedure

To configure the traffic-control profile the interface set:

1. Configure the traffic-control profile.  

```

[edit dynamic-profiles multiplay class-of-service]
user@host# edit traffic control-profiles multiplay

```
2. Configure the scheduler map.  

```

[edit dynamic-profiles multiplay class-of-service traffic control-profiles multiplay]
user@host# set scheduler-map all_smap

```
3. Configure the shaping rate.  

```

[edit dynamic-profiles multiplay class-of-service traffic control-profiles multiplay]
user@host# set shaping-rate 100m

```
4. Configure the guaranteed rate.  

```

[edit dynamic-profiles multiplay class-of-service traffic control-profiles multiplay]
user@host# set guaranteed-rate 20m

```

### Configuring the Interface Set in the Dynamic Profile

#### CLI Quick Configuration

To quickly configure the interface set, copy the following commands and paste them into the router terminal window:

```

[edit]
edit dynamic-profiles multiplay
edit interfaces interface-set $junos-interface-set-name
set interface $junos-interface-ifd-name unit $junos-underlying-interface-unit
top
edit class-of-service interfaces interface-set
set output-traffic-control-profile multiplay

```

### Configuring the Interfaces for the Interface Set

#### Step-by-Step Procedure

To configure the interface variable for the interface set:

1. Configure the dynamic profile for the interface set.  

```

[edit]
user@host#edit dynamic-profiles multiplay

```
2. Configure the interface using the Junos OS predefined variable.  

```

[edit dynamic-profiles multiplay]

```

```
user@host#edit interfaces $junos-interface-ifd-name unit
$junos-underlying-interface-unit
```

3. Configure the family.

```
[edit dynamic-profiles multiplay interfaces $junos-interface-set-name unit
$junos-underlying-interface-unit]
user@host#set family inet unnumbered-address lo0.0 preferred-source-address
100.20.32.2
```

---

### Configuring the Interface Set

#### Step-by-Step Procedure

To configure the interface set:

1. Configure the interface set using the Junos OS predefined variable.

```
[edit dynamic-profiles multiplay]
user@host#edit interfaces interface-set $junos-interface-set-name
```

2. Add the dynamic VLAN interfaces to the interface set.

```
[edit dynamic-profiles multiplay interfaces $junos-interface-set-name]
user@host#set interface $junos-interface-ifd-name unit
$junos-underlying-interface-unit
```

---

### Applying the Traffic Control Profile to the Interface Set

#### Step-by-Step Procedure

You apply the traffic control profile outside of the dynamic profile in the **[edit class-of-service]** hierarchy.

To apply the traffic-control profile:

1. Specify the interface set to which you want to apply the traffic control profile.

```
[edit class-of-service]
user@host#edit interfaces interface-set dynamic-set
```

2. Attach the output-traffic control profile defined in the dynamic profile to the interface set.

```
[edit class-of-service interfaces]
user@host#set output-traffic-control-profile multiplay
```

## Configuring DHCP Access

#### CLI Quick Configuration

To quickly configure DHCP access, copy the following commands and paste them into the router terminal window:

```
[edit]
edit system services dhcp-local-server authentication
set password multiplay
set username-include user-prefix multiplay
up 1
set dynamic-profile dhcp-vlan-prof aggregate-clients replace
set group vlans interface ge-1/0/0
top
edit access address-assignment pool v4 family inet
```

```

set network 100.20.0.0/16
set range limited low 100.20.0.10
set range limited high 100.20.128.250
set dhcp-attributes maximum-lease-time 84600

```

### Configuring the DHCP Local Server

---

#### Step-by-Step Procedure

To configure DHCP access:

1. Configure the DHCP local server.  

```

[edit system]
user@host# edit services dhcp-local-server authentication

```
2. Set the password.  

```

[edit system services dhcp-local-server authentication]
user@host# set password multiplay

```
3. Specify that you want to include optional information in the username.  

```

[edit system services dhcp-local-server authentication]
user@host# set username-include user-prefix multiplay

```
4. Attach the dynamic profile with the interface set.  

```

[edit system services dhcp-local-server]
user@host# set dynamic-profile dhcp-vlan-prof aggregate-clients replace

```
5. Configure a group for the VLAN interface.  

```

[edit system services dhcp-local-server]
user@host# set group vlans interface ge-1/0/0

```

### Configuring Address Assignment Pools

---

#### Step-by-Step Procedure

To configure address assignment pools:

1. Configure the pool of IPv4 addresses.  

```

[edit access]
user@host#edit address-assignment pool v4 family inet

```
2. Configure the family of interfaces in the pool.  

```

[edit access address-assignment pool v4]
user@host#set network 100.20.0.0/16

```
3. Configure the upper and lower bounds of the address range.  

```

[edit access address-assignment pool v4]
user@host#set range limited low 100.20.0.10
user@host#set range limited high 100.20.128.250

```
4. Configure the maximum length of time in seconds for which a subscriber can request and hold a lease.  

```

[edit access address-assignment pool v4]
user@host#set dhcp-attributes maximum-lease-time 84600

```

## Configuring RADIUS Authentication

**CLI Quick Configuration** To quickly configure RADIUS authentication, copy the following commands and paste them into the router terminal window:

```
[edit]
edit access radius-server 172.28.30.108
set secret $9$1u5ErvW87bwgSr4Zji5T
set timeout 5
set retry 5
up 2
edit profile acc-prof
set authentication-order radius
set radius authentication-server 172.28.30.108
```

---

## Configuring RADIUS Access

**Step-by-Step Procedure** To configure RADIUS access:

1. Configure the RADIUS server.  

```
[edit access]
user@host#edit radius-server 172.28.30.108
```
2. Configure the required secret (password) that the local router or switch passes to the RADIUS client.  

```
[edit access radius-server 172.28.30.108]
user@host# set secret $9$1u5ErvW87bwgSr4Zji5T
```
3. Configure the length of time that the local router or switch waits to receive a response from a RADIUS server.  

```
[edit access radius-server 172.28.30.108]
user@host# set timeout 5
```
4. Configure the number of times that the router or switch attempts to contact a RADIUS accounting server.  

```
[edit access radius-server 172.28.30.108]
user@host# set retry 5
```
5. Configure the access profile.  

```
[edit access]
user@host#edit profile acc-prof
```
6. Configure the authentication order.  

```
[edit access profile acc-prof ]
user@host# set authentication-order radius
```
7. Configure the authentication server.  

```
[edit access profile acc-prof]
user@host#set radius authentication-server 172.28.30.108
```

## Results

```

dynamic-profiles {
  vlan-prof {
    interfaces {
      "$junos-interface-ifd-name" {
        unit "$junos-interface-unit" {

## Verification

To confirm that the configuration is correct, perform these tasks:

- [Verifying the Interfaces that are Included in the Interface Set on page 1010](#)
- [Verifying the Traffic Scheduling and Shaping Parameters for the Interface Set on page 1010](#)

### Verifying the Interfaces that are Included in the Interface Set

**Purpose** Verify the interfaces included in the interface set.

**Action** user@host> show interfaces interface-set dynamic-set terse

### Verifying the Traffic Scheduling and Shaping Parameters for the Interface Set

**Purpose** Verify that the traffic scheduling and shaping parameters are applied properly to an interface included in the interface set.

**Action** user@host> show class-of-service interface

**Related Documentation**

- [Configuring an Interface Set of Subscribers in a Dynamic Profile on page 974](#)

## Example: Configuring a Dynamic Service VLAN Interface Set of Subscribers in a Dynamic Profile

---

Interface sets enable you to provide hierarchical scheduling to a group of subscriber interfaces. In this example, by using the `$junos-svlan-interface-set-name` internal dynamic variable when specifying the interface set name, you can locally generate an interface

set name for use by SVLAN interfaces based on the outer tag of the dual-tagged VLAN. The format of the generated variable is *physical\_interface\_name - outer\_VLAN\_tag*.

- [Requirements on page 1011](#)
- [Overview on page 1011](#)
- [Configuration on page 1011](#)
- [Verification on page 1014](#)

## Requirements

Dynamic SVLAN traffic shaping is supported only on Juniper Networks MX Series 3D Universal Edge Routers running Junos OS Release 11.4R2 or later.

Before you begin, configure the subscriber interfaces that you intend to include in the interface set. You can find general configuration instructions for the supported dynamic interface configuration in the Junos OS Subscriber Management, Release 12.3 as follows:

- For dynamic VLAN interfaces, see [“Configuring a Static or Dynamic VLAN Subscriber Interface over Aggregated Ethernet” on page 782](#).
- For dynamic IP demux interfaces, see [“Configuring Dynamic Subscriber Interfaces Using IP Demux Interfaces in Dynamic Profiles” on page 729](#) and [“Configuring a Static or Dynamic IP Demux Subscriber Interface over Aggregated Ethernet” on page 783](#).
- For dynamic VLAN demux interfaces, see [“Configuring Dynamic Subscriber Interfaces Using VLAN Demux Interfaces in Dynamic Profiles” on page 730](#).

## Overview

Interface sets enable you to provide hierarchical scheduling to a group of subscriber interfaces. By using the `$junos-svlan-interface-set-name` internal dynamic variable when specifying the interface set name, you can locally generate an interface set name for use by SVLAN interfaces based on the outer tag of the dual-tagged VLAN. The format of the generated variable is *physical\_interface\_name - outer\_VLAN\_tag*.

This example includes the following statements:

- **interface-set**—Configures the name of the scheduler for dynamic CoS. In this example, you use the `$junos-svlan-interface-set-name` variable to obtain the locally generated interface set name for use by SVLAN interfaces based on the outer tag of the dual-tagged VLAN.
- **output-traffic-control-profile**—Applies an output traffic scheduling and shaping profile to the interface set.
- **output-traffic-control-profile-remaining**—Applies an output traffic scheduling and shaping profile for remaining traffic to the interface set.

## Configuration

<b>CLI Quick Configuration</b>	To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network
--------------------------------	---

configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
[edit]
set dynamic-profiles profile-dhcp-ipdemux interfaces interface-set
  $junos-svlan-interface-set-name interface $junos-interface-ifd-name unit
  $junos-underlying-interface-unit
set dynamic-profiles profile-dhcp-ipdemux interfaces $junos-interface-ifd-name unit
  $junos-underlying-interface-unit
set class-of-service traffic-control-profiles tcp1 scheduler-map schedMap
set class-of-service traffic-control-profiles tcp1 shaping-rate 50m
set class-of-service traffic-control-profiles tcp1 guaranteed-rate 200k
set class-of-service traffic-control-profiles tcp3 scheduler-map ss1q0q1
set class-of-service traffic-control-profiles tcp3 shaping-rate 20m
set class-of-service traffic-control-profiles tcp3 guaranteed-rate 5m
set class-of-service interfaces interface-set ae0-111 output-traffic-control-profile tcp1
set class-of-service interfaces interface-set ae0-111
  output-traffic-control-profile-remaining tcp3
```

#### Step-by-Step Procedure

To configure an SVLAN interface set of subscriber interfaces:

1. Access the dynamic profile you want to modify for interface sets.

```
[edit]
user@host# edit dynamic-profiles profile-dhcp-ipdemux
```

2. Access the dynamic profile interface configuration.

```
[edit dynamic-profiles profile-dhcp-ipdemux]
user@host# edit interfaces
```

3. Configure the SVLAN interface set in the dynamic profile.

The interface set is created dynamically when the subscriber logs in.

```
[edit dynamic-profiles profile-dhcp-ipdemux interfaces]
user@host# edit interface-set $junos-svlan-interface-set-name
```

4. Include dynamic IP demux interface creation within the dynamic interface set.

```
[edit dynamic-profiles profile-dhcp-ipdemux interfaces interface-set
  $junos-svlan-interface-set-name]
user@host# set interface $junos-interface-ifd-name unit
  $junos-underlying-interface-unit
```

5. Access the SVLAN interface set name that you expect **\$junos-svlan-interface-set-name** to generate. For example, to specify the expected interface set name for aggregated Ethernet interface ae0 and outer VLAN tag 111, include **ae0-111** for the **interface-set-name** variable.

```
[edit class-of-service interfaces]
user@host# edit interface-set ae0-111
```

6. Apply traffic shaping and queuing parameters to the SVLAN interface set.

**TIP:** You must configure the interface set in the static **[edit class-of-service]** hierarchy, not in the **[edit dynamic-profiles]** hierarchy.

```
[edit class-of-service interfaces interface-set ae0-111]
user@host# set output-traffic-control-profile tcp1
```

7. Apply traffic shaping and queuing parameters to any remaining traffic on the SVLAN interface set.

```
[edit class-of-service interfaces interface-set ae0-111]
user@host# set output-traffic-control-profile-remaining tcp3
```

## Results

From configuration mode, confirm your configuration by entering the **show dynamic-profiles** command and the **show class-of-service** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show dynamic-profiles
dynamic-profiles {
  profile-dhcp-ipdemux {
    interfaces {
      interface-set "$junos-svlan-interface-set-name" {
        interface "$junos-interface-ifd-name" {
          unit "$junos-underlying-interface-unit";
        }
      }
      "$junos-interface-ifd-name" {
        unit "$junos-underlying-interface-unit";
      }
    }
  }
}
```

```
user@host# show class-of-service
class-of-service {
  traffic-control-profiles {
    tcp1 {
      scheduler-map schedMap;
      shaping-rate 50m;
      guaranteed-rate 200k;
    }
    tcp3 {
      inactive: scheduler-map ss1q0q1;
      shaping-rate 20m;
      guaranteed-rate 5m;
    }
  }
  interfaces {
    interface-set ae0-111 {
      output-traffic-control-profile tcp1;
      output-traffic-control-profile-remaining tcp3;
    }
  }
}
```

## Verification

To confirm that the configuration is correct, perform these tasks:

### Verifying the Interfaces that are Included in the Interface Set

**Purpose** Verify the interfaces that are included in the interface set.

**Action** user@host> show class-of-service interface-set

### Displaying Information for Active Subscribers

**Purpose** Display information for active subscribers.

**Action** user@host> show subscribers detail

## Excess Bandwidth Distribution on MIC and MPC Interfaces Overview

---

Service providers often used tiered services to provide bandwidth for excess traffic as traffic patterns vary. By default, excess bandwidth between a configured guaranteed rate and shaping rate is shared equally among all queues on MIC and MPC interfaces, which might not be optimal for all subscribers to a service.

You can adjust this distribution by configuring the rates and priorities for the excess bandwidth.

By default, when traffic exceeds the shaping or guaranteed rates, the system demotes traffic with guaranteed high (GH) priority and guaranteed medium (GM) priority. You can disable this priority demotion for the MIC and MPC interfaces in your router.

## Traffic Burst Management on MIC and MPC Interfaces Overview

You can manage the impact of bursts of traffic on your network by configuring a burst-size value with the shaping rate or the guaranteed rate. The value is the maximum bytes of rate credit that can accrue for an idle queue or scheduler node. When a queue or node becomes active, the accrued rate credits enable the queue or node to catch up to the configured rate.

**Figure 23: Sample Burst Shaping Rates**

In [Figure 23 on page 1016](#), the network administrator configures a large burst-size value for the shaping rate, then configures a small burst-size value. The larger burst size is subject to a maximum value. The smaller burst size is subject to a minimum value that enables the system to achieve the configured rates.

In both configurations, the scheduler node can burst beyond its shaping rate for a brief interval. The burst of traffic beyond the shaping rate is more noticeable with the larger burst size than the smaller burst size.

- [Guidelines for Configuring the Burst Size on page 1016](#)
- [How the System Calculates the Burst Size on page 1017](#)

### Guidelines for Configuring the Burst Size

Typically, the default burst-size (100 ms) for both scheduler nodes and queues on MIC and MPC interfaces is adequate for most networks. However, if you have intermediate equipment in your network that has very limited buffering and is intolerant of bursts of traffic, you might want to configure a lower value for the burst size.

Use caution when selecting a different burst size for your network. A burst size that is too high can overwhelm downstream networking equipment, causing dropped packets and inefficient network operation. Similarly, a burst size that is too low can prevent the network from achieving your configured rate.

When configuring a burst size, keep the following considerations in mind:

- The system uses an algorithm to determine the actual burst size that is implemented for a node or queue. For example, to reach a shaping rate of 8 Mbps, you must allocate 1Mb of rate credits every second. A shaping rate of 8 Mbps with a burst size of 500,000 bytes of rate-credit per seconds enables the system to transmit at most 500,000 bytes, or 4 Mbps. The system cannot implement a burst size that prevents the rate from being achieved.

For more information, see [“How the System Calculates the Burst Size” on page 1017](#).

- There are minimum and maximum burst sizes for each platform, and different nodes and queue types have different scaling factors. For example, the system ensures the burst cannot be set lower than 1 Mbps for a shaping rate of 8 Mbps. To smoothly shape traffic, rate credits are sent much faster than once per second. The interval at which rate credits are sent varies depending on the platform, the type of rate, and the scheduler level.
- When you have configured adjustments for the shaping rate (either by percentage or through an application such as ANCP or Multicast OIF), the system bases the default and minimum burst-size calculations on the adjusted shaping rate.
- When you have configured cell shaping mode to account for ATM cell tax, the system bases the default and minimum burst-size calculations on the post-tax shaping rate.
- The guaranteed rate and shaping rate share the value specified for the burst size. If the guaranteed rate has a burst size specified, that burst size is used for the shaping rate; if the shaping rate has a burst size specified, that burst size is used for the guaranteed rate. If you have specified a burst size for both rates, the system uses the lesser of the two values.
- The burst size configured for the guaranteed rate cannot exceed the burst-size configured for the shaping rate. The system generates a commit error.
- If you have not configured a guaranteed rate, logical interfaces and interface sets receive a default guaranteed rate from the port speed. Queues receive a default guaranteed rate from the parent logical interface or interface set.

## How the System Calculates the Burst Size

When calculating the burst size, the system uses an exponent of a power of two. For example:

$$\text{Shaping-rate in bps} * 100 \text{ ms} / (8 \text{ bits/byte} * 1000 \text{ ms/s}) = 1,875,000 \text{ bytes}$$

The system then rounds this value up. For example, the system uses the following calculation to determine the burst size for a scheduler node with a shaping rate of 150 Mbps:

$$\text{Max (Shaping rate, Guaranteed rate) bps} * 100 \text{ ms} / (8 \text{ bits/byte} * 1000 \text{ ms/s}) = 1,875,000 \text{ bytes}$$

$$\text{Rounded up to the next higher power of two} = 2,097,150 \text{ (which is } 2^{21}, \text{ or } 0x2000000)$$

The system assigns a single burst size to each of the following rate pairs:

- Shaping rate and guaranteed rate
- Guaranteed high (GH) and guaranteed medium (GM)
- Excess high (EH) and excess low (EL)
- Guaranteed low (GL)

To calculate the burst size for each pair, the system:

- Uses the configured burst-size if only one of the pair is configured.
- Uses the lesser of the two burst sizes if both values are configured.
- Uses the next lower power of two.
- To calculate the minimum burst size, the system uses the greater of the two rates.

## Bandwidth Management for Downstream Traffic in Edge Networks Overview

In a subscriber access network, traffic with different encapsulations can be passed downstream to other customer premise equipment (CPE) through the MX Series router. Managing the bandwidth of downstream ATM traffic to Ethernet interfaces can be especially difficult because of the different Layer 2 encapsulations.

The *overhead accounting* feature enables you to shape traffic based on either frames or cells and assign a byte adjustment value to account for different encapsulations.

This feature is available on MIC and MPC interfaces.

### Guidelines for Configuring the Shaping Mode

*Frame shaping mode* is useful for adjusting downstream traffic with different encapsulations. In frame shaping mode, shaping is based on the number of bytes in the frame, without regard to cell encapsulation or padding overhead. Frame is the default shaping mode on the router.

*Cell shaping mode* is useful for adjusting downstream cell-based traffic. In cell shaping mode, shaping is based on the number of bytes in cells, and accounts for the cell encapsulation and padding overhead.

When you specify cell mode, the resulting traffic stream conforms to the policing rates configured in downstream ATM switches, reducing the number of packet drops in the Ethernet network.

To account for ATM segmentation, the MX Series router adjusts all of the rates by 48/53 to account for ATM AAL5 encapsulation. In addition, the router accounts for cell padding, and internally adjusts each frame by 8 bytes to account for the ATM trailer.

## Guidelines for Configuring Byte Adjustments

When the downstream traffic has different byte sizes per encapsulation, it is useful to configure a *byte adjustment* value to adjust the frame sizes. For example, you can configure the frame shaping mode and a byte adjustment value to account for differences in Layer 2 protocols for downstream Ethernet traffic.

We recommend that you specify a byte adjustment value that represents the difference between the CPE protocol overhead and B-RAS protocol overhead.

The system rounds up the byte adjustment value to the nearest multiple of 4. For example, a value of 6 is rounded to 8, and a value of -10 is rounded to -8.

You do not need to configure a byte adjustment value to account for the downstream ATM network. However, you can specify the byte value to account for additional encapsulations or decapsulations in the downstream network.

## Relationship with Other CoS Features

Enabling the overhead accounting feature affects the resulting shaping rates, guaranteed rate, and excess rate parameters, if they are configured.

The overhead accounting feature also affects the egress shaping overhead feature that you can configure at the chassis level. We recommend that you use the egress shaping-overhead feature to account for the Layer 2 overhead of the outgoing interface, and use the overhead-accounting feature to account for downstream traffic with different encapsulations and cell-based networks.

When both features are configured together, the total byte adjustment value is equal to the adjusted value of the overhead-accounting feature plus the value of the egress-shaping-overhead feature. For example, if the configured byte adjustment value is 40, and the router internally adjusts the size of each frame by 8, the adjusted overhead accounting value is 48. That value is added to the egress shaping overhead of 24 for a total byte adjustment value of 72.

## Setting the Shaping-Rate and Overhead-Accounting Class-of-Service Attributes Based on Access Line Information

You can also use access line parameters in PPPoE discovery packets to set the shaping-rate and overhead-accounting class-of-service attributes on dynamic subscriber interfaces in a broadband access network. This feature is supported on MIC and MPC interfaces on MX Series routers.

The shaping rate is based on the *actual-data-rate-downstream* attribute.

The overhead accounting value is based on the *access-loop-encapsulation* attribute and specifies whether the access loop uses Ethernet (frame mode) or ATM (cell mode).

You can mix ANCP and PPPoE vendor-specific tags for dynamically instantiated static and interface sets so that the shaping rate is first set using PPPoE vendor-specific tags and is later adjusted by ANCP. In this case, the shaping rate value overrides the PPPoE value.

The Access Node or DSLAM may forward access line information using several methods. This feature only uses access line information received in Vendor-Specific Point-to-Point Protocol over Ethernet (PPPoE) Tags [TR-101].

When you enable this feature, the values supplied by the PPPoE vendor-specific tags override the parameters that you have configured in the CLI for shaping-rate and overhead-accounting statements at the **[edit dynamic-profiles profile-name class-of-service traffic-control-profile]** hierarchy level. The shaping rate is based on the actual-data-rate-downstream attribute, and is only overridden if the vs-tag value is less than the configured value.

---

## Setting Class-of-Service Parameters Using PPPoE Vendor-Specific Tags

You can use access line parameters in PPPoE discovery packets to set the shaping-rate and overhead-accounting class-of-service attributes on dynamic subscriber interfaces in a broadband access network. This feature is supported on MPC/MIC interfaces on MX Series routers.

The shaping rate is based on the actual-data-rate-downstream attribute.

The overhead accounting value is based on the access-loop-encapsulation attribute and specifies whether the access loop uses Ethernet (frame mode) or ATM (cell mode).

You can configure class-of-service attributes, for example the shaping-rate, using the CLI, RADIUS vendor-specific attributes, ANCP, multicast, or in this case, PPPoE vendor-specific tags.

### CLI Interaction with PPPoE Vendor-Specific Tags

When you enable this feature, the values supplied by the PPPoE vendor-specific tags override the parameters that you have configured in the CLI for the **shaping-rate** and **overhead-accounting** statements at the **[edit dynamic-profiles profile-name class-of-service traffic-control-profiles]** hierarchy level. The shaping rate is based on the actual-data-rate-downstream attribute, and is only overridden if the vs-tag value is less than the configured value.

To enable this feature, include the **actual-data-rate-downstream** or **access-loop-encapsulation** option with the **vendor-specific-tags** statement at the **[edit dynamic-profiles profile-name class-of-service dynamic-class-of-service-options]** hierarchy level.

## RADIUS Interaction with PPPoE Vendor-Specific Tags

When you enable this feature, the PPPoE vendor-specific tags override the dynamic configuration of the shaping-rate and overhead-accounting values in RADIUS vendor-specific attributes. The shaping-rate value is only overridden if the vs-tag value is less than the RADIUS value.

RADIUS COA can overwrite the existing values. Upon receipt of a RADIUS COA, the RADIUS value overrides the value set from the PPPoE vendor-specific tags.

PPPoE vendor-specific tags can override the RADIUS values, but a later RADIUS COA request can then override that value.

## ANCP Interaction with PPPoE Vendor-Specific Tags

You can mix ANCP and PPPoE vendor-specific tags on dynamic PPPoE interfaces, dynamically instantiated PPPoE interfaces, and ACI-sets. ANCP values override the PPPoE values. In this case, the ANCP shaping rate value overrides the PPPoE value.

## Multicast QoS Adjustment Interaction with PPPoE Vendor-Specific Tags

Multicast QoS adjustments are not affected by this feature. The multicast adjustments adjust the shaping-rate set by PPPoE vendor-specific tags.

## Shaping Rate Restrictions

Shaping rate has the following restrictions regarding the downstream-rate:

- If the downstream-rate is less than the configured shaping-rate (as set in the CLI or using RADIUS attributes) then it is applied, subject to other restrictions. If the downstream-rate is greater than or equal to the configured shaping-rate, no changes are performed.
- The downstream-rate cannot be less than a configured guaranteed-rate. If it is, the downstream-rate is set to the guaranteed-rate.
- The downstream-rate cannot be less than a configured adjust-minimum-rate. If it is, the downstream-rate is set to the adjust-minimum-rate.
- The downstream-rate cannot be less than 1000 bps. If it is, the downstream-rate is set to 1000 bps.
- The downstream-rate cannot be less than the sum of the transmit-rates of all queues.

## Dedicated Queue Scaling for CoS Configurations on MIC and MPC Interfaces Overview

The 30-Gigabit Ethernet Queuing and 60-Gigabit Ethernet Queuing and Enhanced Queuing Ethernet Modular Port Concentrators (MPCs) provide a set of dedicated queues for subscriber interfaces configured with hierarchical scheduling or per-unit scheduling.

The dedicated queues offered on these MPCs enable service providers to reduce costs through different scaling configurations. For example, the 60-Gigabit Ethernet Enhanced Queuing MPC enables service providers to reduce the cost per subscriber by allowing many subscriber interfaces to be created with four or eight queues. Alternatively, the 30-Gigabit Ethernet and 60-Gigabit Ethernet Queuing MPCs enable service providers to reduce hardware costs, but allow fewer subscriber interfaces to be created with four or eight queues.

This topic describes the overall queue, scheduler node, and logical interface scaling for subscriber interfaces created on these MIC and MPC combinations.

### Queue Scaling for MIC and MPC Combinations

[Table 93 on page 1022](#) lists the number of dedicated queues and number of subscribers supported per MPC.

**Table 93: Dedicated Queues for MIC and MPC Interfaces**

MPC	Dedicated Egress Queues	Supported Subscriber Interfaces	Logical Interfaces with 4 Queues	Logical Interfaces with 8 Queues
30-Gigabit Ethernet Queuing MPC	64,000	16,000	16,000 (8000 per PIC)	8000 (4000 per PIC)
60-Gigabit Ethernet Queuing MPC	128,000	32,000	32,000 (8000 per PIC)	16,000 (4000 per PIC)
60-Gigabit Ethernet Enhanced Queuing MPC	512,000	64,000	64,000 (16,000 per PIC)	64,000 (16,000 per PIC)

MPCs vary in the number of Packet Forwarding Engines on board. MPC1s, such as the 30-Gigabit Ethernet MPC, have one Packet Forwarding Engine. MPC2s, such as the 60-Gigabit Ethernet MPC, have two Packet Forwarding Engines. Each Packet Forwarding Engine has two schedulers that share the management of the queues.

A scheduler maps to one-half of a MIC; in CLI configuration statements, that one-half of a MIC corresponds to PIC 0, 1, 2, or 3. MIC ports are partitioned equally across the PICs. A two-port MIC has one port per PIC. A four-port MIC has two ports per PIC.

Each interface-set uses eight queues from total available egress queues.

## Distribution of Queues on 30-Gigabit Ethernet Queuing MPCs

On 30-Gigabit Ethernet Queuing MPCs, each scheduler maps to different PICs. When only one MIC is installed, scheduler 0 maps to PIC 0 and scheduler 1 maps to PIC 1 on the MIC. When two MICs are installed, scheduler 0 can additionally distribute queues to PIC 2 on MIC 1, and scheduler 1 can additionally distribute queues to PIC 3 on MIC 1. However, the distribution of queues to the MICs is not hard-partitioned for 30-Gigabit Ethernet Queuing MPCs or other MPCs. Distribution depends instead on how you allocate the queues to the PICs.

Figure 24 on page 1023 shows the queue distribution on a 30-Gigabit Ethernet Queuing MPC with only one MIC installed. All 64,000 egress queues on the MPC are available to the single Packet Forwarding Engine. On the Packet Forwarding Engine, half of these queues (32,000) are managed by each scheduler. Scheduler 0 contributes all of its 32,000 queues to PIC 0. Scheduler 1 contributes all of its 32,000 queues to PIC 1.

**Figure 24: Distribution of Queues on the 30-Gigabit Ethernet Queuing MPC with One MIC**

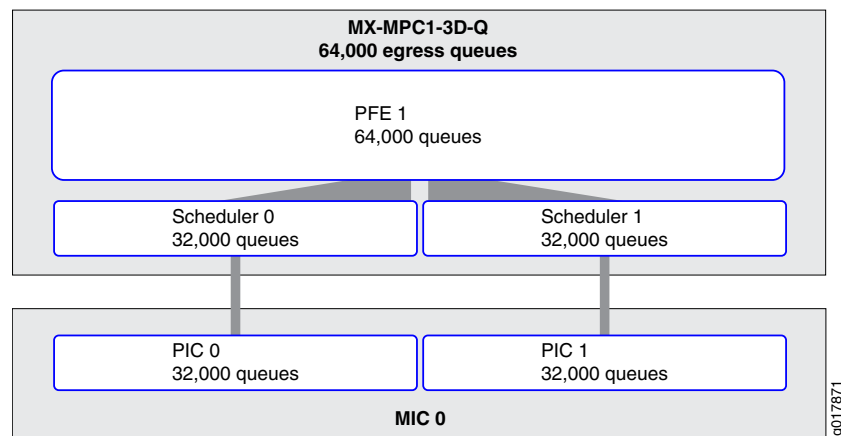

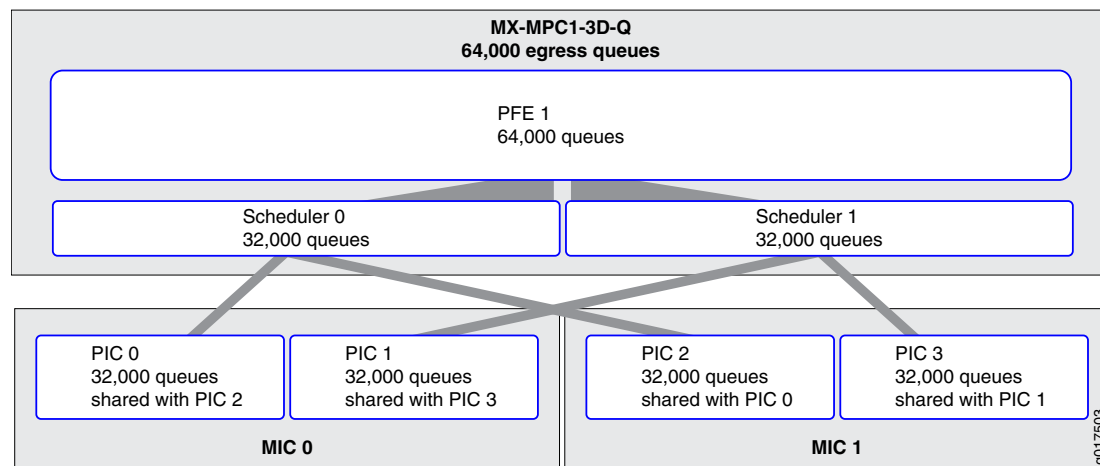

Figure 25 on page 1024 shows the queue distribution on the same MPC with two MICs installed. In this case, each scheduler can supply two PICs, one on each MIC. Because the distribution of the queues across the MICs is not hard-partitioned, you can allocate from 0 to 32,000 queues from each scheduler's pool across the scheduler's associated PICs. For example, you can allocate 32,000 queues from Scheduler 0 to PIC 0, 4000 queues from Scheduler 1 to PIC 1, and 28,000 queues from Scheduler 1 to PIC 3. Alternatively, you can allocate the queues evenly across the PICs, or allocate them in other combinations with the limitation of 32,000 queues per PIC and 32,000 queues per port.

Figure 25: Distribution of Queues on the 30-Gigabit Ethernet Queuing MPC with Two MICs

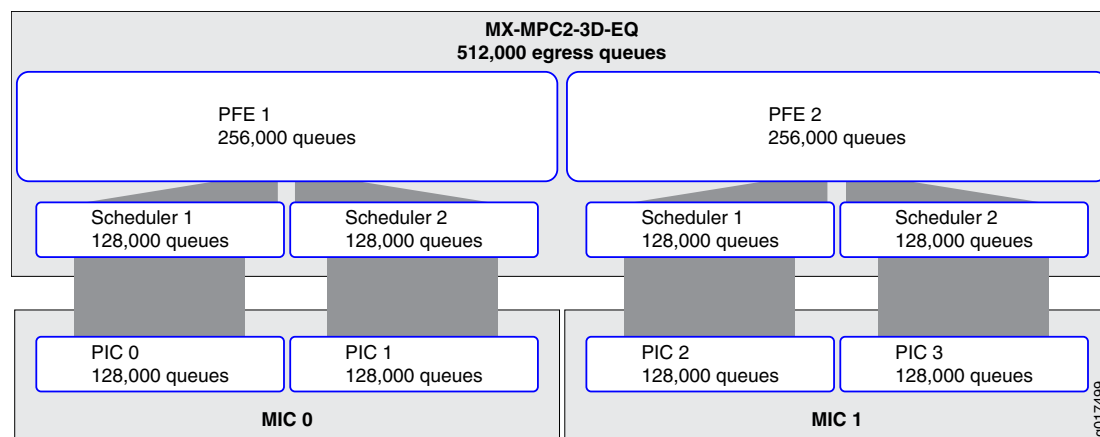

### Distribution of Queues on 60-Gigabit Ethernet MPCs

On 60-Gigabit Ethernet Queuing and Enhanced Queuing Ethernet MPCs, each scheduler maps to a single PIC: PIC 0 or PIC 1 on MIC 0 and PIC 2 or PIC 3 on MIC 1. The distribution of the queues is hard-partitioned for these MPCs and other MPC2s; the only difference in distribution is in the total number of queues available.

For example, [Figure 26 on page 1024](#) shows how queues are distributed on a 60-Gigabit Ethernet Enhanced Queuing MPC. Of the 512,000 egress queues on the MPC, half (256,000) are available to each of the two Packet Forwarding Engines. On each Packet Forwarding Engine, half of these queues (128,000) are managed by each scheduler. The complete scheduler complement (128,000) is available to only one PIC in a MIC. Thus the total number of queues available depends on the number of MICs installed. The MPC must have 2 MICs to achieve the maximum of 512,000 queues. With a single MIC, the MPC can achieve only 256,000 queues.

Figure 26: Distribution of Queues on the 60-Gigabit Ethernet Enhanced Queuing MPC

## Determining Maximum Egress Queues and Subscriber Interfaces per Port

The number of MICs installed in an MPC and the number of ports per MIC do not affect the maximum number of queues available on a given port. These factors affect only how you are able to allocate queues (and, therefore, subscribers) for your network.

For example, a 30-Gigabit Ethernet Queuing MPC supports a maximum of 16,000 subscriber interfaces and has a maximum of 32,000 queues available per PIC. On this card, you can allocate up to 32,000 queues to a single port in each PIC. If you dedicate 4 queues per subscriber interface, you can accommodate a maximum of 8000 subscriber interfaces on a single port, and therefore need at least two ports to reach the maximum 16,000 subscriber interfaces. If you dedicate 8 queues per subscriber interface, you can accommodate a maximum of 4000 subscriber interfaces on a single port, and you need 4 ports for the maximum of 16,000 subscriber interfaces.

The 60-Gigabit Ethernet Enhanced Queuing MPC supports a maximum of 64,000 subscriber interfaces and has a maximum of 128,000 queues per PIC. You can allocate up to 128,000 queues to a single port in each PIC. However, if you dedicate 4 queues per subscriber interface, you can accommodate a maximum of only 16,000 subscriber interfaces on a single MPC port—not 32,000—because the 60-Gigabit Ethernet Enhanced Queuing MPC is limited to 16,000 subscriber interfaces per PIC. If you dedicate 8 queues per subscriber interface, you can also accommodate a maximum of 16,000 subscriber interfaces on a single MPC port. In either case, you need at least 4 ports to reach the maximum of 64,000 subscriber interfaces.

## Managing Remaining Queues

When the number of available dedicated queues on the MPC drops below 10 percent, an SNMP trap is generated to notify you .

When the maximum number of dedicated queues on the MPCs is reached, a system log message, **COSD\_OUT\_OF\_DEDICATED\_QUEUES**, is generated. The system does not provide subsequent subscriber interfaces with a dedicated set of queues. For per-unit scheduling configurations, there are no configurable queues remaining on the MPC.

For hierarchical scheduling configurations, remaining queues are available when the maximum number of dedicated queues is reached on the MPC. Traffic from these logical interfaces are considered unclassified and attached to a common set of queues that are shared by all subsequent logical interfaces. These common queues are the default port queues that are created for every port. You can configure a traffic control profile and attach that to the interface to provide CoS parameters for the remaining queues.

For example, when the 30-Gigabit Ethernet Queuing MPC is configured with 32,000 subscriber interfaces with four queues per subscriber, the MPC can support 16,000 subscribers with a dedicated set of queues. You can provide CoS shaping and scheduling parameters to the remaining queues for those subscriber interfaces by attaching a special traffic-control profile to the interface.

These subscriber interfaces remain with this traffic control profile, even if dedicated queues become available.

## Hierarchical CoS Shaping-Rate Adjustments Overview

This overview describes how MX Series 3D Universal Edge Routers installed in a subscriber access network can adjust hierarchical class-of-service (CoS) parameters to prevent bandwidth contention at subscriber interfaces.

Hierarchical CoS is supported only for subscriber interfaces on EQ DPC or MPC interfaces operating in hierarchical scheduler mode.

The characteristics of voice, data, and video applications vary widely in their requirements for traffic throughput, bandwidth management, delay and jitter tolerance, and buffer depth. To prevent bandwidth contention at subscriber interfaces, you can configure applications such as ANCP and Multicast to perform real-time adjustments to the shaping rate configured for subscriber interfaces for residential gateways. Enabling shaping-rate adjustments on the router can prevent bandwidth contention at the interface from causing degradation of the subscriber's voice, data, or video services.

Depending on the application, shaping-rate adjustments are supported on Enhanced Queueing (EQ) DPCs on MX Series routers and MPC/MIC modules on MX Series routers.

### Types of Shaping-Rate Adjustments

The ANCP application supports *absolute* adjustments to a specific shaping-rate value. You can configure ANCP to communicate the subscriber local loop speed to the MX Series router, which in turn throttles traffic destined to the associated subscriber interface so that it matches the subscriber local loop speed. ANCP acquires subscriber line rate information from DSLAMs and then communicates this data transmission rate for use with CoS.

The OIF mapping and reverse OIF mapping multicast applications support *delta* adjustments that increase or decrease the current shaping rate by a certain value. The system adjusts traffic destined to the subscriber using reverse OIF mapping enabled on a specified multicast interface. Reverse OIF mapping is used to determine the subscriber VLAN interface and the multicast traffic bandwidth on the interface.

### Levels of Shaping-Rate Adjustments

Both absolute and delta adjustments are made to a subscriber's aggregate shaping rate on a level 3 scheduler node.

Adjustments that occur on the scheduler node can also impact the shaping rates for all queues. This adjustment can be undesirable for service providers who want to provide a premium level of service on specific queues.

For delta-based adjustments by multicast applications, you can control the distribution of shaping rates among queues by assigning the percentage of adjustment allowed for each queue. In addition, you can set a minimum adjusted shaping rate for each queue.

Figure 27 on page 1027 shows a sample multicast network with shaping rates adjusted at the scheduler node level. The shaping rate is reduced by 4 Mbps (from 41 Mbps to 37 Mbps) at the scheduler node for subscriber interface 1, which reduces the rates of both the best effort and video on demand (VoD) service queues.

**Figure 27: Scheduler Node and Queues with Adjusted Shaping Rates**

Figure 28 on page 1027 shows the same network with queue-based adjustments enabled for the best-effort queue on subscriber 1. The shaping rate of the best-effort queue is reduced by 4 Mbps (from 5 Mbps to 1 Mbps). The VoD service queue is not affected.

**Figure 28: Queue with Adjusted Shaping Rate**

## Shaping Rate Adjustments for Subscriber Local Loops Overview

---

This overview describes how an MX Series 3D Universal Edge Router installed as an edge router can adjust hierarchical CoS policy for subscriber interfaces for subscriber local loops. You can configure the router to throttle the traffic sent to subscriber local loops so that the traffic does not exceed the current data transmission rate of those lines. This feature ensures that changes to subscriber local loop speeds do not cause bandwidth contention at the subscriber's residential gateway.

In a typical subscriber access network, traffic destined to a subscriber is delivered from the access network, through an edge router, to a DSLAM. The DSLAM multiplexes subscriber traffic through a DSL, also known as a *local loop*, to the subscriber's residential gateway. When line noise or cross talk in a subcarrier causes the error rate on a DSL to exceed a certain threshold, the DSLAM can adapt itself by lowering the data transmission rate to that carrier device. A lower data transmission rate is less susceptible to induced errors.

You can configure an MX Series router to adjust the configured shaping rates on scheduler nodes for subscriber interfaces that represent subscriber local loops. Whenever a DSLAM resynchronizes a subscriber local loop speed, the router adjusts the configured shaping rate for that line so that the aggregate egress traffic to those subscribers is shaped to the local loop speed before the traffic reaches the DSLAM. Unless the maximum amount of bandwidth allocated to the subscriber interface on the router is throttled to the local loop speed, bandwidth contention can occur at the subscriber's residential gateway, which can cause the DSLAM to drop packets. This type of shaping-rate adjustment requires the topology discovery and traffic-monitoring features of the Access Node Control Protocol (ANCP).

You can configure ANCP to communicate the subscriber local loop speed to the MX Series router, which in turn throttles traffic destined to the associated subscriber interface so that it matches the subscriber local loop speed. ANCP acquires subscriber line rate information from DSLAMs and then communicates this data transmission rate for use with CoS.

## Guidelines for Configuring Shaping-Rate Adjustments for Subscriber Local Loops

These guidelines apply to configuring an MX Series 3D Universal Edge Router installed as an edge router to adjust the configured shaping rates on scheduler nodes for subscriber interfaces that represent subscriber local loops. This shaping-rate feature uses the topology discovery and traffic-monitoring features of ANCP.

When you enhance hierarchical CoS policy by configuring ANCP-driven shaping-rate adjustments, consider the following guidelines:

- Shaping-rate adjustments are supported on EQ DPCs and MPCs on MX Series routers.
- Shaping-rate adjustments are supported only for subscriber local loops that terminate at DSLAMs that you have configured as ANCP neighbors of the MX Series router.
- Shaping-rate adjustments are supported only for scheduler nodes for which you have configured an initial shaping rate by including the **shaping-rate** statement in a traffic-control profile applied to the scheduler node. Specify the initial shaping rate as a peak rate, in bits per second (bps), and not as a percentage. Other methods of configuring a shaping rate are not supported with this feature.
- Shaping-rate adjustments are supported only for scheduler nodes that are static logical interface sets that you have configured to operate at Level 3 of the scheduler hierarchy on the router. If an interface set is configured with a logical interface (such as unit 0) and queue, then the interface set is an internal scheduler node (as opposed to a root node or a leaf node) at Level 2 of the hierarchy. However, if there are no traffic control profiles are configured on logical interfaces in an interface set, then the interface set is an internal scheduler node at Level 3 of the hierarchy.
- Shaping-rate adjustments are supported only for subscriber interfaces over physical interfaces that you have configured to operate in hierarchical scheduler mode. Only ports on EQ DPCs in MX Series routers support hierarchical scheduler mode.
- After shaping-rate adjustments are enabled and the router has performed shaping-rate adjustments on a scheduler node, you can configure a new shaping rate by including the **shaping-rate** statement in a traffic-control profile and then applying that profile to that scheduler node. However, this new shaping-rate value does not immediately result in shaping traffic at the new rate. The scheduler node continues to be shaped at rate set by ANCP. Only when the ANCP shaping-rate adjustment feature is disabled is the scheduler node shaped at the newly configured shaping-rate.
- The Layer 2 Tunneling Protocol (L2TP) is often used to carry traffic securely between an L2TP Network Server (LNS) and an L2TP Access Concentrator (LAC). The QoS adjustment feature supports the shaping overhead options that you can use to add a specified number of bytes to the actual packet length when determining shaped session packet length. ANCP shaping-rate adjustments are not supported for ingress traffic, only for egress traffic. To configure the number of bytes to add to the packet at the egress side of the tunnel, include the **egress-shaping-overhead** and **mode** statements at the **[edit chassis fpc slot-number pic pic-number traffic-manager]** hierarchy level. Use the shaping overhead options if you need to account for encapsulation overhead.

For more information about the ANCP protocol, see the [“ANCP Topology Discovery and Traffic Reporting Overview”](#) on page 1254.

## CoS Adjustment Control Profiles Overview

CoS adjustment control profiles control which applications and algorithms can modify a subscriber’s shaping characteristics after a subscriber is instantiated. Subscriber shaping characteristics are configured using the Junos OS CLI or by RADIUS messages. Adjustment control profiles enable subscriber shaping characteristics by to be adjusted by other applications like ANCP, PPPoE tags, and RADIUS Change of Authorization (CoA) after a subscriber is instantiated. Adjustment control profiles are router-wide and apply to both static and dynamic interfaces.

[Table 94 on page 1030](#) describes the terms used to define shaping characteristics.

**Table 94: Terms and Definitions for Shaping Characteristics**

Term	Definition
Shaping-rate	The maximum rate of a scheduler node or queue. Also known as Peak Information Rate (PIR).
Overhead-accounting mode	<p>A class-of-service traffic-control profile attribute that specifies whether the downstream network is a frame-based network, like Ethernet, or a cell-based network, like ATM.</p> <p><b>NOTE:</b> The downstream network is not necessarily the directly attached network. In typical broadband services router (BSR) network configurations, the directly attached network is an Ethernet access network, which provides access to either another frame-based network, or a cell-based network.</p> <p>When cell-mode is specified, the Juniper Networks router adjusts rates (like the shaping-rate) to “rate * 48/53” to account for 5-byte ATM AAL5 headers.</p>
Overhead-accounting bytes	A class-of-service traffic-control profile attribute that specifies the number of bytes per packet to be included or excluded from the shaping mechanism. For example, to properly account for a 4-byte header stripped by the downstream network, set the overhead-accounting bytes to -4. To properly account for a 12-byte header added by the downstream network, set the overhead-accounting bytes to 12.
Effective-shaping-rate	The shaping-rate resulting from three attributes: shaping-rate, overhead-accounting mode, and overhead-accounting bytes.
Rate Adjustment	The adjustment that other applications like ANCP, PPPoE tagging, and RADIUS CoA can make when the shaping rate is configured through the CLI or RADIUS.

## Effective Shaping Rate

CoS is responsible for communicating shaping rate information from the Routing Engine to the Packet Forwarding Engine. The shaping-rate, also known as peak information rate (PIR), is the maximum rate for a scheduler node or queue.

The true rate of a subscriber at the access-loop/CPE is a function of:

- The shaping-rate in effect for the subscriber's household, in bits-per-second.
- Whether the subscriber is connected to a frame-based or cell-based network. This attribute is known in CoS as the **overhead-accounting** mode.
  - **overhead-accounting frame-mode-bytes**—When the **overhead-accounting** mode is set to **frame-mode**, this is the number of bytes in each frame that are accounted for by the shaper. This value represents the number of bytes that are encapsulated and decapsulated by the downstream equipment.
  - **overhead-accounting cell-mode-bytes**—When overhead-accounting mode is set to **cell-mode**, this is the number of bytes in each frame that are accounted for by the shaper for a downstream cell-mode network. This value represents the number of bytes that are encapsulated and decapsulated by the downstream equipment.

You configure the values for the **shaping-rate** and **overhead-accounting** mode options under either the **[edit dynamic-profiles profile-name class-of-service traffic-control-profiles profile-name]** hierarchy level or the **[edit class-of-service traffic-control-profiles profile-name]** hierarchy level. These options are supported on MX Series routers. The applications and specified algorithms configured in the adjustment control profile use the values of these options to adjust the shaping rate for static and dynamically instantiated subscribers.

**NOTE:** Chassis egress-shaping-overhead is not included in the effective rate. Egress-shaping-overhead accounts for the physical interface overhead (ISO OSI Layer 1). Effective shaping-rate is a Layer 2 (ISO OSI) rate.

## Applications and Associated Algorithms in Adjustment Control Profiles

Table 95 on page 1031 describes the applications and their associated default algorithms that can be configured to perform rate adjustments after the subscriber is instantiated.

**Table 95: Adjustment Control Profile Applications and Algorithms**

Application	Default Priority	Default Algorithm	Description
RADIUS-CoA	1	Adjust-always	RADIUS CoA messages can update the subscriber's attributes (like shaping rate) after the subscriber is authenticated and QoS parameters (like shaping rate) are assigned.

Table 95: Adjustment Control Profile Applications and Algorithms (*continued*)

Application	Default Priority	Default Algorithm	Description
ANCP	1	Adjust-always	The ANCP application can modify the existing shaping rate for both static and dynamic logical interfaces, and static interface sets. By default, ANCP can override all other applications. The shaping rate must be specified in order to override it.
PPPoE-Tags	2	Adjust-less	The PPPoE IA tag access-rate-downstream can modify the Junos OS CLI configured shaping- rate value, as well as the RADIUS shaping- rate value. By default, these values can be modified by subsequent RADIUS CoA messages and ANCP actions. These values are conveyed in PPPoE (PADI) discovery packets.

**NOTE:** The lower the priority value, the higher the priority.

You must enable each application to perform rate adjustments. Rate adjustments are global and affect all static and dynamically instantiated subscribers. The following rules apply to adjustment control profiles:

- If no adjustment control profile is configured, the default adjustment control profile is used.
- You can configure a maximum of one adjustment control profile; a commit error occurs if you configure more than one adjustment control profile.
- If an application is not configured with an adjustment control profile, Junos OS uses its default values for priority and algorithm. For example, if ANCP is not configured in the adjustment control profile, the ANCP application is set to a priority of 1 and the algorithm is set to adjust-always.
- Adjustment control profiles apply to both static and dynamic interfaces.
- You can configure the algorithm to the following values:
  - Adjust-never
  - Adjust-always
  - Adjust less
  - Adjust less than or equal
  - Adjust greater
  - Adjust greater than or equal
- When you modify an adjustment control profile, the changes take effect immediately and the modified profile is used for all further adjustments. However, existing adjustments are not reevaluated when you modify the adjustment control profile.

For example, if you have an ANCP adjustment that overrides a PPPoE adjustment on interface ge-1/1/0.100, and then you use the adjustment control profile to change the priority so that the ANCP priority is now lower than the PPPoE priority, Junos OS does not go back and reevaluate the adjustment on ge-1/1/0.100.

## Managing Excess Bandwidth Distribution for Dynamic CoS on MIC and MIC Interfaces

Service providers often used tiered services that must utilize excess bandwidth as traffic patterns vary. By default, excess bandwidth between a configured guaranteed rate and

shaping rate is shared equally among all queues with the same excess priority value, which might not be optimal for all subscribers to a service.

This feature is supported for MIC and MPC interfaces on MX Series routers.

To configure parameters to manage excess bandwidth for subscriber interfaces:

1. Configure the parameters for the interface.
  - a. Configure the guaranteed and shaping rates.

- i. Configure the guaranteed rate:

```
[edit dynamic-profiles profile-name class-of-service traffic-control-profiles
profile-name]
user@host# set guaranteed-rate (rate | $junos-cos-guaranteed-rate) <burst-size
(bytes | $junos-cos-guaranteed-rate-burst) >
```

- ii. Configure the shaping rate:

```
[edit dynamic-profiles profile-name class-of-service traffic-control-profiles
profile-name]
user@host# set shaping-rate (rate | $junos-cos-shaping-rate) <burst-size (bytes
| $junos-cos-shaping-rate-burst) >
```

**TIP:** On MPC/MIC interfaces, the guaranteed rate and the shaping rate share the value specified for the burst size. If the guaranteed rate has a burst size specified, it is used for the shaping rate; if the shaping rate has a burst size specified, it is used for the guaranteed rate. If you have specified a burst for both rates, the system uses the lesser of the two values.

- b. Configure a rate for excess bandwidth.

You can configure an excess rate for all priorities of traffic:

```
[edit dynamic-profiles profile-name class-of-service traffic-control-profiles
profile-name]
user@host# set excess-rate (percent percentage | $junos-cos-excess-rate) |
proportion value )
```

Optionally, you can configure an excess rate specifically for high- and low-priority traffic. When you configure the **excess-rate** statement for an interface, you cannot also configure the **excess-rate-low** and **excess-rate-high** statements.

```
[edit dynamic-profiles profile-name class-of-service traffic-control-profiles
profile-name]
user@host# set excess-rate-high (percent percentage |
$junos-cos-excess-rate-high) | proportion value )
user@host# set excess-rate-low (percent percentage | $junos-cos-excess-rate-low)
| proportion value )
```

**BEST PRACTICE:** We recommend that you configure either a percentage or a proportion of the excess bandwidth for all schedulers

with the same parent in the hierarchy. For example, if you configure interface 1.1 with twenty percent of the excess bandwidth, configure interface 1.2 with eighty percent of the excess bandwidth.

2. (Optional) Configure parameters for the queue.

a. Configure the shaping rate.

```
[edit dynamic-profiles profile-name class-of-service scheduler scheduler-name]
user@host#set shaping-rate (rate | $junos-cos-scheduler-shaping-rate) <burst-size
bytes>
```

b. Configure the excess rate.

```
[edit dynamic-profiles profile-name class-of-service scheduler scheduler-name]
user@host#set excess-rate (percent percentage | percent
$junos-cos-scheduler-excess-rate)
```

c. (Optional) Configure the priority of excess bandwidth for the queue.

```
[edit dynamic-profiles profile-name class-of-service scheduler scheduler-name]
user@host#set excess-priority (low | high | $junos-cos-scheduler-excess-priority
| none)
```

**TIP:**

For queues, you cannot configure the excess rate or excess priority in these cases:

- When the transmit-rate exact statement is configured. In this case, the shaping rate is equal to the transmit rate and the queue does not operate in the excess region.
- When the scheduling priority is configured as strict-high. In this case, the queue gets all available bandwidth and never operates in the excess region.

By default, when traffic exceeds the shaping or guaranteed rates, the system demotes traffic configured with high or medium priority. To disable priority demotion, specify the none option. You cannot configure this option for queues configured with transmit-rate expressed as a percent and when the parent's guaranteed rate is set to zero.

**Related Documentation**

## Configuring Dynamic Shaping Parameters to Account for Overhead in Downstream Traffic Rates

---

You can configure the overhead accounting feature to shape downstream traffic based on either frames or cells.

You can also account for the different byte sizes per encapsulation by configuring a byte adjustment value for the shaping mode.

This feature is supported on MPCs on MX Series routers.

To configure the overhead accounting feature in a dynamic profile:

1. Do one of the following to configure the shaping mode:

- Specify the shaping mode.

Frame shaping mode is enabled by default.

```
[edit dynamic-profiles profile-name class-of-service traffic-control-profiles  
profile-name  
user@host#set overhead-accounting (frame-mode | cell-mode)
```

- Configure a variable for the shaping mode.

```
[edit dynamic-profiles profile-name class-of-service traffic-control-profiles  
profile-name  
user@host#set overhead-accounting $junos-cos-shaping-mode
```

2. (Optional) Do one of the following to configure the byte adjustment value:

- Specify a byte adjustment value.

```
[edit dynamic-profiles profile-name class-of-service traffic-control-profiles  
profile-name  
user@host#set overhead-accounting bytes byte-value
```

- Configure a variable for the byte adjustment.

```
[edit dynamic-profiles profile-name class-of-service traffic-control-profiles  
profile-name  
user@host#set overhead-accounting bytes $junos-cos-byte-adjust
```

**BEST PRACTICE:** We recommend that you specify a byte adjustment value that represents the difference between the customer premise equipment (CPE) protocol overhead and B-RAS protocol overhead.

The available range is –120 through 124 bytes. The system rounds up the byte adjustment value to the nearest multiple of 4. For example, a value of 6 is rounded to 8, and a value of -10 is rounded to -8.

---

## Configuring the Shaping Rate and Overhead Accounting Based on PPPoE Vendor-Specific Tags on Dynamic Subscriber Interfaces

To configure the PPPoE vendor-specific tags feature in a dynamic profile:

**NOTE:** When you enable this feature, the values supplied by the PPPoE vendor-specific tags override the parameters that you have configured for shaping-rate and overhead-accounting statements at the [edit dynamic-profiles *profile-name* class-of-service traffic-control-profile] hierarchy level.

1. (Optional) To configure the shaping rate based on access line information:

```
[edit dynamic-profiles profile-name class-of-service dynamic-class-of-service-options]
user@host# set vendor-specific-tags actual-data-rate-downstream
```

2. (Optional) To configure the overhead-accounting based on access-line information:

```
[edit dynamic-profiles profile-name class-of-service dynamic-class-of-service-options]
user@host# set vendor-specific-tags access-loop-encapsulation
```

## Managing Dedicated and Remaining Queues for Dynamic CoS Configurations on MIC and MPC Interfaces

This topic describes how to manage dedicated and remaining queues for static and dynamic subscriber interfaces configured in dynamic profiles.

You manage queues at the chassis and physical port level in the static configuration hierarchies, then configure dynamic scheduling and shaping parameters for the subscriber interfaces in the dynamic profile.

- [Configuring the Maximum Number of Queues for MIC and MPC Interfaces on page 1039](#)
- [Configuring Remaining Common Queues on MIC and MPC Interfaces on page 1040](#)

### Configuring the Maximum Number of Queues for MIC and MPC Interfaces

30-Gigabit Ethernet Queuing MPCs and 60-Gigabit Ethernet Queuing and Enhanced Queuing MPCs support a dedicated number of queues when configured for hierarchical scheduling and per-unit scheduling configurations.

To scale the number of subscriber interfaces per queue, you can modify the number of queues supported on the MIC.

To configure the number of queues:

1. Specify that you want to configure the MIC.

```
user@host# edit chassis fpc slot-number pic pic-number
```

2. Configure the number of queues.

```
[edit chassis fpc slot-number pic pic-number]  
user@host# setmax-queues-per-interface (8 | 4)
```

## Configuring Remaining Common Queues on MIC and MPC Interfaces

30-Gigabit Ethernet Queuing MPCs and 60-Gigabit Ethernet Queuing and Enhanced Queuing MPCs support a dedicated set of queues when configured with hierarchical scheduling.

When the number of dedicated queues is reached on the module, there can be queues remaining. Traffic from these logical interfaces are considered unclassified and attached to a common set of queues that are shared by all subsequent logical interfaces.

You can configure traffic shaping and scheduling resources for the remaining queues by attaching a special traffic-control profile to the interface. This feature enables you to provide the same shaping and scheduling to remaining queues as the dedicated queues.

To configure the remaining queues on a MIC or MPC interface:

1. Configure CoS parameters in a traffic-control profile.

```
[edit class-of-service]  
user@host# edit traffic-control-profiles profile-name
```

2. Enable hierarchical scheduling for the interface.

```
[edit interfaces interface-name]  
user@host# set hierarchical-scheduler
```

3. Attach the traffic control profiles for the dedicated and remaining queues to the port on which you enabled hierarchical scheduling.

To provide the same shaping and scheduling parameters to dedicated and remaining queues, reference the same traffic-control profile.

- a. Attach the traffic-control profile for the dedicated queues on the interface.

```
[edit class-of-service interfaces interface-name]  
user@host# set output-traffic-control-profile profile-name
```

- b. Attach the traffic-control profile for the remaining queues on the interface.

```
[edit class-of-service interfaces interface-name]  
user@host# set output-traffic-control-profile-remaining profile-name
```

## Providing Accurate Scheduling for a Demux Subscriber Interface of Aggregated Ethernet Links

Unlike VLAN subscriber interfaces, enabling link protection is not required for configuring hierarchical CoS on demux interfaces. Instead, we recommend that you enable targeted distribution on the demux interface to provide accurate scheduling for the aggregated Ethernet links.

Before you begin, configure the subscriber interface with aggregated Ethernet:

- For static and dynamic IP demux interfaces, see ["Configuring a Static or Dynamic IP Demux Subscriber Interface over Aggregated Ethernet" on page 783](#).

- For static and dynamic VLAN demux interfaces, see [“Configuring a Static or Dynamic VLAN Demux Subscriber Interface over Aggregated Ethernet”](#) on page 784.

To provide accurate scheduling for a demux subscriber interface of aggregated Ethernet links:

1. Enable targeted distribution for the demux interface.

See [“Configuring the Distribution Type for Demux Subscribers on Aggregated Ethernet Interfaces”](#) on page 786.

2. Enable hierarchical scheduling on the link aggregation bundle.

See [“Configuring Hierarchical CoS for a Subscriber Interface of Aggregated Ethernet Links”](#) on page 969.

3. (Optional) Enable module redundancy to ensure that CoS resources are provisioned for the aggregated Ethernet links if a module or a link fails. By default, link redundancy is supported.

See [“Configuring Link and Module Redundancy for Demux Subscribers in an Aggregated Ethernet Interface”](#) on page 787.

4. (Optional) Configure rebalancing periodically or manually for the subscribers. See [“Configuring Rebalancing of Demux Subscribers in an Aggregated Ethernet Interface”](#) on page 787.

5. Attach static or dynamic traffic shaping and scheduling parameters at the aggregated Ethernet logical interface or its underlying physical interface. See:

- [Configuring Traffic Scheduling and Shaping for Subscriber Access](#) on page 919
- [Configuring Schedulers in a Dynamic Profile for Subscriber Access](#) on page 921
- [Applying Traffic Shaping and Scheduling to a Subscriber Interface in a Dynamic Profile](#) on page 927
- [Applying Minimal Shaping and Scheduling to Remaining Subscriber Traffic](#) on page 928

## [Configuring the Minimum Adjusted Shaping Rate on Scheduler Nodes for Subscribers](#)

- [Overview](#) on page 1043
- [Configuring a Static Minimum Adjusted Shaping Rate on Scheduler Nodes](#) on page 1043
- [Configuring a Dynamic Minimum Adjusted Shaping Rate on Scheduler Nodes](#) on page 1043

## Overview

Absolute adjustments and delta adjustments are performed at the scheduler node level. You can configure a minimum adjusted shaping rate at the scheduler node level using static or dynamic CoS parameters.

This feature is supported for adjustments performed by the ANCP and multicast applications on both EQ DPCs and MPC/MIC modules on MX Series routers.

**BEST PRACTICE:** For multicast traffic, you can configure a minimum adjusted shaping rate at the queue level. We recommend that you configure the minimum adjusted value at the scheduler node or the queue, but not both.

When you configure a minimum adjusted value for a node and for a scheduler that is referenced by a scheduler map in the same traffic-control-profile, the system uses the minimum value from the scheduler.

This feature is supported for adjustments performed by the ANCP and multicast applications on both EQ DPCs and MPC/MIC modules on MX Series routers.

## Configuring a Static Minimum Adjusted Shaping Rate on Scheduler Nodes

To apply a minimum adjusted shaping rate for a scheduler node:

- Configure the **adjust-minimum** statement for the static traffic-control profile.

```
[edit class-of-service traffic-control-profiles profile-name]
user@host# set adjust-minimum rate
```

## Configuring a Dynamic Minimum Adjusted Shaping Rate on Scheduler Nodes

To apply a minimum adjusted shaping rate for a scheduler node:

- Configure the **adjust-minimum** statement for the dynamic traffic-control profile.

```
[edit dynamic-profiles profile-name class-of-service traffic-control-profiles profile-name]
user@host# set adjust-minimum rate
```

### Related Documentation

- [Verifying the Scheduling and Shaping Configuration for Subscriber Access on page 934](#)
- [Configuring Shaping-Rate Adjustments on Queues on page 1043](#)
- [Hierarchical CoS Shaping-Rate Adjustments Overview on page 1026](#)

## Configuring Shaping-Rate Adjustments on Queues

- [Overview on page 1044](#)
- [Configuring a Static Shaping-Rate Adjustment for Queues on page 1044](#)
- [Configuring a Dynamic Shaping-Rate Adjustment for Queues on page 1045](#)

## Overview

By default, the multicast application adjusts the shaping rates at the scheduler node level. This adjustment also impacts the shaping rates for all queues, which can be undesirable for service providers who want to provide a premium level of service on specific queues.

For multicast applications, you can control the distribution of shaping rates among queues by assigning the percentage of adjustment allowed for each queue. In addition, you can set a minimum adjusted shaping rate for each queue.

This feature is supported for adjustments performed by the multicast application on MPC/MIC modules on MX Series routers.

**BEST PRACTICE:** We recommend that you configure the minimum adjusted value at the scheduler node or the queue, but not both.

When you configure a minimum adjusted value for a node and for a scheduler that is referenced by a scheduler map in the same traffic-control-profile, the system uses the minimum value from the scheduler.

This feature is supported for adjustments performed by the multicast application on MPC/MIC modules on MX Series routers.

## Configuring a Static Shaping-Rate Adjustment for Queues

To configure adjustment parameters for a queue:

1. Configure the percentage of adjustment for the shaping rate.

```
[edit class-of-service schedulers scheduler-name]  
user@host# set adjust-percent percentage
```

2. Configure the minimum adjusted value for the shaping rate.

Do one of the following:

- Configure the minimum adjusted value for the queue.

```
[edit class-of-service schedulers scheduler-name]  
user@host# set adjust-minimum rate
```

- Configure the minimum adjusted value for the node.

```
[edit class-of-service traffic-control-profile profile-name]  
user@host# set adjust-minimum rate
```

**BEST PRACTICE:** Ensure that the minimum adjusted value that you configure does not exceed the shaping rate and is not lower than the configured transmit rate.

## Configuring a Dynamic Shaping-Rate Adjustment for Queues

To configure adjustment parameters for a queue in a dynamic profile:

1. Configure the percentage of adjustment for the shaping rate.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]
user@host# set adjust-percent percentage
```

2. Configure the minimum adjusted value for the shaping rate.

Do one of the following:

- Configure the minimum adjusted value for the queue.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]
user@host# set adjust-minimum (rate | $junos-cos-adjust-minimum)
```

- Configure the minimum adjusted value for the node.

```
[edit dynamic-profiles profile-name class-of-service traffic-control-profile
profile-name]
user@host# set adjust-minimum rate
```

**BEST PRACTICE:** Ensure that the minimum adjusted value that you configure does not exceed the shaping rate and is not lower than the configured transmit rate.

### Related Documentation

## Enabling Shaping-Rate Adjustments for Subscriber Local Loops

You can enhance a CoS implementation by enabling an MX Series 3D Universal Edge Router to adjust the hierarchical CoS policy shaping rate configured for static interface sets that consist of two or more VLANs and represent subscriber local loops. Whenever the digital subscriber line access multiplexer (DSLAM) resynchronizes its data transmission rate to a digital subscriber line (DSL), the router adjusts the shaping rate for the associated subscriber interface so that the maximum bandwidth allocation cannot exceed the current data rate for the associated subscriber local loop. This feature ensures that data

transmission rate adjustments by the DSLAM do not cause bandwidth contention at the subscriber's residential gateway.

This topic includes the following tasks:

- [Configuring Static Logical Interface Sets to Serve as CoS Hierarchical Scheduler Nodes for Subscriber Loops on page 1046](#)
- [Configuring the Logical Interfaces That Compose the Static Logical Interface Sets on page 1047](#)
- [Configuring Hierarchical CoS on the Static Logical Interface Sets That Serve as Hierarchical Scheduler Nodes for Subscriber Local Loops on page 1047](#)
- [Configuring ANCP Functionality That Supports and Drives Shaping-Rate Adjustments for Subscriber Local Loops on page 1049](#)

## Configuring Static Logical Interface Sets to Serve as CoS Hierarchical Scheduler Nodes for Subscriber Loops

To configure a logical interface set, begin by including the **interface-set** statement with the *interface-set-name* option at the **[edit interfaces]** hierarchy level.

An interface set is composed of two or more logical interfaces on the same physical interface. Each logical interface in an interface set corresponds to an individual subscriber service, such as voice, video, or data. To specify either a list of logical unit numbers or the single outer VLAN tag used to identify the logical interfaces that compose the interface set, include statements at the **[edit interfaces interface-set *interface-set-name*]** hierarchy level:

- For an interface set composed of a list of logical interfaces identified by an inner VLAN tag on Ethernet frames (called the customer VLAN, or C-VLAN, tag), you must specify each logical interface by including the **unit** statement with the *logical-unit-number* option.

```
[edit]
interfaces {
  interface-set interface-set-name {
    interface ethernet-interface-name { # EQ DPC port
      unit logical-unit-number;
      unit logical-unit-number;
      ...
    }
    ...
  }
}
```

- For an interface set composed of a set of VLANs grouped at the DSLAM and identified by the same service VLAN (S-VLAN) tag, you must specify the S-VLAN tag as the outer VLAN tag for each VLAN by including the **vlan-tags-outer** statement with the *vlan-tag* option.

```
[edit]
interfaces {
  interface-set interface-set-name {
    interface ethernet-interface-name { # EQ DPC port
      vlan-tags-outer vlan-tag; # Identify the DSLAM
```

```

    }
    ...
  }
}

```

For more information about configuring CoS hierarchical schedulers, see the Junos OS Class of Service Configuration Guide.

## Configuring the Logical Interfaces That Compose the Static Logical Interface Sets

Each underlying physical interface must be configured to operate in hierarchical scheduler mode and to support stacked VLAN tagging on all logical interfaces. To configure, include the **hierarchical-scheduler** statement and the **stacked-vlan-tagging** statement at the **[edit interfaces *ethernet-interface-name*]** hierarchy level.

To associate the individual logical interfaces of an interface set with specific subscriber services provided by the subscriber local loop, bind an S-VLAN tag and a C-VLAN tag to each logical interface that belongs to a scheduler node that represents a subscriber local loop. Ethernet frames sent from the logical interfaces contain an outer VLAN tag that identifies a DSLAM and an inner VLAN tag that identifies a subscriber port on the DSLAM. To configure, include the **vlan-tags** statement at each logical interface:

```

[edit]
interfaces {
  ethernet-interface-name { # EQ DPC port underlying an interface set
    hierarchical-scheduler;
    stacked-vlan-tagging; # Support 802.1Q VLAN dual-tagged frames
    unit logical-unit-number { # Bind S-VLAN and C-VLAN tags to logical interface
      vlan-tags inner tpid.vlan-id outer tpid.vlan-id;
    }
    ...
  }
}

```

For more information about configuring 802.1Q VLANs, see the Junos® OS Network Interfaces.

## Configuring Hierarchical CoS on the Static Logical Interface Sets That Serve as Hierarchical Scheduler Nodes for Subscriber Local Loops

To configure hierarchical CoS on the static logical interface set that serves as the hierarchical scheduler node for a subscriber local loop:

1. For each scheduler node that represents a subscriber local loop, configure an initial shaping rate.

**NOTE:** The CoS shaping-rate feature is supported only for scheduler nodes with a configured shaping rate. The initial shaping rate must be configured by applying a traffic-control profile that includes the **shaping-rate** statement. Specify the initial shaping rate as a peak rate, in bits per second (bps), and not as a percentage. Other methods of configuring a shaping rate are not supported with this feature.

- To enable traffic heading downstream (from the router to the DSLAM) to be gathered into an interface set, include the **interface-set** statement and define the logical interface set name as the *interface-set-name* option at the **[edit class-of-service interfaces]** hierarchy level.
- To apply output traffic scheduling and shaping parameters at the logical interface set level (rather than at the logical unit level), include the **output-traffic-control-profile** statement and specify the name of a traffic-control profile as the *profile-name* option at the **[edit class-of-service interfaces interface-set interface-set-name]** hierarchy level.

To configure, include the following statements:

```
interfaces { # Configure interface-specific CoS for incoming packets
  interface-set interface-set-name { # Configure a hierarchical scheduler
    output-traffic-control-profile tc-profile-name; # Level 3 scheduler node
  }
  ...
}
traffic-control-profiles { # Define traffic-control profiles
  tc-profile-name { # Specify a scheduler map and traffic-shaping parameters
    scheduler-map map-name;
    shaping-rate rate; # This is the "configured shaping rate"
    guaranteed-rate (percent percentage | rate);
    delay-buffer-rate (percent percentage | rate);
  }
  ...
}
```

You can include the statements at the following hierarchy levels:

- **[edit class-of-service]**
  - **[edit dynamic-profiles profile-name class-of-service]**
2. Configure the scheduler maps referenced in the traffic-control profiles applied to the interface sets, the schedulers referenced in those scheduler maps, and the drop profiles referenced in those schedulers.
- A scheduler map establishes the traffic output queues (forwarding classes) for a scheduler node and associates each queue with a specific scheduler map.
  - A scheduler defines queue properties (transmit rate, buffer size, priority, and drop profile) that specify how traffic is treated in the output queue.
  - A drop profile specifies how aggressively the MX Series router drops packets that are managed by a particular scheduler by defining either a segmented or interpolated graph that maps output queue fullness to packet drop probability.

To configure, include the statements at the static **[edit class-of-service]** hierarchy level:

```
[edit]
class-of-service {
  scheduler-maps { # Assign queuing characteristics to output queues
    map-name { # Map output queues to
```

```

    forwarding-class class-name scheduler scheduler-name;
    forwarding-class class-name scheduler scheduler-name;
    ...
  }
  ...
}
schedulers { # Define queuing characteristics
  scheduler-name { # Specify queuing and buffer management
    transmit-rate transmit-rate-option;
    buffer-size buffer-size-option;
    priority priority-level;
    drop-profile-map loss-priority loss-priority-option protocol any drop-profile
      drop-profile-name;
    ...
  }
}
drop-profiles { # Define random early detection (RED) for the delay buffer
  drop-profile-name { # Specify how to drop packets from an output queue
    drop-profile-name { # Map a queue fullness to a drop probability
      fill-level percentage drop-probability percentage; # Option 1: segmented
      fill-level percentage drop-probability percentage;
      ...
    }
    interpolate { # Option 2: interpolated
      drop-probability [ values ];
      fill-level [ values ];
    }
  }
  ...
}
}

```

For more information about configuring scheduler maps, schedulers, and drop profiles, see the Junos OS Class of Service Configuration Guide.

## Configuring ANCP Functionality That Supports and Drives Shaping-Rate Adjustments for Subscriber Local Loops

To configure the Access Node Control Protocol (ANCP) functionality that supports and drives the shaping-rate adjustments for subscriber local loops:

- Enable ANCP to monitor subscriber local loop rates at the DSLAMs and communicate this information to CoS.
- Configure each DSLAM as an ANCP neighbor of the router so that TCP connections can be established between the router and each DSLAM.
- Identify the subscriber interface sets whose traffic is monitored and shaped by ANCP, and associate those interface sets with the corresponding identifiers configured on the access node (DSLAM) to uniquely identify the subscriber local loops within the access network.

ANCP uses this information to build a mapping of subscribers to subscriber interfaces. When ANCP receives port management messages from a DSLAM or other access

node, it uses the access identifier contained in the message to determine which hierarchical scheduler node corresponds to the subscriber.

To configure, include statements at the **[edit protocols ancp]** hierarchy level:

```
[edit]
protocols {
  ancp {
    qos-adjust; # Enable ANCP to monitor and adjust CoS shaping rates
    neighbor ip-address; # Configure each DSLAM as an ANCP neighbor
    ...
    interfaces { # Identify subscribers for which ANCP can adjust shaping rates
      interface-set {
        interface-set-name {
          access-identifier identifier-string; # DSLAM ID for the local loop
        }
      }
      ...
    }
    ...
  }
  ...
}
```

---

## Disabling Shaping-Rate Adjustments for Subscriber Local Loops

---

To disable hierarchical CoS shaping-rate adjustments for subscriber local loops:

- Disable hierarchical CoS traffic-shaping adjustment by ANCP:

```
[edit protocols ancp]
user@host# delete qos-adjust
```

Traffic-shaping parameters for all subscriber local loops revert to their current configured values.

**Related  
Documentation**

## Disabling Hierarchical Bandwidth Adjustment for Subscriber Interfaces with Reverse-OIF Mapping

You can disable hierarchical bandwidth adjustment for all subscriber interfaces with reverse OIF mapping enabled on a specified multicast interface. Reverse OIF mapping is used to determine the subscriber VLAN interface and the multicast traffic bandwidth on the interface.

To disable hierarchical bandwidth adjustment:

1. Specify that you want to access the subscriber interfaces with reverse-OIF mapping enabled.

```
[edit routing-instances routing-instance routing-options multicast interface
interface-name]
user@host# edit reverse-oif-mapping
```

2. Disable hierarchical bandwidth adjustment for all subscriber interfaces on the interface.

```
user@host# set no-qos-adjust
```

### Related Documentation

- [Example: Configuring Multicast with Subscriber VLANs](#)

## Verifying the Configuration of Shaping-Rate Adjustments for Subscriber Local Loops

**Purpose** Display the configured shaping rate and the adjusted shaping rate for each logical interface set configured for hierarchical CoS.

**NOTE:** After shaping-rate adjustments are enabled and the router has performed shaping-rate adjustments on a scheduler node, you can configure a new shaping rate by including the `shaping-rate` statement in a traffic-control profile and then applying that profile to that scheduler node. However, this new shaping-rate value does not immediately result in shaping traffic at the new rate. The scheduler node continues to be shaped at rate set by ANCP. Only when the ANCP shaping-rate adjustment feature is disabled is the scheduler node shaped at the newly configured shaping-rate.

**Action** Issue the `show class-of-service interface-set` operational command.

### Related Documentation

- [Enabling Shaping-Rate Adjustments for Subscriber Local Loops on page 1045](#)

## Verifying the Configuration of ANCP for Shaping-Rate Adjustments

---

**Purpose** Use to display or clear information about the ANCP configuration for shaping-rate adjustments.

- Action**
- To display ANCP neighbor information, issue the **show ancp neighbor** operational command.
  - To clear ANCP neighbors, issue the **clear ancp neighbor** operational command.
  - To display ANCP subscriber information, issue the **show ancp subscriber** operational command.
  - To display ANCP class-of-service information, issue the **show ancp cos** operational command.

If ANCP is not yet enabled, the process starts when you commit a configuration that contains the **protocols ancp** stanza.

- Related Documentation**
- [ANCP Topology Discovery and Traffic Reporting Overview on page 1254](#)
  - [Configuring ANCP on page 1274](#)

## Configuring CoS Adjustment Control Profiles

---

To configure adjustment control profiles:

**NOTE:** You can only configure one adjustment control profile.

1. Configure the adjustment control profile name.

```
[edit]
user@host# edit class-of-service adjustment-control-profiles profile-name
```

2. (Optional) Configure the adjustment controls for the Access Node Control Protocol (ANCP) application:

```
[edit class-of-service adjustment-control-profiles profile-name ]
user@host# set application ancp priority priority algorithm algorithm
```

3. (Optional) Configure the adjustment controls for the RADIUS CoA application:

```
[edit class-of-service adjustment-control-profiles profile-name ]
user@host# set application radius-coa priority priority algorithm algorithm
```

4. (Optional) Configure the adjustment controls for the PPPoE tags:

```
[edit class-of-service adjustment-control-profiles profile-name ]
user@host# set application pppoe-tags priority priority algorithm algorithm
```

5. (Optional) Verify your configuration.

```
[edit class-of-service adjustment-control-profiles acp1]
user@host# show class-of-service adjustment-control-profiles
```

```
name: ANCP, priority: 1, algorithm: less;
name: RADIUS CoA, priority: 1, algorithm: always;
name: PPPoE IA tags, priority: 2, algorithm: less;
```

---

## Verifying the CoS Adjustment Control Profile Configuration

---

**Purpose** View the class-of-service (CoS) adjustment control profile.

**Action**

- To display the CoS adjustment control profile:  

```
user@host> show class-of-service adjustment-control-profile profile-name
```

```
user@host> show class-of-service adjustment-control-profile acp1
name: ANCP, priority: 1, algorithm: less
name: RADIUS CoA, priority: 1, algorithm: always
name: PPPoE IA tags, priority: 2, algorithm: less
```

```
user@host>
```

- Related Documentation**

# Bandwidth Management for Dynamic CoS Examples

- [Example: Configuring Dynamic Shaping Parameters to Account for Overhead in Downstream Traffic Rates on page 1055](#)
- [Example: Configuring Hierarchical CoS Shaping-Rate Adjustments for Subscriber Local Loops on page 1058](#)

## Example: Configuring Dynamic Shaping Parameters to Account for Overhead in Downstream Traffic Rates

This topic describes two scenarios for which you can configure dynamic shaping parameters to account for packet overhead in a downstream network.

The RADIUS administrator supplies the initial values on the RADIUS server, and the service activation is performed at subscriber login.

[Figure 29 on page 1055](#) shows the sample network that the examples reference.

**Figure 29: Sample Network Topology for Downstream Traffic**

## Managing Traffic with Different Encapsulations

In this example, the MX Series router shown in [Figure 29 on page 1055](#) sends stacked VLAN frames to the DSLAM, and the DSLAM sends single-tagged VLAN frames to the residential gateway.

To accurately shape traffic at the residential gateway, the MX Series router must account for the different frame sizes. The difference between the stacked VLAN (S-VLAN) frames sent by the router and the single-tagged VLAN frames received at the residential gateway is a 4-byte VLAN tag. The residential gateway receives frames that are 4 bytes less.

To account for the different frame sizes, you configure the frame shaping mode with -4 byte adjustment:

1. Configure the traffic shaping parameters in the dynamic profile and attach them to the interface.

Enabling the overhead accounting feature affects the resulting shaping rate, guaranteed rate, and excess rate parameters, if they are configured.

```
[edit]
dynamic-profiles {
  ethernet-downstream-network {
    interfaces {
      $junos-interface-ifd-name {
        unit $junos-underlying-interface-unit {
          family inet;
        }
      }
    }
  }
  class-of-service {
    traffic-control-profiles {
      tcp-example-overhead-accounting-frame-mode {
        excess-rate percent $junos-cos-excess-rate
        guaranteed-rate $junos-cos-guaranteed-rate
        overhead-accounting $junos-cos-shaping-mode bytes $junos-cos-byte-adjust
        shaping-rate $junos-cos-shaping-rate;
      }
    }
    interfaces {
      $junos-interface-ifd-name {
        unit "$junos-underlying-interface-unit" {
          output-traffic-control-profile tcp1;
        }
      }
    }
  }
}
```

Table 96 on page 1056 lists the initial values defined by the RADIUS administrator for the shaping rates.

**Table 96: Initial Shaping Values at Subscriber Login**

Predefined Variable	RADIUS Tag	Value
\$junos-cos-shaping-rate	T02	10m
\$junos-cos-guaranteed-rate	T03	2m
\$junos-cos-excess-rate	T05	50
\$junos-cos-shaping-mode	T07	frame-mode
\$junos-cos-byte-adjust	T08	-4

2. Verify the adjusted rates.

```

user@host#show class-of-service traffic-control-profile
Traffic control profile: tcp-example-overhead-accounting-frame-mode, Index:
61785
Excess rate 50
Shaping rate: 10000000
Guaranteed rate: 2000000
Overhead accounting mode: Frame Mode
Overhead bytes: -4

```

## Managing Downstream Cell-Based Traffic

In this example, the DSLAM and residential gateway shown in [Figure 29 on page 1055](#) are connected through an ATM cell-based network. The MX Series router sends Ethernet frames to the DSLAM, and the DSLAM sends ATM cells to the residential gateway.

To accurately shape traffic at the residential gateway, the MX Series router must account for the different physical network characteristics.

The administrator does not need to configure a byte adjustment value to account for the downstream ATM network, but has the option of configuring a byte adjustment value to account for different encapsulations or decapsulations.

To account for the different frame sizes, configure cell shaping mode:

1. Configure the traffic shaping parameters in the dynamic profile and attach them to the interface.

Enabling the overhead accounting feature affects the resulting shaping rate, guaranteed rate, and excess rate parameters, if they are configured.

```

[edit]
dynamic-profiles {
  atm-downstream-network {
    interfaces {
      $junos-interface-ifd-name {
        unit $junos-underlying-interface-unit {
          family inet;
        }
      }
    }
  }
  class-of-service {
    traffic-control-profiles {
      tcp-example-overhead-accounting-cell-mode {
        excess-rate percent $junos-cos-excess-rate
        guaranteed-rate $junos-cos-guaranteed-rate
        overhead-accounting $junos-cos-shaping-mode
        shaping-rate $junos-cos-shaping-rate
      }
    }
  }
  interfaces {
    $junos-interface-ifd-name {
      unit "$junos-underlying-interface-unit" {
        output-traffic-control-profile tcp1;
      }
    }
  }
}

```

```

    }
  }
}

```

Table 97 on page 1058 lists the initial values defined by the RADIUS administrator for the shaping rates.

**Table 97: Initial Shaping Values at Subscriber Login**

Predefined Variable	RADIUS Tag	Value
\$junos-cos-shaping-rate	T02	10m
\$junos-cos-guaranteed-rate	T03	2m
\$junos-cos-excess-rate	T05	50
\$junos-cos-shaping-mode	T07	cell-mode

2. Verify the adjusted rates.

```

user@host#show class-of-service traffic-control-profile
Traffic control profile: tcp-example-overhead-accounting-cell-mode, Index:
61785
Shaping rate: 10000000
Excess rate 50
Guaranteed rate: 2000000
Overhead accounting Cell Mode
Overhead bytes: 0

```

To account for ATM segmentation, the MX Series router adjusts all of the rates by 48/53 to account for ATM AAL5 encapsulation. In addition, the router accounts for cell padding, and internally adjusts each frame by 8 bytes to account for the ATM trailer.

- Related Documentation**
- [Configuring Dynamic Shaping Parameters to Account for Overhead in Downstream Traffic Rates on page 1038](#)

## Example: Configuring Hierarchical CoS Shaping-Rate Adjustments for Subscriber Local Loops

This example shows how you can enable shaping-rate adjustments for static logical interface sets that represent subscriber local loops:

1. Configure static logical interface sets to serve as CoS hierarchical scheduler nodes for subscriber local loops.

This example uses a single scheduler node that represents two subscriber local loops. The scheduler node is a static logical interface composed of two logical interfaces. The underlying physical interface is port 0 on a Gigabit Ethernet EQ DPC in slot 4, PIC 0:

```
[edit]
interfaces {
  interface-set ifset-of-logical-interfaces {
    interface ge-4/0/0 {
      unit 1;
      unit 2;
    }
  }
  ge-4/0/0 {
    description "access interface ge-4/0/0";
    hierarchical-scheduler;
    stacked-vlan-tagging;
    unit 1 {
      description "DSL type ADSL1 = 0x01";
      proxy-arp;
      vlan-tags outer 1 inner 1; # S-VLAN tag is '1' and C-VLAN tag is '1'
      family inet { # Specify a secondary loopback address
        unnumbered-address lo0.0 preferred-source-address 192.168.7.3;
      }
    }
    unit 2 {
      description "DSL type ADSL1 = 0x01";
      proxy-arp;
      vlan-tags outer 1 inner 2; # S-VLAN tag is '1' and C-VLAN tag is '2'
      family inet { # Specify a secondary loopback address
        unnumbered-address lo0.0 preferred-source-address 192.168.7.4;
      }
    }
  }
}
```

2. Begin configuring hierarchical CoS on the static logical interface set that serves as the hierarchical scheduler node for the group of subscriber local loops.

```
[edit]
class-of-service {
  interfaces {
    interface-set ifset-of-logical-interfaces {
      output-traffic-control-profile tcp-premium-with-4-queues;
    }
  }
}
```

3. Configure the traffic-control profiles that can be applied to the scheduler node:

```
[edit]
class-of-service {
  traffic-control-profiles {
    tcp-basic-rate { # Specify a scheduler map and traffic controls
      shaping-rate 10m;
    }
    tcp-premium-with-4-queues { # Specify a scheduler map and traffic controls
```

```
        scheduler-map smap-premium-4q;  
        shaping-rate 20m;  
        guaranteed-rate 10m;  
        delay-buffer-rate 5m;  
    }  
}  
}
```

In this example, the **tcp-premium-with-4-queues** traffic-control profile is applied to the interface set. The other profile provides a lower shaping rate and no guaranteed rate.

4. Configure the scheduler map **smap-premium-4q** that is referenced in the traffic-control profile for the scheduler node:

```
[edit]  
class-of-service {  
  scheduler-maps { # Define the queues that comprise each scheduler node  
    smap-premium-4q { # Map each queue in the scheduler node to a scheduler  
      forwarding-class be scheduler be_sch;  
      forwarding-class af scheduler af_sch;  
      forwarding-class ef scheduler ef_sch;  
      forwarding-class nc scheduler nc_sch;  
    }  
  }  
}
```

5. Configure the four schedulers (referenced in the scheduler map) that define the four output queues for the scheduler node:

```
[edit]  
class-of-service {  
  schedulers { # Define scheduling characteristics of each queue  
    be_sch { # Transmit rate and buffer management parameters  
      transmit-rate percent 10;  
      buffer-size remainder;  
      priority low;  
    }  
    ef_sch { # Transmit rate and buffer management parameters  
      ...  
    }  
    af_sch { # Transmit rate and buffer management parameters  
      ...  
    }  
    nc_sch { # Transmit rate and buffer management parameters  
      ...  
    }  
  }  
}
```

6. Enable ANCP to communicate with the DSLAM to adjust the CoS shaping rate for the scheduler node.

You must enable the ANCP feature for performing CoS traffic shaping adjustments, configure the DSLAM as an ANCP neighbor, and specify the DSLAM-assigned identifier for the subscriber local loop represented by the scheduler node:

```
[edit]
```

```

protocols {
  ancp {
    qos-adjust; # Enable ANCP to adjust CoS shaping rates
    neighbor 10.2.3.4; # Configure the DSLAM as an ANCP neighbor
    interfaces { # Identify subscribers for which ANCP can adjust shaping rates
      interface-set {
        ifset-of-logical-interfaces {
          access-identifier "dslam port 2/3"; # DSLAM ID for the local loop
        }
      }
    }
  }
}

```

**NOTE:** If ANCP is not yet enabled, the process starts when you commit a configuration that contains the `protocols ancp` stanza.

7. You can display the configured shaping rate and the adjusted shaping rate for each logical interface set configured for hierarchical CoS, issue the **show class-of-service interface-set** operational command.

## CLI-Activated Subscriber Services

---

Subscriber management enables you to use the Junos OS CLI to locally activate and deactivate dynamic subscriber services. CLI-based activation and deactivation provides local control for dynamic subscriber services that is similar to subscriber management's change of authorization (CoA) feature. CoA is considered a remote activation method because the commands, or triggers, are received from a remote server, such as a RADIUS or provisioning server. Both the CoA and CLI-based methods enable you to manage services for subscribers who are currently logged in to the network—you can activate a new service for the subscriber or deactivate a current service.

The CLI-based feature activates the specified service—you cannot use it to modify a subscriber's dynamic profile instantiation or to modify user-defined variables in a dynamic profile. You can, however, include variables that are defined for the service in the dynamic profile.

Subscriber management does not support accounting for CLI-activated subscriber services. Accounting for any service is disabled by default. Therefore when you use the CLI to activate a service, it is activated with accounting disabled, and there is no way to explicitly enable accounting for the service. CLI deactivation of a service previously activated (such as by RADIUS) has no effect on accounting for that service.

CLI-based activation and deactivation is useful in service provider networks that do not use provisioning servers or RADIUS servers to activate and deactivate subscriber services. The local control provided by the CLI-based operations enables service providers to add and remove services for existing subscribers without requiring that the subscriber log out and then log in again to complete the change. For example, a service provider might allow subscribers to log in and initially use the default service, which provides basic features. After the default service is established, the provider might then use CLI-activation to

upgrade qualified subscribers to an advanced service, in addition to retaining the initial service. Later, the provider can use CLI-deactivation to terminate the subscriber's advanced service session. The subscriber retains the initial service until the service is deactivated.

CLI-based activation or deactivation of a subscriber service fails if any of the following conditions exist:

- A RADIUS CoA operation or a previous CLI-based activation or deactivation is currently in progress for the subscriber. Only one dynamic request can be active for the subscriber.
- A unified in-service software upgrade (unified ISSU) operation is active.
- The specified service could not be activated or deactivated.

A CLI-based activation or deactivation of a subscriber service also fails if a PCRF has successfully activated any services for the subscriber. You must override the PCRF provisioning to be able to activate or deactivate services for such a subscriber. For more information, see [“Disabling PCRF Control of a Subscriber Session” on page 518](#).

#### Related Documentation

---

## Activating and Deactivating Subscriber Services Locally with the CLI

---

Subscriber management enables you to use the Junos OS CLI to locally activate or deactivate dynamic subscriber services for subscribers who are currently logged in to the network. You can activate an initial service for the subscriber, provide an additional service, or deactivate the subscriber's current service.

#### NOTE:

A CLI-based activation or deactivation of a subscriber service fails if any of the following conditions exist:

- A RADIUS CoA operation or a previous CLI-based activation or deactivation is active for the subscriber.
- A unified in-service software upgrade (unified ISSU) operation is active.
- The specified service could not be activated or deactivated.

A CLI-based activation or deactivation of a subscriber service also fails if a PCRF has successfully activated any services for the subscriber. You must override the PCRF provisioning to be able to activate or deactivate services for such a subscriber. For more information, see [“Disabling PCRF Control of a Subscriber Session” on page 518](#).

---

To use the CLI to activate a subscriber service:

1. (Optional) Verify the subscriber's ID, and ensure that provisioning is not enabled. To display the session IDs of all current subscribers, use the **show subscribers detail** or **show network-access aaa subscribers** command.

```
user@host> show network-access aaa subscribers session-id 55 detail
Type: dhcp
Username: larry@isp5.net
Stripped username: larry
AAA Logical system/Routing instance: default:default
Target Logical system/Routing instance: default:retail-onlinecompany-ca
Access-profile:retailer-onlinecompany-sjc
Session ID: 55
Accounting Session ID: 55
Multi Accounting Session ID: 0
IP Address: 192.168.44.104
Authentication State: AuthStateActive
Accounting State: Acc-Start-Send
Provisioning-type: none
Service name: basic-service
Service State: SvcActive
Session ID: 56
Session uptime: 00:01:45
```

2. Activate the service for the subscriber.

```
user@host> request network-access aaa subscriber add session-id 55 service-profile
gold-service
```

3. (Optional) Verify that the new service is activated for the subscriber. (The initial **basic-service** is also listed because it has not been deactivated.)

```
user@host> show network-access aaa subscribers session-id 55 detail
Type: dhcp
Username: larry@isp5.net
Stripped username: larry
AAA Logical system/Routing instance: default:default
Target Logical system/Routing instance: default:retail-onlinecompany-ca
Access-profile:retailer-onlinecompany-sjc
Session ID: 55
Accounting Session ID: 55
Multi Accounting Session ID: 0
IP Address: 192.168.44.104
Authentication State: AuthStateActive
Accounting State: Acc-Start-Send
Provisioning-type: none
Service name: basic-service
Service State: SvcActive
Session ID: 56
Session uptime: 00:02:15
Service name: gold-service
Service State: SvcActive
Session ID: 57
Session uptime: 00:00:30
```

To use the CLI to deactivate a subscriber service:

1. Display the active services for the specified subscriber. The following example shows that the **basic-service** and **gold-service** are active.

```
user@host> show network-access aaa subscribers session-id 55 detail
Type: dhcp
Username: larry@isp5.net
Stripped username: larry
AAA Logical system/Routing instance: default:default
Target Logical system/Routing instance: default:retail-onlinecompany-ca
Access-profile:retailer-onlinecompany-sjc
Session ID: 55
Accounting Session ID: 55
Multi Accounting Session ID: 0
IP Address: 192.168.44.104
Authentication State: AuthStateActive
Accounting State: Acc-Start-Send
Provisioning-type: none
Service name: basic-service
  Service State: SvcActive
  Session ID: 56
  Session uptime: 00:02:15
Service name: gold-service
  Service State: SvcActive
  Session ID: 57
  Session uptime: 00:00:30
```

2. Deactivate the service for the subscriber. The following example deletes the subscriber's **basic-service** service.

```
user@host> request network-access aaa subscriber delete session-id 55 service-profile
basic-service
```

3. (Optional) Verify that the deleted service is no longer active for the subscriber. (The **gold-service** is still listed because it has not been deactivated.)

```
user@host> show network-access aaa subscribers session-id 55 detail
Type: dhcp
Username: larry@isp5.net
Stripped username: larry
AAA Logical system/Routing instance: default:default
Target Logical system/Routing instance: default:retail-onlinecompany-ca
Access-profile:retailer-onlinecompany-sjc
Session ID: 55
Accounting Session ID: 55
Multi Accounting Session ID: 0
IP Address: 192.168.44.104
Authentication State: AuthStateActive
Accounting State: Acc-Start-Send
Provisioning-type: none
Service name: gold-service
  Service State: SvcActive
  Session ID: 57
  Session uptime: 00:00:30
```

## Using the CLI to Modify Traffic-Control Profiles That Are Currently Applied to Subscribers

---

Subscriber management enables you to use the CLI to modify a traffic-control profile that is currently applied to existing subscribers. This feature allows you to update subscribers who are initially assigned the default traffic-control profile, which might have limited features.

**TIP:** You specify the default traffic-control profile with the **predefined-variable-defaults** statement and the **cos-traffic-control-profile** variable at the **[edit dynamic-profiles *profile-name* class-of-service]** hierarchy level.

There are two methods you can use to modify an traffic-control profile that is in use—global and per-subscriber. The global method modifies the traffic-control profile for all subscribers currently using the traffic-control profile. The per-subscriber method modifies the traffic-control profile for a particular subscriber—all other subscribers currently using the traffic-control profile remain unaffected.

The global and per-subscriber methods share the following characteristics:

- They modify traffic-control profiles that are currently applied to active subscribers.
- Neither method creates new traffic-control profiles; they modify existing traffic-control profiles that have been previously created using the **traffic-control-profiles** statement at the **[edit dynamic-profiles *profile-name* class-of-service]** hierarchy level.
- Modifications are transparent to the active subscribers who are using the modified profile. The modified traffic-control profile is assigned without requiring any action by the subscriber.
- Both methods are useful when updating subscribers who are initially assigned the default traffic-control profile, which might have limited features. You specify the default traffic-control profile with the **predefined-variable-defaults** statement and the **cos-traffic-control-profile** variable at the **[edit dynamic-profiles *profile-name* class-of-service]** hierarchy level.

**NOTE:** To support CLI modification of traffic-control profiles in an IPv4/IPv6 dual-stack environment, you must have the `aggregate-clients replace` statement enabled at the `[edit system services dhcp-local-server group group-name dynamic-profile profile-name]` hierarchy

This topic includes the following tasks:

- [Using the CLI to Globally Modify a Traffic-Control Profile Currently Applied to Multiple Subscribers on page 1070](#)
- [Using the CLI to Modify a Traffic-Control Profile for a Specific Current Subscriber on page 1070](#)

## Using the CLI to Globally Modify a Traffic-Control Profile Currently Applied to Multiple Subscribers

To make a global modification for all current subscribers assigned a particular traffic-control profile, you change one or more parameters for the traffic-control profile and **commit** the changes.

In this example, the statement changes the shaping rate for the existing traffic-control profile named **TCP-silver**. After the change, the new shaping rate applies to all subscribers currently using **TCP-silver**.

1. Access the traffic-control profile you want to modify.

```
[edit dynamic-profiles business-profile class-of-service]
user@host# edit traffic-control-profiles TCP-silver
```

2. Specify the parameters that you want to modify in the traffic-control profile.

```
[edit dynamic-profiles business-profile class-of-service traffic-control-profiles
TCP-silver]
user@host# set shaping-rate 20m
```

3. Commit the configuration change to update the traffic-control profile. All current subscribers using **TCP-silver** now have the new **shaping-rate**.

## Using the CLI to Modify a Traffic-Control Profile for a Specific Current Subscriber

To make a per-subscriber modification for a specific subscriber that is currently assigned a traffic-control profile, you specify the name of the new traffic-control profile to use.

In this example, the command replaces the existing traffic-control profile with the profile named **TCP-gold**. The new traffic-control profile applies only to the subscriber identified by session ID **2551**.

- Request that the traffic-control profile named **TCP-gold** be applied to session ID 2551.

```
user@host> request network-access aaa subscriber modify session-id 2551
junos-cos-traffic-control-profile TCP-gold
```

The system then displays the status message, **Successful completion**, indicating that the modification is successful. The subscriber identified by session ID 2551 now uses the **TCP-gold** traffic-control profile.

## Default Subscriber Service Overview

Subscriber management enables you to specify a default subscriber service for DHCP subscribers. The default service (dynamic profile) is applied to subscribers when the subscriber logs in. By configuring a default service, you can apply a particular service (for example, a basic service) to subscribers who are not explicitly assigned a service.

When a subscriber logs in, the configured default service is always activated, even when remote service provisioning or RADIUS service activation is configured for the subscriber. The default service is deactivated only when the subscriber is successfully provisioned by the PCRF by means of the GX-Plus application. (Remote provisioning is configured by the **provisioning-order** statement at the **[edit access profile]** hierarchy level.)

In all other cases, the default service remains active. For example, if RADIUS authentication is configured but service activation is not, the default subscriber service remains activated. Likewise, if RADIUS authentication is not configured, the default subscriber service remains activated.

Default services can also be deactivated either with a RADIUS CoA deactivate request or with the **request network-access aaa subscriber delete session-id** command.

To create and assign a default subscriber service, you must complete the following operations:

- Create the service—Ensure that the service you want to use has been configured in a dynamic profile. The actual service is no different than any other service used for subscriber management.
- Specify the default service—Use the Junos OS CLI to specify the service that is used as the default service.
- Specify the interfaces on which the default service is assigned —Use the Junos OS CLI to specify that the default service is used globally, for a group of interfaces, or for a specific interface.

## Configuring a Default Subscriber Service

Subscriber management enables you to specify a default subscriber service for DHCP (and DHCPv6) local server and DHCP relay agent. The default service is the service (dynamic profile) that is applied to subscribers when they log in.

Default services are subsequently deactivated in any of the following circumstances:

- A PCRF responds to AAA for the subscriber.
- A RADIUS CoA deactivation request is issued.
- You deactivate the service manually through the CLI.

To configure a default subscriber service:

1. Ensure that the service you want to use as the default has been configured in a dynamic profile.
2. Specify the default service.

The following example configures the default service for DHCP local server subscribers.

```
[edit system services dhcp-local-server]
user@host# set service-profile retailer1-subscriber
```

3. Attach the default service—you can attach the profile globally, for a group of interfaces, or for a specific interface.

The following example attaches the profile to a named group of interfaces for DHCP local server.

- Specify the group to which the default service is attached.

```
[edit system services dhcp-local-server]
user@host# set group subscriber-svl
```

- Specify the dynamic profile that defines the default service.

```
[edit system services dhcp-local-server group subscriber-svl]
user@host# set dynamic-profile retailer1-subscriber
```

## Dynamic Firewall Filters Overview

---

Firewall filters provide rules that define whether to accept or reject packets that are transiting an interface on a router. The subscriber management feature supports four categories of firewall filters—classic filters, parameterized filters, Ascend-Data-Filters, and fast update filters.

- Classic filters are compiled at commit time and then, when a service is activated, an interface-specific clone of the filter is created and attached to a logical interface. Classic filters are static filters; they cannot contain subscriber-specific terms (also called rules). Classic filters can be applied to interfaces dynamically. This dynamic application is performed by associating input or output filters with a dynamic profile. When triggered, a dynamic profile can apply a named filter or a filter specified in RADIUS to an interface.
- Parameterized filters add the ability to configure firewall filters under a dynamic profile. The filter definitions utilize dynamic-profile variables, which allow you to customize your configuration at session creation time. You can configure a general filter under a dynamic profile and then provide policing rates, destination addresses, ports, and so forth when a dynamic session is activated.
- Ascend-Data-Filters create policies for subscriber traffic. The filter is configured on the RADIUS server and contains rules that specifically match conditions for traffic and define an action for the router to perform.
- Fast update filters are similar to classic filters in many ways. However, fast update filters support subscriber-specific, rather than interface-specific, filter values. Fast update filters also allow individual filter terms to be incrementally added or removed from filters without requiring that the entire filter be recompiled for each modification. Fast update filters are essential for networking environments in which multiple subscribers might share the same logical interface.

You configure firewall filters to determine whether to accept or reject traffic before it enters or exits an interface to which the firewall filter is applied. An *input* (or *ingress*) firewall filter is applied to packets that are entering a network. An *output* (or *egress*) firewall filter is applied to packets that are exiting a network. You can configure firewall filters to subject packets to filtering or class-of-service (CoS) marking (grouping similar types of traffic together and treating each type of traffic as a class with its own level of service priority).

## Classic Filters Overview

The dynamic firewall feature supports classic filters, parameterized filters, and fast update filters. Classic filters are compiled at commit time. When a service activation takes place, the router creates an interface-specific clone of the filter and attaches the clone to the specified logical interface. Classic filters are static filters; they cannot contain subscriber-specific terms, as opposed to fast update filters, which are subscriber-specific. Parameterized filters and policers have their configuration customized at session creation time.

This overview covers:

- [Classic Filter Types on page 1077](#)
- [Classic Filter Components on page 1077](#)
- [Classic Filter Processing on page 1078](#)
- [Guidelines for Creating and Applying Classic Filters for Subscriber Interfaces on page 1079](#)

## Classic Filter Types

The following classic filter types are supported:

- Port (Layer 2) firewall filter—Port firewall filters apply to Layer 2 switch ports. You can apply port firewall filters only in the ingress direction on a physical port.
- VLAN firewall filter—VLAN firewall filters provide access control for packets that enter a VLAN, are bridged within a VLAN, and leave a VLAN. You can apply VLAN firewall filters in both ingress and egress directions on a VLAN. VLAN firewall filters are applied to all packets that are forwarded to or forwarded from the VLAN.
- Router (Layer 3) firewall filter—You can apply a router firewall filter in both ingress and egress directions on Layer 3 (routed) interfaces.

## Classic Filter Components

When creating a classic filter, you first define the family address type (**inet** or **inet6**) and then you define one or more terms that specify the filtering criteria and the action to take when a match occurs.

Each term, or rule, consists of the following components:

- Match conditions—Specifies values or fields that the packet must contain. You can define various match conditions, including:
  - IP source address field
  - IP destination address field
  - Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) source port field

- IP protocol field
  - Internet Control Message Protocol (ICMP) packet type
  - TCP flags
  - interfaces
- Actions—Specifies what to do when a match condition occurs. Possible actions are to accept or discard a packet. In addition, packets can be counted to collect statistical information. If no action is specified for a term, the default action is to accept the packet.

## Classic Filter Processing

The order of the terms within a classic filter is important. Packets are tested against each term in the order in which the terms are listed in the firewall filter configuration. When a firewall filter contains multiple terms, the router takes a top-down approach and compares a packet against the first term in the firewall filter. If the packet matches the first term, the router executes the action defined by that term to either accept or reject the packet, and no other terms are evaluated. If the router does not find a match between the packet and first term, it then compares the packet to the next term in the firewall filter by using the same match process. If no match occurs between the packet and the second term, the router continues to compare the packet to each successive term defined in the firewall filter until a match is found. If a packet does not match any terms in a firewall filter, the default action is to discard the packet.

You can also specify a precedence (from 0 through 255) for input and output filters within a dynamic profile to force filter processing in a particular order. Setting a lower precedence value for a filter gives it a higher precedence within the dynamic profile. Filters with lower precedence values are applied to interfaces before filters with higher precedence values. A precedence of zero (the default) gives the filter the highest precedence. If no precedence is specified, the filter receives a precedence of zero (highest precedence). Filters with matching precedence (zero or otherwise) are applied in random order.

**NOTE:** Dynamic filters do not process outbound packets that are sourced from the routing engine. To filter outbound packets that are sourced from the routing engine, you can create static outbound filters for each interface.

---

## Guidelines for Creating and Applying Classic Filters for Subscriber Interfaces

This release supports the dynamic configuration of firewall filters. However, you can also continue to create static firewall filters for interfaces as you do normally, and then dynamically apply those filters to statically created interfaces using dynamic profiles. You can also use dynamic profiles to attach input and output filters through RADIUS.

When creating and applying filters, keep the following in mind:

- This release supports dynamic application of only input and output filters.
- The filters must be interface-specific.
- You can create family-specific **inet** and **inet6** filters.
- You can create interface-specific filters at the **unit** level that apply to any family type (**inet** or **inet6**) configured on the interface.
- You can add or remove both IPv4 and IPv6 filters with the same service activation or deactivation.
- You can remove one filter type without impacting the other type of filter. For example, you can remove IPv6 filters and leave the current IPv4 filters active.
- You can chain up to five input filters and four output filters together.
- If you do not configure and apply a filter, the interface uses the default group filter configuration.
- You cannot modify or delete a firewall filter while subscribers on the same logical interface are bound.

## Basic Classic Filter Syntax

This section provides the basic classic filter CLI statement syntax. The first part of this syntax provides the CLI statements to associate an input and output filter with a dynamic profile. The second part of this syntax represents the configured input and output filters applied to the dynamic profile. When a DHCP event occurs, the dynamic profile applies the specified filters to the DHCP client interface on the router.

```
[edit]
dynamic-profiles [profile-name] {
  interfaces {
```

```
[$junos-interface-ifd-name] {
  unit [$junos-underlying-interface-unit] {
    family family {
      filter {
        input {
          [filter-name];
          precedence [precedence];
        }
        output {
          [filter-name];
          precedence [precedence];
        }
      }
    }
  }
}
[edit]
firewall {
  family [family] {
    filter [filter-name] {
      [desired filter configuration]
    }
    filter [filter-name] {
      [desired filter configuration]
    }
  }
}
```

## Ascend-Data-Filter Policies for Subscriber Management Overview

Subscriber management enables you to use Ascend-Data-Filters to create policies for subscriber traffic. An Ascend-Data-Filter is a binary value that is configured on the RADIUS server. The filter contains rules that specify match conditions for traffic and an action for the router to perform (such as accept or discard the traffic). The match conditions might include the source and destination IP address or port, the protocol, the filter direction, the traffic class, and policer information.

Subscriber management uses a dynamic profile to obtain the Ascend-Data-Filter attribute (RADIUS attribute 242) from the RADIUS server and apply the policy to a subscriber session. Dynamic profiles support Ascend-Data-Filters for **inet** and **inet6** family types, and both families can be present in a dynamic profile. You include Junos OS predefined variables in the dynamic profiles — **\$junos-adf-rule-v4** for family **inet** and **\$junos-adf-rule-v6** for **inet6**. The Ascend-Data-Filter attribute can include rules for both address families. The predefined variables map the Ascend-Data-Filter rules for the respective family to the Junos OS firewall filter process. A firewall filter is created and attached to the subscriber's logical interface.

You can also configure a static Ascend-Data-Filter by manually entering the required binary data as a hexadecimal string in a dynamic profile. A statically configured Ascend-Data-Filter in a dynamic profile takes precedence over an Ascend-Data-Filter attribute that is received from RADIUS. The static method is time-consuming to configure; it is typically used only for testing purposes.

The Ascend-Data-Filter attribute is supported in RADIUS Access-Accept and Change of Authorization (CoA) messages.

CoA updates existing filters based on the Ascend-Data-Filter Type field, as shown in the following list:

- If the Type field is 1, IPv4 rules are updated and IPv6 rules are unchanged. The opposite is true if the Type field is 3.
- If both Type 1 and 3 are specified, then all rules are updated.
- If the CoA has no Ascend-Data-Filter rules, then the existing rules are unchanged.

## Filter Naming Conventions

Each Ascend-Data-Filter has a unique name, which is assigned by the dynamic firewall process, dfwd. The assigned names are displayed in the results of the **show subscriber extensive** and **show firewall** commands. Ascend-Data-Filters use the following naming convention:

*\_\_junos\_adf\_session#-interfacename-family-direction*

For example:

*\_\_junos\_adf\_33847-ge/1/0/4.53-init-in*

Each Ascend-Data-Filter rule maps to a single term, and the term names are simply **t0**, **t1**, ..., **tn**. If you configure the **counter** option, the router adds a count action to each term that is created. The counter names are a combination of the term names with **-cnt** appended. For example **t0-cnt** and **t1-cnt**.

## Use of Multiple Sessions with Ascend-Data-Filters on an Interface

An interface can have multiple subscriber sessions, each session using its own Ascend-Data-Filter rules. When an Ascend-Data-Filter is applied to a subscriber session, the rules are created independently of any other filters and are added to the interface filter list. The Ascend-Data-Filter rules for the other sessions on the same interface are also added to the filter list. All packets that are processed for the interface must go through all filters, and the filters are applied according to the precedence you set.

Because the filter list can be a combination of several rules, you must consider how the multiple filters coexist. You must ensure that the filters are designed and applied correctly in order to provide the desired filtering and resulting action. For example, a session might have a filter that accepts traffic from Subscriber-A and discards all other traffic. However, a second session on the same interface might have a filter that accepts traffic from Subscriber-B only and discards other traffic. When the two filters are combined in the filter list, traffic from Subscriber-B is discarded by the first filter, and traffic from

Subscriber-A is discarded by the second filter. As a result, no traffic is accepted on the interface because the two filters essentially cancel out each other and discard all traffic.

### Optional ADF Filter Requirement for Some Subscribers

When you include either of the predefined variables—`$junos-adf-rule-v4` or `$junos-adf-rule-v6`—in the dynamic profile, by default the RADIUS reply message must include the Ascend-Data-Filter attribute (RADIUS attribute 242) for each subscriber. If the attribute is not included, the router reports an error.

A service provider might apply the same dynamic profile to a mixed pool of subscribers, such that the attribute is included by RADIUS for some of the subscribers and is not included for others. By default, the router returns an error for each of the subscribers without the attribute, consuming system resources. You can configure the dynamic profile to accommodate such a mixture of subscribers by making the attribute requirement optional. To do so, and to suppress attribute error reporting, specify the **not-mandatory** option with the **adf** statement at the **[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number family family filter]** hierarchy level. With this configuration, the Ascend-Data-filter is simply not created when the Ascend-Data-Filter attribute is not present.

## Firewall Filters and Enhanced Network Services Mode Overview

Under normal conditions, every firewall filter is generated in two different formats -- compiled and term-based. The compiled format is used by the routing engine (RE) kernel, FPCs, and MS-DPs. The term-based format is used by MPCs. Compiled firewall filters are duplicated for each interface or logical interface to which they are applied. Term-based filters, instead of being duplicated, are referenced by each interface or logical interface.

When a combination of MPCs and any other cards populate a chassis, the creation of both firewall filter file formats is necessary. In most networks, the creation of both filter formats and any amount of duplication for compiled firewall filters has no effect on the router. However, in subscriber management networks that include thousands of statically configured subscriber interfaces, creating filters in multiple formats and duplicating those filters for each interface can utilize a large portion of router memory resources. You can use either Enhanced IP Network Services mode or Enhanced Ethernet Network Services mode to improve the scaling and performance specific to routing filters in a subscriber access network that uses statically configured subscriber interfaces.

In configurations where interfaces are created either statically or dynamically and firewall filters are applied dynamically, you must configure the chassis network services to run in enhanced mode. In configurations where interfaces are created statically and firewall filters are applied statically, you must configure chassis network services to run in enhanced mode and also configure each firewall filter for enhanced mode.

[Table 99 on page 1086](#) shows the configuration options when determining enhanced network services mode usage.

**Table 99: Enhanced Network Services Mode and Firewall Filter Use Case Determination**

Interface and Filter Configuration	Chassis Enhanced Mode Required	Firewall Filter Enhanced Mode Required
Dynamically-created interfaces and dynamically-applied filters	Yes	No
Statically-created interfaces and dynamically-applied filters	Yes	No
Statically-created interfaces and statically-applied filters	Yes	Yes

To achieve significant resource savings for the router, combine chassis and filter enhanced mode configuration as follows:

- Install only MPCs in the chassis.

**NOTE:** Configuring chassis network services to run one of the enhanced network services modes results in the router enabling only MPCs and MS-DPCs. Because MS-DPCs use compiled firewall filter format, a router chassis that is configured for one of the enhanced network services modes, configuring standard (non-enhanced) firewall filters for use with any MS-DPCs can decrease optimal resource efficiency.

- When configuring static interfaces on the router, configure chassis network services to run either Enhanced IP Network Services mode or Enhanced Ethernet Network Services mode.
- When statically applying firewall filters to statically-created interfaces, configure any firewall filters for enhanced mode to limit the filter creation to only term-based format.

**NOTE:** Any firewall filters that are not configured for enhanced mode are created in both compiled and term-based format, even if the chassis is running one of the enhanced network services modes.

## Hierarchical Policer Overview

Hierarchical policers rate-limit premium traffic separately from the aggregate traffic on an interface as determined by different configured rates. Hierarchical policing uses two token buckets to maintain two rates: an aggregate and a high priority rate, such as 10Mbps and 2Mbps. The traffic is marked differently based on the class of service. Two classes

of service are defined for this use: expedited forwarding (EF) and non-expedited forwarding (non-EF). The EF traffic has a user-selectable rate, such as 2Mbps, that is guaranteed before being subject to marking. If there is no EF traffic present, then the non-EF traffic can use up to the 10Mbps rate before being marked. If there is EF traffic present, then the EF traffic is assured up to the 2Mbps (from the 10Mbps) before it becomes subject to marking, but also consumes from the non-EF rate. In this example the EF traffic is guaranteed the 2Mbps and the non-EF traffic has the remaining 8Mbps before being marked.

Hierarchical Policing has the following characteristics:

- Ingress traffic is first classified into premium and non-premium traffic prior to applying a policer.
- The hierarchal policer contains two policers: premium and aggregate. The premium traffic is policed by both the premium policer and aggregate policer. Although premium policer rate-limits the premium traffic, the aggregate policer only decrements the credits but does not drop the packets. The non-premium traffic is rate-limited only by the aggregate policer. Therefore, the premium traffic is assured to have the bandwidth configured for premium and the non-premium traffic is policed to the remaining bandwidth.

## Hierarchical Policer as Filter Action

Hierarchical policer as filter action enables you to have hierarchial policers as one type of filter action. This is useful in provider edge applications using aggregate policing for general traffic and to apply a separate policer for premium traffic on a logical or physical interface. An interface-specific filter can have a hierarchical policer as a filter action whether or not the hierarchal policer is a logical interface policer. A non-interface-specific filter can only have a hierarchical policer without using logical interface-specific as a filter action. The following table summarizes where you can use an interface-specific filter.

Interface-specific Filter	Hierarchical Policer Logical-interface-policer	Allowed
no	no	yes
no	yes	no
yes	no	yes
yes	no	yes

To enable all hierarchical policers of the same name in one filter to share the same policer instance in PFE, use the **filter-specific** statement at the **[edit firewall]** hierarchy level.

## Interface-Shared Filters Overview

Interface-shared filters can be defined statically or dynamically, but can only be applied using dynamic profiles, and are supported for both client and service sessions. The same

interface-shared instance can be attached to multiple interfaces only if these interfaces reference the same interface-shared filter name and have the same shared-name. The shared-name can either be populated from `$junos-interface-set-name`, where the related client session provides the value, or from a service session variable.

With VLAN subscriber interfaces that use the agent-circuit-identifier information, many subscribers share the same underlying logical interface. Because some of these subscribers are related to each other as part of the same household, you must apply an interface-shared filter to the subscriber logical interfaces that make up the household to be able to filter and police these related subscribers at a household level. All interfaces that share the same interface-shared filter instance share the same set of counters and policer actions.

The base filter name of a parameterized filter is assigned depending upon the profile name and the contents of the filter definition. Therefore, when an interface-shared filter is used with parameterized filters, all service sessions that want to share the same instance of an interface-shared filter must have the exact same parameterized filter and profile. A service session uses a different instance of the interface-shared filter if either the parameterized filter or the profile is different.

---

## Enhanced Policer Statistics Overview

---

Enhanced policer statistics enable you to display additional statistics for policers as follows:

- Offered packet statistics for traffic subjected to policing.
- OOS packet statistics for packets that are marked out-of-specification (out-of-spec) by the policer. Changes to all packets that have out-of-spec actions, such as discard, color marking, or forwarding-class, are included in this counter.
- Transmitted packet statistics for traffic that is not discarded by the policer. When the policer action is discard, the statistics are the same as the in-spec statistics; when the policer action is non-discard (loss-priority or forwarding-class), the statistics are included in this counter.

This feature is supported on MPC/MIC interfaces on MX Series routers and Multi-Rate Ethernet Enhanced Queuing IP Services DPC with SFP and XFP.

To enable this feature, include the **enhanced-policer** statement at the **[edit chassis]** hierarchy level.

The new **detail** option has been added to the **show firewall**, **show firewall filter *filter-name***, and **show policer** commands.

## Fast Update Filters Overview

The dynamic firewall feature supports classic filters and fast update filters. Fast update filters support subscriber-specific filter values, as opposed to classic filters, which are interface-specific. Fast update filters allow individual filter terms, or rules, to be added or removed from filters without requiring that you recompile the filter after each modification—terms are added and removed when subscriber services are added and removed.

Using the fast update filters feature involves three distinct operations:

1. Creating the filter—You define fast update filters under the **[edit dynamic-profiles profile-name firewall family family]** hierarchy. The **dynamic-profiles** stanza enables you to use dynamic variables to create subscriber-specific configurations for the filter's match terms. See [“Configuring Fast Update Filters” on page 1125](#).
2. Associating the filter with a dynamic profile—You use the **[edit dynamic-profiles profile-name interface interface-name unit unit-number family family]** hierarchy to associate the filter with a dynamic profile. This is the same procedure used for classic filters. See [“Associating Fast Update Filters with Interfaces in a Dynamic Profile” on page 1135](#).
3. Attaching the filter to an interface—When a subscriber logs in, the dynamic profile instantiates the subscriber session and applies the properties of the profile, including the fast update filter, to the session interface. This is the same procedure used for classic filters. Also, similar to classic filters, the name of fast update filters can be provided in a user's RADIUS file.

When a dynamic profile instantiates a subscriber session and applies a fast update filter, the router verifies that the filter is not already present on the session interface. If the filter is not present, the router adds the filter. If the filter is already present on the interface, the router simply adds any new terms that are not in the existing filter. This procedure is reversed when subscriber sessions are deleted. Any terms that were added by a session are then removed when the session is deleted. The filter is deleted when the last subscriber session is deleted.

**NOTE:** You can optionally specify that a term can be added only once and cannot be modified. See [“Match Conditions and Actions in Fast Update Filters” on page 1093](#).

This overview covers:

- [Guidelines for Creating and Applying Fast Update Filters on page 1091](#)

## Fast Update Filter Components

When creating a fast update filter, you define one or more terms that specify the filtering criteria and the action to take when a match occurs.

Each term consists of the following components:

- Match condition—Specifies values or fields that the packet must contain. You can match a maximum of five fields in a fast update filter. A match condition can contain a single value or range. This differs from classic filters, in which terms can have multiple values. However, you can use additional terms to specify multiple ranges. [“Fast Update Filter Match Conditions” on page 1128](#) lists the supported match conditions for fast update filters. The order in which the terms appear in a fast update filter is not important, because the router examines the most specific term first. (Classic filters examine the terms in the order in which the terms are listed.)
- Action—Specifies what to do when a packet matches the match condition. If no action is specified for a term, the default action is to accept the packet. [“Fast Update Filter Actions and Action Modifiers” on page 1129](#) lists the supported actions for fast update filters.

Terms that are added to the filter during session instantiation must have a unique set of match conditions. Two terms overlap, or conflict, if a packet can match both sets of conditions—as a result, there are two different actions for the packet. You can ensure that terms are unique by using the `$junos-subscriber-ip-address` variable as the **source-address** (for an input filter) or **destination-address** (for an output filter) in the **from** statement. You must then supply the **source-address** or **destination-address** condition, as appropriate, as the first condition in the **match-order** statement.

## Fast Update Filter Processing

You must use the **match-order** statement to explicitly specify the order in which the router examines filter match conditions. Also, the router examines only those conditions that you include in the **match-order** statement. When a fast update filter contains multiple terms, the router compares a packet against the terms starting with the most specific condition first. When the packet first matches a condition, the router performs the action defined in the term to either accept or reject the packet, and then no other terms are evaluated. If the router does not find a match between the packet and first term, it then compares the packet to the next term in the filter. The router continues to compare the packet to the next specified term until a match is found. If there is no match after all terms have been examined, the router silently drops the packet.

You can specify a precedence (from 0 through 255) for input and output filters within a dynamic profile to force filter processing in a particular order. Setting a lower precedence value for a filter gives it a higher precedence within the dynamic profile. Filters with lower

precedence values are applied to interfaces before filters with higher precedence values. A precedence of zero (the default) gives the filter the highest precedence. If no precedence is specified, the filter receives a precedence of zero (highest precedence). Filters with matching precedence (zero or otherwise) are applied in random order.

## Fast Update Filter Names

When a filter is attached to an interface, the router first searches for a classic filter with the specified name, and then uses the classic filter. If no classic filter exists with that name, the router then searches in the dynamic profile for a fast update filter with the specified name, and uses that filter.

If two different dynamic profiles include a fast update filter with the same name, the **match-order** specification of the two filters must be identical. If the two filters are activated on the same interface, the terms are added together.

The router includes the filter name in **show firewall** command results. The router also creates unique names for filter terms and counters for the **show firewall** command.

When a fast update filter is created by the activation of a dynamic profile, the router creates an interface-specific name for the filter. The name uses the following format, which is also used for classic filters:

**<filter-name>-<interface-name>.<subunit>-<direction>**

For example, an input filter named **httpFilter** on interface **ge-1/0/0.5** is named as follows (**in** indicates an input filter and **out** indicates an output filter):

**http-filter-ge-1/0/0.5-in**

The router creates unique names for the filter terms and counters by appending the session ID to all term and counter names. Terms that use the **only-at-create** statement have a session-id of 0. Terms and counters use the following format:

**<term-name>-<session-id>**

**<counter-name>-<session-id>**

## Guidelines for Creating and Applying Fast Update Filters

Fast update filters enable you to create subscriber-specific firewall filters and dynamically apply these filters to statically created interfaces using dynamic profiles. Individual terms can be added to, or removed from, a filter without requiring that the entire filter be recompiled.

When creating and applying fast update filters, keep the following in mind:

- This release supports dynamic application of input and output filters.
- You cannot use the same fast update filter as both an input and output filter in the same dynamic profile attached to an interface.
- Fast update filters must always include terms that permit DHCP traffic to pass. See [“Configuring Filters to Permit Expected Traffic” on page 1129](#).

- You can create **family inet** and **inet6** filters.
- You can add or remove both IPv4 and IPv6 filters with the same service activation or deactivation.
- You can remove one filter type without impacting the other type of filter. For example, you can remove IPv6 filters and leave the current IPv4 filters active.
- The **interface-specific** statement is required for all fast update filters.
- The **match-order** statement is required—you must explicitly state the order of the match fields in a fast update filter. See [“Configuring the Match Order for Fast Update Filters” on page 1126](#).
- The **match-order** statement uses an implied wildcard for conditions that you specify in the statement. If you specify a condition that is not also configured in the **from** specification of a filter term, the router considers that a wildcard for that condition.
- A filter term can have only a single value or range; however, you can configure multiple terms to specify multiple ranges.
- You can match a maximum of five match conditions in a filter.

## Basic Fast Update Filter Syntax

This section shows the basic fast update filter statement syntax. The first part of this syntax provides the CLI statements to associate an input and output filter with a dynamic profile. The second part of this syntax represents the configured input and output filters associated to the dynamic profile. When a DHCP event occurs, the dynamic profile applies the specified filters to the DHCP client interface on the router.

```
[edit dynamic-profiles profile-name]  
interfaces {  
  $junos-interface-ifd-name {  
    unit $junos-underlying-interface-unit {  
      family family {  
        filter {  
          input filter-name;  
          precedence precedence;  
          output filter-name;  
          precedence precedence;  
        }  
      }  
    }  
  }  
}
```

```

}
[edit dynamic-profiles profile-name]
firewall {
  family family {
    fast-update-filter filter-name {
      [desired filter configuration]
    }
    fast-update-filter filter-name {
      [desired filter configuration]
    }
  }
}
}

```

## Match Conditions and Actions in Fast Update Filters

To create a fast update filter, you use the **term** statement to specify conditions that a packet must have, and to specify the action the router performs when those conditions exist in the packet.

This section covers:

- [Match Conditions on page 1093](#)
- [Actions on page 1094](#)
- [Adding Terms Only Once on page 1094](#)

### Match Conditions

Match conditions specify characteristics that a packet must have—if the conditions exist in the packet, the router then performs the specified action. You use the **from** keyword in the **term** statement to specify match conditions for the filter. The packet must match all conditions in the **from** specification for the action to be performed, which also means that their order in the **from** specification is not important.

An individual condition in a **from** specification can contain a single value or range. You can match a maximum of five match conditions in a filter.

[“Fast Update Filter Match Conditions” on page 1128](#) lists the match conditions you can use in fast update filters.

**NOTE:** The router uses an implied wildcard for conditions that you include in the **match-order** statement. If you include a condition that is *not* configured in the **from** specification of a filter term, the router considers that a wildcard for the condition.

For example, if you include the **dscp** condition in the **match-order** statement, but do not configure a **dscp** value in the **from** specification of the filter term, the router performs the action configured in the **then** specification of the filter on all DSCP values.

## Actions

Actions and action modifiers specify the operation the router performs when a particular match condition exists in a packet. You use the **then** keyword in the **term** statement to specify the actions to perform on packets whose characteristics match the conditions specified in the preceding **from** specification.

Action modifiers are actions taken in addition to the specified action. You can configure any combination of action modifiers. For the action or action modifier to take effect, all conditions in the **from** specification must match. If you specify **log** as one of the actions in a term, this constitutes a termination action; whether any additional terms in the filter are processed depends on the traffic through the filter. The action modifier operations carry a default **accept** action. For example, if you specify an action modifier and do not specify an action, the specified action modifier is implemented and the packet is accepted.

[“Fast Update Filter Actions and Action Modifiers” on page 1129](#) lists the actions and action modifiers you can use in fast update filters.

## Adding Terms Only Once

You can optionally specify that a term can be added only when the fast update filter is first created, and cannot be later changed by adding or removing conditions. We recommend that you only use the **only-at-create** option for terms that do not include subscriber-specific data in their match conditions, such as common or default terms (counting the default drop packet, for instance).

## Dynamic Service Sets Overview

A service set is a collection of services to be performed by an Adaptive Services (AS) or Multiservices PIC. You configure a service-set definition at the **[edit services]** hierarchy level. You can then apply the service set to one or more interfaces on the router. The service set can be applied either dynamically or statically.

To dynamically associate a service set to interfaces you include the **service-set** statement with the **input** or **output** statement at the **[edit dynamic-profiles *profile-name* interfaces *interface-name* unit *logical-unit-number* family *family* service]** hierarchy level.

To statically associate a defined service set with an interface, you include the **service-set** statement with the **input** or **output** statement at the **[edit interfaces *interface-name* unit *logical-unit-number* family *family* service]** hierarchy level.

## Parameterized Filters Overview

---

Parameterized filters are configured under a dynamic profile. The filter definition can utilize dynamic-profile variables, allowing their configuration to be customized at session creation time. The user can configure a general baseline filter under a dynamic profile and then provide specific variables of that filter when a dynamic session is activated. These variables can include policing rates, destination addresses, ports, and other items.

In order to provide better scaling, the system analyzes a dynamic profile, and then determines whether the set of variables for one session is the same as for a previous session. Each set of variables is assigned a unique identifier (UID). If a matching filter already exists, the session creates an interface-specific filter copy of that filter template. If the filter does not already exist, the session reads the configuration and compiles a new filter. This filter is installed as a template with an interface-specific filter copy for the current session pointing at it.

- [Sample Dynamic-Profile Configuration for Parameterized Filters on page 1100](#)

---

## Unique Identifiers for Firewall Variables in Dynamic Profiles

The system uses unique identifiers (UIDs) to aid with scaling. The UID enables the system to determine when configuration objects from multiple subscribers are identical and can be shared. In many situations, such as a filter definition, sharing a single filter program among multiple subscribers instead of creating a new program for every subscriber helps to conserve system resources.

Within a dynamic profile a UID is used to name a configuration object. The system assigns the value of the UID (the object's name) based upon all the variables contained within that configuration stanza along with the dynamic profile's name. The assigned UID value consists of the UID name combined with the string `_UID` and a unique number. For instance, the UID `$my-filter` might be given the value `my-filter_UID1022`.

You must first define a UID under the **variable** stanza using the option **uid**. The UID must be defined at the end, after all the variables that are assigned values externally.

```
dynamic-profile test-profile {  
  [variables] {  
    ... [other variables] ...  
    [my-filter] {  
      uid;  
    }  
  }  
}
```

After a UID has been defined, it can then be used to name an object:

```
dynamic-profile test-profile {
  firewall {
    family inet {
      filter [$my-filter] {
        ... [filter definition that makes use of other variables] ...
      }
    }
  }
}
```

As previously described, the system assigns the value of **\$my-filter** depending on the values of the variables used within that filter's definition.

The UID is also used in any other place that the object's name is used. For example, here is an interface stanza to use **\$my-filter** as an input filter:

```
dynamic-profile [test-profile] {
  interfaces {
    [$junos-interface-ifd-name] {
      unit [$junos-interface-unit] {
        family inet {
          filter {
            input [$my-filter];
          }
        }
      }
    }
  }
}
```

You can define multiple configuration objects of the same type (that is, multiple filters) as long as each one uses its own, individual, UID. To ensure that the system selects the correct object when assigning a name, use the **uid-reference** variable.

When the uid-reference is used, it is effectively evaluated twice. First, the value of the uid-reference variable is retrieved. Second, that value is used as the name of a UID and that UID value is retrieved. A uid-reference with a value that is not the name of a UID is considered an error.

A uid-reference is defined similarly to any other variable:

```
dynamic-profile [test-profile] {
  variables {
    [my-filter-selector] {
      uid-reference;
    }
  }
}
```

A uid-reference is used wherever the name of the object is needed. One example is the name of the input filter in the following interface stanza:

```
dynamic-profile [test-profile] {
  interfaces {
```

```
[$junos-interface-ifd-name] {  
  unit [$junos-interface-unit] {  
    family inet {  
      filter {  
        input [$my-filter-selector];  
      }  
    }  
  }  
}
```

Consider the case where two parameterized filters are defined: **\$my-filter-1** and **\$my-filter-2**. The **\$my-filter-selector** variable might be assigned the value **my-filter-1** or **my-filter-2**, depending upon which filter is appropriate.

---

## Sample Dynamic-Profile Configuration for Parameterized Filters

In the following sample configuration, the **my-svc-prof** profile provides two different filters: **my-filt-1gw** and **my-filt-2gw**. These filters match on either one or two gateway addresses and apply a policer for that traffic. The name of the filter to apply, the gateway addresses, and the bandwidth for the policer are passed into the service profile from the RADIUS service activation. The **uid-reference** type supports selection of a particular UID generated object out of multiple objects in the profile. The **UID** type indicates that a variable is used for UID generation.

```
dynamic-profile {  
  [my-svc-prof] {  
    variable {  
      [my-in-filter] {  
        mandatory;  
        uid-reference;  
      }  
      gw1 {  
        mandatory;  
      }  
      gw2 {  
        mandatory;  
      }  
      bw {  
        mandatory;  
      }  
      my-filt-1gw {  
        uid;  
      }  
      my-filt-2gw {  
        uid;  
      }  
      [my-policer] {  
        uid;  
      }  
    }  
  }  
  interfaces {  
    [$junos-interface-ifd-name] {
```

```

unit [$junos-underlying-interface-unit] {
    family inet {
        filter {
            input [$my-in-filter];
        }
    }
}
}
firewall {
    policer [$my-policer] {
        if-exceeding {
            bandwidth-limit $bw;
            burst-size-limit 15000;
        }
        then discard;
    }
    family inet {
        filter [$my-filt-1gw] {
            interface-specific;
            term t0 {
                from {
                    destination-address $gw1;
                }
                then {
                    policer [$my-policer];
                }
            }
            term last {
                then {
                    count drops;
                    discard;
                }
            }
        }
    }
    filter [$my-filt-2gw] {
        interface-specific;

- [Example: Dynamic-Profile Parsing on page 1106](#)

## Example: Dynamic-Profile Parsing

The following example shows the basic dynamic-profile parsing steps for “[Dynamic Profile Configuration and UID Substitution Comparison for Parameterized Filters](#)” on [page 1102](#). The steps apply to any parameterized filter.

1. Read **dynamic-profiles my-svc-prof interface ge-1/0/0 unit 7 family inet filter input** and get the value **my-filt-1gw\_UID1022**. The **my-in-filter** variable received the name of the UID (**my-filt-1gw**) from the first service parameter. The name **my-filt-1gw\_UID1022** comes from the value of the **my-filt-1gw** UID.
2. Determine whether a static filter called **my-filt-1gw\_UID1022** exists. If so, this is the existing classic filter case and not a parameterized filter.
3. Try to read **dynamic-profile my-svc-prof firewall family inet fast-update-filter my-filt-1gw\_UID1022**. If this exists, this is a fast update filter, not a parameterized filter.
4. Try to read **dynamic-profile my-svc-prof firewall family inet filter my-filt-1gw\_UID1022**. If this does not exist, return a “filter not found” error.
5. Search for a template named **my-filt-1gw\_UID1022**. If it does not exist:
  - a. Read the parameterized filter configuration. This adds the match destination address **207.17.137.239** and the policer **my-policer\_UID1005** as the action.
  - b. Determine whether **my-policer\_UID1005** exists. If it does not, read the **dynamic-profile my-svc-prof firewall policer my-policer\_UID1005** configuration and create the **my-policer\_UID1005** policer.
  - c. Compile the **my-filt-1gw\_UID1022** filter.
  - d. Install **my-filt-1gw\_UID1022** as a filter template.

6. Create and install an interface-specific filter reference named `my-filt-1gw_UID1022-ge-1/0/0.7-in` with **my-filt-1gw\_UID1022** as its template.
7. Attach **my-filt-1gw\_UID1022-ge-1/0/0.7-in** to interface **ge-1/0/0.7**.

When subsequent sessions are created with the same parameters, the system returns the same **my-filt-1gw\_UID1022** filter name. In this case, Step 5 finds the existing filter template and proceeds directly to Step 6.

## Parameterized Filters Configuration Considerations

Keep the following considerations in mind when configuring parameterized filters.

- [Subscriber IP Address on page 1107](#)
- [Interaction with Static Configuration on page 1107](#)
- [Interface-Specific on page 1108](#)
- [Service Session Support on page 1108](#)
- [Filter Naming Conventions on page 1108](#)

### Subscriber IP Address

In most deployment scenarios, the interface is based on the subscriber's IP address. Because subscribers may not be unique, they cannot be used in determining similar filters and policers. Do not use the **junos-subscriber-ip-address** IP address as a match candidate. Doing so causes unique filters per subscriber, which inhibits scaling.

### Interaction with Static Configuration

Searching for a filter to attach takes place in the following order:

1. Static filter. For example, **firewall family inet filter my-filter**.
2. Fast update filter within the current dynamic profile. For example, **dynamic-profile [profile-name] firewall family inet fast-update-filter my-filter**.
3. Parameterized filter within the current dynamic profile. For example, **dynamic-profile [profile-name] firewall family inet filter**.

The following static configuration objects may be referenced by a parameterized filter. The search order is first in the static configuration and then in the current dynamic-profile:

- firewall policer
- firewall hierarchical-policer

- three-color policer
- policy-options prefix-list

If an object in the static configuration is being used by an active parameterized filter, you cannot delete that object from the configuration while the subscriber is logged in.

## Interface-Specific

All dynamic service filters must be defined as interface-specific.

## Service Session Support

Parameterized filters and policers are supported for service activations only, not client sessions.

## Filter Naming Conventions

The base filter name is based on the interface and direction (ingress and egress) appended to it. With parameterized filters, the filter-naming process comes from the UID.

## Guidelines for Creating and Applying Parameterized Filters for Subscriber Interfaces

This release supports the dynamic configuration of firewall filters. However, you can also continue to create static firewall filters for interfaces as you do normally, and then dynamically apply those filters to statically created interfaces using dynamic profiles. You can also use dynamic profiles to attach input and output filters through RADIUS.

When creating and applying filters, keep the following in mind:

- This release supports dynamic application of only input and output filters.
- The filters must be interface-specific.
- You can create family-specific **inet** and **inet6** filters.
- You can create interface-specific filters at the **unit** level that apply to any family type (**inet** or **inet6**) configured on the interface.

- You can add or remove both IPv4 and IPv6 filters with the same service activation or deactivation.
- You can remove one filter type without impacting the other type of filter. For example, you can remove IPv6 filters and leave the current IPv4 filters active.
- You can chain up to five input filters and four output filters together.
- If you do not configure and apply a filter, the interface uses the default group filter configuration.
- You cannot modify a firewall filter while subscribers on the same logical interface are bound.

## Parameterized Filter Processing Overview

---

When creating a parameterized filter, you first define the family address type (**inet** or **inet6**) and then you define one or more terms that specify the filtering criteria and the action to take when a match occurs.

Each term, or rule, consists of the following components:

- Match conditions—Specifies values or fields that the packet must contain. You can define various match conditions, including:
  - IP source address field
  - IP destination address field
  - Transmission Control Protocol (TCP) or User Datagram Protocol (UDP) source port field
  - IP protocol field
  - Internet Control Message Protocol (ICMP) packet type
  - TCP flags
  - interfaces
- Actions—Specifies what to do when a match condition occurs. Possible actions are to accept or discard a packet. In addition, packets can be counted to collect statistical information. If no action is specified for a term, the default action is to accept the packet.

The processing of parameterized filters is the same as classic filters. The order of the terms within a parameterized filter is important. Packets are tested against each term in the order in which the terms are listed in the firewall filter configuration. When a firewall filter contains multiple terms, the router takes a top-down approach and compares a packet against the first term in the firewall filter. If the packet matches the first term, the router executes the action defined by that term to either accept or reject the packet, and no other terms are evaluated. If the router does not find a match between the packet and first term, it then compares the packet to the next term in the firewall filter by using the same match process. If no match occurs between the packet and the second term, the router continues to compare the packet to each successive term defined in the firewall

filter until a match is found. If a packet does not match any terms in a firewall filter, the default action is to discard the packet.

You can also specify a precedence (from 0 through 255) for input and output filters within a dynamic profile to force filter processing in a particular order. Setting a lower precedence value for a filter gives it a higher precedence within the dynamic profile. Filters with lower precedence values are applied to interfaces before filters with higher precedence values. A precedence of zero (the default) gives the filter the highest precedence. If no precedence is specified, the filter receives a precedence of zero (highest precedence). Filters with matching precedence (zero or otherwise) are applied in an unspecified order.

**NOTE:** Parameterized filters do not support outbound packets that are sourced from the routing engine.

---

## IPv4 Parameterized Filter Match Conditions

---

The following IPv4 match conditions are supported for parameterized filters. Their syntax is the same as the static filter syntax.

address  
destination-address  
destination-port  
destination-port-except  
destination-prefix-list  
dscp  
dscp-except  
forwarding-class  
forwarding-class-except

source-port  
source-port-except

source-prefix-list  
ttl  
ttl-except

**Related Documentation** • Standard Firewall Filter Match Conditions for IPv4 Traffic

## IPv6 Parameterized Filter Match Conditions

---

The following IPv6 match conditions are supported for parameterized filters. Their syntax is the same as the static filter syntax.

address  
destination-address  
destination-port  
destination-port-except  
destination-prefix-list  
forwarding-class  
forwarding-class-except  
icmp-code  
icmp-code-except  
icmp-type  
icmp-type-except  
loss-priority  
loss-priority-except  
packet-length  
packet-length-except  
port  
port-except  
prefix-list  
service-filter-hit  
source-address  
source-port  
source-port-except  
source-prefix-list  
traffic-class  
traffic-class-except

## Parameterized Filter Actions and Modifiers

---

The following actions and modifiers are supported for parameterized filters. Their syntax is the same as the static filter syntax.

accept  
count  
discard  
forwarding-class

hierarchical-policer  
log  
loss-priority  
next  
policer  
port-mirror  
port-mirror-instance  
reject  
routing-instance  
sample  
service-accounting  
service-filter-hit  
three-color-policer

## Dynamically Attaching Statically Created Filters for a Specific Interface Family Type

You can dynamically attach statically created filters for either IPv4 (**inet**) or IPv6 (**inet6**) interface types. These filters apply only to interfaces of the specified type.

Before you can attach a statically created filter using a dynamic profile.

1. Create the filters you want to attach.

See the Junos OS Firewall Filters and Traffic Policers Configuration Guide for detailed information about classic firewall filters and how to create them. See [“Configuring Fast Update Filters” on page 1125](#) for information about creating fast update filters.

2. Create a basic dynamic profile.

See [“Configuring a Basic Dynamic Profile” on page 633](#).

To dynamically attach statically created input and output filters:

1. Specify the unit family type you want to use when dynamically attaching the filters.

- a. For IPv4 interfaces, specify the **inet** unit family.

```
[edit dynamic-profiles access-profile interfaces ge-1/1/1 unit 1]
user@host# set family inet
```

- b. For IPv6 interfaces, specify the **inet6** unit family.

```
[edit dynamic-profiles access-profile interfaces ge-1/1/1 unit 1]
user@host# set family inet6
```

2. Specify the input filter in the dynamic profile.

```
[edit dynamic-profiles access-profile interfaces ge-1/1/1 unit 1 family inet]
user@host# set filter input static-input-filter
```

3. Specify the output filter in the dynamic profile.

**NOTE:** The following example specifies an optional precedence value for the output filter.

```
[edit dynamic-profiles access-profile interfaces ge-1/1/1 unit 1 family inet]
user@host# set filter output static-output-filter precedence 50
```

---

## Dynamically Attaching Statically Created Filters for Any Interface Type

You can dynamically attach statically created filters for any interface type. These filters apply to any interfaces that are created using the dynamic profile.

**NOTE:** For an L2TP LNS on MX Series routers, you can attach firewall for static LNS sessions by configuring these at logical interfaces directly on the inline services device (**si-fpc/pic/port**). RADIUS-configured firewall attachments are not supported.

Before you can attach a statically created filter using a dynamic profile.

1. Create the filters you want to attach.

See the Junos OS Firewall Filters and Traffic Policers Configuration Guide for detailed information about classic firewall filters and how to create them. See [“Configuring Fast Update Filters” on page 1125](#) for information about creating fast update filters.

2. Create a basic dynamic profile.

See [“Configuring a Basic Dynamic Profile” on page 633](#).

To dynamically attach statically created input and output filters for all interfaces created dynamically using the dynamic profile:

1. Access the dynamic profile, interface, and unit that you want to use when applying the static filters.

```
[edit]
user@host# edit dynamic-profiles access-profile interfaces ge-1/1/1 unit 1
```

2. Specify the input filter for the interface unit.

```
[edit dynamic-profiles access-profile interfaces ge-1/1/1 unit 1]
user@host# set filter input static-input-filter
```

3. Specify the output filter for the interface unit.

```
[edit dynamic-profiles access-profile interfaces ge-1/1/1 unit 1]
user@host# set filter output static-output-filter
```

## Dynamically Attaching Filters Using RADIUS Variables

You can attach filters to static interfaces by using dynamic profiles. By specifying a variable for the input and output filters, the dynamic profile uses RADIUS VSA attributes for ingress and egress policy.

RADIUS VSA	Attribute Name	Variable
26–10	Ingress-Policy-Name	\$junos-input-filter
26–11	Egress-Policy-Name	\$junos-output-filter
26–106	IPv6-Ingress-Policy-Name	\$junos-input-ipv6-filter
26–107	IPv6-Egress-Policy-Name	\$junos-output-ipv6-filter

Before you can attach a filter using RADIUS.

1. Create a basic dynamic profile.

See [“Configuring a Basic Dynamic Profile” on page 633](#).

2. Ensure that RADIUS ingress and egress policies are configured appropriately.

See [“Configuring RADIUS Server Parameters for Subscriber Access” on page 35](#).

To dynamically attach IPv4 input and output filters using RADIUS:

1. Specify the dynamic profile you want to attach, the interface, the logical unit number, and family **inet**.

```
[edit]
user@host# edit dynamic-profiles myProfile interface ge-1/1/1 unit 1 family inet
```

2. Specify the IPv4 input filter variable in the dynamic profile.

```
[edit dynamic-profiles myProfile interfaces ge-1/1/1 unit 1 family inet]
user@host# set filter input $junos-input-filter
```

3. Specify the IPv4 output filter variable in the dynamic profile.

```
[edit dynamic-profiles myProfile interfaces ge-1/1/1 unit 1 family inet]
user@host# set filter output $junos-output-filter
```

To dynamically attach IPv6 input and output filters using RADIUS:

1. Specify the dynamic profile you want to attach, the interface, the logical unit number, and family **inet6**.

```
[edit]
user@host# edit dynamic-profiles myProfile interface ge-1/1/1 unit 1 family inet6
```

2. Specify the IPv6 input filter variable in the dynamic profile.

```
[edit dynamic-profiles myProfile interfaces ge-1/1/1 unit 1 family inet6]
user@host# set filter input $junos-input-ipv6-filter
```

3. Specify the IPv6 output filter variable in the dynamic profile.

```
[edit dynamic-profiles myProfile interfaces ge-1/1/1 unit 1 family inet6]
user@host# set filter output $junos-output-ipv6-filter
```

- For more information about Junos default groups, see the CLI User Guide
- For more information about firewall filters, see the Junos OS Firewall Filters and Traffic Policers Configuration Guide

## Defining Dynamic Filter Processing Order

You can force filter processing to occur in a particular order by using the **precedence** statement. You specify a precedence for input and output filters within a dynamic profile at the `[edit dynamic-profiles profile-name interfaces (interface-name | demux0) unit logical-unit-number family family]` hierarchy level.

The precedence range is from 0 through 250. Setting a lower precedence value for a filter gives it a higher precedence within the dynamic profile. A precedence of zero (the default) gives the filter the highest precedence. If no precedence is specified, the filter receives a precedence of zero (highest precedence). Filters with matching precedence (zero or otherwise) are applied in random order.

Before you define a precedence for a filter in a dynamic profile.

1. Create the filters you want to attach to the dynamic profile.

See the Junos OS Firewall Filters and Traffic Policers Configuration Guide for detailed information about firewall filters and how to create them.

2. Create a basic dynamic profile.

See [“Configuring a Basic Dynamic Profile” on page 633](#).

3. Attach the filters to the dynamic profile.

See [“Dynamically Attaching Statically Created Filters for Any Interface Type” on page 1114](#), [“Dynamically Attaching Statically Created Filters for a Specific Interface Family Type” on page 1113](#), or [“Dynamically Attaching Filters Using RADIUS Variables” on page 1115](#).

To define a precedence for an input and output filter:

1. Specify the input filter precedence in the dynamic profile.

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number
family family]
user@host# set filter input precedence 50
```

2. Specify the output filter precedence in the dynamic profile.

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number
family family]
user@host# set filter output precedence 5
```

## Configuring Firewall Filter Bypass

You can streamline the filter process, decrease the amount of packet handling for each filter in a chain, and effectively bypass unnecessary filters by using the **service-filter-hit**

match/action combination at the `[edit firewall family family-name filter filter-name term term-name]` hierarchy level.

To bypass firewall filters using the **service-filter-hit** match/action combination, you configure the **service-filter-hit** action in at least one filter in the chain and configure **service-filter-hit** match condition in any subsequent filters that you want to bypass. All packets must pass through each filter in a chain. However, after the **service-filter-hit** flag is set in a packet, the packet “bypasses” any subsequent filters that contain the **service-filter-hit** match condition and more efficiently passes (accepts) marked packets and accelerating the filter process.

**NOTE:** When using the **service-filter-hit** match/action combination, the order in which the filters are applied is important. You can ensure the order in which the filters are processed by specifying a filter precedence value for the interface. See “[Defining Dynamic Filter Processing Order](#)” on page 1117 for more information about dynamic filter processing.

To bypass filter processing:

1. Specify the **service-filter-hit** action for any filters in a filter chain.

```
[edit firewall family inet filter video term 1]
user@host# set then service-filter-hit
```

When the match conditions for the filter are met, the **service-filter-hit** action is set to indicate to subsequent filters that further processing is unnecessary.

2. Specify the **service-filter-hit** match condition in any filters with a lower precedence (that is, a higher [precedence](#) statement value) that you want to detect **service-filter-hit** actions applied from previous filters in the chain.

```
[edit firewall family inet filter data term 1]
user@host# set from service-filter-hit
```

3. Configure the filter to pass (accept) any packet that has a **service-filter-hit** action applied from any previous filters.

```
[edit firewall family inet filter data term 1]
user@host# set then accept
```

## Configuring Service Packet Counting

Service packet counting is used by the router to provide volume statistics for subscribers on a per-service session basis.

You can count service packets, applying them to a specific named counter (`_junos-dyn-service-counter`), for use by RADIUS, by specifying the **service-accounting** action at the `[edit firewall family family-name filter filter-name term term-name then]` hierarchy level.

See “Configuring Per-Service Session Accounting” on page 34 for additional information, including descriptions of the RADIUS VSAs used for per-service session accounting.

To enable service packet counting:

1. Configure any match conditions that you want to count using the service accounting action. For example:

```
[edit firewall family inet filter filtername term term-name]
user@host# set from source-address address
```

2. Specify the **service-accounting** action for the filter.

```
[edit firewall family inet filter filtername term term-name]
user@host# set then service-accounting
```

When the match conditions for the filter are met, the packet is counted and applied to the well-known service counter (`_junos-dyn-service-counter`) for use by the RADIUS server. This counter provides the volume statistics for per-service accounting.

**TIP:** Do not configure the **service-accounting** action with a **count** action in the same term.

## Configuring a Filter for Use with Enhanced Network Services Mode

For a statically-applied enhanced mode filter to function on statically created interfaces, you must include the **enhanced mode** statement in each filter. However, you do not need to configure the **enhanced mode** statement in filters that are dynamically applied to either static or dynamically-created interfaces.

**NOTE:** For either static or dynamic interfaces to use enhanced network services mode, you must configure the router chassis network services to use either Enhanced IP Network Services mode or Enhanced Ethernet Network Services mode. By configuring chassis network services to run in one of the enhanced modes, the router enables only MPCs and MS-DPCs in the chassis. See [“Firewall Filters and Enhanced Network Services Mode Overview” on page 1085](#) for details.

To configure a stateless firewall filter to use enhanced mode:

1. Create or edit the stateless firewall filter.

**NOTE:** You can configure enhanced mode firewall filters for only **inet** and **inet6** filter families.

For IPv4:

```
[edit]
user@host# edit firewall family inet filter filter-name
```

For IPv6:

```
[edit]
user@host# edit firewall family inet6 filter filter-name
```

2. Specify the filter as an enhanced mode filter.

```
[edit firewall family inet filter filter-name]
user@host# set enhanced-mode
```

3. Configure or modify any filter terms.

See any of the filter configuration examples described in the Junos OS Firewall Filters and Traffic Policers Configuration Guide.

## Dynamically Applying Ascend-Data-Filter Policies to Subscriber Sessions

Subscriber management enables you to use dynamic profiles to dynamically apply policies that are defined in Ascend-Data-Filters (RADIUS attribute 242) to subscriber sessions. The dynamic profiles include a Junos OS predefined variable that maps the rules and actions defined in the Ascend-Data-Filter to Junos OS features. The RADIUS administrator configures the Ascend-Data-Filter on the RADIUS server in a separate operation.

Subscriber management dynamic profiles use the following Junos OS predefined variables to map family-specific Ascend-Data-Filter rules to Junos OS filter functionality:

- **\$junos-adf-rule-v4**—Used for IPv4 family **inet**.
- **\$junos-adf-rule-v6**—Used for IPv6 family **inet6**.

To configure a dynamic profile to dynamically apply the policy defined by an Ascend-Data-Filter to a subscriber session:

1. Specify the dynamic profile in which you want to include the Ascend-Data-Filter. Specify the interface, the logical unit number, and the family type.

```
[edit]
user@host# edit dynamic-profiles profile-name interfaces interface-name unit
logical-unit-number family family
```

2. Specify that you want to include an Ascend-Data-Filter in the dynamic profile.

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number
family family]
user@host# edit filter adf
```

3. Specify the Junos OS predefined variable that maps the Ascend-Data-Filter actions to Junos OS filter functionality. Use the variable that corresponds to the specified family type.

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number
family family filter adf]
user@host# set rule ($junos-adf-rule-v4 | $junos-adf-rule-v6)
```

**NOTE:** You can also statically configure the Ascend-Data-Filter in this step by entering the filter in hexadecimal format, rather than use a predefined variable. You might use a static filter for testing purposes.

4. (Optional) Suppress error-reporting in the event the RADIUS reply messages do not include the Ascend-Data-Filter attribute.

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number
family family filter adf]
user@host# set not-mandatory
```

5. (Optional) Enable the counter feature. The counter increments each time a packet matches the rule.

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number
family family filter adf]
user@host# set counter
```

6. (Optional) Specify the input precedence used to establish the order in which filters on the interface are applied. A lower precedence value equals a higher precedence. The precedence relates to other dynamic filters configured on the same interface.

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number
family family filter adf]
user@host# set input-precedence precedence
```

7. (Optional) Specify the output precedence used to establish the order in which filters on the interface are applied. A lower precedence value equals a higher precedence. The precedence relates to other dynamic filters configured on the same interface.

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number
family family filter adf]
user@host# set output-precedence precedence
```

## Configuring Unicast RPF and Fail Filters in Dynamic Profiles for Subscriber Interfaces

This topic provides a summary of unicast RPF configuration for subscriber interfaces in dynamic profiles on MX Series routers. Unicast RPF provides a way to reduce the effect of denial-of-service attacks on IPv4 and IPv6 interfaces by checking the source IP address against the routing table. Packets that do not match are silently discarded, unless an optional fail filter is configured. The fail filter performs an additional check and directs some action be taken on certain packets. Typical actions include logging the packets or passing them even though they failed the RPF check.

**NOTE:** Although the fail filter is technically optional, for dynamic profiles in a DHCP environment you must configure a filter to pass DHCP packets. By default, the RPF check prevents DHCP packets from being accepted on interfaces protected by the RPF check. The fail filter identifies the DHCP packets and passes them on.

To configure unicast RPF in dynamic profiles:

1. Enable unicast RPF on one or more interfaces in a dynamic profile.  
See [“Configuring Unicast RPF in Dynamic Profiles for Subscriber Interfaces” on page 1123](#).
2. (Optional) Create a fail filter to evaluate failed packets and perform further actions.  
See [“Configuring a Fail Filter for Unicast RPF in Dynamic Profiles for Subscriber Interfaces” on page 1124](#).

### Related Documentation

## Configuring Unicast RPF in Dynamic Profiles for Subscriber Interfaces

This topic describes how to configure unicast RPF for subscriber interfaces in dynamic profiles on MX Series routers.

To configure a unicast RPF with a fail filter in a dynamic profile:

1. Access the dynamic profile.  
[edit]  
user@host# **edit dynamic-profiles** *profile-name*
2. Access the interface and specify the address family  
[edit dynamic-profiles *profile-name*]  
user@host# **edit interfaces** *interface-name* unit *logical-unit-number* **family** *inet*
3. Configure the RPF check and specify the fail filter.  
[edit dynamic-profiles *profile-name* interface *interface-name* unit *logical-unit-number* family *inet*]

```
user@host# set rpf-check fail-filter filter-name
```

**Related  
Documentation**

## Configuring a Fail Filter for Unicast RPF in Dynamic Profiles for Subscriber Interfaces

This topic describes how to configure a fail filter at the **[edit firewall]** hierarchy level that can be optionally applied by unicast RPF for subscriber interfaces in dynamic profiles on MX Series routers.

**NOTE:** In contrast to statically configured fail filters, RPF-check fail filters used in a dynamic profile cannot be specific to a particular interface.

To configure a firewall fail filter:

1. Create the filter.

```
[edit]  
user@host# edit firewall family inet filter filter-name
```

2. Specify a term for the filter.

```
[edit firewall family inet filter filter-name]  
user@host# edit term term-name
```

3. Configure the match conditions for the filter.

```
[edit firewall family inet filter filter-name term term-name]  
user@host# set from match-conditions
```

4. Configure the actions to be taken for the matching packets.

```
[edit firewall family inet filter filter-name term term-name]  
user@host# set then actions
```

5. (Optional) Repeat Steps 3 and 4 for additional filter terms.

## Configuring Fast Update Filters

---

You configure a fast update filter in a dynamic profile—this enables you to use dynamic variables in the filter configuration. After you configure fast update filters, you then use the **dynamic-profiles** syntax to associate the filter with the subscriber interface.

To configure a fast update filter for subscriber access:

1. Access the dynamic profile you want to use.

```
[edit]  
user@host# edit dynamic-profiles myProfile
```

2. Specify that you want to configure a firewall, and specify the family.

```
[edit dynamic-profiles myProfile]  
user@host# edit firewall family inet
```

3. Specify that you want to configure a fast update filter and assign a name to the filter.

```
[edit dynamic-profiles myProfile firewall family inet]  
user@host# edit fast-update-filter httpFilter
```

4. Specify the **interface-specific** statement. This statement is mandatory.

```
[edit dynamic-profiles myProfile firewall family inet fast-update-filter httpFilter]  
user@host# set interface-specific
```

5. Configure the match order to use for the filter terms.

```
[edit dynamic-profiles myProfile firewall family inet fast-update-filter httpFilter]
user@host# set match-order [source-address protocol destination-port]
```

See [“Configuring the Match Order for Fast Update Filters” on page 1126](#).

6. Specify that you want to configure a term for the filter and assign the name to the term. Configure the match conditions and actions for the term.

```
[edit dynamic-profiles myProfile firewall family inet fast-update-filter httpFilter]
user@host# edit term term1
```

```
[edit dynamic-profiles myProfile firewall family inet fast-update-filter httpFilter term
term1]
user@host# set from protocol tcp
user@host# set from source-address $junos-subscriber-ip-address
user@host# set from destination-port http
user@host# set then count http-cnt
```

See [“Configuring Terms for Fast Update Filters” on page 1127](#).

---

## Configuring the Match Order for Fast Update Filters

You must include the **match-order** statement to explicitly specify the order in which router examines the match conditions. The router examines only those match conditions that you include in the statement. You can match a maximum of five conditions.

**NOTE:** If the **match-order** statement contains a condition that is not specified in the **from** statement of a term, the router considers that a wildcard for that condition.

If you use the same fast update filter in multiple dynamic profiles, you must configure the same match order for all profiles.

To configure the order in which the router examines the match conditions of a fast update filter:

1. Access the fast update filter:

```
[edit dynamic-profiles myProfile]
```

```
user@host# edit firewall family inet fast-update-filter httpFilter
```

2. Specify the mandatory **interface-specific** statement.

```
[edit dynamic-profiles myProfile firewall family inet fast-update-filter httpFilter]
user@host# set interface-specific
```

3. Configure the match order for the match conditions in the filter. Use brackets to enclose multiple match conditions.

```
[edit dynamic-profiles myProfile firewall family inet fast-update-filter httpFilter]
user@host# set match-order [source-address protocol destination-port]
```

## Configuring Terms for Fast Update Filters

A fast update filter consists of one or more terms. A term is made up of one or more match conditions and the action to take when a packet matches the specified conditions.

To configure a term for a fast update filter:

1. Access the fast update filter.

```
[edit dynamic-profiles myProfile]
user@host# edit firewall family inet fast-update-filter httpFilter
```

2. Create the new term and assign a name to the term.

```
[edit dynamic-profiles myProfile firewall family inet fast-update-filter httpFilter]
user@host# set term term1
```

3. Configure the match condition for the term. See [“Fast Update Filter Match Conditions” on page 1128](#) for the supported match conditions for fast update filters.

```
[edit dynamic-profiles myProfile firewall family inet fast-update-filter httpFilter]
user@host# set from protocol tcp
user@host# set from source-address $junos-subscriber-ip-address
user@host# set from destination-port http
```

4. Configure the action that the router takes when the match conditions are met. See [“Fast Update Filter Actions and Action Modifiers” on page 1129](#) for the supported actions for fast update filters.

```
[edit dynamic-profiles myProfile firewall family inet fast-update-filter httpFilter]
user@host# set then accept
```

5. (Optional) Configure the action modifiers that you want the router to take when the match conditions are met. See [“Fast Update Filter Actions and Action Modifiers” on page 1129](#) for the supported action-modifiers for fast update filters.

```
[edit dynamic-profiles myProfile firewall family inet fast-update-filter httpFilter]
user@host# set then count http-cnt
```

6. (Optional) Configure the term to be added only once, when the fast update filter is first created.

```
[edit dynamic-profiles myProfile firewall family inet fast-update-filter httpFilter]
user@host# set only-at-create
```

## Fast Update Filter Match Conditions

Table 101: Fast Update Filter Match Conditions

Match Condition	Description
<b>destination-address</b> <i>prefix</i>	IP destination address field.
<b>destination-port</b> <i>number</i>	TCP or UDP destination port field. Can be a single number, a single range, or one of the standard port synonyms.
<b>dscp</b> <i>number</i>	Differentiated services code point. Can be a single number, a single range, or the standard synonyms. IPv4 only.
<b>match-terms</b> <i>string-of-conditions</i>	Series of match conditions. Enclose the string within quotation marks and use semicolons to separate entries. For example, <b>match-terms "protocol tcp; destination-port http"</b> ; Dynamic profile variables are not allowed in the string.
<b>protocol</b> <i>number</i>	IP protocol field. Can be a single number, a single range, or one of the standard protocol synonyms. IPv4 only.
<b>source-address</b> <i>prefix</i>	IP source address field.
<b>source-port</b> <i>number</i>	TCP or UDP source port field. Can be a single number, a single range, or one of the standard protocol synonyms.

## Fast Update Filter Actions and Action Modifiers

Table 102: Fast Update Filter Actions and Action Modifiers

Action or Action Modifier	Description
<b>Actions</b>	
<b>accept</b>	Accept the packet.
<b>action-terms</b> <i>string-of-actions</i>	A series of multiple actions or action modifiers. Enclose the string within quotation marks and use semicolons to separate entries. For example, <b>action-terms</b> "log; count http-cnt";. Dynamic profile variables are not allowed in the string.
<b>discard</b>	Drop the packet silently, without sending an Internet Control Message Protocol (ICMP) message.
<b>ignore-term</b>	Do not add this term to the filter. All match conditions and actions are ignored.
<b>port-mirror</b>	Port mirror packets.
<b>routing-instance</b> <i>routing-instance</i>	Forward packets to specified routing instance.
<b>Action Modifiers</b>	
<b>count</b> <i>counter-name</i>	Increment the specified counter.
<b>forwarding-class</b> <i>class</i>	Classify the packet into one of the following forwarding classes: <b>as</b> , <b>assured-forwarding</b> , <b>best-effort</b> , <b>expedited-forwarding</b> , or <b>network-control</b> .
<b>log</b>	Log the packet header information.
<b>loss-priority</b> (high   medium-high   medium-low   low)	Set the loss priority level for packets.
<b>policer</b> <i>policer-name</i>	Rate-limit packets based on the specified policer.

## Configuring Filters to Permit Expected Traffic

You must explicitly configure your firewall filter to permit expected traffic, such as DHCP traffic, to pass. Otherwise, the expected traffic is denied when the filter is applied to the interface. This requirement applies to both classic and fast update filters.

The following example shows a fast update filter that might be used to accept DHCP traffic. The actual filter you use depends on the expected traffic in your network.

In the example, the term **allow-dhcp** accepts all DHCP traffic from all source addresses. The term also includes the **only-at-create** option to specify that the term is applied only

when the filter is first applied. The term **sub-allow-dhcp** includes the Junos OS predefined variable **\$junos-subscriber-ip-address**, which permits all subscriber-specific DHCP traffic.

The **match-order** statement configuration lists the conditions from most-specific to least-specific, as recommended in [“Configuring the Match Order for Fast Update Filters” on page 1126](#). Because this filter is designed to permit ingress DHCP traffic, the **source-address** condition is listed first.

```
firewall {
  family inet {
    fast-update-filter psf1 {
      interface-specific;
      match-order [ source-address destination-address protocol destination-port ];
      term allow-dhcp {
        only-at-create;
        from {
          source-address 0.0.0.0/32;
          destination-address 255.255.255.255/32;
          destination-port 67;
          protocol udp;
        }
        then accept;
      }
      term sub-allow-dhcp {
        from {
          source-address $junos-subscriber-ip-address;
          destination-address 192.168.1.2/32;
          destination-port 67;
          protocol udp;
        }
        then accept;
      }
    }
  }
}
```

---

## Avoiding Conflicts When Terms Match

A fast update filter can contain multiple terms, each with a variety of match conditions. However, when you configure multiple terms in a filter, you must ensure that the terms do not overlap, or conflict with each other. Two terms are considered to overlap when it is possible for a packet to match all conditions of both terms. Because each term specifies a different action for matches, the router cannot determine which action to take. When terms overlap, a conflict error occurs and the session fails when the dynamic profile attempts to apply the filter. The error log indicates the overlapping terms.

## How the Router Evaluates Terms in a Filter

The router creates a table of match conditions when examining terms. The table, which is similar to a routing table, is based on the conditions included in the **match-order** statement. When the router receives a packet, the router examines the packet's contents in the sequence specified in the **match-order** statement.

For example, using the sample configuration in the following Match-Order Example, the router first examines the packet's **source-address**, then the **destination-address**, and finally the **destination-port**. As shown in the following table, the two terms in the filter do not overlap because each term has a different **destination-port** specification. The router then takes the appropriate filter action for the term that matches the **destination-port** value of the packet.

Term	source-address	destination-address	destination-port	Action
t55	subscriber's address	3.1.1.2/32	http	count t55_cntr accept
t999	subscriber's address	3.1.1.2/32	https	count t999_cntr accept

### Match-Order Example

```

firewall {
  family inet {
    fast-update-filter psf1 {
      interface-specific;
      match-order [ source-address destination-address destination-port ];
      term t55 {
        from {
          source-address $junos-subscriber-ip-address;
          destination-address 3.1.1.2/32;
          destination-port http;
        }
        then {
          count t55_cntr;
          accept;
        }
      }
      term t999 {
        from {
          source-address $junos-subscriber-ip-address;
          destination-address 3.1.1.2/32;
          destination-port https;
        }
        then {
          count t999_cntr;
          accept;
        }
      }
    }
  }
}

```

}

## Using Implied Wildcards

This section shows an example of how you might use an implied wildcard specification in the match configuration. A condition in the **match-order** statement is an implied wildcard when that condition is not configured in the **from** specification of a term in the filter.

**NOTE:** When you use ranges (for example, a range of values or a wildcard) in terms, the ranges must not overlap—overlapping ranges create a conflict error. However, you can configure a range in one term and an exact match in another term. For example, in the following filter table, the wildcard destination port value in term **t3** does not overlap the destination port specifications in terms **t55** and **t999** because the **http** and **https** values are exact matches.

In the Implied Wildcard Example configuration, the router views the **destination-port** condition in the **match-order** statement as an implied wildcard for term **t3**, because there is no **destination-port** value configured in that term. As a result, the wildcard specifies that for term **t3** any **destination-port** value is accepted. The filter table appears as follows:

Term	source-address	destination-address	destination-port	Action
t3	subscriber's address	3.1.1.2/32	any (wildcard)	count t3_cntr accept
t55	subscriber's address	3.1.1.2/32	http	count t55_cntr accept
t999	subscriber's address	3.1.1.2/32	https	count t999_cntr accept

In the following filter configuration, traffic with a destination port of **http** matches term **t55** and traffic with a destination port of **https** matches term **t999**. Traffic with a destination port other than **http** or **https** matches term **t3**, which is the implied wildcard.

### Implied Wildcard Example

```

firewall {
  family inet {
    fast-update-filter psf1 {
      interface-specific;
      match-order [ source-address destination-address dscp protocol destination-port ];
      term t3 {
        from {
          source-address $junos-subscriber-ip-address;
          destination-address 3.1.1.2/32;
        }
        then {

```

```
        count t3_cntr;
        accept;
    }
}
term t55 {
    from {
        source-address $junos-subscriber-ip-address;
        destination-address 3.1.1.2/32;
        destination-port http;
    }
    then {
        count t55_cntr;
        accept;
    }
}
term t999 {
    from {
        source-address $junos-subscriber-ip-address;
        destination-address 3.1.1.2/32;
        destination-port https;
    }
    then {
        count t999_cntr;
        accept;
    }
}
}
```

Conflict Caused by Overlapping Ranges

This section shows two examples of overlapping ranges in terms. When you use ranges (such as a wildcard or a range of values) in terms, the ranges must not overlap—overlapping ranges create a conflict error and the session fails.

In the following filter configuration, the **destination-port** ranges in the two terms overlap. Ports in the range from 50 through 80 match both term **src0** and term **src1**, which each specify different actions to take.

**NOTE:** You can configure a range in one term and an exact match in another term. See the section, *Using Implied Wildcards*, for an example that uses a wildcard for a match condition in one term and an exact match for the condition in a second term.

Term	source-address	destination-address	destination-port	Action
src0	subscriber's address	10.1.1.2/32	0–80	count c1_cntr accept

Term	source-address	destination-address	destination-port	Action
src1	subscriber's address	10.1.1.2/32	50–100	count c2_cntr accept

### Overlapping Ranges Example 1

```

firewall {
  family inet {
    fast-update-filter fuf-src {
      interface-specific;
      match-order [ source-address destination-address destination-port ];
      term src0 {
        from {
          source-address $junos-subscriber-ip-address;
          destination-address 10.1.1.2/32;
          destination-port 0–80;
        }
        then {
          count c1_cntr;
          accept;
        }
      }
      term src1 {
        from {
          source-address $junos-subscriber-ip-address;
          destination-address 10.1.1.2/32;
          destination-port 50–100;
        }
        then {
          count c2_cntr;
          accept;
        }
      }
    }
  }
}

```

In this filter configuration, the **protocol** specification in terms **src21** and **src22** use the implied wildcard, which configures a range for each term. Because overlapping ranges are not allowed, a conflict error results.

Term	source-address	destination-address	protocol	destination-port	Action
src20	subscriber's address	10.1.1.2/32	udp	any (wildcard)	count c20_cntr accept
src21	subscriber's address	10.1.1.2/32	any (wildcard)	http	count c21_cntr accept
src21	subscriber's address	10.1.1.2/32	any (wildcard)	https	count c22_cntr accept

### Overlapping Ranges Example 2

```

firewall {
  family inet {
    fast-update-filter fuf-src2 {
      interface-specific;
      match-order [ source-address destination-address protocol destination-port ];
      term src20 {
        from {
          source-address $junos-subscriber-ip-address;
          destination-address 10.1.1.2/32;
          protocol udp;
        }
        then {
          count c20_cntr;
          accept;
        }
      }
      term src21 {
        from {
          source-address $junos-subscriber-ip-address;
          destination-address 10.1.1.2/32;
          destination-port http;
        }
        then {
          count c21_cntr;
          accept;
        }
      }
      term src22 {
        from {
          source-address $junos-subscriber-ip-address;
          destination-address 10.1.1.2/32;
          destination-port https;
        }
        then {
          count c22_cntr;
          accept;
        }
      }
    }
  }
}

```

## Associating Fast Update Filters with Interfaces in a Dynamic Profile

After you configure the fast update filter, you reference the filter in the **interfaces** stanza of a dynamic profile. When the dynamic profile instantiates a subscriber session, the router applies the terms of the filter to the interface.

To apply a fast update filter to an interface in a dynamic profile:

1. Access the dynamic profile you want to use.

```
[edit]
user@host# edit dynamic-profiles myProfile
```

2. Specify the interface for the dynamic profile—use the dynamic interface variable.

```
[edit dynamic-profiles myProfile]
user@host# edit interfaces $junos-interface-ifd-name
```

3. Specify the underlying interface—use the unit number variable.

```
[edit dynamic-profiles myProfile interfaces "$junos-interface-ifd-name"]
user@host# edit unit $junos-underlying-interface-unit
```

4. Specify the family. Use `inet` if you are using IPv4 filters or `inet6` for IPv6 filters.

```
[edit dynamic-profiles myProfile interfaces "$junos-interface-ifd-name" unit
"$junos-underlying-interface-unit"]
user@host# edit family inet
```

5. Specify the filters that you want to apply to the interface.

```
[edit dynamic-profiles myProfile interfaces "$junos-interface-ifd-name" unit
"$junos-underlying-interface-unit" family inet]
user@host# set filter input httpFilter
user@host# set filter output myOutFilter
```

## Verifying and Managing Firewall Filter Configuration

**Purpose** View or manage information for firewall filters:

**NOTE:** The router creates unique names for fast update filters and for filter terms and counters. See *Naming Fast Update Filters* in [“Fast Update Filters Overview” on page 1089](#) for information.

**Action** • To display statistics for firewall filters:

```
user@host> show firewall
```

- To display firewall log information:

```
user@host> show firewall log
```

- To clear filter counters:

```
user@host> clear firewall all
```

# Configuring Service Sets in Dynamic Profiles

- [Associating Service Sets with Interfaces in a Dynamic Profile on page 1139](#)
- [Verifying and Managing Service Sets Information on page 1140](#)

## Associating Service Sets with Interfaces in a Dynamic Profile

---

After you configure a service set, you use a dynamic profile to dynamically associate the service set with interfaces. You reference the filter in the **interfaces** stanza of a dynamic profile. When the dynamic profile instantiates a subscriber session, the router applies the terms of the filter to the interface.

To apply a service set to an interface in a dynamic profile:

1. Access the dynamic profile you want to use.

```
[edit]
user@host# edit dynamic-profiles myProfile
```

2. Specify the interface for the dynamic profile—use the dynamic interface variable.

```
[edit dynamic-profiles myProfile]
user@host# edit interfaces $junos-interface-ifd-name
```

3. Specify the underlying interface—use the unit number variable.

```
[edit dynamic-profiles myProfile interfaces "$junos-interface-ifd-name"]
user@host# edit unit $junos-underlying-interface-unit
```

4. Specify the family. Dynamic service sets are supported only on **family inet** (IPv4).

```
[edit dynamic-profiles myProfile interfaces "$junos-interface-ifd-name" unit
"$junos-underlying-interface-unit"]
user@host# edit family inet
```

5. Specify the input and output service sets that you want to apply to the interface.

```
[edit dynamic-profiles myProfile interfaces "$junos-interface-ifd-name" unit
"$junos-underlying-interface-unit" family inet]
user@host# set service input service-set inputService_200
user@host# set service input post-service-filter postService_15
user@host# set service output service-set outputService_320
```

## Examples: Configuring Static Filters

---

This topic provides some static filter configuration examples.

```
firewall {
  policer p1 {
    if-exceeding {
      bandwidth-limit 5m;
      burst-size-limit 10m;
    }
    then discard;
  }
  family inet {
    filter dfwd {
      interface-specific;
      term 1 {
        from {
          source-address {
            192.1.1.0/24;
          }
        }
        then {
          count c1;
          next term;
        }
      }
      term 2 {
```

```
        from {
            source-address {
                192.2.1.0/24;
            }
        }
        then count c2;
    }
    term 3 {
        then accept;
    }
}
filter dfwd1 {
    interface-specific;
    term 1 {
        from {
            address {
                192.1.1.0/24;
            }
        }
        then {
            discard;
        }
    }
}
filter tos {
    interface-specific;
    term 1 {
        from {
            precedence priority;
        }
        then forwarding-class assured-forwarding;
    }
    term 2 {
        then {
            log;
            accept;
        }
    }
}

## Example: Configuring Dynamic Ascend-Data-Filter Support for Subscriber Access

This example shows how to configure support for dynamic Ascend-Data-Filter policies.

- [Requirements on page 1144](#)
- [Overview on page 1144](#)
- [Configuration on page 1144](#)
- [Verification on page 1145](#)

### Requirements

- Ensure that the Ascend-Data-Filter has been configured on the RADIUS server.
- Create the dynamic profile. See [“Dynamic Profiles Overview” on page 602](#).
- Configure RADIUS support. See [“Configuring RADIUS Server Parameters for Subscriber Access” on page 35](#).

### Overview

Ascend-Data-Filters are configured on a RADIUS server, and contain rules that create policies. Subscriber management uses a dynamic profile to obtain the Ascend-Data-Filter attribute (RADIUS attribute 242) from the RADIUS server and apply the policy to a subscriber session.

- Specify the dynamic profile to use to apply the Ascend-Data-Filter policy to the subscriber session.
- Specify the Junos OS predefined variable that maps the Ascend-Data-Filter rules to Junos OS filter functionality.
- Configure optional settings, which include counting the rule usage and setting the precedence order for the filter.

### Configuration

**Step-by-Step Procedure**

To configure dynamic Ascend-Data-Filter support:

1. Specify the dynamic profile in which you want to include the Ascend-Data-Filter, and configure the interface, the logical unit number, and the family type.

[edit]

```
user@host# edit dynamic-profiles adf-profile-v4 interfaces
```

```
  $junos-interface-ifd-name unit $junos-underlying-interface-unit family inet
```

- Specify that you want to include an Ascend-Data-Filter in the dynamic profile and provide the Junos OS predefined variable as the rule that maps the Ascend-Data-Filter actions to Junos OS filter functionality.

```
[edit dynamic-profiles adf-profile-v4 interfaces "$junos-interface-ifd-name" unit
"$junos-underlying-interface-unit" family inet]
user@host# set filter adf rule $junos-adf-rule-v4
```

- Enable the counter for the rule.

```
[edit dynamic-profiles adf-profile-v4 interfaces "$junos-interface-ifd-name" unit
"$junos-underlying-interface-unit" family inet]
user@host# set filter adf counter
```

- Specify the precedence for received packets on the interface.

```
[edit dynamic-profiles adf-profile-v4 interfaces "$junos-interface-ifd-name" unit
"$junos-underlying-interface-unit" family inet]
user@host# set filter adf input-precedence 75
```

- Specify the precedence for transmitted packets on the interface.

```
[edit dynamic-profiles adf-profile-v4 interfaces "$junos-interface-ifd-name" unit
"$junos-underlying-interface-unit" family inet]
user@host# set filter adf output precedence 80
```

**Results** From configuration mode, confirm your configuration by entering the **show dynamic-profiles** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show dynamic-profiles
...
adf-profile-v4 {
  interfaces {
    "$junos-interface-ifd-name" {
      unit "$junos-underlying-interface-unit" {
        family inet {
          filter {
            adf {
              rule "$junos-adf-rule-v4";
              counter;
              input-precedence 75;
              output-precedence 80;
            }
          }
        }
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying that Dynamic Ascend-Data-Filter Rules Are Applied to Subscriber Sessions on page 1146](#)
- [Verifying Dynamic Ascend-Data-Filter Usage on page 1147](#)

### Verifying that Dynamic Ascend-Data-Filter Rules Are Applied to Subscriber Sessions

---

**Purpose** Verify that the Ascend-Data-Filter rules were attached to the subscriber.

**Action** From operational mode, enter the **show subscribers extensive** command.

```
user@host>show subscribers extensive
Type: DHCP
User Name: user1-adf
IP Address: 192.168.1.10
IP Netmask: 255.255.255.0
Logical System: default
Routing Instance: default
Interface: ge-1/0/0.0
Interface type: Static
Dynamic Profile Name: adf-profile-v4
MAC Address: 00:10:94:00:00:01
State: Active
Radius Accounting ID: 5
Login Time: 2010-08-12 14:06:27 PDT
ADF IPv4 Input Filter Name: __junos_adf_5-ge-1/0/0.0-inet-in
Rule 0: 010101000000000000d87f920000180000000000000000000000
      from {
        destination-address 216.127.146.0/24;
      }
      then {
        accept;
      }
Rule 1: 0100010000000000000000000000000000000000060000000001900020000
      from {
        protocol 6;
        destination-port 25;
      }
      then {
        discard;
      }
Rule 2: 01010100000000000000000000000000000000000000000000000000000
      then {
        accept;
      }
```

**Meaning** The output shows the information for the dynamic profile, including Ascend-Data-Filter rules. Verify the following information:

- The User Name field indicates the correct subscriber.
- The Dynamic Profile Name field is correct for the subscriber.
- The correct Ascend-Data-Filter rules are applied to the subscriber. The display shows the rules that are configured on the RADIUS server.

### Verifying Dynamic Ascend-Data-Filter Usage

**Purpose** Verify usage of the dynamic Ascend-Data-Filter. Counter statistics are displayed when the **counter** option is configured for the **adf** command in the dynamic profile.

**Action** From operational mode, enter the **show firewall** command.

```
user@host> show firewall
```

```
Filter: __junos_adf_5-ge-1/0/0.0-inet-in
```

```
Counters:
```

Name	Bytes	Packets
t0-cnt	32758	22
t1-cnt	22199	15
t2-cnt	21723	14

**Meaning** The output shows the name of the filter and lists the counter activity. If the **counter** option is not configured, the output displays only the filter name.

**Related Documentation**

- [Ascend-Data-Filter Policies for Subscriber Management Overview on page 1080](#)
- [Dynamically Applying Ascend-Data-Filter Policies to Subscriber Sessions on page 1121](#)

### Example: Configuring Static Ascend-Data-Filter Support for Subscriber Access

This example shows how to configure support for static Ascend-Data-Filter policies. In a static configuration, you manually configure the Ascend-Data-Filter as part of the dynamic profile configuration. This procedure differs from dynamic configuration, in which the Ascend-Data-Filter is defined on the RADIUS server and then subscriber management uses a predefined variable to map the Ascend-Data-Filter rules to Junos OS filter functionality. Because creating a static Ascend-Data-Filter configuration can be labor-intensive, you might typically use this method for testing purposes.

- [Requirements on page 1147](#)
- [Overview on page 1148](#)
- [Configuration on page 1148](#)
- [Verification on page 1150](#)

#### Requirements

- Create the dynamic profile. See “[Dynamic Profiles Overview](#)” on page 602.
- Configure RADIUS support. See “[Configuring RADIUS Server Parameters for Subscriber Access](#)” on page 35.

## Overview

Ascend-Data-Filters contain rules that create policies. Subscriber management uses a dynamic profile to apply the policy to a subscriber session. You manually configure the Ascend-Data-Filter as part of the dynamic policy.

- Specify the dynamic profile to use to apply the Ascend-Data-Filter policy to the subscriber session.
- Configure the Ascend-Data-Filter.
- Configure optional settings, which include counting the rule usage and setting the precedence for received and transmitted traffic.

## Configuration

### Step-by-Step Procedure

To configure static Ascend-Data-Filter support:

1. Specify the dynamic profile in which you want to create the Ascend-Data-Filter, and configure the interface, the logical unit number, and the family type.  
  
[edit]  
user@host# **edit dynamic-profiles adf-profile-v4 interfaces**  
          **\$junos-interface-ifd-name unit \$junos-underlying-interface-unit family inet**
2. Configure the Ascend-Data-Filter. Enclose the filter values within quotation marks. You can configure multiple Ascend-Data-Filter rules in the same dynamic profile.  
  
[edit dynamic-profiles adf-profile-v4 interfaces "\$junos-interface-ifd-name" unit "\$junos-underlying-interface-unit" family inet]  
user@host# **set filter adf rule "01000100 0A020100 00000000 18000000 00000000 00000000"**
3. Enable the counter for the rule.  
  
[edit dynamic-profiles adf-profile-v4 interfaces "\$junos-interface-ifd-name" unit "\$junos-underlying-interface-unit" family inet]  
user@host# **set filter adf counter**
4. Specify the precedence for received packets on the interface.  
  
[edit dynamic-profiles adf-profile-v4 interfaces "\$junos-interface-ifd-name" unit "\$junos-underlying-interface-unit" family inet]  
user@host# **set filter adf input-precedence 80**
5. Specify the precedence for transmitted packets on the interface.  
  
[edit dynamic-profiles adf-profile-v4 interfaces "\$junos-interface-ifd-name" unit "\$junos-underlying-interface-unit" family inet]  
user@host# **set filter adf output precedence 85**

**Results** From configuration mode, confirm your configuration by entering the **show dynamic-profiles** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show dynamic-profiles
```

```

...
adf-profile-v4 {
  interfaces {
    "$junos-interface-ifd-name" {
      unit "$junos-underlying-interface-unit" {
        family inet {
          filter {
            adf {
              rule "01000100 0A020100 00000000 18000000 00000000 00000000";
              counter;
              input-precedence 80;
              output-precedence 85;
            }
          }
        }
      }
    }
  }
}
...

```

If you are done configuring the device, enter **commit** from configuration mode.

## Results

The Ascend-Data-Filter rule defined in Step 2 of the procedure configures an input policy that filters all packets from network 10.2.1.0 with wildcard mask 255.255.255.0 to any destination.

Table 103 on page 1149 lists the values specified in the Ascend-Data-Filter rule.

**Table 103: Ascend-Data-Filter Rule**

Action or Classifier	Hex Value	Junos OS Filter Function
Type	01	IPv4

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying that Static Ascend-Data-Filter Rules are Applied to Subscriber Sessions on page 1150](#)
- [Verifying Static Ascend-Data-Filter Usage on page 1151](#)

### Verifying that Static Ascend-Data-Filter Rules are Applied to Subscriber Sessions

**Purpose** Verify that the Ascend-Data-Filter rules you manually configured were attached to the subscriber.

**Action** From operational mode, enter the **show subscribers extensive** command.

```

user@host>show subscriber extensive
Type: DHCP
User Name: user1-adf
IP Address: 192.168.1.10
IP Netmask: 255.255.255.0
Logical System: default
Routing Instance: default
Interface: ge-1/0/0.0
Interface type: Static
Dynamic Profile Name: adf-profile-v4
MAC Address: 00:10:94:00:00:01
State: Active
Radius Accounting ID: 5
Login Time: 2010-08-12 14:06:27 PDT
ADF IPv4 Input Filter Name: __junos_adf_5-ge-1/0/0.0-inet-in
Rule 0: 010001000A0201000000000001800000000000000000000000
      from {
        destination-address 10.2.1.0/24;
      }
      then {
        accept;
      }

```

**Meaning** The output shows the information for the dynamic profile, including Ascend-Data-Filter rules. Verify the following information:

- The User Name field indicates the correct subscriber.
- The Dynamic Profile Name field is correct for the subscriber.

- The correct static Ascend-Data-Filter rule is applied to the subscriber.

### Verifying Static Ascend-Data-Filter Usage

**Purpose** Verify usage of the static Ascend-Data-Filter. Counter statistics are displayed when the **counter** option is configured for the **adf** command in the dynamic profile.

**Action** From operational mode, enter the **show firewall** command.

```
user@host> show firewall
```

```
Filter: __junos_adf_5-ge-1/0/0.0-inet-in
Counters:
Name          Bytes          Packets
t0-cnt        32758           22
```

**Meaning** The output shows the name of the filter and the lists counter activity. If the **counter** option is not configured, the output displays only the filter name.

## Example: Configuring Fast Update Filters for Subscriber Access

This example shows you how to configure a fast update filter that is an input filter that counts the HTTP and non-HTTP packets from a subscriber. In the example, you use the firewall stanza to create the filter and the interfaces stanza to attach the filter.

```
[edit dynamic-profiles myProfile]
firewall {
  family inet {
    fast-update-filter httpFilter {
      interface-specific;
      match-order [source-address protocol destination-port];
      term term1 {
        from {
          protocol tcp;
          source-address $junos-subscriber-ip-address;
          destination-port http;
        }
        then {
          count http-cnt;
        }
      }
      term term2 {
        from {
          protocol tcp;
          source-address $junos-subscriber-ip-address;
        }
        then {
          count non-http-cnt;
        }
      }
    }
  }
}
```

```
    }  
  }  
}  
}  
interfaces {  
  "$junos-interface-ifd-name" {  
    unit "$junos-underlying-interface-unit" {  
      family inet {  
        filter {  
          input httpFilter;  
        }  
      }  
    }  
  }  
}
```

## Example: Bypassing Firewall Filters

This example describes how to configure multiple filters using the **service-filter-hit** match/action combination and contains the following sections:

- [Before You Begin on page 1152](#)
- [Filter Bypass Overview on page 1152](#)
- [Configuring Filter Bypass on page 1153](#)

### Before You Begin

When using the **service-filter-hit** match/action combination, keep the following in mind:

- The order in which the filters are applied is important. You can ensure the order in which the filters are processed by specifying a filter precedence value for the interface. See [“Defining Dynamic Filter Processing Order” on page 1117](#) for more information about dynamic filter processing and how to use the **precedence** statement.
- The following example uses policers to further define the match conditions each filter uses. These filters are not described here. To better understand how to configure policers, see “Statement Hierarchy for Configuring Policers” in the Junos OS Firewall Filters and Traffic Policers Configuration Guide.

### Filter Bypass Overview

Packets must pass through each filter in a chain. However, if you create a chain of filters to process different types of packets (for example, voice, video, and data packets), you can streamline the filter process, decreasing the amount of packet handling for each filter in the chain, effectively bypassing unnecessary filters, by using the **service-filter-hit** match/action combination at the **[edit firewall family *family-name* filter *filter-name* term *term-name*]** hierarchy level.

Figure 30 on page 1153 shows the logical processing flow through a chain of three filters (voice, video, and data) where only processing for a specific data type is desired. This configuration example shows an ingress filter flow. Though subsequent ingress filters in a chain can detect whether the **service-filter-hit** action is set, egress filters do not. To bypass egress filters, you must also configure the **service-filter-hit** match/action combination on those filters.

Figure 30: Logical Flow Example for Filter Bypass Processing

## Configuring Filter Bypass

- [Configuring the Voice Filter on page 1153](#)
- [Configuring the Video Filter on page 1154](#)
- [Configuring the Data Filter on page 1154](#)
- [Results on page 1154](#)

### CLI Quick Configuration

To quickly configure this example:

```
[edit]
set firewall filter voice term T1 from address 1.1.1.1/32
set firewall filter voice term T1 from source-port 5004-5005
set firewall filter voice term T1 then forwarding-class assured-forwarding service-filter-hit
  accept
set firewall filter voice term default then accept
set firewall filter video term T1 from service-filter-hit
set firewall filter video term T1 then accept
set firewall filter video term T2 from source-address 10.10.10.10/32
set firewall filter video term T2 then policer video-policer service-filter-hit accept
set firewall filter video term default then accept
set firewall filter data term T1 from service-filter-hit
set firewall filter data term T1 then accept
set firewall filter data term T2 then policer data-policer service-filter-hit accept
```

### Configuring the Voice Filter

### Step-by-Step Procedure

To configure the voice filter for the logical flow in [Figure 30 on page 1153](#):

1. Configure the filter to apply the assured forwarding class and set the **service-filter-hit** action for traffic from a specific address and port range (over which voice traffic is expected).

```
[edit]
set firewall filter voice term T1 from address 1.1.1.1/32
set firewall filter voice term T1 from source-port 5004-5005
```

```
set firewall filter voice term T1 then forwarding-class assured-forwarding
service-filter-hit accept
```

2. Configure the filter default action to pass (accept) packet traffic from any other address or port range.

```
[edit]
set firewall filter voice term default then accept
```

### Configuring the Video Filter

#### Step-by-Step Procedure

To configure the video filter for the logical flow in [Figure 30 on page 1153](#):

1. Configure the filter to pass (accept) incoming packets that are tagged by the **service-filter-hit** action.  
  

```
[edit]
set firewall filter video term T1 from service-filter-hit
set firewall filter video term T1 then accept
```
2. Configure the filter to apply a video policer and set the **service-filter-hit** action for traffic from a specific address (over which video traffic is expected).  
  

```
[edit]
set firewall filter video term T2 from source-address 10.10.10.10/32
set firewall filter video term T2 then policer video-policer service-filter-hit accept
```
3. Configure the filter default action to pass (accept) packet traffic from any other address or port range.  
  

```
[edit]
set firewall filter video term default then accept
```

### Configuring the Data Filter

#### Step-by-Step Procedure

To configure the data filter for the logical flow in [Figure 30 on page 1153](#):

1. Configure the filter to pass (accept) incoming packets that are tagged by the **service-filter-hit** action.  
  

```
[edit]
set firewall filter data term T1 from service-filter-hit
set firewall filter data term T1 then accept
```
2. Configure the filter to apply a data policer and set the **service-filter-hit** action for traffic from a specific address (over which video traffic is expected).  
  

```
[edit]
set firewall filter data term T2 then policer data-policer service-filter-hit accept
```

### Results

Display the results of the configuration:

```
[edit firewall]
user@host# show
filter voice {
```

```
term T1 {
  from {
    address {
      1.1.1.1/32;
    }
    source-port 5004-5005;
  }
  then {
    forwarding-class assured-forwarding;
    service-filter-hit;
    accept;
  }
}
term default {
  then accept;
}
}
filter video {
  term T1 {
    from {
      service-filter-hit;
    }
    then accept;
  }
  term T2 {
    from {
      source-address {
        10.10.10.10/32;
      }
    }
    then {
      policer video_policer;
      service-filter-hit;
      accept;
    }
  }
  term default {
    then accept;
  }
}
filter data {
  term T1 {
    from {
      service-filter-hit;
    }
    then accept;
  }
  term T2 {
    then {
      policer data_policer;
      service-filter-hit;
      accept;
    }
  }
}
```

## Example: Configuring Hierarchical Policers as Filter Actions

This example shows how to configure a hierarchical policer and apply the policer to ingress Layer 3 traffic at a logical interface on the MX-series platform.

- [Requirements on page 1156](#)
- [Overview on page 1156](#)
- [Configuration on page 1156](#)
- [Verification on page 1159](#)

### Requirements

Before you begin, be sure that your environment meets the following requirements:

- Supported on MX Series routers.

### Overview

In this example, you configure a hierarchical policer as a filter action.

### Configuration

- [Example: Hierarchical Policer as Filter Action on page 1156](#)
- [Example: Defining the Interface: on page 1158](#)

---

#### Example: Hierarchical Policer as Filter Action

**Step-by-Step Procedure**

You can have hierarchical policers as one type of filter action. To configure a firewall filter:

1. Configure the family address type for a firewall filter:

```
[edit firewall]
user@host# set family inet
```

2. Specify the filter name:

```
[edit firewall family inet]
user@host# set filter inet-filter
```

3. Specify the term name:

```
[edit firewall family inet filter inet-filter]
user@host# set term t1
```

4. In each firewall filter term, specify the match conditions to use to match components of a packet:

```
[edit firewall family inet filter inet-filter term t1]
user@host# set from precedence critical-ecp immediate priority
user@host# set from protocol tcp
```

5. In each firewall filter term, specify the actions to take if the packet matches all the condition in that term:

```
[edit firewall family inet filter inet-filter term t1]
user@host# set then hierarchical-policer HP1
```

6. (Optional) Enable all hierarchical policers in one filter to share the same policer instance in PFE:

```
[edit firewall family inet filter inet-filter term t1]
user@host# set then hierarchical-policer HP1 filter-specific
```

**Results** Confirm the configuration by entering the **show firewall** configuration command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show firewall
family inet {
  filter inet-filter {
    interface-specific;
    term t1 {
      from {
        precedence [ critical-ecp immediate priority ];
        protocol tcp;
      }
      then hierarchical-policer HP1;
    }
    term t2 {
      from {
        precedence [ internet-control routine ];
        protocol tcp;
      }
      then hierarchical-policer HP2;
    }
  }
}
family inet6 {
  filter inet6-filter {
    interface-specific;
    term t1 {
      from {
        next-header [ tcp udp ];
        forwarding-class [ assured-forwarding expedited-forwarding ];
      }
      then hierarchical-policer HP1;
    }
    term t2 {
      from {
        next-header [ tcp udp icmpv6 ospf rsvp ];

```

```
        forwarding-class [ network-control best-effort ];
    }
    then hierarchical-policer HP2;
}
}
}
```

---

#### Example: Defining the Interface:

##### Step-by-Step Procedure

To define the interface:

1. Enable configuration of the physical interface:

```
[edit]
user@host# edit interfaces ge-1/2/0 unit 0
```

2. Configure the family address:

```
[edit interfaces ge-1/2/0 unit 0]
user@host# set family inet address 10.100.16.2/24
```

3. Specify the filter name:

```
[edit interfaces ge-1/2/0 unit 0 family inet]
user@host# set filter inet-filter
user@host# set address 10.100.16.2/24
```

##### Results

Confirm the configuration by entering the **show interfaces** configuration command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit]
user@host# show interfaces
interfaces {
  ge-1/2/0 {
    unit 0 {
      family inet {
        filter {
          input inet-filter;
        }
        address 10.100.16.2/24;
      }
      family inet6 {
        input-hierarchical-policer shared_HP;
        address 1A23:120B::7634:AD01:4D/120;
      }
    }
  }
  ge-1/2/1 {
    unit 0 {
      family inet {
        input-hierarchical-policer shared_HP;
        address 10.100.16.2/24;
      }
    }
  }
}
```

```
}
}
```

## Verification

Confirm that the configuration is working properly.

- [Displaying Packets for the Firewall on page 1159](#)

### Displaying Packets for the Firewall

**Purpose** Verify the number of packets evaluated by the policer. Premium policer counters are not supported.

**Action** Use the **show firewall** operational mode command. The command output displays the number of packets.

```
[edit]
user@host# show firewall

Filter: __default_bpdu_filter__

Filter: utp_4550-ge-1/0/0.100-in
Counters:
Name                               Bytes      Packets
c_ef-ge-1/0/0.0-i                  1696750    15425
c_other-ge-1/0/0.0-i                0          0
Policers:
Name                               Packets
hp_abc-filter-ge-1/0/0.0-i         7509
```

- Related Documentation**
- [Hierarchical Policer Overview on page 1086](#)
  - [Hierarchical Policer as Filter Action on page 1087](#)
  - [filter-specific on page 1575](#)

## Example: Interface-Shared Filter Configuration

Before you can attach an interface-shared filter using a dynamic profile.

- Create a basic dynamic profile.

See “[Configuring a Basic Dynamic Profile](#)” on page 633.

To configure an interface-shared filter using a dynamic profile that is used to implement agent-circuit-identifier VLAN household filtering:

1. Access the dynamic profile you want to use.

```
[edit]
user@host# edit dynamic-profiles profile-name
```

2. Specify the interfaces.

```
[edit dynamic-profiles profile-name]
```

```
user@host# edit interfaces interface-name
```

3. Specify the unit.

```
[edit dynamic-profiles profile-name interfaces interface-name]  
user@host# edit unit $junos-interface-unit
```

4. Specify the family.

```
[edit dynamic-profiles profile-name interfaces interface-name unit  
"$junos-interface-unit"]  
user@host# edit family family-name
```

5. Specify the input filter and the filter terms for the interface unit.

```
[edit dynamic-profiles profile-name interfaces interface-name unit  
"$junos-interface-unit" family family-name]  
user@host# edit input $junos-input-filter shared-name $junos-interface-set-name  
precedence precedence-number
```

6. Specify the output filter and the filter terms for the interface unit.

```
[edit dynamic-profiles profile-name interfaces interface-name unit  
"$junos-interface-unit" family family-name]  
user@host# edit output $junos-output-filter shared-name $junos-interface-set-name  
precedence precedence-number
```

7. Specify that you want to configure a firewall, and specify the family.

```
[edit dynamic-profiles profile-name]  
user@host# edit firewall family family-name
```

8. Specify the filter.

```
[edit dynamic-profiles profile-name firewall family family-name]  
user@host# edit filter filter-name
```

9. Specify the interface-shared filter.

```
[edit dynamic-profiles profile-name firewall family family-name filter filter-name]  
user@host# set interface-shared
```

In the following example using an interface-shared filter, you configure a dynamic profile that is used to implement agent-circuit-identifier VLAN household filtering. If

**\$junos-input-filter** is FILTER1 and **\$junos-interface-set-name** is AC11, then a filter with the name FILTER1-AC11-in is created and attached to the demux0 unit. When a subsequent login from the same household occurs, it is in the same VLAN. If **\$junos-input-filter** is also FILTER1, the next demux0 interface also has the FILTER1-AC11-in filter attached. A low value precedence was used with the interface-shared filter. If you want to have the interface-shared filter applied first, then you must give a higher precedence to any other filters that are attached to the same interfaces.

```
[edit]  
dynamic-profile {  
  client-profile {  
    interfaces {  
      demux0 {  
        unit $junos-interface-unit {  
          family inet {  
            filter {
```

Before you begin:

- Configure the dynamic profile that you intend to use to apply the RPF check.

See [“Configuring a Basic Dynamic Profile” on page 633](#).

## Overview

Large amounts of unauthorized traffic—such as attempts to flood a network with fake service requests in a denial-of-service (DoS) attack—can consume network resources and deny service to legitimate users. One way to help prevent DoS and distributed denial-of-service (DDoS) attacks is to verify that incoming traffic originates from legitimate network sources.

Unicast RPF helps ensure that a traffic source is legitimate (authorized) by comparing the source address of each packet that arrives on an interface to the forwarding-table entry for its source address. If the router uses the same interface that the packet arrived on to reply to the packet's source, this verifies that the packet originated from an authorized source, and the router forwards the packet. If the router does not use the same interface that the packet arrived on to reply to the packet's source, the packet might have originated from an unauthorized source, and the router discards the packet, or passes it to a fail filter.

The fail filter enables you to set criteria for packets you want to be passed in spite of failing the RPF check, such as DHCP packets, which are dropped by default.

On MX Series routers, you can configure unicast RPF in a dynamic profile to apply the configuration to one or more subscriber interfaces. See [Configuring Unicast RPF](#) for more information about the behavior and limitations of unicast RPF on MX Series routers.

In this example, you configure the router to protect against potential DoS and DDoS attacks from the Internet perpetrated through IPv4 packets arriving on dynamically created VLAN demux interfaces. The dynamic profile, `vlan-demux-prof`, establishes that VLAN demux interfaces are automatically created for subscribers. Unicast RPF is enabled on the dynamic interfaces by the `rpf-check` term.

By default, unicast RPF prevents Dynamic Host Configuration Protocol (DHCP) packets from being accepted on interfaces to which it applies. When DHCP packets are discarded, no new subscribers can be created by the dynamic profile. To enable interfaces to accept DHCP packets, you must apply a fail filter that properly sorts through the packets that fail the check and identifies the DHCP packets. In this example, you configure the **`allow-dhcp`** term in the filter **`rpf-pass-dhcp`**. This term matches, counts, and accepts IPv4 packets that are destined for the DHCP port and any address. The **`default`** term drops all other packets that fail the RPF check.

This example does not show all possible configuration choices.

## Configuration

To enable unicast RPF with a fail filter in a dynamic profile, perform these tasks:

- [Configuring the Dynamic Profile to Apply RPF Checking to Dynamic VLAN Demux Interfaces on page 1163](#)
- [Configuring the RPF-Check Fail Filter on page 1164](#)

### Configuring the Dynamic Profile to Apply RPF Checking to Dynamic VLAN Demux Interfaces

#### CLI Quick Configuration

To quickly configure the dynamic profile to apply unicast RPF to dynamically created VLAN demux interfaces, copy the following commands, paste them in a text file, remove any line breaks, and then copy and paste the commands into the CLI.

```
edit dynamic-profiles vlan-demux-prof interfaces demux0
edit unit $junos-interface-unit
set demux-options underlying-interface $junos-interface-ifd-name
set vlan-id $junos-vlan-id
edit family inet
set unnumbered-address lo0.0
set rpf-check fail-filter rpf-pass-dhcp
```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [Using the CLI Editor in Configuration Mode](#).

To configure unicast RPF on the router:

1. Create a dynamic profile.  

```
[edit]
user@host# edit dynamic-profiles vlan-demux-prof
```
2. Specify that the dynamic VLAN profile use the demux interface.  

```
[edit dynamic-profiles vlan-demux-prof]
user@host# edit interfaces demux0
```
3. Specify that the dynamic profile applies the demux interface unit value to the dynamic VLANs.  

```
[edit dynamic-profiles vlan-demux-prof interfaces demux0]
user@host# edit unit $junos-interface-unit
```
4. Specify the logical underlying interface for the dynamic VLANs.  

```
[edit dynamic-profiles vlan-demux-prof interfaces demux0 unit $junos-interface-unit]
user@host# set demux-options underlying-interface $junos-interface-ifd-name
```
5. Configure the variable that results in dynamically created VLAN IDs.  

```
[edit dynamic-profiles vlan-demux-prof interfaces demux0 unit $junos-interface-unit]
user@host# set vlan-id $junos-vlan-id
```
6. Configure the IPv4 address family for the demux interfaces.  

```
[edit dynamic-profiles vlan-demux-prof interfaces demux0 unit $junos-interface-unit]
```

```
user@host# edit family inet
```

7. Configure the unnumbered address for the family.

```
[edit dynamic-profiles vlan-demux-prof interfaces demux0 unit $junos-interface-unit  
family inet]  
user@host# set unnumbered-address lo0.0
```

8. Configure unicast RPF and specify the fail filter that is applied to incoming packets that fail the check.

```
[edit dynamic-profiles vlan-demux-prof interfaces demux0 unit $junos-interface-unit  
family inet]  
user@host# set fail-filter fail-filter rpf-pass-dhcp
```

---

### Configuring the RPF-Check Fail Filter

---

**CLI Quick Configuration** To quickly configure the unicast RPF-check fail filter, copy the following commands, paste them in a text file, remove any line breaks, and then copy and paste the commands into the CLI.

```
edit firewall family inet filter rpf-pass-dhcp  
edit term allow-dhcp  
set from destination-port dhcp  
set from destination-address 255.255.255.255/32  
set then count rpf-dhcp-traffic  
set then accept  
up  
edit term default  
set then discard
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure the RPF-check fail filter:

1. Create the fail filter.

```
[edit firewall]  
user@host# edit family inet filter rpf-pass-dhcp
```

2. Define the filter term that identifies DHCP packets based on the DHCP destination port, then counts and passes the packets.

```
[edit firewall family inet filter rpf-pass-dhcp]  
user@host# edit term allow-dhcp  
user@host# set from destination-port dhcp  
user@host# set from destination-address 255.255.255.255/32  
user@host# set then count rpf-dhcp-traffic  
user@host# set then accept
```

3. Define the filter term that drops all other failed packets.

```
[edit firewall filter rpf-pass-dhcp]  
user@host# edit term default  
user@host# set then discard
```

**Results** From configuration mode, confirm the unicast RPF configuration by entering the **show dynamic-profiles** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show dynamic-profiles
vlan-demux-prof {
  interfaces {
    demux0 {
      unit "$junos-interface-unit" {
        vlan-id "$junos-vlan-id";
        demux-options {
          underlying-interface "$junos-interface-ifd-name";
        }
        family inet {
          unnumbered-address lo0.0;
          rpf-check {
            fail-filter rpf-pass-dhcp;
          }
        }
      }
    }
  }
}
```

From configuration mode, confirm the fail filter configuration by entering the **show firewall** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show firewall
family inet {
  filter rpf-pass-dhcp {
    term allow-dhcp {
      from {
        destination-address {
          255.255.255.255/32;
        }
        destination-port dhcp;
      }
      then {
        count rpf-dhcp-traffic;
        accept;
      }
    }
    term default {
      then {
        discard;
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is correct, perform these tasks:

- [Verifying That Unicast RPF Is Enabled on the Router on page 1166](#)

---

### Verifying That Unicast RPF Is Enabled on the Router

---

**Purpose** Verify that unicast RPF is enabled.

**Action** Verify that unicast RPF is enabled by using the **show subscribers extensive** command.

```
user@host> show subscribers extensive
Type: VLAN
  Logical System: default
  Routing Instance: default
  Interface: ae0.1073741824
  Interface type: Dynamic
  Dynamic Profile Name: vlan-demux-prof
  State: Active
  Session ID: 9
  VLAN Id: 100
  Login Time: 2011-08-26 08:17:00 PDT
  IPv4 rpf-check Fail Filter Name: rpf-pass-dhcp
```

**Meaning** The IPv4 rpf-check Fail Filter Name field displays **rpf-pass-dhcp**, the name of the fail filter applied by the dynamic profile for IPv4 packets failing the RPF check.

# Redirecting HTTP Requests Overview

- [Redirecting HTTP Requests Overview on page 1167](#)

## Redirecting HTTP Requests Overview

---

HTTP request traffic from subscribers is aggregated from access networks onto a Broadband Remote Access Server (B-RAS) router, where HTTP traffic can be intercepted and redirected to a captive portal. A captive portal provides authentication and authorization services for redirected subscribers before granting access to protected servers outside of a walled garden. A walled garden defines a group of servers where access is provided to subscribers without reauthorization through a captive portal. You can use a captive portal page as the initial page a subscriber sees after logging in to a subscriber session and as a page used to receive and manage HTTP requests to unauthorized Web resources.

The HTTP redirect service implements a data handler and a control handler and registers them with service rules applicable to the HTTP applications. These rules are parsed by the captive-portal-content-delivery process on the routing engine. The data handler applies the rules to HTTP data flows and handles rewriting the IP destination address or sending an HTTP 302 response with a preconfigured redirect URL. In addition, the control handler maintains a connection with the captive-portal-content-delivery process on the routing engine to learn configuration changes, such as the redirect URL and the rewrite IP destination and port pair. To achieve faster performance, the control handler maintains a cache of relevant configured entities, such as URLs on Multiservices DPC.

Packet flow differs depending on the following configurations:

- Walled garden as a service filter—HTTP traffic destined to servers within the walled garden does not flow to Multiservices DPC. However, any HTTP traffic destined outside of the walled garden flows to the Multiservices DPC.
- Walled garden as an HTTP policy term—All HTTP traffic flows to the Multiservices DPC. The HTTP service handler determines whether traffic is allowed to go to a walled garden.
- HTTP request packet—If the flow is destined to servers within the walled garden, no action is taken.

An HTTP redirect service can be attached to either a static or dynamic interface. For dynamic subscriber management, HTTP services can be attached dynamically at subscriber login or by using a change of authorization (CoA).

Redundant multiservice PIC and DPC support for HTTP redirect distributes captive portal content delivery rules to both PICs to leverage all framework support (for IPv4 only). Data traffic is sent only to the active PIC and rule processing is performed on the active PIC.

## Configuring HTTP Redirect Services

---

You can configure a walled garden with services and policies.

To configure the HTTP redirect service:

1. Configure the packet and installation.

```
[edit chassis]
fpc 1 {
  pic 0 {
    adaptive-services {
      service-package {
        extension-provider {
          control-cores 1;
          data-cores 7;
          object-cache-size 1024;
          policy-db-size 64;
          package jservices-cpcd;
          syslog {
            daemon any;
            external any;
          }
        }
      }
    }
  }
}
```

2. Configure the units and assign the VLAN IDs.

```
[edit interfaces]
ge-0/0/1 {
  vlan-tagging;
  unit 1 {
    vlan-id 100;
    family inet {
      address 100.20.1.1/24;
    }
  }
}
```

```
    }  
  }
```

3. Configure the policy options.

```
  policy-options {  
    prefix-list google {  
      74.125.19.0/24;  
    }  
  }
```

4. Configure the service options.

```
  firewall {  
    family inet {  
      service-filter walled {  
        term google {  
          from {  
            destination-prefix-list {  
              google;  
            }  
          }  
          then skip;  
        }  
        term http {  
          from {  
            destination-port [ 80 8080 443 ];  
          }  
          then service;  
        }  
        term skip {  
          then skip;  
        }  
      }  
      service-filter fromSRC {  
        term SRC {  
          from {  
            source-address {  
              10.1.2.3/32;  
            }  
            source-port 8800;  
          }  
          then service;  
        }  
        term skip {  
          then skip;  
        }  
      }  
      service-filter test {  
        term t1 {  
          from {  
            protocol icmp;  
          }  
          then service;  
        }  
      }  
    }  
  }
```

```
}
```

5. Configure the captive portal content delivery services.

```
services {
  captive-portal-content-delivery {
    rule test {
      match-direction input;
      term t1 {
        then {
          rewrite;
        }
      }
    }
    profile ipda-rewrite {
      cpcdd-rules test;
      ipda-rewrite-options {
        destination-address 10.1.2.3;
        destination-port 8800;
      }
    }
    traceoptions {
      file cpcdd;
      flag all;
    }
  }
  service-set sset1 {
    captive-portal-content-delivery-profile ipda-rewrite;
    interface-service {
      service-interface ms-1/0/0;
    }
  }
  stateful-firewall {
    rule Rule1 {
      match-direction input-output;
      term 1 {
        from {
          applications [ junos-icmp-all junos-dhcp-server junos-tftp junos-http ];
        }
        then {
          accept;
        }
      }
      term 2 {
        from {
          applications SRC;
        }
        then {
          accept;
        }
      }
    }
  }
}
```

6. Configure the applications.

```
applications {  
  application SRC {  
    protocol tcp;  
    destination-port 8800;  
  }  
}
```

## Example: Walled Garden as a Service Filter

---

Service filters are configured under the firewall and are not specific to captive portal content delivery. The following example shows a walled garden with one server, which is the captive portal:

```
[edit firewall family inet]
root@host# show
service-filter walled {
  term 1 {
    from {
      destination-address {
        100.20.2.3/32; ## this is the address of captive portal
      }
      destination-port 80;
    }
    then skip; ## skip service DPC for http traffic
    ## destined to captive portal
  }
}
```

The following example shows a walled garden within a subnet:

```
service-filter walled-net {
  term 2 {
    from {
      destination-prefix-list {
        100.20.2.0/24; ## '100.20.2.0/24' is not defined
      }
    }
    then skip;
  }
}
```

```
}  
}
```

The following example shows the configuration of an IPv6 walled garden:

```
[edit services captive-portal-content-delivery]  
rule walled-garden {  
  match-direction input-output  
  term 1 {  
    from {  
      destination-address 2001:2002:0:1::/64; ## captival portal resides here  
      destination-port 80;  
    }  
    then {  
      accept;  
    }  
  }  
}
```

---

## Example: Walled Garden as an HTTP Service Rule

HTTP service rule configuration resides under the services hierarchy and uses the captive portal and content delivery (captive-portal-content-delivery) service. The following example shows a walled garden configured as an HTTP service rule:

```
[edit services captive-portal-content-delivery]  
rule walled-garden {  
  match-direction input-output  
  term 1 {  
    from {  
      destination-address 100.20.2.3/32; ## captive portal  
      destination-port 80;  
    }  
    then {  
      accept;  
    }  
  }  
}
```

When a remote HTTP redirect server is used, you need to configure an HTTP service rule to rewrite the IP-DA of incoming HTTP requests on the service router so that the requests reach the remote HTTP redirect server before being redirected to a captive portal. If the destination port is not specified, the default behavior is determined by the rewrite configuration. If no rewrite configuration is available, the destination port is not rewritten. The following example shows a configuration for IP-DA rewrite:

```
[edit services captive-portal-content-delivery]  
rule ipda-rewrite {  
  match-direction input-output;  
  term 1 {  
    from {  
      applications junos-http;  
    }  
    then {  
      rewrite destination-address 100.20.2.10; # this is the remote
```

```

        # redirect server.
    }
}

```

## Example: HTTP Service Within a Service Set

To become part of a service set, you must configure an HTTP service rule under a service set. In the following example, you can use `http-service` as an option in the service order configuration:

```

[edit services]
service-set http-redirect-walled {
  cpcd-rules walled-garden;
  cpcd-rules redirect;
}

```

You can also put rules in a rule set and then configure the service set as in the following example:

```

[edit services]
service-set http-redirect-walled {
  cpcd-rule-sets redirect-with-walled-garden;
}

```

## Example: HTTP Service Attached to a Static Interface

The following example shows an HTTP service set attached to a static interface:

```

[edit interfaces ge-1/0/1]
root@hostr# show
unit 0 {
  family inet {
    service {
      input {
        service-set http-redirect-walled;
      }
      output {
        service-set http-redirect-walled;
      }
    }
  }
  address 10.1.3.2/24;
}

```

The following example uses a service filter as a walled garden by defining a rule named `redirect`, referencing the rule in a profile named `http-redirect`, configuring a service set named `http-redirect` that references the `http-redirect` captive portal content delivery profile, and attaching the `http-redirect` service set to static interface `ge-1/0/1.0`.

```

[edit services]
captive-portal-content-delivery {
  rule redirect {
    match-direction input;
    term t1 {

```

```
        from {
            destination-address {
                100.0.1.1/32;
            }
        }
        then {
            redirect http://www.google.com;
        }
    }
}
profile http-redirect {
    cpcd-rules redirect;
}
}
service-set http-redirect {
    captive-portal-content-delivery-profile http-redirect;
    interface-service {
        service-interface ms-1/0/0;
    }
}

[edit interfaces ge-1/0/1]
unit 0 {
    family inet {
        service {
            input {
                service-set http-redirect service-filter walled;
            }
            output {
                service-set http-redirect;
            }
        }
        address 10.1.3.2/24;
    }
}
```

The following example shows an IPv6 static service attachment:

```
[edit interfaces ge-1/0/1]
unit 0 {
    family inet6 {
        service {
            input {
                service-set http-redirect6 service-filter walled6;
            }
            output {
                service-set http-redirect6 service-filter walled6;
            }
        }
        address 2001:2002::1;
    }
}
```

This example configures the service filter for walled6:

```
firewall {
    family inet6 {
```

```

service-filter walled6 {
  term google {
    from {
      destination-prefix-list {
        google6;
      }
    }
    then skip;
  }
  term http {
    from {
      destination-port [ 80 8080 443 ];
    }
    then service;
  }
  term skip {
    then skip;
  }
}
}
}

```

### Example: HTTP Service Attached to a Dynamic Interface

A dynamic service attachment uses a dynamic profile. In the following dynamic profile example, the name of the service set can be populated dynamically for each subscriber at instantiation time. This dynamic profile encapsulates a service attachment point associated with a statically preprovisioned service set sset-1.

```

dynamic-profiles {
  profile prof-2 { # parameterized service attachment
    interfaces {
      $junos-interface-ifd-name {
        unit $junos-interface-unit {
          family inet {
            service {
              input {
                service-set $junos-service-set service-filter $junos-service-filter;
                post-input-filter $junos-post-input-filter ;
              }
              output {
                service-set $junos-service-set;
              }
            }
          }
        }
      }
    }
  }
}
}
}
}
}

```

To handle scalability more efficiently, in the following example the name of the service set can be populated dynamically for each subscriber at instantiation time.

```

dynamic-profiles {

```

```
profile prof-2 { # parameterized service attachment
  interfaces {
    $junos-interface-ifd-name {
      unit $junos-interface-unit {
        family inet {
          service {
            input {
              service-set $junos-service-set service-filter $junos-service-filter;
              post-input-filter $junos-post-input-filter ;
            }
            output {
              service-set $junos-service-set;
            }
          }
        }
      }
    }
  }
}
```

The following attaches a service set dynamically at family inet6:

```
dynamic-profiles {
  profile prof-1 {
    interfaces {
      $junos-interface-ifd-name {
        unit $junos-interface-unit {
          family inet6 {
            service {
              input {
                service-set sset-1 service-filter fltr-1;
                post-input-filter pfltr-1 ;
              }
              output {
                service-set sset-1 service-filter fltr-1;
              }
            }
          }
        }
      }
    }
  }
}
```

---

## Example: Configuring Redundant Multiservice

- [Requirements on page 1179](#)
- [Overview on page 1179](#)
- [Configuration on page 1179](#)
- [Verification on page 1180](#)

## Requirements

- Multiservices DPC PIC

## Overview

This procedure shows how to configure redundant multiservice support.

## Configuration

### Example: Configuring Redundant Multiservice for IPv4

#### Step-by-Step Procedure

1. Configure the interface:  

```
[edit interfaces]
user@host# set interface rms0
```
2. Configure the redundant multiservice service set:  

```
[edit services]
user@host# set service-interface rms0
```
3. Configure the redundant multiservice service set attachment:  

```
[edit interfaces]
user@host# set ge-1/0/0 unit 100
```

#### Results

Confirm the configuration by entering the **show redundancy-options** configuration command.

```
show redundancy-options
redundancy-options {
  primary ms-2/1/0;
  secondary ms-3/1/0;
  hot-standby;
}
unit 0 {
  family inet;
}
```

Confirm the service set configuration by entering the **show captive-portal-content-delivery-profile** configuration command.

```
show captive-portal-content-delivery-profile httpRedirect
interface-service {
  service-interface rms0;
}
```

Confirm the service set attachment by entering the **show show vlan-id** configuration command.

```
show vlan-id 100
family inet {
  service {
    input {
      service-set sset10 service-filter walled;
    }
  }
}
```

```
output {  
  service-set sset10;  
}  
}  
address 192.1.4.1/24;  
}
```

## Verification

---

### Displaying Redundant Multiservice Configuration

<b>Purpose</b>	Verify the redundant multiservice configuration.
<b>Action</b>	user@host> <b>show interfaces redundancy detail</b>
<b>Related Documentation</b>	<ul style="list-style-type: none"><li>Failover of the Control Service PICs</li></ul>

---

## Example: Configuring Destination Address Rewrite for HTTP Redirect

- [Requirements on page 1180](#)
- [Overview on page 1180](#)
- [Configuration on page 1180](#)
- [Verification on page 1181](#)

## Requirements

- Multiservices DPC PIC

## Overview

This procedure shows how to configure an DA rewrite rule. The destination port is not specified and the default behavior is determined by the rewrite configuration. If no rewrite configuration is available, the destination port is not rewritten.

## Configuration

---

### Example: Configuring a Rewrite Rule

<b>Step-by-Step Procedure</b>	<ol style="list-style-type: none"><li>1. Configure the service rule: <pre>[edit services captive-portal-content-delivery] user@host# set rule da-rewrite</pre></li><li>2. Specify the term name: <pre>[edit services captive-portal-content-delivery da-rewrite] user@host# set term t1</pre></li><li>3. Specify the match conditions for the term: <pre>[edit services captive-portal-content-delivery da-rewrite inet-filter term t1] user@host# set from applications junos-http</pre></li></ol>
-------------------------------	---

4. Specify the actions to take if the packet matches all the conditions in that term:

```
[edit services captive-portal-content-delivery da-rewrite inet-filter term t1]
user@host# set then rewrite destination-address 2001:2002::1;
```

**Results** Confirm the configuration by entering the **show services** configuration command. If the command output does not display the intended configuration, repeat the instructions in this procedure to correct the configuration.

```
[edit services captive-portal-content-delivery]
rule da-rewrite {
  match-direction input-output
  term 1 {
    from {
      applications junos-http;
    }
    then {
      rewrite destination-address 2001:2002::1; # this is the remote redirect server.
    }
  }
}
```

The following example shows the configuration for an IPv6-DA rewrite service rule. Because the destination port is not specified, the default behavior is determined by the rewrite configuration. If no rewrite configuration is available, the destination port is not rewritten.

```
[edit services captive-portal-content-delivery]
rule ipv6da-rewrite {
  match-direction input-output
  term 1 {
    from {
      applications junos-http;
    }
    then {
      rewrite destination-address 2001:2002::1; # this is the remote
      # redirect server.
    }
  }
}
```

## Verification

### Displaying HTTP Redirect configuration

**Purpose** Verify the HTTP requests are redirected to the server.

**Action** user@host> **show services detail**

# Subscriber Secure Policy Traffic Mirroring Overview

- [Subscriber Secure Policy Overview on page 1185](#)
- [Subscriber Secure Policy Licensing Requirements on page 1186](#)

## Subscriber Secure Policy Overview

---

Subscriber secure policy enables you to mirror traffic on a per-subscriber basis. You can mirror the content of subscriber traffic as well as monitor events related to the subscriber session that is being mirrored.

Subscriber secure policy mirroring can be based on information provided by either RADIUS or Dynamic Tasking Control Protocol (DTCP), and can mirror both IPv4 and IPv6 traffic. Configuration of subscriber secure policy mirroring is independent of the actual mirroring session—you can configure the mirroring parameters at any time. Also, you can use a single RADIUS or DTCP server to provision mirroring operations on multiple routers in a service provider's network. To provide security, the ability to configure, access, and view the subscriber secure policy components and configuration is restricted to authorized users.

After subscriber secure policy is triggered, both the subscriber incoming and outgoing traffic are mirrored. The original traffic is sent to its intended destination and the mirrored traffic is sent to a mediation device for analysis. The actual mirroring operation is transparent to subscribers whose traffic is being mirrored. A special UDP/IP header is prepended to each mirrored packet sent to the mediation device. The mediation device uses the header to differentiate multiple mirrored streams that arrive from different sources.

## Subscriber Secure Policy for Subscribers on VLANs

Interface-based subscriber secure policy is supported on dynamic, authenticated VLAN interfaces and VLAN demux interfaces. When you enable subscriber secure policy for these interfaces, traffic for all configured families (inet, inet6) including Layer 2 and Layer 3 control traffic is mirrored. The mirrored packets include Layer 2 encapsulations.

## Traffic Filtering For DTCP-Initiated Subscriber Secure Policy Mirrored Traffic

You can filter mirrored traffic before it is sent to a mediation device. With this feature, service providers can reduce the volume of traffic sent to a mediation device. For some types of traffic, such as IPTV or video on demand, you do not need to mirror the entire content of the traffic because the content may already be known or controlled by the service provider.

## Mirroring-Related Event Reporting

Subscriber secure policy also supports the use of SNMPv3 traps to report events related to the mirroring operation to an external device. Types of information sent in traps include identifying information for subscribers, such as username or IP address, and subscriber session events, such as login or logout events or mirroring session activation or deactivation. The traps map to messages defined in the *Lawfully Authorized Electronic Surveillance (LAES) for IP Network Access, American National Standard for Telecommunications*.

## RADIUS-Initiated Subscriber Secure Policy Overview

---

RADIUS-initiated mirroring creates secure policies based on RADIUS VSAs and uses RADIUS attributes to identify the subscriber whose traffic is to be mirrored. Mirroring is initiated without regard to the subscriber location, router, interface, or type of traffic.

The mirroring operation can be initiated by RADIUS messages as follows:

- **Subscriber login**—Mirroring starts when the subscriber logs in and the router receives the trigger in a RADIUS Access-Accept message. Using triggers in RADIUS Access-Accept messages enables you to mirror per-subscriber traffic without regard to how often the subscriber logs in or out, or which router or interface the subscriber uses.
- **In-session**—Mirroring starts when the router receives the trigger in a RADIUS change of authorization request (CoA-Request) message. Using triggers in CoA-Request messages enables you to immediately mirror traffic of a subscriber who is already logged in.

## Subscriber Secure Policy Traffic Mirroring Architecture Using RADIUS

Figure 31 on page 1188 shows the architecture of the RADIUS-initiated subscriber secure policy mirroring environment.

Figure 31: RADIUS-Initiated Subscriber Secure Policy Architecture

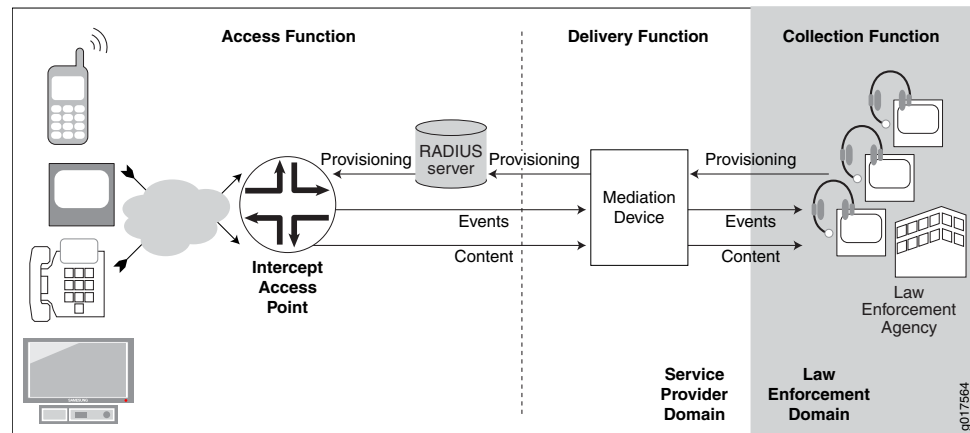

Table 104 on page 1188 describes the functions and components of a RADIUS-initiated subscriber secure policy traffic mirroring environment.

Table 104: RADIUS-Initiated Subscriber Secure Policy Functions and Components

Function or Component	Description
Collection function	<p>The collection function is responsible for collecting intercepted content and identifying information from the delivery function.</p> <p>The collection function is the responsibility of the law enforcement agency (LEA).</p>
Delivery function	<p>The delivery function delivers information that it receives from the access function to the collection function.</p> <p>The delivery function is performed by the mediation device.</p>
Access function	<p>The access function has access to the intercept target's traffic content and intercept-related events. It is responsible for collecting this information and sending it to the delivery function.</p> <p>The access function is the responsibility of intercept access points (IAPs).</p>

**Table 104: RADIUS-Initiated Subscriber Secure Policy Functions and Components** (*continued*)

Function or Component	Description
Events	Intercept-related events, such as login or logout events or mirroring session activation or deactivation. The router sends the events to the mediation device in SNMP traps.
LEA	Law enforcement agency. The LEA provides intercept targets to the service provider who provisions the mediation device.
Mediation device	<p>The mediation device receives provisioning information from the LEA, and it uses the information to send provisioning information to the RADIUS server.</p> <p>The mediation device also receives intercept-related events and intercepted content from the router, and delivers the events and intercepted content to the LEA.</p>
RADIUS server	The RADIUS server receives provisioning information from the mediation device. It identifies subscribers whose traffic is to be mirrored, and triggers mirroring sessions on the IAP (the router) by including mirroring-related RADIUS attributes and VSAs in Access-Accept or CoA-Request messages that it sends to the IAP.
IAP	<p>Intercept access point. In a subscriber access network the Juniper Networks router is the IAP.</p> <p>Using subscriber secure policies, the IAP intercepts traffic to and from the subscriber whose traffic is being mirrored. It encapsulates the intercepted content in a packet header and delivers it to the mediation device, while also sending the content to the intended destination.</p> <p>The IAP also sends intercept-related events to the mediation device using SNMP traps.</p>

## RADIUS-Initiated Traffic Mirroring Process at Subscriber Login

Figure 33 on page 1191 shows the process for a RADIUS-initiated subscriber mirroring operation that is initiated when the mirrored subscriber logs in.

**Figure 33: RADIUS-Initiated Subscriber Secure Policy Model at Login**

1— The LEA sends provisioning information for a subscriber whose traffic is to be mirrored over the HI-1 interface to the mediation device.	6— The IAP sends the original subscriber traffic to its intended destination.
2— The mediation device sends the provisioning information over the INI-1 interface to the RADIUS server.	7— As subscriber-related events occur, the IAP sends the events in SNMP traps over the INI-2 interface to the mediation device.
3— The subscriber logs in, requesting authentication by the RADIUS server.	8— The mediation device provides the events over the HI-2 interface to the LEA.
4— The RADIUS server authenticates the subscriber and sends an Access-Accept message containing mirroring-related RADIUS attributes in Juniper Networks VSAs to the IAP (the router).	9— The IAP encapsulates the mirrored content in a packet header and sends it over the INI-3 interface to the mediation device. The IAP uses the destination IP address of the mediation device that it received in the Access-Accept message from the RADIUS server.
5— The IAP creates a subscriber secure policy based on the mirroring VSAs and begins mirroring the subscriber's traffic.	10— The mediation device sends mirrored content over the HI-3 interface to the LEA.

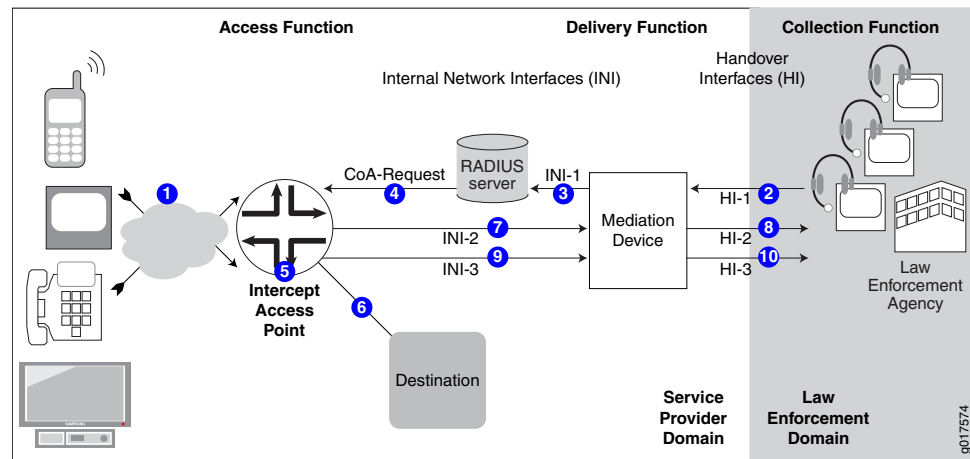

- Related Documentation**

## RADIUS-Initiated Traffic Mirroring Process for Logged-In Subscribers

Figure 34 on page 1192 shows the process for a RADIUS-initiated subscriber mirroring operation that is initiated after the subscriber has logged in.

Figure 34: RADIUS-Initiated Subscriber Secure Policy Model After Login

1— The subscriber logs in, requesting authentication by the RADIUS server. The RADIUS server authenticates the subscriber (no mirroring activity occurs).	6— The IAP sends the original subscriber traffic to its intended destination.
2— The LEA sends provisioning information for a subscriber whose traffic is to be mirrored over the HI-1 interface to the mediation device.	7— As subscriber-related events occur, the IAP sends the events in SNMP traps over the INI-2 interface to the mediation device.
3— The mediation device sends the provisioning information over the INI-1 interface to the RADIUS server.	8— The mediation device provides events over the HI-2 interface to the LEA.
4— The RADIUS server sends a CoA message containing the mirroring-related RADIUS attributes and VSAs to the IAP (the router).	9— The IAP encapsulates the mirrored subscriber content in a packet header and sends it to the mediation device over the INI-3 interface. The IAP uses the destination IP address that it received in the Access-Accept message from the RADIUS server.
5— The RADIUS CoA message initiates the mirroring operation. The IAP creates the subscriber secure policy based on the mirroring VSAs and immediately begins mirroring subscriber traffic.	10— The mediation device sends mirrored content over the HI-3 interface to the LEA.

## Subscriber Secure Policy Support for IPv4 Multicast Traffic

---

IP multicast traffic is used for applications such as audio or video streaming, IPTV, video conferencing, or online gaming. Multicast traffic is sent to multiple subscribers who have joined a multicast group.

Secure subscriber policy allows for the mirroring of IPv4 multicast traffic sent to a specific subscriber. If multiple subscribers whose traffic requires mirroring join the same multicast session, the subscriber secure policy feature mirrors each subscriber's traffic and forwards it separately to the mediation device with the proper prepended header.

Mirroring of multicast traffic is supported only for subscribers in the default logical system.

You can enable and disable the mirroring of multicast traffic on a per-chassis basis. You cannot enable or disable it on a per-subscriber basis.

### Triggering the Mirroring of IPv4 Multicast Traffic

Multicast traffic being sent towards a subscriber does not contain much of the identifying information used to trigger mirroring of a subscriber's unicast traffic. For example, the multicast packet contains the multicast group address in the destination address of the packet instead of the subscriber's IP address. It also does not contain the user name or MAC address of the subscriber, and does not include information obtained by RADIUS or DHCP. Therefore, methods of identifying multicast traffic that is received by a subscriber are not the same as methods of identifying a subscriber's unicast traffic or multicast traffic that is sent by a subscriber.

To join a multicast group, a subscriber sends an IGMP join request, and it receives a reply. The reply contains the multicast groups to which the subscriber is registered. Triggering the mirroring of multicast traffic is based on the sending of the IGMP join request and the information in the IGMP reply. If the subscriber's unicast traffic is already being mirrored either through DTCP-initiated or RADIUS-initiated traffic mirroring, and the subscriber sends an IGMP join request, mirroring of multicast traffic sent to the subscriber is initiated. The traffic being mirrored is based on the groups contained in the IGMP reply.

## RADIUS Attributes Used for Subscriber Secure Policy

Table 106 on page 1194 lists the RADIUS VSAs that are associated with subscriber secure policy. If these VSAs are present in the RADIUS Access-Accept message for a subscriber, the action specified in the LI-Action attribute takes effect.

Mirroring VSAs that the RADIUS server sends to the router are salt-encrypted. Salt encryption is a random string of data used to modify a password hash.

**Table 106: RADIUS-Based Mirroring Attributes**

Attribute Number	Attribute Name	Description	Value
[26-58]	LI-Action	Traffic mirroring action	Salt-encrypted integer <ul style="list-style-type: none"> <li>• 0 = stop mirroring</li> <li>• 1 = start mirroring</li> <li>• 2 = no action</li> </ul>
[26-59]	Med-Dev-Handle	Identifier that associates mirrored traffic with a specific subscriber  Med-Dev-Handle includes: <ul style="list-style-type: none"> <li>• Intercept-Identifier</li> <li>• Acct-Session-ID (optional)</li> </ul>	Salt-encrypted string
[26-60]	Med-Ip-Address	IP address of mediation device to which mirrored traffic is forwarded	Salt-encrypted IP address
[26-61]	Med-Port-Number	UDP port in the mediation device to which mirrored traffic is forwarded	Salt-encrypted integer

If a subscriber is already logged in, Table 107 on page 1194 lists the RADIUS attributes that can be present in RADIUS CoA messages to identify the subscriber whose traffic is to have a mirroring action applied (activation or deactivation).

**Table 107: RADIUS Attributes Used in CoA Messages to Identify Subscribers for Traffic Mirroring**

Attribute Number	Attribute Name
[1]	User-Name
[44]	Acct-Session-ID

## Triggering Subscriber Secure Policy for Subscribers on Dynamic Authenticated VLANs

**BEST PRACTICE:** When you have DHCPv4/DHCPv6 subscribers over VLANs, two sessions are created for each subscriber—one for the Layer 2 VLAN, and one for DHCP. In this case, we recommend that you use one trigger that matches both the DHCP and the VLAN session.

If authentication is performed on both the VLAN session and the DHCP session, we recommend that you use a separate, unique username for the VLAN and DHCP sessions to allow RADIUS to distinguish on which of the sessions to trigger subscriber secure policy traffic mirroring. Otherwise, when the DHCP session is authenticated and activated, traffic mirroring fails.

## Using the Packet Header to Track Subscribers on the Mediation Device

When the router sends mirrored traffic to the mediation device, it encapsulates it in a packet header. [Figure 35 on page 1195](#) is the mirrored packet header and payload that the router sends to the mediation device.

**Figure 35: Mirrored Packet Header and Payload**

[Table 108 on page 1196](#) describes the fields in the packet header of mirrored packets.

Table 108: Mirrored Packet Header and Payload Field Descriptions

Field	Value	Length (Bits)
<b>IP Header</b>		
Version	4	4
IHL	5	4
Type of Service	0	8
Total Length	Dynamically computed	16
Identification	Dynamically computed	16
Flags	Dynamically computed	3
Fragment Offset	Dynamically computed	13
Time to Live	255	8
Protocol	17	8
Header Checksum	Dynamically computed	16
Source Address	IP address of the router interface that sends mirrored traffic to the mediation device	32
Destination Address	IP address of the mediation device to which mirrored traffic is forwarded (VSA 26-60)	32
<b>UDP Header</b>		
Source Port	UDP port number on the router from which mirrored traffic is sent to the mediation device	16
Destination Port	UDP port on the mediation device to which mirrored traffic is forwarded (VSA 26-61)	16
Length	Dynamically computed	16
Checksum	0	16
<b>Mirror Header</b>		

**Table 108: Mirrored Packet Header and Payload Field Descriptions** (*continued*)

Field	Value	Length (Bits)
V (mirror header value)	0	2
Intercept ID	See "Format of the Mirror Header Values Used to Track Subscribers and Subscriber Sessions" on page 1198 for details	30
Session-ID	See "Format of the Mirror Header Values Used to Track Subscribers and Subscriber Sessions" on page 1198 for details	32

## Format of the Mirror Header Values Used to Track Subscribers and Subscriber Sessions

The packet header includes mirror header attributes that the mediation device can use to track subscribers and subscriber sessions. The router creates values for these attributes based on information that it receives from RADIUS. There are three mirror header attributes in the packet header:

- V (mirror header value)—Used by the router to specify how the values of the Session ID and Intercept ID are determined. The value received from RADIUS can be a 0 or a 1. However, the value is always 0 in the packet header sent to the mediation device.
- Session ID—Used by the mediation device to identify the session of the mirrored subscriber. The value is assigned to a subscriber session by the Junos OS. The Session ID changes with each new session for a subscriber.
- Intercept ID—Used along with the Session ID by the mediation device to track a subscriber across multiple login and logout events. The value is assigned to a subscriber whose traffic is being intercepted. The Intercept ID is constant; it does not change as a subscriber logs in and logs out of sessions.

The values of the Intercept ID and the Session ID are determined by the value that the router receives in VSA 26-59. VSA 26-59 is declared as a hexadecimal string that can be either 4 bytes or 8 bytes long. The mirror header value specifies whether a 4-byte value or an 8-byte value is used to form the Intercept ID and the Session ID.

### 4-Byte Format

The 4-byte format allows you to manually specify the Intercept ID. The Session ID value is automatically created based on the least significant 32 bits of the Acct-Session-ID (RADIUS attribute 44).

To use the 4-byte format of VSA 26-59, you configure the first two most significant bits of the VSA to a value of 1, which indicates a single word in the VSA. The remaining 30 bits of the word form the Intercept ID value.

For example, a value of 40000010 for VSA 26-59 configures the following fields in the mirror header, as shown in [Figure 36 on page 1198](#):

- V = 1
- Intercept ID = 0x10

**Figure 36: 4-Byte Format of VSA 26-59**

### 8-Byte Format

The 8-byte format of VSA 26-59 enables you to manually specify both the Session-ID value and the Intercept ID value.

To use the 8-byte format, you configure the first two most significant bits of the first word of the VSA to a value of 0, which indicates two words in the VSA. The remaining 30 bits of the first word form the Intercept ID value, and the second word is the Session-ID field. You cannot change the order of these two words.

For example, a value of 00000300000000090 in VSA 26-59 configures the following fields in the mirror header, as shown in [Figure 37 on page 1199](#):

- V = 0
- Intercept-ID = 0x300
- Session-ID = 0x90

**Figure 37: 8-Byte Format of VSA 26-59**

## Subscriber Secure Policy and L2TP LAC Subscribers

RADIUS-initiated per-subscriber traffic mirroring can be applied to subscribers whose traffic is tunneled with L2TP. Both subscriber ingress traffic (from the subscriber into the tunnel) and subscriber egress traffic (from the tunnel to the subscriber) are mirrored at the subscriber-facing ingress interface on the LAC. The ingress traffic is mirrored after PPPoE decapsulation and before L2TP encapsulation. The egress traffic is mirrored after L2TP decapsulation. The mirrored packet includes the complete HDLC frame sent to the LNS rather than only the IP datagram.

**Related Documentation**

- [Subscriber Secure Policy Overview on page 1185](#)
- [Configuring RADIUS-Initiated Subscriber Secure Policy Mirroring Overview on page 1201](#)
- [RADIUS Attributes Used for Subscriber Secure Policy on page 1194](#)

## Subscriber Secure Policy and L2TP LNS Subscribers

Dynamic Tasking Control Protocol (DTCP)-initiated and RADIUS-initiated per-subscriber traffic mirroring can be applied to Point-to-Point Protocol (PPP) subscribers whose traffic is tunneled with Layer 2 Tunneling Protocol (L2TP). At the L2TP network server (LNS), both subscriber ingress traffic (from the L2TP access concentrator, or LAC, to the LNS) and subscriber egress traffic (from the LNS to the LAC) are mirrored at the inline services (si) interface corresponding to the subscriber. Ingress traffic is mirrored after decapsulation of L2TP, HDLC, and PPP headers. The egress traffic is mirrored before the IP datagram is encapsulated. The mirrored traffic contains only the IP datagram belonging to the subscriber.

## Configuring RADIUS-Initiated Subscriber Secure Policy Mirroring Overview

---

Before you configure subscriber secure policy traffic mirroring, note the following:

- Subscriber secure policy mirroring runs on the radius-flow-tap service infrastructure. To configure the subscriber secure policy service, you must have the same privileges that are required to configure the radius-flow-tap service.
- The subscriber secure policy feature requires some system resources while mirroring, encrypting, and sending traffic to the mediation device. For example, you might elect to use a 10-Gigabit Ethernet interface for the tunnel to the mediation device if you expect the amount of traffic you plan to mirror to approach 1 Gbps of actual user data.

To configure the subscriber secure policy service:

1. Configure tunnel interfaces (vt interfaces) that are used to send mirrored content to the mediation device.  
[See “Configuring Tunnel Interfaces for Subscriber Secure Policy Mirroring” on page 1203.](#)
2. Configure radius-flow-tap service support for secure subscriber policy. This support includes optional forwarding-class information that the subscriber secure policy service uses to send mirrored traffic to the content destination device.  
[See “Configuring Support for Subscriber Secure Policy Mirroring” on page 1204.](#)
3. Configure an access profile that specifies the RADIUS-related support for subscriber secure policy on the router, including a list of one or more RADIUS authentication

servers. The router uses the list of specified servers for both authentication and dynamic request operations. You must also configure the RADIUS dynamic request feature, which provides the CoA message support used in-session traffic mirroring.

See [“Configuring RADIUS Server Support for Subscriber Secure Policy Mirroring” on page 1205](#).

4. Ensure that the following support is also configured:

- The RADIUS record of the mirrored subscriber must include the RADIUS attributes and VSAs required for subscriber secure policy mirroring. See [“RADIUS Attributes Used for Subscriber Secure Policy” on page 1194](#) for descriptions of the supported attributes used in RADIUS Accept-Accept and CoA messages.
- The mediation device must be configured to accept the mirrored content.

5. (Optional) Enable the mirroring of IPv4 multicast traffic on the router.

See [“Enabling Subscriber Secure Policy Mirroring for IPv4 Multicast Traffic” on page 1206](#).

6. (Optional) Configure SNMPv3 trap support to report mirroring-related events to the mediation device.

See [“Configuring SNMPv3 Traps for Subscriber Secure Policy Mirroring” on page 1247](#).

To terminate an active subscriber mirroring session at any time.

See [“Terminating RADIUS-Initiated Subscriber Traffic Mirroring” on page 1206](#).

## Guidelines for Configuring Subscriber Secure Policy Mirroring

The subscriber secure policy service uses the radius-flow-tap service infrastructure.

When configuring subscriber secure policy mirroring, consider the following guidelines regarding the relationship between subscriber secure policy service and the radius-flow-tap service:

- The radius-flow-tap service **[edit services radius-flow-tap]** and the flow-tap service **[edit services flow-tap]** cannot run simultaneously on the router. Therefore, flow-tap and subscriber secure policy mirroring cannot run simultaneously on the same router.
- You can configure one instance of the radius-flow-tap service on the router. Subscriber secure policy RADIUS-initiated mirroring and DTCP-initiated mirroring use the radius-flow-tap service.
- If you delete the radius-flow-tap service all subscriber secure policy mirroring stops.

---

## Configuring Tunnel Interfaces for Subscriber Secure Policy Mirroring

---

The router, acting as the IAP, uses tunnel interfaces (vt interfaces) to send mirrored traffic to the mediation device. The IAP equally distributes the mirrored traffic across the available tunnel interfaces.

Because the MX Series 3D Universal Edge Routers do not support Tunnel Services PICs, you create a pool tunnel interfaces on MX Series routers at the **[edit chassis]** hierarchy level.

You can configure up to 2048 mirrored subscriber sessions per chassis.

To configure a pool of tunnel interfaces for use by subscriber secure policy mirroring:

1. Access the chassis configuration, and specify the slot number of the DPC, MPC, or MIC.
  - On the MX80 router, the range is 0 through 1.
  - On other MX Series routers, if two System Control Boards (SCBs), are installed, the range is 0 through 11. If three SCBs are installed, the range is 0 through 5 and 7 through 11.

```
[edit chassis]
user@host# edit fpc 1
```

2. Configure the PIC number of the FPC.
  - On MX80 routers, if the FPC is 0, the PIC number can only be 0. If the FPC is 1, the PIC range is 0 through 3.
  - For all other MX Series routers, the range is 0 through 3.

```
[edit chassis fpc 1]
user@host# edit pic 1
```

3. Specify that the FPC and PIC are to be used for tunnel interfaces.

```
[edit chassis fpc 1 pic 1]
user@host# edit tunnel-services
```

4. Specify the amount of bandwidth to reserve for tunnel traffic on each Packet Forwarding Engine.
  - 1g indicates that 1 Gbps of bandwidth is reserved for tunnel traffic.
  - 10g indicates that 10 Gbps of bandwidth is reserved for tunnel traffic.

If you specify a bandwidth that is not compatible, tunnel services are not activated. For example, you cannot specify a bandwidth of 1 Gbps for a Packet Forwarding Engine on a 10-Gigabit Ethernet 4-port DPC.

```
[edit chassis fpc 1 pic 1 tunnel-services]
user@host#
user@host# set bandwidth 1g
```

5. Configure the tunnel interfaces, including the family.

To configure subscriber secure policy mirroring for IPv6 traffic, configure the tunnel interfaces for both the **inet** and **inet6** families.

```
[edit interfaces]
user@host# set vt-1/1/0 unit 0 family inet
user@host# set vt-1/1/0 unit 0 family inet6
```

## Configuring Support for Subscriber Secure Policy Mirroring

Subscriber secure policy runs on the radius-flow-tap service. This topic describes the steps to configure radius-flow-tap support for RADIUS-initiated and DTCP-initiated subscriber secure policy mirroring.

To configure the radius-flow-tap service to support subscriber secure policy mirroring:

1. Configure the flow-tap service used for subscriber secure policy mirroring.

```
[edit services]
user@host# edit radius-flow-tap
```

2. Assign the tunnel interfaces that the radius-flow-tap service uses.

```
[edit services radius-flow-tap]
user@host# set interfaces vt-1/1/0.0
```

If a currently used tunnel interface is deleted from the pool of interfaces, the active mirroring sessions are redistributed from the deleted interface to other tunnel interfaces in the pool. Also, when a new tunnel interface is added into the pool, the service adds the new interface to the list of interfaces available for new mirroring sessions or for existing sessions transferred from a failed interface.

3. Specify the source IP address that the radius-flow-tap service uses for mirroring. This address is used in the IP header prepended to mirrored packets that are sent to the content destination device.

```
[edit services radius-flow-tap]
user@host# set source-ipv4-address ipv4-address
```

4. (Optional) Specify the forwarding class that is applied to the mirrored packets sent to the mediation device.

If you do not specify a forwarding class, mirrored packets inherit the forwarding class from the original packet (which is the forwarding class set by default classification that CoS applies to the packet on the ingress interface).

```
[edit services radius-flow-tap]
user@host# set forwarding-class class-name
```

5. (Optional) Specify the lawful intercept policy that determines what traffic, if any, is not sent to the mediation device.

You can add or change a lawful intercept policy any time, but a changed policy does not apply to a currently enabled policy. To change a policy, add a policy with a new name, use DTCP DISABLE to turn off the current policy, and use DTCP ENABLE to point to the new policy name.

```
[edit services radius-flow-tap]
user@host# set policy policy-name
```

## Configuring RADIUS Server Support for Subscriber Secure Policy Mirroring

This topic describes how to configure support for the RADIUS server that initiates subscriber-based traffic mirroring. You create an access profile to specify the RADIUS server support.

To configure the router's interaction with the RADIUS server in support of subscriber secure policy mirroring:

1. Create the access profile and assign a name.

```
[edit access]
user@host# edit profile profile-name
```

2. Specify RADIUS as the authentication method.

```
[edit access profile profile-name]
user@host# set authentication-order radius
```

3. Specify the IP address of the RADIUS server that performs authentication. This server also performs dynamic request (CoA) functions.

```
[edit access profile profile-name]
user@host# set radius authentication-server ip-address
```

4. Specify the secret to use when communicating with the RADIUS server.

```
[edit access profile profile-name]
user@host# set radius-server server-address secret password
```

5. Specify other optional RADIUS configuration settings as needed, such as accounting support.

## Enabling Subscriber Secure Policy Mirroring for IPv4 Multicast Traffic

---

This topic describes the steps to enable subscriber secure policy mirroring of IPv4 multicast traffic. You can enable and disable IPv4 multicast intercept on a per chassis basis.

To configure the radius-flow-tap service to support subscriber secure policy mirroring:

1. Configure the flow-tap service used for subscriber secure policy mirroring.

```
[edit services]
user@host# edit radius-flow-tap
```

2. Enable the interception of multicast traffic.

```
[edit services radius-flow-tap]
user@host# set multicast-interception
```

---

## Terminating RADIUS-Initiated Subscriber Traffic Mirroring

---

You can terminate RADIUS-initiated traffic mirroring sessions by the following action:

- RADIUS CoA message receipt—Terminated upon receipt of a CoA message with the VSA 26-58 (LI-Action) value of 0. The RADIUS administrator configures the LI-Action of 0 in the mirrored subscriber's RADIUS record.

## DTCP-Initiated Subscriber Secure Policy Overview

---

Dynamic Tasking Control Protocol (DTCP)-initiated mirroring creates secure policies to mirror traffic for the subscriber based on DTCP messages. The attributes in a DTCP ADD message trigger the router to start mirroring traffic and specify the interface on which the mirroring takes place. The mirroring operations can be initiated by DTCP messages as follows:

- **Subscriber login**—Mirroring starts on the specified interface when the subscriber logs in. The DTCP ADD message must be sent to the router before the subscriber logs in.
- **In-session**—Mirroring starts for all subscribers that match the trigger supplied in the DTCP ADD message when the router receives a DTCP ADD message.

## Subscriber Secure Policy Traffic Mirroring Architecture Using DTCP

---

[Figure 38 on page 1208](#) shows the architecture of the DTCP-initiated subscriber secure policy mirroring environment.

Figure 38: DTCP-Initiated Subscriber Secure Policy Architecture

Table 109 on page 1208 describes the functions and components of a DTCP-initiated subscriber secure policy traffic mirroring environment.

**Table 109: DTCP-Initiated Subscriber Secure Policy Functions and Components**

Function or Component	Description
Collection function	<p>The collection function is responsible for collecting intercepted content and identifying information from the delivery function.</p> <p>The collection function is the responsibility of the law-enforcement agency (LEA).</p>
Delivery function	<p>The delivery function delivers information that it receives from the access function to the collection function.</p> <p>The delivery function is performed by the mediation device.</p>
Access function	<p>The access function has access to the intercept target's traffic content and intercept-related events. It is responsible for collecting this information and sending it to the delivery function.</p> <p>The access function is performed by intercept access points (IAPs).</p>
Events	Intercept-related events, such as login or logout events or mirroring session activation or deactivation. The router sends the events to the mediation device in SNMP traps.
LEA	Law enforcement agency. The LEA provides intercept targets to the service provider who provisions the mediation device.

**Table 109: DTCP-Initiated Subscriber Secure Policy Functions and Components** (*continued*)

Function or Component	Description
Mediation device	<p>The mediation device receives provisioning information from the LEA, and it uses the information to send provisioning information to the IAP (the router).</p> <p>The mediation device also receives intercept-related events and intercepted content from the router, and delivers the events and content to the LEA.</p>
IAP	<p>Intercept access point. In a subscriber access network the Juniper Networks router is the IAP.</p> <p>Using subscriber secure policies, the IAP intercepts traffic to and from the subscriber whose traffic is being mirrored. It encapsulates the intercepted content in a packet header and delivers it to the mediation device, while also sending the traffic to the intended destination.</p> <p>The IAP also sends intercept-related events to the mediation device using SNMP traps.</p>

## Subscriber Secure Policy Support for IPv4 Multicast Traffic

---

IP multicast traffic is used for applications such as audio or video streaming, IPTV, video conferencing, or online gaming. Multicast traffic is sent to multiple subscribers who have joined a multicast group.

Secure subscriber policy allows for the mirroring of IPv4 multicast traffic sent to a specific subscriber. If multiple subscribers whose traffic requires mirroring join the same multicast session, the subscriber secure policy feature mirrors each subscriber's traffic and forwards it separately to the mediation device with the proper prepended header.

Mirroring of multicast traffic is supported only for subscribers in the default logical system.

You can enable and disable the mirroring of multicast traffic on a per-chassis basis. You cannot enable or disable it on a per-subscriber basis.

### Triggering the Mirroring of IPv4 Multicast Traffic

Multicast traffic being sent towards a subscriber does not contain much of the identifying information used to trigger mirroring of a subscriber's unicast traffic. For example, the multicast packet contains the multicast group address in the destination address of the packet instead of the subscriber's IP address. It also does not contain the user name or MAC address of the subscriber, and does not include information obtained by RADIUS or DHCP. Therefore, methods of identifying multicast traffic that is received by a subscriber are not the same as methods of identifying a subscriber's unicast traffic or multicast traffic that is sent by a subscriber.

To join a multicast group, a subscriber sends an IGMP join request, and it receives a reply. The reply contains the multicast groups to which the subscriber is registered. Triggering the mirroring of multicast traffic is based on the sending of the IGMP join request and the information in the IGMP reply. If the subscriber's unicast traffic is already being mirrored either through DTCP-initiated or RADIUS-initiated traffic mirroring, and the subscriber sends an IGMP join request, mirroring of multicast traffic sent to the subscriber is initiated. The traffic being mirrored is based on the groups contained in the IGMP reply.

**Related Documentation**

- [Enabling Subscriber Secure Policy Mirroring for IPv4 Multicast Traffic on page 1206](#)

## Subscriber Secure Policy and L2TP LNS Subscribers

---

Dynamic Tasking Control Protocol (DTCP)-initiated and RADIUS-initiated per-subscriber traffic mirroring can be applied to Point-to-Point Protocol (PPP) subscribers whose traffic is tunneled with Layer 2 Tunneling Protocol (L2TP). At the L2TP network server (LNS), both subscriber ingress traffic (from the L2TP access concentrator, or LAC, to the LNS) and subscriber egress traffic (from the LNS to the LAC) are mirrored at the inline services (si) interface corresponding to the subscriber. Ingress traffic is mirrored after decapsulation of L2TP, HDLC, and PPP headers. The egress traffic is mirrored before the IP datagram is encapsulated. The mirrored traffic contains only the IP datagram belonging to the subscriber.

## DTCP Messages Used for Subscriber Secure Policy

---

You can use DTCP to provision traffic mirroring on the router by sending DTCP messages from the mediation device to the router.

There are three types of DTCP messages:

- **ADD**—Triggers mirroring of subscriber secure policy sessions. You include an attribute that triggers the router to begin mirroring a subscriber session. You can also include attributes that identify where to send the mirrored session data and how to uniquely identify traffic when simultaneous intercepts are active. The ADD message also provides instructions to populate fields in the encapsulation header for packets sent to the mediation device.
- **LIST**—Requests information about sessions that are currently being mirrored. This information is returned in a LIST response.
- **DELETE**—Removes a subscriber mirroring trigger or can be used to disable all mirroring.

- Related Documentation**

  - [DELETE DTCP on page 1235](#)
  - [LIST DTCP on page 1239](#)

## DTCP Traffic Mirroring Triggers

---

[Table 111 on page 1214](#) lists the DTCP attributes that you can use in DTCP ADD messages to trigger traffic mirroring.

Table 111: DTCP Mirroring Triggers for Use in ADD Messages

Attribute Name	DTCP Message Semantic	Description
Account Session ID	X-Act-Sess-Id	<p>Trigger that is based on the text string of the Account Session ID associated with the subscriber session.</p> <p>If the subscriber logs out, the intercept terminates. We recommend that you use other triggers to ensure that all sessions for a subscriber are intercepted.</p>
Calling Station ID	X-Call-Sta-Id	<p>Trigger that is based on the text string of the Calling Station ID associated with the subscriber.</p> <p>If the subscriber is not logged on, the policy is applied at any current or subsequent subscriber log in.</p>
Drop Policy Name	X-Drop-Policy	<p>Trigger that is based on the name of the configured lawful intercept policy.</p>
IP Address	X-IP-Addr	<p>Trigger for the IPv4 address that is associated with a subscriber.</p> <p>If you use the IP Address trigger, and the subscriber is not using the default logical system, you must include the Logical System attribute in your DTCP message. If the subscriber is not using the default routing instance, you must include the Routing Instance attribute in your DTCP message.</p>
Interface Identifier	X-Interface-Id	<p>Trigger for subscribers that are configured to use a specific router interface. All subscribers that use the interface have their traffic mirrored.</p> <p>Add this attribute as a text string that identifies the physical interface; for example, <b>ge-0/0/0.1</b> or <b>demux0.107472834</b>.</p>

Table 111: DTCP Mirroring Triggers for Use in ADD Messages (*continued*)

Attribute Name	DTCP Message Semantic	Description
NAS Port ID	X-NAS-Port-Id	Trigger that is based on the NAS port ID of the subscriber.
Remote Circuit ID	X-RM-Circuit-Id	<p>For DHCP subscribers, trigger that is used with the Remote Agent ID to specify the DHCP option 82 that is associated with this session to completely specify a trigger.</p> <p>For PPPoE subscribers, agent circuit ID (ACI) in the PPPoE Intermediate Agent (PPPoE IA) tag.</p>
Remote Agent ID	X-RM-Agent-Id	<p>For DHCP subscribers, trigger that is used with the Remote Circuit ID to specify the session or by itself to completely specify the trigger.</p> <p>For PPPoE subscribers, agent remote identifier (ARI) in the PPPoE Intermediate Agent (PPPoE IA) tag.</p>
Logical System	X-Logical-System	<p>Trigger attribute that you can use with the IP Address or Subscriber User Name triggers. It is ignored for other triggers.</p> <p>The value <b>default</b> is used if no logical system exists for the subscriber.</p>
Routing Instance	X-Router-Instance	<p>Trigger attribute that you can use with the IP Address or Subscriber User Name triggers. It is ignored for other triggers.</p> <p>The value <b>default</b> is used if no routing instance exists for the subscriber.</p>

Table 111: DTCP Mirroring Triggers for Use in ADD Messages (*continued*)

Attribute Name	DTCP Message Semantic	Description
Subscriber User Name	X-UserName	<p>Trigger based on a subscriber username.</p> <p>If you use the Subscriber User Name trigger, and the subscriber is not using the default logical system, you must include the Logical System attribute in your DTCP message. If the subscriber is not using the default routing instance, you must include the Routing Instance attribute in your DTCP message.</p>

## Triggering Subscriber Secure Policy for Subscribers on Dynamic Authenticated VLANs

**BEST PRACTICE:** When you have DHCPv4/DHCPv6 subscribers over VLANs, two sessions are created for each subscriber—one for the Layer 2 VLAN, and one for DHCP. In this case do not use a trigger, such as Remote Circuit ID (ACI), that applies to both the VLAN and the DHCP sessions. If the DHCP and VLAN sessions match the same trigger, the DHCP subscriber login fails and subscriber secure policy is not triggered. You need to select a traffic mirroring trigger that matches only one of these sessions.

## Order in Which Trigger Attributes Are Processed

If a subscriber matches more than one of the DTCP mirroring triggers, the router processes mirroring triggers in ADD messages in the following order:

1. Account Session ID
2. Calling Station ID
3. IP Address
4. Interface Identifier
5. NAS Port ID
6. Remote Agent ID
7. Subscriber User Name
8. Drop Policy Name

## Packet Header for Mirrored Traffic Sent to Mediation Device

When the router sends mirrored traffic to the mediation device, it encapsulates the mirrored payload in a packet header before it sends the mirrored traffic to the mediation device.

Figure 41 on page 1218 is the mirrored packet header that the router sends to the mediation device.

**Figure 41: Mirrored Packet Header**

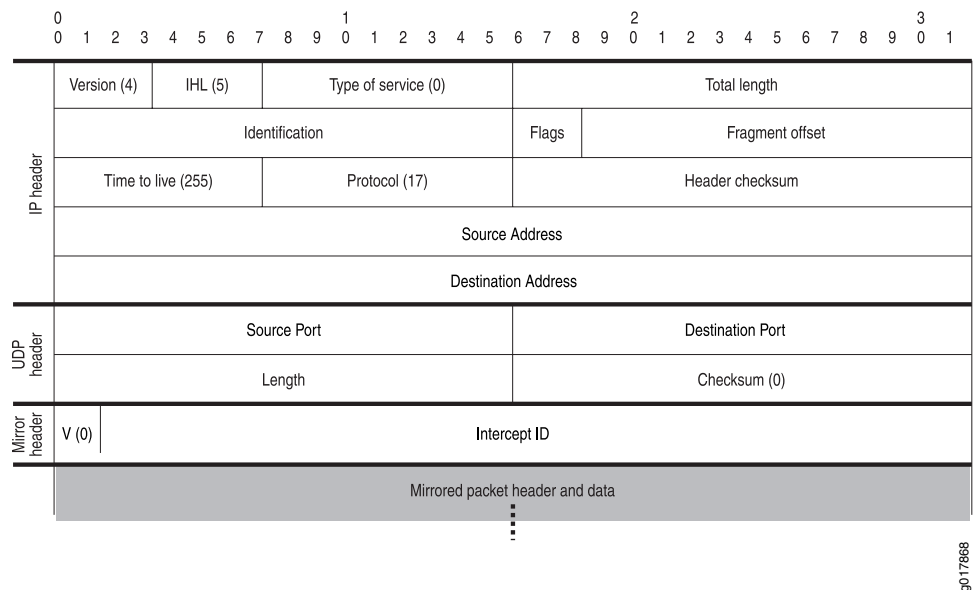

Table 112 on page 1218 describes the fields in the packet header of mirrored packets.

**Table 112: Mirrored Packet Header and Payload Field Descriptions**

Field	Value	Length (Bits)
<b>IP Header</b>		
Version	4	4
IHL	5	4
Type of Service	0	8
Total Length	Dynamically computed	16
Identification	Dynamically computed	16
Flags	Dynamically computed	3
Fragment Offset	Dynamically computed	13

**Table 112: Mirrored Packet Header and Payload Field Descriptions** (*continued*)

Field	Value	Length (Bits)
Time to Live	255	8
Protocol	17	8
Header Checksum	Dynamically computed	16
Source Address	IP address of the router interface that sends mirrored traffic to the mediation device	32
Destination Address	IP address of the mediation device to which mirrored traffic is forwarded. This value is taken from the X-JTap-Cdest-Dest-Address attribute that is sent to the router in the DTCP ADD command.	32
<b>UDP Header</b>		
Source Port	UDP port number on the router from which mirrored traffic is sent to the mediation device	16
Destination Port	UDP port on the mediation device to which mirrored traffic is forwarded. This value is taken from the X-JTap-Cdest-Dest-Port attribute that is sent to the router in the DTCP ADD command.	16
Length	Dynamically computed	16
Checksum	0	16
<b>Mirror Header</b>		
V (mirror header value)	0	2
Intercept ID	Value of the X-MD-Intercept-Id that is sent to the router in the DTCP ADD command.	30

## Configuring DTCP-Initiated Subscriber Secure Policy Mirroring Overview

---

Before you configure subscriber secure policy traffic mirroring, note the following:

- Subscriber secure policy mirroring runs on the radius-flow-tap service infrastructure. To configure the subscriber secure policy service, you need the same privileges that are required to configure the radius-flow-tap service.
- The subscriber secure policy feature requires some system resources while mirroring, encrypting, and sending traffic to the mediation device. For example, you might elect to use a 10-Gigabit Ethernet interface for the tunnel and mediation device if you expect the amount of traffic you plan to mirror to approach 1 Gbps of actual user data.

To configure DTCP-initiated subscriber secure policy service:

1. Configure tunnel interfaces that are used to send mirrored content to the mediation device.  
  
[See “Configuring Tunnel Interfaces for Subscriber Secure Policy Mirroring” on page 1203.](#)
2. Configure the radius-flow-tap service support for secure subscriber policy. This support includes configuring the tunnels and optional forwarding-class information that the

subscriber secure policy service uses to send mirrored traffic to the content destination device.

See [“Configuring Support for Subscriber Secure Policy Mirroring” on page 1204](#).

3. Configure the mediation device as a user on the router. This user account allows the router to receive DTCP messages from the mediation device.

See [“Configuring the Mediation Device as a User on the Router” on page 1227](#).

4. Configure the mediation device to provision traffic mirroring on the router.

See [“Configuring the Mediation Device to Provision Traffic Mirroring” on page 1228](#).

5. Configure a DTCP-over-SSH connection to the mediation device.

See [“Configuring a DTCP-over-SSH Connection to the Mediation Device” on page 1228](#).

6. (Optional) Enable mirroring of IPv4 multicast traffic on the router.

See [“Enabling Subscriber Secure Policy Mirroring for IPv4 Multicast Traffic” on page 1206](#)

7. Configure SNMPv3 trap support to report mirroring information to an external device.

See [“Configuring SNMPv3 Traps for Subscriber Secure Policy Mirroring” on page 1247](#).

You can terminate an active subscriber mirroring session at any time.

See [“Terminating DTCP-Initiated Subscriber Traffic Mirroring Sessions” on page 1229](#).

**Related  
Documentation**

- [DTCP-Initiated Subscriber Secure Policy Overview on page 1207](#)
- [Intercept-Related Events Transmitted to the Mediation Device on page 1245](#)

---

## Guidelines for Configuring Subscriber Secure Policy Mirroring

---

The subscriber secure policy service uses the radius-flow-tap service infrastructure.

When configuring subscriber secure policy mirroring, consider the following guidelines regarding the relationship between subscriber secure policy service and the radius-flow-tap service:

- The radius-flow-tap service [**edit services radius-flow-tap**] and the flow-tap service [**edit services flow-tap**] cannot run simultaneously on the router. Therefore, flow-tap and subscriber secure policy mirroring cannot run simultaneously on the same router.
- You can configure one instance of the radius-flow-tap service on the router. Subscriber secure policy RADIUS-initiated mirroring and DTCP-initiated mirroring use the radius-flow-tap service.
- If you delete the radius-flow-tap service all subscriber secure policy mirroring stops.

**Related  
Documentation**

- [Subscriber Secure Policy Overview on page 1185](#)
- [Configuring RADIUS-Initiated Subscriber Secure Policy Mirroring Overview on page 1201](#)
- [Configuring DTCP-Initiated Subscriber Secure Policy Mirroring Overview on page 1221](#)

- [Configuring Support for Subscriber Secure Policy Mirroring on page 1204](#)

## Configuring Tunnel Interfaces for Subscriber Secure Policy Mirroring

The router, acting as the IAP, uses tunnel interfaces (vt interfaces) to send mirrored traffic to the mediation device. The IAP equally distributes the mirrored traffic across the available tunnel interfaces.

Because the MX Series 3D Universal Edge Routers do not support Tunnel Services PICs, you create a pool tunnel interfaces on MX Series routers at the **[edit chassis]** hierarchy level.

You can configure up to 2048 mirrored subscriber sessions per chassis.

To configure a pool of tunnel interfaces for use by subscriber secure policy mirroring:

1. Access the chassis configuration, and specify the slot number of the DPC, MPC, or MIC.
  - On the MX80 router, the range is 0 through 1.
  - On other MX Series routers, if two System Control Boards (SCBs), are installed, the range is 0 through 11. If three SCBs are installed, the range is 0 through 5 and 7 through 11.

```
[edit chassis]
user@host# edit fpc 1
```

2. Configure the PIC number of the FPC.
  - On MX80 routers, if the FPC is 0, the PIC number can only be 0. If the FPC is 1, the PIC range is 0 through 3.
  - For all other MX Series routers, the range is 0 through 3.

```
[edit chassis fpc 1]
user@host# edit pic 1
```

3. Specify that the FPC and PIC are to be used for tunnel interfaces.

```
[edit chassis fpc 1 pic 1]
user@host# edit tunnel-services
```

4. Specify the amount of bandwidth to reserve for tunnel traffic on each Packet Forwarding Engine.
  - 1g indicates that 1 Gbps of bandwidth is reserved for tunnel traffic.
  - 10g indicates that 10 Gbps of bandwidth is reserved for tunnel traffic.

If you specify a bandwidth that is not compatible, tunnel services are not activated. For example, you cannot specify a bandwidth of 1 Gbps for a Packet Forwarding Engine on a 10-Gigabit Ethernet 4-port DPC.

```
[edit chassis fpc 1 pic 1 tunnel-services]
user@host#
```

```
user@host# set bandwidth 1g
```

5. Configure the tunnel interfaces, including the family.

To configure subscriber secure policy mirroring for IPv6 traffic, configure the tunnel interfaces for both the **inet** and **inet6** families.

```
[edit interfaces]
user@host# set vt-1/1/0 unit 0 family inet
user@host# set vt-1/1/0 unit 0 family inet6
```

## Configuring Support for Subscriber Secure Policy Mirroring

Subscriber secure policy runs on the radius-flow-tap service. This topic describes the steps to configure radius-flow-tap support for RADIUS-initiated and DTCP-initiated subscriber secure policy mirroring.

To configure the radius-flow-tap service to support subscriber secure policy mirroring:

1. Configure the flow-tap service used for subscriber secure policy mirroring.

```
[edit services]
user@host# edit radius-flow-tap
```

2. Assign the tunnel interfaces that the radius-flow-tap service uses.

```
[edit services radius-flow-tap]
user@host# set interfaces vt-1/1/0.0
```

If a currently used tunnel interface is deleted from the pool of interfaces, the active mirroring sessions are redistributed from the deleted interface to other tunnel interfaces in the pool. Also, when a new tunnel interface is added into the pool, the service adds the new interface to the list of interfaces available for new mirroring sessions or for existing sessions transferred from a failed interface.

3. Specify the source IP address that the radius-flow-tap service uses for mirroring. This address is used in the IP header prepended to mirrored packets that are sent to the content destination device.

```
[edit services radius-flow-tap]
user@host# set source-ipv4-address ipv4-address
```

4. (Optional) Specify the forwarding class that is applied to the mirrored packets sent to the mediation device.

If you do not specify a forwarding class, mirrored packets inherit the forwarding class from the original packet (which is the forwarding class set by default classification that CoS applies to the packet on the ingress interface).

```
[edit services radius-flow-tap]
user@host# set forwarding-class class-name
```

5. (Optional) Specify the lawful intercept policy that determines what traffic, if any, is not sent to the mediation device.

You can add or change a lawful intercept policy any time, but a changed policy does not apply to a currently enabled policy. To change a policy, add a policy with a new name, use DTCP DISABLE to turn off the current policy, and use DTCP ENABLE to point to the new policy name.

```
[edit services radius-flow-tap]
user@host# set policy policy-name
```

## Example: Configuring Traffic That Is Mirrored Using DTCP-Initiated Subscriber Secure Policy

---

This example shows how to configure traffic that is mirrored using DTCP-initiated subscriber secure policy.

- [Requirements on page 1225](#)
- [Overview on page 1225](#)
- [Configuration on page 1226](#)

### Requirements

- Juniper Networks MX Series routers.
- Junos OS Release 12.3R1 or later.

### Overview

This example drops all video on demand TCP traffic from subnet 10.0.0.0/8 to any subscriber on which the policy named vod is enabled.

To configure traffic mirroring using DTCP-initiated subscriber secure policy:

1. Create a policy.
2. Set up the policy to filter IPv4 or IPv6 traffic by source or destination address, or port, protocol, or DSCP value.
3. Apply the policy using the DTCP attribute X-Drop-Policy.
4. Use the X-Drop-Policy with the ADD DTCP command to begin filtering traffic when mirroring is triggered.

**NOTE:** To begin filtering traffic that is currently being mirrored, use the X-Drop-Policy attribute with the new ENABLE DTCP command. To stop filtering traffic that is currently being mirrored, use the X-Drop-Policy attribute with the new DISABLE DTCP command.

## Configuration

### Step-by-Step Procedure

To configure filtering mirrored traffic before it is sent to a mediation device:

1. Specify that you want to configure radius-flow-tap.  

```
[edit services]
user@host# edit radius-flow-tap
```
2. Specify that you want to configure a video on demand policy.  

```
[edit services radius-flow-tap]
user@host# edit policy vod
```
3. Specify inet as the family that you want to use.  

```
[edit services radius-flow-tap vod]
user@host# edit inet
```
4. Specify t1 as the term name for the IPv4 drop-policy.  

```
[edit services radius-flow-tap vod inet]
user@host# edit drop-policy t1
```
5. Specify the source address for the drop-policy.  

```
[edit services radius-flow-tap vod inet drop-policy t1]
user@host# edit source-address 10.0.0.0/8
```
6. Specify the match criteria that you want to use.  

```
[edit services radius-flow-tap vod inet drop-policy t1]
user@host# set protocol tcp
```

**Results** From configuration mode, confirm your configuration by entering the **show services** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit services radius-flow-tap policy]
vod {
  inet {
    drop-policy t1 {
      from {
        source-address {
          10.0.0.0/8;
        }
        protocol tcp;
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Configuring the Mediation Device as a User on the Router

In order for the router to receive DTCP messages from the mediation device, you need to configure the mediation device as a user on the router. To do so, create a login class that provides flow-tap operation permission and then create a login account that uses the login class.

To configure the mediation device as a user on the router:

1. Create the login class and configure **flow-tap-operation** permissions for the class.

- a. Specify that you want to configure login properties.

```
[edit system]
user@host# edit login
```

- b. Create and name the class.

```
[edit system login]
user@host# edit class class-name
```

- c. Configure the **flow-tap-operation** permission for the class.

```
[edit system login class class-name]
user@host# set permissions flow-tap-operation
```

2. Create the user login account for the mediation device.

- a. Create the user account.

```
[edit system login]
user@host# edit user username
```

- b. Configure the user ID.

```
[edit system login user username]
user@host# set uid uid-value
```

- c. Configure the class for the user account.

```
[edit system login user username]
user@host# set class class-name
```

- d. Configure the authentication for the user account.

```
[edit system login user username]
user@host# set authentication encrypted-password password
```

## Configuring a DTCP-over-SSH Connection to the Mediation Device

---

DTCP-initiated subscriber secure policy requires a DTCP-over-SSH connection for the flow-tap service. This connection is used to send provisioning information from the mediation device to the router.

To enable the DTCP-over-SSH flow-tap service to support subscriber secure policy mirroring:

1. Access the **flow-tap-dtcp** service.

```
[edit system services]
user@host# edit flow-tap-dtcp
```

2. Enable SSH support for DTCP.

```
[edit system services flow-tap-dtcp]
user@host# set ssh
```

3. (Optional) Configure maximum number of established connections allowed for the DTCP service.

```
[edit system services flow-tap-service ssh]
user@host# set connection-limit limit
```

4. (Optional) Configure the maximum number of connection attempts allowed per minute for DTCP.

```
[edit system services flow-tap-service ssh]
user@host# set rate-limit limit
```

## Configuring the Mediation Device to Provision Traffic Mirroring

---

To set up the mediation device to provision traffic mirroring on the router, use the following DTCP messages:

- To configure traffic-mirroring triggers, use the **ADD DTCP** message.
- To remove an existing traffic-mirroring trigger, use the **DELETE DTCP** message.
- To show existing traffic-mirroring triggers, use the **LIST DTCP** message.

For an example of how to use the DTCP messages, see “[Example: Using DTCP Messages to Trigger, Verify, and Disable Traffic Mirroring for Subscribers](#)” on page 1240.

## Enabling Subscriber Secure Policy Mirroring for IPv4 Multicast Traffic

---

This topic describes the steps to enable subscriber secure policy mirroring of IPv4 multicast traffic. You can enable and disable IPv4 multicast intercept on a per chassis basis.

To configure the radius-flow-tap service to support subscriber secure policy mirroring:

1. Configure the flow-tap service used for subscriber secure policy mirroring.

```
[edit services]
user@host# edit radius-flow-tap
```

2. Enable the interception of multicast traffic.

```
[edit services radius-flow-tap]
user@host# set multicast-interception
```

## Terminating DTCP-Initiated Subscriber Traffic Mirroring Sessions

---

You can terminate DTCP-initiated traffic mirroring sessions by the following action:

- DTCP DELETE message receipt—Terminated upon receipt of a DTCP DELETE message. The DTCP administrator configures the DELETE message to include the same mirroring attributes that are used in the ADD message to initiate mirroring.

## CHAPTER 77

# DTCP Messages Used for DTCP-Initiated Subscriber Secure Policy Mirroring

- Example: Using DTCP Messages to Trigger, Verify, and Disable Traffic Mirroring for Subscribers on page 1240

## ADD DTCP

---

**Syntax**    **ADD DTCP/0.7**  
              **Csource-ID:** *user-name*  
              **Cdest-ID:** *variable*  
              **Priority:** *priority-number*  
              **X-Drop-Policy:** *policy-name*  
              **X-JTap-Cdest-Dest-Address:** *ipv4-address*  
              **X-JTap-Cdest-Dest-Port:** *udp-port*  
              **X-JTap-Cdest-Source-Address:** *ipv4-address*  
              **X-JTap-Cdest-Source-Port:** *port-number*  
              **X-JTap-Cdest-TTL:** *time-to-live*  
              **X-MD-Intercept-Id:** *8-byte-id*  
              **Dtcp-trigger:** *trigger-value*  
              **Dtcp-attribute:** *attribute-value*  
              **Flags:** *flag*  
              **Seq:** *sequence-number*  
              **Authentication-Info:** *ssh-authentication-string*

**Description**    Specify the DTCP attributes used in ADD messages to cause the router to trigger traffic mirroring and provide instructions to populate fields in the encapsulation header for packets sent to the mediation device.

The DTCP ADD message can be sent either before or after subscribers log in through the interface.

The following attributes are added to the packet header of mirrored packets that the router sends to the mediation device. These attributes are required in the DTCP ADD message.

- **X-JTap-Cdest-Dest-Address**
- **X-JTap-Cdest-Dest-Port**
- **X-MD-Intercept-Id**

**Options**        **Csource-ID:** *user-name*—Username on the router. This username must be configured as a DTCP user on the router using the **set system login class** or **set system login user** statements.

**Cdest-ID:** *variable*—ID of the mediation device.

**Flags:** *flag*—STATIC is the only flag supported.

**Priority:** *priority-number*—This implementation of DTCP does not use the priority number.

**X-Drop-Policy** *policy-name*—Name of the policy used to determine which mirrored packets are no longer sent to the mediation device.

**X-JTap-Cdest-Dest-Address:** *ipv4-address*—Destination IPv4 address of the mediation device to which intercepted packets are sent. You must include this attribute in your ADD messages.. It is used in the header of mirrored traffic that is sent to the mediation device.

**X-JTap-Cdest-Dest-Port:** *udp-port*—Destination port of the mediation device to which intercepted packets are sent. You must include this attribute in your ADD messages. It is used in the header of mirrored traffic that is sent to the mediation device.

**X-JTap-Cdest-Source-Address:** *ipv4-address*—Source IPv4 address. You must include this attribute in your ADD messages. If the value entered does not match the value configured on the router using the **set services radius-flow-tap source-ipv4-address source-ipv4-address** statement, it is replaced by configured value.

**X-JTap-Cdest-Source-Port:** *port-number*—Source port. You must include this attribute in your ADD messages. If the value entered does not match the value of X-Jtap-Cdest-Dest-Port, it is ignored.

**X-JTap-Cdest-TTL:** *time-to-live*—TTL value to be used in the forwarded packet.

**X-MD-Intercept-Id 8-byte-id**—An Id that is used to identify a subscriber. You must include this attribute in your ADD messages. This ID is used in the header of mirrored traffic that is sent to the mediation device to allow the device to track a subscriber. The X-MD-Intercept-ID attribute must consist of 8-bytes, and the first two bits must be 00.

**Dtcp-trigger:** *trigger-value*—DTCP attribute used to trigger traffic mirroring. [“DTCP Traffic Mirroring Triggers” on page 1213](#) lists the DTCP attributes that you can use in DTCP ADD messages to trigger traffic mirroring.

**Dtcp-attribute:** *attribute-value*—DTCP attribute included in the ADD messages. [“DTCP Traffic Mirroring Triggers” on page 1213](#) lists the DTCP attributes that you can use in ADD messages.

**Seq:** *sequence-number*—Number added by the mediation device. DTCP messages contain a monotonically increasing sequence number for each successive message.

**Authentication-Info:** *ssh-authentication-string*—String used when you are using SSH to connect to the router.

**Required Privilege Level**

Not applicable.

## Example: Using DTCP Messages to Trigger, Verify, and Disable Traffic Mirroring for Subscribers

---

This example shows how to create DTCP messages to do the following:

- Trigger traffic mirroring for two subscribers based on interface ID.
- Trigger a drop policy if one does not already exist.
- Remove an existing drop policy.
- Verify that subscriber traffic on the two interfaces is being mirrored.
- Disable traffic mirroring on the two subscriber interfaces.
- Verify that traffic mirroring was stopped on the two subscriber interfaces.

In this example, SSH is being used to communicate with the router.

## Creating DTCP ADD Messages to Trigger Traffic Mirroring

This section shows examples of DTCP ADD messages on a mediation device that use the interface ID to trigger traffic mirroring on interfaces demux0.30010002 and demux0.30010001.

```

## Creating DTCP ENABLE Messages to Trigger Traffic Mirroring

This section shows an example of DTCP ENABLE messages on a mediation device that use the interface ID to trigger traffic mirroring on interfaces demux0.30010002 and demux0.30010001.

```
ENABLE DTCP/0.8
Csource-ID: ft-user1
Cdest-ID: cd1
X-Drop-Policy: vod
Flags: STATIC
```

## Creating DTCP DISABLE Messages to Trigger Traffic Mirroring

This section shows examples of DTCP DISABLE messages on a mediation device that use the interface ID to trigger traffic mirroring on interfaces demux0.30010002 and demux0.30010001. Whether you used DTCP ADD plus a policy or DTCP ADD and DTCP ENABLE, you can turn the policy off with DTCP DISABLE.

```
DISABLE DTCP/0.8

X-Drop-Policy: vod
Flags: STATIC
```

## Using LIST Messages to Verify That Subscriber Traffic Is Being Mirrored

This section shows examples of a LIST message on the mediation device. The LIST message requests information about the subscribers being mirrored. The information is returned in a LIST response. The response shows that traffic for the two interfaces—demux0.30010002 and demux0.30010001—is being mirrored.

## Intercept-Related Events Transmitted to the Mediation Device

---

You can use SNMPv3 traps to report intercept-related events to the mediation device. These events include identifying information for subscribers, such as username or IP address, and subscriber session events, such as login or logout events or mirroring session activation or deactivation. The router sends the events to the mediation device in SNMP traps. Using SNMPv3 provides secure traps that are visible only to authorized individuals on the intended secure mediation device. The traps help support compliance with the Communications Assistance for Law Enforcement Act (CALEA), which defines electronic surveillance guidelines for telecommunications companies.

The supported SNMPv3 traps map to messages defined by the *Lawfully Authorized Electronic Surveillance (LAES) for IP Network Access, American Nation Standard For Telecommunications*. “[SNMP Traps for Subscriber Secure Policy LAES Compliance](#)” on [page 1245](#) describes the supported SNMPv3 traps and their related LAES messages.

## Configuring SNMPv3 Traps for Subscriber Secure Policy Mirroring

---

This topic provides an overview of the SNMPv3 configuration process as it pertains to subscriber secure policy. The steps are described in detail in Chapter 7, “Configuring SNMPv3” in the Network Management Configuration Guide.

To configure SNMPv3 trap support for subscriber secure policy and to send the trap information to the mediation device:

1. Configure the MIB view.  
See [Configuring MIB Views](#).
2. Configure the trap notification and trap notification filter. See the following topics:
  - [Configuring the SNMPv3 Trap Notification](#)
  - [Configuring the Trap Notification Filter](#)
3. Configure the target device. The target device is the mediation device that receives the trap information.  
See [Configuring SNMPv3 Traps on a Device Running Junos OS](#).
4. Configure the SNMPv3 user, authentication method and password, and privacy method and password. See the following topics:
  - [Creating SNMPv3 Users](#)
  - [Configuring the SNMPv3 Authentication Type](#)
  - [Configuring the Encryption Type](#)
5. Configure user access privileges to management information.  
See [Defining Access Privileges for an SNMP Group](#).

## ANCP Topology Discovery and Traffic Reporting Overview

---

This topic describes ANCP as a means to monitor and modify subscriber traffic in the access network.

Access Node Control Protocol (ANCP) acts as a control plane between a service-oriented Layer 3 edge device and a Layer 2 access node. The access nodes—ANCP *neighbors*—are network devices that terminate access loops from subscribers; for DSL access loops, the access node is a DSL access multiplexer (DSLAM). Queuing and scheduling mechanisms for subscriber traffic must avoid congestion within the access network while contending with multiple flows and distinct CoS requirements. These mechanisms require the edge device—a router acting as a broadband network gateway (BNG), often also called a network access server (NAS)—to provide information about the access network and subscriber traffic.

The ANCP agent always reports upstream and downstream traffic rates to AAA and only downstream traffic rates to CoS. By default, the ANCP agent reports *net data rates*, that is, the portion of the total data rate that can be used to transmit user information. You can enable CoS to more accurately shape subscriber traffic by configuring the ANCP agent to adjust the net data rate by a fixed percentage for each line type. This *adjusted* or *calculated* rate is the net data rate reduced by the amount of technology overhead incurred by each DSL line type. The result is a closer approximation of the rate of subscriber data traffic.

You can monitor ANCP events and operations by including the **traceoptions** statement at the **[edit protocols ancp]** hierarchy level.

ANCP is supported on VLAN over Ethernet and VLAN demux over aggregated Ethernet interfaces.

ANCP was developed as an extension of *RFC 3292, General Switch Management Protocol (GSMP) V3*, but is now defined in *RFC 6320, Protocol for Access Node Control Mechanism in Broadband Networks*.

- [Topology Discovery on page 1254](#)
- [Subscriber Services on page 1255](#)
- [ANCP Interfaces and Access Loop Circuit Identifiers on page 1255](#)
- [ANCP Neighbors on page 1256](#)

### Topology Discovery

The router uses topology discovery to collect information from the access node. The information includes the following:

- Topology of the access network
- DSL line state
- Actual upstream and downstream net data rates of a synchronized DSL link

- Maximum attainable upstream and downstream net data rates
- Interleaving delay

## Subscriber Services

The router receives the service profile for the subscribers from a RADIUS server. Most of the services are enforced by the router itself. The router shapes the aggregate egress traffic to subscribers based on the local loop throughput reported by the DSLAM. This traffic shaping optimizes traffic flow while avoiding traffic drops in the access node.

Some service attributes, such as interleaving delay and multicast channel information, are enforced at the access node. The ANCP agent provides the line configuration mechanism that the edge device can use to pass the line configuration on to the access nodes. Typically, multiple profiles are provisioned on the access node. The router instructs the access node which profile to use for a given subscriber.

Subscribers typically receive some combination of voice, data, and video services. Each service can be provisioned on a VLAN. A subscriber might receive only a single service over a single VLAN configured on a logical interface. A group of VLANs carrying services to a subscriber is an *interface set*. Subscribers are identified based on the unique access loop circuit identifier that is configured on the access node through which they receive traffic. You must configure the ANCP agent to associate this identifier with the logical interface or interface set. When the ANCP agent receives a port management message from an access node, it uses the access loop circuit identifier contained in the message to determine which logical interface or interface set corresponds to the subscriber.

**NOTE:** The ANCP access loop circuit identifier is equivalent to the agent circuit ID used in DHCP and PPPoE packets to identify the DSLAM interface from which subscriber requests are initiated.

## ANCP Interfaces and Access Loop Circuit Identifiers

You can configure a logical interface by specifying the interface name at the **[edit protocols ancp interfaces]** hierarchy level. Include the **access-identifier** statement when you do so to associate the access loop circuit identifier with the interface. You can configure an interface set by including the **interface-set** statement at the **[edit protocols ancp interfaces]** hierarchy level. Associate the access loop circuit identifier with the interface set by including the **access-identifier** statement at the **[edit protocols ancp interfaces interface-set interface-set-name]** hierarchy level.

The access loop circuit identifier is typically unique across the network; no two interfaces across multiple neighbors (access nodes) share the same identifier. However, in some networks, the identifier might be unique only for a given neighbor. In this case you must associate each identifier with the node's IP address to disambiguate identifiers that are duplicated within the network. To do so, include the **neighbor ip-address** statement with the **access-identifier** statement for both interfaces and interface sets.

**NOTE:** ANCP support is limited to traffic shaping when the identifiers are unique only within an access node (and therefore duplicate identifiers can be present in the network). ANCP support for RADIUS authentication and accounting requires that the identifiers be unique across the network. The DHCP and PPPoE processes are not aware of the access node IP addresses and consequently cannot distinguish between duplicate identifiers. This situation prevents the AAA services framework from correlating a DHCP or PPPoE client session with an access line for RADIUS authentication and accounting.

**BEST PRACTICE:** We recommend that you configure each access loop circuit identifier to be unique across the network.

Some access nodes might not be running the current IETF implementation of ANCP. Instead, they run an earlier version. You can enable the ANCP agent to operate in backwards-compatible mode with all neighbors by including the **pre-ietf-mode** statement at the **[edit protocols ancp]** hierarchy level.

You can control how many discovery table entries are accepted from any neighbor by including the **maximum-discovery-table-entries** statement at the **[edit protocols ancp]** hierarchy level.

## ANCP Neighbors

The ANCP agent exchanges adjacency messages with neighbors. If an adjacency message is not received from a neighbor within the expected period, then the neighbor is considered to be down and is disconnected. You can adjust how long the ANCP agent waits for adjacency messages from all neighbors by including the **adjacency-timer** statement at the **[edit protocols ancp]** hierarchy level. The interval between adjacency messages is automatically set to one-third the value of the adjacency timer.

The ANCP agent can monitor and shape traffic only for access nodes that are configured as ANCP neighbors. Neighbors can establish TCP connections with the router. Include the **neighbor** statement at the **[edit protocols ancp]** hierarchy level to configure an access node as an ANCP neighbor.

You can also configure parameters for a specific neighbor that override global or default configurations by including any of the following statements at the **[edit protocols ancp neighbor ip-address]** hierarchy level:

- **adjacency-timer**—Adjust the interval between adjacency messages exchanged with this neighbor.
- **ietf-mode**—Prevent the ANCP agent from operating in a backwards-compatible mode for this neighbor; for neighbors that use the current IETF implementation of ANCP.

- **maximum-discovery-table-entries**—Specify how many discovery table entries are accepted from this neighbor.
- **pre-ietf-mode**—Enable the ANCP agent to operate in a backwards-compatible mode for this neighbor; for neighbors that use the original IETF implementation of ANCP rather than the current implementation.

- [Triggering ANCP OAM on page 1284](#)

## Traffic Rate Reporting and Adjustment by ANCP

The ANCP agent monitors the subscriber traffic reported by the DSLAM and passes the traffic information to AAA and CoS. The *net data rate* is the portion of the total subscriber traffic rate that is used to transmit user information. This is the rate that the ANCP agent reports by default and is also called the *unadjusted* traffic rate. However, each DSL line type has a certain technology overhead; so the rate for user data is actually less than the net data rate.

You can configure the ANCP agent to adjust the net data rate by a fixed percentage for each line type. This *adjusted* or *calculated* rate provides CoS with a more accurate accounting of subscriber traffic and thus enables CoS to correctly shape subscriber traffic.

The ANCP agent reports the traffic rates differently to AAA and CoS.

- The ANCP agent always reports the unadjusted and adjusted rates for both upstream and downstream traffic rates to AAA in response to a AAA request.
- The ANCP agent always reports unadjusted downstream traffic rates to CoS in support of CoS traffic shaping. It never reports upstream traffic rates to CoS because CoS does not shape upstream traffic. You can configure the ANCP agent to report the adjusted downstream traffic rate to CoS.

When you remove a shaping rate configuration that the ANCP agent previously applied, the traffic shaping rate reverts to the CoS session shaping as determined by the CoS traffic control profiles specified in the dynamic profile. If the ANCP agent remains running but loses a connection to a particular neighbor whose subscriber traffic is adjusted as a result of ANCP, the adjusted rate remains in effect. The rate currently in effect changes only when the ANCP agent restores the connection and sends fresh updates to CoS, or when you remove the **qos-adjust** statement.

- [Traffic Rate Adjustment on page 1258](#)
- [Traffic Rate Reporting and Shaping Scenarios on page 1258](#)
- [Recommended Traffic Shaping Rates on page 1259](#)
- [ANCP Keepalives on page 1260](#)

## Traffic Rate Adjustment

When a DSLAM determines the data rate on the subscriber local loop, it ignores the additional headers on the DSL line that are associated with the overhead of the access mode (ATM or Ethernet) and the technology of the DSL line type. However, when the ANCP agent subsequently reports a net data rate, by default it includes this overhead and therefore reports a slightly higher value than the actual subscriber data rate seen by the DSLAM.

CoS attempts to avoid traffic drops in the access node by adjusting the traffic shaping rate that it applies to downstream traffic for a particular VLAN or set of VLANs. The discrepancy between the actual user data rate and the ANCP agent-reported net data rate reduces the accuracy of CoS traffic shaping.

The ANCP agent can send CoS more accurate information by dynamically adjusting the net data rate down according to a fixed percentage that accounts for the traffic overhead. You configure the adjustment by including one or more of the **qos-adjust-dsl-line-type** statements at the **[edit protocols ancp]** hierarchy level. Each of these statements sets an adjustment factor for a particular DSL line type such as ADSL or VDS2. The adjustment factor is a percentage value that the ANCP agent applies to the traffic rates it receives from the DSLAM and may subsequently report. The percentage accounts for the traffic overhead for that line type. That is, you configure the statements for all relevant line types, and the ANCP agent applies the appropriate adjustment when it identifies the line type for the interface. The adjustment factor applies globally for all subscribers of the particular DSL line type associated with the statement: ADSL, ADSL2, ADSL+, SDS1, VDS1, or VDS2. Although the ANCP agent calculates the rate, it does not report the adjusted downstream traffic rate to CoS unless you also include the **qos-adjust** statement at the **[edit protocols ancp]** hierarchy level.

The **qos-adjust-dsl-line-type** statements are enabled by default with an adjustment factor of 100 percent, meaning that, by default the ANCP agent effectively makes no adjustment to the rates. In this case, when the ANCP agent is configured to report rates to CoS, it simply reports the net data rate that includes the overhead.

**NOTE:** The ANCP agent automatically includes the adjusted rate when it reports to RADIUS.

---

## Traffic Rate Reporting and Shaping Scenarios

Table 114 on page 1259 lists combinations of ANCP and CoS configurations and their consequences for traffic rate reporting and shaping. In this example, the following configuration applies:

- The DSL line type is ADSL.
- The ADSL adjustment factor is set to 85 percent.
- The value for Actual-Net-Data-Rate-Downstream is 1 Mbps.
- The value for Actual-Net-Data-Rate-Upstream is 5 Mbps.

- A CoS traffic control profile named **tcp1** is configured as follows.

```
traffic-control-profiles {
  tcp1 {
    shaping-rate 5M
    overhead-accounting bytes 124
  }
}
```

Table 114: ANCP Traffic Rate Reporting and Shaping Scenarios

Scenario	ANCP configuration includes the qos-adjust statement	CoS configuration includes the tcp1 traffic control profile	Traffic rate adjusted by	Expected Rate
1	No	Yes	CoS	<5Mbps
2	Yes	Yes	ANCP and CoS	<1Mbps
3	Yes	No	ANCP	<1Mbps

- Scenario 1—The ANCP agent adjusts the rate it receives from the DSLAM. The ANCP agent does not report any rate to CoS. The CoS adjustment is determined by the overhead accounting bytes set in the traffic control profile, **tcp1**. The expected final traffic rate is the **tcp1** shaping rate minus the adjustments performed by CoS based on the overhead accounting bytes in the profile, or 5 Mbps - 124 bps.
- Scenario 2—The ANCP agent adjusts the rate it receives from the DSLAM. The ANCP agent reports the adjusted rate to CoS. CoS then applies an overhead adjustment to the ANCP agent-adjusted rate. The CoS adjustment is determined by the overhead accounting bytes set in the traffic control profile, **tcp1**. The expected final traffic rate is the product of the DSLAM-reported rate times the ANCP adjustment factor for the line, minus the adjustments performed by CoS based on the overhead accounting bytes in the profile, or (1 Mbps x 0.85) - 124 bps.
- Scenario 3—The ANCP agent adjusts the rate it receives from the DSLAM. The ANCP agent reports the adjusted rate to CoS. CoS has no traffic control profile, so it does not further adjust the rate received from the ANCP agent. The expected final traffic rate is the product of the DSLAM-reported rate times the ANCP adjustment factor for the line, or 1 Mbps x 0.85.

## Recommended Traffic Shaping Rates

To handle a situation where the router does not receive information from the access node about the downstream and upstream calculated traffic rates for an interface, you can specify recommended *advisory* values for shaping the traffic sent to the interface so that it matches the subscriber local loop speed.

The transmit speed is the recommended traffic value in bits per second used for downstream traffic for an ANCP interface, and is conveyed in the Juniper Networks VSA, Downstream-Calculated-Qos-Rate (IANA 4874, 26–141). The receive speed is the recommended traffic value in bits per second used for upstream traffic for an ANCP

interface, and is conveyed in the Juniper Networks VSA, Upstream-Calculated-Qos-Rate VSA (IANA 4874, 26-142).

To set the recommended shaping rate that is used as the default values for these VSAs, include the **downstream-rate** and **upstream-rate** statements at the **[edit interfaces interface-name unit logical-unit-number advisory-options]** hierarchy level.

## ANCP Keepalives

The ANCP agent sends a keepalive message to CoS at specific intervals. If CoS does not receive a keepalive in the expected time, it reverts the shaping rate changes it made in response to the ANCP agent. You can adjust how long CoS waits for a keepalive message by including the **maximum-helper-restart-time** statement at the **[edit protocols ancp]** hierarchy level. The interval between keepalive messages is automatically set to one-third the value of the maximum helper restart time. For example, if you set the maximum helper restart time to 120 seconds, then the ANCP agent sends keepalive messages every 40 seconds. In this example, if CoS does not receive a keepalive message within 120 seconds, then it reverts any ANCP-derived policy changes.

## ANCP Interactions with AAA ---

The ANCP agent reports both unadjusted (net) data rates and adjusted data rates for subscriber traffic to AAA for RADIUS authentication and accounting of subscriber sessions. The adjusted data rate enables RADIUS to allocate the appropriate services (including class of service) to PPPoE sessions during authentication. The rate reports also enable RADIUS accounting to track the class of service actually provided for the PPPoE sessions, which in turn enables accurate billing for subscriber services.

The access nodes send ANCP DSL attributes in ANCP messages to the router, where they are stored in the shared database. AAA maps the ANCP DSL attributes to both the Juniper Networks DSL VSAs (used by RADIUS) and the DSL Forum VSA subattributes (also called the DSL Forum VSAs). RADIUS uses these attributes during authentication and accounting for PPPoE sessions on the subscriber access line. The attributes persist even when the ANCP session to a given node has ended, enabling RADIUS to later apply these attributes to new sessions on that subscriber access line. To remove the attributes, you must delete the access line from the ANCP configuration.

The RADIUS profile must be configured to include the **juniper-dsl-attributes** option, or AAA does not report the attributes to RADIUS. If the ANCP DSL attributes are unavailable, AAA maps the session's advisory upstream and downstream data rates (as configured

on the session's underlying interface) to the Juniper Networks VSAs, Upstream-Calculated-Qos-Rate [26-142] and Downstream-Calculated-Qos-Rate [26-141], respectively. AAA subsequently provides only these VSAs to RADIUS.

For successful authentication and accounting by RADIUS, AAA has to correlate PPPoE and DHCP IP demux sessions with their access lines and their associated DSL attributes. Some access nodes provide the ACI in PADI/PADR packets for the PPPoE sessions or in the DHCP discovery packets for DHCP IP demux sessions..

When the access loop circuit identifier is not provided in a 1:1 VLAN model with interface sets, you must associate the underlying interface for the sessions with the identifier and the interface set. If you do not configure this association, then only the advisory traffic rates are provided to RADIUS. This configuration has no effect when the identifier is provided by the access node.

For the N:1 VLAN model with interface sets, the access node must provide the ACI. If you configure the underlying interface for this model when the access node does not provide the identifier, the subscriber sessions can be incorrectly correlated with access lines.

AAA reports values to RADIUS for the Juniper Networks VSAs 26-141 and 26-142 according to the following scheme:

1. When the PPPoE or DHCP IP demux subscriber session can be correlated with an access line, then the ANCP agent adjusts the downstream and upstream traffic rates reported by the access node according to the ANCP CoS configuration. The agent then maps the adjusted rates to Upstream-Calculated-Qos-Rate [26-142] and Downstream-Calculated-Qos-Rate [26-141].
2. If the session cannot be correlated with an access line, but the PPPoE or DHCP discovery packet includes the DSL Forum VSA and the Access-Loop-Encapsulation subattribute includes a value for the AAL5 data link, then the ANCP agent adjusts the Actual-Data-Rate-Downstream and Actual-Data-Rate-Upstream subattributes to account for the ATM 48/53 cell tax. The adjusted rates mapped to Upstream-Calculated-Qos-Rate [26-142] and Downstream-Calculated-Qos-Rate [26-141].
3. If neither of the preceding sets of conditions is satisfied, then the ANCP agent simply maps the recommended downstream and upstream data rates to Upstream-Calculated-Qos-Rate [26-142] and Downstream-Calculated-Qos-Rate [26-141]. The recommended rates are either configured statically for the VLAN or VLAN demux interfaces or are in the dynamic profile that creates the interfaces.

To map an ACI to a static VLAN demux interface, include the **access-identifier *identifier*** statement, and optionally the **neighbor *neighbor-ip-address*** statement, at the **[edit protocols ancp interfaces demux0 *logical-unit-number*]** hierarchy level.

To configure advisory upstream and downstream data rates on a static VLAN demux interface, include the **upstream-rate *rate*** or **downstream-rate *rate*** statements at the **[edit interfaces demux0 unit *logical-unit-number*]** hierarchy level.

To configure an underlying interface for the PPPoE sessions in an interface set, include the **underlying-interface *interface-name*** statement at the **[edit protocols ancp interfaces interface-set *interface-set-name*]** hierarchy level.

When an ACI, and therefore a subscriber access line, has been mapped to an interface or interface set, the ACI can be re-mapped to a different interface or set. When this happens, traffic shaping is adjusted accordingly for the interfaces or interface sets involved. This capability is useful for the Business Services model, where a PPPoE session that is initially classified as a residential household can be reclassified as a business subscriber during RADIUS authentication by using a Junos OS ICE AAA framework Op-Script application.

In the Business Services Model, the PPPoE session initially represents a residential household until RADIUS authentication and authorization takes place. The ANCP agent dynamically maps the household's access line to the appropriate subscriber interface and applies CoS traffic shaping to the interface. During authentication and authorization, the Op-Script application may classify the PPPoE session as a business subscriber rather than a residential subscriber. If this occurs, the application creates multiple static VLANs and groups them into an interface set. Based on the ANCP configuration, the application then statically maps the subscriber's access line to this static interface set. This interface set can include only static interfaces.

The ANCP agent reverts CoS traffic shaping from the interface previously used by the subscriber and instead applies the shaping to the interface set. This reversion means that the CoS process applies to the interface the next shaping rate in its adjustment control profile.

## ANCP Operations in Different Network Configurations

---

This topic describes different types of supported network configurations and the sequence of events for ANCP operations in representative sample network topologies.

ANCP supports the following cases:

- Static VLAN interfaces over Ethernet without interface sets
- Static VLAN demux interfaces over Ethernet without interface sets
- Static VLAN interfaces over aggregated Ethernet with interface sets
- Static VLAN demux interfaces over aggregated Ethernet with interface sets

The 1:1 and N:1 configuration models determine how VLANs are correlated with households. A network can include one or both of the models:

- 1:1 model—A single household is configured per VLAN or VLAN demux interface.
- N:1 model—Two or more households are configured per VLAN or VLAN demux interface.

PPPoE sessions are dynamically created as needed for each of the devices in a household. Each household can include multiple CPE devices that access the Internet. In all cases, each household is identified by a unique access loop circuit identifier that is assigned by the access node. Additional identifiers are used in some configurations.

CoS traffic shaping is based on the subscriber downstream traffic rate that the ANCP agent receives from the access node, adjusts for overhead, and then passes to CoS. CoS can shape subscriber traffic at the level of the household or the session:

- Household shaping—Only aggregate traffic to the household is shaped. Household shaping results from applying a CoS traffic control profile to the static VLAN or VLAN demux interface or to the interface set.
- Session shaping—The traffic rate to individual devices in the household is shaped. Session shaping results from specifying a CoS traffic control profile in the dynamic PPPoE profile that creates the subscriber session. Depending on the network configuration, session shaping may employ shared priority queues to shape all sessions identically or individual priority queues to shape the sessions separately.

An interface set groups the dynamic PPPoE sessions for a household. PPPoE subscribers are placed into interface sets by one of the following means:

- The RADIUS Access-Accept message during PPPoE session authentication.
- The dynamic PPPoE profile that creates the session.

The following sections illustrate several possible configurations and lists the sequence of events for the ANCP agent operations in each case.

## ANCP Network Using N:1 and 1:1 Configuration Models without Interface Sets

In this sample topology, two households are configured for one underlying static VLAN or VLAN demux interface (N:1; dual-tagged VLAN) and a single household is configured for another underlying interface (1:1; single-tagged VLAN) (Figure 42 on page 1264). In addition to the unique access loop circuit identifier assigned by the access node, each household is further identified by the VLAN, which is mapped to the identifier in the ANCP agent configuration. CoS traffic shaping for sessions can employ only shared priority queues to shape all sessions identically; individual priority queues to shape the sessions separately are not supported.

**Figure 42: Sample ANCP Topology Without Interface Sets (1:1 and N:1 Model)**

## Sequence of ANCP Events: Static VLAN or VLAN Demux Interfaces over Ethernet Without Interface Sets

The following sequence of events is for the topology in [Figure 42 on page 1264](#) with static VLAN interfaces over Ethernet without interface sets.

1. A network device in the household initiates PPPoE discovery.
2. PPPoE creates a dynamic PPPoE session on the underlying static VLAN or VLAN demux interface and applies the advisory options configured on the VLAN to the session.
3. The access node independently provides the ANCP agent with the ANCP DSL attributes for an access line identified by an access loop circuit identifier.
4. The ANCP agent sends CoS the adjusted downstream data rate for the static VLAN or demux VLAN mapped to the access loop circuit identifier. The ANCP agent stores all DSL attributes, including the adjusted upstream data rate, in the router's shared database.
5. AAA correlates the dynamic PPPoE session with the access line by matching the underlying interface of the session to the static VLAN or VLAN demux interface associated with the access loop circuit identifier in the ANCP agent configuration.
6. AAA retrieves the ANCP DSL attributes for the access line from the router's shared database and maps them to the Juniper Networks DSL VSAs in the RADIUS Access-Request and Accounting-Request messages. If the DSL attributes are unavailable, the session's advisory upstream and downstream data rates are mapped to the Upstream-Calculated-Qos-Rate VSA (26-142) and Downstream-Calculated-Qos-Rate (26-141) VSAs, respectively. These VSAs are then included in the RADIUS messages.

## ANCP Network Using N:1 Configuration Model with Interface Sets

In this topology, multiple households are configured for each underlying static VLAN or VLAN demux interface (Figure 43 on page 1266). The VLANs are dual-tagged. Each household includes several CPE devices that access the Internet. In addition to the unique access loop circuit identifier assigned by the access node, the household is further identified by the interface set. The interface set groups the dynamic PPPoE sessions for the individual subscriber devices. It is either explicitly configured in the dynamic PPPoE profile or specified in the RADIUS Access-Accept message during PPPoE session authentication. Session shaping can employ shared priority queues to shape all sessions identically or individual queues to shape the sessions separately.

**Figure 43: Sample ANCP Topology with Interface Sets (N:1 Model)**

In this N:1 model with interface sets, the access node must add the DSL Forum VSA to the PPPoE PADI and PADR discovery packets that it passes to the router during the establishment of dynamic PPPoE sessions. The VSA includes the access loop circuit identifier for the household. This inclusion enables AAA to correlate the PPPoE sessions with their respective subscriber access lines and DSL attributes during RADIUS authentication and accounting. If the access loop circuit identifier is not present, AAA cannot make the correlation and subsequently reports only the advisory upstream and downstream data rates to RADIUS Authentication and Accounting.

When the dynamic PPPoE profile is configured with the **\$junos-interface-set-name** predefined variable, the configuration of the access node, router, and RADIUS server must be synchronized with regard to the access loop circuit identifier and interface set:

- The RADIUS Access-Accept message must contain the Juniper Networks Qos-Interface-Set-Name VSA (26-130).
- The CoS Layer 2 configuration must explicitly identify the interface set that is named in the Qos-Interface-Set-Name VSA (26-130).
- The ANCP agent configuration must map an access loop circuit identifier to the interface set that is named in the Qos-Interface-Set-Name VSA (26-130).

### Sequence of ANCP Events: Static VLAN Interfaces over Ethernet with Interface Sets

The following sequence of events is for the topology in [Figure 43 on page 1266](#) with static VLAN interfaces over Ethernet with interface sets.

1. A network device in the household initiates PPPoE discovery.
2. The access node adds the DSL Forum VSA tag with the access loop circuit identifier for the household to the PPPoE PADI and PADR discovery packets. (The identifier is known to PPPoE as the agent circuit identifier.)
3. PPPoE creates a dynamic PPPoE session with the provided access loop circuit identifier on the underlying static VLAN and applies the advisory options configured on the VLAN to the session.
4. The access node independently provides the ANCP agent with the ANCP DSL attributes for an access line identified by an access loop circuit identifier.
5. The ANCP agent provides CoS with the adjusted downstream data rate for the interface set mapped to the access loop circuit identifier. The ANCP agent stores all ANCP DSL attributes, including the adjusted upstream and downstream data rates, in the router's shared database.
6. AAA correlates the dynamic PPPoE session with the access line by matching the session identifier received in the DSL Forum VSA to the access loop circuit identifier configured for the interface set in the ANCP agent configuration.
7. AAA retrieves the ANCP DSL attributes for the access line from the router's shared database and maps them to the Juniper Networks DSL VSAs in the RADIUS Access-Request and Accounting-Request messages. If the DSL attributes are unavailable, the session's advisory upstream and downstream data rates are mapped to the Upstream-Calculated-Qos-Rate VSA (26-142) and Downstream-Calculated-Qos-Rate (26-141) VSAs, respectively. These VSAs are then included in the RADIUS messages.
8. When authentication is completed, the dynamic PPPoE session is placed into the interface set configured in the dynamic PPPoE profile. The profile specifies a named interface set or the **\$junos-interface-set-name** predefined variable, which indicates that the interface set is named in the RADIUS Access-Accept message.

## ANCP Network Using 1:1 Configuration Model with Interface Sets

In this topology, a single household is configured for each underlying static VLAN or VLAN demux interface (Figure 44 on page 1268). The VLANs are dual-tagged. Each household includes several CPE devices that access the Internet. In addition to the unique access loop circuit identifier assigned by the access node, the household is further identified by the interface set. The interface set is either explicitly configured in the dynamic PPPoE profile or specified in the RADIUS Access-Accept message during PPPoE session authentication. Session shaping can employ shared priority queues to shape all sessions identically or individual queues to shape the sessions separately.

Figure 44: Sample ANCP Topology with Interface Sets (1:1 Model)

In this 1:1 model with interface sets, the ANCP agent configuration must map the underlying interface for the PPPoE sessions in an interface set to both the access loop circuit identifier and the interface set. This configuration enables AAA to correlate the PPPoE sessions with their respective subscriber access lines and DSL attributes during RADIUS authentication and accounting.

When the dynamic PPPoE profile is configured with the `$junos-interface-set-name` predefined variable, the configuration of the access node, router, and RADIUS server must be synchronized with regard to the access loop circuit identifier and interface set:

- The RADIUS Access-Accept message must contain the Juniper Networks Qos-Interface-Set-Name VSA (26-130).
- The CoS Layer 2 configuration must explicitly identify the interface set that is named in the Qos-Interface-Set-Name VSA (26-130).

- The ANCP agent configuration must map an access loop circuit identifier to the interface set that is named in the Qos-Interface-Set-Name VSA (26-130).

## Sequence of ANCP Events: Static VLAN Demux Interfaces over Aggregated Ethernet with Interface Sets

The following sequence of events is for the topology in [Figure 44 on page 1268](#) with static VLAN demux interfaces over aggregated Ethernet with interface sets.

1. A network device in the household initiates PPPoE discovery.
2. PPPoE creates a dynamic PPPoE session with the provided access loop circuit identifier on the underlying static VLAN demux interface and applies the advisory options configured on the VLAN to the session.
3. The access node independently provides the ANCP agent with the ANCP DSL attributes for an access line identified by an access loop circuit identifier.
4. The ANCP agent provides CoS with the adjusted downstream data rate for the interface set mapped to the access loop circuit identifier. The ANCP agent stores all ANCP DSL attributes, including the adjusted upstream and downstream data rates, in the router's shared database.
5. AAA correlates the dynamic PPPoE session with the access line by matching the underlying interface of the session to the underlying interface configured for the interface set in the ANCP agent configuration.
6. AAA retrieves the ANCP DSL attributes for the access line from the router's shared database and maps them to the Juniper Networks DSL VSAs in the RADIUS Access-Request and Accounting-Request messages. If the DSL attributes are unavailable, the session's advisory upstream and downstream data rates are mapped to the Upstream-Calculated-Qos-Rate VSA (26-142) and Downstream-Calculated-Qos-Rate (26-141) VSAs, respectively. These VSAs are then included in the RADIUS messages.
7. When authentication is completed, the dynamic PPPoE session is placed into the interface set configured in the dynamic PPPoE profile. The profile specifies a named interface set or the `$junos-interface-set-name` predefined variable, which indicates that the interface set is named in the RADIUS Access-Accept message.

## ANCP DSL Attributes Mapped to Juniper Networks DSL Vendor-Specific Attributes

Digital Subscriber Line (DSL) attributes are RADIUS vendor-specific attributes (VSAs) that are defined by the DSL Forum in RFC 4679, *DSL Forum Vendor-Specific RADIUS Attributes*. The attributes transport DSL information that is not supported by standard

RADIUS attributes and which conveys details about the associated DSL subscriber line and traffic. These attributes are contained as subattributes in the single DSL Forum VSA (IANA vendor ID 3561). An ANCP access node can provide this information to the router in a PPPoE PADI message during PPPoE subscriber discovery.

The access node can also report the same information about the DSL subscriber line and traffic information by means of the ANCP DSL TLVs or attributes carried in ANCP messages to the router. The ANCP attributes are defined in RFC 6320, *Protocol for Access Node Control Mechanism in Broadband Networks*. These ANCP DSL attributes correspond to Juniper Networks (IANA vendor ID 4874) DSL VSAs and to DSL Forum VSAs.

The router simply passes the DSL line and traffic information that it receives from the access node to the RADIUS server, without performing any parsing or manipulation. A RADIUS authentication or accounting message can contain any combination of the DSL Forum VSAs and the Juniper Networks DSL VSAs. You can configure the RADIUS access profile to exclude one or more individual attributes, or all DSL Forum attributes, from being included in RADIUS messages.

[Table 115 on page 1270](#) shows the relationship between the ANCP DSL attributes, Juniper Networks DSL VSAs, and DSL Forum VSAs.

**Table 115: Mapping ANCP DSL Attributes to Juniper Networks DSL VSAs and DSL Forum VSAs**

ANCP DSL Attribute Name	Juniper Networks VSA Name [Number]	DSL Forum VSA Name [Number]

## Preservation of CoS Shaping Across ANCP Restarts

When the ANCP agent stops due to a process or GRES, CoS enforces the ANCP downstream shaping-rates until the CoS keepalive timer expires. When the timer expires, CoS reverts to the CoS shaping-rate configured for the interfaces.

You configure the CoS keepalive timer by including the **maximum-helper-restart-time seconds** statement at the **[edit protocols ancp]** hierarchy level. It specifies how much

time other daemons such as CoS wait for ANCP to restart and is used to configure the CoS rate update keepalive timer.

The ANCP agent does not maintain TCP sessions from neighbors across the restart or GRES. When it restarts, it must re-establish sessions with neighbors and subscriber sessions before the timer expires. For all the re-established sessions, the ANCP agent updates CoS with the updated downstream shaping rates and provides DSL line attributes to the session database for AAA.

If CoS stops or restarts while ANCP is up, the ANCP agent retransmits all known subscriber downstream rates to CoS. Any existing adjusted shaping rates that have not been updated revert to the configured CoS shaping rates when the CoS restart timer expires.

## Configuring ANCP

---

You can configure ANCP to enable a service-oriented Layer 3 edge device to discover information about the topology of a connected access network. ANCP can also provide details about subscriber traffic and enable the adjustment of QoS traffic shaping for subscribers.

To configure ANCP:

1. Specify each ANCP neighboring access node to be monitored and optionally configure neighbor parameters.  
[See “Configuring ANCP Neighbors” on page 1275.](#)
2. Specify the subscribers reached by a VLAN or a set of VLANs through a particular access node.  
[See “Associating an Access Node with Subscribers for ANCP Operations” on page 1276.](#)
3. (Optional) Configure the adjacency timer.  
[See “Specifying the Interval Between ANCP Adjacency Messages” on page 1277.](#)
4. (Optional) Specify the maximum number of discovery table entries that are accepted.  
[See “Specifying the Maximum Number of Discovery Table Entries” on page 1278](#)
5. (Optional) Configure ANCP to work with an early IETF draft.  
[See “Configuring ANCP for Backward Compatibility” on page 1278.](#)
6. (Optional) Configure the graceful restart timer.  
[See “Specifying How Long Processes Wait for ANCP Restart to Complete” on page 1279.](#)
7. (Optional) Configure an adjustment factor per DSL line type for the downstream and upstream data rates that the ANCP agent reports to AAA.  
[See “Setting a Global Adjustment Factor per DSL Subscriber Line for ANCP Agent-Reported Traffic Rates” on page 1279.](#)
8. (Optional) Configure the ANCP agent to report unadjusted downstream traffic rates to CoS.  
[See “Configuring the ANCP Agent to Report Traffic Rates to CoS” on page 1280.](#)
9. (Optional) Specify a recommended shaping rate to be applied by RADIUS to downstream or upstream traffic per ANCP interface.  
[See “Setting a Recommended Shaping Rate for Traffic on ANCP Interfaces” on page 1281.](#)
10. (Optional) Configure AAA to Include or Exclude Juniper Networks DSL VSAs in RADIUS authentication and accounting messages.  
[See “Configuring AAA to Include Juniper Networks DSL VSAs in RADIUS Messages” on page 1283.](#)
11. (Optional) Configure trace options for troubleshooting the configuration.

See [“Tracing ANCP Operations for Subscriber Access”](#) on page 1287.

  - [Triggering ANCP OAM](#) on page 1284

## Configuring ANCP Neighbors

---

You must configure each neighboring access node that you want the ANCP agent to monitor and potentially shape traffic for. Some neighbor settings override globally configured values.

To configure an ANCP neighbor:

1. Specify the IP address of the neighbor.

```
[edit protocols ancp]
user@host# set neighbor 10.2.3.4
```

2. (Optional) Configure the neighbor to operate in a backward-compatible mode when it does not support the current IETF standard and the backward-compatible mode is not configured globally.

```
[edit protocols ancp neighbor 10.2.3.4]
user@host# set pre-ietf-mode
```

3. (Optional) Override the globally configured backward-compatible mode when the neighbor supports the current IETF standard.

```
[edit protocols ancp neighbor 10.2.3.4]
user@host# set ietf-mode
```

4. (Optional) Configure the interval in seconds between ANCP adjacency messages exchanged with this neighbor.

```
[edit protocols ancp neighbor 10.2.3.4]
user@host# set adjacency-timer 20
```

5. (Optional) Specify the maximum number of discovery table entries that are accepted from this neighbor.

```
[edit protocols ancp neighbor 10.2.3.4]
user@host# set maximum-discovery-table-entries 10000
```

## Associating an Access Node with Subscribers for ANCP Operations

---

Subscribers are identified by a unique access loop circuit identifier that is associated with a logical interface for a single VLAN or with a named set of VLANs through which traffic is sent to the subscribers. The access loop circuit identifier must be unique either across the network or for individual ANCP neighbors (access nodes). When the identifier is unique only for a neighbor, you must also specify the neighbor's IP address.

**NOTE:** ANCP support is limited to traffic shaping when the identifiers are unique only within an access node (and therefore duplicate identifiers can be present in the network). ANCP support for RADIUS authentication and accounting requires that the identifiers be unique across the network. The DHCP and PPPoE processes are not aware of the access node IP addresses and consequently cannot distinguish between duplicate identifiers. This situation prevents the AAA services framework from correlating a DHCP or PPPoE client session with an access line for RADIUS authentication and accounting.

**BEST PRACTICE:** We recommend that you configure each access loop circuit identifier to be unique across the network.

You can configure an interface set to group several VLAN interfaces. An interface set is typically used to group CPE devices in a subscriber household for traffic shaping.

To associate an access loop circuit identifier with a set of VLAN interfaces for subscribers:

1. Specify the name of the interface set and the unique access loop circuit identifier for the access node.

```
[edit protocols ancp interfaces]
user@host# set interface-set vlan5 access-identifier "dslam port 2/3"
```

2. (Optional) Specify the access node address when the identifier is unique only to the node.

```
[edit protocols ancp interfaces]
user@host# set interface-set vlan5 neighbor 10.3.5.6
```

To associate an access loop circuit identifier with a single VLAN:

1. Specify the logical interface and the unique access loop circuit identifier for the access node.

```
[edit protocols ancp interfaces]
user@host# set ge-1/0/4.12 access-identifier "dslam port-2-10"
```

2. (Optional) Specify the access node address when the identifier is unique only to the node.

```
[edit protocols ancp interfaces]
```

```
user@host# set ge-1/0/4.12 neighbor 10.12.3.4
```

To associate an access loop circuit identifier with a static VLAN demux interface:

1. Specify the logical interface and the unique access loop circuit identifier for the access node.

```
[edit protocols ancp interfaces]
user@host# set demux0.100 access-identifier aci_100_1_0
```

2. (Optional) Specify the access node address when the identifier is unique only to the node.

```
[edit protocols ancp interfaces]
user@host# set demux0.100 neighbor 10.100.0.1
```

- Related Documentation**

  - [interfaces on page 1662](#)

## Specifying the Interval Between ANCP Adjacency Messages

When the ANCP agent and a neighbor negotiate to establish an adjacency, each proposes a value for the interval between the adjacency messages that they exchange after it is established. The larger of the values proposed by the agent and the neighbor is selected for the interval between subsequent adjacency messages exchanged by the agent and the neighbor. You can specify the interval value that the ANCP agent proposes for either all neighbors or a specific neighbor.

To configure the proposed interval between ANCP adjacency messages for all neighbors:

- Specify the time in seconds.

```
[edit protocols ancp]
user@host# set adjacency-timer 20
```

To configure the proposed interval between ANCP adjacency messages for a specific neighbor:

- Specify the time in seconds.

```
[edit protocols ancp neighbor 10.2.3.4]
user@host# set adjacency-timer 20
```

- Related Documentation**
- [Configuring ANCP on page 1274](#)
  - [Configuring ANCP Neighbors on page 1275](#)

## Specifying the Maximum Number of Discovery Table Entries

---

You can specify the maximum number of discovery table entries accepted from all neighbors or from a particular neighbor.

To configure the maximum number of entries for all neighbors:

- Specify the number of entries.

```
[edit protocols ancp]
user@host# set maximum-discovery-table-entries 5000
```

To configure the maximum number of entries for a specific neighbor:

- Specify the number of entries.

```
[edit protocols ancp neighbor 10.2.3.4]
user@host# set maximum-discovery-table-entries 5000
```

- Related Documentation**
- [Configuring ANCP on page 1274](#)
  - [Configuring ANCP Neighbors on page 1275](#)

## Configuring ANCP for Backward Compatibility

---

You can configure ANCP to operate in a mode compatible with the protocol as it was initially proposed to operate. This backward-compatible or pre-IETF mode is compatible with Internet draft draft-wadhwa-gsmp-l2control-configuration-00.txt, *GSMP extensions for layer2 control (L2C)*. Setting this backward-compatible mode enables interoperation with devices that are not compatible with the later ANCP Internet drafts or RFC 6320, *Protocol for Access Node Control Mechanism in Broadband Networks*.

When this mode is configured globally for all neighbors, you can override it for a particular neighbor that supports the IETF draft or standard.

To configure the ANCP agent to operate in a backward-compatible mode for all neighbors:

- Specify the pre-IETF mode.

```
[edit protocols ancp]
user@host# set pre-ietf-mode
```

To configure the ANCP agent to operate in a backward-compatible mode for a specific neighbor:

- Specify the pre-IETF mode.

```
[edit protocols ancp neighbor 10.2.3.4]
user@host# set pre-ietf-mode
```

- To override the globally configured backward-compatible mode for a specific neighbor:  
Specify the IETF mode.

```
[edit protocols ancp neighbor 10.2.3.4]
user@host# set ietf-mode
```

- Related Documentation**
- [Configuring ANCP on page 1274](#)
  - [Configuring ANCP Neighbors on page 1275](#)

## Specifying How Long Processes Wait for ANCP Restart to Complete

You can specify how long other processes wait for the ANCP agent to restart. The ANCP agent sends a keepalive message to CoS at intervals equal to one-third the value of the maximum helper restart time. For example, when you configure the maximum restart time to 120 seconds, the ANCP agent sends a keepalive message every 40 seconds.

If CoS does not receive a keepalive message within the maximum helper restart time, it considers ANCP to be down and immediately reverts any traffic shaping updates that were implemented as a result of ANCP monitoring to the configured values. Consequently, traffic to the subscribers is not effectively shaped, potentially resulting in traffic drops in the DSLAMs. The configured values are maintained until ANCP comes back up and sends fresh traffic shaping updates to CoS.

To configure how long other processes wait for ANCP to restart:

- Specify the time in seconds.
- ```
[edit protocols ancp]
user@host# set maximum-helper-restart-time 150
```

- Related Documentation**
- [Configuring ANCP on page 1274](#)
  - [Configuring ANCP to Adjust CoS Traffic Shaping](#)
  - [qos-adjust on page 1834](#)

## Setting a Global Adjustment Factor per DSL Subscriber Line for ANCP Agent-Reported Traffic Rates

The ANCP agent always reports both upstream and downstream rates to AAA. When a DSLAM calculates the data rate on the subscriber local loop, it ignores the additional headers on the DSL line that are associated with the overhead of the access mode (ATM or Ethernet). When the ANCP agent reports the net upstream data rate or the net downstream data rate, it includes the headers in its calculation and therefore reports a slightly higher value than that calculated by the DSLAM; this is the unadjusted data rate.

The ANCP agent also reports adjusted data rates to AAA. You can configure the agent to adjust the traffic rate to account for the header overhead by including one or more of the **qos-adjust-dsl-line-type** statements. Each of these statements sets an adjustment factor for a particular DSL line type that applies a percentage value to the total downstream and upstream data rates reported by the ANCP agent. That is, you configure the statements for all relevant line types, and the agent applies the appropriate

adjustment when it identifies the line type for the interface. The adjustment factor applies globally for all subscribers of that DSL line type. By default, the ANCP agent applies an adjustment factor of 100 percent to all DSL lines, meaning that no adjustment is made. The ANCP agent simply passes on the DSL line rates that include the header information.

**NOTE:** The ANCP agent reports only unadjusted downstream data rates to CoS, and reports to CoS only when you include the `qos-adjust` statement at the `[edit protocols ancp]` hierarchy level.

To apply a global adjustment factor for DSL subscriber lines:

- Specify the adjustment factor percentage for the desired subscriber line.

```
[edit protocols ancp]
user@host# set qos-adjust-adsl adjustment-factor
user@host# set qos-adjust-adsl2 adjustment-factor
user@host# set qos-adjust-adsl2-plus adjustment-factor
user@host# set qos-adjust-sdsl adjustment-factor
user@host# set qos-adjust-vdsl adjustment-factor
user@host# set qos-adjust-vdsl2 adjustment-factor
```

---

## Configuring the ANCP Agent to Report Traffic Rates to CoS

---

By default, the ANCP agent does not report the traffic rate on subscriber access lines to CoS. You can include the `qos-adjust` statement at the `[edit protocols ancp]` hierarchy level to configure the ANCP agent to report unadjusted or net downstream data rates to CoS for all subscribers in the network. This information enables CoS to subsequently shape the traffic on these access lines.

When a DSLAM calculates the data rate on the subscriber local loop, it ignores the additional headers on the DSL line that are associated with the overhead of the access mode (ATM or Ethernet). The unadjusted downstream data rate includes these headers in its calculation and therefore reports a slightly higher value than that calculated by the DSLAM. The ANCP agent also reports to CoS the traffic mode and the traffic rate overhead.

**NOTE:** The ANCP agent never reports upstream traffic rates to CoS, nor does it report adjusted downstream traffic rates to CoS.

If CoS does not receive a keepalive message within the maximum helper restart time, it considers ANCP to be down and immediately reverts to the configured values any traffic shaping updates that were modified as a result of traffic reports from the ANCP agent. The configured values are maintained until ANCP comes back up and sends fresh traffic updates to CoS.

However, if ANCP remains running but loses the connection to a neighbor, CoS does not revert to its configured values. In this case, CoS changes the shaping rate for the subscriber traffic only if the ANCP agent restores the connection to that neighbor and reports new traffic rates to CoS or if you remove the **qos-adjust** statement.

To configure the ANCP agent to report unadjusted downstream traffic rates to CoS for traffic shaping:

- Specify that the ANCP agent reports traffic rates to CoS.

```
[edit protocols ancp]  
user@host# set qos-adjust
```

## Setting a Recommended Shaping Rate for Traffic on ANCP Interfaces

When the access node sends information about the downstream and upstream calculated traffic rates for an interface, those values are used to shape the traffic sent to the interface so that it matches the subscriber local loop speed. You can specify recommended values that are used when the router does not receive this information from the access node. In this event, these recommended values are used as the default values for the following Juniper VSAs:

- Downstream-Calculated-Qos-Rate (IANA 4871, 26–141)—Conveys the transmit speed, which is the recommended traffic value in bits per second used for downstream traffic for an ANCP interface.
- Upstream-Calculated-Qos-Rate (IANA 4874, 26–142)—Conveys the receive speed, which is the recommended traffic value in bits per second used for upstream traffic for an ANCP interface.

You can configure the recommended rates either on static VLAN and VLAN demux interfaces, or you can specify them in a dynamic profile for dynamic VLAN and VLAN demux interfaces or interface sets.

To configure recommended traffic shaping values for a static interface:

1. Set the rate in bits per second for downstream traffic for the interface.

```
[edit interfaces interface-name unit logical-unit-number advisory-options]  
user@host# set downstream-rate rate
```

2. Set the rate in bits per second for upstream traffic for the interface.

```
[edit interfaces interface-name unit logical-unit-number advisory-options]  
user@host# set upstream-rate rate
```

For example, to set the recommended downstream rate to 16 Mbps and the recommended upstream rate to 1 Mbps on VLAN demux interface demux0.10301:

```
[edit interfaces demux0 unit 10301 advisory-options]  
user@host# set downstream-rate 16M  
user@host# set upstream-rate 1M
```

To configure recommended traffic shaping values for a dynamic interface:

1. Set the rate in bits per second for downstream traffic in the dynamic profile.

```
[edit dynamic-profiles profile-name interfaces $junos-interface-ifd-name unit  
$junos-interface-unit advisory-options]  
user@host# set downstream-rate rate
```

2. Set the rate in bits per second for upstream traffic in the dynamic profile.

```
[edit dynamic-profiles profile-name interfaces $junos-interface-ifd-name unit  
$junos-interface-unit advisory-options]  
user@host# set upstream-rate rate
```

For example, to configure the dynamic profile ancp-dyn-vlan2 to set the recommended downstream rate to 10 Mbps and the recommended upstream rate to 1 Mbps on all interfaces in the dynamically created interface set:

```
[edit dynamic-profiles ancp-dyn-vlan2 interfaces $junos-interface-ifd-name unit  
$junos-interface-unit advisory-options]  
user@host# set downstream-rate 10M  
user@host# set upstream-rate 1M
```

To configure recommended traffic shaping values for a dynamic interface set:

1. Set the rate in bits per second for downstream traffic in the dynamic profile.

```
[edit dynamic-profiles profile-name interfaces interface-set $junos-interface-set-name  
interface $junos-interface-ifd-name advisory-options]  
user@host# set downstream-rate rate
```

2. Set the rate in bits per second for upstream traffic in the dynamic profile.

```
[edit dynamic-profiles profile-name interfaces interface-set $junos-interface-set-name  
interface $junos-interface-ifd-name advisory-options]  
user@host# set upstream-rate rate
```

For example, to configure the dynamic profile ancp-dyn-vlan1 to set the recommended downstream rate to 12 Mbps and the recommended upstream rate to 2 Mbps on all interfaces in the dynamically created interface set:

```
[edit dynamic-profiles ancp-dyn-vlan1 interfaces interface-set $junos-interface-set-name
  interface $junos-interface-ifd-name advisory-options]
user@host# set downstream-rate 12M
user@host# set upstream-rate 2M
```

- Related Documentation**
- [Configuring ANCP on page 1274](#)
  - [Configuring AAA to Include Juniper Networks DSL VSAs in RADIUS Messages on page 1283](#)
  - [Juniper Networks VSAs Supported by the AAA Service Framework on page 88](#)
  - [ANCP Topology Discovery and Traffic Reporting Overview on page 1254](#)

## Configuring AAA to Include Juniper Networks DSL VSAs in RADIUS Messages

You can include the **juniper-dsl-attributes** statement to configure AAA to add the set of Juniper Networks DSL VSAs to the RADIUS authentication and accounting request messages for subscribers. By default, these VSAs are not added to any RADIUS message. See “[ANCP DSL Attributes Mapped to Juniper Networks DSL Vendor-Specific Attributes](#)” on page 1269 for a table of the Juniper Networks DSL VSAs.

After you have configured the inclusion of the Juniper Networks VSAs, you can subsequently exclude one or more of the VSAs from being transmitted. To do so, include the **exclude** statement at the **[edit access profile *profile-name* radius attributes]** hierarchy level, and specify which VSAs to exclude.

In contrast to the Juniper Networks DSL VSAs (vendor ID 4874), the DSL Forum VSA (vendor ID 3561) is added to all RADIUS messages by default. The DSL Forum VSA conveys individual DSL Forum attributes. See “[DSL Forum Vendor-Specific Attributes](#)” on page 96 for a table of these VSAs. You can use the **exclude** statement at the **[edit access profile *profile-name* radius attributes]** hierarchy level to prevent this VSA from being included in any RADIUS message.

To add the Juniper Networks DSL VSAs to RADIUS messages:

- Configure the inclusion trigger.
 

```
[edit access profile profile-name radius options]
user@host# set juniper-dsl-attributes
```

To exclude specific Juniper Networks DSL VSAs from RADIUS messages:

- Configure the exclusion trigger.
 

```
[edit access profile profile-name radius attributes]
user@host# set exclude vsa-option
```

For example, to exclude the interleaving delay VSAs, configure the following statements:

```
[edit access profile profile-name radius attributes]
user@host# set exclude max-interlv-delay-dn
user@host# set excludemax-interlv-delay-up
```

To exclude the DSL Forum (RFC 4679) VSA from RADIUS messages:

- Configure the exclusion trigger.

```
[edit access profile profile-name radius attributes]  
user@host# set exclude dsl-forum-attributes
```

## Triggering ANCP OAM

You can trigger ANCP OAM to perform a loopback test on the local loop between the access node and the CPE to help isolate simple faults. On an ATM-based local loop, the ANCP operation triggers the access node to generate ATM (F4/F5) loopback cells on the local loop. On an Ethernet-based local loop, the ANCP operation triggers the access node to generate an Ethernet loopback message on the local loop. When the test completes, the access node sends a message to the router with the results.

Issue the **request ancp oam neighbor** command from CLI operational mode to initiate testing of a local loop identified by the IP address or system name of the ANCP neighbor and the access loop circuit identifier for a subscriber on that access node.

Issue the **request ancp oam interface** command from CLI operational mode to initiate testing of a local loop identified by the ANCP interface or interface set associated with a subscriber and the access loop circuit identifier for a subscriber on that access node.

With both commands, you can also specify how many times the test must be run and how long the router waits for a response to the OAM request.

To initiate ANCP local loop testing:

- Identify the loop by the subscriber identifier and the neighbor's IP address; optionally specify how many times the test runs and the timeout period.

```
user@host> request ancp oam neighbor ip-address 192.168.32.5 subscriber "dslam  
port-2-10" count 5 timeout 600
```

- Identify the loop by the subscriber identifier and the neighbor's system name; optionally specify how many times the test runs and the timeout period.

```
user@host> request ancp oam neighbor system-name ba:ad:be:ef:10:10 subscriber  
"dslam port-2-10" count 10 timeout 600
```

- Identify the loop by the subscriber identifier and the interface associated with the subscriber; optionally specify how many times the test runs and the timeout period.

```
user@host> request ancp oam interface ge-1/0/2.12 identifier-string timeout 15
```

- Identify the loop by the subscriber identifier and the set of interfaces associated with the subscriber; optionally specify how many times the test runs and the timeout period.

```
user@host> request ancp oam interface interface-set vlan5 identifier-string count 3
```

## Verifying and Monitoring ANCP Neighbors

**Purpose** View ANCP neighbor information:

- Action**
- To display summary information about all ANCP neighbors:

```
user@host> show ancp neighbor
```

- To display information about a specific ANCP neighbor, add the IP address or MAC address to the command:

```
user@host> show ancp neighbor 10.25.64.21
```

- To display detailed information, add **detail** to the command:

```
user@host> show ancp neighbor detail
```

```
user@host> show ancp neighbor ba:ad:be:ef:10:10 detail
```

- To display a count of ANCP neighbors in various states and the total number of neighbors, or a count of DSL lines in various states for all subscribers for a particular neighbor:

```
user@host> show ancp summary neighbor
```

```
user@host> show ancp summary neighbor 10.25.64.21
```

- To display total and state-wise counts of both ANCP neighbors and subscribers:

```
user@host> show ancp summary
```

**Related Documentation**

- Junos OS Operational Mode Commands

## Clearing ANCP Neighbors

**Purpose** Clear ANCP neighbor information.

- Action**
- To clear connections with all ANCP neighbors:

```
user@host> clear ancp neighbor
```

- To clear the connection with a specific ANCP neighbor, add the IP address or MAC address to the command:

```
user@host> clear ancp neighbor ip-address 10.25.64.21
```

```
user@host> clear ancp neighbor system-name ba:ad:be:ef:10:10
```

- To verify that the connection has been cleared:

```
user@host> show ancp neighbor
user@host> show ancp neighbor 10.25.64.21
user@host> show ancp neighbor ba:ad:be:ef:10:10
```

**Related Documentation**

- Junos OS Operational Mode Commands

---

## Verifying and Monitoring ANCP Subscribers

---

**Purpose** View ANCP subscriber (local access loop) information:

- Action**
- To display summary information about all ANCP subscribers:  

```
user@host> show ancp subscriber
```
  - To display information about all ANCP subscribers connected through a particular ANCP neighbor:  

```
user@host> show ancp subscriber neighbor 10.25.64.21
```
  - To display information about an ANCP subscriber specified by the access loop circuit identifier:  

```
user@host> show ancp subscriber "port-2-11"
```
  - To display detailed information, add **detail** to the command:  

```
user@host> show ancp subscriber detail
user@host> show ancp subscriber neighbor 10.25.64.21 detail
```
  - To display a count of subscribers in various states and the total number of subscribers:  

```
user@host> show ancp summary subscriber
```
  - To display total and state-wise counts of both ANCP neighbors and subscribers:  

```
user@host> show ancp summary
```

**Related Documentation**

- Junos OS Operational Mode Commands

---

## Clearing ANCP Subscribers

---

**Purpose** Clear ANCP subscriber information.

- Action**
- To clear connections with all ANCP subscribers:  

```
user@host> clear ancp subscriber
```
  - To clear the connection with an ANCP subscriber identified by a particular access loop circuit identifier on all neighbors, add the identifier to the command:  

```
user@host> clear ancp subscriber identifier port-2-10
```

- To clear the connection with an ANCP subscriber identified by a particular access loop circuit identifier on a specific neighbor, add the identifier and either the IP address or MAC address to the command:

```
user@host> clear ancp subscriber identifier port-2-10 ip-address 10.25.64.21
```

```
user@host> clear ancp subscriber identifier port-2-10 system-name ba:ad:be:ef:10:10
```

- To verify that the connection has been cleared:

```
user@host> show ancp subscriber
```

#### Related Documentation

## Verifying and Monitoring CoS for ANCP Subscribers

**Purpose** View ANCP CoS state information:

- Action**
- To display summary information about the CoS state for all ANCP subscribers:

```
user@host> show ancp cos
```

- To display information about the CoS state for an ANCP subscriber specified by the access loop circuit identifier:

```
user@host> show ancp cos "port-2-11"
```

- To display the most recently updated CoS information:

```
user@host> show ancp cos last-update
```

- To display the CoS information that is pending (will be used to update the fields):

```
user@host> show ancp cos pending-update
```

#### Related Documentation

## Tracing ANCP Operations for Subscriber Access

The Junos OS trace feature tracks ANCP operations and records events in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

1. Important events are logged in a file located in the **/var/log** directory. By default, the router uses the filename **ancpd**. You can specify a different filename, but you cannot change the directory in which trace files are located.
2. When the trace log file **filename** reaches 128 kilobytes (KB), it is compressed and renamed **filename.0.gz**. Subsequent events are logged in a new file called **filename**, until it reaches capacity again. At this point, **filename.0.gz** is renamed **filename.1.gz** and **filename** is compressed and renamed **filename.0.gz**. This process repeats until

the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)

By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

To configure ANCP tracing operations:

1. (Optional) Configure a trace log filename.  
See [“Configuring the ANCP Trace Log Filename” on page 1288](#).
2. (Optional) Configure the number and size of trace logs.  
See [“Configuring the Number and Size of ANCP Log Files” on page 1289](#).
3. (Optional) Configure user access to trace logs.  
See [“Configuring Access to the ANCP Log File” on page 1289](#).
4. (Optional) Configure a regular expression to filter the information to be included in the trace log.  
See [“Configuring a Regular Expression for ANCP Messages to Be Logged” on page 1290](#).
5. (Optional) Configure flags to specify which events are logged.  
See [“Configuring the ANCP Tracing Flags” on page 1290](#).
6. (Optional) Configure a severity level for messages to specify which event messages are logged.  
See [“Configuring the Severity Level to Filter Which ANCP Messages Are Logged” on page 1290](#).

**Related Documentation** • [Configuring ANCP on page 1274](#)

---

## Configuring the ANCP Trace Log Filename

---

By default, the name of the file that records trace output for ANCP is **ancpd**. You can specify a different name with the **file** option.

To configure the filename for ANCP tracing operations:

- Specify the name of the file used for the trace output.

```
[edit protocols ancp traceoptions]  
user@host# set file ancp_1
```

**Related Documentation** • [Tracing ANCP Operations for Subscriber Access on page 1287](#)

## Configuring the Number and Size of ANCP Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format *.number.gz*. The newest archived file is *.0.gz* and the oldest archived file is *.(maximum number)-1.gz*. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, *filename*, reaches 2 MB, *filename* is compressed and renamed *filename.0.gz*, and a new file called *filename* is created. When the new *filename* reaches 2 MB, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until there are 20 trace files. Then the oldest file, *filename.19.gz*, is simply overwritten when the next oldest file, *filename.18.gz* is compressed and renamed to *filename.19.gz*.

To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output.

```
[edit protocols ancp traceoptions]
user@host# set file ancp_1_logfile_1 files 20 size 2097152
```

## Configuring Access to the ANCP Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

To specify that all users can read the log file:

- Configure the log file to be world-readable.

```
[edit protocols ancp traceoptions]
user@host# set file ancp_1_logfile_1 world-readable
```

To explicitly set the default behavior, only the user who configured tracing can read the log file:

- Configure the log file to be no-world-readable.

```
[edit protocols ancp traceoptions]
user@host# set file ancp_1_logfile_1 no-world-readable
```

- Related Documentation**
- [Tracing ANCP Operations for Subscriber Access on page 1287](#)

---

## Configuring a Regular Expression for ANCP Messages to Be Logged

By default, the trace operation output includes all messages relevant to the logged events.

You can refine the output by including regular expressions to be matched.

To configure regular expressions to be matched:

- Configure the regular expression.  

```
[edit protocols ancp traceoptions]  
user@host# set file ancp_1 _logfile_1 match regex
```

- Related Documentation**
- [Tracing ANCP Operations for Subscriber Access on page 1287](#)

---

## Configuring the ANCP Tracing Flags

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

To configure the flags for the events to be logged:

- Configure the flags.  

```
[edit protocols ancp traceoptions]  
user@host# set flag restart
```

- Related Documentation**
- [Tracing ANCP Operations for Subscriber Access on page 1287](#)

---

## Configuring the Severity Level to Filter Which ANCP Messages Are Logged

The messages associated with a logged event are categorized according to severity level. You can use the severity level to determine which messages are logged for the event type. The severity level that you configure depends on the issue that you are trying to resolve. In some cases you might be interested in seeing all messages relevant to the logged event, so you specify **all** or **verbose**. Either choice generates a large amount of output. You can specify a more restrictive severity level, such as **notice** or **info** to filter the messages. By default, the trace operation output includes only messages with a severity level of **error**.

To configure the type of messages to be logged:

- Configure the message severity level.  

```
[edit protocols ancp traceoptions]  
user@host# set level severity
```

## Example: Configuring an ANCP Network with Interface Sets and N:1 Static Demux VLANs over Aggregated Ethernet

---

This example describes how to configure an ANCP network topology that manages subscriber access for several households by grouping individual devices into interface sets, providing access and services through one dedicated C-VLAN per household, and shaping traffic on a per-household basis. In this N:1 configuration, dual-tagged VLANs are configured over a single, underlying, static VLAN demux interfaces over aggregated Ethernet.

- [Requirements on page 1291](#)
- [Overview on page 1291](#)
- [Configuration on page 1296](#)
- [Verification on page 1308](#)

### Requirements

This example uses the following hardware and software components:

- MX Series 3D Universal Edge Router with only MPCs installed for VLAN demux support
- RADIUS server
- DSLAM access node
- Junos OS Release 12.2 or later

Before you begin configuring the example, be sure you have:

- Thoroughly read and understood the following topics:
  - [ANCP Topology Discovery and Traffic Reporting Overview on page 1254](#)
  - [ANCP Operations in Different Network Configurations on page 1262](#)
- Configured your access node.
- Configured your RADIUS server.

### Overview

ANCP provides a means to configure, maintain, and monitor local access lines between access nodes (DSLAMs) and subscribers. Associated CoS configurations shape the downstream subscriber traffic. ANCP can enable more accurate traffic shaping by adjusting net data rates to discount the packet overhead of the access lines and then providing these adjusted rates to CoS.

The network topology in this example includes a dual-tagged (C-VLAN/S-VLAN) VLAN configuration over a static VLAN demux interface that is in turn configured over aggregated Ethernet for redundancy. This topology is an N:1 configuration model because—although each C-VLAN corresponds to one subscriber household—all the C-VLANs are configured over the same underlying VLAN demux interface. Multiple end-user devices in each household—or rather the dynamic PPPoE sessions established by each device—are grouped by household into interface sets. The grouping is accomplished by a separate dynamic profile configured for each C-VLAN. The ANCP agent configuration maps the access loop circuit identifier for the household's access line to an interface set. CoS applies a traffic control profile to each interface set to shape the subscriber-directed traffic on a per-household basis. The CoS shaping rate is dynamically updated based upon the DSL attributes provided by the access node for each household's access line.

Figure 45 on page 1292 shows S-VLAN 103, configured on demux0, servicing the access node. C-VLANs 1, 2, and 3 each service a single household (subscriber). The respective households are identified by unique access loop circuit identifiers. The dynamic PPPoE sessions for devices in each household are grouped for monitoring and traffic shaping into interface sets 10301, 10302, and 10303.

**Figure 45: N:1 ANCP Topology with Interface Sets and VLAN Demux Interface over Aggregated Ethernet**

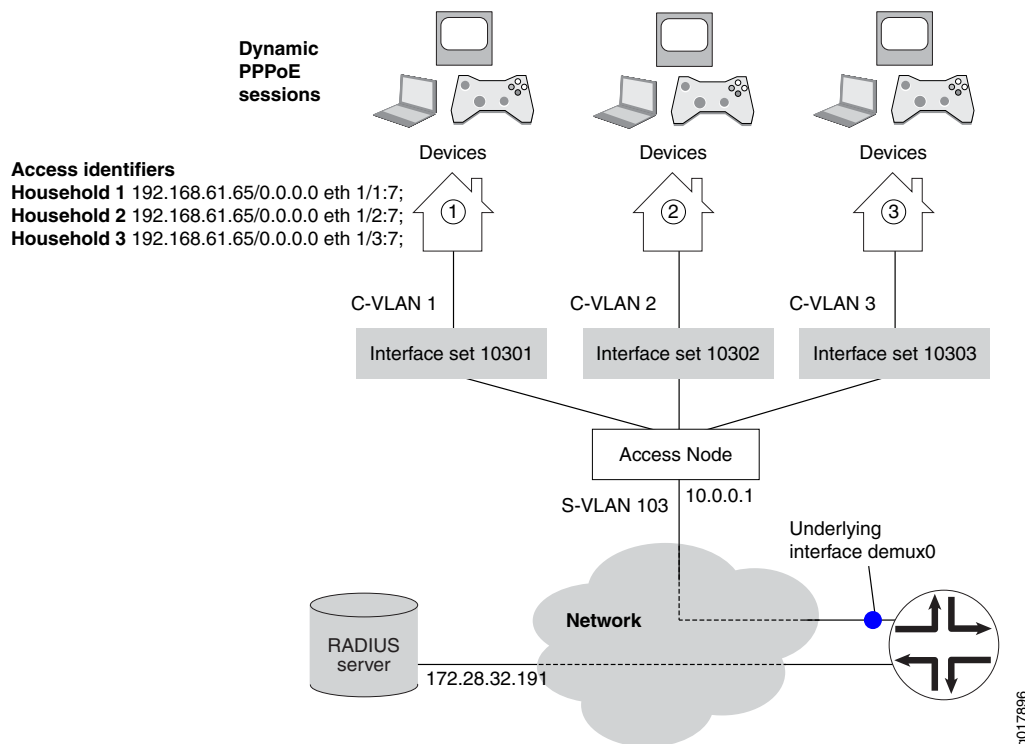

Table 116 on page 1293 describes the configuration components used in this example.

|                                     | lo0.0                     | Loopback interface for use in the access network. The loopback interface is automatically used for unnumbered interfaces.                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                                     | pp0                       | PPP interface on which the PPPoE subscriber logical interfaces are created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Table 116: Configuration Components used in ANCP N:1 Topology Example with Interface Sets (*continued*)

| Configuration Component or Property | Component Name or Setting        | Description                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface sets                      | 10301                            | Set of interfaces in which the sessions for the devices in a particular household are created. Each interface set is specified in a dynamic profile for that household. ANCP associates each interface set with an access loop circuit identifier and a VLAN demux logical interface (C-VLAN). CoS applies a traffic control profile to each interface set. |
|                                     | 10302                            |                                                                                                                                                                                                                                                                                                                                                             |
|                                     | 10303                            |                                                                                                                                                                                                                                                                                                                                                             |
| Advisory traffic rates              | downstream-rate                  | Recommended rate for downstream traffic in the absence of traffic rate information from the access node.                                                                                                                                                                                                                                                    |
|                                     | upstream-rate                    | Recommended rate for upstream traffic in the absence of traffic rate information from the access node.                                                                                                                                                                                                                                                      |
| Traffic control profile             | tcp1                             | CoS profile that shapes the downstream subscriber traffic rate; in this example, shaping is adjusted for ATM packet overhead. The profile is applied to the interface sets.                                                                                                                                                                                 |
| IP addresses                        | 10.0.0.1                         | Address of the ANCP access node that monitors the subscriber households.                                                                                                                                                                                                                                                                                    |
|                                     | 100.0.0.1/32                     | Address of the loopback interface, lo0.                                                                                                                                                                                                                                                                                                                     |
|                                     | 172.28.32.191                    | Address of the RADIUS accounting server and authentication server.                                                                                                                                                                                                                                                                                          |
| Access circuit loop identifiers     | 192.168.61.65/0.0.0.0 eth 1/1:7; | Identifier for the local access circuit from the access node to the subscriber household. It identifies the household. ANCP associates each identifier with an interface set.                                                                                                                                                                               |
|                                     | 192.168.61.65/0.0.0.0 eth 1/2:7; |                                                                                                                                                                                                                                                                                                                                                             |
|                                     | 192.168.61.65/0.0.0.0 eth 1/3:7; |                                                                                                                                                                                                                                                                                                                                                             |

The ANCP agent configuration includes the following elements:

- The IP address for the access node (DSLAM) is specified as 10.0.0.1. The interval between ANCP adjacency messages sent between neighbors is set to 5 seconds.
- The ANCP agent is enabled to report adjusted data rates to CoS to improve the accuracy of downstream traffic shaping. The ANCP agent adjusts the net data rates for ADSL lines by ninety percent and for ADSL2 lines by ninety-five percent.
- Each interface set is associated with both the access loop circuit identifier unique to the subscriber household and the relevant underlying VLAN demux interface.

The RADIUS configuration on the router includes the following elements:

- The IP address (172.28.32.191) for the authentication and accounting server, as well as the secret password for accessing the server.
- The subscriber access profile, radius-profile, specifies that RADIUS is used for authentication.
- Juniper Networks DSL VSAs are included in RADIUS request messages, but the DSL Forum VSA attributes are excluded from RADIUS messages
- Accounting sessions are configured to be recognized in decimal format.

## Configuration

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see [Using the CLI Editor in Configuration Mode](#).

To configure an ANCP network with static N:1 demux VLANs to the subscriber households, perform these tasks:

- [Configuring the Dynamic PPPoE Profiles on page 1298](#)
- [Configuring the Static VLAN Demux Interface over Aggregated Ethernet on page 1300](#)
- [Configuring Class of Service on page 1304](#)
- [Configuring ANCP on page 1305](#)
- [Configuring RADIUS Authentication and Accounting on page 1306](#)

### CLI Quick Configuration

To quickly configure the ANCP network described in this example, copy the following commands, paste them in a text file, remove any line breaks, and then copy and paste the commands into the CLI.

```
# Dynamic Profiles
edit dynamic-profiles ancp-10301
set interfaces interface-set 10301 interface pp0 unit "$junos-interface-unit"
edit interfaces pp0 unit "$junos-interface-unit"
set ppp-options chap
set ppp-options pap
set pppoe-options underlying-interface "$junos-underlying-interface"
set keepalives interval 30
set family inet unnumbered-address lo0.0
top
edit dynamic-profiles ancp-10302
set interfaces interface-set 10302 interface pp0 unit "$junos-interface-unit"
edit interfaces pp0 unit "$junos-interface-unit"
set ppp-options chap
set ppp-options pap
set pppoe-options underlying-interface "$junos-underlying-interface"
set keepalives interval 30
set family inet unnumbered-address lo0.0
top
edit dynamic-profiles ancp-10303
set interfaces interface-set 10303 interface pp0 unit "$junos-interface-unit"
edit interfaces pp0 unit "$junos-interface-unit"
```

```

set ppp-options chap
set ppp-options pap
set pppoe-options underlying-interface "$junos-underlying-interface"
set keepalives interval 30
set family inet unnumbered-address lo0.0

### Configuring the Dynamic PPPoE Profiles

---

- Step-by-Step Procedure** In this procedure, you configure a dynamic profile for each C-VLAN: ancp-10301, ancp-10302, and ancp-10303.
1. Configure the interface set that the PPPoE sessions on this C-VLAN are placed in.  

```
[edit dynamic-profiles ancp-10301]
user@host1# edit interfaces interface-set 10301
```
  2. Configure the logical interfaces to be dynamically instantiated for the interface set.  

```
[edit dynamic-profiles ancp-10301 interfaces interface-set 10301]
user@host1# set interface pp0 unit "$junos-interface-unit"
```
  3. Configure CHAP and PAP authentication as properties of the dynamic PPPoE logical interfaces.  

```
[edit dynamic-profiles ancp-10301 interfaces pp0 unit "$junos-interface-unit"]
user@host1# set ppp-options chap
user@host1# set ppp-options pap
```
  4. Configure the logical underlying interface on which the router creates the dynamic PPPoE logical interface; this is the interface on which the subscriber logs in.  

```
[edit dynamic-profiles ancp-10301 interfaces pp0 unit "$junos-interface-unit"]
user@host1# set pppoe-options underlying-interface "$junos-underlying-interface"
```

- Specify the interval between successive keepalive requests.

```
[edit dynamic-profiles ancp-10301 interfaces pp0 unit "$junos-interface-unit"]
user@host1# set keepalives interval 30
```

- Configure the IPv4 protocol family and that the local (unnumbered) address can be derived from the loopback address for the dynamic PPPoE logical interfaces.

```
[edit dynamic-profiles ancp-10301 interfaces pp0 unit "$junos-interface-unit"]
user@host1# set family inet unnumbered-address lo0.0
```

- Repeat Steps 1 through 6 for the second dynamic profile, ancp-10302, and the third dynamic profile, ancp-10303.

**Results** From configuration mode, confirm the dynamic profile configuration by entering the **show dynamic-profiles** command.

```
[edit]
user@host# show dynamic-profiles
ancp-10301 {
  interfaces {
    interface-set 10301 {
      interface pp0 {
        unit "$junos-interface-unit";
      }
    }
  }
  pp0 {
    unit "$junos-interface-unit" {
      ppp-options {
        chap;
        pap;
      }
      pppoe-options {
        underlying-interface "$junos-underlying-interface";
      }
      keepalives interval 30;
      family inet {
        unnumbered-address lo0.0;
      }
    }
  }
}
ancp-10302 {
  interfaces {
    interface-set 10302 {
      interface pp0 {
        unit "$junos-interface-unit";
      }
    }
  }
  pp0 {
    unit "$junos-interface-unit" {
      ppp-options {
        chap;
        pap;
      }
    }
  }
}
```

```

    pppoe-options {
        underlying-interface "$junos-underlying-interface";
    }
    keepalives interval 30;
    family inet {
        unnumbered-address lo0.0;
    }
}
}
}
}
ancp-10303 {
    interfaces {
        interface-set 10303 {
            interface pp0 {
                unit "$junos-interface-unit";
            }
        }
        pp0 {
            unit "$junos-interface-unit" {
                ppp-options {
                    chap;
                    pap;
                }
                pppoe-options {
                    underlying-interface "$junos-underlying-interface";
                }
                keepalives interval 30;
                family inet {
                    unnumbered-address lo0.0;
                }
            }
        }
    }
}

```

When you are done configuring the device, enter **commit** from configuration mode.

## Configuring the Static VLAN Demux Interface over Aggregated Ethernet

## Step-by-Step Procedure

1. Enable hierarchical scheduling on this interface.  

```
[edit interfaces ge-1/0/1]  
user@host1# set hierarchical-scheduler
```
2. Specify this interface as the primary member of the aggregated Ethernet bundle.  

```
[edit interfaces ge-1/0/1]  
user@host1# set gigether-options 802.3ad ae0 primary
```
3. Enable hierarchical scheduling on a second interface.  

```
[edit interfaces ge-1/0/2]  
user@host1# set hierarchical-scheduler
```
4. Specify this interface as the backup member of the aggregated Ethernet bundle.  

```
[edit interfaces ge-1/0/2]
```

```
user@host1# set gigeether-options 802.3ad ae0 backup
```

5. Enable hierarchical scheduling on the aggregated Ethernet interface.

```
[edit interfaces ae0]
user@host1# set hierarchical-scheduler
```

6. Enable stacked VLAN tagging for all logical interfaces on the aggregated Ethernet interface.

```
[edit interfaces ae0]
user@host1# set stacked-vlan-tagging
```

7. Enable link protection as a property of the aggregated Ethernet interface.

```
[edit interfaces ae0]
user@host1# set aggregated-ether-options link-protection
```

8. Configure VLAN demux interface demux0.10301.

- a. Configure the router to respond to ARP requests on the interface.

```
[edit interfaces demux0 unit 10301]
user@host1# set proxy-arp
```

- b. Configure the outer VLAN tag to identify the access node (S-VLAN) and the inner VLAN tag to identify the subscriber port on the access node (C-VLAN).

```
[edit interfaces demux0 unit 10301]
user@host1# set vlan tags outer 103 inner 1
```

- c. Specify that the VLAN demux interface runs on the underlying aggregated Ethernet interface.

```
[edit interfaces demux0 unit 10301]
user@host1# set demux-options underlying-interface ae0
```

- d. Prevent multiple PPPoE sessions from being created for the same PPPoE subscriber on this VLAN demux interface.

```
[edit interfaces demux0 unit 10301]
user@host1# set family pppoe duplicate-protection
```

- e. Configure the dynamic profile that is instantiated on the VLAN demux interface.

```
[edit interfaces demux0 unit 10301]
user@host1# set family pppoe dynamic-profile ancp-10301
```

- f. Configure the recommended upstream and downstream traffic rates.

```
[edit interfaces demux0 unit 10301]
user@host1# set advisory-options upstream-rate 1m
user@host1# set advisory-options downstream-rate 16m
```

9. Configure VLAN demux interface demux0.10302.

- a. Configure the router to respond to ARP requests on the interface.

```
[edit interfaces demux0 unit 10302]
user@host1# set proxy-arp
```

- b. Configure the outer VLAN tag to identify the access node (S-VLAN) and the inner VLAN tag to identify the subscriber port on the access node (C-VLAN).

```
[edit interfaces demux0 unit 10302]
user@host1# set vlan tags outer 103 inner 2
```

- c. Specify that the VLAN demux interface runs on the underlying aggregated Ethernet interface.

```
[edit interfaces demux0 unit 10302]
user@host1# set demux-options underlying-interface ae0
```

- d. Prevent multiple PPPoE sessions from being created for the same PPPoE subscriber on this VLAN demux interface.

```
[edit interfaces demux0 unit 10302]
user@host1# set family pppoe duplicate-protection
```

- e. Configure the dynamic profile that is instantiated on the VLAN demux interface.

```
[edit interfaces demux0 unit 10302]
user@host1# set family pppoe dynamic-profile ancp-10302
```

- f. Configure the recommended upstream and downstream traffic rates.

```
[edit interfaces demux0 unit 10302]
user@host1# set advisory-options upstream-rate 1m
user@host1# set advisory-options downstream-rate 16m
```

- 10. Configure VLAN demux interface demux0.10303.

- a. Configure the router to respond to ARP requests on the interface.

```
[edit interfaces demux0 unit 10303]
user@host1# set proxy-arp
```

- b. Configure the outer VLAN tag to identify the access node (S-VLAN) and the inner VLAN tag to identify the subscriber port on the access node (C-VLAN).

```
[edit interfaces demux0 unit 10303]
user@host1# set vlan tags outer 103 inner 3
```

- c. Specify that the VLAN demux interface runs on the underlying aggregated Ethernet interface.

```
[edit interfaces demux0 unit 10303]
user@host1# set demux-options underlying-interface ae0
```

- d. Prevent multiple PPPoE sessions from being created for the same PPPoE subscriber on this VLAN demux interface.

```
[edit interfaces demux0 unit 10303]
user@host1# set family pppoe duplicate-protection
```

- e. Configure the dynamic profile that is instantiated on the VLAN demux interface.

```
[edit interfaces demux0 unit 10303]
user@host1# set family pppoe dynamic-profile ancp-10303
```

- f. Configure the recommended upstream and downstream traffic rates.

```
[edit interfaces demux0 unit 10303]
user@host1# set advisory-options upstream-rate 1m
user@host1# set advisory-options downstream-rate 16m
```

- 11. Configure the IPv4 protocol family and the address of the loopback interface.

```
[edit interfaces lo0]
user@host1# set unit 0 family inet address 100.0.0.1/32
```

**Results** From configuration mode, confirm the static VLAN demux configuration by entering the **show interfaces** command.

```
[edit]
user@host# show interfaces
ge-1/0/1 {
  hierarchical-scheduler;

}

```

When you are done configuring the device, enter **commit** from configuration mode.

### Configuring ANCP

#### Step-by-Step Procedure

1. Configure the access node address.  

```

[edit protocols ancp]
user@host1# set neighbor 10.0.0.1

```
2. Configure the ANCP agent to report adjusted downstream traffic rates to CoS.  

```

[edit protocols ancp]
user@host1# set qos-adjust

```
3. Specify an overhead adjustment of the traffic on ADSL and ADSL2 lines to 90 percent and 95 percent, respectively, of the net data rate.  

```

[edit protocols ancp]
user@host1# set qos-adjust-adsl 90
user@host1# set qos-adjust-adsl2 95

```
4. Specify an interval of 5 seconds between adjacency messages sent to all ANCP neighbors.  

```

[edit protocols ancp]
user@host1# set adjacency-timer 5

```
5. Associate the access loop circuit identifier with the interface sets for each C-VLAN.  

```

[edit protocols ancp]
user@host1# set interfaces interface-set 10301 access-identifier
"192.168.61.65/0.0.0.0 eth 1/1:7;"
user@host1# set interfaces interface-set 10302 access-identifier
"192.168.61.65/0.0.0.0 eth 1/2:7;"
user@host1# set interfaces interface-set 10303 access-identifier
"192.168.61.65/0.0.0.0 eth 1/3:7;"

```
6. Specify the underlying interface for the interface sets.  

```

[edit protocols ancp]
user@host1# set interfaces interface-set 10301 underlying-interface demux0.10301

```

```
user@host1# set interfaces interface-set 10302 underlying-interface demux0.10302
user@host1# set interfaces interface-set 10303 underlying-interface demux0.10303
```

7. Configure the size of the ANCP trace log files.

```
[edit protocols ancp traceoptions]
user@host1# set file ancpd size 512m
```

8. Configure flags for tracing ANCP configuration and CoS operations.

```
[edit protocols ancp traceoptions]
user@host1# set flag config
user@host1# set flag cos
```

**Results** From configuration mode, confirm the ANCP agent configuration by entering the **show ancp** command.

```
[edit]
user@host# show ancp
traceoptions {
  file ancpd size 512m;
  flag config;
  flag cos;
}
qos-adjust;
adjacency-timer 5;
qos-adjust-adsl 90;
qos-adjust-adsl2 95;
interfaces {
  interface-set {

      underlying-interface demux0.10301;
    }
    10302 {
      access-identifier "192.168.61.65/0.0.0.0 eth 1/2:7;";
      underlying-interface demux0.10302;
    }
    10303 {
      access-identifier "192.168.61.65/0.0.0.0 eth 1/3:7;";
      underlying-interface demux0.10303;
    }
  }
}
neighbor 10.0.0.1;
```

When you are done configuring the device, enter **commit** from configuration mode.

---

### Configuring RADIUS Authentication and Accounting

---

#### Step-by-Step Procedure

1. Configure the password for the RADIUS server.

```
[edit access]
user@host1# set radius-server 172.28.32.191 secret
"$9$MUeL7VgoGqmTwYmTz3tpWLx"
```

2. Specify that RADIUS is used to authenticate subscribers.

```
[edit access]
user@host1# set profile radius-profile authentication-order radius
```

3. Configure the RADIUS authentication and accounting server.

```
[edit access]
user@host1# set profile radius-profile radius authentication-server 172.28.32.191
user@host1# set profile radius-profile radius accounting-server 172.28.32.191
```

4. Configure options for the RADIUS server: The format used to identify the accounting session and that Juniper Networks DSL VSAs are added to RADIUS request messages.

```
[edit access]
user@host1# set profile radius-profile radius options accounting-session-id-format decimal
user@host1# set profile radius-profile radius options juniper-dsl-attributes
```

5. Exclude DSL Forum VSA attributes from being included in RADIUS messages.

```
[edit access]
user@host1# set profile radius-profile radius attribute exclude dsl-forum-attributes access-request
user@host1# set profile radius-profile radius attribute exclude dsl-forum-attributes accounting-start
user@host1# set profile radius-profile radius attribute exclude dsl-forum-attributes accounting-stop
```

**Results** From configuration mode, confirm the RADIUS configuration by entering the **show access** command.

```
[edit]
user@host# show access
radius-server {
  172.28.32.191 secret "$9$MUeL7VgoGqmTwYmTz3tpWLx"; ## SECRET-DATA
}
profile radius-profile {
  radius {
    authentication-server 172.28.32.191;
    accounting-server 172.28.32.191;
    options {
      accounting-session-id-format decimal;
      juniper-dsl-attributes;
    }
    attributes {
      exclude {
        dsl-forum-attributes [ access-request accounting-start accounting-stop ];
      }
    }
  }
}
```

When you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying the Aggregated Ethernet Interface Configuration on page 1308](#)
- [Verifying the Traffic Scheduling and Shaping Parameters for the Interface Set on page 1308](#)
- [Verifying the demux0 Interface Configuration on page 1309](#)
- [Verifying the pp0 Interface Configuration on page 1309](#)
- [Verifying the ANCP Agent Configuration on page 1310](#)

### Verifying the Aggregated Ethernet Interface Configuration

**Purpose** Verify that the interface values match your configuration, the link is up, and traffic is flowing.

**Action** From operational mode, enter the **show interfaces redundancy** command.

```
user@host> show interfaces redundancy
Interface  State           Last change  Primary    Secondary  Current status
ae0        On primary          ge-1/0/1     ge-1/0/2   both up
```

From operational mode, enter the **show interfaces ae0** command.

```
user@host> show interfaces ae0
Physical interface: ae0, Enabled, Physical link is Up
  Interface index: 128, SNMP ifIndex: 606
  Link-level type: Ethernet, MTU: 1522, Speed: 1Gbps, BPDU Error: None,
  MAC-REWRITE Error: None, Loopback: Disabled, Source filtering: Disabled,
  Flow control: Disabled, Minimum links needed: 1, Minimum bandwidth needed: 0
  Device flags   : Present Running
  Interface flags: SNMP-Traps Internal: 0x4000
  Current address: 00:1f:12:b8:ef:c0, Hardware address: 00:1f:12:b8:ef:c0
  Last flapped   : 2012-03-11 13:24:18 PST (2d 03:34 ago)
  Input rate     : 1984 bps (2 pps)
  Output rate    : 0 bps (0 pps)

Logical interface ae0.32767 (Index 69) (SNMP ifIndex 709)
  Flags: SNMP-Traps 0x4004000 VLAN-Tag [ 0x0000.0 ] Encapsulation: ENET2
  Statistics          Packets      pps      Bytes      bps
  Bundle:
    Input :           371259         2    46036116    1984
    Output:              0         0         0         0
  Protocol multiservice, MTU: Unlimited
  Flags: Is-Primary
```

**Meaning** The **show interfaces redundancy** output shows the redundant link configuration and that both link interfaces are up. The **show interfaces ae0** output shows that the aggregated Ethernet interface is up and that traffic is being received on the logical interface.

### Verifying the Traffic Scheduling and Shaping Parameters for the Interface Set

**Purpose** Verify that the traffic scheduling and shaping parameters are configured and applied properly.

**Action** user@host> show class-of-service

### Verifying the demux0 Interface Configuration

**Purpose** Verify that the VLAN demux interface displays the configured PPPoE family attributes and the member links in the aggregated Ethernet bundle.

**Action** From operational mode, enter the **show interfaces demux0** command for each VLAN.

```
user@host> show interfaces demux0.10301
Logical interface demux0.10301 (Index 76) (SNMP ifIndex 61160)
  Flags: SNMP-Traps 0x4000 VLAN-Tag [ 0x8100.100 ]
  Encapsulation: ENET2
  Demux:
    Underlying interface: ae0 (Index 199)
  Link:
    ge-1/0/1
    ge-1/0/2
  Input packets : 2
  Output packets: 18575
  Protocol pppoe
    Dynamic Profile: ancp-10301,
    Service Name Table: None,
    Max Sessions: 16000, Duplicate Protection: On,
    AC Name: pppoe-server-1
```

Alternatively, you can enter **show pppoe underlying-interfaces detail** to display the state and PPPoE family configuration for all configured underlying interfaces.

**Meaning** The output shows the name of the underlying interface, the member links of the aggregated bundle, and the PPPoE family configuration. The output shows packet counts when traffic is present on the logical interface.

### Verifying the pp0 Interface Configuration

**Purpose** Verify that the interface values match your configuration.

**Action** From operational mode, enter the **show interfaces pp0** command.

```
user@host> show interfaces pp0.100
Logical interface pp0.100 (Index 71) (SNMP ifIndex 710)
  Flags: Point-To-Point SNMP-Traps 0x4000 Encapsulation: PPPoE
  PPPoE:
    State: SessionUp, Session ID: 1,
    Session AC name: pppoe-server-1, Remote MAC address: 00:90:1a:00:18:34,
    Underlying interface: demux0.10301 (Index 70)
  Link:
    ge-5/0/3.32767
    ge-5/1/2.32767
  Input packets : 18572
  Output packets: 18572
  Keepalive settings: Interval 10 seconds, Up-count 1, Down-count 3
  Keepalive: Input: 0 (never), Output: 18566 (00:00:02 ago)
  LCP state: Opened
  NCP state: inet: Opened, inet6: Not-configured, iso: Not-configured, mpls:
  Not-configured
  CHAP state: Closed
```

```
PAP state: Success
Protocol inet, MTU: 1500
Flags: Sendbroadcast-pkt-to-re
Addresses, Flags: Is-Primary
Local: 45.63.24.1
```

**Meaning** This output shows information about the PPPoE logical interface created on the underlying VLAN demux interface. The output includes the PPPoE family and aggregated Ethernet redundant link information, and shows input and output traffic for the PPPoE interface.

---

### Verifying the ANCP Agent Configuration

---

**Purpose** Verify that the ANCP values match your configuration and that traffic is flowing.

**Action** From operational mode, enter the **show ancp subscriber** command.

```
user@host> show ancp subscriber detail
Interface  State           Last change  Primary      Secondary    Current status
ae0        On primary          ge-1/0/1     ge-1/0/2     both up
```

From operational mode, enter the **show ancp cos** command.

```
user@host> show ancp cos

Qos Adjust Flag:      TRUE
Keepalive Timer:      30 secs
Cos State:            WRITE_READY
Connect Time:         Mon Mar 19 15:03:01 2012
Session Time:         Mon Mar 19 15:03:13 2012
Routing Instance Time: Mon Mar 19 15:03:14 2012
Keepalive Time:       Not Set
Rate Update Time:     Mon Mar 19 15:03:15 2012
```

| Type   | Name  | Index | Pending Update | Last Update |
|--------|-------|-------|----------------|-------------|
| iflset | 10301 | 1     | None           | 64 Kbps     |
| iflset | 10302 | 2     | None           | 64 Kbps     |
| iflset | 10303 | 71    | None           | 64 Kbps     |

**Meaning** The **show ancp subscriber** output shows subscriber line information such as state and the various traffic rates collected by the ANCP agent—displayed for each subscriber as identified by the access loop circuit identifier. The **show ancp cos** output shows that the ANCP agent is configured to send adjusted rate data to CoS, that keepalives are configured for a 30-second interval, and that the interface sets 10301, 10302, and 10303 are configured and their traffic rates are updating

# Dynamic IGMP Configuration Overview

- [Dynamic IGMP Configuration Overview on page 1313](#)

## Dynamic IGMP Configuration Overview

---

The Internet Group Management Protocol (IGMP) is a host to router signaling protocol for IPv4 used to support IP multicasting. This protocol manages the membership of hosts and routers in multicast groups. IP hosts use IGMP to report their multicast group memberships to any immediately neighboring multicast routers. Multicast routers use IGMP to learn, for each of their attached physical networks, which groups have members.

Subscriber access supports the configuration of IGMP within the **dynamic profiles** hierarchy. By specifying IGMP statements within a dynamic profile, you can dynamically apply IGMP configuration when a subscriber connects to an interface using a particular access technology (DHCP), enabling the subscriber to access a carrier (multicast) network.

# Dynamic MLD Configuration Overview

- [Dynamic MLD Configuration Overview on page 1315](#)

## Dynamic MLD Configuration Overview

---

The Multicast Listener Discovery (MLD) Protocol manages the membership of hosts and routers in multicast groups. IP version 6 (IPv6) multicast routers use MLD to learn, for each of their attached physical networks, which groups have interested listeners. Each router maintains a list of host multicast addresses that have listeners for each subnet, as well as a timer for each address. However, the router does not need to know the address of the listeners—just the address of the hosts. The router provides addresses to the multicast routing protocol it uses; this ensures that multicast packets are delivered to all subnets where there are interested listeners. In this way, MLD is used as the transport for the Protocol Independent Multicast (PIM) protocol.

Subscriber access supports the configuration of MLD within the **dynamic profiles** hierarchy for dynamically created interfaces. By specifying MLD statements within a dynamic profile, you can dynamically apply MLD configuration when a subscriber connects to an interface using a particular access technology (DHCP), enabling the subscriber to access a carrier (multicast) network.

# Dynamic Router Advertisement Overview

- [Dynamic Router Advertisement Configuration Overview on page 1317](#)

## Dynamic Router Advertisement Configuration Overview

---

In a network deployment where router interfaces are configured statically, you might need to configure the Router Advertisement Protocol on only a small number of interfaces on which it might run. However, in a subscriber access network, static configuration of the Router Advertisement Protocol becomes impractical because the number of interfaces that potentially need the Router Advertisement Protocol increases substantially. In addition, deploying services in a dynamic environment requires dynamic modifications to interfaces as they are created.

Subscriber access supports the configuration of the Router Advertisement Protocol at the **[edit dynamic-profiles *profile-name* protocols]** hierarchy level. By specifying Router Advertisement Protocol statements within a dynamic profile, you can dynamically apply a Router Advertisement configuration when a subscriber connects to an interface using a particular access technology (for example, DHCP), enabling the subscriber to access a carrier (multicast) network.

To minimally configure the Router Advertisement Protocol requires that you include the **router-advertisement** statement at the **[edit dynamic-profiles *profile-name* protocols]** hierarchy level and the **interface** statement along with the *\$junos-interface-name* dynamic variable. All other statements are optional.

**NOTE:** Statements used for Router Advertisement Protocol configuration at the **[edit dynamic-profiles *profile-name* protocols]** hierarchy level are identical in function to those same statements used for static Router Advertisement Protocol configuration, with the exception of the interface and prefix statements, which use dynamic variables.

## PART 18

# Subscriber Access Examples

- [Service Profile Examples on page 1321](#)

# Service Profile Examples

- [Example: Configuring a Tiered Service Profile for Subscriber Access on page 1321](#)

## Example: Configuring a Tiered Service Profile for Subscriber Access

---

This example shows how to configure a tiered service profile for subscribers.

The profile contains three services:

- Gold—Subscribers that pay for this service are allocated 10M bandwidth for data, voice, and video services.
- Silver—Subscribers that pay for this service are allocated 5M bandwidth for data, voice, and video services.
- Bronze—Subscribers that pay for this service are allocated 1M bandwidth for the data service only.

Each subscriber is allocated a VLAN that is created statically. Subscribers log in using DHCP and authenticate using RADIUS. The subscribers can migrate from one service to another when they change subscriptions.

To configure a profile for a tiered service:

1. Configure the VLAN interfaces associated with each subscriber. Enable hierarchical scheduling for the interface.

```

interfaces {
  ge-2/0/0 {
    description subscribers;
    hierarchical-scheduler;
    stacked-vlan-tagging;
    unit 1 {
      vlan-tags outer 100 inner 100;
      family inet {
        unnumbered-address lo0.0 preferred-source-address 100.0.0.1;
      }
    }
    unit 2 {
      family inet {
        vlan-tags outer 101 inner 101;
        unnumbered-address lo0.0 preferred-source-address 100.0.0.1;
      }
    }
  }
}

```

```
    }  
    unit 3 {  
        vlan-tags outer 102 inner 102;  
        family inet {  
            unnumbered-address lo0.0 preferred-source-address 100.0.0.1;  
        }  
    }  
}  
}
```

2. Configure the static CoS parameters.

In this example, each offering (video, voice, and data) is assigned a queue, and each service (Gold, Silver, and Bronze) is assigned a scheduler.

```
class-of-service {  
    forwarding-classes {  
        queue 0 data;  
        queue 1 voice;  
        queue 2 video;  
    }  
    scheduler-maps {  
        bronze_service_smap {  
            forwarding-class data scheduler data_sch;  
        }  
        silver_service_smap {  
            forwarding-class data scheduler data_sch;  
            forwarding-class voice scheduler silver_voice_sch;  
            forwarding-class video scheduler silver_video_sch;  
        }  
        gold_service_smap {  
            forwarding-class data scheduler data_sch;  
            forwarding-class voice scheduler gold_voice_sch;  
            forwarding-class video scheduler gold_video_sch;  
        }  
    }  
    schedulers {  
        data_sch {  
            transmit-rate percent 20;  
            buffer-size remainder;  
            priority low;  
        }  
        silver_voice_sch {  
            transmit-rate percent 30;  
            buffer-size remainder;  
            priority high;  
        }  
        silver_video_sch {  
            transmit-rate percent 30;  
            buffer-size remainder;  
            priority medium;  
        }  
        gold_voice_sch {  
            transmit-rate percent 40;  
            buffer-size remainder;  
            priority high;  
        }  
    }  
}
```

```

    gold_video_sch {
        transmit-rate percent 40;
        buffer-size remainder;
        priority medium;
    }
}
}

```

3. Configure the dynamic profile for the service.

The scheduler maps configured for each service are referenced in the dynamic profile.

```

dynamic-profiles {
    subscriber_profile {
        interfaces {
            "$junos-interface-ifd-name" {
                unit "$junos-underlying-interface-unit" {
                    family inet;
                }
            }
        }
        class-of-service {
            traffic-control-profiles {
                subscriber_tcp {
                    scheduler-map $smap;
                    shaping-rate $shaping-rate;
                    guaranteed-rate $guaranteed-rate;
                    delay-buffer-rate $delay-buffer-rate;
                }
            }
            interfaces {
                "$junos-interface-ifd-name" {
                    unit "$junos-underlying-interface-unit" {
                        output-traffic-control-profile subscriber_tcp;
                    }
                }
            }
        }
    }
}

```

4. Configure access for the subscribers.

The DHCP relay agent forwards DHCP request and reply packets between a DHCP client and a DHCP server. You use DHCP relay to obtain configuration parameters, including an IP address, for subscribers. In this example, one DHCP server, address 100.20.42.1, can be used by subscribers.

The DHCP relay configuration is attached to an active server group named `service_provider_group`.

The subscribers are grouped together within the `subscriber_group`, and identifies characteristics such as authentication, username info, and the associated interfaces for the group members. In this example, it also identifies the active server group and the dynamic interface that is used by the subscribers in the group.

```

forwarding-options {
    dhcp-relay {
        server-group {

```

```
        service_provider_group {  
            100.20.42.1;  
        }  
    }  
    group subscriber_group {  
        active-server-group service_provider_group;  
        dynamic-profile subscriber_profile;  
        interface ge-2/0/0.1;  
        interface ge-2/0/0.2;  
        interface ge-2/0/0.3;  
    }  
}  
}
```

| <b>Release Information</b>      | Statement introduced in Junos OS Release 11.4.<br>Support at the [edit access profile <i>profile-name</i> client <i>client-name</i> l2tp] hierarchy level introduced in Junos OS Release 12.1.                                                                                                                                                                                                                                                                                         |
| <b>Description</b>              | Specify a AAA access profile that overrides the AAA access profile configured for the routing instance with the <b>access-profile</b> statement. You can configure a profile to specify the RADIUS server settings for a tunnel group or for a LAC client, or both. The AAA access profile configured for the client takes precedence over the AAA access profile configured for the tunnel group, which takes precedence over the access profile configured for the routing instance. |
| <b>Options</b>                  | <i>profile-name</i> —Name of the local access profile for the tunnel group or client.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Required Privilege Level</b> | interface—To view this statement in the configuration.<br>interface-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                |

## access (Dynamic Access Routes)

**Syntax**

```
access {
  route prefix {
    next-hop next-hop;
    metric route-cost;
    preference route-distance;
    tag route-tag;
  }
}
```

**Hierarchy Level** [edit dynamic-profiles [routing-options](#)]

**Release Information** Statement introduced in Junos OS Release 9.5.

**Description** Dynamically configure access routes.

**BEST PRACTICE:** We recommend that you always include the [access-internal](#) stanza in the dynamic-profile when the `access` stanza is present for framed-route support.

**Options** The remaining statements are explained separately.

**Required Privilege Level**

- routing—To view this statement in the configuration.
- routing-control—To add this statement to the configuration.

## access-identifier

---

- Syntax** `access-identifier identifier-string;`
- Hierarchy Level** [edit protocols ancp [interfaces](#) *interface-name*],  
[edit protocols ancp interfaces [interface-set](#)]
- Release Information** Statement introduced in Junos OS Release 9.4.
- Description** Associate an access-loop circuit identifier (ACI) with the VLAN or set of VLANs that carry traffic to the subscriber using that access loop; identify a particular subscriber. This statement requires that the name of the interface or interface set is statically configured or deterministic. This means that it can be used with dynamic or static interface sets, VLAN-tagged interface sets, or static VLAN/VLAN demux interfaces.
- Options** *identifier-string*—Unique identifier string for the access loop circuit; also configured on the access node.
- Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

## access-internal (Dynamic Access-Internal Routes)

---

**Syntax**    `access-internal {  
              route subscriber-ip-address {  
                  qualified-next-hop underlying-interface {  
                      mac-address address;  
                  }  
              }  
          }`

**Hierarchy Level**    [edit dynamic-profiles [routing-options](#)]

**Release Information**    Statement introduced in Junos OS Release 9.5.

**Description**    Dynamically configure access-internal routes. Access-internal routes are optional, but are used instead of access routes if the next-hop address is not specified in the Framed-Route Attribute [22] for IPv4 or the Framed-IPv6-Route attribute [99] for IPv6.

.....  
**BEST PRACTICE:** We recommend that you always include the `access-internal` stanza in the dynamic-profile when the `access` stanza is present for framed-route support.  
.....

The remaining statements are explained separately.

**Required Privilege Level**    routing—To view this statement in the configuration.  
                                  routing-control—To add this statement to the configuration.

```

**Hierarchy Level** [edit access]

**Release Information** Statement introduced in Junos OS Release 9.0.  
Statement introduced in Junos OS Release 12.1 for EX Series switches.

**Description** Configure address-assignment pools that can be used by different client applications.

**NOTE:** Subordinate statement support depends on the platform. See individual statement topics for more detailed support information.

**Options** *pool-name*—Name assigned to an address-assignment pool.

The remaining statements are explained separately.

**Required Privilege Level** admin—To view this statement in the configuration.  
admin-control—To add this statement to the configuration.

| <b>Description</b>              | Configure an Ascend-Data-Filter that the dynamic profile applies to a subscriber session.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Options</b>                  | <p><b>counter</b>—Enable a counter that increments each time the Ascend-Data-Filter rule is used. Typically used for testing purposes.</p> <p><b>not-mandatory</b>—Suppress router from reporting an error when the RADIUS reply message does not include the \$junos-adf-rule-v4 or \$junos-adf-rule-v6 variable that is configured for the Ascend-Data-Filter in the dynamic profile. In this circumstance, the Ascend-Data-Filter is not created.</p> <p><b>precedence</b>—Precedence value that sets the order in which dynamic service filters are applied on the interface. The lower the precedence value, the higher the precedence that is given. The precedence setting is used in conjunction with the precedence settings of all dynamic service filters configured (not only Ascend-Data-Filters) on the same interface to establish the order. For example, the order also includes any configured <b>input</b> <i>filter-name</i> <b>precedence</b> <i>precedence</i> and <b>output</b> <i>filter-name</i> <b>precedence</b> <i>precedence</i> statements.</p> <p><b>Range:</b> 0 through 255</p> <p><b>Default:</b> 0</p> <p><b>rule-value</b>—Ascend-Data-Filter rule. You can specify either a Junos predefined variable that maps the Ascend-Data-Filter actions to Junos filter functionality or you can manually configure the Ascend-Data-Filter rule. The router supports two predefined variables depending on family type: <b>\$junos-adf-rule-v4</b> for family <b>inet</b> and <b>\$junos-adf-rule-v6</b> for family <b>inet6</b>.</p> |
| <b>Required Privilege Level</b> | <p><b>interface</b>—To view this statement in the configuration.</p> <p><b>interface-control</b>—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b>              | <p>Override the DHCP relay agent information option (option 82) in DHCP packets destined for a DHCP server. The use of this option causes the DHCP relay agent to perform one of the following actions, depending on how it is configured:</p> <ul style="list-style-type: none"><li>• If the DHCP relay agent is configured to add option 82 information to DHCP packets, it clears the existing option 82 values from the DHCP packets and inserts the new values before forwarding the packets to the DHCP server.</li><li>• If the DHCP relay agent is not configured to add option 82 information to DHCP packets, it clears the existing option 82 values from the packets, but does not add any new values before forwarding the packets to the DHCP server.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b>              | Configure how many attempts are made to reconfigure all DHCP clients or only the DHCP clients serviced by the specified group of interfaces before reconfiguration is considered to have failed. A group configuration takes precedence over a DHCP local server configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b>              | <p>Specify the order in which the router tries to negotiate PPP authentication protocols when verifying that a PPP client can access the network. By default, the router tries to negotiate Challenge Handshake Authentication Protocol (CHAP) authentication first, and then tries Password Authentication Protocol (PAP) authentication if the attempt to negotiate CHAP authentication is unsuccessful.</p> <p>You can specify one or both authentication protocols. If you specify both CHAP and PAP in either order, you must enclose the set of protocol names within square brackets ([ ]).</p> |
| <b>Options</b>                  | <p><b><i>authentication-protocols</i></b>—One or both of the following PPP authentication protocols:</p> <ul style="list-style-type: none"><li>• <b>chap</b>—Challenge Handshake Authentication Protocol</li><li>• <b>pap</b>—Password Authentication Protocol</li></ul>                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b>              | Set the order in which the Junos OS tries different authentication methods when verifying that a client can access the router or switch. For each login attempt, the software tries the authentication methods in order, from first to last.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b>         | <p>For a single-rate two-color policer, configure the bandwidth limit as a number of bits per second. Single-rate two-color policing uses the single token bucket algorithm to measure traffic-flow conformance to a two-color policer rate limit.</p> <p>Traffic at the interface that conforms to the bandwidth limit is categorized green. Traffic that exceeds the specified rate is also categorized as green provided that sufficient tokens remain in the single token bucket. Packets in a green flow are implicitly marked with <b>low</b> packet loss priority (PLP) and then passed through the interface.</p> <p>Traffic that exceeds the specified rate when insufficient tokens remain in the single token bucket is categorized red. Depending on the configuration of the two-color policer, packets in a red traffic flow might be implicitly discarded; or the packets might be re-marked with a specified forwarding class, a specified PLP, or both, and then passed through the interface.</p> <div style="margin-top: 20px;">  <p><b>NOTE:</b> This statement specifies the bandwidth limit as an absolute number of bits per second. Alternatively, for single-rate two-color policers only, you can use the <code>bandwidth-percent <i>percentage</i></code> statement to specify the bandwidth limit as a percentage of either the physical interface port speed or the configured logical interface shaping rate.</p> </div> <p>Single-rate two-color policing allows bursts of traffic for short periods, whereas single-rate and two-rate three-color policing allows more sustained bursts of traffic.</p> <p>Hierarchical policing is a form of two-color policing that applies different policing actions based on whether the packets are classified for expedited forwarding (EF) or for a lower priority. You apply a hierarchical policer to ingress Layer 2 traffic to allow bursts of EF traffic for short period and bursts of non-EF traffic for short periods, with EF traffic always taking precedence over non-EF traffic.</p> |
| <b>Options</b>             | <p><b><i>bps</i></b>—You can specify the number of bits per second either as a decimal number or as a decimal number followed by the abbreviation <b>k</b> (1000), <b>m</b> (1,000,000), or <b>g</b> (1,000,000,000).</p> <p><b>Range:</b> (M Series, MX Series, and T Series routers) 8000 through 50,000,000,000</p> <p><b>Default:</b> None.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Release Information</b> | Statement introduced before Junos OS Release 7.4.<br>Support at the [edit <code>dynamic-profiles ... if-exceeding</code> ] hierarchy level introduced in Junos OS Release 11.4.                                                                                                                                          |
| <b>Description</b>         | For a single-rate two-color policer, configure the bandwidth limit as a percentage value. Single-rate two-color policing uses the <i>single token bucket algorithm</i> to measure traffic-flow conformance to a two-color policer rate limit.                                                                            |

Traffic at the interface that conforms to the bandwidth limit is categorized green. Traffic that exceeds the specified rate is also categorized as green provided that sufficient tokens remain in the single token bucket. Packets in a green flow are implicitly marked with **low** packet loss priority and then passed through the interface.

Traffic that exceeds the specified rate when insufficient tokens remain in the single token bucket is categorized red. Depending on the configuration of the two-color policer, packets in a red traffic flow might be implicitly discarded; or the packets might be re-marked with a specified forwarding class, a specified PLP, or both, and then passed through the interface.

**NOTE:** This statement specifies the bandwidth limit as a percentage of either the physical interface port speed or the configured logical interface shaping rate. Alternatively, you can use the `bandwidth-limit bps` statement to specify the bandwidth limit as an absolute number of bits per second.

The function of the bandwidth limit is extended by the burst size (configured using the `burst-size-limit bytes` statement) to allow bursts of traffic up to a limit based on the overall traffic load:

- When a single-rate two-color policer is applied to the input or output traffic at an interface, the initial capacity for traffic bursting is equal to the number of bytes specified by this statement.
- During periods of relatively low traffic (traffic that arrives at or departs from the interface at overall rates below the token arrival rate), unused tokens accumulate in the bucket, but only up to the configured token bucket depth.

Single-rate two-color policing allows bursts of traffic for short periods, whereas single-rate and two-rate three-color policing allows more sustained bursts of traffic.

Hierarchical policing is a form of two-color policing that applies different policing actions based on whether the packets are classified for expedited forwarding (EF) or for a lower

priority. You apply a hierarchical policer to ingress Layer 2 traffic to allows bursts of EF traffic for short period and bursts of non-EF traffic for short periods, with EF traffic always taking precedence over non-EF traffic.

**Options** *percentage*—Traffic rate as a percentage of either the physical interface media rate or the logical interface configured shaping rate. You can configure a shaping rate on a logical interface by using class-of-service statement.

**NOTE:** You cannot rate-limit based on bandwidth percentage for aggregate, tunnel, and software interfaces. The bandwidth percentage policer cannot be used for forwarding table filters. Bandwidth percentage policers can only be used for interface-specific filters.

**Range:** 0 through 100

**Default:** None.

| <b>Release Information</b> | Statement introduced before Junos OS Release 7.4.<br>Support at the [edit <b>dynamic-profiles</b> ... <b>if-exceeding</b> ] hierarchy level introduced in Junos OS Release 11.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>         | <p>For a single-rate two-color policer, configure the burst size as a number of bytes. The burst size allows for short periods of traffic bursting (back-to-back traffic at average rates that exceed the configured bandwidth limit). Single-rate two-color policing uses the <i>single token bucket algorithm</i> to measure traffic-flow conformance to a two-color policer rate limit.</p> <p>Traffic at the interface that conforms to the bandwidth limit is categorized green. Traffic that exceeds the specified rate is also categorized as green provided that sufficient tokens remain in the single token bucket. Packets in a green flow are implicitly marked with <b>low</b> packet loss priority and then passed through the interface.</p> <p>Traffic that exceeds the specified rate when insufficient tokens remain in the single token bucket is categorized red. Depending on the configuration of the two-color policer, packets in a red traffic flow might be implicitly discarded; or the packets might be re-marked with a specified forwarding class, a specified PLP, or both, and then passed through the interface.</p> <p>The burst size extends the function of the bandwidth limit (configured using either the <b>bandwidth-limit</b> <i>bps</i> statement or the <b>bandwidth-percent</b> <i>percentage</i> statement) to allow bursts of traffic up to a limit based on the overall traffic load:</p> <ul style="list-style-type: none"> <li>• When a single-rate two-color policer is applied to the input or output traffic at an interface, the initial capacity for traffic bursting is equal to the number of bytes specified by this statement.</li> <li>• During periods of relatively low traffic (traffic that arrives at or departs from the interface at overall rates below the token arrival rate), unused tokens accumulate in the bucket, but only up to the configured token bucket depth.</li> </ul> <p>Single-rate two-color policing allows bursts of traffic for short periods, whereas single-rate and two-rate three-color policing allows more sustained bursts of traffic.</p> <p>Hierarchical policing is a form of two-color policing that applies different policing actions based on whether the packets are classified for expedited forwarding (EF) or for a lower priority. You apply a hierarchical policer to ingress Layer 2 traffic to allow bursts of EF traffic for short period and bursts of non-EF traffic for short periods, with EF traffic always taking precedence over non-EF traffic.</p> |

Table 117 on page 1424 summarizes the relationship between the **bandwidth-limit** and the token arrival rate. This information is useful in calculating the minimum **burst-size-limit**.

**Table 117: Bandwidth Limits and Token Rates**

| Bandwidth Limit     | Token Rate         |
|---------------------|--------------------|
| 0-333 Mbps          | low (262 $\mu$ s)  |
| 334-666 Mbps        | high (8.2 $\mu$ s) |
| 667-1333 Mbps       | low                |
| 1334 Mbps and above | high               |

The burst-size limit enforced is based on the burst-size limit you configure. For a rate-limited logical interface, the Packet Forwarding Engine calculates the optimum burst-size-limit values and then applies the value closest to the burst-size-limit value specified in the policer configuration.

On MX Series routers, the burst-size limit is not as freely configurable as it is on other platforms. Junos OS does not support an unlimited combination of policer bandwidth and burst-size limits on MX Series routers. For a single-rate two-color policer on an MX Series router, the minimum supported burst-size limit is equivalent to the amount of traffic allowed by the policer bandwidth limit in a time span of 1 millisecond. For example, for a policer configured with a **bandwidth-limit** value of 1 Gbps, the minimum supported value for **burst-size-limit** on an MX Series router is 125 KB. If you configure a value that is smaller than the minimum, Junos OS overrides the configuration and applies the actual minimum.

**Options** *bytes*—Burst-size limit in bytes. The minimum recommended value is the maximum transmission unit (MTU) of the IP packets being policed. You can specify the value either as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000).

**Range:** 1500 through 100,000,000,000

**Default:** None

**Required Privilege Level** firewall—To view this statement in the configuration.  
 firewall-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 13.1.                                                                                                                                                                                                                                 |
| <b>Description</b>              | Specify the character that the router uses as a separator between the concatenated values in the Calling-Station-ID (RADIUS IETF attribute 31) string. The router uses the delimiter when you configure more than one value in the <b>calling-station-id-format</b> statement. |
| <b>Default</b>                  | The hash (#) character.                                                                                                                                                                                                                                                        |
| <b>Options</b>                  | <b><i>delimiter-character</i></b> —Character to use for the delimiter. You must enclose the delimiter character in quotation marks (" ").                                                                                                                                      |
| <b>Required Privilege Level</b> | admin—To view this statement in the configuration.<br>admin-control—To add this statement to the configuration.                                                                                                                                                                |

| <b>Description</b>              | Specify the information that the router includes in the Calling-Station-ID (RADIUS IETF attribute 31) that is passed to the RADIUS server during authentication and accounting. You can include one or more optional values in any combination.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Default</b>                  | The router displays the Calling-Station-ID set by the client.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Options</b>                  | <p><b>agent-circuit-id</b>—Include the agent circuit identifier (ACI) string, which uniquely identifies the subscriber's access node and the digital subscriber line (DSL) on the access node. The ACI string is stored in either the DHCP option 82 field of DHCP messages (for DHCP traffic), or in the DSL Forum Agent-Circuit-ID VSA [26-1] of PPPoE PADI and PADR control packets (for PPPoE traffic).</p> <p><b>agent-remote-id</b>—Include the agent remote identifier (ARI) string, which identifies the subscriber on the digital subscriber line access multiplexer (DSLAM) interface that initiated the service request. The ARI string is stored in either the DHCP option 82 field of DHCP messages (for DHCP traffic), or in the DSL Forum Agent-Remote-ID VSA [26-2] of PPPoE PADI and PADR control packets (for PPPoE traffic).</p> <p><b>interface-description</b>—Include the interface description.</p> <p><b>nas-identifier</b>—Include the NAS-identifier (RADIUS IETF attribute 32), which specifies the name of the NAS that originated the authentication or accounting request.</p> |
| <b>Required Privilege Level</b> | admin—To view this statement in the configuration.<br>admin-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## challenge-length (Static and Dynamic PPP)

---

- Syntax** challenge-length minimum *minimum-length* maximum *maximum-length*;
- Hierarchy Level** [edit dynamic-profiles *profile-name* interfaces pp0 unit “\$junos-interface-unit” ppp-options [chap](#)],  
[edit interfaces pp0 unit *unit-number* ppp-options [chap](#)]
- Release Information** Statement introduced in Junos OS Release 12.2.
- Description** Modify the length of the Challenge Handshake Authentication Protocol (CHAP) challenge by specifying the minimum and maximum allowable length, in bytes.

.....

**BEST PRACTICE:** We recommend that you configure both the minimum length and the maximum length of the CHAP challenge to at least 16 bytes.

.....

- Options** *minimum-length*—Minimum length, in bytes, of the CHAP challenge.  
**Range:** 8 through 63  
**Default:** 16
- maximum-length*—Maximum length, in bytes, of the CHAP challenge. The *maximum-length* must be equal to or greater than the *minimum-length*.  
**Range:** 8 through 63  
**Default:** 32
- Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

| <b>Description</b>              | Delete all DHCP clients or only the DHCP clients serviced by the specified group of interfaces when reconfiguration fails; that is, when the maximum number of retry attempts have been made without success. A group configuration takes precedence over a DHCP local server configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Default</b>                  | Restores the original client configuration when reconfiguration fails.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

           }

**Hierarchy Level**    [edit access *profile* *profile-name*]

**Release Information**    Statement introduced before Junos OS Release 7.4.

**Description**    Configure the peer identity.

**NOTE:** Subordinate statement support depends on the platform. See individual statement topics for more detailed support information.

**Options** *client-name*—A peer identity. For L2TP clients, you can use a special name to configure a default client. This client enables the LNS to accept any LAC to establish the session. On M Series routers, use \* for the default client configuration. On MX Series routers, use **default**.

The remaining statements are explained separately.

**Required Privilege Level** admin—To view this statement in the configuration.  
admin-control—To add this statement to the configuration.

## client-accounting-algorithm

---

**Syntax** client-accounting-algorithm (direct | round-robin);

**Hierarchy Level** [edit access profile *profile-name* radius [options](#)]

**Release Information** Statement introduced in Junos OS Release 10.0.

**Description** Configure the access method the router uses to access RADIUS accounting servers.

**Default** direct

**Options** **direct**—Use the direct method.  
**round-robin**—Use the round-robin method.

**Required Privilege Level** admin—To view this statement in the configuration.  
admin-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b>              | Configure DHCP relay to use option 60 and option 82 information to uniquely identify DHCP subscribers when primary subscriber identification fails. The statement always uses the <b>option60-and-option82</b> option. Specifying the option has no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Hierarchy Level</b>          | [edit access profile <i>profile-name</i> radius <b>options</b> ]                                                                                                                                                                                                                                                      |
| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.1.                                                                                                                                                                                                                                                                        |
| <b>Description</b>              | Specify that when a CoA operation includes a change to a client profile dynamic variable that cannot be applied (such as an update to a non-existent filter), the router does not apply any changes to client profile dynamic variables in the request, and responds with a NACK message.                             |
| <b>Default</b>                  | If you do not configure this statement, the router does not apply any incorrect variable updates but does make any other changes to the client profile dynamic variables, and then responds with an ACK message.                                                                                                      |
| <b>Required Privilege Level</b> | <b>admin</b> —To view this statement in the configuration.<br><b>admin-control</b> —To add this statement to the configuration.                                                                                                                                                                                       |

| <b>Description</b>              | <p>For a three-color policer, configure the way preclassified packets are metered. In color-blind mode, the local router ignores the preclassification of packets and can assign a higher or lower packet loss priority.</p> <p>For example, suppose an upstream router assigned medium-high packet loss priority to a packet because the packet exceeded the committed information rate on the upstream router interface.</p> <ul style="list-style-type: none"> <li>• If the local router applies color-aware policing to the packet, the router <i>cannot</i> change the packet loss priority to low, even if the packet conforms to the configured committed information route on the local router interface.</li> </ul> <div style="margin-top: 10px;">  <p><b>NOTE:</b> A color-aware policer cannot be applied to Layer 2 traffic.</p> </div> <ul style="list-style-type: none"> <li>• If the local router applies color-blind policing to the packet, the router <i>can</i> change the packet loss priority to low if the packet conforms to the configured committed information route on the local router interface.</li> </ul> |
| <b>Default</b>                  | If you omit the <b>color-blind</b> statement, the default behavior is color-aware mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Release Information</b> | Statement introduced in Junos OS Release 7.4.<br>Support at the [edit <a href="#">dynamic-profiles ... single-rate</a> ] and [edit <a href="#">dynamic-profiles ... two-rate</a> ] hierarchy levels introduced in Junos OS Release 11.4.                                                                                                                                                                  |
| <b>Description</b>         | For a three-color policer, configure the committed burst size (CBS) as a number of bytes.                                                                                                                                                                                                                                                                                                                 |

**NOTE:** When you include the `committed-burst-size` statement in the configuration, you must also include the `committed-information-rate` statement at the same hierarchy level.

In three-color policing, a committed information rate (CIR) defines the guaranteed bandwidth for traffic arriving at or departing from the interface under normal line conditions. A flow of traffic at an average rate that conforms to the CIR is categorized green.

During periods of average traffic rates below the CIR, any unused bandwidth capacity accumulates up to a maximum amount defined by the CBS. Short periods of bursting traffic (back-to-back traffic at averages rates that exceed the CIR) are also categorized as green provided that unused bandwidth capacity is available.

Traffic that exceeds both the CIR and the CBS is considered nonconforming.

Single-rate three-color policers use a *dual token bucket algorithm* to measure traffic against a single rate limit. Nonconforming traffic is categorized as yellow or red, based on the **excess-burst-size** statement included in the policer configuration.

Two-rate three-color policers use a *dual-rate dual token bucket algorithm* to measure traffic against two rate limits. Nonconforming traffic is categorized as yellow or red based on the **peak-information-rate** and **peak-burst-rate** statements included in the policer configuration.

| <b>Release Information</b> | Statement introduced in Junos OS Release 7.4.<br>Support at the [edit <code>dynamic-profiles ... single-rate</code> ] and [edit <code>dynamic-profiles ... two-rate</code> ] hierarchy levels introduced in Junos OS Release 11.4.                                                                                                                                                      |
| <b>Description</b>         | For a three-color policer, configure the committed information rate as a number of bits per second. The committed information rate (CIR) is the guaranteed bandwidth for traffic arriving at or departing from the interface under normal line conditions.                                                                                                                              |

**NOTE:** When you include the `committed-information-rate` statement in the configuration, you must also include the `committed-burst-size` statement at the same hierarchy level.

In three-color policing, a CIR defines the guaranteed bandwidth for traffic arriving at or departing from the interface under normal line conditions. A flow of traffic at an average rate that conforms to the CIR is categorized green.

During periods of average traffic rates below the CIR, any unused bandwidth capacity accumulates up to a maximum amount defined by the committed burst size (CBS). Short periods of bursting traffic (back-to-back traffic at averages rates that exceed the CIR) are also categorized as green provided that unused bandwidth capacity is available.

Traffic that exceeds both the CIR and the CBS is considered nonconforming.

Single-rate three-color policers use a *dual token bucket algorithm* to measure traffic against a single rate limit. Nonconforming traffic is categorized as yellow or red, based on the **excess-burst-size** statement included in the policer configuration.

Two-rate three-color policers use a *dual-rate dual token bucket algorithm* to measure traffic against two rate limits. Nonconforming traffic is categorized as yellow or red based on the **peak-information-rate** and **peak-burst-rate** statements included in the policer configuration.

**Options** `bps`—Number of bits per second. You can specify a value in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation `k` (1000), `m` (1,000,000), or `g` (1,000,000,000).

**Range:** 1500 through 100,000,000,000 bps

**Required Privilege Level** firewall—To view this statement in the configuration.  
firewall-control—To add this statement to the configuration.

## concurrent-data-sessions

---

**Syntax** concurrent-data-sessions *max-session-number*;

**Hierarchy Level** [edit services service-set *services-set-name* subscriber-profile *profile-name* enable *service-name*]

**Release Information** Statement introduced in Junos OS Release 11.4.

**Description** Specify the maximum number of sessions that are concurrently enabled for the named service. The system randomly selects the number of sessions and enables the named service, whereas other sessions are not allotted the named service. This facilitates to increase the limit on the number of resources a service can use.

**Options** *max-session-number*—Maximum number of sessions concurrently enabled for the named service.

The remaining statements are explained separately.

**Required Privilege Level** admin—To view this statement in the configuration.  
admin-control—To add this statement to the configuration.

## connect-actively

| <b>Release Information</b>      | Statement introduced in Junos OS Release 10.4.                                                                                                                                                                          |
| <b>Description</b>              | Specify the characters that the router uses to separate usernames from domain names.                                                                                                                                    |
| <b>Default</b>                  | The @ character.                                                                                                                                                                                                        |
| <b>Options</b>                  | <b><i>delimiter-character</i></b> —One or more characters used as delimiters. You can specify a maximum of eight delimiters. You cannot use the semicolon (;) as a delimiter. Do not include spaces between characters. |
| <b>Required Privilege Level</b> | admin—To view this statement in the configuration.<br>admin-control—To add this statement to the configuration.                                                                                                         |

## demux0 (Dynamic Interface)

---

**Syntax**

```
demux0 {  
    unit logical-unit-number {  
        demux-options {  
            underlying-interface interface-name  
        }  
        family family {  
            access-concentrator name;  
            address address;  
            demux-source {  
                source-prefix;  
            }  
            duplicate-protection;  
            dynamic-profile profile-name;  
            filter {  
                input filter-name;  
                output filter-name;  
            }  
            mac-validate (loose | strict):  
            max-sessions number;  
            max-sessions-vsa-ignore;  
            rpf-check {  
                fail-filter filter-name;  
                mode loose;  
            }  
            service-name-table table-name  
            short-cycle-protection <lockout-time-min minimum-seconds lockout-time-max  
                maximum-seconds>;  
            unnumbered-address interface-name <preferred-source-address address>;  
        }  
        filter {  
            input filter-name;  
            output filter-name;  
        }  
        vlan-id number;  
    }  
}
```

**Hierarchy Level** [edit [dynamic-profiles profile-name interfaces](#)]

**Release Information** Statement introduced in Junos OS Release 9.3.

**Description** Configure the logical demultiplexing (demux) interface in a dynamic profile.

Logical IP demux interfaces do not support IPv4 and IPv6 dual stack.

The remaining statements are explained separately.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b>              | <p>Enable failure detection. The BFD failure detection timers are adaptive and can be adjusted to be faster or slower. For example, the timers can adapt to a higher value if the adjacency fails, or a neighbor can negotiate a higher value for a timer than the one configured.</p> <p>The remaining statement is explained separately.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.0.<br>Statement introduced in Junos OS Release 12.1 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b>              | <p>Configure Dynamic Host Configuration Protocol (DHCP) local server options on the router or switch and enable the router or switch to function as an extended DHCP local server. The DHCP local server receives DHCP request and reply packets from DHCP clients and then responds with an IP address and other optional configuration information to the client.</p> <p>The extended DHCP local server is incompatible with the DHCP server on J Series routers and so is not supported on J Series routers. Also, the DHCP local server and the DHCP/BOOTP relay server, which are configured under the <b>[edit forwarding-options helpers]</b> hierarchy level, cannot both be enabled on the router or switch at the same time. The extended DHCP local server is fully compatible with the extended DHCP relay feature.</p> <p>The <b>dhcpv6</b> stanza configures the router or switch to support Dynamic Host Configuration Protocol for IPv6 (DHCPv6). The DHCPv6 local server is fully compatible with the extended DHCP local server and the extended DHCP relay feature.</p> |
|                                 | <div>  <p><b>NOTE:</b> When you configure the <b>dhcp-local-server</b> statement at the routing instance hierarchy level, you must use a routing instance type of <b>virtual-router</b>.</p> </div>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Release Information** Statement introduced in Junos OS Release 8.3.

**Description** Configure extended Dynamic Host Configuration Protocol (DHCP) relay and DHCPv6 relay options on the router and enable the router to function as a DHCP relay agent. A DHCP relay agent forwards DHCP request and reply packets between a DHCP client and a DHCP server.

DHCP relay supports the attachment of dynamic profiles and also interacts with the local AAA Service Framework to use back-end authentication servers, such as RADIUS, to provide subscriber authentication. You can attach dynamic profiles and configure authentication support on a global basis or for a specific group of interfaces.

The extended DHCP and DHCPv6 relay agent options configured with the **dhcp-relay** and **dhcpv6** statements are incompatible with the DHCP/BOOTP relay agent options configured with the **bootp** statement. As a result, the extended DHCP or DHCPv6 relay agent and the DHCP/BOOTP relay agent cannot both be enabled on the router at the same time.

The remaining statements are explained separately.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

**Release Information** Statement introduced in Junos OS Release 9.6.  
Statement introduced in Junos OS Release 12.3 for EX Series switches.

**Description** Configure DHCPv6 local server options on the router or switch and enable the router or switch to function as a server for the DHCP protocol for IP version 6 (IPv6). The DHCPv6 local server sends and receives packets using the IPv6 protocol and informs IPv6 of the routing requirements of router clients. The local server works together with the AAA service framework to control subscriber access and accounting.

The DHCPv6 local server is fully compatible with the extended DHCP local server and DHCP relay agent.

The remaining statements are explained separately.

**Required Privilege Level** system—To view this statement in the configuration.  
system-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 11.2.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b>              | Configure the LAC to use only the silent failover method when resynchronizing with the peer LNS in the event of LAC failover. This command prevents the default behavior, wherein the LAC first attempts to use the failover protocol and then falls back on the silent failover method. This configuration can be useful when routers that act as the LNS are configured for silent failover or incorrectly negotiate use of the failover protocol even though they do not support it. |

## domain (Domain Map)

---

**Syntax**

```
domain {  
  delimiter [delimiter-character];  
  map domain-map-name {  
    aaa-logical-system logical-system-name {  
      aaa-routing-instance routing-instance-name;  
    }  
    aaa-routing-instance routing-instance-name;  
    access-profile profile-name;  
    address-pool pool-name;  
    dynamic-profile profile-name;  
    padn destination-address {  
      mask destination-mask;  
      metric route-metric;  
    }  
    strip-domain;  
    target-logical-system logical-system-name {  
      target-routing-instance routing-instance-name;  
    }  
    target-routing-instance routing-instance-name;  
    tunnel-profile profile-name;  
  }  
  parse-direction (left-to-right | right-to-left);  
}
```

**Hierarchy Level** [edit access]

**Release Information** Statement introduced in Junos OS Release 10.4.

**Description** Configure a domain map, which is used to map access options and session parameters for subscriber sessions.

The remaining statements are explained separately.

**Required Privilege Level** admin—To view this statement in the configuration.  
admin-control—To add this statement to the configuration.

| <b>Description</b>              | <p>Specify a recommended shaping rate to be applied to downstream traffic on an interface.</p> <p>For ANCP interfaces, this configured rate is used as the default value for the Juniper VSA Downstream-Calculated-Qos-Rate (26–141) when the router has not received and processed the attributes from the access node.</p> <p>For L2TP, the rate is configured on an underlying PPPoE logical interface for a subscriber on an MX Series router acting as a LAC. When the subscriber is tunneled, this rate, referred to as speed for L2TP, is sent to the LNS in the ICCN message as AVP 24.</p>     |
| <b>Options</b>                  | <b>rate</b> —Traffic rate in bits per second.<br><b>Range:</b> 1000 through 4,294,967,295 bits per second                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## drop-policy (Subscriber Secure Policy)

---

**Syntax**    `drop-policy rule-name {  
                  from {  
                    apply-groups group-name;  
                    apply-groups-except group-name;  
                    destination-address address;  
                    destination-port port-number;  
                    dscp dscp-value;  
                    protocol protocol;  
                    source-address address;  
                    source-port port-number;  
                  }  
                }`

**Hierarchy Level**    [edit services [radius-flow-tap policy policy-name inet](#)| [inet6](#)]

**Release Information**    Statement introduced in Junos OS Release 12.3.

**Description**    Specify the drop-policy that is applied to mirrored packets sent to a mediation device.

**Options**    *rule-name*—Define the term name.

The remaining statements are explained separately.

**Required Privilege**    flow-tap—To view this statement in the configuration.

**Level**    flow-tap-control—To add this statement to the configuration.

| <b>Description</b>         | <p>Within the drop-profile map, specify the name of the drop profile to use for random early detection (RED) for a specific packet-loss priority (PLP) level and protocol type. A drop profile maps a fill level (fullness of a queue) to a drop probability (probability that a packet will be dropped). When a packet arrives, RED checks the queue fill level. If the fill level corresponds to a nonzero drop probability, the RED algorithm determines whether to drop the arriving packet.</p> <p>You enable RED by applying a drop profile to a scheduler.</p> <p>You configure drop profiles statically (at the <b>[edit class-of-service drop-profiles]</b> hierarchy level).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 10.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b>              | <p>Specify a dynamic profile to instantiate a dynamic PPPoE interface. You can associate a dynamic profile with a named service entry, <b>empty</b> service entry, or <b>any</b> service entry configured in a PPPoE service name table, or with an agent circuit identifier/agent remote identifier (ACI/ARI) pair defined for these services.</p> <p>The dynamic profile associated with a service entry in a PPPoE service name table overrides the dynamic profile associated with the PPPoE underlying interface on which the dynamic PPPoE interface is created.</p> <p>If you include the <b>dynamic-profile</b> statement at the <code>[edit protocols pppoe service-name-tables <i>table-name</i> service <i>service-name</i> agent-specifier aci <i>circuit-id-string</i> ari <i>remote-id-string</i>]</code> hierarchy level, you cannot also include the <b>static-interface</b> statement at this level. The <b>dynamic-profile</b> and <b>static-interface</b> statements are mutually exclusive for ACI/ARI pair configurations.</p> |
| <b>Options</b>                  | <b><i>profile-name</i></b> —Name of the dynamic profile that the router uses to instantiate a dynamic PPPoE interface.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Release Information</b> | Statement introduced in Junos OS Release 10.4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>         | Dynamic interface configuration of the logical link-layer encapsulation type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Options</b>             | <p><b>atm-ccc-cell-relay</b>—Use ATM cell-relay encapsulation.</p> <p><b>atm-ccc-vc-mux</b>—Use ATM virtual circuit (VC) multiplex encapsulation on circuit cross-connect (CCC) circuits. When you use this encapsulation type, you can configure the <b>ccc</b> family only.</p> <p><b>atm-cisco-nlpid</b>—Use Cisco ATM network layer protocol ID (NLPID) encapsulation. When you use this encapsulation type, you can configure the <b>inet</b> family only.</p> <p><b>atm-mlppp-llc</b>—For ATM2 IQ interfaces only, use Multilink Point-to-Point Protocol (MLPPP) over AAL5 LLC. For this encapsulation type, your router must be equipped with a link services or voice services PIC. MLPPP over ATM encapsulation is not supported on ATM2 IQ OC48 interfaces.</p> <p><b>atm-nlpid</b>—Use ATM NLPID encapsulation. When you use this encapsulation type, you can configure the <b>inet</b> family only.</p> <p><b>atm-ppp-llc</b>—For ATM2 IQ interfaces only, use PPP over AAL5 LLC encapsulation.</p> <p><b>atm-ppp-vc-mux</b>—For ATM2 IQ interfaces only, use PPP over ATM AAL5 multiplex encapsulation.</p> <p><b>atm-snap</b>—Use ATM subnetwork attachment point (SNAP) encapsulation.</p> <p><b>atm-tcc-snap</b>—Use ATM SNAP encapsulation on translational cross-connect (TCC) circuits.</p> <p><b>atm-tcc-vc-mux</b>—Use ATM VC multiplex encapsulation on TCC circuits. When you use this encapsulation type, you can configure the <b>tcc</b> family only.</p> <p><b>atm-vc-mux</b>—Use ATM VC multiplex encapsulation. When you use this encapsulation type, you can configure the <b>inet</b> family only.</p> <p><b>ether-over-atm-llc</b>—For interfaces that carry IPv4 traffic, use Ethernet over ATM LLC encapsulation. When you use this encapsulation type, you cannot configure multipoint interfaces.</p> |

**ether-vpls-over-atm-llc**—For ATM2 IQ interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.

**ether-vpls-over-fr**—For E1, T1, E3, T3, and SONET interfaces only, use the Ethernet virtual private LAN service (VPLS) over Frame Relay encapsulation to support Bridged Ethernet over Frame Relay encapsulated TDM interfaces for VPLS applications, as per *Multiprotocol Interconnect over Frame Relay* (RFC 2427 [1490]).

**ether-vpls-over-ppp**—For E1, T1, E3, T3 and SONET interfaces only, use the Ethernet virtual private LAN service (VPLS) over PPP encapsulation to support Bridged Ethernet over PPP encapsulated TDM interfaces for VPLS applications.

**ethernet**—Use Ethernet II encapsulation (as described in RFC 894, *A Standard for the Transmission of IP Datagrams over Ethernet Networks*).

**ethernet-vpls**—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard Tag Protocol ID (TPID) values.

**extended-vlan-vpls**—Use extended virtual LAN (VLAN) VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled and that must accept packets carrying TPIDs 0x8100, 0x9100, and 0x9901.

.....  
**NOTE:** The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.  
.....

**frame-relay-ccc**—Use Frame Relay encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

**frame-relay-ppp**—Use PPP over Frame Relay circuits. When you use this encapsulation type, you can configure the **ppp** family only. J Series routers do not support **frame-relay-ppp** encapsulation.

**frame-relay-tcc**—Use Frame Relay encapsulation on TCC circuits for connecting unlike media. When you use this encapsulation type, you can configure the **tcc** family only.

**frame-relay-ether-type**—Use Frame Relay ether type encapsulation for compatibility with Cisco Frame Relay. The physical interface must be configured with **flexible-frame-relay** encapsulation.

**frame-relay-ether-type-tcc**—Use Frame Relay ether type TCC for Cisco-compatible Frame Relay on TCC circuits to connect unlike media. The physical interface must be configured with **flexible-frame-relay** encapsulation.

**multilink-frame-relay-end-to-end**—Use MLFR FRF.15 encapsulation. This encapsulation is used only on multilink, link services, and voice services interfaces and their constituent T1 or E1 interfaces, and is supported on LSQ and redundant LSQ interfaces.

**multilink-ppp**—Use MLPPP encapsulation. This encapsulation is used only on multilink, link services, and voice services interfaces and their constituent T1 or E1 interfaces.

**ppp-over-ether**—For underlying Ethernet interfaces on J Series Services routers, use PPP over Ethernet encapsulation. When you use this encapsulation type, you cannot configure the interface address. Instead, configure the interface address on the PPP interface. You also use PPP over Ethernet encapsulation to configure an underlying Ethernet interface for a dynamic PPPoE logical interface on M120 and M320 Series routers with Intelligent Queuing 2 (IQ2) PICs, and on MX Series routers with MPCs.

**ppp-over-ether-over-atm-llc**—For underlying ATM interfaces on J Series Services routers only, use PPP over Ethernet over ATM LLC encapsulation. When you use this encapsulation type, you cannot configure the interface address. Instead, configure the interface address on the PPP interface.

**vlan-bridge**—Use Ethernet VLAN bridge encapsulation on Ethernet interfaces that have IEEE 802.1Q tagging, flexible ethernet services, and bridging enabled, and that must accept packets carrying TPID 0x8100 or a user-defined TPID.

**vlan-ccc**—Use Ethernet virtual LAN (VLAN) encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

**vlan-vci-ccc**—Use ATM-to-Ethernet interworking encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

**vlan-tcc**—Use Ethernet VLAN encapsulation on TCC circuits. When you use this encapsulation type, you can configure the **tcc** family only.

**vlan-vpls**—Use Ethernet VLAN encapsulation on VPLS circuits.

| <b>Release Information</b> | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Switches ( <b>vlan-ccc</b> and <b>vlan-tcc</b> options only).<br>Statement introduced in Junos OS Release 12.2 for the ACX Series Universal Access Routers. Only the <b>atm-ccc-cell-relay</b> and <b>atm-ccc-vc-mux</b> options are supported on ACX Series routers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b>         | Configure a logical link-layer encapsulation type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Options</b>             | <p><b>atm-ccc-cell-relay</b>—Use ATM cell-relay encapsulation.</p> <p><b>atm-ccc-vc-mux</b>—Use ATM virtual circuit (VC) multiplex encapsulation on CCC circuits. When you use this encapsulation type, you can configure the <b>ccc</b> family only.</p> <p><b>atm-cisco-nlpid</b>—Use Cisco ATM network layer protocol identifier (NLPID) encapsulation. When you use this encapsulation type, you can configure the <b>inet</b> family only.</p> <p><b>atm-mlppp-llc</b>—For ATM2 IQ interfaces only, use Multilink Point-to-Point (MLPPP) over AAL5 LLC. For this encapsulation type, your router must be equipped with a Link Services or Voice Services PIC. MLPPP over ATM encapsulation is not supported on ATM2 IQ OC48 interfaces.</p> <p><b>atm-nlpid</b>—Use ATM NLPID encapsulation. When you use this encapsulation type, you can configure the <b>inet</b> family only.</p> <p><b>atm-ppp-llc</b>—(ATM2 IQ interfaces and MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP only) Use PPP over AAL5 LLC encapsulation.</p> <p><b>atm-ppp-vc-mux</b>—(ATM2 IQ interfaces and MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP only) Use PPP over ATM AAL5 multiplex encapsulation.</p> <p><b>atm-snap</b>—(All interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) Use ATM subnetwork attachment point (SNAP) encapsulation.</p> <p><b>atm-tcc-snap</b>—Use ATM SNAP encapsulation on translational cross-connect (TCC) circuits.</p> |

**atm-tcc-vc-mux**—Use ATM VC multiplex encapsulation on TCC circuits. When you use this encapsulation type, you can configure the **tcc** family only.

**atm-vc-mux**—(All interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) Use ATM VC multiplex encapsulation. When you use this encapsulation type, you can configure the **inet** family only.

**ether-over-atm-llc**—(All IP interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) For interfaces that carry IP traffic, use Ethernet over ATM LLC encapsulation. When you use this encapsulation type, you cannot configure multipoint interfaces.

**ether-vpls-over-atm-llc**—For ATM2 IQ interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.

**ether-vpls-over-fr**—For E1, T1, E3, T3, and SONET interfaces only, use the Ethernet virtual private LAN service (VPLS) over Frame Relay encapsulation to support Bridged Ethernet over Frame Relay encapsulated TDM interfaces for VPLS applications, per RFC 2427, *Multiprotocol Interconnect over Frame Relay*.

**NOTE:** The SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP, the Channelized SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP, and the DS3/E3 MIC do not support Ethernet over Frame Relay encapsulation.

**ether-vpls-over-ppp**—For E1, T1, E3, T3, and SONET interfaces only, use the Ethernet virtual private LAN service (VPLS) over Point-to-Point Protocol (PPP) encapsulation to support Bridged Ethernet over PPP-encapsulated TDM interfaces for VPLS applications.

**ethernet**—Use Ethernet II encapsulation (as described in RFC 894, *A Standard for the Transmission of IP Datagrams over Ethernet Networks*).

**ethernet-ccc**—Use Ethernet CCC encapsulation on Ethernet interfaces.

**ethernet-vpls**—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard Tag Protocol ID (TPID) values.

**NOTE:** The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.

**ethernet-vpls-fr**—Use in a VPLS setup when a CE device is connected to a PE device over a time-division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer layer 2 Frame Relay connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use the MAC address to forward the packet into a given VPLS instance.

**frame-relay-ccc**—Use Frame Relay encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

**frame-relay-ether-type**—Use Frame Relay ether type encapsulation for compatibility with Cisco Frame Relay. The physical interface must be configured with flexible-frame-relay encapsulation.

**frame-relay-ether-type-tcc**—Use Frame Relay ether type TCC for Cisco-compatible Frame Relay on TCC circuits to connect different media. The physical interface must be configured with flexible-frame-relay encapsulation.

**frame-relay-ppp**—Use PPP over Frame Relay circuits. When you use this encapsulation type, you can configure the **ppp** family only. J Series routers do not support frame-relay-ppp encapsulation.

**frame-relay-tcc**—Use Frame Relay encapsulation on TCC circuits for connecting different media. When you use this encapsulation type, you can configure the **tcc** family only.

**gre-fragmentation**—For adaptive services interfaces only, use GRE fragmentation encapsulation to enable fragmentation of IPv4 packets in GRE tunnels. This encapsulation clears the do not fragment (DF) bit in the packet header. If the packet's size exceeds the tunnel's maximum transmission unit (MTU) value, the packet is fragmented before encapsulation.

**multilink-frame-relay-end-to-end**—Use MLFR FRF.15 encapsulation. This encapsulation is used only on multilink, link services, and voice services interfaces and their constituent T1 or E1 interfaces, and is supported on LSQ and redundant LSQ interfaces.

**multilink-ppp**—Use MLPPP encapsulation. This encapsulation is used only on multilink, link services, and voice services interfaces and their constituent T1 or E1 interfaces.

**ppp-over-ether**—For underlying Ethernet interfaces on J Series routers, use PPP over Ethernet encapsulation. When you use this encapsulation type, you cannot configure the interface address. Instead, configure the interface address on the PPP interface. You also use PPP over Ethernet encapsulation to configure an underlying Ethernet interface for a dynamic PPPoE logical interface on M120 and M320 routers with Intelligent Queuing 2 (IQ2) PICs, and on MX Series routers with MPCs.

**ppp-over-ether-over-atm-llc**—(J Series routers and MX Series routers with MPCs using the ATM MIC with SFP only) For underlying ATM interfaces, use PPP over Ethernet over ATM LLC encapsulation. When you use this encapsulation type, you cannot configure the interface address. Instead, configure the interface address on the PPP interface.

**vlan-bridge**—Use Ethernet VLAN bridge encapsulation on Ethernet interfaces that have IEEE 802.1Q tagging, flexible-ethernet-services, and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID.

**vlan-ccc**—Use Ethernet virtual LAN (VLAN) encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

**vlan-vci-ccc**—Use ATM-to-Ethernet interworking encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

**vlan-tcc**—Use Ethernet VLAN encapsulation on TCC circuits. When you use this encapsulation type, you can configure the **tcc** family only.

**vlan-vpls**—Use Ethernet VLAN encapsulation on VPLS circuits.

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b>              | <p>Display the collection of policer detailed statistics. An FPC restart is required after changing this configuration.</p> <p>When you commit a configuration that contains the <b>enhanced-policer</b> statement at the <b>[edit chassis]</b> hierarchy level, a warning message is displayed stating that all the FPCs in the router need to be rebooted for the configuration changes to become effective. At this point, you must confirm that you want to proceed with the reboot of the FPCs. If you do not reboot the FPCs, the FPCs return all 0s (zeros) when you perform a query for the retrieval of detailed statistics—for example, when you issue the <b>show firewall detail</b> command.</p> |
| <b>Required Privilege Level</b> | interface—To view this statement in the configuration.<br>interface-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b>              | <p>Configure the exact match criteria used with the DHCP relay agent selective processing feature. DHCP relay agent compares the configured match string with the option-specific string received in DHCP client packets. If there is an exact left-to-right match, DHCP performs the action you define for the match criteria.</p> <p>You can configure an unlimited number of match strings. Match strings do not support wildcard attributes.</p> <p>The <b>local-server-group</b> option is not supported for DHCPv6 relay agent.</p>                                                               |
| <b>Options</b>                  | <p><b><i>ascii-string</i></b>—ASCII string of 1 through 255 alphanumeric characters.</p> <p><b><i>hexadecimal-string</i></b>—Hexadecimal string of 1 through 255 hexadecimal characters (0 through 9, a through f, A through F).</p> <p>The remaining statements are explained separately.</p>                                                                                                                                                                                                                                                                                                          |

| <b>Release Information</b> | Statement introduced in Junos OS Release 7.4.<br>Support at the [edit <b>dynamic-profiles</b> ... <b>single-rate</b> ] hierarchy level introduced in Junos Release OS 11.4.                                                                           |
| <b>Description</b>         | For a single-rate three-color policer, configure the excess burst size (EBS) as a number of bytes. The EBS allows for moderate periods of bursting traffic that exceeds both the committed information rate (CIR) and the committed burst size (CBS). |

**NOTE:** When you include the `excess-burst-size` statement in the configuration, you must also include the `committed-burst-size` and `committed-information-rate` statements at the same hierarchy level.

Traffic that exceeds both the CIR and the CBS is considered nonconforming.

Single-rate three-color policing uses a *dual token bucket algorithm* to measure traffic against a single rate limit. Nonconforming traffic is categorized as yellow or red based on the **excess-burst-size** statement included in the policer configuration.

During periods of traffic that conforms to the CIR, any unused portion of the guaranteed bandwidth capacity accumulates in the first token bucket, up to the maximum number of bytes defined by the CBS. If any accumulated bandwidth capacity overflows the first bucket, the excess accumulates in a second token bucket, up to the maximum number of bytes defined by the EBS.

A nonconforming traffic flow is categorized yellow if its size conforms to bandwidth capacity accumulated in the first token bucket. Packets in a yellow flow are marked with **medium-high** packet loss priority (PLP) and then passed through the interface.

A nonconforming traffic flow is categorized red if its size exceeds the bandwidth capacity accumulated in the second token bucket. Packets in a red traffic flow are marked with **high** PLP and then either passed through the interface or optionally discarded.

| <b>Description</b>         | <p>Configure the router or switch to exclude the specified attributes from the specified type of RADIUS message.</p> <p>Not all attributes are available in all types of RADIUS messages. By default, the router or switch includes the specified attributes in RADIUS Access-Request, Acct-On, Acct-Off, Acct-Start, and Acct-Stop messages.</p> |

**Options** RADIUS attribute type—RADIUS attribute, Juniper Networks (vendor ID 4874) VSA number and name, or DSL Forum (vendor ID 3561) VSA number and name.

- **acc-aggr-cir-id-asc**—Juniper Networks VSA 26-112, Acc-Aggr-Cir-Id-Asc.
- **acc-aggr-cir-id-bin**—Juniper Networks VSA 26-111, Acc-Aggr-Cir-Id-Bin.
- **acc-loop-cir-id**—Juniper Networks VSA 26-110, Acc-Loop-Cir-Id.
- **accounting-authentic**—RADIUS attribute 45, Acct-Authentic.
- **accounting-delay-time**—RADIUS attribute 41, Acct-Delay-Time.
- **accounting-session-id**—RADIUS attribute 44, Acct-Session-Id.
- **accounting-terminate-cause**—RADIUS attribute 49, Acct-Terminate-Cause.
- **act-data-rate-dn**—Juniper Networks VSA 26-114, Act-Data-Rate-Dn
- **act-data-rate-up**—Juniper Networks VSA 26-113, Act-Data-Rate-Up
- **act-interlv-delay-dn**—Juniper Networks VSA 26-126, Act-Interlv-Delay-Dn
- **act-interlv-delay-up**—Juniper Networks VSA 26-124, Act-Interlv-Delay-Up
- **att-data-rate-dn**—Juniper Networks VSA 26-118, Att-Data-Rate-Dn
- **att-data-rate-up**—Juniper Networks VSA 26-117, Att-Data-Rate-Up
- **called-station-id**—RADIUS attribute 30, Called-Station-Id.
- **calling-station-id**—RADIUS attribute 31, Calling-Station-Id.
- **class**—RADIUS attribute 25, Class.
- **dhcp-gi-address**—Juniper Networks VSA 26-57, DHCP-GI-Address.
- **dhcp-mac-address**—Juniper Networks VSA 26-56, DHCP-MAC-Address.
- **dhcp-options**—Juniper Networks VSA 26-55, DHCP-Options.
- **downstream-calculated-qos-rate**—Juniper Networks VSA 26-141
- **dsl-forum-attributes**—DSL Forum VSA (vendor ID 3561) as described in RFC 4679, *DSL Forum Vendor-Specific RADIUS Attributes*
- **dsl-line-state**—Juniper Networks VSA 26-127, DSL-Line-State
- **dsl-type**—Juniper Networks VSA 26-128, DSL-Type
- **event-timestamp**—RADIUS attribute 55, Event-Timestamp.
- **framed-ip-address**—RADIUS attribute 8, Framed-IP-Address.
- **framed-ip-netmask**—RADIUS attribute 9, Framed-IP-Netmask.
- **input-filter**—Juniper Networks VSA 26-10, Ingress-Policy-Name.
- **input-gigapackets**—Juniper Networks VSA 26-42, Acct-Input-Gigapackets.
- **input-gigawords**—RADIUS attribute 52, Acct-Input-Gigawords.
- **interface-description**—Juniper Networks VSA 26-53, Interface-Desc.

- **max-data-rate-dn**—Juniper Networks VSA 26-120, Max-Data-Rate-Dn
- **max-data-rate-up**—Juniper Networks VSA 26-119, Max-Data-Rate-Up
- **max-interlv-delay-dn**—Juniper Networks VSA 26-125, Max-Interlv-Delay-Dn
- **max-interlv-delay-up**—Juniper Networks VSA 26-123, Max-Interlv-Delay-Up
- **min-data-rate-dn**—Juniper Networks VSA 26-116, Min-Data-Rate-Dn
- **min-data-rate-up**—Juniper Networks VSA 26-115, Min-Data-Rate-Up
- **min-lp-data-rate-dn**—Juniper Networks VSA 26-122, Min-Lp-Data-Rate-Dn
- **min-lp-data-rate-up**—Juniper Networks VSA 26-121, Min-Lp-Data-Rate-Up
- **nas-identifier**—RADIUS attribute 32, NAS-Identifier.
- **nas-port**—RADIUS attribute 5, NAS-Port.
- **nas-port-id**—RADIUS attribute 87, NAS-Port-Id.
- **nas-port-type**—RADIUS attribute 61, NAS-Port-Type.
- **output-filter**—Juniper Networks VSA 26-11, Egress-Policy-Name.
- **output-gigapackets**—Juniper Networks VSA 25-43, Acct-Output-Gigapackets.
- **output-gigawords**—RADIUS attribute 53, Acct-Output-Gigawords.
- **upstream-calculated-qos-rate**—Juniper Networks VSA 26-142

RADIUS message type

- **access-request**—RADIUS Access-Accept messages.
- **accounting-off**—RADIUS Accounting-Off messages.
- **accounting-on**—RADIUS Accounting-On messages.
- **accounting-start**—RADIUS Accounting-Start messages.
- **accounting-stop**—RADIUS Accounting-Stop messages.

## family (Address-Assignment Pools)

**Syntax**

```
family family {
    dhcp-attributes {
        [protocol-specific attributes]
    }
    host hostname {
        hardware-address mac-address;
        ip-address ip-address;
    }
    network ip-prefix /<prefix-length>;
    prefix ipv6-prefix;
    range range-name {
        high upper-limit;
        low lower-limit;
        prefix-length prefix-length;
    }
}
```

**Hierarchy Level** [edit access address-assignment **pool** *pool-name*]

**Release Information** Statement introduced in Junos OS Release 9.0.  
Statement introduced in Junos OS Release 12.3 for EX Series switches.

**Description** Configure the protocol family for the address-assignment pool.

**NOTE:** Subordinate statement support depends on the platform. See individual statement topics for more detailed support information.

**Options** *family*—Protocol family:

- **inet**—Internet Protocol version 4 suite
- **inet6**—Internet Protocol version 6 suite

The remaining statements are explained separately.

**Required Privilege Level** admin—To view this statement in the configuration.  
admin-control—To add this statement to the configuration.

## family (Dynamic Firewalls)

---

**Syntax**    `family family {  
              fast-update-filter filter-name {  
                  interface-specific;  
                  match-order [match-order];  
                  term term-name {  
                      from {  
                          match-conditions;  
                      }  
                      then {  
                          action;  
                          action-modifiers;  
                      }  
                      only-at-create;  
                  }  
              }  
          }`

**Hierarchy Level**    [edit [dynamic-profiles](#) *profile-name* [firewall](#)]

**Release Information**    Statement introduced in Junos OS Release 9.6.

**Description**    Configure protocol family information for firewall filters in a dynamic profile.

**Options**    *family*—Protocol family:

- **inet**—Internet Protocol version 4 suite
- **inet6**—Internet Protocol version 6 suite

The remaining statements are explained separately.

**Required Privilege Level**    interface—To view this statement in the configuration.  
                                  interface-control—To add this statement to the configuration.

**Related Documentation**    • [Configuring Fast Update Filters on page 1125](#)

## family (Dynamic Demux Interface)

**Syntax**    `family family {`  
                   `access-concentrator name;`  
                   `address address;`  
                   `demux-source {`  
                     `source-address;`  
                   `}`  
                   `duplicate-protection;`  
                   `dynamic-profile profile-name;`  
                   `filter {`  
                     `input filter-name;`  
                     `output filter-name;`  
                   `}`  
                   `mac-validate (loose | strict);`  
                   `max-sessions number;`  
                   `max-sessions-vsa-ignore;`  
                   `service-name-table table-name;`  
                   `short-cycle-protection <lockout-time-min minimum-seconds lockout-time-max`  
                     `maximum-seconds>;`  
                   `unnumbered-address interface-name <preferred-source-address address>;`  
                   `}`

**Hierarchy Level**    `[edit dynamic-profiles profile-name interfaces demux0 unit logical-unit-number]`

**Release Information**    Statement introduced in Junos OS Release 9.3.  
                               Option **pppoe** introduced in Junos OS Release 11.2.

**Description**    Configure protocol family information for the logical interface.

**NOTE:** Not all subordinate stanzas are available to every protocol family.

**Options**    *family*—Protocol family:

- **inet**—Internet Protocol version 4 suite
- **inet6**—Internet Protocol version 6 suite
- **pppoe**—(MX Series routers with MPCs only) Point-to-Point Protocol over Ethernet

The remaining statements are explained separately.

**Required Privilege**    interface—To view this statement in the configuration.  
**Level**                interface-control—To add this statement to the configuration.

## family (Dynamic Standard Interface)

```
Syntax  family family {
    access-concentrator name;
    address address;
    duplicate-protection;
    dynamic-profile profile-name;
    filter {
        adf {
            counter;
            input-precedence precedence;
            not-mandatory;
            output-precedence precedence;
            rule rule-value;
        }
        input filter-name {
            precedence precedence;
        }
        output filter-name {
            precedence precedence;
        }
    }
    mac-validate (loose | strict);
    max-sessions number;
    max-sessions-vsa-ignore;
    rpf-check {
        fail-filter filter-name;
        mode loose;
    }
    service {
        input {
            service-set service-set-name {
                service-filter filter-name;
            }
            post-service-filter filter-name;
        }
        output {
            service-set service-set-name {
                service-filter filter-name;
            }
        }
    }
    service-name-table table-name
    short-cycle-protection <lockout-time-min minimum-seconds lockout-time-max
        maximum-seconds>;
    unnumbered-address interface-name <preferred-source-address address>;
}
```

**Hierarchy Level** [edit **dynamic-profiles** *profile-name* **interfaces** *interface-name* **unit** *logical-unit-number*]

**Release Information** Statement introduced in Junos OS Release 9.2.  
Option **pppoe** introduced in Junos OS Release 11.2.

**Description** Configure protocol family information for the logical interface.

NOTE: Not all subordinate stanzas are available to every protocol family.

**Options**    *family*—Protocol family:

- **inet**—IP version 4 suite
- **inet6**—IP version 6 suite
- **pppoe**—(MX Series routers with MPCs only) Point-to-Point Protocol over Ethernet
- **vpls**—Virtual private LAN service

The remaining statements are explained separately.

**Required Privilege Level**    interface—To view this statement in the configuration.  
                                         interface-control—To add this statement to the configuration.

**Related Documentation**    • For general information about configuring static interfaces, see the Junos® OS Network Interfaces.

## firewall (Dynamic Firewalls)

---

**Syntax**    firewall {  
              family *family* {  
                  fast-update-filter *filter-name* {  
                      interface-specific;  
                      match-order [*match-order*];  
                      term *term-name* {  
                          from {  
                              match-conditions;  
                          }  
                          then {  
                              action;  
                              action-modifiers;  
                          }  
                          only-at-create;  
                      }  
                  }  
              }  
          }

**Hierarchy Level**    [edit [dynamic-profiles](#) *profile-name*]

**Release Information**    Statement introduced in Junos OS Release 9.6.

**Description**    Configure firewall filters in a dynamic profile.

The remaining statements are explained separately.

**Required Privilege Level**    interface—To view this statement in the configuration.  
                                  interface-control—To add this statement to the configuration.

| <b>Description</b>              | <p>Configure how DHCP relay agent handles DHCP snooped packets on specific interfaces. The router determines the DHCP snooping action to perform based on a combination of the <b>forward-snooped-clients</b> configuration and the configuration of either the <b>allow-snooped-clients</b> statement or the <b>no-allow-snooped-clients</b> statement.</p> <p>The router also uses this statement to determine how to handle snooped BOOTREPLY packets received on nonconfigured interfaces.</p> |
| <b>Options</b>                  | <p><b>all-interfaces</b>—Perform the action on all interfaces.</p> <p><b>configured-interfaces</b>—Perform the action only on configured interfaces.</p> <p><b>non-configured-interfaces</b>—Perform the action only on nonconfigured interfaces.</p>                                                                                                                                                                                                                                              |
| <b>Required Privilege Level</b> | <p>interface—To view this statement in the configuration.</p> <p>interface-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                 |

```

**Hierarchy Level** [edit chassis]

**Release Information** Statement introduced in Junos OS Release 8.2.  
**port-mirror-instance** option introduced in Junos OS Release 9.3.

**Description** Configure properties for the DPC or MPC and corresponding Packet Forwarding Engines to create tunnel interfaces.

(MX Series Virtual Chassis only) To configure properties for MPCs in a member router in an MX Series Virtual Chassis configuration, you must specify the router's Virtual Chassis member number *before* the **fpc** statement. Specify the member number in the form **member member-id**, where **member-id** is 0 or 1. If you do not specify the member number before the **fpc** statement, the commit operation fails and the software displays an error message indicating that the **fpc** statement must include the member number for routers in Virtual Chassis mode.

**Options** **fpc slot-number**—Specify the slot number of the DPC.

**Range:** 0 through 11

**pic number**—Specify the number of the Packet Forwarding Engine. Each DPC includes four Packet Forwarding Engines.

**Range:** 0 through 4

**port-mirror-instance port-mirroring-instance-name-fpc-level**—Associate a port-mirroring instance with the DPC and its corresponding PICs. The port-mirroring instance is configured under the **[edit forwarding-options port-mirroring]** hierarchy level.

The remaining statements are explained separately.
