# Subscriber Access Configuration Guide

Release

13.1

---

Published: 2013-02-12

Juniper Networks, Inc.  
1194 North Mathilda Avenue  
Sunnyvale, California 94089  
USA  
408-745-2000  
[www.juniper.net](http://www.juniper.net)

This product includes the Envoy SNMP Engine, developed by Epilogue Technology, an Integrated Systems Company. Copyright © 1986-1997, Epilogue Technology Corporation. All rights reserved. This program and its documentation were developed at private expense, and no part of them is in the public domain.

This product includes memory allocation software developed by Mark Moraes, copyright © 1988, 1989, 1993, University of Toronto.

This product includes FreeBSD software developed by the University of California, Berkeley, and its contributors. All of the documentation and software included in the 4.4BSD and 4.4BSD-Lite Releases is copyrighted by the Regents of the University of California. Copyright © 1979, 1980, 1983, 1986, 1988, 1989, 1991, 1992, 1993, 1994. The Regents of the University of California. All rights reserved.

GateD software copyright © 1995, the Regents of the University. All rights reserved. Gate Daemon was originated and developed through release 3.0 by Cornell University and its collaborators. Gated is based on Kirton's EGP, UC Berkeley's routing daemon (routed), and DCN's HELLO routing protocol. Development of Gated has been supported in part by the National Science Foundation. Portions of the GateD software copyright © 1988, Regents of the University of California. All rights reserved. Portions of the GateD software copyright © 1991, D. L. S. Associates.

This product includes software developed by Maker Communications, Inc., copyright © 1996, 1997, Maker Communications, Inc.

Juniper Networks, Junos, Steel-Belted Radius, NetScreen, and ScreenOS are registered trademarks of Juniper Networks, Inc. in the United States and other countries. The Juniper Networks Logo, the Junos logo, and JunosE are trademarks of Juniper Networks, Inc. All other trademarks, service marks, registered trademarks, or registered service marks are the property of their respective owners.

Juniper Networks assumes no responsibility for any inaccuracies in this document. Juniper Networks reserves the right to change, modify, transfer, or otherwise revise this publication without notice.

Products made or sold by Juniper Networks or components thereof might be covered by one or more of the following patents that are owned by or licensed to Juniper Networks: U.S. Patent Nos. 5,473,599, 5,905,725, 5,909,440, 6,192,051, 6,333,650, 6,359,479, 6,406,312, 6,429,706, 6,459,579, 6,493,347, 6,538,518, 6,538,899, 6,552,918, 6,567,902, 6,578,186, and 6,590,785.

#### *Junos® OS Subscriber Access Configuration Guide*

Release 13.1

Copyright © 2013, Juniper Networks, Inc.

All rights reserved.

#### Revision History

March 2013—Junos OS 13.1

The information in this document is current as of the date on the title page.

#### YEAR 2000 NOTICE

Juniper Networks hardware and software products are Year 2000 compliant. Junos OS has no known time-related limitations through the year 2038. However, the NTP application is known to have some difficulty in the year 2036.

#### END USER LICENSE AGREEMENT

The Juniper Networks product that is the subject of this technical documentation consists of (or is intended for use with) Juniper Networks software. Use of such software is subject to the terms and conditions of the End User License Agreement ("EULA") posted at <http://www.juniper.net/support/eula.html>. By downloading, installing or using such software, you agree to the terms and conditions of that EULA.

# Abbreviated Table of Contents

	About This Guide .....	lxv
Part 1	Managing Access Networks	
Chapter 1	Subscriber Access Overview .....	3
Part 2	AAA Service Framework for Subscriber Access	
Chapter 2	Configuring the AAA Service Framework for Subscriber Access .....	19
Chapter 3	Configuring Address-Assignment Pools for Subscriber Access .....	155
Chapter 4	Configuring Domain Maps for Subscriber Access .....	167
Chapter 5	AAA and Remote Subscriber Access Configuration Examples .....	179
Part 3	DHCP Local Server for Subscriber Access	
Chapter 6	DHCP Local Server Overview .....	185
Chapter 7	Configuring DHCP Local Server .....	195
Chapter 8	DHCP Local Server Examples .....	245
Part 4	DHCP Relay Agent for Subscriber Access	
Chapter 9	DHCP Relay Agent Overview .....	257
Chapter 10	Configuring DHCP Relay Agent .....	265
Chapter 11	DHCP Relay Agent Examples .....	321
Part 5	PPP for Subscriber Access	
Chapter 12	Dynamic Profiles for PPP Overview .....	343
Chapter 13	Configuring PPP for Subscriber Access .....	345
Chapter 14	Configuring Subscriber Services for MLPPP Interfaces .....	353
Part 6	L2TP for Subscriber Access	
Chapter 15	L2TP for Subscriber Access Overview .....	359
Chapter 16	Configuring L2TP for Subscriber Access .....	373
Part 7	Diameter Base Protocol and Applications for Subscriber Access	
Chapter 17	Diameter Base Protocol Overview .....	421
Chapter 18	Configuring Diameter Base Protocol .....	437

Chapter 19	JSRC and Juniper Networks Session Resource Control (SRC) Overview .....	451
Chapter 20	Configuring JSRC for Subscriber Access .....	457
Chapter 21	Subscribers on Static Interfaces .....	461
Chapter 22	Configuring Subscribers over Static Interfaces .....	465
Chapter 23	PTSP and Juniper Networks Session and Resource Control (SRC) .....	481
Chapter 24	Configuring the PTSP Application .....	491
Chapter 25	Configuring Packet-Triggered Subscriber Services .....	495
Chapter 26	Gx-Plus Overview .....	507
Chapter 27	Configuring Gx-Plus .....	515
Part 8	Mobile IP Access	
Chapter 28	Mobile IP Overview .....	523
Chapter 29	Configuring Mobile IP .....	535
Part 9	ATM for Subscriber Access	
Chapter 30	ATM for Subscriber Access Overview .....	547
Chapter 31	Configuring ATM for Subscriber Access .....	553
Chapter 32	ATM for Subscriber Access Examples .....	557
Part 10	Dynamic Profiles for Access and Services	
Chapter 33	Dynamic Profiles Overview .....	601
Chapter 34	Configuring Dynamic Profiles .....	633
Chapter 35	Configuring Dynamic Access and Access-Internal Routes for Subscriber Management .....	647
Chapter 36	Dynamic Profile Examples .....	655
Part 11	Dynamic VLANs	
Chapter 37	Dynamic VLAN Overview .....	661
Chapter 38	Configuring Dynamic VLANs .....	673
Chapter 39	Dynamic VLAN Examples .....	709
Part 12	Subscriber Interfaces	
Chapter 40	Subscriber Interface Overview .....	715
Chapter 41	Configuring Subscriber Interfaces for Dynamic Profiles .....	723
Chapter 42	Subscriber Interface Examples .....	737
Chapter 43	Subscriber Interfaces over Aggregated Ethernet Overview .....	773
Chapter 44	Configuring Subscriber Interfaces over Aggregated Ethernet .....	781
Chapter 45	Subscriber Interfaces over Aggregated Ethernet Examples .....	793
Chapter 46	Dynamic PPPoE Subscriber Interfaces Overview .....	841
Chapter 47	Configuring Dynamic PPPoE Subscriber Interfaces .....	857

Chapter 48	Dynamic PPPoE Subscriber Interfaces Examples . . . . .	875
Chapter 49	MPLS Pseudowire Subscriber Interfaces Overview . . . . .	881
Chapter 50	Configuring MPLS Pseudowire Subscriber Interfaces . . . . .	889
Part 13	Class of Service for Subscriber Access	
Chapter 51	Dynamic CoS for Subscriber Access Overview . . . . .	905
Chapter 52	Configuration Summary of Dynamic CoS for Subscriber Access . . . . .	913
Chapter 53	Configuring Dynamic Shaping and Scheduling for Subscriber Access . . .	919
Chapter 54	RADIUS and Dynamic CoS Overview . . . . .	935
Chapter 55	Configuring RADIUS for Dynamic CoS . . . . .	945
Chapter 56	Interface Solutions for Dynamic CoS Overview . . . . .	959
Chapter 57	Configuring Interface Solutions for Dynamic CoS . . . . .	969
Chapter 58	Dynamic CoS for Subscriber Access Examples . . . . .	977
Chapter 59	Bandwidth Management for Dynamic CoS Overview . . . . .	1015
Chapter 60	Configuring Bandwidth Management Parameters for Dynamic CoS . . .	1035
Chapter 61	Bandwidth Management for Dynamic CoS Examples . . . . .	1055
Part 14	Subscriber Service Activation	
Chapter 62	Subscriber Service Activation Overview . . . . .	1065
Part 15	Dynamic Firewall Filters, Service Sets and HTTP Redirect for Subscriber Access	
Chapter 63	Dynamic Firewall Filters and Service Sets Overview . . . . .	1075
Chapter 64	Parameterized Filters . . . . .	1097
Chapter 65	Configuring Filters for Dynamic Profiles . . . . .	1113
Chapter 66	Configuring Fast Update Filters . . . . .	1125
Chapter 67	Configuring Service Sets in Dynamic Profiles . . . . .	1139
Chapter 68	Firewall Filter Examples . . . . .	1141
Chapter 69	Redirecting HTTP Requests Overview . . . . .	1167
Chapter 70	Configuring HTTP Redirect . . . . .	1169
Chapter 71	HTTP Redirect Examples . . . . .	1173
Part 16	Subscriber Secure Policy Traffic Mirroring	
Chapter 72	Subscriber Secure Policy Traffic Mirroring Overview . . . . .	1185
Chapter 73	Overview of Subscriber Secure Policy Using RADIUS . . . . .	1187
Chapter 74	Configuring RADIUS-Initiated Subscriber Secure Policy Traffic Mirroring . . . . .	1201
Chapter 75	Overview of Subscriber Secure Policy Using DTCP . . . . .	1207
Chapter 76	Configuring DTCP-Initiated Subscriber Secure Policy Mirroring . . . . .	1221

Chapter 77	DTCP Messages Used for DTCP-Initiated Subscriber Secure Policy Mirroring . . . . .	1231
Chapter 78	Reporting Intercept-Related Events for Subscriber Secure Policy . . . . .	1245
Part 17	Protocols for Subscriber Access	
Chapter 79	ANCP Overview . . . . .	1253
Chapter 80	Configuring ANCP . . . . .	1273
Chapter 81	Dynamic IGMP Configuration Overview . . . . .	1313
Chapter 82	Dynamic MLD Configuration Overview . . . . .	1315
Chapter 83	Dynamic Router Advertisement Overview . . . . .	1317
Part 18	Subscriber Access Examples	
Chapter 84	Service Profile Examples . . . . .	1321
Part 19	Complete Configuration Statement Hierarchy and Summary of Statements for Subscriber Access	
Chapter 85	Subscriber Access Statement Hierarchy . . . . .	1327
Chapter 86	Subscriber Access Configuration Statements . . . . .	1355
Part 20	Index	
	Index . . . . .	2037
	Index of Statements and Commands . . . . .	2079

# Table of Contents

	<b>About This Guide</b> .....	<b>lxv</b>
	JUNOS Documentation and Release Notes .....	lxv
	Objectives .....	lxvi
	Audience .....	lxvi
	Supported Routing Platforms .....	lxvii
	Using the Indexes .....	lxvii
	Using the Examples in This Manual .....	lxvii
	Merging a Full Example .....	lxvii
	Merging a Snippet .....	lxviii
	Documentation Conventions .....	lxviii
	Documentation Feedback .....	lxx
	Requesting Technical Support .....	lxx
	Self-Help Online Tools and Resources .....	lxxi
	Opening a Case with JTAC .....	lxxi
<b>Part 1</b>	<b>Managing Access Networks</b>	
<b>Chapter 1</b>	<b>Subscriber Access Overview</b> .....	<b>3</b>
	Subscriber Access Overview .....	3
	Subscriber Access Terms and Acronyms .....	4
	Subscriber Access Environment .....	4
	Relationship Between Subscribers and Interfaces in an Access Network .....	5
	Subscriber Access Support Considerations .....	5
	Platform Support .....	5
	Interface Support .....	6
	DPC Support .....	6
	Routing Engine Support .....	6
	Logical System Support .....	6
	Subscriber Access Licensing Overview .....	6
	Subscriber Management Unified ISSU Support .....	7
	Unified ISSU Support for DHCP Access Model .....	7
	Unified ISSU Support for PPPoE Access Model .....	7
	Verifying and Monitoring Subscriber Management Unified ISSU State .....	8
	Subscriber Access Operation Flow Using DHCP Relay .....	8

	Subscriber Activation and Service Management in an Access Network . . . . .	9
	Components of a Dynamic Profile . . . . .	10
	Router Predefined Variables Used by Dynamic Profiles . . . . .	10
	Configuring Subscriber Access . . . . .	10
	Collecting Subscriber Access Logs Before Contacting Juniper Technical Support . . . . .	13
	Compressing Troubleshooting Logs from /var/logs to Send to Juniper Technical Support . . . . .	15
<b>Part 2</b>	<b>AAA Service Framework for Subscriber Access</b>	
<b>Chapter 2</b>	<b>Configuring the AAA Service Framework for Subscriber Access . . . . .</b>	<b>19</b>
	AAA Service Framework Overview . . . . .	21
	Configuring Router or Switch Interaction with RADIUS Servers . . . . .	23
	Configuring Authentication and Accounting Parameters for Subscriber Access . . . . .	24
	Specifying the Authentication and Accounting Methods for Subscriber Access . . . . .	24
	RADIUS Acct-On and Acct-Off Messages . . . . .	25
	RADIUS Accounting Statistics for Subscriber Access Overview . . . . .	26
	Understanding RADIUS Accounting Duplicate Reporting . . . . .	28
	Configuring Per-Subscriber Session Accounting . . . . .	29
	Retaining Authentication and Accounting Information During Session Startup . . . . .	31
	Preservation of RADIUS Accounting Information During an Accounting Server Outage . . . . .	31
	Configuring Per-Service Session Accounting . . . . .	34
	Configuring RADIUS Server Parameters for Subscriber Access . . . . .	35
	Specifying RADIUS Authentication and Accounting Servers for Subscriber Access . . . . .	36
	Configuring Back-up Options for RADIUS Accounting . . . . .	37
	Forcing the Router to Contact the Accounting Server Immediately . . . . .	38
	Monitoring Pending RADIUS Accounting Stop Messages . . . . .	38
	RADIUS Server Options for Subscriber Access . . . . .	40
	Global RADIUS Options for Subscriber Access . . . . .	42
	DNS Address Assignment Precedence . . . . .	43
	Manual Configuration of the NAS-Port-ID RADIUS Attribute . . . . .	43
	Manual Configuration of the NAS-Port-Type RADIUS Attribute . . . . .	44
	Configuring RADIUS Server Options for Subscriber Access . . . . .	46
	Configuring RADIUS Options for Subscriber Access Globally . . . . .	48
	Configuring a NAS-Port-ID with Additional Options . . . . .	49
	Configuring a Calling-Station-ID with Additional Attributes . . . . .	50
	Configuring How RADIUS Attributes Are Used for Subscriber Access . . . . .	52
	RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN Overview . . . . .	57
	NAS-Port-Type RADIUS Attribute . . . . .	57
	NAS-Port RADIUS Attribute . . . . .	58
	NAS-Port Options Configuration and Subscriber Network Access Models . . . . .	58

NAS-Port Options Definition .....	58
Guidelines for Configuring RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN .....	59
Configuring RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN .....	60
Configuring the RADIUS NAS-Port-Type per Physical Interface .....	62
Configuring the RADIUS NAS-Port-Type per VLAN .....	63
Configuring the RADIUS NAS-Port-Type per Stacked VLAN .....	64
Configuring the RADIUS NAS-Port Extended Format per Physical Interface ....	66
Configuring the RADIUS NAS-Port Extended Format per VLAN .....	68
Configuring the RADIUS NAS-Port Extended Format per Stacked VLAN .....	69
Centrally Configured Opaque DHCP Options .....	72
Data Flow for RADIUS-Sourced DHCP Options .....	73
Multiple VSA 26-55 Instances Configuration .....	74
DHCP Options That Cannot Be Centrally Configured .....	74
Monitoring DHCP Options Configured on RADIUS Servers .....	75
Using RADIUS Dynamic Requests for Subscriber Access Management .....	77
Dynamic Service Activation During Login Overview .....	77
RADIUS-Initiated Change of Authorization (CoA) Overview .....	78
CoA Messages .....	78
Qualifications for Change of Authorization .....	78
Message Exchange .....	79
RADIUS-Initiated Disconnect Overview .....	79
Disconnect Messages .....	80
Qualifications for Disconnect .....	80
Message Exchange .....	80
Configuring RADIUS-Initiated Dynamic Request Support .....	81
Verifying and Managing the RADIUS Dynamic-Request Feature .....	81
RADIUS Attributes and Juniper Networks VSAs Supported by the AAA Service Framework .....	81
RADIUS IETF Attributes Supported by the AAA Service Framework .....	82
Juniper Networks VSAs Supported by the AAA Service Framework .....	88
DSL Forum Vendor-Specific Attributes .....	96
AAA Access Messages and Supported RADIUS Attributes and Juniper Networks VSAs for Junos OS .....	98
AAA Accounting Messages and Supported RADIUS Attributes and Juniper Networks VSAs for Junos OS .....	103
DSL Forum VSAs Support in AAA Access and Accounting Messages for Junos OS .....	107
Error-Cause Codes (RADIUS Attribute 101) for Dynamic Requests .....	108
Mapping Application Terminate Reasons and RADIUS Terminate Codes .....	109
AAA Terminate Reasons .....	111
DHCP Terminate Reasons .....	111
L2TP Terminate Reasons .....	112
PPP Terminate Reasons .....	128
Configuring Custom Terminate Reason Mappings .....	135
Configuring an Access Profile for Subscriber Management .....	137
Attaching Access Profiles .....	137
RADIUS Support for Dynamic Router Advertisement .....	138

	DNS Name Server Address Overview . . . . .	138
	Configuring DNS Name Server Addresses for Subscriber Management . . . . .	139
	Understanding Session Options for Subscriber Access . . . . .	141
	Configuring Subscriber Session Options . . . . .	143
	Removing Inactive Dynamic Subscriber VLANs . . . . .	144
	AAA Configuration Testing and Troubleshooting . . . . .	144
	Testing a Subscriber AAA Configuration . . . . .	145
	Tracing Subscriber Management Database Operations for Subscriber Access . . . . .	147
	Configuring the Subscriber Management Database Trace Log Filename . . . . .	148
	Configuring the Number and Size of Subscriber Management Database Log Files . . . . .	148
	Configuring Access to the Subscriber Management Database Log File . . . . .	149
	Configuring a Regular Expression for Subscriber Management Database Messages to Be Logged . . . . .	149
	Configuring the Subscriber Management Database Tracing Flags . . . . .	149
	Tracing Subscriber Management Session Database Replication Operations for Subscriber Access . . . . .	150
	Configuring the Number and Size of Subscriber Management Session Database Replication Log Files . . . . .	151
	Configuring a Regular Expression for Subscriber Management Session Database Replication Messages to Be Logged . . . . .	151
	Configuring Access to the Subscriber Management Session Database Replication Log File . . . . .	152
	Configuring the Subscriber Management Session Database Replication Trace Log Filename . . . . .	152
	Configuring the Subscriber Management Session Database Replication Tracing Flags . . . . .	152
	Verifying and Managing Subscriber AAA Information . . . . .	153
<b>Chapter 3</b>	<b>Configuring Address-Assignment Pools for Subscriber Access . . . . .</b>	<b>155</b>
	Address-Assignment Pools Overview . . . . .	155
	Configuring Address-Assignment Pools . . . . .	156
	Configuring an Address-Assignment Pool Name and Addresses . . . . .	157
	Configuring a Named Address Range for Dynamic Address Assignment . . . . .	157
	Configuring Address-Assignment Pool Linking . . . . .	158
	Configuring Static Address Assignment . . . . .	159
	Configuring an Address-Assignment Pool for Router Advertisement . . . . .	159
	Configuring Address-Assignment Pool Usage Threshold Traps . . . . .	160
	Configuring DHCP Client-Specific Attributes . . . . .	160
	DHCP Attributes for Address-Assignment Pools . . . . .	161
	Address-Assignment Pools Licensing Requirements . . . . .	163
	Tracing General Authentication Service Processes . . . . .	163
	Configuring the General Authentication Service Processes Trace Log Filename . . . . .	164
	Configuring the Number and Size of General Authentication Service Processes Log Files . . . . .	164
	Configuring Access to the Log File . . . . .	165
	Configuring a Regular Expression for Lines to Be Logged . . . . .	165

	Configuring the Trace Operation . . . . .	166
<b>Chapter 4</b>	<b>Configuring Domain Maps for Subscriber Access . . . . .</b>	<b>167</b>
	Domain Mapping Overview . . . . .	168
	Default Domain Map . . . . .	169
	Configuring a Domain Map . . . . .	169
	Specifying an Access Profile in a Domain Map . . . . .	170
	Specifying a Dynamic Profile in a Domain Map . . . . .	171
	Specifying an Address Pool in a Domain Map . . . . .	172
	Specifying an AAA Logical System/Routing Instance in a Domain Map . . . . .	172
	Specifying a Target Logical System/Routing Instance in a Domain Map . . . . .	174
	Configuring Domain Name Usage for Domain Maps . . . . .	175
	Specifying Domain Name Delimiters . . . . .	175
	Specifying the Parsing Direction for Domain Names . . . . .	176
	Enabling Domain Name Stripping . . . . .	176
	Specifying a Tunnel Profile in a Domain Map . . . . .	177
	Configuring PADN Parameters for a Domain Map . . . . .	177
	Verifying and Managing Domain Map Configuration . . . . .	178
<b>Chapter 5</b>	<b>AAA and Remote Subscriber Access Configuration Examples . . . . .</b>	<b>179</b>
	Example: Configuring RADIUS-Based Subscriber Authentication and Accounting . . . . .	179
	Example: Configuring an Address-Assignment Pool . . . . .	181
<b>Part 3</b>	<b>DHCP Local Server for Subscriber Access</b>	
<b>Chapter 6</b>	<b>DHCP Local Server Overview . . . . .</b>	<b>185</b>
	Extended DHCP Local Server Overview . . . . .	186
	Interaction Among the DHCP Client, Extended DHCP Local Server, and Address-Assignment Pools . . . . .	186
	Providing DHCP Client Configuration Information . . . . .	187
	Minimal Configuration for Clients . . . . .	188
	DHCP Local Server and Address-Assignment Pools . . . . .	188
	DHCP Liveness Detection . . . . .	189
	DHCPv6 Local Server Overview . . . . .	190
	DHCP Local Server Handling of Client Information Request Messages . . . . .	191
	Dynamic Profile Attachment to DHCP Subscriber Interfaces Overview . . . . .	192
	Multiple DHCP Subscribers Sharing the Same VLAN Logical Interface . . . . .	193
	Primary Dynamic Profile . . . . .	193
	Port Number Requirements for DHCP Firewall Filters . . . . .	194
<b>Chapter 7</b>	<b>Configuring DHCP Local Server . . . . .</b>	<b>195</b>
	DHCP Duplicate Client Differentiation Using Client Subinterface Overview . . . . .	196
	Guidelines for Configuring Support for DHCP Duplicate Clients . . . . .	197
	Configuring DHCP Duplicate Client Support . . . . .	198
	Using External AAA Authentication Services with DHCP . . . . .	198
	Configuring How the Extended DHCP Local Server Determines Which Address-Assignment Pool to Use . . . . .	199
	Grouping Interfaces with Common DHCP Configurations . . . . .	201
	Guidelines for Configuring Interface Ranges . . . . .	202

Group-Specific DHCP Local Server Options . . . . .	203
Overriding Default DHCP Local Server Configuration Settings . . . . .	204
Specifying the Maximum Number of DHCP Clients Per Interface . . . . .	205
Disabling ARP Table Population . . . . .	206
Configuring DHCP Snooped Packets Forwarding Support for DHCP Local Server . . . . .	207
DHCP Auto Logout Overview . . . . .	208
Auto Logout Overview . . . . .	209
How DHCP Identifies and Releases Clients . . . . .	209
Option 60 and Option 82 Requirements . . . . .	210
Automatically Logging Out DHCP Clients . . . . .	210
Enabling Processing of Client Information Requests . . . . .	211
Enabling DHCPv6 Rapid Commit Support . . . . .	212
Deleting DHCP Local Server and DHCP Relay Override Settings . . . . .	213
Use of DHCP Option 50 and DHCPv6 IA_NA Option to Request a Specific IP Address . . . . .	213
Multiple Address Assignment for DHCPv6 Clients . . . . .	214
Multiple Address Assignment Using Local Address Pools or RADIUS . . . . .	214
Junos OS Predefined Variable for Multiple DHCPv6 Address Assignment . . . . .	214
Specifying the Delegated Address Pool for IPv6 Prefix Assignment . . . . .	215
Subscriber Binding Retention During Interface Delete Events . . . . .	215
Configuring the Router to Maintain DHCP Subscribers During Interface Delete Events . . . . .	216
Verifying and Managing the DHCP Maintain Subscribers Feature . . . . .	216
Clearing DHCP Bindings for Subscriber Access . . . . .	217
Configuring the Router to Strictly Enforce the Subscriber Scaling License . . . . .	219
Attaching Dynamic Profiles to DHCP Subscriber Interfaces . . . . .	220
Attaching a Dynamic Profile to All DHCP Subscriber Interfaces . . . . .	220
Attaching a Dynamic Profile to a Group of DHCP Subscriber Interfaces . . . . .	220
Configuring Passwords for Usernames . . . . .	221
Creating Unique Usernames for DHCP Clients . . . . .	222
Understanding Dynamic Reconfiguration of Extended DHCP Local Server Clients . . . . .	224
Default Client/Server Interaction . . . . .	224
Dynamic Client/Server Interaction for DHCPv4 . . . . .	225
Dynamic Client/Server Interaction for DHCPv6 . . . . .	225
Dynamic Configuration Options . . . . .	226
Configuring Extended DHCP Local Server Dynamic Client Reconfiguration . . . . .	227
Configuring Dynamic Reconfiguration Attempts for DHCP Clients . . . . .	229
Configuring Deletion of the Client When Dynamic Reconfiguration Fails . . . . .	230
Configuring Reconfiguration of the Client on Receipt of RADIUS-Initiated Disconnect . . . . .	230
Configuring a Token for DHCP Local Server Authentication . . . . .	231
Requesting DHCP Local Server to Initiate Reconfiguration of Client Bindings . . . . .	231
Preventing Binding of Clients That Do Not Support Reconfigure Messages . . . . .	232
DHCP Liveness Detection Overview . . . . .	233
Configuring Detection of DHCP Local Server Client Connectivity . . . . .	234
Verifying and Managing DHCP Local Server Configuration . . . . .	236
Verifying and Managing DHCPv6 Local Server Configuration . . . . .	236

	Graceful Routing Engine Switchover . . . . .	237
	Tracing Extended DHCP Operations . . . . .	238
	Configuring the Extended DHCP Log Filename . . . . .	239
	Configuring the Number and Size of Extended DHCP Log Files . . . . .	240
	Configuring Access to the Extended DHCP Log File . . . . .	240
	Configuring a Regular Expression for Extended DHCP Messages to Be Logged . . . . .	241
	Configuring the Extended DHCP Tracing Flags . . . . .	241
	Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged . . . . .	242
	Tracing Extended DHCP Operations for Specific Interfaces . . . . .	243
<b>Chapter 8</b>	<b>DHCP Local Server Examples . . . . .</b>	<b>245</b>
	Example: Minimum Extended DHCP Local Server Configuration . . . . .	245
	Example: Extended DHCP Local Server Configuration with Optional Pool Matching . . . . .	245
	Example: Extended DHCPv6 Local Server Configuration . . . . .	246
	Example: Configuring a DHCP Firewall Filter to Protect the Routing Engine . . . .	247
	Example: Configuring Group Liveness Detection for DHCP Local Server Clients . . . . .	251
<b>Part 4</b>	<b>DHCP Relay Agent for Subscriber Access</b>	
<b>Chapter 9</b>	<b>DHCP Relay Agent Overview . . . . .</b>	<b>257</b>
	Extended DHCP Relay Agent Overview . . . . .	258
	Interaction Among the DHCP Relay Agent, DHCP Client, and DHCP Servers . . . . .	259
	DHCP Liveness Detection . . . . .	259
	DHCPv6 Relay Agent Overview . . . . .	260
	DHCP Relay Proxy Overview . . . . .	261
	Interaction Among DHCP Relay Proxy, DHCP Client, and DHCP Servers . . . .	262
	Dynamic Profile Attachment to DHCP Subscriber Interfaces Overview . . . . .	263
	Multiple DHCP Subscribers Sharing the Same VLAN Logical Interface . . . .	263
	Primary Dynamic Profile . . . . .	264
<b>Chapter 10</b>	<b>Configuring DHCP Relay Agent . . . . .</b>	<b>265</b>
	DHCP Duplicate Client Differentiation Using Client Subinterface Overview . . . .	266
	Guidelines for Configuring Support for DHCP Duplicate Clients . . . . .	267
	Configuring DHCP Duplicate Client Support . . . . .	268
	Using External AAA Authentication Services with DHCP . . . . .	268
	Grouping Interfaces with Common DHCP Configurations . . . . .	269
	Guidelines for Configuring Interface Ranges . . . . .	270
	Group-Specific DHCP Relay Options . . . . .	272
	Overriding the Default DHCP Relay Configuration Settings . . . . .	273
	Overwriting giaddr Information . . . . .	274
	Replacing the DHCP Relay Request and Release Packet Source Address . . . . .	275
	Overriding Option 82 Information . . . . .	275
	Using Layer 2 Unicast Transmission for DHCP Packets . . . . .	276
	Trusting Option 82 Information . . . . .	276
	Disabling ARP Table Population . . . . .	277

Specifying the Maximum Number of DHCP Clients Per Interface . . . . .	278
DHCP Snooping Support . . . . .	279
Configuring DHCP Snooping for DHCP Relay Agent . . . . .	280
Enabling and Disabling DHCP Snooped Packets Support for DHCP Relay Agent . . . . .	281
Configuring DHCP Snooped Packets Forwarding Support for DHCP Relay Agent . . . . .	286
DHCP Auto Logout Overview . . . . .	288
Auto Logout Overview . . . . .	288
How DHCP Identifies and Releases Clients . . . . .	288
Option 60 and Option 82 Requirements . . . . .	289
DHCP Relay Agent Option 82 Value for Auto Logout . . . . .	289
Automatically Logging Out DHCP Clients . . . . .	290
Sending Release Messages When Clients Are Deleted . . . . .	291
Subscriber Binding Retention During Interface Delete Events . . . . .	292
Configuring the Router to Maintain DHCP Subscribers During Interface Delete Events . . . . .	293
Verifying and Managing the DHCP Maintain Subscribers Feature . . . . .	293
Clearing DHCP Bindings for Subscriber Access . . . . .	294
DHCP Liveness Detection Overview . . . . .	296
Configuring Detection of DHCP Relay or DHCP Relay Proxy Client Connectivity . . . . .	297
Disabling DHCP Relay . . . . .	299
Disabling Automatic Binding of Stray DHCP Requests . . . . .	299
DHCP Options and Selective Traffic Processing Overview . . . . .	301
Using DHCP Option Information to Selectively Process DHCP Client Traffic . . . . .	303
Displaying a Count of DHCP Packets That Are Dropped or Forwarded During Selective Processing That Is Based on DHCP Option Strings . . . . .	304
Enabling and Disabling Insertion of Option 82 Information . . . . .	305
Configuring Agent Circuit ID Information . . . . .	305
Configuring an Option 82 Prefix . . . . .	306
Using a Textual Description in Option 82 . . . . .	307
Configuring Server Groups . . . . .	308
Configuring Active Server Groups . . . . .	308
Enabling DHCP Relay Proxy Mode . . . . .	309
Inserting DHCPv6 Interface-ID Option (Option 18) In DHCPv6 Packets . . . . .	309
Attaching Dynamic Profiles to DHCP Subscriber Interfaces . . . . .	310
Attaching a Dynamic Profile to All DHCP Subscriber Interfaces . . . . .	310
Attaching a Dynamic Profile to a Group of DHCP Subscriber Interfaces . . . . .	311
Verifying and Managing DHCP Relay Configuration . . . . .	311
Verifying and Managing DHCPv6 Relay Configuration . . . . .	312
Tracing Extended DHCP Operations . . . . .	312
Configuring the Extended DHCP Log Filename . . . . .	314
Configuring the Number and Size of Extended DHCP Log Files . . . . .	314
Configuring Access to the Extended DHCP Log File . . . . .	315
Configuring a Regular Expression for Extended DHCP Messages to Be Logged . . . . .	316
Configuring the Extended DHCP Tracing Flags . . . . .	316

	Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged . . . . .	316
	Tracing Extended DHCP Operations for Specific Interfaces . . . . .	317
	Disabling DHCP Relay . . . . .	319
<b>Chapter 11</b>	<b>DHCP Relay Agent Examples . . . . .</b>	<b>321</b>
	Example: Minimum DHCP Relay Agent Configuration . . . . .	321
	Example: DHCP Relay Agent Configuration with Multiple Clients and Servers . . . . .	322
	Example: Configuring DHCP Snooping Support for DHCP Relay Agent . . . . .	323
	Example: Enabling DHCP Snooping Support for DHCPv6 Relay Agent . . . . .	325
	Example: Configuring DHCP Relay Agent Selective Traffic Processing Based on DHCP Option Strings . . . . .	329
	Example: Configuring DHCP and DHCPv6 Relay Agent Group-Level Selective Traffic Processing . . . . .	333
	Example: Configuring Global Liveness Detection for DHCP Relay Agent Clients . . . . .	337
<b>Part 5</b>	<b>PPP for Subscriber Access</b>	
<b>Chapter 12</b>	<b>Dynamic Profiles for PPP Overview . . . . .</b>	<b>343</b>
	Dynamic Profiles for PPP Subscriber Interfaces Overview . . . . .	343
<b>Chapter 13</b>	<b>Configuring PPP for Subscriber Access . . . . .</b>	<b>345</b>
	Configuring Dynamic Authentication for PPP Subscribers . . . . .	345
	Controlling the Negotiation Order of PPP Authentication Protocols . . . . .	347
	Modifying the CHAP Challenge Length . . . . .	349
	Attaching Dynamic Profiles to Static PPP Subscriber Interfaces . . . . .	350
	Understanding How the Router Processes Subscriber-Initiated PPP Fast Keepalive Requests . . . . .	351
	How PPP Fast Keepalive Processing Works . . . . .	351
	Statistics Display for PPP Fast Keepalive . . . . .	352
	Effect of Changing the Forwarding Class Configuration . . . . .	352
	Verifying and Managing PPP Configuration for Subscriber Management . . . . .	352
<b>Chapter 14</b>	<b>Configuring Subscriber Services for MLPPP Interfaces . . . . .</b>	<b>353</b>
	Dynamic PPP Subscriber Services for Static MLPPP Interfaces . . . . .	353
	Hardware Requirements for PPP Subscriber Services on Non-Ethernet Interfaces . . . . .	354
	Configuring PPP Subscriber Services for MLPPP Bundles . . . . .	354
	Enabling PPP Subscriber Services for Static Non-Ethernet Interfaces . . . . .	355
	Attaching Dynamic Profiles to MLPPP Bundles . . . . .	355
<b>Part 6</b>	<b>L2TP for Subscriber Access</b>	
<b>Chapter 15</b>	<b>L2TP for Subscriber Access Overview . . . . .</b>	<b>359</b>
	L2TP for Subscriber Access Overview . . . . .	359
	L2TP Terminology . . . . .	361
	L2TP Implementation . . . . .	362
	Sequence of Events on the LAC . . . . .	363
	Sequence of Events on the LNS . . . . .	364

	LAC Tunnel Selection Overview . . . . .	364
	Tunnel Selection Failover Between Preference Levels . . . . .	365
	Tunnel Selection Failover Within a Preference Level . . . . .	366
	Tunnel Selection and Maximum Sessions per Tunnel . . . . .	367
	Tunnel Selection with Weighted Load Balancing . . . . .	367
	L2TP Failover and Peer Resynchronization . . . . .	367
	L2TP and Graceful Routing Engine Switchover . . . . .	369
	IP Packet Fragment Reassembly for L2TP Overview . . . . .	369
	Transmission of Tx Connect-Speed and Rx Connect-Speed AVPs from LAC to LNS . . . . .	370
<b>Chapter 16</b>	<b>Configuring L2TP for Subscriber Access . . . . .</b>	<b>373</b>
	Configuring an L2TP LAC . . . . .	374
	Configuring a Tunnel Profile for Subscriber Access . . . . .	375
	Configuring the L2TP LAC Tunnel Selection Parameters . . . . .	377
	Configuring LAC Tunnel Selection Failover Within a Preference Level . . . . .	377
	Configuring Weighted Load Balancing for LAC Tunnel Sessions . . . . .	378
	Preventing the LAC from Sending Calling Number AVP 22 to the LNS . . . . .	379
	Configuring the Method to Set the LAC Connection Speeds to the LNS . . . . .	379
	Transmission of the Receive Connect Speed AVP When Transmit and Receive Connect Speeds are Equal . . . . .	380
	Preventing the LAC From Negotiating L2TP Failover Protocol . . . . .	381
	Setting the Format for the Tunnel Name . . . . .	381
	Configuring the Number of L2TP Control Message Retransmissions . . . . .	382
	Setting the L2TP Tunnel Idle Timeout . . . . .	383
	Setting the L2TP Destruct Timeout . . . . .	384
	Configuring an L2TP LNS with Inline Service Interfaces . . . . .	384
	Applying PPP Attributes to L2TP LNS Subscribers with a User Group Profile . . . . .	386
	Applying PPP Attributes to L2TP LNS Subscribers Per Inline Service Interface . . . . .	387
	Configuring IP Inline Reassembly for L2TP . . . . .	388
	Configuring an L2TP Access Profile on the LNS . . . . .	390
	Configuring a AAA Local Access Profile on the LNS . . . . .	391
	Configuring an Address-Assignment Pool for L2TP LNS with Inline Services . . . . .	392
	Configuring the L2TP LNS Peer Interface . . . . .	393
	Enabling Inline Service Interfaces . . . . .	394
	Configuring an Inline Service Interface for L2TP LNS . . . . .	394
	Configuring Options for the LNS Inline Services Logical Interface . . . . .	395
	Configuring an L2TP Tunnel Group for LNS Sessions with Inline Services Interfaces . . . . .	396
	Configuring a Pool of Inline Services Interfaces for Dynamic LNS Sessions . . . . .	397
	Configuring a Dynamic Profile for Dynamic LNS Sessions . . . . .	398
	Tracing L2TP Operations for Subscriber Access . . . . .	399
	Configuring the L2TP Trace Log Filename . . . . .	400
	Configuring the Number and Size of L2TP Log Files . . . . .	401
	Configuring Access to the L2TP Log File . . . . .	401
	Configuring a Regular Expression for L2TP Messages to Be Logged . . . . .	402
	Configuring the L2TP Tracing Flags . . . . .	402

	Configuring the Severity Level to Filter Which L2TP Messages Are Logged . . . .	402
	Verifying and Managing L2TP for Subscriber Access . . . . .	403
	Testing L2TP Tunnel Configurations from the LAC . . . . .	404
	Example: Configuring an L2TP LNS . . . . .	406
<b>Part 7</b>	<b>Diameter Base Protocol and Applications for Subscriber Access</b>	
<b>Chapter 17</b>	<b>Diameter Base Protocol Overview . . . . .</b>	<b>421</b>
	Diameter Base Protocol Overview . . . . .	421
	Messages Used by Diameter Applications . . . . .	423
	Diameter AVPs and Diameter Applications . . . . .	427
<b>Chapter 18</b>	<b>Configuring Diameter Base Protocol . . . . .</b>	<b>437</b>
	Configuring Diameter . . . . .	437
	Configuring the Origin Attributes of the Diameter Instance . . . . .	438
	Configuring Diameter Peers . . . . .	439
	Configuring Diameter Network Elements . . . . .	439
	Configuring the Diameter Transport . . . . .	440
	Tracing Diameter Base Protocol Processes for Subscriber Access . . . . .	441
	Configuring the Diameter Base Protocol Trace Log Filename . . . . .	442
	Configuring the Number and Size of Diameter Base Protocol Log Files . . . . .	442
	Configuring Access to the Diameter Base Protocol Log File . . . . .	443
	Configuring a Regular Expression for Diameter Base Protocol Messages to Be Logged . . . . .	443
	Configuring the Diameter Base Protocol Tracing Flags . . . . .	444
	Configuring the Severity Level to Filter Which Diameter Base Protocol Messages Are Logged . . . . .	444
	Verifying Diameter Node, Instance, and Route Information . . . . .	444
	Verifying and Managing Diameter Function Information . . . . .	445
	Verifying and Managing Diameter Peer Information . . . . .	446
	Verifying Diameter Network Element Information . . . . .	447
	Troubleshooting Diameter Network Configuration . . . . .	448
	Troubleshooting Diameter Network Connectivity . . . . .	448
<b>Chapter 19</b>	<b>JSRC and Juniper Networks Session Resource Control (SRC) Overview . . . . .</b>	<b>451</b>
	Juniper Networks Session and Resource Control (SRC) and JSRC Overview . . .	451
	Hardware Requirements for JSRC for Subscriber Access . . . . .	452
	Service Accounting with JSRC . . . . .	452
	Understanding JSRC-SAE Interactions . . . . .	454
	Subscriber Login . . . . .	454
	Subscriber Service Activation and Deactivation . . . . .	455
	Subscriber Resynchronization . . . . .	455
	Subscriber Session Terminated by the SAE . . . . .	455
	Statistics Collection and Reporting per Service Rule . . . . .	456
	Subscriber Logout . . . . .	456
<b>Chapter 20</b>	<b>Configuring JSRC for Subscriber Access . . . . .</b>	<b>457</b>
	Configuring JSRC . . . . .	457
	Configuring the JSRC Partition . . . . .	458

	Assigning a Partition to JSRC . . . . .	459
	Authorizing Subscribers with JSRC . . . . .	459
	Provisioning Subscribers with JSRC . . . . .	460
	Configuring Service Accounting with JSRC . . . . .	460
<b>Chapter 21</b>	<b>Subscribers on Static Interfaces . . . . .</b>	<b>461</b>
	Subscribers on Static Interfaces Overview . . . . .	461
<b>Chapter 22</b>	<b>Configuring Subscribers over Static Interfaces . . . . .</b>	<b>465</b>
	Configuring Subscribers over Static Interfaces . . . . .	466
	Specifying the Static Subscriber Global Access Profile . . . . .	467
	Specifying the Static Subscriber Global Dynamic Profile . . . . .	468
	Enabling Multiple Subscribers on a VLAN Logical Interface for All Static Subscribers . . . . .	468
	Configuring the Static Subscriber Global Authentication Password . . . . .	469
	Configuring the Static Subscriber Global Username . . . . .	469
	Creating a Static Subscriber Group . . . . .	470
	Specifying the Static Subscriber Group Access Profile . . . . .	471
	Specifying the Static Subscriber Group Dynamic Profile . . . . .	471
	Enabling Multiple Subscribers on a VLAN Logical Interface for a Static Subscriber Group . . . . .	472
	Configuring the Static Subscriber Group Authentication Password . . . . .	472
	Configuring the Static Subscriber Group Username . . . . .	473
	Forcing a Static Subscriber to Be Logged Out . . . . .	474
	Resetting the State of an Interface for Static Subscriber Login . . . . .	474
	Forcing a Group of Static Subscribers to Be Logged Out . . . . .	474
	Resetting the State of an Interface Group for Static Subscriber Login . . . . .	474
	Verifying Information about Subscriber Sessions on Static Interfaces . . . . .	475
	Tracing Static Subscriber Operations . . . . .	475
	Configuring the Static Subscribers Trace Log Filename . . . . .	476
	Configuring the Number and Size of Static Subscribers Log Files . . . . .	476
	Configuring Access to the Static Subscribers Log File . . . . .	477
	Configuring a Regular Expression for Static Subscriber Messages to Be Logged . . . . .	477
	Configuring the Static Subscribers Tracing Flags . . . . .	478
	Configuring the Severity Level to Filter Which Static Subscriber Messages Are Logged . . . . .	478
	Example: Configuring Static Subscribers for Subscriber Access . . . . .	478
<b>Chapter 23</b>	<b>PTSP and Juniper Networks Session and Resource Control (SRC) . . . . .</b>	<b>481</b>
	PTSP Overview . . . . .	481
	Hardware Requirements for PTSP for Subscriber Access . . . . .	482
	Juniper Networks Session and Resource Control (SRC) and PTSP Overview . .	482
	Understanding PTSP-SAE Interactions . . . . .	483
	Packet-Triggered Subscribers Services Overview . . . . .	484
	Subscriber Identification Method for PTSP Partition . . . . .	486
	PTSP Services on Aggregated and Redundant Services PICs . . . . .	486
	Understanding the Subscriber Profiles for Client Sessions per PSTP Partition . .	488

<b>Chapter 24</b>	<b>Configuring the PTSP Application . . . . .</b>	<b>491</b>
	Configuring the PTSP Application . . . . .	491
	Configuring the PTSP Partition . . . . .	492
	Assigning the PTSP Partition . . . . .	492
	Tracing Packet-Triggered Subscriber Operations . . . . .	493
	Configuring the Packet-Triggered Subscribers Trace Log Filename . . . . .	494
	Configuring the Size of Packet-Triggered Subscribers Log Files . . . . .	494
	Configuring the Packet-Triggered Subscribers Tracing Flags . . . . .	494
<b>Chapter 25</b>	<b>Configuring Packet-Triggered Subscriber Services . . . . .</b>	<b>495</b>
	Configuring PTSP . . . . .	495
	Configuring the Multiservices DPC for PTSP . . . . .	496
	Enabling the PTSP Service Package on the Multiservices DPC . . . . .	496
	Configuring Services Interface for PTSP . . . . .	496
	Configuring PTSP Service Rules . . . . .	497
	Configuring Static PTSP Rules . . . . .	497
	Configuring PTSP Rule Sets . . . . .	499
	Configuring PTSP Service Sets . . . . .	500
	Configuring the PTSP Forwarding Instance . . . . .	500
	Configuring a Statistics Profile for PTSP . . . . .	502
	Configuring the File Properties for Statistics Data Output . . . . .	503
	Configuring the Profile Properties for Statistics Data Output . . . . .	503
	Configuring the Record Type for Statistics Data . . . . .	504
	Tracing PTSP Operations . . . . .	504
	Verifying and Managing PTSP Configuration . . . . .	505
<b>Chapter 26</b>	<b>Gx-Plus Overview . . . . .</b>	<b>507</b>
	Gx-Plus for Provisioning Subscribers Overview . . . . .	507
	Understanding Gx-Plus Interactions Between the Router and the PCRF . . . . .	509
	Subscriber Login . . . . .	509
	Fault Tolerance and Event Notification . . . . .	511
	PCRF-Generated Discovery . . . . .	512
	Subscriber Accounting . . . . .	513
	Subscriber Logout . . . . .	513
<b>Chapter 27</b>	<b>Configuring Gx-Plus . . . . .</b>	<b>515</b>
	Configuring Gx-Plus . . . . .	515
	Configuring the Gx-Plus Partition . . . . .	516
	Configuring Gx-Plus Global Attributes . . . . .	517
	Provisioning Subscribers with Gx-Plus . . . . .	518
	Disabling PCRF Control of a Subscriber Session . . . . .	518
<b>Part 8</b>	<b>Mobile IP Access</b>	
<b>Chapter 28</b>	<b>Mobile IP Overview . . . . .</b>	<b>523</b>
	Mobile IP Home Agent Elements and Behavior . . . . .	523
	Mobile IP Registration . . . . .	526
	Home Address Assignment . . . . .	526
	Authentication . . . . .	526
	Reauthentication . . . . .	527

	AAA Authentication . . . . .	527
	Local Authentication . . . . .	528
	Accounting . . . . .	529
	Mobile IP Routing and Forwarding . . . . .	530
	Mobile IP in the WiMAX Environment . . . . .	531
<b>Chapter 29</b>	<b>Configuring Mobile IP . . . . .</b>	<b>535</b>
	Configuring Mobile IP . . . . .	535
	Configuring the Mobile IP Authentication Method . . . . .	536
	Configuring the Mobile IP Home Agent . . . . .	536
	Configuring the Local Authentication Attributes for the Mobile Node . . . . .	537
	Configuring Accounting for Mobile IP Subscribers . . . . .	538
	Configuring Dynamic Home Assignment for the Mobile Node . . . . .	538
	Configuring the Access Type for Mobile IP . . . . .	539
	Tracing Mobile IP Operations for Subscriber Access . . . . .	539
	Configuring the Mobile IP Trace Log Filename . . . . .	541
	Configuring the Number and Size of Mobile IP Log Files . . . . .	541
	Configuring Access to the Mobile IP Log File . . . . .	542
	Configuring a Regular Expression for Mobile IP Messages to Be Logged . . . . .	542
	Configuring the Mobile IP Tracing Flags . . . . .	542
	Configuring the Severity Level to Filter Which Mobile IP Messages Are Logged . . . . .	543
<b>Part 9</b>	<b>ATM for Subscriber Access</b>	
<b>Chapter 30</b>	<b>ATM for Subscriber Access Overview . . . . .</b>	<b>547</b>
	ATM for Subscriber Access Overview . . . . .	547
	Supported Configurations for ATM Subscriber Access . . . . .	547
	PPP-over-Ethernet-over-ATM Configurations . . . . .	548
	Routed IP-over-ATM Configurations . . . . .	548
	Bridged IP-over-Ethernet-over-ATM Configurations . . . . .	549
	PPP-over-ATM Configurations . . . . .	549
	Configuration and Encapsulation Types for ATM Subscriber Access . . . . .	550
	ATM for Subscriber Access Encapsulation Types Overview . . . . .	551
<b>Chapter 31</b>	<b>Configuring ATM for Subscriber Access . . . . .</b>	<b>553</b>
	Configuring ATM for Subscriber Access . . . . .	553
	Guidelines for Configuring ATM for Subscriber Access . . . . .	555
	Verifying and Managing ATM Configurations for Subscriber Access . . . . .	556
<b>Chapter 32</b>	<b>ATM for Subscriber Access Examples . . . . .</b>	<b>557</b>
	Example: Configuring a Dynamic PPPoE Subscriber Interface over ATM . . . . .	557
	Example: Configuring a Static PPPoE Subscriber Interface over ATM . . . . .	566
	Example: Configuring a Static Subscriber Interface for IP Access over ATM . . . . .	574
	Example: Configuring a Static Subscriber Interface for IP Access over Ethernet over ATM . . . . .	580
	Example: Configuring a Static PPP Subscriber Interface over ATM . . . . .	587

<b>Part 10</b>	<b>Dynamic Profiles for Access and Services</b>	
<b>Chapter 33</b>	<b>Dynamic Profiles Overview</b>	<b>601</b>
	Dynamic Profiles Overview	602
	Dynamic Profile Interface Support	602
	What Dynamic Profiles Do	602
	How Dynamic Profiles Work	603
	Dynamic Profile Version Creation	603
	Dynamic Profile Semantic Checking	604
	Dynamic Variables Overview	605
	How Dynamic Variables Work	605
	Default Values for Predefined Variables	605
	Unique Identifier (UID) for Parameterized Filters	606
	Junos OS Predefined Variables	606
	Junos OS Predefined Variables That Correspond to RADIUS Attributes and VSAs	622
	User-Defined Variables	628
	Variable Expressions Overview	628
	Access Profiles and Service Profiles Overview	631
	Functionality Supported in Access and Service Profiles	632
<b>Chapter 34</b>	<b>Configuring Dynamic Profiles</b>	<b>633</b>
	Configuring a Basic Dynamic Profile	633
	Configuring Predefined Dynamic Variables in Dynamic Profiles	635
	Configuring Default Values for Predefined Variables in a Dynamic Profile	635
	Configuring User-Defined Dynamic Variables in Dynamic Profiles	636
	Configuring Variable Expressions in Dynamic Profiles	638
	Configuring a Dynamic Profile for Client Access	639
	Configuring a Dynamic Profile for Various Levels of Services	641
	Configuring Unique Identifiers for Parameterized Filters in Dynamic Profiles	642
	Enabling Dynamic Profiles to use Multiple Versions	643
	Modifying Dynamic Profiles with Versioning Disabled	644
<b>Chapter 35</b>	<b>Configuring Dynamic Access and Access-Internal Routes for Subscriber Management</b>	<b>647</b>
	Access and Access-Internal Routes for Subscriber Management	647
	Overview of Access Routes and Access-Internal Routes Removal After Graceful Routing Engine Switchover	648
	Benefits of Delaying Removal of Access Routes and Access-Internal Routes	649
	Graceful Restart and Delayed Removal of Access Routes and Access-Internal Routes	649
	Nonstop Active Routing and Delayed Removal of Access Routes and Access-Internal Routes	649
	Configuring Dynamic Access Routes for Subscriber Management	650
	Configuring Dynamic Access-Internal Routes for DHCP Subscriber Management	651
	Configuring Dynamic Access-Internal Routes for PPP Subscriber Management	652

	Delaying Removal of Access Routes and Access-Internal Routes After Graceful Routing Engine Switchover . . . . .	653
	Verifying the Configuration of Access and Access-Internal Routes for Subscriber Management . . . . .	653
<b>Chapter 36</b>	<b>Dynamic Profile Examples . . . . .</b>	<b>655</b>
	Example: IGMP Dynamic Profile . . . . .	655
	Example: Firewall Dynamic Profile . . . . .	656
	Example: Minimum MLPPP Dynamic Profile . . . . .	656
	Example: Minimum PPPoE Dynamic Profile . . . . .	657
	Example: Subscriber Secure Policy Dynamic Profile . . . . .	657
<b>Part 11</b>	<b>Dynamic VLANs</b>	
<b>Chapter 37</b>	<b>Dynamic VLAN Overview . . . . .</b>	<b>661</b>
	Dynamic 802.1Q VLAN Overview . . . . .	661
	Static VLAN Configuration . . . . .	661
	Dynamic VLAN Configuration . . . . .	661
	Agent Circuit Identifier-Based Dynamic VLANs Overview . . . . .	662
	VLAN Architectures and Subscriber Identification . . . . .	662
	ACI-Based Dynamic VLANs and Agent Circuit Identifier Interface Sets . . . .	663
	Agent Circuit Identifier-Based Dynamic VLANs Components Overview . . . . .	664
	ACI-Based Dynamic Subscriber Interface . . . . .	664
	Dynamic ACI Interface Set . . . . .	664
	Dynamic or Static Underlying VLAN Interface . . . . .	665
	Static Physical Interface . . . . .	665
	Agent Circuit Identifier-Based Dynamic VLANs Bandwidth Management	
	Overview . . . . .	666
	CoS Shaping Rate Adjustment . . . . .	666
	CoS Overhead Accounting Adjustment . . . . .	667
	Dynamic Profiles and Adjustment of CoS Shaping Rate and Overhead	
	Accounting . . . . .	667
	Guidelines for Configuring Adjustment of CoS Shaping Rate and Overhead	
	Accounting . . . . .	668
	Restrictions for Configuring Adjustment of CoS Shaping Rate and Overhead	
	Accounting for Dynamic ACI Interface Sets . . . . .	669
	Ethernet OAM Support for Service VLANs Overview . . . . .	669
	Ethernet OAM Support for Service VLANs Terms and Acronyms . . . . .	670
	Components of Ethernet OAM Support for Service VLANs . . . . .	670
	How Ethernet OAM Support for Service VLANs Works . . . . .	671
	Restrictions for Using Ethernet OAM Support for Service VLANs . . . . .	672
<b>Chapter 38</b>	<b>Configuring Dynamic VLANs . . . . .</b>	<b>673</b>
	Configuring VLAN Dynamic Profiles . . . . .	673
	Configuring a VLAN Dynamic Profile for Creating Single-Tag VLANs Using	
	Standard TPID Values . . . . .	674
	Configuring a VLAN Dynamic Profile for Creating Single-Tag VLANs Using	
	Any TPID Values . . . . .	676
	Configuring a Stacked VLAN Dynamic Profile . . . . .	677

Configuring a VLAN Dynamic Profile That Associates VLAN Interfaces with Separate Routing Instances . . . . .	678
Configuring VLAN Interfaces to Use Dynamic Profiles . . . . .	680
Associating a Single-Tag VLAN Dynamic Profile with an Interface . . . . .	680
Associating a Stacked VLAN Dynamic Profile with an Interface . . . . .	681
Configuring Which VLAN Ethernet Packet Types Dynamic Profiles Can Accept . . . . .	681
Configuring the VLAN Ethernet Packet Type for Single-Tag VLAN Dynamic Profiles . . . . .	681
Configuring the VLAN Ethernet Packet Type for Stacked VLAN Dynamic Profiles . . . . .	682
Configuring an Authentication Password for VLAN or Stacked VLAN Ranges . .	683
Configuring VLAN Ranges for Use with Dynamic Profiles . . . . .	684
Configuring Single-Level VLAN Ranges for Use with VLAN Dynamic Profiles . . . . .	684
Configuring Stacked VLAN Ranges for Use with Stacked VLAN Dynamic Profiles . . . . .	685
Configuring Dynamic Mixed VLAN Ranges . . . . .	686
Configuring VLAN Dynamic Profile Override . . . . .	687
Configuring Dynamic Authentication for VLAN Interfaces . . . . .	688
Configuring VLAN Interface Username Information for AAA Authentication . .	689
Option 82 Suboptions in Authentication Usernames for Autosense VLANs . .	690
Automatically Removing VLANs with No Subscribers . . . . .	691
Configuring Dynamic VLANs Based on Agent Circuit Identifier Information . . .	692
Defining Agent Circuit Identifier Interface Sets . . . . .	694
Configuring Dynamic Underlying VLAN Interfaces to Use Agent Circuit Identifier Information . . . . .	696
Configuring Static Underlying VLAN Interfaces to Use Agent Circuit Identifier Information . . . . .	698
Configuring Dynamic VLAN Subscriber Interfaces Based on Agent Circuit Identifier Information . . . . .	699
Adjusting the CoS Shaping Rate and Overhead Accounting Parameters for Agent Circuit Identifier-Based Dynamic VLANs . . . . .	701
Configuring Ethernet OAM Support for Service VLANs with Double-Tagged Customer VLANs . . . . .	702
Verifying and Managing Dynamic VLAN Configuration . . . . .	706
Verifying and Managing Agent Circuit Identifier-Based Dynamic VLAN Configuration . . . . .	706
Clearing Agent Circuit Identifier Interface Sets . . . . .	707
<b>Chapter 39 Dynamic VLAN Examples . . . . .</b>	<b>709</b>
Example: Configuring a VLAN Dynamic Profile for VLANs with a TPID of 0x8100 . . . . .	709
Example: Configuring a VLAN Dynamic Profile for VLANs with Any TPID Value and Enabling Demux Interfaces over the VLAN Interface . . . . .	709
Example: Configuring a Stacked VLAN Dynamic Profile . . . . .	710
Example: Dynamic VLAN Interface Configuration . . . . .	710
Example: Dynamic Stacked VLAN Interface Configuration . . . . .	710
Example: Dynamic Flexible VLAN Interface Configuration . . . . .	711

	Example: Configuring a Flexible VLAN Interface for Use with a Nonstandard Ethertype . . . . .	711
<b>Part 12</b>	<b>Subscriber Interfaces</b>	
<b>Chapter 40</b>	<b>Subscriber Interface Overview . . . . .</b>	<b>715</b>
	Subscriber Interface Overview . . . . .	715
	Statically Identifying Subscribers . . . . .	715
	Dynamically Identifying Subscribers . . . . .	716
	Static Subscriber Interfaces and VLAN Overview . . . . .	716
	Subscriber Interfaces and Demultiplexing Overview . . . . .	717
	Interface Sets of Static Demux Interfaces . . . . .	717
	Dynamic Demultiplexing Interfaces . . . . .	717
	Guidelines for Configuring Demux Interfaces for Subscriber Access . . . . .	718
	IP Demux Interfaces over Static or Dynamic VLAN Demux Interfaces . . . . .	718
	MAC Address Validation for Subscriber Interfaces Overview . . . . .	719
	Supported Types of Subscriber Interfaces . . . . .	720
	Trusted Addresses . . . . .	720
	Types of MAC Address Validation . . . . .	720
<b>Chapter 41</b>	<b>Configuring Subscriber Interfaces for Dynamic Profiles . . . . .</b>	<b>723</b>
	Configuring Static Subscriber Interfaces in Dynamic Profiles . . . . .	723
	Configuring a Subscriber Interface with a Static VLAN Interface . . . . .	724
	Configuring Static Subscriber Interfaces Using IP Demux Interfaces . . . . .	724
	Configuring Static Subscriber Interfaces Using VLAN Demux Interfaces . . . . .	725
	Associating Dynamic Profiles with Statically Created Interfaces . . . . .	726
	Configuring a Subscriber Interface Using a Set of Static IP Demux Interfaces . . . . .	727
	Configuring a Subscriber Interface Using a Set of Static VLAN Demux Interfaces . . . . .	728
	Configuring Dynamic Subscriber Interfaces Using IP Demux Interfaces in Dynamic Profiles . . . . .	729
	Configuring Dynamic Subscriber Interfaces Using VLAN Demux Interfaces in Dynamic Profiles . . . . .	730
	Configuring MAC Address Validation for Subscriber Interfaces . . . . .	731
	Configuring MAC Address Validation for Static Subscriber Interfaces . . . . .	732
	Configuring MAC Address Validation for Dynamic Subscriber Interfaces . . . . .	733
	Verifying Configuration and Status of Dynamic Subscribers and Associated Sessions, Services, and Firewall Filters . . . . .	734
<b>Chapter 42</b>	<b>Subscriber Interface Examples . . . . .</b>	<b>737</b>
	Example: Configuring a Static Subscriber Interface on a Gigabit Ethernet VLAN Interface (Multiple Logical Units) . . . . .	737
	Example: Configuring a Static Subscriber Interface on a Gigabit Ethernet VLAN Interface . . . . .	738
	Example: Configuring a Static Subscriber Interface on a Gigabit Ethernet VLAN Interface (No Autonegotiation) . . . . .	738
	Example: Configuring a Static Subscriber Interface with a Loopback . . . . .	738
	Example: Configuring Dynamic Subscriber Interfaces on IP Demux Interfaces . . . . .	739
	Example: Configuring IPv6 Addressing for a Dynamic IP Demux Interface over Static VLANs . . . . .	741

	Example: Configuring IPv6 Addressing for a Dynamic IP Demux Interface over Dynamic VLANs . . . . .	742
	Example: Configuring a Dynamic IP Demux Interface with Dual Stacking . . . . .	745
	Example: Configuring IPv4 Static VLAN Demux Interfaces over a Gigabit Ethernet Underlying Interface with DHCP Local Server . . . . .	748
	Example: Configuring IPv4 Dynamic VLAN Demux Interfaces over a Gigabit Ethernet Underlying Interface with DHCP Local Server . . . . .	750
	Example: Dynamic IP Demux Subscriber Interfaces over Dynamic VLAN Demux Interfaces . . . . .	753
	Example: Concurrent Configuration of Dynamic DHCP IP Demux and PPPoE Demux Interfaces over the Same VLAN Demux Interface . . . . .	759
	Example: Configuring CoS on Static LSQ MLPPP Bundle Interfaces . . . . .	768
<b>Chapter 43</b>	<b>Subscriber Interfaces over Aggregated Ethernet Overview . . . . .</b>	<b>773</b>
	Static and Dynamic VLAN Subscriber Interfaces over Aggregated Ethernet Overview . . . . .	773
	Guidelines for Configuring an Aggregated Ethernet Logical Interface to Support a Static or Dynamic VLAN Subscriber Interface . . . . .	773
	Static or Dynamic Demux Subscriber Interfaces over Aggregated Ethernet Overview . . . . .	774
	Options for Aggregated Ethernet Logical Interfaces That Support Demux Subscriber Interfaces . . . . .	774
	Hardware Requirements with Static or Dynamic Demux Subscriber Interfaces over Aggregated Ethernet . . . . .	775
	Features Supported with Static or Dynamic Demux Subscriber Interfaces over Aggregated Ethernet . . . . .	775
	Distribution of Demux Subscribers in an Aggregated Ethernet Interface . . . . .	776
	Distribution Models . . . . .	776
	Sample Targeted Distribution Topology . . . . .	777
	Redundancy and Redistribution Mechanisms . . . . .	777
	Considerations and Best Practices . . . . .	778
<b>Chapter 44</b>	<b>Configuring Subscriber Interfaces over Aggregated Ethernet . . . . .</b>	<b>781</b>
	Configuring a Static or Dynamic VLAN Subscriber Interface over Aggregated Ethernet . . . . .	782
	Configuring a Static or Dynamic IP Demux Subscriber Interface over Aggregated Ethernet . . . . .	783
	Configuring a Static or Dynamic VLAN Demux Subscriber Interface over Aggregated Ethernet . . . . .	784
	Configuring the Distribution Type for Demux Subscribers on Aggregated Ethernet Interfaces . . . . .	786

	Configuring Link and Module Redundancy for Demux Subscribers in an Aggregated Ethernet Interface . . . . .	787
	Configuring Rebalancing of Demux Subscribers in an Aggregated Ethernet Interface . . . . .	787
	Configuring Periodic Rebalancing of Subscribers in an Aggregated Ethernet Interface . . . . .	788
	Configuring Manual Rebalancing of Subscribers on an Aggregated Ethernet Interface . . . . .	788
	Verifying the Distribution of Demux Subscribers in an Aggregated Ethernet Interface . . . . .	788
	Configuring the PPPoE Family for an Underlying Interface . . . . .	789
	Configuring the Distribution Type for PPPoE Subscribers on Aggregated Ethernet Interfaces . . . . .	791
	Verifying the Distribution of PPPoE Subscribers in an Aggregated Ethernet Interface . . . . .	791
<b>Chapter 45</b>	<b>Subscriber Interfaces over Aggregated Ethernet Examples . . . . .</b>	<b>793</b>
	Example: Configuring a Static Subscriber Interface on a VLAN Interface over Aggregated Ethernet . . . . .	793
	Example: Configuring a Static Subscriber Interface on an IP Demux Interface over Aggregated Ethernet . . . . .	796
	Example: Configuring a Static Subscriber Interface on a VLAN Interface over Aggregated Ethernet . . . . .	798
	Example: Configuring IPv4 Static VLAN Demux Interfaces over an Aggregated Ethernet Underlying Interface with DHCP Local Server . . . . .	801
	Example: Separating Targeted Multicast Traffic for Demux Subscribers on Aggregated Ethernet Interfaces . . . . .	804
	Example: Configuring IPv4 Dynamic VLAN Demux Interfaces over an Aggregated Ethernet Underlying Interface with DHCP Local Server . . . . .	814
	Example: Configuring IPv6 Dynamic VLAN Demux Interfaces over an Aggregated Ethernet Underlying Interface with DHCP Local Server . . . . .	817
	Example: Configuring IPv4 Dynamic Stacked VLAN Demux Interfaces over an Aggregated Ethernet Underlying Interface with DHCP Local Server . . . . .	820
	Example: Configuring a Static PPPoE Subscriber Interface on a Static Underlying VLAN Demux Interface over Aggregated Ethernet . . . . .	823
	Example: Configuring a Dynamic PPPoE Subscriber Interface on a Static Underlying VLAN Demux Interface over Aggregated Ethernet . . . . .	828
	Example: Configuring a Dynamic PPPoE Subscriber Interface on a Dynamic Underlying VLAN Demux Interface over Aggregated Ethernet . . . . .	834
<b>Chapter 46</b>	<b>Dynamic PPPoE Subscriber Interfaces Overview . . . . .</b>	<b>841</b>
	Subscriber Interfaces and PPPoE Overview . . . . .	841
	Benefits of Using Dynamic PPPoE Subscriber Interfaces . . . . .	842
	Supported Platforms for Dynamic PPPoE Subscriber Interfaces . . . . .	843

Sequence of Operations for PPPoE Subscriber Access . . . . .	843
Sequence When a PPPoE Subscriber Logs In . . . . .	843
Sequence When a PPPoE Subscriber Logs Out . . . . .	844
Dynamic PPPoE Subscriber Interfaces over Static Underlying Interfaces	
Overview . . . . .	845
PPPoE Dynamic Profile Configuration . . . . .	845
PPPoE Underlying Interface Configuration . . . . .	846
Address Assignment for Dynamic PPPoE Subscriber Interfaces . . . . .	846
Guidelines for Configuring Dynamic PPPoE Subscriber Interfaces . . . . .	847
PPPoE Maximum Session Limit Overview . . . . .	848
Per-Interface Configuration for PPPoE Maximum Session Limit Using the	
CLI . . . . .	848
Per-Subscriber Configuration for PPPoE Maximum Session Limit Using	
RADIUS . . . . .	848
Override of PPPoE Maximum Session Limit from RADIUS . . . . .	849
Guidelines for Using PPPoE Maximum Session Limit from RADIUS . . . . .	850
PPPoE Subscriber Session Lockout Overview . . . . .	851
Benefits of Using PPPoE Subscriber Session Lockout . . . . .	851
Supported Platforms and Underlying Interfaces for PPPoE Subscriber	
Session Lockout . . . . .	852
How PPPoE Subscriber Session Lockout Works . . . . .	852
PPPoE Subscriber Session Lockout Period . . . . .	853
PPPoE Subscriber Session Lockout and Duplicate Protection . . . . .	853
PPPoE Subscriber Session Lockout and Automatic Removal of Dynamic	
Subscriber VLANs . . . . .	854
Understanding the Lockout Period for PPPoE Subscriber Session Lockout . . . . .	854
Duration of PPPoE Subscriber Session Lockout Period . . . . .	854
How the Router Determines the PPPoE Subscriber Session Lockout	
Period . . . . .	855
<b>Chapter 47</b>	
<b>Configuring Dynamic PPPoE Subscriber Interfaces . . . . .</b>	<b>857</b>
Configuring Dynamic PPPoE Subscriber Interfaces Using Dynamic Profiles . . . . .	857
Configuring a Basic PPPoE Dynamic Profile . . . . .	858
Configuring a PPPoE Dynamic Profile with Additional Options . . . . .	861
Configuring an Underlying Interface for Dynamic PPPoE Subscriber	
Interfaces . . . . .	863
Limiting the Maximum Number of PPPoE Sessions on the Underlying	
Interface . . . . .	866
Assigning a Dynamic Profile and Routing Instance to a Service Name or ACI/ARI	
Pair for Dynamic PPPoE Interface Creation . . . . .	868
Configuring Lockout of PPPoE Subscriber Sessions . . . . .	870
Clearing Lockout of PPPoE Subscriber Sessions . . . . .	871
Verifying and Managing Dynamic PPPoE Configuration . . . . .	872

<b>Chapter 48</b>	<b>Dynamic PPPoE Subscriber Interfaces Examples . . . . .</b>	<b>875</b>
	Example: Configuring a Dynamic PPPoE Subscriber Interface on a Static Gigabit Ethernet VLAN Interface . . . . .	875
	Example: Configuring a PPPoE Service Name Table for Dynamic Subscriber Interface Creation . . . . .	877
	Evaluation Order for Matching Client Information in PPPoE Service Name Tables . . . . .	880
<b>Chapter 49</b>	<b>MPLS Pseudowire Subscriber Interfaces Overview . . . . .</b>	<b>881</b>
	Pseudowire Subscriber Logical Interfaces Overview . . . . .	881
	Hierarchical CoS on MPLS Pseudowire Subscriber Interfaces Overview . . . . .	883
	CoS Two-Level Hierarchical Scheduling on MPLS Pseudowire Subscriber Interfaces . . . . .	883
	CoS Three-Level Hierarchical Scheduling on MPLS Pseudowire Subscriber Interfaces . . . . .	885
	Three-Level Scheduling Hierarchy Case 1: Pseudowire Logical Interfaces over a Transport Logical Interface . . . . .	885
	Three-Level Scheduling Hierarchy Case 2: Pseudowire Service Interfaces over a Pseudowire Service Interface Set . . . . .	886
	Three-Level Scheduling Hierarchy Combined Deployment Scenario . . . . .	886
	CoS Configuration Overview for MPLS Pseudowire Subscriber Interfaces . . . . .	887
<b>Chapter 50</b>	<b>Configuring MPLS Pseudowire Subscriber Interfaces . . . . .</b>	<b>889</b>
	Configuring a Pseudowire Subscriber Logical Interface . . . . .	889
	Configuring the Maximum Number of Pseudowire Logical Interface Devices Supported on the Router . . . . .	891
	Configuring a Pseudowire Subscriber Logical Interface Device . . . . .	891
	Configuring the Transport Logical Interface for a Pseudowire Subscriber Logical Interface . . . . .	892
	Configuring Layer 2 Circuit Signaling for Pseudowire Subscriber Logical Interfaces . . . . .	893
	Configuring Layer 2 VPN Signaling for Pseudowire Subscriber Logical Interfaces . . . . .	894
	Configuring the Service Logical Interface for a Pseudowire Subscriber Logical Interface . . . . .	895
	Configuring CoS Two-Level Hierarchical Scheduling for MPLS Pseudowire Subscriber Interfaces . . . . .	896
	Configuring CoS Three-Level Hierarchical Scheduling for MPLS Pseudowire Subscriber Interfaces (Logical Interfaces over a Transport Logical Interface) . . . . .	897
	Configuring CoS Three-Level Hierarchical Scheduling for MPLS Pseudowire Subscriber Interfaces (Logical Interfaces over a Pseudowire Interface Set) . . . . .	899

	IPv6 Parameterized Filter Match Conditions . . . . .	1111
	Parameterized Filter Actions and Modifiers . . . . .	1111
	Parameterized Filter Policer Actions . . . . .	1112
<b>Chapter 65</b>	<b>Configuring Filters for Dynamic Profiles . . . . .</b>	<b>1113</b>
	Dynamically Attaching Statically Created Filters for a Specific Interface Family Type . . . . .	1113
	Dynamically Attaching Statically Created Filters for Any Interface Type . . . . .	1114
	Dynamically Attaching Filters Using RADIUS Variables . . . . .	1115
	Defining Dynamic Filter Processing Order . . . . .	1117
	Configuring Firewall Filter Bypass . . . . .	1117
	Configuring Service Packet Counting . . . . .	1118
	Configuring a Filter for Use with Enhanced Network Services Mode . . . . .	1119
	Dynamically Applying Ascend-Data-Filter Policies to Subscriber Sessions . . . . .	1121
	Verifying and Managing Dynamic Ascend-Data-Filter Policy Configuration . . . . .	1122
	Configuring Unicast RPF and Fail Filters in Dynamic Profiles for Subscriber Interfaces . . . . .	1123
	Configuring Unicast RPF in Dynamic Profiles for Subscriber Interfaces . . . . .	1123
	Configuring a Fail Filter for Unicast RPF in Dynamic Profiles for Subscriber Interfaces . . . . .	1124
<b>Chapter 66</b>	<b>Configuring Fast Update Filters . . . . .</b>	<b>1125</b>
	Configuring Fast Update Filters . . . . .	1125
	Configuring the Match Order for Fast Update Filters . . . . .	1126

	Configuring Terms for Fast Update Filters . . . . .	1127
	Fast Update Filter Match Conditions . . . . .	1128
	Fast Update Filter Actions and Action Modifiers . . . . .	1129
	Configuring Filters to Permit Expected Traffic . . . . .	1129
	Avoiding Conflicts When Terms Match . . . . .	1130
	How the Router Evaluates Terms in a Filter . . . . .	1131
	Using Implied Wildcards . . . . .	1132
	Conflict Caused by Overlapping Ranges . . . . .	1133
	Associating Fast Update Filters with Interfaces in a Dynamic Profile . . . . .	1135
	Verifying and Managing Firewall Filter Configuration . . . . .	1136
<b>Chapter 67</b>	<b>Configuring Service Sets in Dynamic Profiles . . . . .</b>	<b>1139</b>
	Associating Service Sets with Interfaces in a Dynamic Profile . . . . .	1139
	Verifying and Managing Service Sets Information . . . . .	1140
<b>Chapter 68</b>	<b>Firewall Filter Examples . . . . .</b>	<b>1141</b>
	Examples: Configuring Static Filters . . . . .	1141
	Example: Configuring Dynamic Ascend-Data-Filter Support for Subscriber Access . . . . .	1144
	Example: Configuring Static Ascend-Data-Filter Support for Subscriber Access . . . . .	1147
	Example: Configuring Fast Update Filters for Subscriber Access . . . . .	1151
	Example: Bypassing Firewall Filters . . . . .	1152
	Example: Configuring Hierarchical Policers as Filter Actions . . . . .	1156
	Example: Interface-Shared Filter Configuration . . . . .	1159
	Example: Configuring Unicast RPF in a Dynamic Profile on MX Series Routers . .	1161
<b>Chapter 69</b>	<b>Redirecting HTTP Requests Overview . . . . .</b>	<b>1167</b>
	Redirecting HTTP Requests Overview . . . . .	1167
<b>Chapter 70</b>	<b>Configuring HTTP Redirect . . . . .</b>	<b>1169</b>
	Configuring HTTP Redirect Services . . . . .	1169
	Verifying HTTP Redirect Requests . . . . .	1172
<b>Chapter 71</b>	<b>HTTP Redirect Examples . . . . .</b>	<b>1173</b>
	Example: Walled Garden as a Service Filter . . . . .	1173
	Example: Walled Garden as an HTTP Service Rule . . . . .	1174
	Example: HTTP Service Within a Service Set . . . . .	1175
	Example: HTTP Service Attached to a Static Interface . . . . .	1175
	Example: HTTP Service Attached to a Dynamic Interface . . . . .	1177
	Example: Configuring Redundant Multiservice . . . . .	1178
	Example: Configuring Destination Address Rewrite for HTTP Redirect . . . . .	1180
<b>Part 16</b>	<b>Subscriber Secure Policy Traffic Mirroring</b>	
<b>Chapter 72</b>	<b>Subscriber Secure Policy Traffic Mirroring Overview . . . . .</b>	<b>1185</b>
	Subscriber Secure Policy Overview . . . . .	1185
	Subscriber Secure Policy for Subscribers on VLANs . . . . .	1185
	Traffic Filtering For DTCP-Initiated Subscriber Secure Policy Mirrored Traffic . . . . .	1186

	Mirroring-Related Event Reporting . . . . .	1186
	Subscriber Secure Policy Licensing Requirements . . . . .	1186
<b>Chapter 73</b>	<b>Overview of Subscriber Secure Policy Using RADIUS . . . . .</b>	<b>1187</b>
	RADIUS-Initiated Subscriber Secure Policy Overview . . . . .	1187
	Subscriber Secure Policy Traffic Mirroring Architecture Using RADIUS . . . . .	1188
	RADIUS-Initiated Traffic Mirroring Interfaces . . . . .	1190
	RADIUS-Initiated Traffic Mirroring Process at Subscriber Login . . . . .	1191
	RADIUS-Initiated Traffic Mirroring Process for Logged-In Subscribers . . . . .	1192
	Subscriber Secure Policy Support for IPv4 Multicast Traffic . . . . .	1193
	Triggering the Mirroring of IPv4 Multicast Traffic . . . . .	1193
	RADIUS Attributes Used for Subscriber Secure Policy . . . . .	1194
	Triggering Subscriber Secure Policy for Subscribers on Dynamic Authenticated VLANs . . . . .	1195
	Using the Packet Header to Track Subscribers on the Mediation Device . . . . .	1195
	Format of the Mirror Header Values Used to Track Subscribers and Subscriber Sessions . . . . .	1198
	4-Byte Format . . . . .	1198
	8-Byte Format . . . . .	1198
	Subscriber Secure Policy and L2TP LAC Subscribers . . . . .	1199
	Subscriber Secure Policy and L2TP LNS Subscribers . . . . .	1199
<b>Chapter 74</b>	<b>Configuring RADIUS-Initiated Subscriber Secure Policy Traffic Mirroring . . . . .</b>	<b>1201</b>
	Configuring RADIUS-Initiated Subscriber Secure Policy Mirroring Overview . . .	1201
	Guidelines for Configuring Subscriber Secure Policy Mirroring . . . . .	1202
	Configuring Tunnel Interfaces for Subscriber Secure Policy Mirroring . . . . .	1203
	Configuring Support for Subscriber Secure Policy Mirroring . . . . .	1204
	Configuring RADIUS Server Support for Subscriber Secure Policy Mirroring . . .	1205
	Enabling Subscriber Secure Policy Mirroring for IPv4 Multicast Traffic . . . . .	1206
	Terminating RADIUS-Initiated Subscriber Traffic Mirroring . . . . .	1206
<b>Chapter 75</b>	<b>Overview of Subscriber Secure Policy Using DTCP . . . . .</b>	<b>1207</b>
	DTCP-Initiated Subscriber Secure Policy Overview . . . . .	1207
	Subscriber Secure Policy Traffic Mirroring Architecture Using DTCP . . . . .	1207
	DTCP-Initiated Traffic Mirroring Interfaces . . . . .	1209
	DTCP-Initiated Traffic Mirroring Process . . . . .	1211
	Subscriber Secure Policy Support for IPv4 Multicast Traffic . . . . .	1212
	Triggering the Mirroring of IPv4 Multicast Traffic . . . . .	1212
	Subscriber Secure Policy and L2TP LNS Subscribers . . . . .	1212
	DTCP Messages Used for Subscriber Secure Policy . . . . .	1213
	DTCP Traffic Mirroring Triggers . . . . .	1213
	Triggering Subscriber Secure Policy for Subscribers on Dynamic Authenticated VLANs . . . . .	1216
	Order in Which Trigger Attributes Are Processed . . . . .	1216
	Packet Header for Mirrored Traffic Sent to Mediation Device . . . . .	1218
<b>Chapter 76</b>	<b>Configuring DTCP-Initiated Subscriber Secure Policy Mirroring . . . . .</b>	<b>1221</b>
	Configuring DTCP-Initiated Subscriber Secure Policy Mirroring Overview . . . . .	1221
	Guidelines for Configuring Subscriber Secure Policy Mirroring . . . . .	1222
	Configuring Tunnel Interfaces for Subscriber Secure Policy Mirroring . . . . .	1223

	Configuring Support for Subscriber Secure Policy Mirroring . . . . .	1224
	Example: Configuring Traffic That Is Mirrored Using DTCP-Initiated Subscriber Secure Policy . . . . .	1225
	Configuring the Mediation Device as a User on the Router . . . . .	1227
	Configuring a DTCP-over-SSH Connection to the Mediation Device . . . . .	1228
	Configuring the Mediation Device to Provision Traffic Mirroring . . . . .	1228
	Enabling Subscriber Secure Policy Mirroring for IPv4 Multicast Traffic . . . . .	1229
	Terminating DTCP-Initiated Subscriber Traffic Mirroring Sessions . . . . .	1229
<b>Chapter 77</b>	<b>DTCP Messages Used for DTCP-Initiated Subscriber Secure Policy Mirroring . . . . .</b>	<b>1231</b>
	ADD DTCP . . . . .	1232
	DELETE DTCP . . . . .	1235
	DISABLE DTCP . . . . .	1237
	ENABLE DTCP . . . . .	1238
	LIST DTCP . . . . .	1239
	Example: Using DTCP Messages to Trigger, Verify, and Disable Traffic Mirroring for Subscribers . . . . .	1240
	Creating DTCP ADD Messages to Trigger Traffic Mirroring . . . . .	1241
	Creating DTCP ENABLE Messages to Trigger Traffic Mirroring . . . . .	1242
	Creating DTCP DISABLE Messages to Trigger Traffic Mirroring . . . . .	1242
	Using LIST Messages to Verify That Subscriber Traffic Is Being Mirrored . . . . .	1242
	Using DELETE Messages to Remove Traffic Mirroring Triggers . . . . .	1243
	Using Disable Messages to Disable Traffic Mirroring Triggers . . . . .	1244
	Using Enable Messages to Enable Traffic Mirroring Triggers . . . . .	1244
	Verifying That Traffic Mirroring Was Stopped on the Subscriber Interfaces . . . . .	1244
<b>Chapter 78</b>	<b>Reporting Intercept-Related Events for Subscriber Secure Policy . . . . .</b>	<b>1245</b>
	Intercept-Related Events Transmitted to the Mediation Device . . . . .	1245
	SNMP Traps for Subscriber Secure Policy LAES Compliance . . . . .	1245
	Configuring SNMPv3 Traps for Subscriber Secure Policy Mirroring . . . . .	1247
	Example: SNMPv3 Traps Configuration for Subscriber Secure Policy Mirroring . . . . .	1247
<b>Part 17</b>	<b>Protocols for Subscriber Access</b>	
<b>Chapter 79</b>	<b>ANCP Overview . . . . .</b>	<b>1253</b>
	ANCP Topology Discovery and Traffic Reporting Overview . . . . .	1254
	Topology Discovery . . . . .	1254
	Subscriber Services . . . . .	1255
	ANCP Interfaces and Access Loop Circuit Identifiers . . . . .	1255
	ANCP Neighbors . . . . .	1256
	Traffic Rate Reporting and Adjustment by ANCP . . . . .	1257
	Traffic Rate Adjustment . . . . .	1258
	Traffic Rate Reporting and Shaping Scenarios . . . . .	1258
	Recommended Traffic Shaping Rates . . . . .	1259
	ANCP Keepalives . . . . .	1260
	ANCP Interactions with AAA . . . . .	1260

	ANCP Operations in Different Network Configurations . . . . .	1262
	ANCP Network Using N:1 and 1:1 Configuration Models without Interface Sets . . . . .	1264
	Sequence of ANCP Events: Static VLAN or VLAN Demux Interfaces over Ethernet Without Interface Sets . . . . .	1265
	ANCP Network Using N:1 Configuration Model with Interface Sets . . . . .	1266
	Sequence of ANCP Events: Static VLAN Interfaces over Ethernet with Interface Sets . . . . .	1267
	ANCP Network Using 1:1 Configuration Model with Interface Sets . . . . .	1268
	Sequence of ANCP Events: Static VLAN Demux Interfaces over Aggregated Ethernet with Interface Sets . . . . .	1269
	ANCP DSL Attributes Mapped to Juniper Networks DSL Vendor-Specific Attributes . . . . .	1269
	Preservation of CoS Shaping Across ANCP Restarts . . . . .	1271
<b>Chapter 80</b>	<b>Configuring ANCP . . . . .</b>	<b>1273</b>
	Configuring ANCP . . . . .	1274
	Configuring ANCP Neighbors . . . . .	1275
	Associating an Access Node with Subscribers for ANCP Operations . . . . .	1276
	Specifying the Interval Between ANCP Adjacency Messages . . . . .	1277
	Specifying the Maximum Number of Discovery Table Entries . . . . .	1278
	Configuring ANCP for Backward Compatibility . . . . .	1278
	Specifying How Long Processes Wait for ANCP Restart to Complete . . . . .	1279
	Setting a Global Adjustment Factor per DSL Subscriber Line for ANCP Agent-Reported Traffic Rates . . . . .	1279
	Configuring the ANCP Agent to Report Traffic Rates to CoS . . . . .	1280
	Setting a Recommended Shaping Rate for Traffic on ANCP Interfaces . . . . .	1281
	Configuring AAA to Include Juniper Networks DSL VSAs in RADIUS Messages . . . . .	1283
	Triggering ANCP OAM . . . . .	1284
	Verifying and Monitoring ANCP Neighbors . . . . .	1285
	Clearing ANCP Neighbors . . . . .	1285
	Verifying and Monitoring ANCP Subscribers . . . . .	1286
	Clearing ANCP Subscribers . . . . .	1286
	Verifying and Monitoring CoS for ANCP Subscribers . . . . .	1287
	Tracing ANCP Operations for Subscriber Access . . . . .	1287
	Configuring the ANCP Trace Log Filename . . . . .	1288
	Configuring the Number and Size of ANCP Log Files . . . . .	1289
	Configuring Access to the ANCP Log File . . . . .	1289
	Configuring a Regular Expression for ANCP Messages to Be Logged . . . . .	1290
	Configuring the ANCP Tracing Flags . . . . .	1290
	Configuring the Severity Level to Filter Which ANCP Messages Are Logged . . . . .	1290
	Example: Configuring an ANCP Network with Interface Sets and N:1 Static Demux VLANs over Aggregated Ethernet . . . . .	1291
<b>Chapter 81</b>	<b>Dynamic IGMP Configuration Overview . . . . .</b>	<b>1313</b>
	Dynamic IGMP Configuration Overview . . . . .	1313

# About This Guide

This preface provides the following guidelines for using the *Junos<sup>®</sup> OS Subscriber Access Configuration Guide*:

- [JUNOS Documentation and Release Notes on page lxxv](#)
- [Objectives on page lxxvi](#)
- [Audience on page lxxvi](#)
- [Supported Routing Platforms on page lxxvii](#)
- [Using the Indexes on page lxxvii](#)
- [Using the Examples in This Manual on page lxxvii](#)
- [Documentation Conventions on page lxxviii](#)
- [Documentation Feedback on page lxxx](#)
- [Requesting Technical Support on page lxxx](#)

## JUNOS Documentation and Release Notes

---

For a list of related JUNOS documentation, see <http://www.juniper.net/techpubs/software/junos/>.

If the information in the latest release notes differs from the information in the documentation, follow the *JUNOS Release Notes*.

To obtain the most current version of all Juniper Networks<sup>®</sup> technical documentation, see the product documentation page on the Juniper Networks website at <http://www.juniper.net/techpubs/>.

Juniper Networks supports a technical book program to publish books by Juniper Networks engineers and subject matter experts with book publishers around the world. These books go beyond the technical documentation to explore the nuances of network architecture, deployment, and administration using the Junos operating system (Junos OS) and Juniper Networks devices. In addition, the Juniper Networks Technical Library, published in conjunction with O'Reilly Media, explores improving network security, reliability, and availability using Junos OS configuration techniques. All the books are for sale at technical bookstores and book outlets around the world. The current list can be viewed at <http://www.juniper.net/books>.

## Objectives

---

This guide provides an overview of the subscriber access management features of the Junos OS and describes how to configure and manage remote subscriber access on the routing platform.

**NOTE:** For additional information about Junos OS—either corrections to or information that might have been omitted from this guide—see the software release notes at <http://www.juniper.net>.

## Audience

---

This guide is designed for network administrators who are configuring and monitoring Juniper Networks MX Series Ethernet Services Routers.

To use this guide, you need a broad understanding of networks in general, the Internet in particular, networking principles, and network configuration. You must also be familiar with one or more of the following Internet routing protocols:

- Border Gateway Protocol (BGP)
- Distance Vector Multicast Routing Protocol (DVMRP)
- Intermediate System-to-Intermediate System (IS-IS)
- Internet Control Message Protocol (ICMP) router discovery
- Internet Group Management Protocol (IGMP)
- Multiprotocol Label Switching (MPLS)
- Open Shortest Path First (OSPF)
- Protocol-Independent Multicast (PIM)
- Resource Reservation Protocol (RSVP)
- Routing Information Protocol (RIP)
- Simple Network Management Protocol (SNMP)

Personnel operating the equipment must be trained and competent; must not conduct themselves in a careless, willfully negligent, or hostile manner; and must abide by the instructions provided by the documentation.

## Supported Routing Platforms

---

For the features described in this manual, the Junos OS currently supports the following routing platforms:

- MX Series routers

## Using the Indexes

---

This reference contains two indexes: a complete index that includes topic entries, and an index of statements and commands only.

In the index of statements and commands, an entry refers to a statement summary section only. In the complete index, the entry for a configuration statement or command contains at least two parts:

- The primary entry refers to the statement summary section.
- The secondary entry, usage guidelines, refers to the section in a configuration guidelines chapter that describes how to use the statement or command.

## Using the Examples in This Manual

---

If you want to use the examples in this manual, you can use the **load merge** or the **load merge relative** command. These commands cause the software to merge the incoming configuration into the current candidate configuration. The example does not become active until you commit the candidate configuration.

If the example configuration contains the top level of the hierarchy (or multiple hierarchies), the example is a *full example*. In this case, use the **load merge** command.

If the example configuration does not start at the top level of the hierarchy, the example is a *snippet*. In this case, use the **load merge relative** command. These procedures are described in the following sections.

### Merging a Full Example

To merge a full example, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration example into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following configuration to a file and name the file **ex-script.conf**. Copy the **ex-script.conf** file to the **/var/tmp** directory on your routing platform.

```
system {
  scripts {
    commit {
      file ex-script.xml;
    }
  }
}
```

```
}
interfaces {
  fxp0 {
    disable;
    unit 0 {
      family inet {
        address 10.0.0.1/24;
      }
    }
  }
}
```

2. Merge the contents of the file into your routing platform configuration by issuing the **load merge** configuration mode command:

```
[edit]
user@host# load merge /var/tmp/ex-script.conf
load complete
```

## Merging a Snippet

To merge a snippet, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration snippet into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following snippet to a file and name the file **ex-script-snippet.conf**. Copy the **ex-script-snippet.conf** file to the **/var/tmp** directory on your routing platform.

```
commit {
  file ex-script-snippet.xml; }
```

2. Move to the hierarchy level that is relevant for this snippet by issuing the following configuration mode command:

```
[edit]
user@host# edit system scripts
[edit system scripts]
```

3. Merge the contents of the file into your routing platform configuration by issuing the **load merge relative** configuration mode command:

```
[edit system scripts]
user@host# load merge relative /var/tmp/ex-script-snippet.conf
load complete
```

For more information about the **load** command, see the CLI User Guide.

---

## Documentation Conventions

Table 1 on page [lxix](#) defines notice icons used in this guide.

Table 1: Notice Icons

Icon	Meaning	Description
	Informational note	Indicates important features or instructions.
	Caution	Indicates a situation that might result in loss of data or hardware damage.
	Warning	Alerts you to the risk of personal injury or death.
	Laser warning	Alerts you to the risk of personal injury from a laser.

Table 2 on page [lxix](#) defines the text and syntax conventions used in this guide.

Table 2: Text and Syntax Conventions

Convention	Description	Examples
<b>Bold text like this</b>	Represents text that you type.	To enter configuration mode, type the <b>configure</b> command:  <code>user@host&gt; configure</code>
Fixed-width text like this	Represents output that appears on the terminal screen.	<code>user@host&gt; show chassis alarms</code> <code>No alarms currently active</code>
<i>Italic text like this</i>	<ul style="list-style-type: none"> <li>Introduces or emphasizes important new terms.</li> <li>Identifies book names.</li> <li>Identifies RFC and Internet draft titles.</li> </ul>	<ul style="list-style-type: none"> <li>A policy <i>term</i> is a named structure that defines match conditions and actions.</li> <li><i>Junos OS System Basics Configuration Guide</i></li> <li>RFC 1997, <i>BGP Communities Attribute</i></li> </ul>
<i>Italic text like this</i>	Represents variables (options for which you substitute a value) in commands or configuration statements.	Configure the machine's domain name:  [edit] root@# <b>set system domain-name</b> <i>domain-name</i>
Text like this	Represents names of configuration statements, commands, files, and directories; configuration hierarchy levels; or labels on routing platform components.	<ul style="list-style-type: none"> <li>To configure a stub area, include the <b>stub</b> statement at the [edit <b>protocols ospf area area-id</b>] hierarchy level.</li> <li>The console port is labeled <b>CONSOLE</b>.</li> </ul>
< > (angle brackets)	Enclose optional keywords or variables.	<code>stub &lt;default-metric metric&gt;;</code>

Table 2: Text and Syntax Conventions (*continued*)

Convention	Description	Examples
(pipe symbol)	Indicates a choice between the mutually exclusive keywords or variables on either side of the symbol. The set of choices is often enclosed in parentheses for clarity.	<b>broadcast   multicast</b>  <i>(string1   string2   string3)</i>
# (pound sign)	Indicates a comment specified on the same line as the configuration statement to which it applies.	<b>rsvp { # Required for dynamic MPLS only</b>
[ ] (square brackets)	Enclose a variable for which you can substitute one or more values.	<b>community name members [ community-ids ]</b>
Indentation and braces ( { } )	Identify a level in the configuration hierarchy.	<b>[edit]</b> routing-options { static { route default { nexthop <i>address</i> ; retain; } } }
;(semicolon)	Identifies a leaf statement at a configuration hierarchy level.	
<b>J-Web GUI Conventions</b>		
<b>Bold text like this</b>	Represents J-Web graphical user interface (GUI) items you click or select.	<ul style="list-style-type: none"> <li>In the Logical Interfaces box, select <b>All Interfaces</b>.</li> <li>To cancel the configuration, click <b>Cancel</b>.</li> </ul>
> (bold right angle bracket)	Separates levels in a hierarchy of J-Web selections.	In the configuration editor hierarchy, select <b>Protocols&gt;Ospf</b> .

## Documentation Feedback

We encourage you to provide feedback, comments, and suggestions so that we can improve the documentation. You can send your comments to [techpubs-comments@juniper.net](mailto:techpubs-comments@juniper.net), or fill out the documentation feedback form at <https://www.juniper.net/cgi-bin/docbugreport/>. If you are using e-mail, be sure to include the following information with your comments:

- Document or topic name
- URL or page number
- Software release version (if applicable)

## Requesting Technical Support

Technical product support is available through the Juniper Networks Technical Assistance Center (JTAC). If you are a customer with an active J-Care or JNASC support contract,

or are covered under warranty, and need postsales technical support, you can access our tools and resources online or open a case with JTAC.

- JTAC policies—For a complete understanding of our JTAC procedures and policies, review the JTAC User Guide located at <http://www.juniper.net/us/en/local/pdf/resource-guides/7100059-en.pdf>.
- Product warranties—For product warranty information, visit <http://www.juniper.net/support/warranty/>.
- JTAC Hours of Operation —The JTAC centers have resources available 24 hours a day, 7 days a week, 365 days a year.

## Self-Help Online Tools and Resources

For quick and easy problem resolution, Juniper Networks has designed an online self-service portal called the Customer Support Center (CSC) that provides you with the following features:

- Find CSC offerings: <http://www.juniper.net/customers/support/>
- Find product documentation: <http://www.juniper.net/techpubs/>
- Find solutions and answer questions using our Knowledge Base: <http://kb.juniper.net/>
- Download the latest versions of software and review release notes: <http://www.juniper.net/customers/csc/software/>
- Search technical bulletins for relevant hardware and software notifications: <https://www.juniper.net/alerts/>
- Join and participate in the Juniper Networks Community Forum: <http://www.juniper.net/company/communities/>
- Open a case online in the CSC Case Management tool: <http://www.juniper.net/cm/>

To verify service entitlement by product serial number, use our Serial Number Entitlement (SNE) Tool: <https://tools.juniper.net/SerialNumberEntitlementSearch/>

## Opening a Case with JTAC

You can open a case with JTAC on the Web or by telephone.

- Use the Case Management tool in the CSC at <http://www.juniper.net/cm/>.
- Call 1-888-314-JTAC (1-888-314-5822 toll-free in the USA, Canada, and Mexico).

For international or direct-dial options in countries without toll-free numbers, visit us at <http://www.juniper.net/support/requesting-support.html>

## Subscriber Access Overview

---

The Juniper Networks Junos OS subscriber access feature provides subscriber access, authentication, and service creation, activation, and deactivation. You can also collect accounting information and statistics for subscriber service sessions.

The subscriber access feature supports both CLI and AAA-based configuration (such as RADIUS) for subscribers. Access and services start when the router receives a message from a client (such as a DHCP discover message). For RADIUS clients, RADIUS Access-Accept messages and Change-of-Authorization-Request (CoA-Request) messages can create, modify, and delete subscriber sessions as well as activate and deactivate service sessions. You can use CLI commands to create a dynamic profile, which acts as a template of user attributes.

A subscriber service is based on the combination of a defined dynamic profile and attributes configured through authentication. Dynamic profiles can include dynamic firewall filters, class-of-service (CoS) settings, and protocol (IGMP) settings that define access limits for subscribers and the scope of a service granted to the subscriber after access is obtained.

The subscriber access feature provides the following convenience and flexibility to service providers and subscribers:

- Service providers can separate services and access technology and eliminate unprofitable flat-rate billing. They gain the ability to efficiently design, manage, and deliver services that subscribers want, and then bill subscribers based on connect time, bandwidth, and the actual service used.
- Subscribers benefit by gaining access to multiple simultaneous services. Depending on the service provider configuration, subscribers can dynamically connect to and disconnect from various services when they want and for however long they want. Subscribers can be billed based on the service level and usage, rather than being charged a set rate regardless of usage.

## Subscriber Access Terms and Acronyms

[Table 3 on page 4](#) defines terms and acronyms that are used in this discussion of subscriber access.

**Table 3: Subscriber Access Terms and Acronyms**

Term	Definition
AAA method for subscriber authentication	The AAA method that uses authentication (for example, including RADIUS VSAs in the Access-Accept packet) to verify a subscriber and activate a service when the subscriber logs in.
Dynamic profile	A template that defines a set of characteristics that are combined with authorization attributes and are dynamically assigned to static interfaces to provide dynamic subscriber access and services for broadband applications.
RADIUS CoA method	The method that uses RADIUS CoA-Request messages and VSAs to activate a service for a subscriber that is already logged in.
Subscriber access technology	The technology used by a subscriber to access services (for example, DHCP).

### Related Documentation

- [Subscriber Access Environment on page 4](#)
- [Subscriber Access Licensing Overview on page 6](#)
- [Subscriber Access Operation Flow Using DHCP Relay on page 8](#)
- [Configuring Subscriber Access on page 10](#)

---

## Subscriber Access Environment

A subscriber access environment can include various components, including subscriber access technologies and authentication protocols.

The subscriber access technologies include:

- Dynamic Host Configuration Protocol (DHCP) server
  - Local DHCP server
  - External DHCP server
- Point-to-Point Protocol (PPP)

The subscriber authentication protocols include the RADIUS server.

Figure 1 on page 5 shows an example of a basic subscriber access network.

**Figure 1: Subscriber Access Network Example**

**Related Documentation**

- [Subscriber Access Overview on page 3](#)

## Relationship Between Subscribers and Interfaces in an Access Network

To the router, a subscriber is an authenticated user. This release supports configurations of only one subscriber per logical interface. However, a subscriber can be either one authenticated client or a group of clients on a single, authenticated VLAN.

**Related Documentation**

- [Subscriber Interface Overview on page 715](#)

## Subscriber Access Support Considerations

The subscriber access feature is limited to MX Series 3D Universal Edge Routers and the interfaces you can use when configuring dynamic profiles.

### Platform Support

Even though many statements appear in the CLI for various other platforms, Juniper Networks supports subscriber access DHCP configuration on MX Series routers only. In addition, PPPoE configuration is currently supported on MX Series routers, M120 routers, and M320 routers.

## Interface Support

You can use dynamic profiles to configure statically created interfaces and also to create and configure interfaces dynamically. Subscriber interfaces support IPv4 and IPv6 addressing.

To identify subscribers statically, you can reference a static VLAN interface in a dynamic profile. To identify subscribers dynamically, you create variables for demux interfaces that are dynamically created when subscribers log in.

The subscriber access feature supports the following device types:

- GE -- Gigabit Ethernet
- XE -- 10-Gigabit Ethernet
- AE -- Aggregated Ethernet

## DPC Support

Certain subscriber management features require the use of specific dense port concentrators (DPCs) on the MX series router. For a list of the MX series DPCs and the features they support, see the [MX Series 3D Universal Edge Routers Line Card Guide](#).

## Routing Engine Support

Subscriber management features require the use of either the RE-S-2000 or RE-S-1800 routing engine. The RE-S-1300 routing engine is not supported for use with subscriber management configurations.

## Logical System Support

Subscriber management is supported in the default logical system only.

- Related Documentation**
- [Relationship Between Subscribers and Interfaces in an Access Network on page 5](#)
  - [Configuring Subscriber Access on page 10](#)

---

## Subscriber Access Licensing Overview

To enable some Juniper Networks Junos OS features or router scaling levels, you might have to purchase, install, and manage separate software license packs. The presence on the router of the appropriate software license keys (passwords) determines whether you can configure and use certain features or configure a feature to a predetermined scale.

- Related Documentation**
- [Configuring the Router to Strictly Enforce the Subscriber Scaling License on page 219](#)
  - For information about installing and managing Junos OS licenses, see the Installation and Upgrade Guide

## Subscriber Management Unified ISSU Support

The unified in-service software upgrade (unified ISSU) feature supports both the DHCP access model and the PPPoE access model used by subscriber management. This support ensures that the router preserves active DHCP and PPPoE subscriber sessions and session services after a unified ISSU has completed.

The Junos OS High Availability Configuration Guide describes the supported platforms and modules, CLI statements, and procedures you use to configure and initiate unified ISSU. You can use the **issu** flag with the [traceoptions](#) statement to trace subscriber management unified ISSU events. You can also use the **show system subscriber-management summary** command to display information about the unified ISSU state.

This overview describes specific considerations for unified ISSU support of the DHCP and PPPoE access models for subscriber management, and covers the following topics:

- [Unified ISSU Support for DHCP Access Model on page 7](#)
- [Unified ISSU Support for PPPoE Access Model on page 7](#)

### Unified ISSU Support for DHCP Access Model

Unified ISSU supports the subscriber management DHCP access model, which includes DHCP local server, DHCPv6 local server, DHCP relay, and DHCP relay proxy.

Accounting, filter, and class of service (CoS) statistics for DHCP subscribers are preserved after a unified ISSU on MPC/MIC interfaces on MX Series routers.

### Unified ISSU Support for PPPoE Access Model

Unified ISSU supports the subscriber management PPPoE access model for static and dynamic PPPoE access, and includes the following features:

- Terminated, non-tunneled PPPoE connections configured with static or dynamic PPP logical interfaces and static or dynamic underlying interfaces
- Subscriber services on single-link PPP interfaces
- Preservation of statistics for accounting, filter, and CoS on MPC/MIC interfaces

Accounting statistics for PPPoE subscribers are *not* preserved after a unified ISSU on Enhanced Intelligent Queuing 2 (IQ2E) PICs on M120 and M320 routers.

Unified ISSU for the subscriber management PPPoE access model *does not support* Multilink Point-to-Point Protocol (MLPPP) bundle interfaces. MLPPP bundle interfaces require the use of an Adaptive Services PIC or Multiservices PIC to provide PPP subscriber services. These PICs do not support unified ISSU.

#### Related Documentation

- [Verifying and Monitoring Subscriber Management Unified ISSU State on page 8](#)
- [Unified ISSU Support on MX Series 3D Universal Edge Routers](#) in Unified ISSU System Requirements

- For information about unified ISSU, see the Junos OS High Availability Configuration Guide

---

## Verifying and Monitoring Subscriber Management Unified ISSU State

---

**Purpose** Display the state of unified ISSU for subscriber management features.

**Action** The first example indicates that control plane quiescing as part of unified ISSU is not in progress (for example, unified ISSU has not been started, has already completed, or control plane quiescing has not started). The second example shows that unified ISSU is in progress and that a participating subscriber management daemon requires 198 seconds to quiesce the control plane.

```
user@host> show system subscriber-management summary
```

```
General:
```

Graceful Restart	Enabled
Mastership	Master
Database	Available
Chassisd ISSU State	IDLE
ISSU State	IDLE
ISSU Wait	0

```
user@host> show system subscriber-management summary
```

```
General:
```

Graceful Restart	Enabled
Mastership	Master
Database	Available
Chassisd ISSU State	DAEMON_ISSU_PREPARE
ISSU State	PREPARE
ISSU Wait	198

- Related Documentation**
- [Subscriber Management Unified ISSU Support on page 7](#)
  - See the “Unified ISSU” chapter in the Junos OS High Availability Configuration Guide

---

## Subscriber Access Operation Flow Using DHCP Relay

---

The subscriber access feature requires that a subscriber (for example, a DHCP client) send a discover message to the router interface to initialize dynamic configuration of that interface.

[Figure 2 on page 9](#) shows the flow of operations that occurs when the router is using DHCP relay to enable access for a subscriber.

Figure 2: Subscriber Access Operation Flow

The following general sequence occurs during access configuration for a DHCP client:

1. The client issues a DHCP discover message.
2. The router issues an authorization request to the RADIUS server.
3. The RADIUS server issues an authorization response to the router.
4. The router passes the DHCP discover message through to the DHCP server.
5. The DHCP server issues an IP address for the client.
6. The router DHCP component sends an acknowledgement back to the client.

The subscriber now has access to the network and the authorized service.

#### Related Documentation

- [Subscriber Access Overview on page 3](#)
- [Configuring Subscriber Access on page 10](#)

## Subscriber Activation and Service Management in an Access Network

The subscriber access feature uses dynamic profiles to activate subscribers and manage services.

A dynamic profile is a set of characteristics, defined in a template, that the router uses to provide dynamic subscriber access and services.

By using dynamic profiles you can:

- Define access for your network
- Define different service levels for subscribers
- Preprovision services that you can activate later

Using AAA-based login (RADIUS-based login or RADIUS CoA) you can:

- Provide subscribers with dynamic activation and deactivation based on service selection

- Provide greater flexibility and efficient management for a large number of subscribers and services

## Components of a Dynamic Profile

You can use dynamic profiles to define various router components for subscriber access.

These components include the following:

- Dynamic firewall filters—Includes input and output filters to enforce rules that define whether to permit or deny packets that are transmitting an interface on the router. To apply dynamic firewall filters to the subscriber interface, you configure static input and output firewall filters and reference those filters in dynamic profiles.
- Dynamic Class of Service (CoS)—Includes CoS values that define a service for a subscriber. For example, you can configure the shaping rate for traffic in a video service by referencing CoS statements in a dynamic profile.
- Dynamic signaling protocol—Includes dynamic IGMP configuration for host to router signaling for IPv4 to support IP multicasting.

## Router Predefined Variables Used by Dynamic Profiles

The router contains many predefined variables. These variables enable dynamic association of certain interface-specific values to incoming subscriber requests. You must specify these predefined variables in certain statements within a dynamic profile. When a client accesses the router, the dynamic profile configuration replaces the predefined variable with the actual data from an incoming client data packet and configuration (local and RADIUS).

---

## Configuring Subscriber Access

To configure subscriber access:

1. Configure the client access protocol.

- Configure DHCP local server.  
See “[Extended DHCP Local Server Overview](#)” on page 186.
- Configure DHCP relay.  
See “[Extended DHCP Relay Agent Overview](#)” on page 258.
- Configure PPP.

See the “Configuring Logical Interface Properties” and “Configuring Point-to-Point Protocol over Ethernet” chapters of the Junos® OS Network Interfaces.

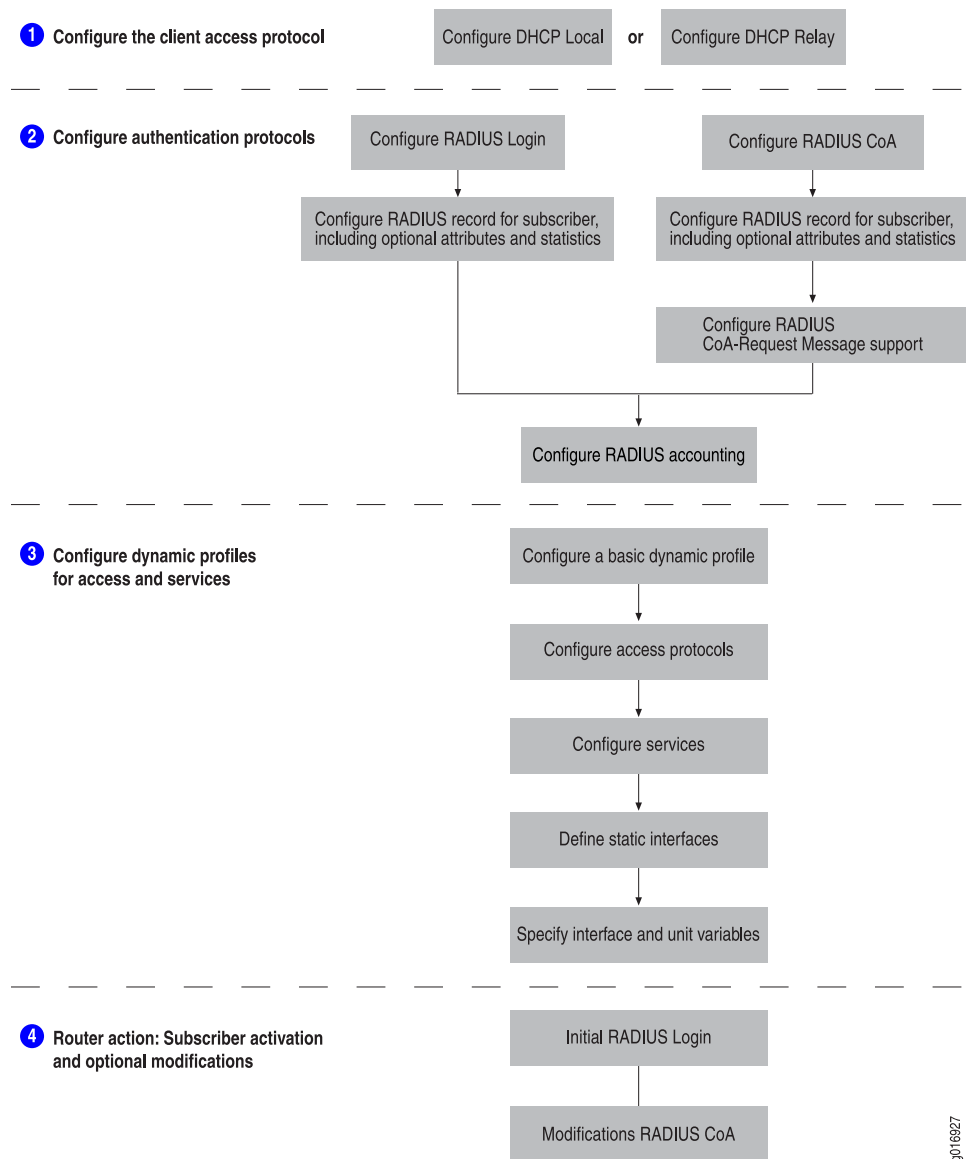

2. Configure subscriber authentication, accounting, and addressing.
  - a. Configure RADIUS:
    1. Specify the RADIUS servers.  
See [“Specifying RADIUS Authentication and Accounting Servers for Subscriber Access”](#) on page 36.
    2. Specify any optional server attributes.  
See [“Configuring RADIUS Server Options for Subscriber Access”](#) on page 46.
    3. (Optional) Configure the CoA feature for the RADIUS dynamic-request server to change or deactivate the service after login.  
See [“Configuring RADIUS-Initiated Dynamic Request Support”](#) on page 81.
    4. Configure subscriber accounting (RADIUS accounting).  
See [“Configuring Per-Subscriber Session Accounting”](#) on page 29.
  - b. Configure addressing:
    - See [“Configuring Address-Assignment Pools”](#) on page 156.
3. Create and manage dynamic profiles for access and service.
  - a. Configure a basic dynamic profile.  
See [“Configuring a Basic Dynamic Profile”](#) on page 633.  
See [“Example: Minimum PPPoE Dynamic Profile”](#) on page 657
  - b. Configure a dynamic profile for access.  
See [“Configuring a Dynamic Profile for Client Access”](#) on page 639.
  - c. Configure a dynamic profile for services.  
See [“Configuring a Dynamic Profile for Various Levels of Services”](#) on page 641.
  - d. Configure a default subscriber service.  
See [“Configuring a Default Subscriber Service”](#) on page 1071.
  - e. Configure the static subscriber interfaces to be referenced in the dynamic profile.  
See [“Configuring a Subscriber Interface with a Static VLAN Interface”](#) on page 724.
  - f. Specify the interface-name and unit variables that the router uses to dynamically associate to a subscriber’s incoming interface.  
See [“Associating Dynamic Profiles with Statically Created Interfaces”](#) on page 726.
  - g. Add, modify, or delete dynamic profile values to manage subscriber access and services.  
See [“Modifying Dynamic Profiles with Versioning Disabled”](#) on page 644.

The router dynamically activates or modifies the subscriber service using the RADIUS configuration.

- When the subscriber logs in, the router dynamically activates the service.  
See [“Dynamic Service Activation During Login Overview” on page 77.](#)
- If RADIUS CoA has been configured, the router can dynamically modify the service for a subscriber.  
See [“RADIUS-Initiated Change of Authorization \(CoA\) Overview” on page 78.](#)

Figure 3 on page 12 shows the configuration sequence you perform for DHCP-based subscriber access. It also shows the dynamic configuration performed by the router.

**Figure 3: Subscriber Access Configuration Workflow**

---

## Collecting Subscriber Access Logs Before Contacting Juniper Technical Support

---

**Problem** When you experience a subscriber access problem in your network, we recommend that you collect certain logs before you contact Juniper Technical Support. This topic shows you the most useful logs for a variety of network implementations. In addition to the relevant log information, you must also collect standard troubleshooting information and send it to Juniper Technical Support in your request for assistance.

**Solution** To collect standard troubleshooting information:

- Redirect the command output to a file.

```
user@host> request support information | save rsi-1
```

To configure logging to assist Juniper Technical Support:

1. Review the following blocks of statements to determine which apply to your configuration.

[edit]

```
set system syslog archive size 100m files 25
set system auto-configuration traceoptions file filename
set system auto-configuration traceoptions file filename size 100m files 25
set protocols ppp-service traceoptions file filename size 100m files 25
set protocols ppp-service traceoptions level all
set protocols ppp-service traceoptions flag all
set protocols ppp traceoptions file filename size 100m files 25
set protocols ppp traceoptions level all
set protocols ppp traceoptions flag all
set protocols ppp monitor-session all
set interfaces pp0 traceoptions flag all
set demux traceoptions file filename size 100m files 25
set demux traceoptions level all
set demux traceoptions flag all
set system processes dhcp-service traceoptions file filename
set system processes dhcp-service traceoptions file size 100m
set system processes dhcp-service traceoptions file files 25
set system processes dhcp-service traceoptions flag all
set class-of-service traceoptions file filename
set class-of-service traceoptions file size 100m
set class-of-service traceoptions flag all
set class-of-service traceoptions file files 25
set routing-options traceoptions file filename
set routing-options traceoptions file size 100m
set routing-options traceoptions flag all
set routing-options traceoptions file files 25
set interfaces traceoptions file filename
set interfaces traceoptions file size 100m
set interfaces traceoptions flag all
set interfaces traceoptions file files 25
set system processes general-authentication-service traceoptions file filename
set system processes general-authentication-service traceoptions file size 100m
set system processes general-authentication-service traceoptions flag all
set system processes general-authentication-service traceoptions file files 25
```

2. Copy the relevant statements into a text file and modify the log filenames as you want.
3. Copy the statements from the text file and paste them into the CLI on your router to configure logging.
4. Commit the logging configuration to begin collecting information.

**NOTE:** The maximum file size for DHCP local server and DHCP relay log files is 1 GB. The maximum number of log files for DHCP local server and DHCP relay is 1000.

---

**BEST PRACTICE:** Enable these logs only to collect information when troubleshooting specific problems. Enabling these logs during normal operations can result in reduced system performance.

**Related Documentation**

- [Compressing Troubleshooting Logs from /var/logs to Send to Juniper Technical Support on page 15](#)

## Compressing Troubleshooting Logs from /var/logs to Send to Juniper Technical Support

**Problem** You have collected logs on your device and need to send them to Juniper Technical Support. This topic shows you how to compress the logs into a single file for each Routing Engine to more conveniently send the logs.

**Solution** You can compress all the log files in the **/var/log** directories of the master and backup (if present) Routing Engines into a single **.tgz** file for each Routing Engine, which enables you to send the logs to JTAC in a convenient package. You can use either the CLI or the command shell to perform these tasks; because of its ease of use, only the CLI version is shown here.

1. Access the device through the management IP address or console, typically on the master Routing Engine, RE0.

```
user@host>
```

2. Archive and compress all the log files on RE0 and put them in **/var/tmp**.

```
user@host> file archive compress source /var/log/* destination /var/tmp/re0.tgz
/usr/bin/tar: Removing leading `/' from member names
```

3. Confirm that the compressed archive file has been created.

```
user@host> file list /var/tmp
baseline-config.conf
gres-tp
idp_license_info
install
jinstall-12.2-20120328.0-domestic-signed.tgz
krt_gencfg_filter.txt
preinstall_boot_loader.conf
re0.tgz
rtsdb
sec-download
vi.recover
```

On devices with a single Routing Engine, skip to Step 10.

4. Log in to the backup Routing Engine, RE1, and access the CLI.

**NOTE:** 1 is appended to the hostname in the prompt to signify that you are on RE1.

```
user@host> request routing-engine login backup
% cli
user@host11>
```

5. Archive and compress all the log files on RE1 and put them in **/var/tmp**.

```
user@host1> file archive compress source /var/log/* destination /var/tmp/re1.tgz
/usr/bin/tar: Removing leading '/' from member names
```

6. Confirm that the compressed archive file has been created.

```
user@host1> file list /var/tmp
baseline-config.conf
gres-tp
idp_license_info
install
jinstall-12.2-20120328.0-domestic-signed.tgz
krt_gencfg_filter.txt
preinstall_boot_loader.conf
re1.tgz
rtsdb
sec-download
vi.recover
%
```

7. Exit the remote login to the backup Routing Engine to return to the master Routing Engine. Note that the previously appended **1** is removed from the hostname in the prompt to signify that you are back on RE0.

```
user@host1> exit
rlogin: connection closed
```

```
user@host1>
```

8. Copy the compressed archive file from RE1 to RE0.

```
user@host> file copy re1:/var/tmp/re1.tgz /var/tmp
```

9. Confirm the presence of the copied file.

```
user@host> file list /var/tmp
baseline-config.conf
gres-tp
idp_license_info
install
jinstall-12.2-20120328.0-domestic-signed.tgz
krt_gencfg_filter.txt
preinstall_boot_loader.conf
re0.tgz
re1.tgz
rtsdb
sec-download
vi.recover
%
```

10. Copy the files directly from the master Routing Engine to any local host using FTP, SCP, JWEB, or (on some devices) a mounted USB.

## AAA Service Framework Overview

The authentication, authorization, and accounting (AAA) Service Framework provides a single point of contact for all the authentication, authorization, accounting, address assignment, and dynamic request services that the router supports for network access. The framework supports authentication and authorization through external servers, such as RADIUS. The framework also supports accounting and dynamic-request change of

authorization (CoA) and disconnect operations through external servers, and address assignment through a combination of local address-assignment pools and RADIUS.

When interacting with external back-end RADIUS servers, the AAA Service Framework supports standard RADIUS attributes and Juniper Networks vendor specific attributes (VSAs). The AAA Service Framework also includes an integrated RADIUS client that is compatible with RADIUS servers that conform to RFC-2865, *Remote Authentication Dial In User Service (RADIUS)*, RFC-2866, *RADIUS Accounting*, and RFC-3576, *Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)*, and which can initiate requests.

You create the following types of configurations to manage subscriber access.

- **Authentication**—Authentication parameters defined in the access profile determine the authentication component of the AAA processing. For example, subscribers can be authenticated using an external authentication service such as RADIUS.
- **Accounting**—Accounting parameters in the access profile specify the accounting part of the AAA processing. For example, the parameters determine how the router collects and uses subscriber statistics. You can also configure AAA to enable the router to collect statistics on a per-service session basis for subscribers.
- **RADIUS-initiated dynamic requests**—A list of authentication server IP addresses in the access profile specify the RADIUS servers that can initiate dynamic requests to the router. Dynamic requests include CoA requests, which specify VSA modifications and service changes, and disconnect requests, which terminate subscriber sessions. The list of authentication servers also provide RADIUS-based dynamic service activation and deactivation during subscriber login.
- **Address assignment**—The AAA Service Framework assigns addresses to subscribers based on the configuration of local address-assignment pools. For example, the AAA framework collaborates with RADIUS servers to assign addresses from the specified pools.
- **Subscriber secure policy**—RADIUS VSAs and attributes provide RADIUS-initiated traffic mirroring on a per-subscriber basis.

## Configuring Router or Switch Interaction with RADIUS Servers

You specify the RADIUS servers that the router or switch can use and you configure how the router or switch interacts with the servers. You can configure the router or switch to use multiple RADIUS servers on the network.

To specify a RADIUS server and how the router or switch interacts with the server:

1. Configure the IP address of the RADIUS server and specify that you want to configure the router or switch interaction with the server.

```
[edit access]
user@host# edit radius-server 192.168.1.250
```

2. (Optional) Configure the RADIUS server accounting port number. The default accounting port number is 1813.

```
[edit access radius-server 192.168.1.250]
user@host# set accounting-port 1813
```

3. (Optional) Configure the port number the router or switch uses to contact the RADIUS server. The default port number is 1812.

```
[edit access radius-server 192.168.1.250]
user@host# set port 18914
```

4. (Optional) Configure the number of times that the router or switch attempts to contact a RADIUS accounting server. You can configure the router or switch to retry from 1 through 16 times. The default setting is 3 retry attempts.

```
[edit access radius-server 192.168.1.250]
user@host# set retry 4
```

5. Configure the required secret (password) that the local router or switch passes to the RADIUS client. Secrets enclosed in quotation marks can contain spaces.

```
[edit access radius-server 192.168.1.250]
user@host# set secret $nt1UE1*7688+
```

6. (Optional) Configure the maximum number of outstanding requests that a RADIUS server can maintain. An outstanding request is a request to which the RADIUS server has not yet responded. You can limit the number from 0 through 2000 outstanding requests per RADIUS server. The default setting is 1000 outstanding requests per server.

```
[edit access radius-server 192.168.1.250]
user@host# set max-outstanding-requests 500
```

7. Configure the source address for the RADIUS server. Each RADIUS request sent to a RADIUS server uses the specified source address. The source address is a valid IPv4 address configured on one of the router or switch interfaces.

```
[edit access radius-server 192.168.1.250]
user@host# set source-address 192.168.1.100
```

8. (Optional) Configure the length of time that the local router or switch waits to receive a response from a RADIUS server. By default, the router or switch waits 3 seconds. You can configure the timeout to be from 1 through 90 seconds.

```
[edit access radius-server 192.168.1.250]  
user@host# set timeout 45
```

- [Example: Configuring RADIUS-Based Subscriber Authentication and Accounting on page 179](#)

---

## Configuring Authentication and Accounting Parameters for Subscriber Access

You use an access profile to configure authentication and accounting support for the subscriber access management feature. The access profile enables you to specify the type of methods used for authentication and accounting. You can also configure how subscriber access management collects and uses accounting statistics.

To configure authentication and accounting for subscriber access:

1. Specify the authentication and accounting methods to use.

See “[Specifying the Authentication and Accounting Methods for Subscriber Access](#)” on page 24.

2. Specify how accounting statistics are collected.

See “[Configuring Per-Subscriber Session Accounting](#)” on page 29.

**Related  
Documentation**

- [Configuring Router or Switch Interaction with RADIUS Servers on page 23](#)
- [Example: Configuring RADIUS-Based Subscriber Authentication and Accounting on page 179](#)

---

## Specifying the Authentication and Accounting Methods for Subscriber Access

You can specify the authentication and accounting methods that subscriber access management uses.

You can configure multiple authentication and accounting methods—the **authentication-order** and **accounting order** statements specify the order in which the subscriber access management feature uses the methods. For example, an authentication entry of **radius password** specifies that RADIUS authentication is performed first and, if it fails, local authentication (**password**) is done.

You can specify the following authentication methods:

**NOTE:** For this release, you must always specify the **radius** authentication method. Subscriber access management does not support the **password** keyword (the default), and authentication fails when no method is specified.

- **password**—Local authentication
- **radius**—RADIUS-based authentication

You can specify the following accounting methods:

- **radius**—RADIUS-based accounting

To configure the authentication and accounting methods for subscriber access management:

1. Specify the authentication methods and the order in which they are used. For this release, only **radius** is supported.

```
[edit access profile isp-bos-metro-fiber-basic]
user@host# set authentication-order radius
```

2. Specify the accounting method.

```
[edit access profile isp-bos-metro-fiber-basic]
user@host# set accounting order radius
```

## RADIUS Acct-On and Acct-Off Messages

Subscriber management supports RADIUS Acct-On and Acct-Off messages to indicate the current state of RADIUS accounting support.

RADIUS Acct-On messages indicate that accounting is being supported. Subscriber management issues Acct-On messages in the following situations:

- Accounting is enabled through configuration (for example, an accounting server is configured).
- A new access profile is configured and committed for a logical system/routing instance context. However, no Acct-On message is sent if the accounting server exists prior to the access profile and if it is simply modified.

- The router performs a cold reboot.
- The router performs a warm reboot and there are no subscribers currently logged in.
- The Authd process restarts and there are no active subscribers.

RADIUS Acct-Off messages indicate that accounting is not supported. Subscriber management issues Acct-Off messages in the following situations:

- The Authd process is terminated and there are no active subscribers.
- The router is shut down and accounting servers are currently configured (this action also logs out all current subscribers).
- The router is rebooted and redundancy is disabled.

**Related  
Documentation**

---

## RADIUS Accounting Statistics for Subscriber Access Overview

---

The AAA Service Framework enables you to configure how the router collects and uses accounting statistics for subscriber management.

For example, you can specify when statistics collection is terminated, the order in which different accounting methods are used, the types of statistics collected, and how often statistics are collected. You can also configure the router to request that the RADIUS server immediately update the accounting statistics when certain events occur, such as when a subscriber logs in or when a change of authorization (CoA) occurs.

Subscriber management provides two levels of subscriber accounting—subscriber session and service session. In subscriber session accounting, the router collects statistics for the entire subscriber session. In service session accounting, the router collects statistics for specific service sessions for the subscriber.

**NOTE:** Subscriber management counts forwarded packets only. Dropped traffic (for example, as a result of a filter action) and control traffic are not included in the accounting statistics.

---

The router uses the RADIUS attributes and Juniper Networks VSAs listed in [Table 4 on page 27](#) to provide the accounting statistics for subscriber and service sessions. If the session has both IPv4 and IPv6 families enabled, the router reports statistics for both families.

**NOTE:**

RADIUS reports subscriber statistics as an aggregate of both IPv4 statistics and IPv6 statistics.

- For an IPv4-only configuration, the standard RADIUS attributes report the IPv4 statistics and the IPv6 VSA results are all reported as 0.
- For an IPv6-only configuration, the standard RADIUS attributes and the IPv6 VSA statistics are identical, both reporting the IPv6 statistics.
- When both IPv4 and IPv6 are configured, the standard RADIUS attributes report the combined IPv4 and IPv6 statistics. The IPv6 VSAs report IPv6 statistics.

**Table 4: RADIUS Attributes and VSAs Used for Per-Subscriber Session Accounting**

Attribute Number	Attribute Name	Type of Statistics
26–151	IPv6-Acct-Input-Octets	IPv6
26–152	IPv6-Acct-Output-Octets	IPv6
26–153	IPv6-Acct-Input-Packets	IPv6
26–154	IPv6-Acct-Output-Packets	IPv6
26–155	IPv6-Acct-Input-Gigawords	IPv6
26–156	IPv6-Acct-Output-Gigawords	IPv6
47	Acct-Input-Packets	IPv4 and IPv6 aggregation
48	Acct-Output-Packets	IPv4 and IPv6 aggregation
52	Acct-Input-Gigawords	IPv4 and IPv6 aggregation
53	Acct-Output-Gigawords	IPv4 and IPv6 aggregation

## Understanding RADIUS Accounting Duplicate Reporting

When you configure RADIUS accounting, by default the router sends the accounting reports to the accounting servers in the context in which the subscriber was last authenticated. However, in a Layer 3 wholesale network environment, the wholesaler and retailer might use different RADIUS accounting servers, and both might want to receive accounting reports. In this situation, you can configure RADIUS accounting duplicate reporting, which sends reports to both the wholesaler and the retailer accounting servers.

Table 5 on page 28 shows where subscriber management sends the accounting reports when you enable duplicate reporting. Subscriber management sends duplicate reports based on the access profile in which you configure the **duplication** statement, where the subscriber resides, and how the subscriber is authenticated.

**NOTE:** You can also enable accounting duplicate reporting based on the domain map configuration—you configure subscribers to authenticate with a non-default routing instance and a target logical system/routing instance of default/default. The accounting reports are then sent to both the authentication context and the default/default context.

Table 5: Duplicate RADIUS Accounting Reporting

Access Profile in Which Duplication Is Configured	Where Subscriber Is Authenticated	Subscriber's Target Logical System/Routing Instance	Accounting Servers Where Accounting Reports Are Sent
retailer A	wholesaler	retailer A	wholesaler and retailer A
retailer A	retailer A	retailer A	wholesaler (default/default context)  <b>NOTE:</b> This is the domain map configuration described in the Note preceding this table.
wholesaler	wholesaler and retailer A	retailer A	wholesaler and retailer A
wholesaler and retailer B	wholesaler and retailer A	retailer B	wholesaler, retailer A, and retailer B

Table 5: Duplicate RADIUS Accounting Reporting (*continued*)

Access Profile in Which Duplication Is Configured	Where Subscriber Is Authenticated	Subscriber's Target Logical System/Routing Instance	Accounting Servers Where Accounting Reports Are Sent
not configured (default)	any	any	single report sent to accounting servers in the context in which subscriber was last authenticated

**Related Documentation**

- [Configuring Per-Subscriber Session Accounting on page 29](#)

## Configuring Per-Subscriber Session Accounting

To configure accounting for a subscriber session, you use an access profile, and specify how the subscriber access management feature collects and uses the accounting statistics. The router uses the RADIUS attributes and Juniper Networks VSAs discussed in [“RADIUS Accounting Statistics for Subscriber Access Overview” on page 26](#) to provide the accounting statistics for the subscriber session.

To configure accounting for a subscriber session:

1. At the **[edit access profile *profile-name*]** hierarchy level, specify that you want to configure accounting.

```
[edit access profile profile-name]  
user@host# edit accounting
```

2. (Optional) Configure AAA to issue an Acct-Stop message if the AAA server denies access to the subscriber.

```
[edit access profile profile-name accounting]  
user@host# set accounting-stop-on-access-deny
```

3. (Optional) Configure AAA to send an Acct-Stop message if the subscriber fails AAA but is granted access by the AAA server.

```
[edit access profile profile-name accounting]  
user@host# set accounting-stop-on-failure
```

4. (Optional) Configure the router or switch to send an Acct-Update message to the RADIUS accounting server when a CoA occurs.

```
[edit access profile profile-name accounting]  
user@host# set coa-immediate-update
```

5. (Optional) Configure subscriber management to send the RADIUS accounting report to both the wholesaler and the retailer accounting servers.

```
[edit access profile profile-name accounting]  
user@host# set duplication
```

6. (Optional) Configure the router or switch to send an Acct-Update message to the RADIUS accounting server when the router or switch receives a response (for example, an ACK or timeout) to the Acct-Start message.

```
[edit access profile profile-name accounting]
user@host# set immediate-update
```

7. (Optional) Configure the order in which multiple accounting methods are used.

```
[edit access profile profile-name accounting]
user@host# set order [ accounting-order ]
```

8. (Optional) Configure the types of statistics to gather. You can specify that the router or switch collect both volume and time statistics or only time statistics for subscriber sessions. When you change the type of statistics being collected, current subscribers continue to use the previous collection specification. Subscribers who log in after the change use the new specification.

```
[edit access profile profile-name accounting]
user@host# set statistics (time | volume-time)
```

9. (Optional) Override the default behavior and specify that, after a CoA action that changes the RADIUS Class attribute, accounting reports for the subscriber's service sessions continue to use the original Class attribute that was assigned when the service sessions were created. The new Class attribute value is used in accounting reports for the subscriber session only. By default, the accounting reports for both the subscriber session and the subscriber's service sessions use the new Class attribute value.

```
[edit access profile profile-name accounting]
user@host# set coa-no-override service-class-attribute
```

10. (Optional) Configure the number of minutes between accounting updates. You can configure an interval from 10 through 1440 minutes. All values are rounded up to the next higher multiple of 10. For example, the values 811 through 819 are all accepted by the CLI, but are all rounded up to 820.

```
[edit access profile profile-name accounting]
user@host# set update-interval minutes
```

11. (Optional) Configure the authd process to wait for an Acct-On-Ack response message from RADIUS before sending any new authentication and accounting updates to the RADIUS server. This configuration ensures that when a new subscriber session starts, the authentication and accounting information for the new session does not get deleted when RADIUS clears previously existing session state information.

```
[edit access profile profile-name accounting]
user@host# set wait-for-acct-on-ack
```

12. (Optional) Configure the authd process to send an Acct-On message when the first RADIUS server is added to the access profile, and to send an Acct-Off message when the last RADIUS server is removed from the access profile. This configuration enables you to monitor whether the access profile has an active RADIUS server.

```
[edit access profile profile-name accounting]
user@host# set send-acct-status-on-config-change
```

- Related Documentation**
- [RADIUS Accounting Statistics for Subscriber Access Overview on page 26](#)

  - [Configuring Per-Service Session Accounting on page 34](#)
  - [Retaining Authentication and Accounting Information During Session Startup on page 31](#)
  - [Example: Configuring RADIUS-Based Subscriber Authentication and Accounting on page 179](#)

## Retaining Authentication and Accounting Information During Session Startup

At subscriber session startup, the Junos OS **authd** process sends an Acct-On message to the RADIUS server and the new session starts authentication and accounting operations. However, in some service provider environments, upon receipt of the Acct-On message, the RADIUS server cleans up the previous session state and removes accounting statistics. In this scenario, the RADIUS server's cleanup operation can inadvertently delete the new session's authentication and accounting information, which might include customer billing information.

To ensure that the new session's authentication and accounting information is not deleted, you can optionally use the **wait-for-acct-on-ack** statement to configure the **authd** process to wait for an Acct-On-Ack response message from the RADIUS accounting server, so the RADIUS cleanup can finish before **authd** sends any new authentication and accounting updates.

You configure this feature for an access profile for a logical system and routing instance context. All authentication requests fail until the router receives an Acct-On-Ack response from a RADIUS accounting server that is configured in the access profile. If multiple RADIUS accounting servers are configured for the access profile, **authd** waits until the first response is received.

You can also configure the **authd** process to send accounting messages when the RADIUS server status changes for an access profile. This configuration enables you to monitor whether the access profile has an active RADIUS server. You use the **send-acct-status-on-config-change** statement to specify that **authd** send an Acct-On message when the first RADIUS server is added to an access profile, and to send an Acct-Off message when the last RADIUS server is deleted from the access profile.

- Related Documentation**
- [Configuring Per-Subscriber Session Accounting on page 29](#)

## Preservation of RADIUS Accounting Information During an Accounting Server Outage

If the router loses contact with the RADIUS accounting server, as represented in [Figure 4 on page 32](#), whether due to a server outage or a problem in the network connecting to the server, you can lose all the billing information that would have been received by the server. RADIUS accounting backup preserves the accounting data that accumulates during the outage. If you have not configured RADIUS accounting backup, the accounting data is lost for the duration of the outage from the time when the router has exhausted

its attempts to resume contact with the RADIUS server. The configurable retry value determines the number of times the router attempts to contact the server.

**Figure 4: Topology with Loss of Access to Accounting Server**

By default, the router must wait until the revert timer expires before it can attempt to contact the non-responsive server again. However, when you configure accounting backup, the revert timer is disabled and the router immediately retries its accounting requests as soon as the router fails to receive accounting acknowledgments. Accounting backup follows this sequence:

1. The router fails to receive accounting acknowledgments from the server.
2. The router immediately attempts to contact the accounting server and marks the server as offline if the router does not receive an acknowledgment before exhausting the number of retries.
3. The router next attempts to contact in turn each additional accounting server configured in the RADIUS profile.

If a server is reached, then the router resumes sending accounting requests to this server.

4. If none of the servers responds or if no other servers are in the profile, the router declares a timeout and begins backing up the accounting data. It withholds all accounting stop messages and does not forward new accounting requests to the server.

5. During the outage, the router sends a single pending accounting stop message to the servers at periodic intervals.
6. If one of the servers acknowledges receipt, then the router sends all the pending stop messages to that server in batches at the same interval until all the stored stop messages have been sent. However, any new accounting requests are sent immediately rather than being held and sent periodically.

The router replays accounting stop messages to the server in the correct order because it preserves both the temporal order among subscribers and the causal order between service and session stop requests for each subscriber. Only accounting stop messages are backed up, because they include the start time and duration of sessions and all the accounting statistics. This makes it unnecessary to withhold the accounting start messages, which eventually time out. Interim updates are not backed up and time out as well; if the session remains active, then the next interim update after the server connection is restored provides the interim accounting information.

You can configure the number of accounting stop messages that the router can queue pending restoration of contact with the accounting server. To preserve current accounting data in preference to collecting new accounting data, subscriber logins fail as soon as the maximum number of messages has been withheld. Subscriber logins resume immediately when the pending queue drops below the queue limit.

**NOTE:** Service accounting stop messages are withheld for a maximum of ten services per subscriber. If a subscriber attempts to activate an eleventh service while that accounting server is offline, the activation fails.

The router can hold the pending accounting messages for up to 24 hours. When the configurable maximum holding period passes, all accounting stop messages still in the pending queue are flushed, even if the accounting server has come back online. A consequence of this is that subscriber logins resume immediately if they were failing because the maximum pending limit had been reached.

All pending messages are also flushed in either of the following circumstances:

- If you remove the last accounting server from the access profile, because then there is no place to send the messages.
- If you remove the accounting backup configuration.

While the router is withholding accounting stop messages, you can force the router to attempt contact with the accounting server immediately, rather than allowing it to wait until the periodic interval has expired. When you do so, the router first replays a batch of stop messages to the server, with one of the following outcomes:

- If the router receives an acknowledgment of receipt, then it marks the server as online and begins replaying all remaining pending stop messages in batches.
- If the router does not receive the acknowledgment, then it resumes sending a single pending accounting stop message at the periodic interval.

When a subscriber logs out while the accounting server is offline, the accounting stop requests for the subscriber and the session are queued and replayed to the server when it comes online. In this case, the subscriber session and service session information is retained, so that the router can send a correct accounting request when the server comes back online.

In the event of a graceful Routing Engine switchover while the accounting server is offline, the pending stop messages can be replayed from the active Routing Engine when the server is online again.

**NOTE:** When RADIUS accounting backup is configured, you must use different servers for RADIUS authentication and accounting. Subscriber authentication fails when the same server is configured for both authentication and accounting.

If the RADIUS server acts on behalf of other back-end RADIUS accounting or authentication servers and forwards requests to them, subscribers can be authenticated but accounting requests are not sent out.

## Configuring Per-Service Session Accounting

---

Subscriber management enables you to configure the router to collect statistics on a per-service session basis for subscribers. Per-service session accounting requires two operations. First, RADIUS must be configured to provide the name of the service, the accounting interval to use, and the type of statistics to collect (either time statistics or a combination of time and volume statistics). Second, if RADIUS VSA 26-69 is configured for time and volume statistics, you must also configure a firewall or fast update firewall filter that counts service packets—the service packet information provides the volume statistics.

The router uses the RADIUS attributes and Juniper Networks VSAs discussed in “[RADIUS Accounting Statistics for Subscriber Access Overview](#)” on page 26 to provide the accounting statistics for the subscriber session.

**NOTE:** The collection of time-only service statistics is supported for all service sessions. However, time and volume statistics are provided for only firewall and fast update firewall service sessions.

To configure the router to provide per-service accounting statistics:

1. Ensure that the required RADIUS VSAs are configured.  
See [Table 6 on page 35](#) for the VSAs that the router uses for per-service accounting.

2. Configure the classic firewall filter or fast update filter to count the service packets.

See [“Configuring Service Packet Counting” on page 1118](#).

**Table 6: Juniper Networks VSAs Used for Per-Service Session Accounting**

Attribute Number	Attribute Name	Description	Value
26-69	Service-Statistics	Enable or disable statistics for the service	<ul style="list-style-type: none"> <li>0 = disable</li> <li>1 = enable time statistics</li> <li>2 = enable time and volume statistics</li> </ul>
26-83	Service-Session	Service string sent in accounting stop and start messages from the router to the RADIUS server	string: service-name, with parameter values that are sent from RADIUS server in attribute 26-65.
26-140	Service-Interim-Acct-Interval	Amount of time between interim accounting updates for this service	<ul style="list-style-type: none"> <li>range = 600–86400 seconds</li> <li>0 = disabled</li> </ul> <p><b>NOTE:</b> Values are rounded up to the next higher multiple of 10 minutes. For example, a setting of 900 seconds (15 minutes) is rounded up to 20 minutes (1200 seconds).</p>

## Configuring RADIUS Server Parameters for Subscriber Access

Include the **radius** statement at the **[edit access profile *profile-name*]** hierarchy level to specify the RADIUS parameters for the subscriber access manager feature. The following list provides an overview of the parameters you can configure:

- The IP addresses of one or more RADIUS authentication and accounting servers.
- Options for the RADIUS servers, such as the following:
  - Format (decimal or description) used for the accounting session
  - Method (round-robin or direct) the router or switch uses to communicate with the servers
  - NAS identifier to use for RADIUS requests

- Revert time setting that specifies when the router or switch reverts to using the primary RADIUS server
- Delimiter character and format for the NAS-Port-ID (RADIUS attribute 87) and Calling-Station-ID (RADIUS attribute 31)
- The RADIUS attributes to be ignored or excluded from RADIUS messages.

To configure RADIUS server parameters:

1. Specify that you want to configure RADIUS support.

```
[edit access profile isp-bos-metro-fiber-basic]  
user@host# edit radius
```

2. Specify the addresses of RADIUS authentication and accounting servers.

See [“Specifying RADIUS Authentication and Accounting Servers for Subscriber Access” on page 36](#).

3. Configure the RADIUS server options.

See [“Configuring RADIUS Server Options for Subscriber Access” on page 46](#).

4. Configure RADIUS attributes that are ignored or excluded from RADIUS messages.

See [“Configuring How RADIUS Attributes Are Used for Subscriber Access” on page 52](#).

#### Related Documentation

---

## Specifying RADIUS Authentication and Accounting Servers for Subscriber Access

You can specify one or more RADIUS authentication or accounting servers to use for subscriber access management.

To configure RADIUS authentication and accounting support:

1. Specify that you want to configure RADIUS support.

```
[edit access profile isp-bos-metro-fiber-basic]  
user@host# edit radius
```

2. Specify the IP address of the RADIUS server used for authentication.

```
[edit access profile isp-bos-metro-fiber-basic radius]  
user@host# set authentication-server 192.168.1.251
```

3. Specify the IP address of the RADIUS server used for accounting.

```
[edit access profile isp-bos-metro-fiber-basic radius]  
user@host# set accounting-server 192.168.1.250
```

To configure multiple RADIUS authentication or accounting servers:

- Specify the IP addresses of all RADIUS servers used for authentication or accounting.

```
[edit access profile isp-bos-metro-fiber-basic radius]
user@host# set authentication-server 192.168.1.251 192.168.1.252
user@host# set accounting-server 192.168.1.250 192.168.1.251
```

## Configuring Back-up Options for RADIUS Accounting

You can configure RADIUS accounting backup to preserve accounting data when the accounting server is unavailable because of a server or network outage. When backup is configured, RADIUS accounting stop messages are withheld and queued to be sent when connectivity is restored. You can specify the maximum number of stop messages that can be queued. When this maximum is reached, subsequent new subscriber logins fail because there is no remaining capacity to preserve accounting data for new sessions.

You can also configure how long the queued messages can be held. When this period expires, all pending accounting stops are flushed from the queue, even if the accounting server has come back online.

**NOTE:** Configuring accounting backup disables the revert timer. An error message is generated if you attempt to configure the `revert-interval` statement at the `[edit access profile profile-name options]` or `[edit access radius-options]` hierarchy levels.

**CAUTION:** Before you configure RADIUS accounting backup, ensure that RADIUS accounting and RADIUS authentication are configured on different servers. Subscriber authentication fails when the same server is configured for both authentication and accounting.

1. Enable accounting backup to use the default values.

```
[edit access ]
user@host# set accounting-backup-options
```

2. (Optional) Configure the number of accounting stops that the router can preserve while the accounting server is offline.

```
[edit access accounting-backup-options]
user@host# set max-pending-accounting-stops number
```

3. (Optional) Configure how long the router holds pending accounting stops before flushing them.

```
[edit access accounting-backup-options]
user@host# set max-withhold-time hold-time
```

For example, the following statements configure the backup options for all subscriber accounting; these statements specify that the router holds no more than 32,000 pending accounting stops—at which point all subsequent subscriber logins fail—and holds them no longer than 6 hours—at which point all pending messages are flushed and subscriber logins resume if they were failing:

```
[edit access accounting-backup-options]
user@host# set max-pending-accounting-stops 32000
user@host# set max-withhold-time 360
```

**Related  
Documentation**

- [Preservation of RADIUS Accounting Information During an Accounting Server Outage on page 31](#)
- [Forcing the Router to Contact the Accounting Server Immediately on page 38](#)

---

## Forcing the Router to Contact the Accounting Server Immediately

In the event of an accounting server outage while RADIUS accounting backup is enabled, by default the router waits for a time interval to expire before contacting the offline server. Rather than waiting for that interval to pass, you can force the router to immediately contact the server by issuing the **request network-access aaa replay pending-accounting-stops** command. The router sends a batch of pending accounting stop requests to the server. If the router receives an acknowledgment from the server, then the router continues to replay the pending messages to the server in batches at the periodic interval. If the router does not get that acknowledgment, then it resumes sending a single pending accounting stop message at the periodic interval.

To force the router to immediately contact the offline accounting server:

- Request the messages to be replayed.  

```
user@host> request network-access aaa replay pending-accounting-stops
```

**Related  
Documentation**

- [Preservation of RADIUS Accounting Information During an Accounting Server Outage on page 31](#)

---

## Monitoring Pending RADIUS Accounting Stop Messages

- Purpose**    Display information about RADIUS accounting stop messages that are being withheld due to an inability to contact the RADIUS accounting server.

**Action** When you want to know whether the number of pending accounting-stop messages is nearing the maximum, you can display a simple count of pending requests:

```
user@host> show network-access aaa statistics pending-accounting-stops
Pending accounting stops: 10,000
```

You can use other commands to display more information about the accounting messages. The next example displays information for all services in the accounting session for the user, vjshah29@example.com. Although this example shows only one user, this command actually displays the information for all subscribers for whom accounting is being backed up.

```
user@host> show accounting pending-accounting-stops detail
Type: pppoe
Username: vjshah29@example.com
AAA Logical system/Routing instance: default:default
Access-profile: ce-ppp-profile
Session ID: 84
Accounting Session ID: 84
IP Address: 192.168.0.25
IPv6 Prefix: 2010:9999:18::/48
Authentication State: AuthAcctStopAckWait
Accounting State: Acc-Stop-Stats-Pending
Service name: cos-service
  Service State: SvcInactive
  Session ID: 94
  Session uptime: 00:08:02
  Accounting status: on/time
  Service accounting session ID: 84:94-1352294677
  Service accounting state: Acc-Stop-Stats-Pending
  Accounting interim interval: 600
Service name: filter-service
  Service State: SvcInactive
  Session ID: 93
  Session uptime: 00:08:02
  Accounting status: on/volume+time
  Service accounting session ID: 84:93-1352294677
  Service accounting state: Acc-Stop-Stats-Pending
  Accounting interim interval: 600
Service name: filter-service6
  Service State: SvcInactive
  Session ID: 95
  Session uptime: 00:08:02
  Accounting status: on/volume+time
  Service accounting session ID: 84:95-1352294677
  Service accounting state: Acc-Stop-Stats-Pending
  Accounting interim interval: 600
```

You can display summary information for all users with a particular access profile. In the following example, only a single user, vjshah29@example.com, has the specified access profile, ce-ppp-profile:

```
user@host> show accounting pending-accounting-stops ce-ppp-profile
```

Type:	Username:	Session ID:	Service ID:	Service
pppoe	vjshah29@example.com	84		
pppoe	vjshah29@example.com	84	94	cos-service
pppoe	vjshah29@example.com	84	93	filter-service
pppoe	vjshah29@example.com	84	95	filter-service6

You can also display summary information for all subscribers that have accounting-stop messages pending, regardless of access profile. The next example displays information for two users. Because the subscriber larry@example.com is not shown in the previous example, he must have a different access profile than vjshah29@example.com, even though he has received the same services.

user@host> show accounting pending-accounting-stops terse

Type:	Username:	Session ID:	Service ID:	Service
pppoe	vjshah29@example.com	84		
pppoe	vjshah29@example.com	84	94	cos-service
pppoe	vjshah29@example.com	84	93	filter-service
pppoe	vjshah29@example.com	84	95	filter-service6
pppoe	larry@example.com	85		
pppoe	larry@example.com	85	94	cos-service
pppoe	larry@example.com	85	93	filter-service
pppoe	larry@example.com	85	95	filter-service6

## RADIUS Server Options for Subscriber Access

You can specify options that the router uses when communicating with RADIUS authentication and accounting servers for subscriber access.

The following list describes the RADIUS options you can configure:

- **accounting-session-id-format**—The format the router uses to identify the accounting session. The identifier can be in one of the following formats. The router uses **decimal** format by default.
  - **decimal**—For example, 435264
  - **description**—In the format, **jnpr interface-specifier:subscriber-session-id**. For example, **jnpr fastEthernet 3/2.6:1010101010101**
- **calling-station-id-delimiter**—The character that the router uses as the separator between concatenated values in the Calling-Station-ID string (RADIUS attribute 31).
- **calling-station-id-format**—Optional information that the router includes in the Calling-Station-ID (RADIUS attribute 31).
- **client-accounting-algorithm** and **client-authentication-algorithm**—The method the router uses to access RADIUS accounting and RADIUS authentication servers. You can specify the following methods:
  - **direct**—The default method, in which there is no load balancing. For example, in the direct method, the router always accesses **server1** (the primary server) first, and uses **server2** and **server3** as backup servers.
  - **round-robin**—The method that provides load balancing by rotating router requests among the list of configured RADIUS servers. For example, if three RADIUS servers

are configured to support the router, the router sends the first request to **server1**, and uses **server2** and **server3** as backup servers. The router then sends the second request to **server2**, and uses **server3** and **server1** as backups.

**NOTE:** When a RADIUS server in the round-robin list becomes unreachable, the next reachable server in the round-robin list is used for the current request. That same server is also used for the next request because it is at the top of the list of available servers. As a result, after a server failure, the server that is used takes up the load of two servers.

- **coa-dynamic-variable-validation**—The optional method that the router uses when processing CoA requests that include changes to a client profile dynamic variable that cannot be applied. The optional configuration specifies that when a CoA operation is unable to apply a requested change to a client profile dynamic variable, subscriber management does not apply any changes to client profile dynamic variables in the CoA request and then responds with a NACK. In the default method, subscriber management does not apply the incorrect update but does apply the other changes to the client profile dynamic variables, and then responds with an ACK message.
- **access-loop-id-local**—The Agent-Remote-Id and Agent-Circuit-Id are generated locally when these values are not present in the client database. The interface description of the logical interface is used as the Agent-Remote-Id and the interface description portion of the NAS-Port-Id using the format **<underlying-interface-name>:<outer-tag>-<inner-tag>** is used as the Agent-Circuit-Id.

**NOTE:** The NAS-Port-Id format changes (established by `[set access profile profile-name radius options interface-description-format]`) are applied before generating the Agent-Circuit-Id.

The NAS-Port-Id format (established by `[set access profile profile-name radius options interface-description-format]`) leverages the locally generated Agent-Remote-Id and Agent-Circuit-Id.

- **ethernet-port-type-virtual**—The physical port type of **virtual** that the router uses to authenticate clients. The port type is passed in RADIUS attribute 61 (NAS-Port-Type). By default the router passes a port type of **ethernet** in RADIUS attribute 61.
- **interface-description-format**—The information that is excluded from the interface description that the router passes to RADIUS for inclusion in the RADIUS attribute 87 (NAS-Port-Id). By default, the router includes both the **subinterface** and the **adapter** in the interface description. You can specify:
  - **exclude-adapter**—Exclude the adapter.
  - **exclude-subinterface**—Exclude the subinterface.
- **nas-identifier**—The value for the client RADIUS attribute 32 (NAS-Identifier), which is used for authentication and accounting requests. You can specify a string in the range 1 through 64 characters.

- **nas-port-extended-format**—The extended format for RADIUS attribute 5 (NAS-Port) and for the width of the fields in the NAS-Port attribute that the RADIUS client uses. You can specify:
  - **adapter-width *width***—Number of bits in the adapter field.
  - **port-width *width***—Number of bits in the port field.
  - **slot-width *width***—Number of bits in the slot field.
  - **stacked-vlan-width *width***—Number of bits in the SVLAN ID field.
  - **vlan-width *width***—Number of bits in the VLAN ID field.

**NOTE:** The total of the widths must not exceed 32 bits, or the configuration will fail.

- **nas-port-id-delimiter**—The character used as the separator between values in the NAS-Port-ID string.
- **nas-port-id-format**—Optional information included in RADIUS attribute 87 (NAS-Port-ID).
- **nas-port-type**—The port type used to authenticate subscribers.
- **revert-interval**—The number of seconds that the router waits after a server has become unreachable. The router rechecks the connection to the server when the **revert-interval** expires. If the server is then reachable, it is used in accordance with the order of the server list. You can configure from 0 (off) through 429496729 seconds. The default is 60 seconds.
- **vlan-nas-port-stacked-format**—The format that turns off RADIUS attribute 5 (NAS-Port) to include the S-VLAN ID, in addition to the VLAN ID, for subscribers on Ethernet interfaces.

**Related  
Documentation**

- [Configuring RADIUS Server Options for Subscriber Access on page 46](#)

---

## Global RADIUS Options for Subscriber Access

You can specify options that the router uses when communicating with all configured RADIUS servers for subscriber access.

The following list describes the global RADIUS options you can configure:

- **revert-interval**—The number of seconds that the router waits after a server has become unreachable. The router rechecks the connection to the server when the **revert-interval** expires. If the server is then reachable, it is used in accordance with the order of the server list. You can configure from 0 (off) through 429496729 seconds. The default is 60 seconds.
- **request-rate**—The number of requests per second that the router can send to all configured RADIUS servers collectively. By limiting the flow of requests from the router

to the RADIUS servers, you can prevent the RADIUS servers from being flooded with requests. You can configure from 500 through 4000 requests per second. The default is 500 requests per second.

- Related Documentation**
- [Configuring RADIUS Options for Subscriber Access Globally on page 48](#)
  - [request-rate on page 1866](#)
  - [revert-interval on page 1870](#)

## DNS Address Assignment Precedence

Subscriber management supports three methods for assigning addresses to DHCP clients. When multiple methods are configured, the router uses the following precedence to determine which address to assign to the client.

1. Address defined on the RADIUS server by Internet Assigned Numbers Authority (IANA) vendor ID 4874 attributes 26-4 (Primary-DNS) and 26-5 (Secondary-DNS).
2. Address defined on the RADIUS server by IANA vendor ID 2636 attributes 26-31 (Primary-DNS) and 26-33 (Secondary-DNS).
3. Address defined in the local address pool on the router.

- Related Documentation**
- [Juniper Networks VSAs Supported by the AAA Service Framework on page 88](#)
  - [Address-Assignment Pools Overview on page 155](#)

## Manual Configuration of the NAS-Port-ID RADIUS Attribute

Subscriber management uses the NAS-Port-ID (RADIUS attribute 87) to provide an interface description that identifies the physical interface that is used to authenticate subscribers. The NAS-Port-ID is included in RADIUS Access-Request, Acct-Start, Acct-Stop, Acct-On, and Acct-Off messages.

You can configure access profiles to specify additional information in the NAS-Port-ID. The additional information can be any combination of the interface description (the default value), the Agent Circuit ID, the Agent Remote ID, and the NAS identifier. You can also specify an optional delimiter character, which separates the values in a NAS-Port-ID. The default delimiter character is the hash character (#).

A default NAS-Port-ID consists of the following **interface-description** string:

```
[physical-interface].<interface-type>-<slot>/<adapter>/<port><.subinterface>[:<svlan>-<vlan>]
```

For example: **ge-1/2/0.100:100**

You might optionally configure an access profile that specifies that the NAS-Port-ID includes the NAS identifier, the Agent Circuit ID, and the Agent Remote ID, in addition to the default interface description. For this configuration, the NAS-Port-ID consists of the following string:

`nas-identifier#interface-description#agent-circuit-id#agent-remote-id`

For example:

`retailer25#ge-1/2/0.100:100#ACI 12/1/22/1230:1.1.23#ARI 55/2/23.9999:10.11.1923`

**NOTE:** The NAS-Port-ID displays the configured values in the following order (where # is the delimiter):

`nas-identifier#interface-description#agent-circuit-id#agent-remote-id`

#### Related Documentation

- [Configuring a NAS-Port-ID with Additional Options on page 49](#)
- [RADIUS Server Options for Subscriber Access on page 40](#)

## Manual Configuration of the NAS-Port-Type RADIUS Attribute

Subscriber management uses the NAS-Port-Type (RADIUS attribute 61) to identify the type of physical port that is used to authenticate subscribers. By default, subscriber management uses a NAS-Port-Type of **ethernet**.

You can optionally configure access profiles to provide the value for the NAS-Port-Type attribute, which enables you to explicitly specify the NAS port type that is used for a given connection. For example, you might configure an access profile that specifies that a NAS port type of **wireless** is used for all Ethernet connections that are managed by that access profile.

**NOTE:** The **ethernet-port-type-virtual** configuration statement takes precedence over the **nas-port-type** statement when you include both statements in the same access profile. When you include the **ethernet-port-type-virtual** statement, subscriber management uses the RADIUS attribute value of 5, which specifies a NAS port type of **virtual**.

[Table 7 on page 44](#) shows the supported port type values for RADIUS attribute 61 (NAS-Port-Type) that you can include in an access profile.

**Table 7: RADIUS NAS-Port-Type Values**

Statement Option	NAS-Port-Type Value	Description
<i>value</i>	0–65535	Number that indicates either the IANA-assigned value for the RADIUS port type or a custom number-to-port type defined by the user
<code>adsl-cap</code>	12	Asymmetric DSL, carrierless amplitude phase (CAP) modulation

Table 7: RADIUS NAS-Port-Type Values (*continued*)

Statement Option	NAS-Port-Type Value	Description
adsl-dmt	13	Asymmetric DSL, discrete multitone (DMT)
async	0	Asynchronous
cable	17	Cable
ethernet	15	Ethernet
fdi	21	Fiber Distributed Data Interface
g3-fax	10	G.3 Fax
hdlc-clear-channel	7	HDLC Clear Channel
iapp	25	Inter-Access Point Protocol (IAPP)
isdl	14	ISDN DSL

## Configuring RADIUS Server Options for Subscriber Access

You can specify options that the router or switch uses when communicating with RADIUS authentication and accounting servers for subscriber access.

To configure RADIUS authentication and accounting server options:

1. Specify that you want to configure RADIUS.

```
[edit access profile isp-bos-metro-fiber-basic]
user@host# edit radius
```

2. Specify that you want to configure RADIUS options.

```
[edit access profile isp-bos-metro-fiber-basic radius]
user@host# edit options
```

3. (Optional) Configure the method the router or switch uses to access RADIUS accounting servers.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set client-accounting-algorithm round-robin
```

4. (Optional) Configure the method the router or switch uses to access RADIUS authentication servers.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set client-authentication-algorithm round-robin
```

5. (Optional) Configure the format the router or switch uses to identify the accounting session.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set accounting-session-id-format decimal
```

6. (Optional) Specify that the Agent-Remote-Id and Agent-Circuit-Id are generated locally when these values are not present in the client database.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set access-loop-id-local
```

7. (Optional) Specify the information that is excluded from the interface description that the router or switch passes to RADIUS for inclusion in RADIUS attribute 87 (NAS-Port-Id).

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set interface-description-format exclude-adapter
```

8. (Optional) Configure the value for the client RADIUS attribute 32 (NAS-Identifier), which is used for authentication and accounting requests.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set nas-identifier 56
```

9. (Optional) Configure the RADIUS client to use the extended format for RADIUS attribute 5 (NAS-Port) and specify the width of the fields in the NAS-Port attribute. The total of the widths must not exceed 32 bits, or the configuration fails.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set nas-port-extended-format ae-width 10 slot-width 4 adapter-width
2 port-width 4 stacked-vlan-width 10 vlan-width 2
```

10. (Optional) Configure the delimiter character that the router inserts between values in RADIUS attribute 87 (NAS-Port-ID).

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set nas-port-id-delimiter %
```

11. (Optional) Configure the information that the router includes in RADIUS attribute 87 (NAS-Port-ID).

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set nas-port-id-format agent-circuit-id agent-remote-id
```

12. (Optional) Configure the delimiter character that the router inserts between values in RADIUS attribute 31 (Calling-Station-ID).

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set calling-station-id-delimiter "%"
```

13. (Optional) Configure the information that the router includes in RADIUS attribute 31 (Calling-Station-ID).

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set calling-station-id-format agent-circuit-id agent-remote-id
```

14. (Optional) Configure the port type that is included in RADIUS attribute 61 (NAS-Port-Type). This specifies the port type the router uses to authenticate subscribers.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set nas-port-type ethernet wireless-ieee80211
```

**NOTE:** This statement is ignored if you configure the `ethernet-port-type-virtual` in the same access profile.

15. (Optional) Configure the router or switch to use a port type of `virtual` to authenticate clients.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set ethernet-port-type-virtual
```

**NOTE:** This statement takes precedence over the `nas-port-type` statement if you include both in the same access profile.

16. (Optional) Configure the number of seconds that the router or switch waits after a server has become unreachable.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set revert-interval port-width 1200
```

17. (Optional) Specify that RADIUS attribute 5 (NAS-Port) includes the S-VLAN ID, in addition to the VLAN ID, for subscribers on Ethernet interfaces.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set vlan-nas-port-stacked-format
```

18. (Optional) Configure the router to use the optional behavior when processing CoA requests that include changes to client profile dynamic variables.

```
[edit access profile isp-bos-metro-fiber-basic radius options]
user@host# set coa-dynamic-variable-validation
```

## Configuring RADIUS Options for Subscriber Access Globally

You can configure RADIUS options that apply to all RADIUS servers globally.

To configure RADIUS options globally:

1. Specify that you want to configure RADIUS options.

```
[edit access ]
user@host# edit radius-options
```

2. (Optional) Configure the number of requests per second that the router can send to all the RADIUS servers collectively.

```
[edit access radius-options]
user@host# set request-rate 1000
```

3. (Optional) Configure the number of seconds that the router or switch waits after a server has become unreachable.

```
[edit access radius-options]
user@host# set revert-interval port-width 1200
```

#### Related Documentation

- [Global RADIUS Options for Subscriber Access on page 42](#)
- [request-rate on page 1866](#)
- [revert-interval on page 1870](#)

## Configuring a NAS-Port-ID with Additional Options

You can include optional values in the NAS-Port-ID (RADIUS attribute 87), which identifies the physical interface subscriber management uses to authenticate subscribers. By default, the NAS-Port-ID includes the **interface-description** value that describes the physical interface. You can include the following values in the NAS-Port-ID:

- **agent-circuit-id**
- **agent-remote-id**
- **interface-description**
- **nas-identifier**

To configure an access profile to provide additional options in the NAS-Port-ID:

1. Specify the access profile you want to configure.

```
[edit]
user@host# edit access profile retailer25
```

2. Specify that you want to configure RADIUS options.

```
[edit access profile retailer25]
user@host# edit radius options
```

3. Specify the character to use as the delimiter between the different attribute values in the NAS-Port-ID. By default, subscriber management uses the hash character (#).

```
[edit access profile retailer25 radius options]
user@host# set nas-port-delimiter %
```

4. Specify that you want to configure the format of the NAS-Port-ID.

```
[edit access profile retailer25 radius options]
user@host# edit nas-port-id-format
```

5. Include the interface description in the NAS-Port-ID. (The interface description is not included by default when you configure the **nas-port-id-format** statement.)

```
[edit access profile retailer25 radius options nas-port-id-format]
user@host# set interface-description
```

6. Include the Agent Circuit ID in the NAS-Port-ID.

```
[edit access profile retailer25 radius options nas-port-id-format]
user@host# set agent-circuit-id
```

7. Include the Agent Remote ID in the NAS-Port-ID.

```
[edit access profile retailer25 radius options nas-port-id-format]
user@host# set agent-remote-id
```

8. Include the NAS identifier value in the NAS-Port-ID.

```
[edit access profile retailer25 radius options nas-port-id-format]
user@host# set nas-identifier
```

---

## Configuring a Calling-Station-ID with Additional Attributes

You can configure an alternative value for the Calling-Station-ID (RADIUS IETF attribute 31) in an access profile on the router.

By default, the Calling-Station-ID includes the **agent-circuit-id** string. Optionally, you can configure the Calling-Station-ID to include one or more of the following attributes, in any combination:

- Agent circuit identifier (**agent-circuit-id**)—String that uniquely identifies the subscriber's access node and the digital subscriber line (DSL) on the access node. The agent circuit identifier (ACI) string is stored in either the DHCP option 82 field of DHCP messages for DHCP traffic, or in the DSL Forum Agent-Circuit-ID VSA [26-1] of PPPoE Active Discovery Initiation (PADI) and PPPoE Active Discovery Request (PADR) control packets for PPPoE traffic.
- Agent remote identifier (**agent-remote-id**)—String that identifies the subscriber on the digital subscriber line access multiplexer (DSLAM) interface that initiated the service request. The agent remote identifier (ARI) string is stored in either the DHCP option 82 field for DHCP traffic, or in the DSL Forum Agent-Remote-ID VSA [26-2] for PPPoE traffic.
- Interface description (**interface-description**)—Description of the interface, which is not included in the Calling-Station-ID by default.
- NAS identifier (**nas-identifier**)—Name of the NAS that originated the authentication or accounting request. NAS-Identifier is RADIUS IETF attribute 32.

If you configure the format of the Calling-Station-ID with more than one optional value, a hash character (#) is the default delimiter that the router uses as a separator between the concatenated values in the resulting Calling-Station-ID string. Optionally, you can configure an alternative delimiter character for the Calling-Station-ID to use.

To configure an access profile to provide additional attributes in the Calling-Station-ID:

1. Specify the access profile you want to configure.

```
[edit]
user@host# edit access profile profile-name
```

2. Specify that you want to configure RADIUS options.

```
[edit access profile profile-name]
user@host# edit radius options
```

3. Specify the nondefault character to use as the delimiter between the different attribute values in the Calling-Station-ID.

By default, subscriber management uses the hash character (#) as the delimiter in Calling-Station-ID strings that contain more than one optional value.

```
[edit access profile profile-name radius options]
user@host# set calling-station-id-delimiter delimiter-character
```

4. Configure the value for the NAS-Identifier (RADIUS attribute 32), which is used for authentication and accounting requests.

```
[edit access profile profile-name radius options]
user@host# set nas-identifier identifier-value
```

5. Specify that you want to configure the format of the Calling-Station-ID.

```
[edit access profile profile-name radius options]
user@host# edit calling-station-id-format
```

6. Include the interface description in the Calling-Station-ID.

```
[edit access profile profile-name radius options calling-station-id-format]
user@host# set interface-description
```

7. Include the agent circuit identifier in the Calling-Station-ID.

```
[edit access profile profile-name radius options calling-station-id-format]
user@host# set agent-circuit-id
```

8. Include the agent remote identifier in the Calling-Station-ID.

```
[edit access profile profile-name radius options calling-station-id-format]
user@host# set agent-remote-id
```

9. Include the configured NAS identifier value in the Calling-Station-ID.

```
[edit access profile profile-name radius options calling-station-id-format]
user@host# set nas-identifier
```

#### Example: Calling-Station-ID with Additional Attributes in an Access Profile

The following example creates an access profile named `retailer01` that configures a Calling-Station-ID string that includes the NAS-Identifier (**fox**), interface description, agent circuit identifier, and agent remote identifier optional attributes.

```
[edit access profile retailer01 radius options]
nas-identifier "fox";
calling-station-id-delimiter "*";
calling-station-id format {
  nas-identifier;
  interface-description;
  agent-circuit-id;
  agent-remote-id;
}
```

The resulting Calling-Station-ID string is formatted as follows:

```
fox*ge-1/2/0.100:100*as007*ar921
```

where:

- The NAS-Identifier value is **fox**.
- The Calling-Station-ID delimiter character is **\*** (asterisk).
- The interface description value is **ge-1/2/0.100:100**.
- The agent circuit identifier value is **as007**.
- The agent remote identifier value is **ar921**.

## Configuring How RADIUS Attributes Are Used for Subscriber Access

You can specify the attributes RADIUS ignores in RADIUS Access-Accept messages, and the attributes RADIUS excludes from specified message types.

To configure the attributes RADIUS ignores or excludes:

1. Specify that you want to configure RADIUS.

```
[edit access profile isp-bos-metro-fiber-basic]
user@host# edit radius
```

2. Specify that you want to configure how RADIUS attributes are ignored or excluded.

```
[edit access profile isp-bos-metro-fiber-basic radius]
user@host# edit attributes
```

3. Specify the attributes you want RADIUS to ignore when the attributes are in Access-Accept messages. See [Table 8 on page 52](#) for the attributes you can configure.

```
[edit access profile isp-bos-metro-fiber-basic radius attributes]
user@host# set ignore input-filter output-filter
```

4. Configure RADIUS to exclude the specified attribute from the specified RADIUS message type. See [Table 9 on page 53](#) for the attributes and message type combinations you can configure.

```
[edit access profile isp-bos-metro-fiber-basic radius attributes]
user@host# set exclude input-filter output-filter
```

You use the **ignore** statement to configure the router or switch to ignore a particular attribute in RADIUS Access-Accept messages. By default, the router or switch processes the attributes received from the external AAA server. [Table 8 on page 52](#) lists the attributes supported in the **ignore** statement.

**Table 8: Attributes That Can Be Ignored in RADIUS Access-Accept Messages**

CLI Entry	Attribute Name	Attribute Number
dynamic-iflset-name	Interface-Set-Name	Juniper Networks VSA 26-130

**Table 8: Attributes That Can Be Ignored in RADIUS Access-Accept Messages (*continued*)**

CLI Entry	Attribute Name	Attribute Number
framed-ip-netmask	Framed-Ip-Netmask	RADIUS attribute 9
input-filter	Ingress-Policy-Name	Juniper Networks VSA 26–10
logical-system:routing-instance	Virtual-Router	Juniper Networks VSA 26–1
output-filter	Egress-Policy-Name	Juniper Networks VSA 26–11

You use the **exclude** statement to configure the router or switch to exclude the specified attributes from the specified type of RADIUS message. Not all attributes appear in all types of RADIUS messages—the CLI indicates the RADIUS message type. By default, the router or switch includes the specified attributes in RADIUS Access-Request, Acct-On, Acct-Off, Acct-Start, and Acct-Stop messages. [Table 9 on page 53](#) lists the attributes and message types supported in the **exclude** statement.

**Table 9: Attributes That Can Be Excluded from RADIUS Messages**

## RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN Overview

On MX Series routers with Modular Port Concentrator/Modular Interface Card (MPC/MIC) interfaces, you can configure the NAS-Port-Type (61) RADIUS IETF attribute, and an extended format for the NAS-Port (5) RADIUS IETF attribute, on a per-interface, per-VLAN, or per-stacked VLAN basis. The router passes the NAS-Port and NAS-Port-Type attributes to the RADIUS server during the authentication, authorization, and accounting (AAA) process.

This overview covers the following topics:

- [NAS-Port-Type RADIUS Attribute on page 57](#)
- [NAS-Port RADIUS Attribute on page 58](#)
- [NAS-Port Options Configuration and Subscriber Network Access Models on page 58](#)
- [NAS-Port Options Definition on page 58](#)

### NAS-Port-Type RADIUS Attribute

The NAS-Port-Type attribute specifies the type of physical port that the network access server (NAS) uses to authenticate the subscriber. When you use the **nas-port-type** statement to configure the NAS-Port-Type, you can specify one of several predefined port types, or a user-defined port type value in the range 0 through 65535.

## NAS-Port RADIUS Attribute

The NAS-Port attribute specifies the physical port number of the NAS that is authenticating the user, and is formed by a combination of the physical port's slot number, port number, adapter number, VLAN ID, and S-VLAN ID. The NAS-Port extended format, which you configure with the **nas-port-extended-format** statement, specifies the number of bits (bit width) for each field in the NAS-Port attribute: slot, adapter, port, VLAN, and S-VLAN.

To include stacked VLAN IDs, in addition to VLAN IDs, in the NAS-Port extended format, use the **stacked** option as part of the **nas-port-extended-format** statement. If you do not configure the **stacked** option, stacked VLAN IDs are not included in the extended format.

## NAS-Port Options Configuration and Subscriber Network Access Models

Configuring the NAS-Port-Type and the extended format for NAS-Port on a per-VLAN, per-stacked VLAN, or per-physical interface basis is useful in network configurations that use the following subscriber access models:

- 1:1 access model (per-VLAN basis)—In a 1:1 access model, dedicated customer VLANs (C-VLANs) provide a one-to-one correspondence between an individual subscriber and the VLAN encapsulation.
- N:1 access model (per-S-VLAN basis)—In an N:1 access model, service VLANs are dedicated to a particular service, such as video, voice, or data, instead of to a particular subscriber. Because a service VLAN is typically shared by many subscribers within the same household or in different households, the N:1 access model provides a many-to-one correspondence between individual subscribers and the VLAN encapsulation.
- 1:1 or N:1 access model (per-physical interface basis)—You can configure the NAS-Port-Type and NAS-Port format on a per-physical interface basis for both the 1:1 access model and the N:1 access model.

## NAS-Port Options Definition

As an alternative to globally configuring the NAS-Port-Type and NAS-Port extended format in an access profile, you can configure these attributes on a per-interface, per-VLAN, or per-stacked VLAN basis. To do so, you must create a *NAS-Port options definition*, which includes some or all of the following components:

- NAS-Port-Type value—Specifies the type of physical port that the network access server (NAS) uses to authenticate the subscriber.
- NAS-Port extended format—Configures the number of bits (bit width) for each field in the NAS-Port attribute, including: slot, adapter, port, VLAN, and S-VLAN. Optionally, you can also use the **stacked** option as part of the **nas-port-extended-format** statement to include S-VLAN IDs, in addition to VLAN IDs, in the extended format. If you do not configure the **stacked** option, stacked VLAN IDs are not included in the extended format.
- VLAN ranges or S-VLAN ranges—Defines the VLAN range of subscribers or stacked VLAN range of subscribers to which each NAS-Port options definition applies.

- Related Documentation**
- [Guidelines for Configuring RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN on page 59](#)
  - [Configuring RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN on page 60](#)

## Guidelines for Configuring RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN

---

The following guidelines apply when you configure the NAS-Port-Type attribute and the extended format for the NAS-Port attribute on a per-VLAN, per-stacked VLAN, or per-physical interface basis:

- You can create a maximum of 16 NAS-Port options definitions per physical interface. Each definition can include either a maximum of 32 VLAN ranges or a maximum of 32 stacked VLAN ranges, but cannot include a combination of VLAN ranges and stacked VLAN ranges.
- Configuring the NAS-Port-Type attribute and NAS-Port extended format on a per-VLAN, per-stacked VLAN, or per-physical interface basis overrides the global settings for these attributes configured in an access profile.
- If the NAS-Port-Type attribute and the NAS-Port extended format are not configured on a per-VLAN basis (in a 1:1 access model) or on a per-stacked VLAN basis (in an N:1 access model), the router uses the global settings configured for these attributes in an access profile for all RADIUS request messages.

- Related Documentation**
- [RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN Overview on page 57](#)
  - [Configuring RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN on page 60](#)

## Configuring RADIUS NAS-Port Options for Subscriber Access per Physical Interface, VLAN, or Stacked VLAN

---

On MX Series routers with MPC/MIC interfaces, you can configure the NAS-Port-Type (61) RADIUS IETF attribute, and an extended format for the NAS-Port (5) RADIUS IETF attribute, on a per-physical interface, per-VLAN, or per-stacked VLAN (S-VLAN) basis. The router passes the NAS-Port-Type and NAS-Port attributes to the RADIUS server during the authentication, authorization, and accounting (AAA) process.

To configure the NAS-Port-Type and NAS-Port extended format on a per-physical interface, per-VLAN, or per-stacked VLAN basis, you must create a NAS-Port options definition, which includes the following components:

- NAS-Port-Type value—Specifies the type of physical port that the network access server (NAS) uses to authenticate the subscriber.
- NAS-Port extended format—Configures the number of bits (bit width) for each field in the NAS-Port attribute, which specifies the physical port number of the NAS that is authenticating the subscriber. Fields in the NAS-Port attribute include: slot, adapter, port, VLAN, and S-VLAN. Optionally, you can also use the **stacked** option as part of the **nas-port-extended-format** statement to include S-VLAN IDs, in addition to VLAN IDs, in the extended format. If you do not configure the **stacked** option, stacked VLAN IDs are not included in the extended format.
- VLAN ranges or S-VLAN ranges—Defines the VLAN range of subscribers or stacked VLAN range of subscribers to which each NAS-Port options definition applies.

**NOTE:** You can create a maximum of 16 NAS-Port options definitions per physical interface. Each definition can include a maximum of 32 VLAN ranges or 32 stacked VLAN ranges, but *cannot* include a combination of VLAN ranges and stacked VLAN ranges.

To configure the NAS-Port-Type and NAS-Port extended format on a per-physical interface, per-VLAN, or per-stacked VLAN basis:

1. Specify the physical interface you want to configure.
2. Enable VLAN tagging, stacked VLAN tagging, or flexible VLAN tagging on the interface.
  - For VLAN tagging, see Enabling VLAN Tagging.
  - For stacked VLAN tagging, see Configuring Stacked VLAN Tagging
  - For flexible VLAN tagging, also referred to as mixed tagging, see Enabling VLAN Tagging.
3. Specify that you want to configure RADIUS options for a physical interface, VLAN, or S-VLAN.

```
[edit interfaces interface-name]  
user@host> edit radius-options
```

4. Create a named NAS-Port options definition.

```
[edit interfaces interface-name radius-options]  
user@host# edit nas-port-options nas-port-options-name
```

5. Configure the NAS-Port-Type, and the VLAN ranges or stacked VLAN ranges to which the named NAS-Port options definition applies.
  - For per-physical interface configurations, see [“Configuring the RADIUS NAS-Port-Type per Physical Interface” on page 62](#).
  - For per-VLAN configurations, see [“Configuring the RADIUS NAS-Port-Type per VLAN” on page 63](#).
  - For per-stacked VLAN configurations, see [“Configuring the RADIUS NAS-Port-Type per Stacked VLAN” on page 64](#).
6. Configure the NAS-Port extended format, and the VLAN ranges or stacked VLAN ranges to which the named NAS-Port options definition applies.
  - For per-physical interface configurations, see [“Configuring the RADIUS NAS-Port Extended Format per Physical Interface” on page 66](#).
  - For per-VLAN configurations, see [“Configuring the RADIUS NAS-Port Extended Format per VLAN” on page 68](#).
  - For per-stacked VLAN configurations, see [“Configuring the RADIUS NAS-Port Extended Format per Stacked VLAN” on page 69](#).

## Configuring the RADIUS NAS-Port-Type per Physical Interface

---

As an alternative to globally configuring the NAS-Port-Type (61) RADIUS attribute in an access profile, you can configure the NAS-Port-Type on a per-physical interface basis as part of a NAS-Port options definition. The NAS-Port-Type specifies the type of physical port that the network access server (NAS) uses to authenticate the subscriber.

Configuring NAS-Port options definitions on a per-physical interface basis is useful in network configurations that use a 1:1 access model or an N:1 access model.

To configure the NAS-Port-Type RADIUS attribute per physical interface:

1. Specify the interface you want to configure.

```
[edit]
user@host# edit interfaces interface-name
```

2. Enable VLAN tagging on the interface.

```
[edit interfaces interface-name]
user@host# set vlan-tagging
```

Setting VLAN tagging enables the reception and transmission of 802.1Q VLAN-tagged frames on the interface. You must enable VLAN tagging before you can configure the VLAN ranges to which the NAS-Port options definition applies.

3. Specify that you want to configure RADIUS options for a physical interface.

```
[edit interfaces interface-name]
user@host# edit radius-options
```

4. Create a named NAS-Port options definition.

```
[edit interfaces interface-name radius-options]
user@host# edit nas-port-options nas-port-options-name
```

5. Configure the NAS-Port-Type.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set nas-port-type port-type
```

6. Configure the VLAN range or ranges to which the NAS-Port options definition applies.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set vlan-ranges (any | low-tag-high-tag)
```

Per-physical interface configurations typically require you to create a VLAN range that consists of all VLAN IDs on the physical interface. To do so, use the **any** option with the **vlan-ranges** statement.

The following example shows a per-interface NAS-Port options definition named **subscribers-east** that configures the **wireless-umts** NAS-Port-Type for a VLAN range consisting of all VLAN IDs on Gigabit Ethernet physical interface ge-1/0/0.

```
[edit interfaces ge-1/0/0 radius-options]
nas-port-options subscribers-east {
  nas-port-type wireless-umts;
  vlan-ranges {
```

## Configuring the RADIUS NAS-Port-Type per VLAN

As an alternative to globally configuring the NAS-Port-Type (61) RADIUS attribute in an access profile, you can configure the NAS-Port-Type on a per-VLAN basis as part of a NAS-Port options definition. The NAS-Port-Type specifies the type of physical port that the network access server (NAS) uses to authenticate the subscriber.

Configuring NAS-Port options definitions on a per-VLAN basis is useful in network configurations that use a 1:1 access model.

To configure the NAS-Port-Type RADIUS attribute per VLAN:

1. Specify the interface you want to configure.

```

[edit]
user@host# edit interfaces interface-name

```

2. Enable VLAN tagging on the interface.

```

[edit interfaces interface-name]
user@host# set vlan-tagging

```

Setting VLAN tagging enables the reception and transmission of 802.1Q VLAN-tagged frames on the interface. You must enable VLAN tagging before you can configure the VLAN ranges to which the NAS-Port options definition applies.

3. Specify that you want to configure RADIUS options for a VLAN interface.

```

[edit interfaces interface-name]
user@host# edit radius-options

```

4. Create a named NAS-Port options definition.

```

[edit interfaces interface-name radius-options]
user@host# edit nas-port-options nas-port-options-name

```

5. Configure the NAS-Port-Type.

```

[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]

```

```
user@host# set nas-port-type port-type
```

6. Configure the VLAN range or ranges to which the NAS-Port options definition applies.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]  
user@host# set vlan-ranges (any | low-tag-high-tag)
```

Per-VLAN configurations typically require you to create a VLAN range that consists of a single VLAN ID on the physical interface. To do so, set the *low-tag* and *high-tag* options in the **vlan-ranges** statement to the same value, as shown in the following example.

The following example shows a per-VLAN NAS-Port options definition named subscribers-west that configures the **ethernet** NAS-Port-Type for VLAN ID 3 on Gigabit Ethernet physical interface ge-1/1/0.

```
[edit interfaces ge-1/1/0 radius-options]  
nas-port-options subscribers-west {  
  nas-port-type ethernet;  
  vlan-ranges {  
    3-3;  
  }  
}
```

## Configuring the RADIUS NAS-Port-Type per Stacked VLAN

As an alternative to globally configuring the NAS-Port-Type (61) RADIUS attribute in an access profile, you can configure the NAS-Port-Type on a per-stacked VLAN basis as part of a NAS-Port options definition. The NAS-Port-Type specifies the type of physical port that the network access server (NAS) uses to authenticate the subscriber.

Configuring NAS-Port options definitions on a per-stacked VLAN basis is useful in network configurations that use an N:1 access model.

To configure the NAS-Port-Type RADIUS attribute per stacked VLAN:

1. Specify the interface you want to configure.

```
[edit]  
user@host# edit interfaces interface-name
```

2. Enable stacked VLAN tagging on the interface.

```
[edit interfaces interface-name]
user@host# set stacked-vlan-tagging
```

Setting stacked VLAN tagging enables you to configure dual VLAN tags for all logical interfaces on the physical interface. You must enable stacked VLAN tagging before you can configure the stacked VLAN ranges to which the NAS-Port options definition applies.

3. Specify that you want to configure RADIUS options for a stacked VLAN interface.

```
[edit interfaces interface-name]
user@host# edit radius-options
```

4. Create a named NAS-Port options definition.

```
[edit interfaces interface-name radius-options]
user@host# edit nas-port-options nas-port-options-name
```

5. Configure the NAS-Port-Type.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set nas-port-type port-type
```

6. Configure the stacked VLAN range or ranges to which the NAS-Port options definition applies.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set stacked-vlan-ranges (any | low-outer-tag-high-outer-tag),any
```

Per-stacked VLAN configurations require you to create a stacked VLAN range of subscribers to which the NAS-Port options definition applies. You must configure the low and high outer tags (VLAN IDs) in the range 1 through 4094, and the inner tag (S-VLAN ID) as **any** to represent all S-VLAN ID tags.

7. Repeat Steps 3 through 6 to configure additional NAS-Port options definitions on this interface.

The following example creates two NAS-Port options definitions, subscribers-north and subscribers-south, configured on a per-stacked VLAN basis on Gigabit Ethernet physical interface ge-1/1/0.

The subscribers-north definition configures a NAS-Port-Type user-defined value (4711) for a stacked VLAN range with outer VLAN ID 1 and all inner S-VLAN IDs. The subscribers-south definition configures a NAS-Port-Type user-defined value (4722) for a stacked VLAN range with outer VLAN IDs in the range 2 through 10, and all inner S-VLAN IDs.

```
[edit interfaces ge-2/0/1 radius-options]
nas-port-options subscribers-north {
  nas-port-type 4711;
  stacked-vlan-ranges {
    1-1,any;
  }
}
nas-port-options subscribers-south {
  nas-port-type 4722;
```

```
stacked-vlan-ranges {  
    2-10,any;  
}  
}
```

## Configuring the RADIUS NAS-Port Extended Format per Physical Interface

As an alternative to globally configuring the extended format for the NAS-Port (5) RADIUS attribute in an access profile, you can configure the NAS-Port extended format on a per-physical interface basis as part of a NAS-Port options definition. The NAS-Port extended format configures the number of bits (bit width) in each field in the NAS-Port attribute, including: slot, adapter, port, VLAN, and S-VLAN.

Configuring NAS-Port options definitions on a per-physical interface basis is useful in network configurations that use a 1:1 access model or an N:1 access model.

To configure an extended format for the NAS-Port RADIUS attribute per physical interface:

1. Specify the interface you want to configure.

```
[edit]  
user@host# edit interfaces interface-name
```

2. Enable VLAN tagging on the interface.

```
[edit interfaces interface-name]  
user@host# set vlan-tagging
```

Setting VLAN tagging enables the reception and transmission of 802.1Q VLAN-tagged frames on the interface. You must enable VLAN tagging before you can configure the VLAN ranges to which the NAS-Port options definition applies.

3. Specify that you want to configure RADIUS options for a physical interface.

```
[edit interfaces interface-name]  
user@host# edit radius-options
```

4. Create a named NAS-Port options definition.

```
[edit interfaces interface-name radius-options]  
user@host# edit nas-port-options nas-port-options-name
```

5. Configure the NAS-Port extended format.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set nas-port-extended-format slot-width width adapter-width width
port-width width vlan-width width
```

6. Configure the VLAN range or ranges to which the NAS-Port options definition applies.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set vlan-ranges (any | low-tag-high-tag)
```

Per-physical interface configurations typically require you to create a VLAN range that consists of all VLAN IDs on the physical interface. To do so, use the **any** option with the **vlan-ranges** statement.

The following example shows a per-interface NAS-Port options definition named **boston-subscribers** that configures a NAS-Port extended format consisting of an 8-bit slot field, 8-bit adapter field, 8-bit port field, and 4-bit VLAN field. The **boston-subscribers** definition applies to a VLAN range consisting of all VLAN IDs on Gigabit Ethernet physical interface **ge-2/0/1**.

```
[edit interfaces ge-2/0/1 radius-options]
nas-port-options boston-subscribers {
  nas-port-extended-format {
    slot-width 8;
    adapter-width 8;
    port-width 8;
    vlan-width 4;
  }
  vlan-ranges {
    any;
  }
}
```

## Configuring the RADIUS NAS-Port Extended Format per VLAN

---

As an alternative to globally configuring the extended format for the NAS-Port (5) RADIUS attribute in an access profile, you can configure the NAS-Port extended format on a per-VLAN basis as part of a NAS-Port options definition. The NAS-Port extended format configures the number of bits (bit width) in each field in the NAS-Port attribute, including: slot, adapter, port, VLAN, and S-VLAN.

Configuring NAS-Port options definitions on a per-VLAN basis is useful in network configurations that use a 1:1 access model.

To configure an extended format for the NAS-Port RADIUS attribute per VLAN:

1. Specify the interface you want to configure.

```
[edit]
user@host# edit interfaces interface-name
```

2. Enable VLAN tagging on the interface.

```
[edit interfaces interface-name]
user@host# set vlan-tagging
```

Setting VLAN tagging enables the reception and transmission of 802.1Q VLAN-tagged frames on the interface. You must enable VLAN tagging before you can configure the VLAN ranges to which the NAS-Port options definition applies.

3. Specify that you want to configure RADIUS options for a VLAN interface.

```
[edit interfaces interface-name]
user@host# edit radius-options
```

4. Create a named NAS-Port options definition.

```
[edit interfaces interface-name radius-options]
user@host# edit nas-port-options nas-port-options-name
```

5. Configure the NAS-Port extended format.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set nas-port-extended-format slot-width width adapter-width width
port-width width vlan-width width
```

6. Configure the VLAN range or ranges to which the NAS-Port options definition applies.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]
user@host# set vlan-ranges (any | low-tag-high-tag)
```

Per-VLAN configurations typically require you to create a VLAN range that consists of a single VLAN ID on the physical interface. To do so, set the **low-tag** and **high-tag** options in the **vlan-ranges** statement to the same value, as shown in the following example.

The following example shows a per-VLAN NAS-Port options definition named `paris-subscribers` that configures a NAS-Port extended format consisting of a 4-bit slot field, 2-bit adapter field, 4-bit port field, and 2-bit VLAN field. The `paris-subscribers` definition applies to VLAN ID 1 on Gigabit Ethernet physical interface `ge-1/0/1`.

```
[edit interfaces ge-1/0/1 radius-options]
nas-port-options paris-subscribers {
  nas-port-extended-format {
    slot-width 4;
    adapter-width 2;
    port-width 4;
    vlan-width 2;
  }
  vlan-ranges {
    1-1;
  }
}
```

## Configuring the RADIUS NAS-Port Extended Format per Stacked VLAN

As an alternative to globally configuring the extended format for the NAS-Port (5) RADIUS attribute in an access profile, you can configure the NAS-Port extended format on a per-stacked VLAN basis as part of a NAS-Port options definition. The NAS-Port extended format configures the number of bits (bit width) in each field in the NAS-Port attribute, including: slot, adapter, port, VLAN, and S-VLAN.

Configuring NAS-Port options definitions on a per-stacked VLAN basis is useful in network configurations that use an N:1 access model.

To configure an extended format for the NAS-Port RADIUS attribute per stacked VLAN:

1. Specify the interface you want to configure.

```
[edit]
user@host# edit interfaces interface-name
```

2. Enable stacked VLAN tagging on the interface.

```
[edit interfaces interface-name]
user@host# set stacked-vlan-tagging
```

Setting stacked VLAN tagging enables you to configure dual VLAN tags for all logical interfaces on the physical interface. You must enable stacked VLAN tagging before you can configure the stacked VLAN ranges to which the NAS-Port options definition applies.

3. Specify that you want to configure RADIUS options for a stacked VLAN interface.

```
[edit interfaces interface-name]  
user@host# edit radius-options
```

4. Create a named NAS-Port options definition.

```
[edit interfaces interface-name radius-options]  
user@host# edit nas-port-options nas-port-options-name
```

5. Configure the NAS-Port extended format.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]  
user@host# set nas-port-extended-format slot-width width adapter-width width  
port-width width vlan-width width stacked
```

To include S-VLAN IDs, in addition to VLAN IDs, in the NAS-Port extended format, include the **stacked** option in the **nas-port-extended-format** statement.

6. Configure the stacked VLAN range or ranges to which the NAS-Port options definition applies.

```
[edit interfaces interface-name radius-options nas-port-options nas-port-options-name]  
user@host# set stacked-vlan-ranges (any | low-outer-tag-high-outer-tag),any
```

Per-stacked VLAN configurations require you to create a stacked VLAN range of subscribers to which the NAS-Port options definition applies. You must configure the low and high outer tags (VLAN IDs) in the range 1 through 4094, and the inner tag (S-VLAN ID) as **any** to represent all S-VLAN ID tags.

7. Repeat Steps 3 through 6 to configure additional NAS-Port options definitions on this interface.

The following example creates two NAS-Port options definitions, *chicago-subscribers* and *barcelona-subscribers*, configured on a per-stacked VLAN basis on Gigabit Ethernet physical interface *ge-3/2/1*.

The *chicago-subscribers* definition configures a NAS-Port extended format consisting of a 8-bit slot field, 8-bit adapter field, 8-bit port field, 4-bit stacked VLAN field, and 4-bit VLAN field. Because the **stacked** option is configured in this definition, S-VLAN IDs, in addition to VLAN IDs, are included in the extended format. The *chicago-subscribers* definition applies to a stacked VLAN range with outer VLAN ID 1, and all inner S-VLAN IDs.

The *barcelona-subscribers* definition configures a NAS-Port extended format consisting of a 8-bit slot field, 8-bit adapter field, 8-bit port field, 4-bit stacked VLAN field, and 4-bit VLAN field. Because the **stacked** option is *not* configured in this definition, S-VLAN IDs are not included in the extended format. The *barcelona-subscribers* definition applies to a stacked VLAN range with outer VLAN IDs in the range 2 through 10, and all inner S-VLAN IDs.

```
[edit interfaces ge-3/2/1 radius-options]  
nas-port-options chicago-subscribers {  
  nas-port-extended-format {  
    slot-width 8;  
    adapter-width 8;  
    port-width 8;
```

```
        stacked-vlan-width 4;
        vlan-width 4;
        stacked;
    }
    stacked-vlan-ranges {
        1-1,any;
    }
}
nas-port-options barcelona-subscribers {
    nas-port-extended-format {
        slot-width 8;
        adapter-width 8;
        port-width 8;
        stacked-vlan-width 4;
        vlan-width 4;
    }
    stacked-vlan-ranges {
        2-10,any;
    }
}
```

## Centrally Configured Opaque DHCP Options

---

Subscriber management enables you to centrally configure DHCP options on a RADIUS server and then distribute the options on a per-subscriber basis. This method results in RADIUS-sourced DHCP options—the DHCP options originate at the RADIUS server and are sent to the subscriber. This differs from the traditional client-sourced method (also called DHCP-sourced) of configuring DHCP options, in which the options originate at the client and are sent to the RADIUS server. The subscriber management RADIUS-sourced DHCP options are also considered to be *opaque*, because DHCP local server performs minimal processing and error checking for the DHCP options string before passing the options to the subscriber.

Subscriber management uses Juniper Networks VSA 26-55 (DHCP-Options) to distribute the RADIUS-sourced DHCP options. The RADIUS server includes VSA 26-55 in the Access-Accept message that the server returns during subscriber authentication. The RADIUS server sends the Access-Accept message to the RADIUS client, and then on to DHCP local server for return to the DHCP subscriber. The RADIUS server can include multiple instances of VSA 26-55 in a single Access-Accept message. The RADIUS client concatenates the multiple instances and uses the result as a single instance.

There is no CLI configuration required to enable subscriber management to use the centrally configured DHCP options—the procedure is triggered by the presence of VSA 26-55 in the RADIUS Access-Accept message.

When building the offer packet for the DHCP client, DHCP local server uses the following sequence:

1. Processes any RADIUS-configured parameters that are passed as separate RADIUS attributes; for example, RADIUS attribute 27 (Session Timeout).
2. Processes any client-sourced parameters; for example, RADIUS attributes 53 (DHCP Message Type) and 54 (Server Identifier).
3. Appends (without performing any processing) the opaque DHCP options string contained in the VSA 26-55 received from the RADIUS server.

In addition to supporting central configuration of DHCP options directly on the RADIUS server (RADIUS-sourced options), subscriber management also supports the traditional client-sourced options configuration, in which the router's DHCP component sends the options to the RADIUS server. The client-sourced DHCP options method is supported for both DHCP local server and DHCP relay agent; however, the RADIUS-sourced central configuration method is supported on DHCP local server only. Both the RADIUS-sourced and client-sourced methods support DHCPv4 and DHCPv6 subscribers.

**NOTE:** You can use the RADIUS-sourced and client-sourced methods simultaneously on DHCP local server. However, you must ensure that the central configuration method does not include options that override client-sourced DHCP options, because this can create unpredictable results.

---

- [Data Flow for RADIUS-Sourced DHCP Options on page 73](#)
- [Multiple VSA 26-55 Instances Configuration on page 74](#)
- [DHCP Options That Cannot Be Centrally Configured on page 74](#)

## Data Flow for RADIUS-Sourced DHCP Options

Figure 5 on page 73 shows the procedure subscriber management uses when configuring DHCP options for subscribers.

**Figure 5: DHCP Options Data Flow**

The following general sequence describes the data flow when subscriber management uses RADIUS-sourced DHCP options and VSA 26-55 to configure a DHCP subscriber:

1. The subscriber sends a DHCP discover message (or DHCPv6 solicit message) to the DHCP local server. The message includes client-sourced DHCP options.
2. The DHCP local server initiates authentication with the Junos OS RADIUS client.
3. The RADIUS client sends an Access-Request message on behalf of the subscriber to the external RADIUS server. The message includes the subscriber's client-sourced DHCP options.
4. The external RADIUS server responds by sending an Access-Accept message to the RADIUS client. The Access-Accept message includes the RADIUS-sourced opaque DHCP options in VSA 26-55.
5. The RADIUS client sends the DHCP options string to DHCP local server. If there are multiple VSA 26-55 instances, the RADIUS client first assembles them into a single options string.
6. DHCP local server processes all options into the DHCP offer (or DHCPv6 reply) message, except for the RADIUS-sourced VSA 26-55 DHCP options. After processing all other options, DHCP local server then appends the unmodified VSA 26-55 DHCP options to the message and sends the message to the subscriber.
7. The subscriber is configured with the DHCP options.
8. The following operations occur after the subscriber receives the DHCP options:

- **Accounting**—The RADIUS client sends Acct-Start and Interim-Accounting requests to the RADIUS server, including the RADIUS-sourced DHCP options in VSA 26-55. By default, the DHCP options are included in accounting requests.
- **Renewal**—When the subscriber renews, the cached DHCP options value is returned in the DHCP renew (or DHCPv6 ACK) message. The originally assigned DHCP options cannot be modified during a renew cycle.
- **Logout**—When the subscriber logs out, the RADIUS client sends an Acct-Stop message to the RADIUS server, including the RADIUS-sourced VSA 26-55.

## Multiple VSA 26-55 Instances Configuration

VSA 26-55 supports a maximum size of 247 bytes. If your RADIUS-sourced DHCP options field is greater than 247 bytes, you must break the field up and manually configure multiple instances of VSA 26-55 for the RADIUS server to return. When using multiple instances for an options field, you must place the instances in the packet in the order in which the fragments are to be reassembled by the RADIUS client. The fragments can be of any size of 247 bytes or less.

**BEST PRACTICE:** For ease of configuration and management of your DHCP options, you might want to have one DHCP option per VSA 26-55 instance, regardless of the size of the option field.

When the RADIUS client returns a reassembled opaque options field in an accounting request to the RADIUS server, the client uses 247-byte fragments. If you had originally created instances of fewer than 247 bytes, the returned fragments might not be the same as you originally configured on the RADIUS server.

**NOTE:** If you are configuring Steel-Belted Radius (SBR) to support multiple VSA 26-55 instances, ensure that you specify VSA 26-55 with the RO flags in the Subscriber Management RADIUS dictionary file. The R value indicates a multivalued reply attribute and the O value indicates an ordered attribute.

## DHCP Options That Cannot Be Centrally Configured

Table 10 on page 74 shows the DHCP options that you must not centrally configure on the RADIUS server.

**Table 10: Unsupported Opaque DHCP Options**

DHCP Option	Option Name	Comments
Option 0	Pad Option	Not supported.
Option 51	IP Address Lease Time	Value is provided by RADIUS attribute 27 (Session-Timeout).
Option 52	Option Overload	Not supported.

Table 10: Unsupported Opaque DHCP Options (*continued*)

DHCP Option	Option Name	Comments
Option 53	DHCP Message Type	Value is provided by DHCP local server.
Option 54	Server Identifier	Value is provided by DHCP local server.
Option 55	Parameter Request List	Value is provided by DHCP local server.
Option 255	End	Value is provided by DHCP local server.
–	DHCP magic cookie	Not supported.

## Monitoring DHCP Options Configured on RADIUS Servers

**Purpose** View information for DHCP options that are centrally configured on a RADIUS server and that are distributed using Juniper Networks VSA 26–55 (DHCP-Options).

**Action** To display information for opaque DHCP options:

```

user@host> show subscribers detail
Type: DHCP
IP Address: 192.168.9.7
IP Netmask: 255.255.0.0
Logical System: default
Routing Instance: default
Interface: demux0.1073744127
Interface type: Dynamic
Dynamic Profile Name: dhcp-prof-23
MAC Address: 00:10:95:00:00:98
State: Active
Radius Accounting ID: jnpr :2304
Session Timeout (seconds): 3600
Idle Timeout (seconds): 600
Login Time: 2011-08-25 14:43:52 PDT
DHCP Options: len 52
35 01 01 39 02 02 40 3d 07 01 00 10 94 00 00 08 33 04 00 00
00 3c 0c 15 63 6c 69 65 6e 74 5f 50 6f 72 74 20 2f 2f 36 2f
33 2d 37 2d 30 37 05 01 06 0f 21 2c

```

**Meaning** DHCP Options: len 52  
 35 01 01 39 02 02 40 3d 07 01 00 10 94 00 00 08 33 04 00 00  
 00 3c 0c 15 63 6c 69 65 6e 74 5f 50 6f 72 74 20 2f 2f 36 2f  
 33 2d 37 2d 30 37 05 01 06 0f 21 2c

The DHCP options output provides the following information:

- The **len** field is the total number of hex values in the message.
- The hex values specify the type, length, and value (TLV) of DHCP options, and are converted to decimal to identify the DHCP options, as defined in RFC 2132.

The number of hex values that make up a particular DHCP option varies, depending on the length of the option. For example, the first DHCP option specified in the output includes three sets of hex values (**35 01 01**). The first hex value (**35**) identifies the option type, the second value (**01**) indicates the length of the value entry, which in this case is one set of hex values. The third hex value (**01**) specifies the value for the DHCP option.

In the second DHCP option specification (**39 02 02 40**), the hex value **39** is the type, and the length of **02** specifies that two sets of hex entries make up the value for the option. Therefore, this option specification uses four sets of hex entries; one for the type (**39**), one to specify the length (**02**), and two for the option value (**02 40**).

The third DHCP option is specified by the hex values **3d 07 01 00 10 94 00 00 08**. The hex value **3d** is the type, followed by the length (**07**), which specifies that the next seven sets of hex entries make up the value for the option. Therefore, this option specification uses a total of nine sets of hex entries; one for the type (**3d**), one to specify the length (**07**), and seven for the value of the DHCP option (**01 00 10 94 00 00 08**).

[Table 11 on page 76](#) describes the first two options in more detail.

**Table 11: DHCP Options Description**

Option	Type	Length	Value
35 01 01	35 = decimal 53 (Code 53 in RFC 2132 is the DHCP Message Type option)	01 = the length of the option is one set of hex values (the next set in the list)	01 = value of the message type that is described in RFC 2132. The code 01 specifies a message type of DHCPDISCOVER.
39 02 02 40	39 = decimal 57 (Code 57 is the Maximum DHCP Message Size option)	02 = the length of the option is two sets of hex values (the next two sets in the list)	0240 = converted to a length of 576 octets

## Using RADIUS Dynamic Requests for Subscriber Access Management

---

RADIUS dynamic requests provide an efficient way to centrally manage subscriber sessions. The AAA Service Framework's RADIUS dynamic request support allows RADIUS servers to initiate user-related operations, such as a termination operation, by sending unsolicited request messages to the router. Without the RADIUS dynamic request feature, the only way to disconnect a RADIUS user is from the router, which can be cumbersome and time-consuming in large networks.

In a typical client-server RADIUS environment, the router functions as the client and initiates requests sent to the remote RADIUS server. However, when using RADIUS dynamic requests, the roles are reversed. For example, during a disconnect operation, the remote RADIUS server performs as the client and initiates the request (the disconnect action) — the router functions as the server in the relationship.

You create an access profile to configure the router to support RADIUS dynamic requests. This configuration enables the router to receive and act on the following types of messages from remote RADIUS servers:

- Access-Accept messages—Dynamically activate services based on attributes in RADIUS Access-Accept messages received when a subscriber logs in.
- Change-of-Authorization (CoA) messages—Dynamically modify active sessions based on attributes in CoA messages. CoA messages can include service creation requests, deletion requests, RADIUS attributes, and Juniper Networks VSAs.
- Disconnect messages—Immediately terminate specific subscriber sessions.

## Dynamic Service Activation During Login Overview

---

The AAA Service Framework enables the router to dynamically activate subscriber services as part of a subscriber login operation.

The framework sets up the subscriber session and then completes the service action specified by the Juniper Networks VSA 26–65 that is received in the Access-Accept message. If the service request is unsuccessful, the framework logs out the subscriber.

- [Configuring RADIUS-Initiated Dynamic Request Support on page 81](#)
- [RADIUS-Initiated Disconnect Overview on page 79](#)

## RADIUS-Initiated Change of Authorization (CoA) Overview

---

The AAA Service Framework uses CoA messages to dynamically modify active subscriber sessions. For example, RADIUS attributes in CoA messages might instruct the framework to create, modify, or terminate a subscriber service.

### CoA Messages

Dynamic request support enables the router to receive and process unsolicited CoA messages from external RADIUS servers. RADIUS-initiated CoA messages use the following codes in request and response messages:

- CoA-Request (43)
- CoA-ACK (44)
- CoA-NAK (45)

### Qualifications for Change of Authorization

To complete the change of authorization for a user, you specify identification attributes and session attributes. The identification attributes identify the subscriber. Session attributes specify the operation (activation or deactivation) to perform on the subscriber's session and also include any client attributes for the session (for example, QoS attributes). The AAA Service Framework handles the actual request.

[Table 12 on page 78](#) shows the identification attributes for CoA operations.

**NOTE:** Using the Acct-Session-ID attribute to identify the subscriber session is more explicit than using the User-Name attribute. When you use the Acct-Session-ID, the attribute identifies the specific subscriber and session. When you use the User-Name as the identifier, the CoA operation is applied to the first session that was logged in with the specified username. However, because a subscriber might have multiple sessions associated with the same username, the first session might not be the correct session for the CoA operation.

---

**Table 12: Identification Attributes**

Attribute	Description
User-Name [RADIUS attribute 1]	Subscriber username.
Acct-Session-ID [RADIUS attribute 44]	Specific subscriber and session.

Table 13 on page 79 shows the session attributes for CoA operations. Any additional client attributes that you include depend on your particular session requirements.

**Table 13: Session Attributes**

Attribute	Description
Activate-Service [Juniper Networks VSA 26–65]	Service to activate for the subscriber.
Deactivate-Service [Juniper Networks VSA 26–66]	Service to deactivate for the subscriber.

## Message Exchange

The RADIUS server and the AAA Service Framework on the router exchange messages using UDP. The CoA-Request message sent by the RADIUS server has the same format as the Disconnect-Request packet that is sent for a disconnect operation.

The response is either a CoA-ACK or a CoA-NAK message:

- If the AAA Service Framework successfully changes the authorization, the response is a RADIUS-formatted packet with a CoA-ACK message, and the data filter is applied to the session.
- If AAA Service Framework is unsuccessful, the request is malformed, or attributes are missing, the response is a RADIUS-formatted packet with a CoA-NAK message.

**NOTE:** The AAA Service Framework processes one dynamic request at a time per subscriber. If the framework receives a second dynamic request (either another CoA or a Disconnect-Request) while processing a previous request for the same subscriber, the framework responds with a CoA-NAK message.

### Related Documentation

- [Dynamic Service Activation During Login Overview on page 77](#)
- [RADIUS-Initiated Disconnect Overview on page 79](#)
- [Configuring RADIUS-Initiated Dynamic Request Support on page 81](#)

## RADIUS-Initiated Disconnect Overview

This section describes the AAA Service Framework's support for RADIUS-initiated disconnect dynamic requests. The AAA Service Framework uses disconnect messages to dynamically terminate active subscriber sessions.

## Disconnect Messages

To centrally control the disconnection of remote access subscribers, the RADIUS dynamic request feature on the router receives and processes unsolicited messages from RADIUS servers.

The dynamic request feature uses the existing format of RADIUS disconnect request and response messages. RADIUS-initiated disconnect uses the following codes in its RADIUS request and response messages:

- Disconnect-Request (40)
- Disconnect-ACK (41)
- Disconnect-NAK (42)

## Qualifications for Disconnect

For the AAA Service Framework to disconnect a user, the Disconnect-Request message must contain an attribute with an accounting session ID. The Disconnect-Request message can contain an Acct-Session-Id (44) attribute or an Acct-Multi-Session-Id (50) attribute for the session ID or both. If both the Acct-Session-Id and Acct-Multi-Session-Id attributes are present in the request, the router uses both attributes. If the User-Name (1) attribute is also present in the request, the username and accounting session ID are used to perform the disconnection. The AAA Service Framework handles the actual request.

## Message Exchange

The RADIUS server and the AAA Service Framework exchange messages using UDP. The Disconnect-Request message sent by the RADIUS server has the same format as the CoA-Request packet that is sent for a change of authorization operation.

The disconnect response is either a Disconnect-ACK or a Disconnect-NAK message:

- If the AAA Service Framework successfully disconnects the user, the response is a RADIUS-formatted packet with a Disconnect-ACK message.
- If the AAA Service Framework cannot disconnect the user, the request is malformed, or attributes are missing from the request, the response is a RADIUS-formatted packet with a Disconnect-NAK message.

**NOTE:** The AAA Service Framework processes one dynamic request at a time per subscriber. If the framework receives a second dynamic request while processing a previous request (either a CoA or another Disconnect-Request) for the same subscriber, the framework responds with a Disconnect-NAK message.

## Configuring RADIUS-Initiated Dynamic Request Support

The router uses the list of specified RADIUS authentication servers for both authentication and dynamic request operations. The router listens on UDP port 3799 for dynamic requests.

To configure RADIUS dynamic request support:

- Specify the IP address of the RADIUS server.  

```
[edit access profile isp-bos-metro-fiber-basic radius]  
user@host# set authentication-server 192.168.1.3
```

To configure the router to support dynamic requests from more than one RADIUS server:

- Specify the IP addresses of multiple RADIUS servers.  

```
[edit access profile isp-bos-metro-fiber-basic radius]  
user@host# set authentication-server 192.168.1.3 192.168.10.15
```

## RADIUS Attributes and Juniper Networks VSAs Supported by the AAA Service Framework

The AAA Service Framework supports RADIUS attributes and vendor-specific attributes (VSAs). This support provides tunable parameters that the subscriber access management feature uses when creating subscribers and services.

RADIUS attributes are carried as part of standard RADIUS request and reply messages. The subscriber management access feature uses the RADIUS attributes to exchange specific authentication, authorization, and accounting information. VSAs allow the subscriber access management feature to pass implementation-specific information that provide extended capabilities, such as service activation or deactivation, and enabling and disabling filters.

When you use dynamic profiles, the AAA Service Framework supports the use of Junos OS predefined variables to specify the RADIUS attribute or VSA for the information obtained from the RADIUS server.

## RADIUS IETF Attributes Supported by the AAA Service Framework

Table 14 on page 82 describes the RADIUS IETF attributes that the Junos OS AAA Service Framework supports.

**NOTE:** A “Yes” entry in the Dynamic CoA Support column indicates that the attribute can be dynamically configured by Access-Accept messages and dynamically modified by CoA-Request messages.

**Table 14: Supported RADIUS IETF Attributes**

Attribute Number	Attribute Name	Description	Dynamic CoA Support
1	User-Name	<ul style="list-style-type: none"> <li>• Name of user to be authenticated.</li> <li>• Configurable username override.</li> </ul>	No
2	User-Password	<ul style="list-style-type: none"> <li>• Password of user to be authenticated by Password Authentication Protocol (PAP).</li> <li>• Configurable password override.</li> </ul>	No
4	NAS-IP-Address	IP address of the network access server (NAS) that is requesting authentication of the user.	No

Table 14: Supported RADIUS IETF Attributes (*continued*)

Attribute Number	Attribute Name	Description	Dynamic CoA Support
5	NAS-Port	Physical port number of the NAS that is authenticating the user.  For a tunneled PPP user in an L2TP LNS session, there is no physical port. In this case, the port value is reported as 4194303.	No
6	Service-Type	Type of service the user has requested or the type of service to be provided.	No
8	Framed-IP-Address	<ul style="list-style-type: none"> <li>IP address to be configured for the user.</li> <li>0.0.0.0 or absence is interpreted as 255.255.255.254.</li> </ul>	No
9	Framed-IP-Netmask	<ul style="list-style-type: none"> <li>IP network to be configured for the user when the user is a router or switch to a network.</li> <li>Absence implies 255.255.255.255.</li> </ul>	No
11	Filter-ID	<ul style="list-style-type: none"> <li>Name of the filter list for the user.</li> <li>Interpreted as input policy name.</li> </ul>	Yes
18	Reply-Message	<ul style="list-style-type: none"> <li>Text that may be displayed to the user.</li> <li>Only the first instance of this attribute is used.</li> </ul>	No
22	Framed-Route	String that provides routing information to be configured for the user on the NAS in the format:  <b>&lt;addr&gt;[/&lt;maskLen&gt;] [&lt;nexthop&gt; [&lt;cost&gt;]] [tag &lt;tagValue&gt;] [distance &lt;distValue&gt;]</b>	Yes
25	Class	Arbitrary value that the NAS includes in all accounting packets for the user if supplied by the RADIUS server.	No
27	Session-Timeout	Maximum number of consecutive seconds of service to be provided to the user before termination of the session.	No
31	Calling-Station-ID	Phone number from which the call originated.	No
32	NAS-Identifier	NAS originating the request.	No

Table 14: Supported RADIUS IETF Attributes (*continued*)

Attribute Number	Attribute Name	Description	Dynamic CoA Support
40	Acct-Status-Type	Whether this Accounting-Request marks the beginning of the user service (Start), the end (Stop), or the interim (Interim-Update).	No
41	Acct-Delay-Time	Number of seconds the client has been trying to send a particular record.	No
42	Acct-Input-Octets	Number of octets that have been received from the port during the time this service has been provided.	No
43	Acct-Output-Octets	Number of octets that have been sent to the port during the time this service has been provided.	No
44	Acct-Session-ID	<p>Unique accounting identifier that makes it easy to match start and stop records in a log file. The identifier can be in one of the following formats:</p> <ul style="list-style-type: none"> <li><b>decimal</b>—For example, <b>435264</b></li> <li><b>description</b>—In the generic format, <b>jnpr interface-specifier:subscriber-session-id</b>; For example, <b>jnpr fastEthernet 3/2.6:1010101010101</b></li> </ul>	No
45	Acct-Authentic	Method by which user was authentication: whether by RADIUS, the NAS itself, or another remote authentication protocol.	No
46	Acct-Session-Time	Number of seconds that the user has received service	No
47	Acct-Input-Packets	Number of packets that have been received from the port during the time this service has been provided to a framed user.	No
48	Acct-Output-Packets	Number of packets that have been sent to the port in the course of delivering this service to a framed user.	No

Table 14: Supported RADIUS IETF Attributes (*continued*)

Attribute Number	Attribute Name	Description	Dynamic CoA Support
49	Acct-Terminate-Cause	Reason the service (a PPP session) was terminated. The service can be terminated for the following reasons: <ul style="list-style-type: none"> <li>• User Request (1)—User initiated the disconnect (log out).</li> <li>• Idle Timeout (4)—Idle timer has expired.</li> <li>• Session Timeout (5)—Client reached the maximum continuous time allowed on the service or session.</li> <li>• Admin Reset (6)—System administrator terminated the session.</li> <li>• Port Error (8)—PVC failed; no hardware or no interface.</li> <li>• NAS Error (9)—Negotiation failures, connection failures, or address lease expiration.</li> <li>• NAS Request (10)—PPP challenge timeout, PPP request timeout, tunnel establishment failure, PPP bundle failure, IP address lease expiration, PPP keep-alive failure, tunnel disconnect, or an unaccounted-for error.</li> </ul>	No
52	Acct-Input-Gigawords	Number of times the Acct-Input-Octets counter has wrapped around $2^{32}$ during the time this service has been provided. Can be present in Accounting-Request records only where the Acct-Status-Type is set to Stop or Interim-Update.	No
53	Acct-Output-Gigawords	Number of times the Acct-Output-Octets counter has wrapped around $2^{32}$ in the course of delivering this service. Can be present in Accounting-Request records only where the Acct-Status-Type is set to Stop or Interim-Update.	No
55	Event-Timestamp	Time that this event occurred on the NAS, in seconds, since January 1, 1970 00:00 UTC.	No
61	NAS-Port-Type	Type of physical port the NAS is using to authenticate the user.  For a tunneled PPP user in an L2TP LNS session, there is no physical port. In this case, the port type is <b>Virtual</b> .	No

Table 14: Supported RADIUS IETF Attributes (*continued*)

Attribute Number	Attribute Name	Description	Dynamic CoA Support
64	Tunnel-Type	<ul style="list-style-type: none"> <li>Tunneling protocol to use (in the case of a tunnel initiator) or the tunneling protocol already in use (in the case of a tunnel terminator).</li> <li>Only L2TP tunnels are currently supported.</li> </ul>	No
65	Tunnel-Medium-Type	<ul style="list-style-type: none"> <li>Transport medium to use when creating a tunnel for protocols that can operate over multiple transports.</li> <li>Only IPv4 is currently supported.</li> </ul>	No
66	Tunnel-Client-Endpoint	Address of the initiator end of the tunnel (LAC).	No
67	Tunnel-Server-Endpoint	Address of the server end of the tunnel (LNS).	No
69	Tunnel-Password	Encrypted password used to authenticate to a remote server. Recommended over using VSA Tunnel-Password [26-9] because of the encryption. Do not use both this attribute and the VSA.	No
82	Tunnel-Assignment -Id	Tunnel to which a session is assigned. When user profiles share the same values for Tunnel-Assignment-Id, Tunnel-Server-Endpoint, and Tunnel-Type, the LAC can group these users into the same tunnel. This grouping enables fewer tunnels to be created. (LAC)	No
83	Tunnel-Preference	<ul style="list-style-type: none"> <li>Included in each set of tunneling attributes to indicate the relative preference assigned to each tunnel when more than one set of tunneling attributes is returned by the RADIUS server to the tunnel initiator.</li> <li>Included in the Tunnel-Link-Start, the Tunnel-Link-Reject, and the Tunnel-Link-Stop packets (LAC only).</li> </ul>	No

Table 14: Supported RADIUS IETF Attributes (*continued*)

Attribute Number	Attribute Name	Description	Dynamic CoA Support
85	Acct-Interim-Interval	<p>Number of seconds between each interim accounting update for this session.</p> <p>The router uses the following guidelines for interim accounting:</p> <ul style="list-style-type: none"> <li>Attribute value is within the acceptable range (from 600 through 86,400 seconds)—Accounting is updated at the specified interval.</li> <li>Attribute value of 0—No RADIUS accounting is performed.</li> <li>Attribute value is less than the minimum acceptable value—Accounting is updated at the minimum interval (600 seconds).</li> <li>Attribute value is greater than the maximum acceptable value—Accounting is updated at the maximum interval (86,400 seconds).</li> </ul> <p><b>NOTE:</b> Values are rounded up to the next higher multiple of 10 minutes. For example, a setting of 900 seconds (15 minutes) is rounded up to 20 minutes (1200 seconds).</p>	No
87	NAS-Port-Id	<p>Text string that identifies the physical interface of the NAS that is authenticating the user.</p> <p>For a tunneled PPP user in an L2TP LNS session, there is no physical port, and the NAS-Port-Id value has the following format:</p> <p><i>media:local address:peer address: local tunnel id:peer tunnel id: local session id:peer session id: call serial number.</i> For example, lp:172.20.0.1:192.168.0.2: 3341:21031:16138:11846:2431.</p> <p>The local information refers to the LNS and the peer information refers to the LAC.</p>	No
88	Framed-Pool	Name of an assigned address pool to use to assign an address for the user.	No
90	Tunnel-Client-Auth-Id	Name of the tunnel initiator (LAC) used during the authentication phase of tunnel establishment.	No

Table 14: Supported RADIUS IETF Attributes (*continued*)

Attribute Number	Attribute Name	Description	Dynamic CoA Support
91	Tunnel-Server-Auth-Id	Name of the tunnel terminator (LNS) used during the authentication phase of tunnel establishment.	No
95	NAS-IPv6-Address	Address of the NAS that is requesting authentication of the user.	No
96	Framed-Interface-ID	Interface identifier that is configured for the user.	No
97	Framed-IPv6-Prefix	IPv6 prefix and address that are configured for the user. Prefix lengths of 128 are associated with host addresses. Prefix lengths less than 128 are associated with NDRA prefixes.	No
98	Login-IPv6-Host	System the user connects to when the Login-Service attribute is included.	No
99	Framed-IPv6-Route	IPv6 routing information that is configured for the user.	Yes
100	Framed-IPv6-Pool	Name of the assigned pool used to assign the address and IPv6 prefix for the user.	No
123	Delegated-IPv6-Prefix	IPv6 prefix that is delegated to the user.	No
242	Ascend-Data-Filter	Binary data that specifies RADIUS policy definitions.	Yes

## Juniper Networks VSAs Supported by the AAA Service Framework

Table 15 on page 89 describes Juniper Networks VSAs supported by the Junos OS AAA Service Framework. The AAA Service Framework uses vendor ID 4874, which is assigned to Juniper Networks by the Internet Assigned Numbers Authority (IANA).

**NOTE:** A “Yes” entry in the Dynamic CoA Support column indicates that the attribute can be dynamically configured by Access-Accept messages and dynamically modified by CoA-Request messages.

Table 15: Supported Juniper Networks VSAs

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-1	Virtual-Router	<p>Client logical system:routing instance name. Allowed only from AAA server for “default” logical system:routing instance.</p> <p>When this VSA is not included in the subscriber profile, the routing instance assigned to the subscriber—the one in which the subscriber session comes up—varies by subscriber type.</p> <p>For DHCP and PPPoE subscribers, it is the default routing instance.</p> <p>For L2TP tunnel subscribers, it is the routing instance in which the tunnel resides, whether default or non-default. If the tunnel routing instance is not default and you want the L2TP session to be in the default routing instance, you must use the Virtual-Router VSA to set the desired routing instance.</p>	string: <i>logical system:routing instance</i>	No
26-4	Primary-DNS	Client DNS address negotiated during IPCP.	integer: 4-byte <i>primary-dns-address</i>	No
26-5	Secondary-DNS	Client DNS address negotiated during IPCP	integer: 4-byte <i>secondary-dns-address</i>	No
26-6	Primary-WINS	Client WINS (NBNS) address negotiated during IPCP.	integer: 4-byte <i>primary-wins-address</i>	No
26-7	Secondary-WINS	Client WINS (NBNS) address negotiated during IPCP.	integer: 4-byte <i>secondary-wins-address</i>	No
26-8	Tunnel-Virtual-Router	Virtual router name for tunnel connection.	string: <i>tunnel-virtual-router</i>	No
26-9	Tunnel-Password	<p>Tunnel password in cleartext.</p> <p>Do not use both this VSA and the standard RADIUS attribute Tunnel-Password [69]. The standard attribute is recommended because the password is encrypted when that attribute is used.</p>	string: <i>tunnel-password</i>	No
26-10	Ingress-Policy-Name	Input policy name to apply to client interface.	string: <i>input-policy-name</i>	Yes

Table 15: Supported Juniper Networks VSAs (*continued*)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-11	Egress-Policy-Name	Output policy name to apply to client interface.	string: <i>output-policy-name</i>	Yes
26-23	IGMP-Enable	Whether IGMP is enabled or disabled on a client interface.	integer: <ul style="list-style-type: none"> <li>0=disable</li> <li>1=enable</li> </ul>	Yes
26-25	Redirect-VRouter-Name	Client logical system:routing instance name indicating to which logical system:routing instance the request is redirected for user authentication.	string: <i>logical-system:routing-instance</i>	No
26-33	Tunnel-Max-Sessions	Maximum number of sessions allowed in a tunnel.	integer: 4-octet	No
26-34	Framed-IP-Route-Tag	Route tag to apply to returned framed-ip-address.	integer: 4-octet	No
26-42	Input-Gigapackets	Number of times the input-packets attribute rolls over its 4-octet field.	Integer	No
26-43	Output-Gigapackets	Number of times the output-packets attribute rolls over its 4-octet field.	Integer	No
26-47	Ipv6-Primary-DNS	Client primary IPv6 DNS address negotiated by DHCP.	hexadecimal string: <i>ipv6-primary-dns-address</i>	No
26-48	Ipv6-Secondary-DNS	Client secondary IPv6 DNS address negotiated by DHCP.	hexadecimal string: <i>ipv6-secondary-dns-address</i>	No
26-55	DHCP-Options	Client DHCP options.	string: <i>dhcp-options</i>	No
26-56	DHCP-MAC-Address	Client MAC address.	string: <i>mac-address</i>	No
26-57	DHCP-GI-Address	DHCP relay agent IP address.	integer: 4-octet	No
26-58	LI-Action	Traffic mirroring action.  For dynamic CoA, VSA 26-58 changes the action on the mirrored traffic identified by VSA 26-59.	Salt-encrypted integer  0=stop mirroring 1=start mirroring  2=no action	Yes (together with 26-59)

Table 15: Supported Juniper Networks VSAs (*continued*)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-59	Med-Dev-Handle	Identifier that associates mirrored traffic to a specific subscriber.  For dynamic CoA, VSA 26-58 changes the action on the mirrored traffic identified by VSA 26-59.	Salt-encrypted string	Yes (together with 26-58)
26-60	Med-Ip-Address	IP address of content destination device to which mirrored traffic is forwarded.	Salt-encrypted IP address	No
26-61	Med-Port-Number	UDP port in the content destination device to which mirrored traffic is forwarded.	Salt-encrypted integer	No
26-63	Interface-Desc	Text string that identifies the subscriber's access interface.	string: <i>interface-description</i>	No
26-64	Tunnel-Group	Name of the tunnel group (profile) assigned to a domain map.	string: <i>tunnel-group-name</i>	No
26-65	Activate-Service	Service to activate for the subscriber. Tagged VSA, which supports 8 tags (1-8).	string: <i>service-name</i>	Yes
26-66	Deactivate-Service	Service to deactivate for the subscriber.	string: <i>service-name</i>	No
26-69	Service-Statistics	Whether statistics for the service is enabled or disabled. Tagged VSA, which supports 8 tags (1-8).	<ul style="list-style-type: none"> <li>• 0 = disable</li> <li>• 1 = enable time statistics</li> <li>• 2 = enable time and volume statistics</li> </ul>	Yes
26-71	IGMP-Access-Name	Access list to use for the group (G) filter.	string: 32-octet	Yes
26-72	IGMP-Access-Src-Name	Access list to use for the source-group (S,G) filter.	string: 32-octet	Yes
26-74	MLD-Access-Name	Access list to use for the group (G) filter.	string: 32-octet	Yes
26-75	MLD-Access-Src-Name	Access list to use for the source-group (S,G) filter.	string: 32-octet	Yes
26-77	MLD-Version	MLD protocol version.	integer: 1-octet  <ul style="list-style-type: none"> <li>• 1=MLD version 1</li> <li>• 2=MLD version 2</li> </ul>	Yes

Table 15: Supported Juniper Networks VSAs (*continued*)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-78	IGMP-Version	IGMP protocol version.	integer: 1-octet <ul style="list-style-type: none"> <li>1=IGMP version 1</li> <li>2=IGMP version 2</li> <li>3=IGMP version 3</li> </ul>	Yes
26-83	Service-Session	Name of the service.	string: <i>service-name</i>	No
26-84	Mobile-IP-Algorithm	Authentication algorithm used for Mobile IP registration.	integer: 4-octet	No
26-85	Mobile-IP-SPI	Security parameter index number for Mobile IP registration.	integer: 4-octet	No
26-86	Mobile-IP-Key	Security association MD5 key for Mobile IP registration.	string: key	No
26-87	Mobile-IP-Replay	Replay timestamp for Mobile IP registration.	integer: 4-octet	No
26-89	Mobile-IP-Lifetime	Registration lifetime for Mobile IP registration.	integer: 4-octet	No
26-92	L2C-Up-Stream-Data	Actual upstream rate access loop parameter (ASCII encoded) as defined in GSMP extensions for layer2 control (L2C) Topology Discovery and Line Configuration.	string: actual upstream rate access loop parameter (ASCII encoded)	
26-93	L2C-Down-Stream-Data	Actual downstream rate access loop parameter (ASCII encoded) as defined in GSMP extensions for layer2 control (L2C) Topology Discovery and Line Configuration.	string: actual downstream rate access loop parameter (ASCII encoded)	
26-97	IGMP-Immediate-Leave	IGMP Immediate Leave.	integer: 4-octet <ul style="list-style-type: none"> <li>0=disable</li> <li>1=enable</li> </ul>	Yes
26-100	MLD-Immediate-Leave	MLD Immediate Leave.	integer: 4-octet <ul style="list-style-type: none"> <li>0=disable</li> <li>1=enable</li> </ul>	Yes
26-106	IPv6-Ingress-Policy-Name	Input policy name to apply to a user IPv6 interface.	string: <i>policy-name</i>	Yes

Table 15: Supported Juniper Networks VSAs (*continued*)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-107	IPv6-Egress-Policy-Name	Output policy name to apply to a user IPv6 interface.	string: <i>policy-name</i>	Yes
26-108	CoS-Traffic-Control-Profile-Parameter-Type	<p>CoS traffic-shaping parameter type and description:</p> <ul style="list-style-type: none"> <li>• <b>T01:</b> Scheduler-map name</li> <li>• <b>T02:</b> Shaping rate</li> <li>• <b>T03:</b> Guaranteed rate</li> <li>• <b>T04:</b> Delay-buffer rate</li> <li>• <b>T05:</b> Excess rate</li> <li>• <b>T06:</b> Traffic-control profile</li> <li>• <b>T07:</b> Shaping mode</li> <li>• <b>T08:</b> Byte adjust</li> <li>• <b>T09:</b> Adjust minimum</li> <li>• <b>T10:</b> Excess-rate high</li> <li>• <b>T11:</b> Excess-rate low</li> <li>• <b>T12:</b> Shaping rate burst</li> <li>• <b>T13:</b> Guaranteed rate burst</li> </ul>	<p>Two parts, delimited by white space:</p> <ul style="list-style-type: none"> <li>• Parameter type</li> <li>• Parameter value</li> </ul> <p>Examples:</p> <ul style="list-style-type: none"> <li>• <b>T01 smap_basic</b></li> <li>• <b>T02 50m</b></li> <li>• <b>T03 1m</b></li> <li>• <b>T04 2000</b></li> <li>• <b>T05 200</b></li> <li>• <b>T06 tcp-gold</b></li> <li>• <b>T07 frame-mode</b></li> <li>• <b>T08 50</b></li> </ul>	Yes
26-109	DHCP-Guided-Relay-Server	IP address of DHCP server that DHCP relay agent uses to forward the discover PDUs.	integer: 4-byte <i>ip-address</i>	No
26-110	Acc-Loop-Cir-Id	Identification of the subscriber node connection to the access node.	string: up to 63 ASCII characters	
26-111	Acc-Aggr-Cir-Id-Bin	Unique identification of the DSL line.	integer: 8-octet	
26-112	Acc-Aggr-Cir-Id-Asc	<p>Identification of the uplink on the access node, as in the following examples:</p> <ul style="list-style-type: none"> <li>• Ethernet access aggregation—<b>ethernet slot/port [inner-vlan-id] [outer-vlan-id]</b></li> <li>• ATM aggregation—<b>atm slot/port:vpi.vci</b></li> </ul>	string: up to 63 ASCII characters	
26-113	Act-Data-Rate-Up	Actual upstream data rate of the subscriber's synchronized DSL link.	integer: 4-octet	
26-114	Act-Data-Rate-Dn	Actual downstream data rate of the subscriber's synchronized DSL link.	integer: 4-octet	
26-115	Min-Data-Rate-Up	Minimum upstream data rate configured for the subscriber.	integer: 4-octet	

Table 15: Supported Juniper Networks VSAs (*continued*)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26–116	Min-Data-Rate-Dn	Minimum downstream data rate configured for the subscriber.	integer: 4-octet	
26–117	Att-Data-Rate-Up	Maximum upstream data rate that the subscriber can attain.	integer: 4-octet	
26–118	Att-Data-Rate-Dn	Maximum downstream data rate that the subscriber can attain.	integer: 4-octet	
26–119	Max-Data-Rate-Up	Maximum upstream data rate configured for the subscriber.	integer: 4-octet	
26–120	Max-Data-Rate-Dn	Maximum downstream data rate configured for the subscriber.	integer: 4-octet	
26–121	Min-LP-Data-Rate-Up	Minimum upstream data rate in low power state configured for the subscriber.	integer: 4-octet	
26–122	Min-LP-Data-Rate-Dn	Minimum downstream data rate in low power state configured for the subscriber.	integer: 4-octet	
26–123	Max-Interlv-Delay-Up	Maximum one-way upstream interleaving delay configured for the subscriber.	integer: 4-octet	
26–124	Act-Interlv-Delay-Up	Subscriber's actual one-way upstream interleaving delay..	integer: 4-octet	
26–125	Max-Interlv-Delay-Dn	Maximum one-way downstream interleaving delay configured for the subscriber.	integer: 4-octet	
26–126	Act-Interlv-Delay-Dn	Subscriber's actual one-way downstream interleaving delay.	integer: 4-octet	
26–127	DSL-Line-State	State of the DSL line.	integer: 4-octet <ul style="list-style-type: none"> <li>• 1 = Show uptime</li> <li>• 2 = Idle</li> <li>• 3 = Silent</li> </ul>	
26–128	DSL-Type	Encapsulation used by the subscriber associated with the DSLAM interface from which requests are initiated.		

Table 15: Supported Juniper Networks VSAs (*continued*)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-130	Qos-Set-Name	Interface set to apply to the dynamic profile.	string: <i>interface-set-name</i>	No
26-140	Service-Interim-Acct-Interval	Amount of time between interim accounting updates for this service. Tagged VSA, which supports 8 tags (1-8).	<ul style="list-style-type: none"> <li>range = 600 through 86400 seconds</li> <li>0 = disabled</li> </ul> <p><b>NOTE:</b> Values are rounded up to the next higher multiple of 10 minutes. For example, a setting of 900 seconds (15 minutes) is rounded up to 20 minutes (1200 seconds).</p>	Yes
26-141	Downstream-Calculated-QoS-Rate	Calculated (adjusted) downstream QoS rate in Kbps as set by the ANCP configuration.	range = 1000 through 4,294,967,295	
26-142	Upstream-Calculated-QoS-Rate	Calculated (adjusted) upstream QoS rate in Kbps as set by the ANCP configuration.	range = 1000 through 4,294,967,295	
26-143	Max-Clients-Per-Interface	Maximum allowable client sessions per interface. For DHCP clients, this value is the maximum sessions per logical interface. For PPPoE clients, this value is the maximum sessions (PPPoE interfaces) per PPPoE underlying interface.	integer: 4-octet	No
26-146	CoS-Scheduler-Pmt-Type	<p>CoS scheduler parameter type and description:</p> <ul style="list-style-type: none"> <li>Null: CoS scheduler name</li> <li><b>T01:</b> CoS scheduler transmit rate</li> <li><b>T02:</b> CoS scheduler buffer size</li> <li><b>T03:</b> CoS scheduler priority</li> <li><b>T04:</b> CoS scheduler drop-profile low</li> <li><b>T05:</b> CoS scheduler drop-profile medium-low</li> <li><b>T06:</b> CoS scheduler drop-profile medium-high</li> <li><b>T07:</b> CoS scheduler drop-profile high</li> <li><b>T08:</b> CoS scheduler drop-profile any</li> </ul>	<p>Three parts, delimited by white space:</p> <ul style="list-style-type: none"> <li>Scheduler name</li> <li>Parameter type</li> <li>Parameter value</li> </ul> <p>Examples:</p> <ul style="list-style-type: none"> <li><b>be_sched</b></li> <li><b>be_sched T01 12m</b></li> <li><b>be_sched T02 26</b></li> </ul>	Yes
26-151	IPv6-Acct-Input-Octets	IPv6 receive octets.	integer	No

Table 15: Supported Juniper Networks VSAs (*continued*)

Attribute Number	Attribute Name	Description	Value	Dynamic CoA Support
26-152	IPv6-Acct-Output-Octets	IPv6 transmit octets.	integer	No
26-153	IPv6-Acct-Input-Packets	IPv6 receive packets.	integer	No
26-154	IPv6-Acct-Output-Packets	IPv6 transmit packets.	integer	No
26-155	IPv6-Acct-Input-Gigawords	IPv6 receive gigawords.	integer	No
26-156	IPv6-Acct-Output-Gigawords	IPv6 transmit gigawords.	integer	No
26-158	PPPoE-Padn	Route add for PPPoE sessions	string	No
26-161	IPv6-Delegated-Pool-Name	Address pool used to locally allocate a delegated prefix (IA_PD).	string	No

## DSL Forum Vendor-Specific Attributes

Digital Subscriber Line (DSL) attributes are RADIUS vendor-specific attributes (VSAs) that are defined by the DSL Forum. The attributes transport DSL information that is not supported by standard RADIUS attributes and which convey information about the associated DSL subscriber and data rate. The attributes are defined in RFC 4679, *DSL Forum Vendor-Specific RADIUS Attributes*.

**NOTE:** Junos OS uses the vendor ID 3561, which is assigned by the Internet Assigned Numbers Authority (IANA), for the DSL Forum VSAs.

Subscriber management does not process DSL values—the router simply passes the values received from the subscriber to the RADIUS server, without performing any parsing or manipulation. However, you can manage the content of DSL VSA values either by using the client configuration to restrict the DSL VSAs that the client sends, or by configuring the RADIUS server to ignore unwanted DSL VSAs.

[Table 16 on page 97](#) describes the DSL Forum VSAs.

Table 16: DSL Forum VSAs

Attribute Number	Attribute Name	Description	Value
[26-1]	Agent-Circuit-Id	Identifier for the subscriber agent circuit ID that corresponds to the DSLAM interface from which subscriber requests are initiated	string
[26-2]	Agent-Remote-Id	Unique identifier for the subscriber associated with the DSLAM interface from which requests are initiated	string
[26-129]	Actual-Data-Rate-Upstream	Actual upstream data rate of the subscriber's synchronized DSL link	integer: 4-octet
[26-130]	Actual-Data-Rate-Downstream	Actual downstream data rate of the subscriber's synchronized DSL link	integer: 4-octet
[26-131]	Minimum-Data-Rate-Upstream	Minimum upstream data rate configured for the subscriber	integer: 4-octet
[26-132]	Minimum-Data-Rate-Downstream	Minimum downstream data rate configured for the subscriber	integer: 4-octet
[26-133]	Attainable-Data-Rate-Upstream	Upstream data rate that the subscriber can attain	integer: 4-octet
[26-134]	Attainable-Data-Rate-Downstream	Downstream data rate that the subscriber can attain	integer: 4-octet
[26-135]	Maximum-Data-Rate-Upstream	Maximum upstream data rate configured for the subscriber	integer: 4-octet
[26-136]	Maximum-Data-Rate-Downstream	Maximum downstream data rate configured for the subscriber	integer: 4-octet
[26-137]	Minimum-Data-Rate-Upstream-Low-Power	Minimum upstream data rate in low power state configured for the subscriber	integer: 4-octet
[26-138]	Minimum-Data-Rate-Downstream-Low-Power	Minimum downstream data rate in low power state configured for the subscriber	integer: 4-octet
[26-139]	Maximum-Interleaving-Delay-Upstream	Maximum one-way upstream interleaving delay configured for the subscriber	integer: 4-octet
[26-140]	Actual-Interleaving-Delay-Upstream	Subscriber's actual one-way upstream interleaving delay	integer: 4-octet
[26-141]	Maximum-Interleaving-Delay-Downstream	Maximum one-way downstream interleaving delay configured for the subscriber	integer: 4-octet

Table 16: DSL Forum VSAs (continued)

Attribute Number	Attribute Name	Description	Value
[26-142]	Actual-Interleaving-Delay-Downstream	Subscriber's actual one-way downstream interleaving delay	integer: 4-octet
[26-144]	Access-Loop-Encapsulation	Encapsulation used by the subscriber associated with the DSLAM interface from which requests are initiated	string: 3-byte
[26-254]	IWF-Session	Indication that the interworking function (IWF) has been performed for the subscriber's session	No data field required

**DSL Forum VSAs Support in AAA Access and Accounting Messages for Junos OS**

Table 19 on page 107 lists the DSL Forum VSAs supported by Junos OS in RADIUS Access-Request, Acct-Start, Acct-Stop, Interim-Acct, and CoA-Request messages. A checkmark in a column indicates that the message type supports that attribute. The DSL Forum vendor ID is 3561 (hexadecimal DE9), which is assigned by the IANA.

## Error-Cause Codes (RADIUS Attribute 101) for Dynamic Requests

When a RADIUS-initiated CoA or disconnect operation is unsuccessful, the router includes an error-cause attribute (RADIUS attribute 101) in the CoA-NAK or Disconnect-NAK message that it sends back to the RADIUS server. If the detected error does not map to one of the supported error-cause attributes, the router sends the message without an error-cause attribute. [Table 20 on page 108](#) describes the error-cause codes.

Table 20: Error-Cause Codes (RADIUS Attribute 101)

Code	Value	Description
401	Unsupported attribute	The request contains an attribute that is not supported (for example, a third-party attribute).
402	Missing attribute	A critical attribute (for example, the session identification attribute) is missing from a request.
404	Invalid request	Some other aspect of the request is invalid, such as if one or more attributes are not formatted properly.

Table 20: Error-Cause Codes (RADIUS Attribute 101) (*continued*)

Code	Value	Description
503	Session context not found	The session context identified in the request does not exist on the router.
504	Session context not removable	The subscriber identified by attributes in the request is owned by a component that is not supported.
506	Resources unavailable	A request could not be honored due to lack of available NAS resources (such as memory).

## Mapping Application Terminate Reasons and RADIUS Terminate Codes

The Junos OS software uses default configuration mapping of terminate reasons for various protocols (AAA, DHCP, L2TP, and PPP) to RADIUS Acct-Terminate-Cause attributes. You can optionally create customized mappings between a terminate reason and a RADIUS Acct-Terminate-Cause attribute, enabling you to provide different information about the cause of a termination.

When a AAA, DHCP, L2TP, or PPP session is terminated, the router logs a message for the internal terminate reason and logs another message for the RADIUS Acct-Terminate-Cause attribute (RADIUS attribute 49). RADIUS attribute 49 is also included in RADIUS Acct-Off and Acct-Stop messages. You can use the logged information to help monitor and troubleshoot terminated sessions.

**NOTE:** A single mapping for RADIUS account termination is shared by all clients.

Table 21 on page 109 lists the IETF RADIUS Acct-Terminate-Cause codes that you can use to map application terminate reasons. In addition, you can also configure and use proprietary codes for values beyond 22.

Table 21: Supported RADIUS Acct-Terminate-Cause Codes

Code	Name	Description
1	User Request	User initiated the disconnect (log out)
2	Lost Carrier	DCD was dropped on the port
3	Lost Service	Service can no longer be provided; for example, the user's connection to a host was interrupted
4	Idle Timeout	Idle timer expired
5	Session Timeout	Subscriber reached the maximum continuous time allowed for the service or session

**Table 21: Supported RADIUS Acct-Terminate-Cause Codes** *(continued)*

Code	Name	Description
6	Admin Reset	System administrator reset the port or session
7	Admin Reboot	System administrator terminated the session on the NAS; for example, prior to rebooting the NAS
8	Port Error	NAS detected an error on the port that required ending the session
9	NAS Error	NAS detected an error (other than on the port) that required ending the session
10	NAS Request	NAS ended the session for a non-error reason
11	NAS Reboot	NAS ended the session due to a non-administrative reboot
12	Port Unneeded	NAS ended the session because the resource usage fell below the low threshold; for example, the bandwidth-on-demand algorithm determined that the port was no longer needed
13	Port Preempted	NAS ended the session to allocate the port to a higher-priority use
14	Port Suspended	NAS ended the session to suspend a virtual session
15	Service Unavailable	NAS was unable to provide the requested service
16	Callback	NAS is terminating the current session in order to perform callback for a new session
17	User Error	An error in the user input caused the session to be terminated
18	Host Request	The login host terminated the session normally
19	Supplicant Restart	Supplicant state machine was reinitialized
20	Reauthentication Failure	A previously authenticated supplicant failed to reauthenticate successfully following expiration of the reauthentication timer or explicit reauthentication request by management action
21	Port Reinitialized	The port's MAC has been reinitialized
22	Port Administratively Disabled	The port has been administratively disabled

## AAA Terminate Reasons

[Table 22 on page 111](#) lists the default AAA terminate mappings. The table indicates the supported AAA deny and shutdown reasons and the RADIUS Acct-Terminate-Cause attributes they are mapped to by default.

**Table 22: Default AAA Mappings**

AAA Deny or Shutdown Reason	RADIUS Acct-Terminate-Cause	
	Code	Description
deny address allocation failure	17	user error
deny no resources	10	NAS request
deny server request timeout	17	user error
shutdown administrative reset	6	admin reset
shutdown remote reset	10	NAS request

## Configuring Custom Terminate Reason Mappings

Junos OS supports default configuration mapping of terminate reasons for various protocols (AAA, DHCP, L2TP, and PPP) to RADIUS Acct-Terminate-Cause attributes. When a AAA, DHCP, L2TP, or PPP session is terminated, the router logs a message for the internal terminate reason and logs another message for the RADIUS

Acct-Terminate-Cause attribute (RADIUS attribute 49). RADIUS attribute 49 is also included in RADIUS Acct-Off and Acct-Stop messages.

You can create customized mappings between a terminate reason and a RADIUS Acct-Terminate-Cause attribute to provide different information about the cause of a termination.

To configure customized mappings between a terminate reason and a RADIUS Acct-Terminate-Cause attribute:

1. Edit the **access** hierarchy.

```
[edit]
user@host# edit access
```

2. Edit the **terminate-code** statement.

**NOTE:** Terminate codes do not appear as options on platforms where they are not supported.

```
[edit access]
user@host# edit terminate-code
```

3. Specify the protocol option (aaa | dhcp | l2tp | ppp) that you want to modify.

```
[edit access terminate-code]
user@host# set protocol-option
```

4. Specify the terminate reason that you want to modify.

```
[edit access terminate-code protocol-option]
user@host# set term-reason
```

**NOTE:** Attempts to set a terminate reason mapping to its default value are rejected by the CLI.

5. Specify the RADIUS termination cause value (from 1 through 4294967295) that you want to use for the termination reason.

```
[edit access terminate-code protocol-option term-reason]
user@host# set radius term-cause
```

**NOTE:** Deleting a customized mapping restores the default.

## Configuring an Access Profile for Subscriber Management

Access profiles enable you to specify subscriber access authentication and accounting parameters. After access profiles are created, you can attach them at the **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]** hierarchy level or for use in automatically configuring VLANs or stacked VLANs at the **[edit interfaces *interface-name* auto-configure *vlan-ranges*]** or **[edit interfaces *interface-name* auto-configure *stacked-vlan-ranges*]** hierarchy levels.

To configure an access profile:

1. Edit the access stanza.

```
[edit]
user@host# edit access
```

2. Specify an existing or new access profile name.

```
[edit access]
user@host# edit profile profile-name
```

3. Specify any desired subscriber access authentication and accounting parameters for the access profile.

### Related Documentation

- [Attaching Access Profiles on page 137](#)
- [Configuring Dynamic Authentication for VLAN Interfaces on page 688](#)
- [profile on page 1823](#)

## Attaching Access Profiles

After you have created the access profile that specifies the subscriber access management authentication and accounting parameters, you can attach the profile. Subscriber access management supports attaching access profiles at the following hierarchy levels:

- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]**
- **[edit interfaces *interface-name* auto-configure *vlan-ranges*]**
- **[edit interfaces *interface-name* auto-configure *stacked-vlan-ranges*]**

To attach an access profile:

1. Edit the desired hierarchy level.

```
[edit]
user@host# edit logical-systems LS1 routing-instances R11
```

2. Specify the name of the access profile that you want to attach.

```
[edit logical-systems logical-system-name routing-instances routing-instance-name]
user@host# set access-profile vz-bos-metro-fios-basic
```

## RADIUS Support for Dynamic Router Advertisement

---

The AAA Service Framework enables you to use RADIUS to select the router advertisement prefix used in a subscriber session's dynamic router advertisement configuration.

When a subscriber connects to an interface, the AAA Service Framework selects the router advertisement prefix based on the following order:

1. IPv6-NdRa-Prefix attribute specified in the RADIUS authentication grant—If the AAA Service Framework receives the IPv6-NdRa-Prefix attribute [VSA 26–129] in the RADIUS Access-Accept message, the router uses the returned VSA value.
2. IPv6-NdRa-Pool-Name attribute specified in the RADIUS authentication grant—If the AAA Service Framework receives the IPv6-NdRa-Pool-Name attribute [VSA 26–157] in the RADIUS Access-Accept message, the router is allocated a prefix from the locally configured address-assignment pool that matches the returned VSA.
3. Local configuration—If neither attribute is returned in the RADIUS authentication grant, the AAA Service Framework allocates the router a prefix from the locally configured address pool that is designated for the Router Advertisement protocol on the router.

## DNS Name Server Address Overview

---

When a client attempts to access a domain—for example, `www.example.com`—a request is sent to a Domain Name System (DNS) name server. The name server stores information that correlates domain names with IP addresses; the IP address is used to reach the requested domain. In response to the client request, the name server looks up the IP address for the domain—`192.0.43.10` for `www.example.com`—and returns it to the client.

In your network configuration, you must configure the address of one or more name servers locally on the router or on your RADIUS server. The local configuration supports the following subscriber types:

- DHCPv4 or DHCPv6
- IP over Ethernet (VLAN)
- Terminated PPPoE (IPv4 or IPv6)
- Tunneled PPPoE (IPv4 or IPv6)

You can configure the name server addresses at different levels of granularity: globally (per routing instance), per access profile, or, for DHCP only, per address pool. You can

configure more than one name server in a routing instance or access profile by repeating the statement for each address.

Because you can configure name server addresses at more than one level, the address returned to the client is determined by the order of preference among the levels. The preference depends on the client type.

- For DHCP subscribers, the preference in descending order is  
RADIUS > DHCP address pool > access profile > global
- For non-DHCP subscribers, the preference in descending order is  
RADIUS > access profile > global

According to the preference order, a name server address configured in RADIUS is preferred by all subscriber types over all other configuration levels. For all subscriber types, the global name server address is used only when no other name server addresses are configured. When a name server address is configured only in a DHCP address pool, then no address is available to non-DHCP subscribers.

When you configure multiple addresses for a name server, the order in which you configure them determines the preference within that configuration. The preference according to configuration level supersedes this ordering.

For IPv4 name server addresses, you can use either of two statements to configure the address. Addresses configured with the `domain-name-server-inet` statement take precedence over addresses configured with the `domain-name-server` statement.

There is no restriction on the number of DNS name server addresses that you can configure. For DHCP subscribers, all the addresses are sent in DHCP messages. However, only two addresses—determined by preference order—are sent to PPP subscribers.

All changes in these locally configured DNS name servers affect only new subscribers that subsequently log in. Existing subscribers are not affected by the changes.

---

## Configuring DNS Name Server Addresses for Subscriber Management

---

This topic describes the procedure for configuring DNS name server addresses at the access profile and routing instance levels. For information about configuring addresses in DHCP address pools, see the DHCP topics referenced in the *Related Documentation* section. For information about configuring addresses on your RADIUS server, refer to your RADIUS software documentation. The order in which the name server configurations at different levels are preferred is described in “[DNS Name Server Address Overview](#)” on [page 138](#).

**BEST PRACTICE:** In practice, choose either the `domain-name-server` statement or the `domain-name-server-inet` statement for IPv4 addresses. They both have the same effect and there is no need to use both statements. If you do use both statements, addresses configured with `domain-name-server-inet` are preferred over addresses configured with `domain-name-server`.

To configure DNS name server addresses globally:

1. Configure an IPv4 address.

```
[edit access]
user@host# set domain-name-server-inet dns-address
```

Alternatively, you can use a different statement to configure an IPv4 address.

```
[edit access]
user@host# set domain-name-server dns-address
```

2. Configure an IPv6 address.

```
[edit access]
user@host# set domain-name-server-inet6 dns-address
```

For example, to configure multiple addresses of each type:

```
[edit access]
user@host# set domain-name-server-inet 172.16.25.31
user@host# set domain-name-server-inet 172.16.25.100
user@host# set domain-name-server-inet6 2001:db8:85a3::8a2e:370:81ca
user@host# set domain-name-server-inet6 2001:db8:85a3::8a2e:370:7334
```

To configure DNS name server addresses in an access profile:

1. Configure an IPv4 address.

```
[edit access profile profile-name]
user@host# set domain-name-server-inet dns-address
```

Alternatively, you can use a different statement to configure an IPv4 address.

```
[edit access profile profile-name]
user@host# set domain-name-server dns-address
```

2. Configure an IPv6 address.

```
[edit access profile profile-name]
user@host# set domain-name-server-inet6 dns-address
```

For example, to configure multiple addresses of each type:

```
[edit access profile vrf-s-access]
user@host# set domain-name-server-inet 172.20.10.01
user@host# set domain-name-server-inet 172.20.100.100
user@host# set domain-name-server-inet6 2001:db8:85a3::8a2e:370:ac81
user@host# set domain-name-server-inet6 2001:db8:85a3::8a2e:370:71bfd
```

## Understanding Session Options for Subscriber Access

---

You can limit subscriber access by configuring a session timeout or an idle timeout. Use a session timeout to specify a fixed period of time that the subscriber is permitted to have access. Use an idle timeout to specify a maximum period of time that the subscriber can be idle. You can use these timeouts separately or together. By default, neither timeout is present.

**NOTE:** For all subscriber types other than DHCP (such as L2TP-tunneled and PPP-terminated subscribers), the session timeout value limits the subscriber session. For DHCP subscribers, the session timeout value is used to limit the lease. The lease expires when the timeout value expires. If this value is not supplied by either the CLI or RADIUS, the DHCP lease does not expire.

The idle timeout is based on accounting statistics for the subscriber. The router determines subscriber inactivity by monitoring data traffic, both upstream from the user and downstream to the user. Control traffic is ignored. The subscriber is not considered idle as long as data traffic is detected in either direction.

When either timeout period expires, the non-DHCP subscribers are gracefully logged out, similarly to a RADIUS-initiated disconnect or a CLI-initiated logout. DHCP subscribers are disconnected. The Acct-Terminate-Cause [RADIUS attribute 49] value includes a reason code of 5 for a session timeout and a code of 4 for an idle timeout.

You can configure these limitations to subscriber access on a per-subscriber basis by using the RADIUS attributes Session-Timeout [27] and Idle-Timeout [28]. RADIUS returns these attributes in Access-Accept messages in response to Access-Request messages from the access server.

Service providers often choose to apply the same limitations to large numbers of subscribers. You can reduce the RADIUS provisioning effort for this scenario by defining the limitations for subscribers in an access profile on a per-routing-instance basis. If you do so, RADIUS attributes subsequently returned for a particular subscriber logged in with the profile override the per-routing-instance values.

The available range for setting a timeout is the same whether you configure it in the CLI or through the RADIUS attributes. Session timeouts can be set for 1 minute through 527,040 minutes in the CLI and the corresponding number of seconds (60 through 31,622,400) in the Session-Timeout attribute [27]. Idle timeouts can be set for 10 minutes through 1440 minutes in the CLI and the corresponding number of seconds (600 through 86,400) in the Idle-Timeout attribute [28].

The router interprets the values in the attributes to conform to the supported ranges. For example, for Session-Timeout [27]:

- A value of zero is treated as no timeout.
- A value in the range 1 through 59 is raised to 60 seconds.
- A value that exceeds 31,622,400 is reduced to 31,622,400 seconds.

For Idle-Timeout [28]:

- A value of zero is treated as no timeout.
- A value in the range 1 through 599 is raised to 600 seconds.
- A value that exceeds 86,400 is reduced to 86,400 seconds.

In configurations using dynamically created subscriber VLANs, the idle timeout also deletes the inactive subscriber VLANs when the inactivity threshold has been reached. In addition to deleting inactive dynamic subscriber VLANs, the idle timeout also removes dynamic VLANs when no client sessions were ever created (for example, in the event no client sessions are created on the dynamic VLAN or following the occurrence of an error during session creation or client authentication where no client sessions are created on the dynamic VLAN).

When using the idle timeout for dynamic VLAN removal, keep the following in mind:

- The idle timeout period begins after a dynamic subscriber VLAN interface is created or traffic activity stops on a dynamic subscriber VLAN interface.
- If a new client session is created or a client session is reactivated successfully, the client idle timeout resets.
- The removal of inactive subscriber VLANs functions only with VLANs that have been authenticated.

**Related  
Documentation**

- [Configuring Subscriber Session Options on page 143](#)
- [Removing Inactive Dynamic Subscriber VLANs on page 144](#)

## Configuring Subscriber Session Options

Subscriber session timeouts enable you to place limits on subscriber access based on how long the session has been up, how long the user has been inactive, or both. The subscriber session timeouts apply to both L2TP-tunneled and PPP-terminated subscriber sessions.

**NOTE:** To configure the timeout attributes in RADIUS, refer to the documentation for your RADIUS server.

To configure limitations on subscriber sessions:

1. Edit session options for the router access profile.

```
[edit]
user@host# edit access profile profile-name session-options
```

2. Configure the maximum period a subscriber session can be active.

```
[edit access profile profile-name session-options]
user@host# set client-session-timeout minutes
```

3. Configure the maximum period a subscriber session can be idle.

```
[edit access profile profile-name session-options]
user@host# set client-idle-timeout minutes
```

For example, to configure a client session timeout of 2 hours and an idle timeout of 15 minutes in the **acc-prof** profile:

```
[edit]
access {
  profile {
    acc-prof {
      session-options {
        client-session-timeout 120;
        client-idle-timeout 15;
      }
    }
  }
}
```

## Removing Inactive Dynamic Subscriber VLANs

---

Subscriber session timeouts enable you to place limits on subscriber access based on how long the session has been up, how long the user has been inactive, or both. In configurations using dynamically created subscriber VLANs, the idle timeout also:

- Deletes the inactive subscriber VLANs when the inactivity threshold has been reached.
- Removes dynamic VLANs when no client sessions were ever created (for example, in the event no client sessions are created on the dynamic VLAN or following the occurrence of an error during session creation or client authentication where no client sessions are created on the dynamic VLAN).

**NOTE:** To configure the idle timeout attribute in RADIUS, refer to the documentation for your RADIUS server.

---

To remove inactive dynamic subscriber VLANs:

1. Edit session options for the router access profile.

```
[edit]
user@host# edit access profile profile-name session-options
```

2. Configure the maximum period a subscriber session can remain idle.

```
[edit access profile profile-name session-options]
user@host# set client-idle-timeout minutes
```

## AAA Configuration Testing and Troubleshooting

---

Subscriber management supports a test feature that enables you to check the AAA configuration of a subscriber. You might use the test feature to verify the subscriber's AAA settings and to help troubleshoot or isolate subscriber login problems. The AAA test process creates a pseudo session that authenticates the subscriber, allocates an address for the subscriber, and issues an accounting start packet. The process then issues an accounting stop request, releases the address, and terminates the pseudo session.

The AAA test results provide details about the attributes that subscriber management assigns to the subscriber during login. The attributes might be assigned by RADIUS, a dynamic profile, static interface configuration, or might be statically assigned. You can test the AAA configuration for DHCP, PPP, and authd-lite subscribers. For L2TP clients, the AAA test process displays all tunnel parameters but does not create an actual tunnel session.

NOTE: The **test** command does not support volume-time accounting. If volume-time accounting is configured for the test subscriber, the **test** command replaces the statistics with time-only accounting statistics.

**Related  
Documentation**

- [Testing a Subscriber AAA Configuration on page 145](#)

---

## Testing a Subscriber AAA Configuration

---

**Purpose** Display the AAA attributes that subscriber management assigns to the subscriber during login.

The following example tests the AAA configuration for a PPP subscriber. You can use the **test aaa dhcp user** command to perform a similar test for DHCP subscribers and the **test aaa authd-lite user** command to test authd-lite subscribers.

NOTE: The **test** command does not support volume-time accounting. If volume-time accounting is configured for the test subscriber, the **test** command replaces the statistics with time-only accounting statistics.

**Action** user@host>test aaa ppp user thomastank password 00N15&

## Tracing Subscriber Management Database Operations for Subscriber Access

The Junos OS trace feature tracks subscriber management database operations and records events in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

1. Important events are logged in a file located in the `/var/log` directory. By default, the router uses the filename `smid`. You can specify a different filename, but you cannot change the directory in which trace files are located.
2. When the trace log file *filename* reaches 128 kilobytes (KB), it is compressed and renamed *filename.0.gz*. Subsequent events are logged in a new file called *filename*, until it reaches capacity again. At this point, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)

By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

To configure all aspects of subscriber management database tracing operations:

1. Configure a trace log filename.  
See [“Configuring the Subscriber Management Database Trace Log Filename” on page 148](#).
2. Configure the number and size of trace logs.  
See [“Configuring the Number and Size of Subscriber Management Database Log Files” on page 148](#).
3. Configure user access to trace logs.  
See [“Configuring Access to the Subscriber Management Database Log File” on page 149](#).

4. Configure a regular expression to filter the information to be included in the trace log.  
See [“Configuring a Regular Expression for Subscriber Management Database Messages to Be Logged”](#) on page 149.
5. Configure flags to specify which events are logged.  
See [“Configuring the Subscriber Management Database Tracing Flags”](#) on page 149.

---

## Configuring the Subscriber Management Database Trace Log Filename

By default, the name of the file that records trace output for the subscriber management database is **smid**. You can specify a different name with the **file** option.

To configure the filename for subscriber management database tracing operations:

- Specify the name of the file used for the trace output.  

```
[edit system services subscriber-management traceoptions]  
user@host# set file smi_logfile_1
```

### Related Documentation

- [Tracing Subscriber Management Database Operations for Subscriber Access on page 147](#)

---

## Configuring the Number and Size of Subscriber Management Database Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format **.number.gz**. The newest archived file is **.0.gz** and the oldest archived file is **.(maximum number)-1.gz**. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, **filename**, reaches 2 MB, **filename** is compressed and renamed **filename.0.gz**, and a new file called **filename** is created. When the new **filename** reaches 2 MB, **filename.0.gz** is renamed **filename.1.gz** and **filename** is compressed and renamed **filename.0.gz**. This process repeats until there are 20 trace files. Then the oldest file, **filename.19.gz**, is simply overwritten when the next oldest file, **filename.18.gz** is compressed and renamed to **filename.19.gz**.

To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output.  

```
[edit system services subscriber-management traceoptions]  
user@host# set file smi_1_logfile_1 files 20 size 2097152
```

### Related Documentation

- [Tracing Subscriber Management Database Operations for Subscriber Access on page 147](#)

## Configuring Access to the Subscriber Management Database Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

To specify that all users can read the log file:

- Configure the log file to be world-readable.

```
[edit system services subscriber-management traceoptions]
user@host# set file smi_1_logfile_1 world-readable
```

To explicitly set the default behavior, only the user who configured tracing can read the log file:

- Configure the log file to be no-world-readable.

```
[edit system services subscriber-management traceoptions]
user@host# set file smi_1_logfile_1 no-world-readable
```

### Related Documentation

- [Tracing Subscriber Management Database Operations for Subscriber Access on page 147](#)

## Configuring a Regular Expression for Subscriber Management Database Messages to Be Logged

By default, the trace operation output includes all messages relevant to the logged events.

You can refine the output by including regular expressions to be matched.

To configure regular expressions to be matched:

- Configure the regular expression.

```
[edit system services subscriber-management traceoptions]
user@host# set file smi_1_logfile_1 match regex
```

### Related Documentation

- [Tracing Subscriber Management Database Operations for Subscriber Access on page 147](#)

## Configuring the Subscriber Management Database Tracing Flags

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

To configure the flags for the events to be logged:

- Configure the flags.

```
[edit system services subscriber-management traceoptions]
user@host# set flag flag
```

- Related Documentation**
- [Tracing Subscriber Management Database Operations for Subscriber Access on page 147](#)

## Tracing Subscriber Management Session Database Replication Operations for Subscriber Access

---

The Junos OS trace feature tracks subscriber management database replication operations and records events in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

1. Important events are logged in a file located in the `/var/log` directory. By default, the router uses the filename `bdbrepd`. You can specify a different filename, but you cannot change the directory in which trace files are located.
2. When the trace log file *filename* reaches 128 kilobytes (KB), it is compressed and renamed *filename.0.gz*. Subsequent events are logged in a new file called *filename*, until it reaches capacity again. At this point, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally configure the maximum file size to be from 10 KB through 1 gigabyte (GB). You can also specify the number of trace files to be from 2 through 1000. (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)

By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

To configure all aspects of subscriber management database replication tracing operations:

1. Configure a trace log filename.  
[See “Configuring the Subscriber Management Session Database Replication Trace Log Filename” on page 152.](#)
2. Configure the number and size of trace logs.  
[See “Configuring the Number and Size of Subscriber Management Session Database Replication Log Files” on page 151.](#)
3. Configure user access to trace logs.  
[See “Configuring Access to the Subscriber Management Session Database Replication Log File” on page 152.](#)
4. Configure a regular expression to filter the information to be included in the trace log.

See “Configuring a Regular Expression for Subscriber Management Session Database Replication Messages to Be Logged” on page 151.

5. Configure flags to specify which events are logged.

See “Configuring the Subscriber Management Session Database Replication Tracing Flags” on page 152.

## Configuring the Number and Size of Subscriber Management Session Database Replication Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format *.number.gz*. The newest archived file is *.0.gz* and the oldest archived file is *.(maximum number)-1.gz*. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, *filename*, reaches 2 MB, *filename* is compressed and renamed *filename.0.gz*, and a new file called *filename* is created. When the new *filename* reaches 2 MB, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until there are 20 trace files. Then the oldest file, *filename.19.gz*, is simply overwritten when the next oldest file, *filename.18.gz* is compressed and renamed to *filename.19.gz*.

To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output.

```
[edit system services database-replication traceoptions]
user@host# set file bdbrep_1_logfile_1 files 20 size 2097152
```

### Related Documentation

## Configuring a Regular Expression for Subscriber Management Session Database Replication Messages to Be Logged

By default, the trace operation output includes all messages relevant to the logged events.

You can refine the output by including regular expressions to be matched.

To configure regular expressions to be matched:

- Configure the regular expression.

```
[edit system services database-replication traceoptions]
```

```
user@host# set file bdrep_1_logfile_1 match regex
```

- Related Documentation**
- [Tracing Subscriber Management Session Database Replication Operations for Subscriber Access on page 150](#)

## Configuring Access to the Subscriber Management Session Database Replication Log File

---

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

To specify that all users can read the log file:

- Configure the log file to be world-readable.  

```
[edit system services database-replication traceoptions]  
user@host# set file bdrep_1_logfile_1 world-readable
```

To explicitly set the default behavior, only the user who configured tracing can read the log file:

- Configure the log file to be no-world-readable.  

```
[edit system services database-replication traceoptions]  
user@host# set file bdrep_1_logfile_1 no-world-readable
```

- Related Documentation**
- [Tracing Subscriber Management Session Database Replication Operations for Subscriber Access on page 150](#)

## Configuring the Subscriber Management Session Database Replication Trace Log Filename

---

By default, the name of the file that records trace output for the subscriber management database is **bdbrepd**. You can specify a different name with the **file** option.

To configure the filename for subscriber management database tracing operations:

- Specify the name of the file used for the trace output.  

```
[edit system services database-replication traceoptions]  
user@host# set file bdbrep_logfile_1
```

- Related Documentation**
- [Tracing Subscriber Management Session Database Replication Operations for Subscriber Access on page 150](#)

## Configuring the Subscriber Management Session Database Replication Tracing Flags

---

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

To configure the flags for the events to be logged:

- Configure the flags.  
`[edit system services database-replication traceoptions]  
user@host# set flag flag`

**Related Documentation**   • [Tracing Subscriber Management Session Database Replication Operations for Subscriber Access on page 150](#)

### Address-Assignment Pools Overview

---

The address-assignment pool feature supports subscriber management functionality by enabling you to create IPv4 and IPv6 address pools that different client applications can share. For example, multiple client applications, such as DHCP, can use an address-assignment pool to provide addresses for their particular clients. Client applications can acquire addresses for either authenticated or unauthenticated clients.

Address-assignment pools support both dynamic and static address assignment. In dynamic address assignment, a client is automatically assigned an address from the address-assignment pool. In static address assignment, which is supported for IPv4 pools only, you reserve an address that is then always used by a particular client. Addresses that are reserved for static assignment are removed from the dynamic address pool and cannot be assigned to other clients.

You can configure named address ranges within an address-assignment pool. A named range is a subset of the overall address range. A client application can use named ranges to manage address assignment based on client-specific criteria. For example, for IPv4 address-assignment pools, you might create a named range that is based on a specific

DHCP option 82 value. Then, when a DHCP client request matches the specified option 82 value, an address from the specified range is assigned to the client.

You can link address-assignment pools together to provide backup pools for address assignment. When the primary pool is fully allocated, the router or switch automatically switches to the linked, or secondary, pool and begins allocating addresses from that pool.

You can also explicitly identify that an address-assignment pool is used for ND/RA.

**Related  
Documentation**

- [Configuring Address-Assignment Pools on page 156](#)
- [DNS Address Assignment Precedence on page 43](#)

- [Configuring an Extended DHCP Server with DHCPv6 on EX Series Switches \(CLI Procedure\)](#)

---

## Configuring Address-Assignment Pools

The address-assignment pool feature supports subscriber management functionality by enabling you to create address pools that can be shared by different client applications. An address-assignment pool can support either IPv4 address or IPv6 addresses. You cannot use the same pool for both types of address.

**NOTE:** You cannot use address-assignment pools with the J Series Services Routers DHCP server. Also, address-assignment pools are completely separate from services PIC-based L2TP LNS address pools, which you create with the `address-pool` statement at the `[edit access]` hierarchy level, and NAT pools, which you create with the `pool` statement at the `[edit services nat]` hierarchy level.

To configure an address-assignment pool:

1. Configure the address-assignment pool name and specify the addresses for the pool.  
See [“Configuring an Address-Assignment Pool Name and Addresses” on page 157](#).
2. (Optional) Configure named ranges (subsets) of addresses.  
See [“Configuring a Named Address Range for Dynamic Address Assignment” on page 157](#).
3. (Optional) Configure address-assignment pool linking and specify the secondary pool to use when the primary pool is fully allocated.  
See [“Configuring Address-Assignment Pool Linking” on page 158](#).
4. (Optional) Create static address bindings (IPv4 only).  
See [“Configuring Static Address Assignment” on page 159](#).

5. (Optional) Configure attributes for DHCP clients.  
See [“Configuring DHCP Client-Specific Attributes” on page 160](#).
6. (Optional) Specify that the address-assignment pool is used for router advertisement.  
See [“Configuring an Address-Assignment Pool for Router Advertisement” on page 159](#).

**Related  
Documentation**

- [Address-Assignment Pools Overview on page 155](#)
- [Address-Assignment Pools Licensing Requirements on page 163](#)
- [Example: Configuring an Address-Assignment Pool on page 181](#)

## Configuring an Address-Assignment Pool Name and Addresses

To configure an address-assignment pool, you must specify the name of the pool and configure the addresses for the pool.

To configure an IPv4 address-assignment pool:

1. Configure the name of the pool and specify the IPv4 family.  

```
[edit access]
user@host# edit address-assignment pool isp_1 family inet
```
2. Configure the network address and the prefix length of the addresses in the pool.  

```
[edit access address-assignment pool isp_1 family inet]
user@host# set network 192.168.0.0/16
```

To configure an IPv6 address-assignment pool:

1. Configure the name of the pool and specify the IPv6 family.  

```
[edit access]
user@host# edit address-assignment pool isp_2 family inet6
```
2. Configure the IPv6 network prefix for the address pool. The prefix specification is required when you configure an IPv6 address-assignment pool.  

```
[edit access address-assignment pool isp_2 family inet6]
user@host# set prefix 2008:2009::/32
```

**Related  
Documentation**

- [Address-Assignment Pools Overview on page 155](#)
- [Configuring Address-Assignment Pools on page 156](#)

## Configuring a Named Address Range for Dynamic Address Assignment

You can optionally configure multiple named ranges, or subsets, of addresses within an address-assignment pool. During dynamic address assignment, a client can be assigned an address from a specific named range. To create a named range, you specify a name for the range and define the address range.

To create a named range within an IPv4 address-assignment pool:

1. Specify the name of the address-assignment pool and the IPv4 family.

```
[edit access]
user@host# edit address-assignment pool isp_1 family inet
```

2. Configure the name of the range and the lower and upper boundaries of the addresses in the range.

```
[edit access address-assignment pool isp_1 family inet]
user@host# set range southeast low 192.168.102.2 high 192.168.102.254
```

To create a named range within an IPv6 address-assignment pool:

1. Specify the name of the address-assignment pool and the IPv6 family.

```
[edit access]
user@host# edit address-assignment pool isp_2 family inet6
```

2. Configure the name of the range and define the range. You can define the range based on the lower and upper boundaries of the prefixes in the range, or based on the length of the prefixes in the range.

```
[edit access address-assignment pool isp_2 family inet6]
user@host# set range dsl-range low 2008:2010:2011:0100::/64 high
2008:2010:2011:ffff::/64
user@host# set range fiber-east prefix-length 48
```

## Configuring Address-Assignment Pool Linking

Address-assignment pool linking enables you to specify a secondary address pool for the router to use when the primary address-assignment pool is fully allocated. When the primary pool is has no available addresses, the router automatically switches over to the linked secondary pool and begins allocating addresses from that pool. The router uses a secondary pool only when the primary address-assignment pool is fully allocated.

You can create a chain of multiple linked pools. For example you can link pool A to pool B, and link pool B to pool C. When pool A has no available addresses, the router switches to using pool B for addresses. When pool B is exhausted, the router switches to pool C. There is no limit to the number of linked pools in a chain. However, you cannot create multiple links to or from the same pool—a pool can be linked to only one secondary pool, and a secondary pool can be linked from only one primary pool. Also, two linked primary and secondary pools must be of the same family type, either IPv4 or IPv6.

To link an address-assignment pool to a secondary pool:

1. Specify the name of the primary address-assignment pool.

```
[edit access]
user@host# edit address-assignment pool pool-name
```

2. Configure the secondary pool to which the primary pool will be linked.

```
[edit access address-assignment pool isp_1]
user@host# set link pool-name
```

## Configuring Static Address Assignment

You can optionally create a static IPv4 address binding by reserving a specific address for a particular client. The address is removed from the address-assignment pool so that it is not assigned to another client. When you reserve an address, you identify the client host and create a binding between the client MAC address and the assigned IP address. IPv6 address-assignment pools do not support static address binding.

To configure a static binding for an IPv4 address:

1. Specify the name of the IPv4 address-assignment pool containing the IP address you want to reserve for the client.

```
[edit access]
user@host# edit address-assignment pool isp_1 family inet
```

2. Specify the name of the client for the static binding, the client MAC address, and the IP address to reserve for the client. This configuration specifies that the client with MAC address 90:00:00:01:00:01 is always assigned IP address 192.168.44.12.

```
[edit access address-assignment pool isp_1 family inet]
user@host# set host svale6_boston_net hardware-address 90:00:00:01:00:01
ip-address 192.168.44.12
```

## Configuring an Address-Assignment Pool for Router Advertisement

You can create an address-assignment pool that is explicitly used for router advertisement address assignment. You populate the address-assignment pool using the standard procedure, but you additionally specify that the pool is used for router advertisement.

To create an address-assignment pool that is used for router advertisement:

1. Configure the IPv6 address-assignment pool.

See “[Configuring Address-Assignment Pools](#)” on page 156

2. Specify that the address-assignment pool is used for router advertisement.

```
[edit access address-assignment]
```

```
user@host# set neighbor-discovery-router-advertisement chi-fiber-ra
```

- Related Documentation**
- [Address-Assignment Pools Overview on page 155](#)
  - [Example: Configuring an Address-Assignment Pool on page 181](#)

---

## Configuring Address-Assignment Pool Usage Threshold Traps

You can receive advanced warning that an address pool or linked set of address pools is running short on available addresses by setting usage threshold traps. An address pool has SNMP thresholds associated with it that allow the local address server to signal SNMP traps when certain conditions exist. These thresholds include high utilization threshold and abated utilization threshold. If a pool's outstanding addresses exceed the high utilization threshold and the SNMP trap signaling is enabled, SNMP is notified. Likewise, when a pool's utilization drops below the abated threshold utilization threshold, SNMP is notified. When the system reaches the high utilization value, it sends warning messages. When memory usage falls to the abated utilization value, the system stops sending warning messages.

To set the usage for threshold traps:

- Specify the percentage after which the address pool usage is exceeded that an SNMP trap is generated.

```
[edit access]
user@host# edit address-assignment high-utilization 95
```

To set the abated value for the trap:

- Specify the percentage below which the address pool usage is abated that an SNMP trap is generated.

```
[edit access]
user@host# edit address-assignment abated-utilization 80
```

---

## Configuring DHCP Client-Specific Attributes

You use the address-assignment pool feature to include application-specific attributes when clients obtain an address. The client application, such as DHCP, uses the attributes to determine how addresses are assigned, and to also provide optional application-specific characteristics to the client. For example, the DHCP application might specify that a client that matches certain prerequisite information is dynamically assigned an address from a particular named range. Based on which named range is used, DHCP specifies additional DHCP attributes such as the boot file that the client uses, the lease grace period, and the maximum lease time.

You use the `dhcp-attributes` statement to configure DHCP client-specific attributes for address-assignment pools. “[DHCP Attributes for Address-Assignment Pools](#)” on page 161 describes the supported attributes you can configure for IPv4 and IPv6 address-assignment pools.

To configure address-assignment pool attributes for DHCP clients:

1. Specify the name and IP family of the address-assignment pool.

```
[edit access]
user@host# edit address-assignment pool isp_1 family inet
```

2. Configure optional DHCP client attributes.

```
[edit access address-assignment pool isp_1 family inet]
user@host# set dhcp-attributes boot-server 192.168.200.100 grace-period 3600
maximum-lease-time 18000
```

**NOTE:** The DNS name server addresses that are configurable as DHCP attributes can also be configured globally at the routing instance level and in access profiles. For more information, see “[DNS Name Server Address Overview](#)” on page 138.

## DHCP Attributes for Address-Assignment Pools

Table 26 on page 161 describes the DHCP client attributes that you can use with the `dhcp-attributes` statement when you configure address-assignment pools. Table 27 on page 162 describes the DHCPv6 client attributes for configuring IPv6 address-assignment pools.

Table 26: DHCP Attributes

Attribute	Description	DHCP Option
<code>boot-file</code>	Boot filename advertised to the client, and used by the client to complete configuration.	67
<code>boot-server</code>	Boot server containing the boot file.	66
<code>domain-name</code>	Domain in which clients search for a DHCP server host.	15
<code>grace-period</code>	Grace period offered with the lease.	—
<code>maximum-lease-time</code>	Maximum lease time allowed by the DHCP server.	51

Table 26: DHCP Attributes (*continued*)

Attribute	Description	DHCP Option
<code>name-server</code>	IP address of DNS server to which clients can send DNS queries.	6
<code>netbios-node-type</code>	NetBIOS node type.	46
<code>option</code>	User-defined options.	–
<code>option-match</code>	Option 82 value is mapped to named address range.	–
<code>router</code>	IP address for routers on the subnetwork.	3
<code>server-identifier</code>	IP address used as the DHCP source address	54
<code>tftp-server</code>	Trivial File Transfer Protocol (TFTP) server that the client uses to obtain the client configuration file.	150
<code>wins-server</code>	IP address of the Windows NetBIOS name server.	44

Table 27: DHCPv6 Attributes

Attribute	Description	DHCPv6 Option
<code>dns-server</code>	IPv6 address of DNS server to which clients can send DNS queries.	23
<code>grace-period</code>	Grace period offered with the lease.	–
<code>maximum-lease-time</code>	Maximum lease time allowed by the DHCP server.	–
<code>option</code>	User-defined options.	–
<code>preferred-lifetime</code>	Length of time, in seconds, that the DHCP server keeps the IPv6 prefix active. The DHCPv6 server sends this attribute to the client (router).	–
<code>sip-server-address</code>	IPv6 address of SIP outbound proxy server.	22
<code>sip-server-domain-name</code>	Domain name of the SIP outbound proxy server.	21

Table 27: DHCPv6 Attributes (*continued*)

Attribute	Description	DHCPv6 Option
<a href="#">t1-percentage</a>	Timer that, when it expires, the client (router) sends a request to the originating DHCP server requesting its lease (IP configuration) to be extended. If the lease period is limitless, the client's lease never expires and no request is required. However, because most leases are time-limited, the router monitors this timer and sends a request to the originating DHCP server to ensure that its lease is extended and normal operation continues. T1-percentage is specified as a percentage of the elapsed time for the preferred-lifetime value. This value is sent from the DHCP server to the router.	–
<a href="#">t2-percentage</a>	Timer that, when it expires, the client (router) sends a request to any available DHCP server requesting its lease (IP configuration) to be extended. T2-percentage is sent from the DHCP server to the router.  You specify t2-percentage as a percentage of the value of preferred-lifetime.	–
<a href="#">valid-lifetime</a>	Length of time, in seconds, that the DHCP server keeps the IPv6 prefix valid.	–

## Address-Assignment Pools Licensing Requirements

The address-assignment pool feature is part of the Junos OS Subscriber Management Feature Pack license. You must install and properly configure the license to meet the requirements for using the address-assignment pool feature.

**Related Documentation**

- For information about installing and managing Junos OS licenses, see the “Managing Junos OS Licenses” chapter of the Installation and Upgrade Guide

## Tracing General Authentication Service Processes

The Junos OS trace operations feature tracks general authentication service operations and records events in a log file. By default, the tracing operation is inactive. To trace general authentication service processes, you specify flags in the **traceoptions** statement at the **[edit system processes general-authentication-service]** hierarchy level. The default tracing behavior is the following:

- Important events are logged in a file located in the `/var/log` directory. By default, the router uses the filename, **authd**. You can specify a different filename, but you cannot change the directory (`/var/log`) in which trace files are located.
- When the trace log file **filename** reaches 128 kilobytes (KB), it is compressed and renamed **filename.0.gz**. Subsequent events are logged in a new file called **filename**, until it reaches capacity again. At this point, **filename.0.gz** is renamed **filename.1.gz** and **filename** is compressed and renamed **filename.0.gz**. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). For more information about how log files are created, see the *Junos OS System Log Messages Reference*.

- By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

The general authentication service tracing operations are described in the following sections:

- [Configuring the General Authentication Service Processes Trace Log Filename on page 164](#)
- [Configuring the Number and Size of General Authentication Service Processes Log Files on page 164](#)
- [Configuring Access to the Log File on page 165](#)
- [Configuring a Regular Expression for Lines to Be Logged on page 165](#)
- [Configuring the Trace Operation on page 166](#)

## Configuring the General Authentication Service Processes Trace Log Filename

By default, the name of the file that records trace output for general authentication service is **authd**. You can specify a different name by including the **file** statement at the **[edit system processes general-authentication-service]** hierarchy level:

To configure the filename for general authentication service tracing operations:

- Specify the name of the file used for the trace output.

```
[edit system processes general-authentication-service traceoptions]
user@host# set file aap_logfile_1
```

## Configuring the Number and Size of General Authentication Service Processes Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format **.number.gz**. The newest archived file is **.0.gz** and the oldest archived file is **.(maximum number)-1.gz**. When the current trace log file reaches the maximum size, it is compressed and renamed, and any

existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, *filename*, reaches 2 MB, *filename* is compressed and renamed *filename.0.gz*, and a new file called *filename* is created. When the new *filename* reaches 2 MB, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until there are 20 trace files. Then the oldest file, *filename.19.gz*, is simply overwritten when the next oldest file, *filename.18.gz* is compressed and renamed to *filename.19.gz*.

To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output, by including the **files** and **size** options with the **traceoptions** statement.

```
[edit system processes general-authentication-service traceoptions]
user@host# set file aap_logfile_1 files 20 size 2097152
```

## Configuring Access to the Log File

By default, log files can be accessed only by the user who configures the tracing operation. You can allow all users to read the log file and you can explicitly set the default behavior of the log file.

To specify that all users can read the log file:

- Configure the log file to be world-readable.

```
[edit system processes general-authentication-service traceoptions]
user@host# set file aap_logfile_1 world-readable
```

To explicitly set the default behavior, in which the log file can only be read by the user who configured tracing:

- Configure the log file to be no-world-readable.

```
[edit system processes general-authentication-service traceoptions]
user@host# set file aap_logfile_1 no-world-readable
```

## Configuring a Regular Expression for Lines to Be Logged

By default, the trace operation output includes all lines relevant to the logged events. You can refine the output by including regular expressions (regex) that will be matched.

To configure regular expressions to match:

- Configure the regular expression.

```
[edit system processes general-authentication-service traceoptions]
user@host# set file aap_logfile_1 match regular-expression
```

## Configuring the Trace Operation

By default, only important events are logged. You can specify which trace operations are logged by including specific tracing flags. The following table describes the flags that you can include.

Flag	Description
address-assignment	Trace all address-assignment pool events
all	Trace all tracing operations
configuration	Trace configuration events
framework	Trace authentication framework events
gx-plus	Trace Gx-Plus events
jsrc	Trace JSRC events
ldap	Trace LDAP authentication events
local-authentication	Trace local authentication events
radius	Trace RADIUS authentication events

To configure the flags for the event to be logged:

- Configure the flags.

```
[edit system processes general-authentication-service traceoptions]  
user@host# set flag address-assignment
```

- [Verifying and Managing Domain Map Configuration on page 178](#)

## Domain Mapping Overview

Domain mapping enables you to configure a map that specifies access options and session-specific parameters. The map is based on the domain name of subscriber sessions — the router applies the mapped options and parameters to sessions for subscribers that have the specified domains. For example, you might configure a domain map that is based on the domain name **xyz.com**. The options and parameters in that domain map are then applied when subscribers with the specified domain name (for example, **bob@xyz.com**, **raj@xyz.com**, and **juan@xyz.com**) request an AAA service.

The domain map provides efficiency, and enables you to make changes for a large number of subscribers in one operation. For example, if an address assignment pool becomes exhausted due to the number of subscribers obtaining addresses from the pool, you can create a domain map that specifies that subscribers in a particular domain obtain addresses from a different pool. In another use of the domain map, you might create a new dynamic profile and then configure the domain map to specify which subscribers (by their domain) use that dynamic profile.

**NOTE:** Subscriber management is supported in the default logical system only. The documentation for the subscriber management domain mapping feature describes using the `aaa-logical-system` and `target-logical-system` statements to configure mapping to a non-default logical system. These statements are for future extensions of subscriber management and are not supported in current Junos OS releases.

Table 28 on page 168 describes the access options and parameters you can configure in the domain map.

**Table 28: Domain Map Options and Parameters**

Option	Description
AAA logical system/routing instance	Logical system/routing instance in which AAA sends authentication and accounting requests for the subscriber sessions.  Subscriber management is supported in the default logical system only.
Access profile	Access profile applied to subscriber sessions.
Address pool	Address pool used to allocate addresses to subscribers.
Domain name rules	Rules for domain name usage, including domain name stripping, supported delimiters, and parse direction (delimiters and the parse direction are configured globally).
Dynamic profile	Dynamic profile applied to subscriber sessions.

Table 28: Domain Map Options and Parameters (*continued*)

Option	Description
PADN parameters	PPPoE route information for subscriber sessions.
Target logical system/routing instance	Logical system/routing instance to which the subscriber interface is attached.  Subscriber management is supported in the default logical system only.
Tunnel profile	Tunnel profile applied to subscriber sessions.

## Default Domain Map

You can configure a default domain map that the router uses for subscribers whose domain name does not explicitly match any existing domain map. The router also uses the default domain map when a subscriber username does not include a domain name.

You might configure the default domain map to provide limited feature support for guest subscribers, such as a specific address pool used for guests or the routing instance that provides AAA services. When the router is unable to match a subscriber request to a domain map, the router then uses the rules specified in the default domain map configuration to handle the subscriber request.

**Related Documentation**

- [Configuring a Domain Map on page 169](#)

## Configuring a Domain Map

To configure a domain map for subscriber management:

1. Create the domain map. For the map name, specify the domain name that you want the domain map to use. (Use **default** for the name of the default domain map.)

```
[edit access]
user@host# edit domain map domain-map-name
```

- For example, to create a domain map to be mapped to subscribers with the domain name **xyz.com**:

```
[edit access]
user@host# edit domain map xyz.com
```

- To create a default domain map to be mapped to subscribers with non-matching domain names and subscribers without domain names:

```
[edit access]
user@host# edit domain map default
```

2. (Optional) Specify the access profile used to apply access rules for the domain map.  
See [“Specifying an Access Profile in a Domain Map” on page 170](#).

3. (Optional) For dynamic profiles, clarify the provided dynamic configuration for the subscriber session.  
See [“Specifying a Dynamic Profile in a Domain Map” on page 171.](#)
4. (Optional) Specify the address pool used to allocate address for the domain map.  
See [“Specifying an Address Pool in a Domain Map” on page 172.](#)
5. (Optional) Configure rules for domain names; for example; delimiters, parsing direction, and domain stripping. Delimiters and parsing direction are configured globally for all domain maps. Domain stripping is enabled in the domain map.  
See [“Configuring Domain Name Usage for Domain Maps” on page 175.](#)
6. (Optional) Configure the tunnel profile that provides tunnel definitions for the domain map..  
See [“Specifying a Tunnel Profile in a Domain Map” on page 177.](#)
7. (Optional) Configure the PADN parameters used for PPPoE route information for the domain map.  
See [“Configuring PADN Parameters for a Domain Map” on page 177.](#)

- Related Documentation**
- [Domain Mapping Overview on page 168](#)
  - [Verifying and Managing Domain Map Configuration on page 178](#)

## Specifying an Access Profile in a Domain Map

You use access profiles to specify the access rules and options (for example, the RADIUS authentication server and attributes) that the router applies to subscriber sessions. The domain map feature enables you to apply a specific access profile for subscribers in a particular domain.

Access profiles can be specified or modified in several different ways. If conflicts occur, the router applies the access profiles based on the precedence rules shown in [Table 29 on page 170.](#)

**Table 29: Precedence Rules for Applying Access Profiles**

Precedence (High to Low)	How the Access Profile Is Applied
1	Specified by the RADIUS Redirect-VRouter-Name attribute (VSA 26-25)
2	Specified in the domain map configuration stanza
3	Indirectly specified in the domain map configuration stanza by the AAA logical system/routing instance mapping
4	Specified in the client configuration stanza
5	Specified in the logical system/routing instance configuration stanza

To include an access profile in a domain map:

1. Specify the domain map you want to configure.  

```
[edit access]  
user@host# edit domain map domain-map-name
```
2. Specify the access profile you want to include in the domain map.  

```
[edit access domain map domain-map-name]  
user@host# set access-profile profile-name
```

Related Documentation

- [Domain Mapping Overview on page 168](#)
- [Configuring a Domain Map on page 169](#)

### Specifying a Dynamic Profile in a Domain Map

A dynamic profile defines the set of characteristics that provide dynamic access and services for subscriber sessions (such as class-of-service, protocols, and interface support). The domain map feature enables you to apply a specific dynamic profile based on subscriber domains.

Dynamic profiles are configured at the **[edit dynamic-profiles]** hierarchy, and can be specified or modified in several different ways. If conflicts occur, the router applies the dynamic profiles based on the precedence rules shown in [Table 30 on page 171](#).

Table 30: Precedence Rules for Applying Dynamic Profiles

Precedence (High to Low)	How the Dynamic Profile Is Applied
1	Specified by the RADIUS Virtual-Router attribute (VSA 26-1) or the Redirect-VRouter-Name attribute (VSA 26-25)
2	Specified in the domain map configuration stanza
3	Specified in the client configuration stanza

To include a dynamic profile in a domain map:

1. Specify the domain map you want to configure.  

```
[edit access]  
user@host# edit domain map domain-map-name
```
2. Specify the dynamic profile you want to include in the domain map.  

```
[edit access domain map domain-map-name]  
user@host# set dynamic-profile profile-name
```

Related Documentation

- [Domain Mapping Overview on page 168](#)
- [Configuring a Domain Map on page 169](#)

## Specifying an Address Pool in a Domain Map

You can use the domain map feature to specify the address pool that the router uses to allocate address for subscriber sessions. The address pool can include both IPv4 and IPv6 address ranges.

Address pools can be specified or modified in several different ways. If conflicts occur, the router applies the address pool based on the precedence rules shown in [Table 31 on page 172](#).

**Table 31: Precedence Rules for Determining the Address Pool to Use**

Precedence (High to Low)	How the Address Pool Reference Is Provided
1	Specified by the RADIUS Framed-Pool attribute (RADIUS attribute 88)
2	Configured in the domain map configuration stanza
3	Specified in the client configuration stanza (by address match rules)

To specify the address pool used for a domain map:

1. Specify the domain map you want to configure.

```
[edit access]
user@host# edit domain map domain-map-name
```

2. Specify the address pool you want to use for the domain map.

```
[edit access domain map domain-map-name]
user@host# set address-pool pool-name
```

- Related Documentation**
- [Domain Mapping Overview on page 168](#)
  - [Configuring a Domain Map on page 169](#)

## Specifying an AAA Logical System/Routing Instance in a Domain Map

By default a domain map uses the subscriber logical system/routing instance as the context in which the **authd** daemon sends AAA authentication and accounting requests. You can optionally configure the domain map to direct AAA requests to a particular context based on the subscriber domain name. Specifying a non-default AAA context enables you to manage workflow and traffic load, and to efficiently make changes for a large number of subscribers. For example, after upgrading your RADIUS services, you might configure a domain map to specify that all subscribers in the domain **xyz.com** are now authenticated by a RADIUS server in a particular non-default AAA context.

**NOTE:** Changing the AAA context does not change the subscriber context. You use the **target-logical-system** command to explicitly configure the logical system/routing instance for subscribers.

To configure the default logical system and a non-default routing instance for AAA requests:

1. Specify the domain map you want to configure.

```
[edit access]
user@host# edit domain map domain-map-name
```

2. Specify the non-default routing instance. The AAA logical system is automatically set to the default.

```
[edit access domain map domain-map-name]
user@host# set aaa-routing-instance routing-instance-name
```

**NOTE:** Subscriber management is supported in the default logical system only. The following procedure, which describes configuring a non-default logical system, is for future extensions of subscriber management and is not supported in current Junos OS releases.

To configure a non-default logical system in which you want the **authd** daemon to send AAA requests:

1. Specify the domain map you want to configure.

```
[edit access]
user@host# edit domain map domain-map-name
```

2. Specify the logical system and optionally the non-default routing instance for AAA requests.

- To configure a non-default logical system and default routing instance for AAA requests:

```
[edit access domain map domain-map-name]
user@host# set aaa-logical-system logical-system-name
```

- To configure a non-default logical system and a non-default routing instance for AAA requests:

```
[edit access domain map domain-map-name]
user@host# set aaa-logical-system logical-system-name aaa-routing-instance
routing-instance-name
```

#### Related Documentation

- [Domain Mapping Overview on page 168](#)
- [Configuring a Domain Map on page 169](#)
- [Specifying a Target Logical System/Routing Instance in a Domain Map on page 174](#)

## Specifying a Target Logical System/Routing Instance in a Domain Map

---

By default, the router places a subscriber in the logical system/routing instance of the interface on which the subscriber negotiations start. Subscriber management can then use the authentication server or a domain map to change the subscriber's logical system/routing instance.

To use the domain map method, you configure the domain map to specify the target logical system and routing instance for the subscriber's interface. You can optionally configure the domain map to use the default logical system and a specific non-default routing instance.

To configure a default target logical system and a non-default routing instance for a subscriber's interface:

1. Specify the domain map you want to configure.

```
[edit access]
user@host# edit domain map domain-map-name
```

2. Specify the non-default target routing instance. The target logical system is automatically set to the default.

```
[edit access domain map domain-map-name]
user@host# set target-routing-instance routing-instance-name
```

**NOTE:** Subscriber management is supported in the default logical system only. The following procedure, which describes configuring a non-default target logical system, is for future extensions of subscriber management and is not supported in current Junos OS releases.

---

To configure a non-default target logical system for a subscriber's interface:

1. Specify the domain map you want to configure.

```
[edit access]
user@host# edit domain map domain-map-name
```

2. Specify the target logical system and, optionally, the non-default target routing instance for the subscriber's interface.

- To configure a non-default target logical system and default target routing instance:

```
[edit access domain map domain-map-name]
user@host# set target-logical-system logical-system-name
```

- To configure a non-default target logical system and a non-default target routing instance:

```
[edit access domain map domain-map-name]
user@host# set target-logical-system logical-system-name target-routing-instance
routing-instance-name
```

## Configuring Domain Name Usage for Domain Maps

You can configure how the router determines domain names for the domain mapping feature. At the global level, you can specify rules that are used for domain maps. The global rules enable you to specify additional characters that the router can recognize as domain name delimiters and to specify the direction the router uses to parse domain names. At the domain map level, you can enable domain name stripping. Domain name stripping specifies that the router remove the domain name from the subscriber username prior to performing any additional processing for the domain map.

To configure domain name usage rules for domain maps:

1. (Optional) Configure the domain name delimiters you want the router to recognize for domain maps.  
[See “Specifying Domain Name Delimiters” on page 175.](#)
2. (Optional) Configure the parse direction you want the router to use when determining domain names for domain maps.  
[See “Specifying the Parsing Direction for Domain Names” on page 176.](#)
3. (Optional) Configure the router to remove the domain name from usernames in the domain map before using AAA services.  
[See “Enabling Domain Name Stripping” on page 176.](#)

- Related Documentation**
- [Domain Mapping Overview on page 168](#)
  - [Configuring a Domain Map on page 169](#)

---

## Specifying Domain Name Delimiters

A delimiter is the character that separates a subscriber username from the domain name. Delimiters are commonly used for domain name parsing or stripping. You can specify a maximum of eight delimiters that the router uses to recognize domain names for a domain map. If you do not configure any delimiters, the router uses the @ character by default.

For example, your network might include the subscribers **bob@abc.com**, **pete!xyz.com**, and **maria\pqr.com**. In this case, you configure the router to recognize the characters @, !, and \ as delimiters.

Keep the following guidelines in mind when specifying delimiters:

- You cannot use the semicolon (;) as a delimiter.
- If you configure optional delimiters, you must also specify the @ character (the default delimiter) if you want to continue to use it as a delimiter.

- If you configure optional delimiters and then unconfigure them, the router sets the domain map delimiter back to the default @ character.

To configure domain name delimiters for domain maps:

1. Specify that you want to configure domain attributes.

```
[edit]
user@host# edit access domain
```

2. Specify the characters you want to use as delimiters. Do not include spaces between the delimiters.

```
[edit access domain]
user@host# set delimiter [delimiter-character]
```

**Related  
Documentation**

- [Configuring Domain Name Usage for Domain Maps on page 175](#)

---

## Specifying the Parsing Direction for Domain Names

---

You can specify the direction in which the router performs the parsing operation it uses to identify subscriber domain names for domain maps. During the parsing operation, the router searches the username until it recognizes a delimiter. It then considers anything to the right of the delimiter as the domain. By default, the router parses from right to left, starting at the right-most character in the username.

The parsing direction you use is important when there are nested domain names. For example, for the username **user1@abc.com@xyz.com**, right-to-left parsing produces a domain name of **xyz.com**. For the same username, left-to-right parsing produces a domain name of **abc.com@xyz.com**.

To configure the domain name parsing direction for domain maps:

1. Specify that you want to configure domain attributes.

```
[edit]
user@host# edit access domain
```

2. Specify the parsing direction you want the router to use.

```
[edit access domain]
user@host# set parse-direction (left-to-right | right-to-left)
```

**Related  
Documentation**

- [Configuring Domain Name Usage for Domain Maps on page 175](#)

---

## Enabling Domain Name Stripping

---

You can configure the router to strip the domain name from usernames before any AAA services are used. Domain name stripping is done for domain maps. The router uses the delimiters and parsing direction you globally configure to determine the domain name that is removed. For example, if the router uses the default delimiter and parsing direction **right-to-left**, the username **user1@xyz.com** is stripped to be **user1**.

To configure the router to strip the domain name from usernames in a domain map:

1. Specify the domain map for the stripping operation.

```
[edit]
user@host# edit access domain map domain-map-name
```

2. Enable domain name stripping.

```
[edit access domain map domain-map-name]
user@host# set strip-domain
```

**Related  
Documentation**

- [Configuring Domain Name Usage for Domain Maps on page 175](#)

## Specifying a Tunnel Profile in a Domain Map

Tunnel profiles specify tunnel definitions (for example, a set of L2TP tunnels and their attributes) that the router applies to subscriber sessions. The domain map feature enables you to apply a specific tunnel profile to subscribers in a particular domain.

**NOTE:** A tunnel profile specified by a RADIUS server in the Tunnel-Group attribute (VSA 26-64) takes precedence over the tunnel profile specified in the domain map.

To include an tunnel profile in a domain map:

1. Specify the domain map you want to configure.

```
[edit access]
user@host# edit domain map domain-map-name
```

2. Specify the tunnel profile you want to include in the domain map.

```
[edit access domain map domain-map-name]
user@host# set tunnel-profile profile-name
```

**Related  
Documentation**

## Configuring PADN Parameters for a Domain Map

You can configure PPPoE to receive PPPoE Active Discovery Network (PADN) messages when a subscriber connects to a PPPoE server. The PADN information associates the PPPoE session with a set of routes that the session can use. You can configure the route information in a domain map, which enables you to apply specific PADN information to subscribers in a particular domain. You can configure a maximum of 16 routes in a domain map.

To configure PADN parameters in a domain map:

1. Specify the domain map you want to configure.

```
[edit access]
user@host# edit domain map domain-map-name
```

2. Specify the PADN route information you want to include in the domain map. For each route, include the destination IP address, subnet mask, and route metric.

```
[edit access domain map domain-map-name]
user@host# set padn destination-address mask destination-mask metric route-metric
```

## Example: Configuring an Address-Assignment Pool

This example shows an address-assignment pool configuration that creates two pools, one for IPv4 DHCP clients (**isp\_1**), and a second pool (**chi-fiber-ra**) that is used for router advertisement.

```

[edit access]
address-assignment {
    network-discovery-router-advertisement chi-fiber-ra;
    pool isp_1 {
        family inet {
            network 192.168.0.0/16;
            range southeast {
                low 192.168.102.2 high 192.168.102.254;
            }
            range northeast {
                low 192.168.119.2 high 192.168.119.250;
            }
        }
        host svale6.boston.net {
            hardware-address 90:00:00:01:00:01;
            ip-address 192.168.44.12;
        }
        dhcp-attributes {
            option-match {
                option-82 {
                    circuit-id fiber range northeast;
                }
                option-82 {
                    circuit-id cable_net range southeast;
                }
            }
            boot-file boot.client;
            boot-server 192.168.200.100;
            grace-period 3600;
            maximum-lease-time 18000;
            netbios-node-type p-node;
            router 192.168.44.44 192.168.44.45;
        }
    }
}
pool chi-fiber-ra {
    family inet6 {
        prefix 2008:2009:2010::/48;
        range fiber3 {

```

```
        low 2008:2009:2010::1/64;  
        high 2008:2009:2010::5/64;  
    }  
}  
}
```

This example creates an IPv4 address-assignment pool named **isp-1**, which contains two named address ranges, **southeast** and **northeast**. The address-assignment pool also contains a static binding for client **host sval6.boston.net**. The **ISP\_1** pool configuration also includes the **dhcp-attributes** statement, indicating that the pool is used for DHCP clients. If the option 82 **circuit-id** entry matches the string **fiber**, then DHCP assigns the client an address from the **northeast** range. If the option 82 **circuit-id** matches the string **cable\_net**, DHCP assigns an address from the **southeast** range.

The second address-assignment pool created in this example is **chi-fiber-ra**. The **neighbor-discovery-router-advertisement** statement at the beginning of the syntax specifies that this named address-assignment pool is used for router advertisement. The syntax at the end of the example configures the address-assignment pool named **chi-fiber-ra**.

## Extended DHCP Local Server Overview

---

You can enable the router to function as an extended DHCP local server and configure the extended DHCP local server options on the router. The extended DHCP local server provides an IP address and other configuration information in response to a client request. The DHCP local server supports the attachment of dynamic profiles and also interacts with the local AAA Service Framework to use back-end authentication servers, such as RADIUS, to provide subscriber authentication. You can configure dynamic profile and authentication support on a global basis or for a specific group of interfaces.

The extended DHCP local server enhances traditional DHCP server operation by utilizing centralized address-assignment pools. The address-assignment pools are managed independently of the DHCP local server and can be shared by different client applications.

You can also configure the extended DHCP local server to support IPv6 clients. Both DHCP local server and DHCPv6 local server support the specific address request feature, which enables you to assign a particular address to a client. See [“DHCPv6 Local Server Overview” on page 190](#) for information about the DHCPv6 local server feature.

**NOTE:** You cannot configure the extended DHCP local server and extended DHCP relay on the same interface.

---

To configure the extended DHCP local server on the router, you include the **dhcp-local-server** statement at the **[edit system services]** hierarchy level. See the [“\[edit system services dhcp-local-server\] Hierarchy Level” on page 1348](#) for the complete DHCP local server syntax.

This overview covers:

- [Interaction Among the DHCP Client, Extended DHCP Local Server, and Address-Assignment Pools on page 186](#)
- [Providing DHCP Client Configuration Information on page 187](#)
- [Minimal Configuration for Clients on page 188](#)
- [DHCP Local Server and Address-Assignment Pools on page 188](#)
- [DHCP Liveness Detection on page 189](#)

### Interaction Among the DHCP Client, Extended DHCP Local Server, and Address-Assignment Pools

In a typical carrier edge network configuration, the DHCP client is on the subscriber's computer, and the DHCP local server is configured on the router. The following steps provide a high-level description of the interaction among the DHCP local server, DHCP client, and address-assignment pools:

1. The DHCP client sends a discover packet to one or more DHCP local servers in the network to obtain configuration parameters and an IP address for the subscriber.
2. Each DHCP local server that receives the discover packet then searches its address-assignment pool for the client address and configuration options. Each local server creates an entry in its internal client table to keep track of the client state, then sends a DHCP offer packet to the client.
3. On receipt of the offer packet, the DHCP client selects the DHCP local server from which to obtain configuration information and sends a request packet indicating the DHCP local server selected to grant the address and configuration information.
4. The selected DHCP local server sends an acknowledgement packet to the client that contains the client address lease and configuration parameters. The server also installs the host route and ARP entry, and then monitors the lease state.

## Providing DHCP Client Configuration Information

When the extended DHCP application receives a response from an external authentication server, the response might include information in addition to the IP address and subnet mask. The extended DHCP application uses the information from the authentication grant for the response the DHCP application sends to the DHCP client. The DHCP application can either send the information in its original form or the application might merge the information with local configuration specifications. For example, if the authentication grant includes an address pool name and a local configuration specifies DHCP attributes for that pool, the extended DHCP application merges the authentication results and the attributes in the reply that the server sends to the client.

A local configuration is optional — a client can be fully configured by the external authentication service. However, if the external authentication service does not provide client configuration, you must configure the local address-assignment pool to provide the configuration for the client. When a local configuration specifies options, the extended DHCP application adds the local configuration options to the offer PDU the server sends to the client. If the two sets of options overlap, the options in the authentication response from the external service take precedence.

When you use RADIUS to provide the authentication, the additional information might be in the form of RADIUS attributes and Juniper Networks VSAs. [Table 32 on page 187](#) lists the information that RADIUS might include in the authentication grant. See [“RADIUS Attributes and Juniper Networks VSAs Supported by the AAA Service Framework” on page 81](#) for a complete list of RADIUS attributes and Juniper Networks VSAs that the extended DHCP applications supports for subscriber access management.

**Table 32: Information in Authentication Grant**

Attribute Number	Attribute Name	Description
RADIUS attribute 8	Framed-IP-Address	Client IP address
RADIUS attribute 9	Framed-IP-Netmask	Subnet mask for client IP address (DHCP option 1)

Table 32: Information in Authentication Grant (*continued*)

Attribute Number	Attribute Name	Description
Juniper Networks VSA 26-4	Primary-DNS	Primary domain server (DHCP option 6)
Juniper Networks VSA 26-5	Secondary-DNS	Secondary domain server (DHCP option 6)
Juniper Networks VSA 26-6	Primary-WINS	Primary WINS server (DHCP option 44)
Juniper Networks VSA 26-7	Secondary-WINS	Secondary WINS server (DHCP option 44)
RADIUS attribute 27	Session-Timeout	Lease time
RADIUS attribute 88	Framed-Pool	Address assignment pool name
Juniper Networks VSA 26-109	DHCP-Guided-Relay-Server	DHCP relay server

### Minimal Configuration for Clients

The extended DHCP local server provides a minimal configuration to the DHCP client if the client does not have DHCP option 55 configured. The server provides the subnet mask of the address-assignment pool that is selected for the client. In addition to the subnet mask, the server provides the following values to the client if the information is configured in the selected address-assignment pool:

- **router**—A router located on the client's subnet. This statement is the equivalent of DHCP option 3.
- **domain name**—The name of the domain in which the client searches for a DHCP server host. This is the default domain name that is appended to hostnames that are not fully qualified. This is equivalent to DHCP option 15.
- **domain name server**—A Domain Name System (DNS) name server that is available to the client to resolve hostname-to-client mappings. This is equivalent to DHCP option 6.

### DHCP Local Server and Address-Assignment Pools

In the traditional DHCP server operation, the client address pool and client configuration information reside on the DHCP server. With the extended DHCP local server, the client address and configuration information reside in centralized address-assignment pools, which are managed independently of the DHCP local server and which can be shared by different client applications.

The extended DHCP local server also supports advanced pool matching and the use of named address ranges. You can also configure the local server to use DHCP option 82 information in the client PDU to determine which named address range to use for a

particular client. The client configuration information, which is configured in the address-assignment pool, includes user-defined options, such as boot server, grace period, and lease time.

Configuring the DHCP environment that includes the extended DHCP local server requires two independent configuration operations, which you can complete in any order. In one operation, you configure the extended DHCP local server on the router and specify how the DHCP local server determines which address-assignment pool to use. In the other operation, you configure the address-assignment pools used by the DHCP local server. The address-assignment pools contain the IP addresses, named address ranges, and configuration information for DHCP clients. See [“Configuring Address-Assignment Pools” on page 156](#) for details about creating and using address-assignment pools.

**NOTE:** The extended DHCP local server and the address-assignment pools used by the server must be configured in the same logical system and routing instance.

## DHCP Liveness Detection

Liveness detection for DHCP subscriber IP sessions utilizes an active liveness detection protocol to institute liveness detection checks for relevant clients. Clients are expected to respond to liveness detection requests within a specified amount of time. If the responses are not received within that time for a given number of consecutive attempts, then the liveness detection check fails and a failure action is implemented. You can configure

**NOTE:** DHCP liveness detection either globally or per DHCP group.

## DHCPv6 Local Server Overview

The DHCPv6 local server enhances the extended DHCP local server by providing support for IPv6. When a DHCPv6 client logs in, the DHCPv6 local server uses the AAA service framework to interact with the RADIUS server. The RADIUS server, which is configured independently of DHCP, authenticates the client and supplies the IPv6 prefix and client configuration parameters.

You can configure DHCPv6 local server to communicate the following attributes to the AAA service framework and RADIUS at login time:

- Client username
- Client password

**NOTE:** The client username, which uniquely identifies a subscriber, must be present in the configuration in order for DHCPv6 local server to use RADIUS authentication.

Based on the attributes that the DHCPv6 local server provides, RADIUS returns the information listed in [Table 33 on page 190](#) to configure the client:

**Table 33: RADIUS Attributes and VSAs for DHCPv6 Local Server**

Attribute Number	Attribute Name	Description
27	Session-Timeout	Lease time, in seconds. If not supplied, the lease does not expire
123	Delegated-IPv6-Prefix	Prefix that is delegated to the client
26-143	Max-Clients-Per-Interface	Maximum number of clients allowed per interface

The DHCPv6 local server is compatible with the extended DHCP local server and the extended DHCP relay agent, and can be enabled on the same interface as either the extended DHCP local server or DHCP relay agent.

The DHCPv6 local server provides many of the same features as the extended DHCP local server, including:

- Configuration for a specific interface or for a group of interfaces
- Site-specific usernames and passwords

- Numbered Ethernet interfaces
- Statically configured CoS and filters
- AAA directed login
- Use of the IA\_NA option to assign a specific address to a client

To configure the extended DHCPv6 local server on the router, you include the **dhcpv6** statement at the **[edit system services dhcp-local-server]** hierarchy level. See the “[\[edit system services dhcp-local-server\] Hierarchy Level](#)” on page 1348 for the complete DHCP local server syntax, including the DHCPv6 syntax.

You can also include the **dhcpv6** statement at the following hierarchy levels:

- **[edit logical-systems *logical-system-name* system services dhcp-local-server]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* system services dhcp-local-server]**
- **[edit routing-instances *routing-instance-name* system services dhcp-local-server]**

## DHCP Local Server Handling of Client Information Request Messages

DHCP clients that already have externally provided addresses may solicit further configuration information from a DHCP server by sending a DHCP information request that indicates what information is desired. By default, DHCP local server and DHCPv6 local server ignore any DHCP information requests that they receive. You can override this default behavior to enable processing of these messages. Include the **process-inform** statement at the **[edit system services dhcp-local-server overrides]** or **[edit system services dhcp-local-server dhcpv6 overrides]** hierarchy level.

By default, DHCP relay and DHCP relay proxy automatically forward DHCP information request messages without modification if the messages are received on an interface configured for a DHCP server group. DHCP relay and relay proxy drop information request

messages received on any other interfaces. You cannot disable this default DHCP relay and relay proxy behavior.

The information requested by these clients has typically been configured with the **dhcp-attributes** statement for an address pool defined by the **address-assignment pool** *pool-name* statement at the **[edit access]** hierarchy level.

When you enable processing of DHCP information requests, you can optionally specify the name of the pool from which the local server retrieves the requested configuration information for the client. If you do not specify a local pool, then the local server requests that AAA selects and returns only the name of the relevant pool.

DHCP local server responds to the client with a DHCP acknowledgment message that includes the requested information—if it is available. DHCPv6 local server responds in the same manner but uses a DHCP reply message. No subscriber management is applied as a result of the DHCP information request message.

When DHCPv6 is configured over PPP interfaces, the PPP RADIUS authentication data can be used to select the pool from which the response information is taken. Additionally other RADIUS attributes can also be inserted into the DHCPv6 reply message. If an overlap exists between RADIUS attributes and local pool attributes, the RADIUS values are used instead of the local configuration data. If no RADIUS information is received from the underlying PPP interface, then the behavior is the same as described previously for non-PPP interfaces.

## Dynamic Profile Attachment to DHCP Subscriber Interfaces Overview

The router's DHCP support enables you to attach a dynamic profile to a DHCP subscriber interface. When a DHCP subscriber logs in, the router instantiates the specified dynamic profile and then applies the services defined in the profile to the interface.

You can attach dynamic profiles to all interfaces or you can specify a particular group of interfaces to which the profile is attached. Both the DHCP local server and the DHCP relay agent support the attachment of dynamic profiles to interfaces.

You can enable the following optional features when the dynamic profile is attached. The two options cannot be used together.

- Enable multiple DHCP subscribers to share the same VLAN logical interface. The firewall filters, CoS schedulers, and IGMP configuration of the clients are merged.
- Specify the primary dynamic profile that is instantiated when the first subscriber logs in.

## Multiple DHCP Subscribers Sharing the Same VLAN Logical Interface

The **aggregate-clients** statement specifies that the router merge the firewall filters, CoS schedulers, and IGMP configuration of multiple DHCP clients that are on the same VLAN logical interface (for example, multiple clients belonging to the same household). You can configure the aggregate-clients support for all interfaces or for a group of interfaces. The **aggregate-clients** statement provides the option of either merging (chaining) or replacing software components for each client.

By default, the feature is disabled and a single DHCP client is allowed per VLAN when a dynamic profile is associated with the VLAN logical interface.

When you specify the **merge** option, the router aggregates the software components for multiple subscribers as follows:

- Firewall filters—The filters are chained together using the precedence as the order of execution. If the same firewall filter is attached multiple times, the filter is executed only once.
- CoS schedulers—The different CoS schedulers are merged as if the scheduler map has multiple schedulers. The merge operation for the individual traffic-control-profiles parameters (shaping-rate, delay-buffer-rate, guaranteed-rate) preserves the maximum value for each parameter.
- IGMP configuration—The current IGMP configuration is replaced with the configuration of the newest DHCP client.

When you specify the **replace** option, the entire logical interface is replaced whenever a new client logs in to the network using the same VLAN logical interface. For example, if a customer subscribes to voice, video, and data services on the network, when a voice client logs in, instead of applying a specific voice filter for only that service, the entire voice, video, and data filter chain is applied.

**NOTE:** You cannot use a dynamic demux interface to represent multiple subscribers in a dynamic profile attached to an interface. One dynamic demux interface represents one subscriber. Do not configure the **aggregate-clients** option when attaching a dynamic profile to a demux interface for DHCP.

## Primary Dynamic Profile

The **use-primary** option enables you to specify the primary dynamic profile that is instantiated when the first subscriber logs in. Subsequent subscribers are not assigned the primary dynamic profile; instead, they are assigned the dynamic profile specified for the interface. When the first subscriber logs out, the next subscriber that logs in is assigned the primary dynamic profile.

This feature can conserve logical interfaces in a network where dynamic IP demux interfaces are used to represent subscribers. To conserve interfaces, make sure the primary profile that you specify does not create a demux interface, but provides the initial policies for the primary interface subscriber.

---

## Port Number Requirements for DHCP Firewall Filters

---

When you configure a firewall filter to perform some action on DHCP packets at the Routing Engine, such as protecting the Routing Engine by allowing only proper DHCP packets, you must specify both port 67 (bootps) and port 68 (bootpc) for both the source and destination. The firewall filter acts at both the line cards and the Routing Engine.

This requirement applies to both DHCP local server and DHCP relay, but it applies only when DHCP is provided by the `jdhcpd` process. MX Series routers, M120 routers, and M320 routers use `jdhcpd`. For DHCP relay, that means the configuration is required only at the **[edit forwarding-options dhcp-relay]** hierarchy level and not at the **[edit forwarding-options helpers bootp]** hierarchy level.

DHCP packets received on the line cards are encapsulated by `jdhcpd` with a new UDP header where their source and destination addresses are set to port 68 before being forwarded to the Routing Engine.

For DHCP relay and DHCP proxy, packets sent to the DHCP server from the router have both the source and destination UDP ports set to 67. The DHCP server responds using the same ports. However, when the line card receives these DHCP response packets, it changes both port numbers from 67 to 68 before passing the packets to the Routing Engine. Consequently the filter needs to accept port 67 for packets relayed from the client to the server, and port 68 for packets relayed from the server to the client.

Failure to include both port 67 and port 68 as described here results in most DHCP packets not being accepted.

For complete information about configuring firewall filters in general, see Junos OS Firewall Filters and Traffic Policers Configuration Guide.

## DHCP Duplicate Client Differentiation Using Client Subinterface Overview

---

In some network environments, client IDs and MAC addresses might not be unique, resulting in duplicate clients. For example, two network adapters might be manufactured with the same hardware address, resulting in a duplicate MAC address among the DHCP clients attached to the router. A duplicate DHCP client occurs when a client attempts to get a lease, and that client has the same client ID or the same MAC address as an existing DHCP client.

When DHCP server receives a request from a new client that has a duplicate ID or MAC address, DHCP server terminates the address lease for the existing client and returns the address to its original address pool. DHCP server then assigns a new address and lease to the new client.

By default, both DHCP local server and DHCP relay use the subnet information to differentiate between duplicate clients. However, in some cases, this level of differentiation is not adequate. For example, when multiple subinterfaces share the same underlying loopback interface with the same preferred source address, the interfaces appear to be on the same subnet. In this situation, the default configuration prevents duplicate clients.

You can provide greater differentiation between duplicate clients by configuring DHCP to consider the client subinterface when duplicate clients occur. In this optional configuration, DHCP uniquely identifies:

- The subnet on which the client resides

- The subinterface on which the client resides
- The client within the subnet

**Related  
Documentation**

- [Configuring DHCP Duplicate Client Support on page 198](#)
- [Guidelines for Configuring Support for DHCP Duplicate Clients on page 197](#)

---

## Guidelines for Configuring Support for DHCP Duplicate Clients

---

This topic describes the guidelines for configuring DHCP to include the client subinterface in order to distinguish between duplicate clients (clients with the same MAC address or client ID) in a subscriber access environment.

When configuring DHCP duplicate client support, consider the following guidelines:

- The optional DHCP duplicate client support feature is used for DHCPv4 clients. For DHCPv6, client identification is independent of MAC address.
- For DHCP relay agent configuration:
  - DHCP relay must be configured to insert option 82, regardless of whether or not the incoming packet has option 82.
  - Option 82 must include the Agent Circuit ID suboption (suboption 1).
  - Option 82 must be the interface name, not the interface description.
  - DHCP server must echo option 82 in the server's reply. This is required because of the following:
    - The giaddr inserted by DHCP relay is the same for duplicate clients on different subinterfaces. The DHCP local server uses option 82 when allocating the IP address.
    - DHCP relay uses the echoed option 82 to learn the client subinterface and to construct the client key.
- For the Layer 3 wholesale model:
  - The wholesaler and retailer logical system/routing instances must have the same **duplicate-clients-on-interface** statement configuration.
  - For DHCP relay, the wholesaler and the retailer routing contexts must both be configured with the Agent Circuit ID suboption (suboption 1) in option 82.

**Related  
Documentation**

- [DHCP Duplicate Client Differentiation Using Client Subinterface Overview on page 196](#)

## Configuring DHCP Duplicate Client Support

---

You can optionally configure DHCP local server and DHCP relay to include a client subinterface when distinguishing between two clients that have the same MAC address or client ID. The configuration is a global setting for each logical system/routing instance.

To configure DHCP local server to include the client subinterface:

1. Specify that you want to configure DHCP local server.

```
[edit system services]
user@host# edit dhcp-local-server
```

2. Configure the optional duplicate client support.

```
[edit system services dhcp-local-server]
user@host# set duplicate-clients-on-interface
```

To configure DHCP relay agent to include the client subinterface:

1. Specify that you want to configure DHCP relay agent.

```
[edit forwarding-options]
user@host# edit dhcp-relay
```

2. Configure the optional duplicate client support.

```
[edit system services dhcp-relay]
user@host# set duplicate-clients-on-interface
```

## Using External AAA Authentication Services with DHCP

---

The extended DHCP local server, including DHCPv6 local server, and the extended DHCP relay agent, including DHCPv6 relay agent, support the use of external AAA authentication services, such as RADIUS, to authenticate DHCP clients. When the extended DHCP local server or relay agent receives a discover PDU from a client, the extended DHCP application contacts the AAA server to authenticate the DHCP client. The extended DHCP application can obtain client addresses and DHCP configuration options from the external AAA authentication server.

**NOTE:** This section uses the term *extended DHCP application* to refer to both the extended DHCP local server and the extended DHCP relay agent.

---

The external authentication feature also supports AAA directed logout. If the external AAA service supports a user logout directive, the extended DHCP application honors the logout and responds as though it were requested by a CLI management command. All of the client state information and allocated resources are deleted at logout. The extended

DHCP application supports directed logout using the list of configured authentication servers you specify with the [authentication-server](#) statement at the **[edit access profile profile-name]** hierarchy level.

You can configure either global authentication support or group-specific support.

You must configure the **username-include** statement to enable the use of authentication. The **password** statement is not required and does not cause DHCP to use authentication if the **username-include** statement is not included.

To configure DHCP local server and DHCP relay agent authentication support:

1. Specify that you want to configure authentication options.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# edit authentication
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit authentication
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit authentication
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit authentication
```

2. (Optional) Configure a password that authenticates the username to the external authentication service.

See [“Configuring Passwords for Usernames”](#) on page 221.

3. (Optional) Configure optional features to create a unique username.

See [“Creating Unique Usernames for DHCP Clients”](#) on page 222.

## Configuring How the Extended DHCP Local Server Determines Which Address-Assignment Pool to Use

You can specify the match order in which the extended DHCP local server uses the client data to determine the address-assignment pool that provides the IP address and configuration for a DHCP client. You use the **pool-match-order** statement to specify the match order. If you do not specify the **pool-match-order**, the router uses the default

**ip-address-first** matching to select the address pool. After DHCP local server determines the address assignment pool to use, the server performs the matching based on the criteria you specified in the pool configuration.

In the default **ip-address-first** matching, the server selects the address-assignment pool to use by matching the IP address in the client DHCP request with the network address of the address-assignment pool. If the client request contains the gateway IP address (giaddr), the local server matches the giaddr to the address-assignment pool's address. If there is no giaddr in the request, then the DHCP local server matches the IP address of the receiving interface to the address of the address-assignment pool.

In **external-authority** matching, the DHCP local server receives the address assignment from an external authority, such as RADIUS or Diameter. If RADIUS is the external authority, the DHCP local server uses the Framed-IPv6-Pool attribute (RADIUS attribute 100) to select the pool. If Diameter is the external authority, the server uses the Diameter counterpart of the Framed-IPv6-Pool attribute to determine the pool.

For IPv4 address-assignment pools, you can optionally configure the extended DHCP local server to match the DHCP relay agent information option (option 82) in the client DHCP packets to a named range in the address-assignment pool used for the client. Named ranges are subsets within the overall address-assignment pool address range, which you can configure when you create the address-assignment pool.

**NOTE:** To use the DHCP local server option 82 matching feature with an IPv4 address-assignment pool, you must ensure that the **option-82** statement is included in the **dhcp-attributes** statement for the address-assignment pool.

To configure the matching order the extended DHCP local server uses to determine the address-assignment pool used for a client:

1. Access the **pool-match-order** configuration.

```
[edit system services dhcp-local-server]
user@host# edit pool-match-order
```

2. Specify the pool matching methods in the order in which the router performs the methods. You can specify the methods in any order. All methods are optional—the router uses the **ip-address-first** method by default.

- Configure the router to use an external addressing authority.

```
[edit system services dhcp-local-server pool-match-order]
user@host# set external-authority
```

- Configure the router to use the ip-address-first method.

```
[edit system services dhcp-local-server pool-match-order]
user@host# set ip-address-first
```

- (IPv4 address-assignment pools only) Specify the option 82 matching method.

```
[edit system services dhcp-local-server pool-match-order]
user@host# set option-82
```

## Grouping Interfaces with Common DHCP Configurations

You use the group feature to group together a set of interfaces and then apply a common DHCP configuration to the named interface group. The extended DHCP local server, DHCPv6 local server, DHCP relay agent, and DHCPv6 relay agent all support interface groups.

The following steps create a DHCP local server group; the steps are similar for the DHCPv6 local server, DHCP relay agent, and DHCPv6 relay agent.

To configure a DHCP local server interface group:

1. Specify that you want to configure DHCP local server.

```
[edit system services]
user@host# edit dhcp-local-server
```

2. Create the group and assign a name.

```
[edit system services dhcp-local-server]
user@host# edit group boston
```

3. Specify the names of one or more interfaces on which the extended DHCP application is enabled. You can repeat the `interface interface-name` statement to specify multiple interfaces within the group, but you cannot use the same interface in more than one group.

```
[edit system services dhcp-local-server group boston]
user@host# set interface fe-1/0/1.1
user@host# set interface fe-1/0/1.2
```

4. (Optional) You can use the `upto` option to specify a range of interfaces for a group.

```
[edit system services dhcp-local-server group boston]
user@host# set interface fe-1/0/1.3 upto fe-1/0/1.9
```

5. (Optional) You can use the `exclude` option to exclude a specific interface or a specified range of interfaces from the group. For example:

```
[edit system services dhcp-local-server group boston]
user@host# set interface fe-1/0/1.1 upto fe-1/0/1.102
user@host# set interface fe-1/0/1.6 exclude
user@host# set interface fe-1/0/1.70 upto fe-1/0/1.80 exclude
```

---

## Guidelines for Configuring Interface Ranges

This topic describes guidelines to consider when configuring interface ranges for named interface groups for DHCP local server and DHCP relay. The guidelines refer to the following configuration statement:

```
user@host# set interface interface-name upto upto-interface-name
```

- The start subunit, **interface *interface-name***, serves as the key for the stanza. The remaining configuration settings are considered attributes.
- If the subunit is not included, an implicit .0 subunit is enforced. The implicit subunit is applied to all interfaces when autoconfiguration is enabled. For example, **interface ge-2/2/2** is treated as **interface ge-2/2/2.0**.
- Ranged entries contain the **upto** option, and the configuration applies to all interfaces within the specified range. The start of a ranged entry must be less than the end of the range. Discrete entries apply to a single interface, except in the case of autoconfiguration, in which a 0 (zero) subunit acts as a wildcard.
- Interface stanzas defined within the same router context are dependent and can constrain each other—both DHCP local server and DHCP relay are considered. Interface stanzas defined across different router contexts are independent and do not constrain one another.
- Each interface stanza, whether discrete or ranged, has a unique start subunit across a given router context. For example, the following configuration is not allowed within the same group because **ge-1/0/0.10** is the start subunit for both.

```
interface ge-1/0/0.10 upto ge-1/0/0.30
interface ge-1/0/0.10
```

- Two groups cannot share interface space. For example, the following configuration is not allowed because the three stanzas share the same space and interfere with one another—**interface ge-1/0/0.26** is common to all three.

```
dhcp-relay group diamond interface ge-1/0/0.10 upto ge-1/0/0.30
dhcp-local-server group ruby interface ge-1/0/0.26
dhcp-relay group sapphire interface ge-1/0/0.25 upto ge-1/0/0.35
```

- Two ranges cannot overlap, either within a group or across groups. Overlapping occurs when two interface ranges share common subunit space but neither range is a proper subset of the other. The following ranges overlap:

```
interface ge-1/0/0.10 upto ge-1/0/0.30
interface ge-1/0/0.20 upto ge-1/0/0.40
```

- A range can contain multiple nested ranges. A nested range is a proper subset of another range. When ranges are nested, the smallest matching range applies.

In the following example, the three ranges nest properly:

```
interface ge-1/0/0.10 upto ge-1/0/0.30
interface ge-1/0/0.12 upto ge-1/0/0.15 exclude
interface ge-1/0/0.25 upto ge-1/0/0.29 exclude
```

- Discrete interfaces take precedence over ranges. In the following example, interface **ge-1/0/0.20** takes precedence and enforces an interface client limit of 5.

```
interface ge-1/0/0.10 upto ge-1/0/0.30
interface ge-1/0/0.15 upto ge-1/0/0.25 exclude
interface ge-1/0/0.20 overrides interface-client-limit 5
```

**Related  
Documentation**

- [Grouping Interfaces with Common DHCP Configurations on page 201](#)

## Group-Specific DHCP Local Server Options

You can include the following statements at the **[edit system services dhcp-local-server group group-name]** hierarchy level to set group-specific DHCP local server configuration options, and at the **[edit system services dhcp-local-server]** hierarchy level to set global DHCP local server configuration options. Statements configured at the **[edit system services dhcp-local-server group group-name]** hierarchy level apply only to the named group of interfaces, and override any global DHCP local server settings configured with the same statements at the **[edit system services dhcp-local-server]** hierarchy level.

DHCPv6 local server supports the same set of statements with the exception of the **dynamic-profile** statement.

- **authentication**—Configure the parameters the router sends to the external AAA server.
- **dynamic-profile**—Specify the dynamic profile that is attached to a group of interfaces.
- **interface**—Specify one or more interfaces, or a range of interfaces, that are within the specified group.
- **overrides**—Override the default configuration settings for the extended DHCP local server. For information, see “[Overriding Default DHCP Local Server Configuration Settings](#)” on page 204.

**Related  
Documentation**

- [Grouping Interfaces with Common DHCP Configurations on page 201](#)

## Overriding Default DHCP Local Server Configuration Settings

---

Subscriber management enables you to override certain default DHCP and DHCPv6 local server configuration settings. You can override settings at the global level, for a named group of interfaces, or for a specific interface within a named group.

- To override global default DHCP local server configuration options, include the **overrides** statement and its subordinate statements at the **[edit system services dhcp-local-server]** or **[edit system services dhcp-local-server dhcpv6]** hierarchy level.
- To override DHCP local server configuration options for a named group of interfaces, include the statements at the **[edit system services dhcp-local-server group group-name]** or **[edit system services dhcp-local-server dhcpv6 group]** hierarchy level.
- To override DHCP local server configuration options for a specific interface within a named group of interfaces, include the statements at the **[edit system services dhcp-local-server group group-name interface]** or **[edit system services dhcp-local-server dhcpv6 group group-name interface]** hierarchy level.

To override default DHCP local server configuration settings:

1. Specify that you want to configure override options.

Global override:

```
[edit system services dhcp-local-server]
user@host# edit overrides
```

Group level override:

```
[edit system services dhcp-local-server]
user@host# edit group boston overrides
```

Per-interface override:

```
[edit system services dhcp-local-server]
user@host# edit group boston overrides interface fe-1/0/1.1
```

2. (Optional) Override the maximum number of DHCP clients allowed per interface.  
See [“Specifying the Maximum Number of DHCP Clients Per Interface” on page 205](#).
3. (Optional) Override ARP table population in distrusted environments.  
See [“Disabling ARP Table Population” on page 206](#).
4. (Optional) Configure DHCP client auto logout.  
See [“Automatically Logging Out DHCP Clients” on page 210](#).
5. (Optional) Enable processing of information requests from clients.  
See [“Enabling Processing of Client Information Requests” on page 211](#).
6. (Optional, DHCPv6 only) Specify a delegated pool name to use for DHCPv6 multiple address assignment.  
See [“Specifying the Delegated Address Pool for IPv6 Prefix Assignment” on page 215](#).

7. (Optional, DHCPv6 only) Enable DHCPv6 rapid commit support.  
See [“Enabling DHCPv6 Rapid Commit Support” on page 212](#).
8. (Optional) Delete DHCP override settings.  
See [“Deleting DHCP Local Server and DHCP Relay Override Settings” on page 213](#).

**Related  
Documentation**

- [Group-Specific DHCP Local Server Options on page 203](#)
- [Deleting DHCP Local Server and DHCP Relay Override Settings on page 213](#)

## Specifying the Maximum Number of DHCP Clients Per Interface

By default, there is no limit to the number of DHCP local server or DHCP relay clients allowed on an interface. However, you can override the default setting and specify the maximum number of clients allowed per interface, in the range 1 through 500,000. When the number of clients on the interface reaches the specified limit, no additional DHCP Discover PDUs or DHCPv6 Solicit PDUs are accepted. When the number of clients subsequently drops below the limit, new clients are again accepted.

**NOTE:** The maximum number of DHCP (and DHCPv6) local server clients or DHCP (and DHCPv6) relay clients can also be specified by Juniper Networks VSA 26-143 during client login. The VSA-specified value always takes precedence if the `interface-client-limit` statement specifies a different number.

If the VSA-specified value differs with each client login, DHCP uses the largest limit set by the VSA until there are no clients on the interface.

To configure the maximum number of DHCP clients allowed per interface:

1. Specify that you want to configure override options.
  - For DHCP local server:
 

```
[edit system services dhcp-local-server]
user@host# edit overrides
```
  - For DHCPv6 local server:
 

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit overrides
```
  - For DHCP relay agent:
 

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```
  - For DHCPv6 relay agent:
 

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit overrides
```

2. Configure the maximum number of clients allowed per interface. (DHCP local server, DHCPv6 local server, DHCP relay agent and DHCPv6 relay agent all support the **interface-client-limit** statement.)

```
[edit system services dhcp-local-server overrides]
user@host# set interface-client-limit number
```

## Disabling ARP Table Population

By default, DHCP populates the ARP table with the MAC address of a client when the client binding is established. However, you may choose to use the DHCP **no-arp** statement to hide the subscriber MAC address information, as it appears in ARP table entries.

When running in a trusted environment (that is, when not using the **no-arp** statement), DHCP populates the ARP table with unique MAC addresses contained within the DHCP PDU for each DHCP client:

**Table 34: ARP Table in Trusted Environment**

IP Address	MAC Address
Client 1 IP Address	MAC A
Client 2 IP Address	MAC B
Client 3 IP Address	MAC C

In distrusted environments, you can specify the **no-arp** statement to hide the MAC addresses of clients. When you specify the **no-arp** statement, DHCP does not automatically populate the ARP table with MAC address information from the DHCP PDU for each client. Instead, the system performs an ARP to obtain the MAC address of each client and obtains the MAC address of the immediately attached device (for example, a DSLAM). DHCP populates the ARP table with the same interface MAC address (for example, MAC X from a DSLAM interface) for each client:

**Table 35: ARP Table in Distrusted Environment**

IP Address	MAC Address
Client 1 IP Address	MAC X
Client 2 IP Address	MAC X
Client 3 IP Address	MAC X

To disable ARP table population:

1. Specify that you want to configure override options.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# edit overrides
```

- For DHCP relay:

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Disable ARP table population with client-specific information. (DHCP local server and DHCP relay agent both support the **no-arp** statement.)

- For DHCP local server:

```
[edit system services dhcp-local-server overrides]
user@host# set no-arp
```

- For DHCP relay:

```
[edit forwarding-options dhcp-relay overrides]
user@host# set no-arp
```

#### Related Documentation

## Configuring DHCP Snooped Packets Forwarding Support for DHCP Local Server

You can configure how DHCP local server handles DHCP snooped packets. Depending on the configuration, DHCP local server either forwards or drops the snooped packets it receives.

[Table 36 on page 208](#) indicates the action the router takes for DHCP local server snooped packets.

**NOTE:** Configured interfaces are those interfaces that have been configured with the **group** statement in the `[edit system services dhcp-local-server]` hierarchy. Non-configured interfaces are those that are in the logical system/routing instance but have not been configured by the **group** statement.

Table 36: Actions for DHCP Local Server Snooped Packets

forward-snooped-clients Configuration	Action on Configured Interfaces	Action on Non-Configured Interfaces
forward-snooped-clients not configured	dropped	dropped
all-interfaces	forwarded	forwarded
configured-interfaces	forwarded	dropped
non-configured-interfaces	dropped	forwarded

To configure DHCP snooped packet forwarding for DHCP local server:

1. Specify that you want to configure DHCP local server.

```
[edit]
user@host# edit system services dhcp-local-server
```

2. Enable DHCP snooped packet forwarding for DHCP local server.

```
[edit system services dhcp-local-server]
user@host# edit forward-snooped-clients
```

3. Specify the interfaces that are supported for snooped packet forwarding.

```
[edit system services dhcp-local-server forward-snooped-clients]
user@host# set (all-interfaces | configured-interfaces | non-configured-interfaces)
```

For example, to configure DHCP local server to forward DHCP snooped packets on only configured interfaces:

```
[edit]
system {
  services {
    dhcp-local-server {
      forward-snooped-clients configured-interfaces;
    }
  }
}
```

## DHCP Auto Logout Overview

This topic provides an introduction to the optional DHCP auto logout feature and includes the following sections:

- [Auto Logout Overview on page 209](#)
- [How DHCP Identifies and Releases Clients on page 209](#)
- [Option 60 and Option 82 Requirements on page 210](#)

## Auto Logout Overview

Auto logout is an optional configuration for DHCP local server and DHCP relay agent that improves the efficiency of DHCP IP address assignment. Auto logout enables IP addresses to be immediately released and returned to the address pool when the addresses are no longer used by DHCP clients. DHCP can then assign the addresses to other clients. Without auto logout, an IP address is blocked for the entire lease period, and DHCP must wait until the address lease time expires before reusing the address.

Auto logout is particularly useful when DHCP uses long lease times for IP address assignments and to help avoid allocating duplicate IP addresses for a single client. For example, you might have an environment that includes set-top boxes (STB) that are often upgraded or replaced. Each time a STB is changed, the new STB repeats the DHCP discover process to obtain client configuration information and an IP address. DHCP views the new STB as a completely new client and assigns a new IP address—the previous IP address assigned to the client (the old STB) remains blocked and unavailable until the lease expires. If auto logout is configured in this situation, DHCP recognizes that the new STB is actually the same client and then immediately releases the original IP address. DHCP relay agent acts as a proxy client for auto logout and sends a DHCP release message to the DHCP server.

## How DHCP Identifies and Releases Clients

The auto logout feature requires that DHCP explicitly identify clients. By default, DHCP local server and DHCP relay agent identify clients based on MAC address or Client Identifier. However, in some cases this type of identification might not be sufficient. For example, in the previous STB example, each STB has a different MAC address, so DHCP incorrectly assumes that an upgraded or replacement STB is a new client.

In order to explicitly identify clients, auto logout uses a secondary identification method when the primary identification method is unsuccessful—the primary method is considered unsuccessful if the MAC address or Client Identifier does not match that of an existing client. The secondary identification method is based on the DHCP option 60 and option 82 information in DHCP discover messages.

Both the primary and secondary identification methods use subnet information to differentiate between clients. The primary identification method differentiates between two clients with the same MAC address (or same Client Identifier) if the clients are on different subnets. Similarly, the secondary identification method considers two clients as different if they have the same option 60 and option 82 information, but different subnets.

DHCP local server and DHCP relay agent perform the following operations when auto logout is enabled and the secondary identification method identifies a duplicate client (that is, the discover packet is from an existing client).

- DHCP local server immediately releases the existing address.
- DHCP relay agent immediately releases the existing client and then sends a DHCP release packet to the DHCP server. Sending the release packet ensures that DHCP relay and the DHCP server are synchronized.

If the DHCP relay receives a DISCOVER message from an existing client, the DHCP relay forwards the DISCOVER message to the DHCP server. The DHCP relay preserves the binding if the client's existing IP address is returned by the DHCP server. This behavior is not applicable if the proxy-mode override or client-discover-match functionality are enabled.

**NOTE:** If the DHCP relay agent is in snoop mode, DHCP relay releases the client but does not send a release packet to the DHCP server if the discover packet is for a passive client (a client added as a result of snooped packets) or if the discover packet is a snooped packet.

## Option 60 and Option 82 Requirements

DHCP local server requires that the received discover packet include both DHCP option 60 and option 82. If either option is missing, DHCP local server cannot perform the secondary identification method and auto logout is not used.

DHCP relay agent requires that the received discover packet contain DHCP option 60. DHCP relay determines the option 82 value based on the guidelines provided in [“DHCP Relay Agent Option 82 Value for Auto Logout” on page 289](#).

### Related Documentation

- [Automatically Logging Out DHCP Clients on page 210](#)
- [DHCP Relay Agent Option 82 Value for Auto Logout on page 289](#)
- [Clearing DHCP Bindings for Subscriber Access on page 217](#)

## Automatically Logging Out DHCP Clients

---

You can configure the extended DHCP local server and extended DHCP relay to automatically log out DHCP clients. Auto logout immediately releases an existing client when DHCP receives a discover packet that has the same DHCP option 60 and DHCP option 82 information as the existing client. DHCP then releases the existing client IP address without waiting for the normal lease expiration.

**NOTE:** When the existing client is released, the new client undergoes the normal authentication process. The new client might not receive the same IP address as the original client.

To configure DHCP client auto logout:

1. Specify that you want to configure override options.
  - For DHCP local server:  

```
[edit system services dhcp-local-server]  
user@host# edit overrides
```
  - For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Enable auto logout. (DHCP local server and DHCP relay agent both support the `client-discover-match` statement.)

- For DHCP local server:

```
[edit system services dhcp-local-server overrides]
user@host# set client-discover-match
```

- For DHCP relay:

```
[edit forwarding-options dhcp-relay overrides]
user@host# set client-discover-match
```

**NOTE:** If you change the auto logout configuration, existing clients continue to use the auto logout setting that was configured when they logged in. New clients use the new setting.

## Enabling Processing of Client Information Requests

By default, DHCP local server and DHCPv6 local server do not respond to information request messages from the client. You can enable DHCP local server and DHCPv6 local server to process these messages and respond to them with an acknowledgment (ack or reply message, respectively) and the requested information.

DHCP relay agent automatically forwards the information request messages without modification to the configured server group by means of the interfaces configured for the respective server group. The messages are dropped if they are received on an unconfigured interface. DHCP relay proxy also supports forwarding these messages. You cannot disable forwarding of the information request messages.

Configure one or more local address pools if you want to use a local pool rather than one provided by AAA. See [“Configuring an Address-Assignment Pool Name and Addresses” on page 157](#). For processing information request messages, the address configuration is not necessary. For DHCP local server, you must specify the IPv4 family; for DHCPv6 local server, you must specify the IPv6 family.

See [“Configuring DHCP Client-Specific Attributes” on page 160](#) for details about how to configure the information sought by clients that send information request messages.

To enable processing of DHCP client information request messages:

1. Specify that you want to configure override options.

- For DHCP local server:

```
[edit system services dhcp-local-server overrides]
user@host# set process-inform
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6 overrides]
user@host# set process-inform
```

2. (Optional) Specify a pool name from which DHCP information is returned to the client.

- For DHCP local server:

```
[edit system services dhcp-local-server overrides process-inform]
user@host# set pool pool-name
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6 overrides process-inform]
user@host# set pool pool-name
```

## Enabling DHCPv6 Rapid Commit Support

You can configure the extended DHCPv6 local server to support the DHCPv6 Rapid Commit option (DHCPv6 option 14). When rapid commit is enabled on the extended DHCPv6 local server, the server recognizes the Rapid Commit option in Solicit messages sent from the DHCPv6 client. (DHCPv6 clients are configured separately to include the DHCPv6 Rapid Commit option in the Solicit messages.) The server and client then use a two-message exchange (Solicit and Reply) to configure clients, rather than the default four-message exchange (Solicit, Advertise, Request, and Reply). The two-message exchange provides faster client configuration, and is beneficial in environments in which networks are under a heavy load.

You can configure the DHCPv6 local server to support the Rapid Commit option globally, for a specific group, or for a specific interface. By default, Rapid Commit support is disabled on the DHCPv6 local server.

To configure the DHCPv6 local server to support the DHCPv6 Rapid Commit option:

1. Specify that you want to configure override options.

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit overrides
```

2. Enable rapid commit support.

```
[edit system services dhcp-local-server dhcpv6 overrides]
user@host# set rapid-commit
```

#### Related Documentation

- [Deleting DHCP Local Server and DHCP Relay Override Settings on page 213](#)
- [Extended DHCP Local Server Overview on page 186](#)

## Deleting DHCP Local Server and DHCP Relay Override Settings

You can delete override settings for DHCP local server and DHCP relay globally, for a named group, or for a specific interface within a named group. You can delete a specific override setting or all overrides.

- To delete a specific DHCP override setting at a particular hierarchy level, include the **overrides** statement with the appropriate subordinate statements. For example, to delete the DHCP local server override **no-arp** setting for a group named **marin20**:

```
[edit system services dhcp-local-server]
user@host# delete group marin20 overrides no-arp
```

- To delete all DHCP override settings at a hierarchy level, include the **overrides** statement without any subordinate statements. For example, to delete all DHCP relay overrides for interface **fxp0.0**, which is in group **marin20**:

```
[edit forwarding-options dhcp-relay]
user@host# delete group marin20 interface fxp0.0 overrides
```

## Use of DHCP Option 50 and DHCPv6 IA\_NA Option to Request a Specific IP Address

Subscriber management enables you to specify that DHCP local server assign a particular address to a client. For example, if a client is disconnected, you might use this capability to assign the same address that the client was using prior to being disconnected. If the requested address is available, DHCP assigns it to the client. If the address is unavailable, the DHCP local server offers another address, based on the address allocation process.

Both DHCP local server and DHCPv6 local server support the specific address request feature. DHCP local server uses DHCP option 50 in DHCP DISCOVER messages to request a particular address, while DHCPv6 local server uses the IA\_NA option (Identity Association for Non-Temporary Addresses) in DHCPv6 SOLICIT messages.

**NOTE:** Subscriber management supports only one address for each of the DHCPv6 IA\_NA or IA\_PD address types. If the DHCPv6 client requests more than one address for a given type, the DHCPv6 local server uses only the first address and ignores the other addresses.

---

## Multiple Address Assignment for DHCPv6 Clients

Subscriber management enables you to assign multiple addresses to a single DHCPv6 client. Multiple address support is enabled by default, and is activated when the DHCPv6 local server receives a DHCPv6 Solicit message from a subscriber that contains multiple addresses.

For example, you might use the multiple address assignment feature in a networking environment in which a customer premises equipment (CPE) device requires a host address and a delegated prefix. In such an environment, you can configure subscriber management to assign both a DHCPv6 IA\_NA (Identity Association for Non-Temporary Addresses) and an IA\_PD (Identity Association for Prefix Delegation) address to the client (the CPE device).

- [Multiple Address Assignment Using Local Address Pools or RADIUS on page 214](#)
- [Junos OS Predefined Variable for Multiple DHCPv6 Address Assignment on page 214](#)

### Multiple Address Assignment Using Local Address Pools or RADIUS

You can use either local address pools or RADIUS when assigning multiple addresses to a DHCP client. When at least one address is successfully allocated, the router creates a subscriber entry and binds the entry to the assigned address. If both addresses are successfully allocated, the router creates a single subscriber entry and binds both addresses to that entry.

You can also configure a delegated address pool, which explicitly specifies the address pool that subscriber management uses to assign IPv6 prefixes for subscribers.

### Junos OS Predefined Variable for Multiple DHCPv6 Address Assignment

Subscriber management provides a predefined variable that you can use to dynamically configure DHCPv6 multiple address assignment. You apply the Junos OS predefined variable, `$junos-subscriber-ipv6-multi-address`, as a demux source address in a dynamic profile. When the dynamic profile is attached to a subscriber, the variable is expanded to include both the host and prefix addresses. You use this variable instead of the `$junos-subscriber-ipv6-address` variable, which supports a single IPv6 address.

You include the `$junos-subscriber-ipv6-multi-address` variable at the `[edit dynamic-profile profile-name interfaces interface-name unit logical-unit-number family inet6 demux-source]` hierarchy level.

#### Related Documentation

- [Specifying the Delegated Address Pool for IPv6 Prefix Assignment on page 215](#)
- [Junos OS Predefined Variables on page 606](#)

## Specifying the Delegated Address Pool for IPv6 Prefix Assignment

You can explicitly specify a delegated address pool, which subscriber management uses to assign IPv6 prefixes for subscribers. You can specify the delegated address pool globally, for a specific group of interfaces, or for a particular interface.

**NOTE:** You can also use by Juniper Networks VSA 26-161 to specify the delegated address pool. The VSA-specified value always takes precedence over the **delegated-address** statement.

To configure the delegated address pool for DHCPv6 local server:

1. Specify that you want to configure override options.

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit overrides
```

2. Configure the delegated address pool.

```
[edit system services dhcp-local-server dhcpv6 overrides]
user@host# set delegated-pool paris-cable-12
```

## Subscriber Binding Retention During Interface Delete Events

You can configure the router to maintain DHCP subscribers when an event occurs that normally results in the router deleting the subscriber. For example, by default, the router logs out DHCP subscribers when an interface delete event occurs, such as a DPC reboot or failure. However, if you configure the router to maintain subscribers, the router identifies each subscriber that was on the deleted interface, and resumes normal packet processing for the subscriber when the interface is restored.

**NOTE:** Subscribers are logged off as usual when their lease expires, even if the router is configured to maintain subscribers and the subscriber is on a deleted interface that has not yet been restored.

You configure the router to maintain subscribers on a global basis— the configuration applies to DHCP local server, DHCPv6 local server, and DHCP relay clients in all logical routers and routing instances. When you enable the maintain subscribers feature, the router applies the feature to existing subscribers as well as subscribers who later connect.

If the maintain subscribers feature is enabled on the router, you can explicitly delete a subscriber binding and log out the subscriber by either specifying a lease expiration timeout or using one of the following commands, as appropriate:

- **clear dhcp server binding**
- **clear dhcpv6 server binding**
- **clear dhcp relay binding**

**Related  
Documentation**

- [Configuring the Router to Maintain DHCP Subscribers During Interface Delete Events on page 216](#)
- [Verifying and Managing the DHCP Maintain Subscribers Feature on page 216](#)

---

## Configuring the Router to Maintain DHCP Subscribers During Interface Delete Events

You can specify a configuration in which the router does not log out a subscriber when the subscriber's interface is deleted.

To configure the router to maintain DHCP subscribers when the subscriber interface is deleted:

1. Specify that you want to configure subscriber management.

```
[edit system services]  
user@host# edit subscriber-management
```

2. Configure the router to support the maintain-subscriber feature.

```
[edit system services subscriber-management]  
user@host# edit maintain-subscriber
```

3. Configure the router to enable the maintain-subscriber feature when an interface-delete event occurs.

```
[edit system services subscriber-management maintain-subscriber]  
user@host# set interface-delete
```

**Related  
Documentation**

- [Subscriber Binding Retention During Interface Delete Events on page 215](#)
- [Verifying and Managing the DHCP Maintain Subscribers Feature on page 216](#)

---

## Verifying and Managing the DHCP Maintain Subscribers Feature

**Purpose** Display information related to the DHCP maintain-subscribers feature and explicitly log out maintained clients.

**Action**

- To display DHCP local server binding information for the DHCP maintain subscribers feature:  

```
user@host>show dhcp server binding detail
```
- To display DHCPv6 local server binding information for the DHCP maintain subscribers feature:

```
user@host>show dhcpv6 server binding detail
```

- To display DHCP relay binding information for the DHCP maintain subscribers feature:

```
user@host>show dhcp relay binding detail
```

- To explicitly log out a DHCP local server subscriber when the maintain subscriber feature is enabled:

```
user@host>clear dhcp server binding binding-type
```

- To explicitly log out a DHCPv6 local server subscriber when the maintain subscriber feature is enabled:

```
user@host>clear dhcpv6 server binding binding-type
```

- To explicitly log out a DHCP relay subscriber when the maintain subscriber feature is enabled:

```
user@host>clear dhcp relay binding binding-type
```

#### Related Documentation

## Clearing DHCP Bindings for Subscriber Access

This topic provides the procedure you use to display current DHCP bindings, clear selected bindings, and verify that the specified bindings are successfully cleared.

Subscriber management enables you to clear DHCP bindings at several different levels for DHCP local server and DHCP relay agent. For example, you can clear the DHCP bindings on all interfaces, a group of interfaces, or a specific interface. You can also clear DHCP bindings based on IP address, MAC address, session-ID, DHCPv6 prefix, DHCPv6 Client ID, FPC, PIC, port, VLAN, or stacked VLAN (S-VLAN).

This topic includes examples to show several variations of the clear DHCP binding feature. The examples use DHCP local server commands; however, the procedure and commands are similar for DHCP relay agent, DHCPv6 local server, and DHCPv6 relay agent.

To clear bindings and verify the results for a specific IP address:

1. Display current bindings. Issue the appropriate variation of the **show dhcp server binding** command.

```
user@host> show dhcp server binding
2 clients, (2 bound, 0 selecting, 0 renewing, 0 rebinding)
```

IP address	Hardware address	Type	Lease expires at
192.168.32.1	90:00:00:01:00:01	active	2011-10-17 11:38:47 PST
192.168.32.3	90:00:00:02:00:01	active	2011-00-17 11:38:41 PST

2. Clear the binding you want to remove.

```
user@host> clear dhcp server binding 192.168.32.1
```

3. Verify that the binding has been cleared.

```
user@host> show dhcp server binding
1 clients, (1 bound, 0 selecting, 0 renewing, 0 rebinding)

IP address      Hardware address  Type    Lease expires at
192.168.32.3     90:00:00:02:00:01 active    2011-00-17 11:38:41 PST
```

The following examples show variations of the clear DHCP binding feature. The examples use the DHCP local server version of the commands.

**NOTE:** IP demux interfaces are not supported by the show and clear DHCP bindings commands for DHCP local server and DHCP relay agent.

To clear all bindings:

```
user@host> clear dhcp server binding all
```

To clear bindings on a specific interface:

```
user@host> clear dhcp server binding interface fe-0/0/2
```

To clear all bindings over an interface. This example uses the wildcard option.

```
user@host> clear dhcp server binding ge-1/0/0. *
```

To clear bindings on top of a specific VLAN. This example clears all bindings on top of VLAN 100.

```
user@host> clear dhcp server binding ge-1/0/0:100
```

To clear bindings for a specific S-VLAN. This example clears bindings on S-VLAN 100-200.

```
user@host> clear dhcp server binding ge-1/0/0:100-200
```

To clear all bindings on top of all demux VLANs:

```
user@host> clear dhcp server binding demux0
```

To clear all bindings on top of an underlying interface. This example clears the bindings on all demux VLANs on top of interface ae0:

```
user@host> clear dhcp server binding ae0
```

To clear PPP bindings. This example uses the wildcard feature and clears the PPP bindings over interface pp0.100 and pp0.200.

```
user@host> clear dhcp server binding pp0.*
```

To clear all bindings on an FPC. This example uses the wildcard feature and clears all DHCP bindings on FPC 1.

```
user@host> clear dhcp server binding ge-1/*
```

To clear all bindings on a PIC. This example uses the wildcard feature and clears all DHCP bindings on FPC 1, PIC 0.

```
user@host> clear dhcp server binding ge-1/0/*
```

To clear all bindings on a port. This example uses the wildcard feature and clears all DHCP bindings on FPC 1, PIC 0, port 0.

```
user@host> clear dhcp server binding ge-1/0/0.*
```

## Configuring the Router to Strictly Enforce the Subscriber Scaling License

You can configure the router to strictly enforce the subscriber scaling feature, which is part of the Junos Subscriber Access Feature Pack license. The subscriber scaling feature specifies the maximum number of subscribers that can be logged in at any one time.

When you configure strict scaling license support, the router performs the following actions:

- Strictly enforces the subscriber scaling license and does not allow any grace period. When the number of logged-in subscriber reaches the number allowed by the scaling license, no additional subscribers are allowed to log in.
- Creates the informational log message, "90 percent of installed subscriber scale licenses in use" in `/var/log/messages`, to inform you when you have 10 percent of the total allowed licenses remaining. The router clears this condition when license usage falls below 90 percent. The log message is created again if the 90 percent usage is later reached.

To configure the router to strictly enforce the subscriber scaling license:

1. Specify that you want to configure subscriber management.

```
[edit system services]
user@host# edit subscriber-management
```

2. Configure the router to enforce the scaling license.

```
[edit system services subscriber-management]
user@host# set enforce-strict-scale-limit-license
```

## Attaching Dynamic Profiles to DHCP Subscriber Interfaces

---

This topic describes how to attach a dynamic profile to a DHCP subscriber interface. When a DHCP subscriber logs in, the specified dynamic profile is instantiated and the services defined in the profile are applied to the interface.

This topic contains the following sections:

- [Attaching a Dynamic Profile to All DHCP Subscriber Interfaces on page 220](#)
- [Attaching a Dynamic Profile to a Group of DHCP Subscriber Interfaces on page 220](#)

### Attaching a Dynamic Profile to All DHCP Subscriber Interfaces

To attach a dynamic profile to all DHCP subscriber interfaces:

1. At the DHCP configuration hierarchy, use the **dynamic-profile** statement to specify the name of the dynamic profile to attach to all interfaces.
  - For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# set dynamic-profile vod-profile-22
```
  - For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# set dynamic-profile vod-profile-west
```
2. Optionally, you can configure the attribute to use when attaching the specified profile.

You can include either the **aggregate-clients** option to enable multiple DHCP subscribers to share the same VLAN logical interface, or the **use-primary** option to specify that the primary dynamic profile is used. The **aggregate-clients** option does not apply to demux subscriber interfaces. The two options are mutually exclusive.

  - To enable multiple subscribers to share the same VLAN logical interface:

```
[edit system services dhcp-local-server dynamic-profile]
user@host# set aggregate-clients merge
```
  - To use the primary dynamic profile:

```
[edit forwarding-options dhcp-relay dynamic-profile]
user@host# set use-primary subscriber_profile
```

### Attaching a Dynamic Profile to a Group of DHCP Subscriber Interfaces

Before you begin:

- Configure the interface group.  
[See “Grouping Interfaces with Common DHCP Configurations” on page 201.](#)

To attach a dynamic profile to a group of interfaces:

1. At the DHCP configuration hierarchy, specify the name of the interface group and the dynamic profile to attach to the group.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# set group boston dynamic-profile vod-profile-42
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# set group quebec dynamic-profile vod-profile-east
```

2. Optionally, you can configure the attribute to use when attaching the specified profile.

You can include either the **aggregate-clients** option to enable multiple DHCP subscribers to share the same VLAN logical interface, or the **use-primary** option to specify that the primary dynamic profile is used. The **aggregate-clients** option does not apply to demux subscriber interfaces. The two options are mutually exclusive.

- To enable multiple subscribers to share the same VLAN logical interface:

```
[edit system services dhcp-local-server dynamic-profile]
user@host# set aggregate-clients merge
```

- To use the primary dynamic profile:

```
[edit forwarding-options dhcp-relay dynamic-profile]
user@host# set use-primary subscriber_profile
```

## Configuring Passwords for Usernames

You can configure an optional password that the extended DHCP application presents to the external AAA authentication service to authenticate the specified username.

To configure a password that authenticates the username:

1. Specify that you want to configure authentication options.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# edit authentication
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit authentication
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit authentication
```

2. Configure the password. (DHCP local server, DHCPv6 local server, and DHCP relay agent all support the **password** statement.)

```
[edit system services dhcp-local-server authentication]
user@host# set password myPassword1234
```

- For information about supported characters in passwords, see “Configuring Special Requirements for Plain-Text Passwords” in the Junos OS System Basics Configuration Guide

---

## Creating Unique Usernames for DHCP Clients

---

You can configure the extended DHCP application to include additional information in the username that is passed to the external AAA authentication service when the DHCP client logs in. This additional information enables you to construct usernames that uniquely identify subscribers.

.....

**NOTE:** If you do not include a username in the authentication configuration, the router does not perform authentication; however, the IP address is provided by the local pool if it is configured.

When you use the DHCPv6 local server, you must configure authentication and the client username; otherwise client login fails.

.....

The following list describes the optional information that you can include as part of the username:

- **circuit-type**—The circuit type used by the DHCP client, for example **enet**.
- **client-id**—The client identifier option (option 1). (DHCPv6 local server DHCPv6 relay agent only)
- **delimiter**—The delimiter character that separates components that make up the concatenated username. The default delimiter is a period (.). The semicolon (;) is not supported as a delimiter character.
- **domain-name**—The client domain name as a string. The router adds the @ delimiter to the username.
- **interface-name**—The interface name, including the interface device and associated VLAN IDs.
- **logical-system-name**—The name of the logical system, if the receiving interface is in a logical system.
- **mac-address**—The client MAC address, in a string of the format **xxxx.xxxx.xxxx**. (Not supported for DHCPv6 local server)

- **option-60**—The portion of the option 60 payload that follows the length field. (Not supported for DHCPv6 local server)
- **option-82 <circuit-id> <remote-id>**—The specified contents of the option 82 payload. (Not supported for DHCPv6 local server)
  - **circuit-id**—The payload of the Agent Circuit ID suboption.
  - **remote-id**—The payload of the Agent Remote ID suboption.
  - Both **circuit-id** and **remote-id**—The payloads of both suboptions, in the format: **circuit-id[delimiter]remote-id**.
  - Neither **circuit-id** or **remote-id**—The raw payload of the option 82 from the PDU is concatenated to the username.

**NOTE:** For DHCP relay agent, the option 82 value used in creating the username is based on the option 82 value that is encoded in the outgoing (relayed) PDU.

- **relay-agent-interface-id**—The Interface-ID option (option 18). (DHCPv6 local server only)
- **relay-agent-remote-id**—The DHCPv6 Relay Agent Remote-ID option (option 37). (DHCPv6 local server only)
- **relay-agent-subscriber-id**—The DHCPv6 Relay Agent Subscriber-ID option (option 38). (DHCPv6 local server only)
- **routing-instance-name**—The name of the routing instance, if the receiving interface is in a routing instance.
- **user-prefix**—A string indicating the user prefix.

The router creates the unique username by including the specified additional information in the following order, with the fields separated by a delimiter.

For DHCP local server and DHCP relay agent:

```
user-prefix[delimiter]mac-address[delimiter]logical-system-name[delimiter]
routing-instance-name[delimiter]circuit-type[delimiter]interface-name[delimiter]option-82[delimiter]
option-60@domain-name
```

For DHCPv6 local server:

```
user-prefix[delimiter]logical-system-name[delimiter]routing-instance-name[delimiter]
circuit-type[delimiter]interface-name[delimiter]relay-agent-remote-id[delimiter]
relay-agent-subscriber-id[delimiter]relay-agent-interface-id[delimiter]client-id@domain-name
```

To configure a unique username:

1. Specify that you want to configure authentication.
  - For DHCP local server:
 

```
[edit system services dhcp-local-server]
```

```
user@host# edit authentication
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6]  
user@host# edit authentication
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]  
user@host# edit authentication
```

2. Specify that you want to include optional information in the username. (DHCP local server, DHCPv6 local server, and DHCP relay agent all support the **username-include** statement.)

```
[edit system services dhcp-local-server authentication]  
user@host# set username-include
```

3. (Optional) Specify the optional information you want to include in the username.

```
[edit system services dhcp-local-server authentication username-include]  
user@host# set username-include circuit-type  
user@host# set username-include domain-name isp55.com  
user@host# set username-include mac-address  
user@host# set username-include user-prefix wallybrown
```

The previous **username-include** configuration produces this unique username:

```
wallybrown.0090.1a01.1234.enet@isp55.com
```

## Understanding Dynamic Reconfiguration of Extended DHCP Local Server Clients

Dynamic reconfiguration of clients enables the extended DHCP local server to initiate a client update without waiting for the client to initiate a request.

### Default Client/Server Interaction

Typically the DHCP client initiates all of the basic DHCP client/server interactions. The DHCP server sends information to a client only in response to a request from that client. In subscriber management scenarios, this behavior does not enable a client to be quickly updated with its network address and configuration in the event of server changes.

For example, suppose a service provider restructured its addressing scheme or changed the server IP addresses that it provided to clients. Without dynamic reconfiguration, the service provider typically clears the DHCP server binding table, but cannot inform the DHCP clients that their bindings have been cleared. Consequently, the DHCP client operates as though its IP address is still valid, but it is now unable to communicate over the access network, resulting in an outage. The DHCP local server has to wait for the

client to send a message to renew its lease or rebind to the server. In response, the server sends a NAK message to the client to force it to begin the DHCP connection process again. Alternatively, the provider can wait for customers to make a service call about the network failures and then instruct them to power cycle their customer premises equipment to reinitiate the connection. Neither of these actions is timely or convenient for customers.

### Dynamic Client/Server Interaction for DHCPv4

Dynamic reconfiguration for DHCPv4 is available through a partial implementation of RFC 3203, *DHCP Reconfigure Extension for DHCPv4*. It enables the DHCPv4 local server to send a message to the client to force reconfiguration.

The server sends a `forcerenew` message to a DHCPv4 client, initiating a message exchange. In response, DHCPv4 clients that support the `forcerenew` message then send a lease renewal message to the server. The server rejects the lease renewal request and sends a NAK to the client, causing the client to reinitiate the DHCP connection. A successful reconnection results in the reconfiguration of the DHCP client. Only the exchange of `forcerenew`, `renew`, and NAK messages is supported from RFC 3202. DHCP relay and DHCP relay proxy do not participate in the client reconfiguration or react to `forcerenew` messages other than to forward them to the client.

When the local server state machine starts the reconfiguration process on a bound client, the client transitions to the reconfiguring state and the local server sends a `forcerenew` message to the client. Because the client was in the bound state before entering the reconfiguring state, all subscriber services, such as forwarding and statistics, continue to work. Client statistics are not maintained in the interval between a successful reconfiguration and the subsequent client binding. When the server responds to the client renewal request with a NAK, the client entry is removed from the binding table and final statistics are reported. New statistics are collected when the client sends a discover message to establish a new session.

### Dynamic Client/Server Interaction for DHCPv6

Dynamic reconfiguration for DHCPv6 is available through a partial implementation of RFC 3315, *Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*. It enables the DHCPv6 local server to send a message to the client to force reconfiguration.

DHCPv6 servers send `reconfigure` messages to DHCPv6 clients, initiating a message exchange. In response, DHCPv6 clients that support the `reconfigure` message transition to the renewing state and send a `renew` message to the server. The server returns a reply message with a lifetime of zero (0). The client transitions to the init state and sends a `solicit` message. The server sends an `advertise` message to indicate that it is available for service. The client sends a request for configuration parameters, which the server then includes in its reply. DHCP relay and DHCP relay proxy do not participate in the client reconfiguration or react to `reconfigure` messages other than to forward them to the client.

When a DHCPv6 server is triggered to initiate reconfiguration on a bound DHCPv6 client, the client transitions to the reconfigure state. All subscriber services, such as forwarding and statistics, continue to work. The server then sends the `reconfigure` message to the client. If the DHCPv6 client is already in the reconfigure state, the DHCPv6 server ignores the reconfiguration trigger. For clients in any state other than bound or reconfigure, the

server clears the binding state of the client, as if the **clear dhcpv6 server binding** command had been issued.

## Dynamic Configuration Options

You can enable dynamic reconfiguration for all DHCP clients or only the DHCP clients serviced by a specified group of interfaces, and you can modify the behavior accordingly.

- To enable dynamic reconfiguration with default reconfiguration values for all DHCP clients, include the **reconfigure** statement at the **[edit system services dhcp-local-server]** hierarchy level for DHCPv4 clients, and at the **[edit system services dhcp-local-server dhcpv6]** hierarchy level for DHCPv6 clients.
- Alternatively, to enable dynamic reconfiguration for only the DHCP clients serviced by a specified group of interfaces, include the **reconfigure** statement at the **[edit system services dhcp-local-server group group-name]** hierarchy level for DHCPv4 clients, and at the **[edit system services dhcp-local-server dhcpv6 group group-name]** hierarchy level for DHCPv6 clients.

You can optionally modify the behavior of the reconfiguration process by including the appropriate statements at the **[edit system services dhcp-local-server reconfigure]** hierarchy level for all DHCPv4 clients, and at the **[edit system services dhcp-local-server dhcpv6 reconfigure]** hierarchy level for all DHCPv6 clients. To override this global configuration for only the DHCP clients serviced by a specified group of interfaces, you can include the statements with different values at the **[edit system services dhcp-local-server group group-name reconfigure]** hierarchy level for DHCPv4 clients, and at the **[edit system services dhcp-local-server dhcpv6 group group-name reconfigure]** hierarchy level for DHCPv6 clients.

Include the **attempts** statement to specify how many times the local server sends the **forcerenew** or **reconfigure** message to initiate client reconfiguration. Include the **timeout** statement to set the interval between the first and second attempts. The interval between each subsequent attempt doubles the previous value. For example, if the first value is 2, the first retry is attempted 2 seconds after the first attempt fails. The second retry is attempted 4 seconds after the first retry fails. The third retry is attempted 8 seconds after the second retry fails, and so on.

By default, the DHCP client's original configuration is restored if all of the reconfiguration attempts fail. Include the **clear-on-abort** statement to delete the client instead.

You can configure an authentication token by including the **token** statement. The DHCP local server then includes this token inside the authentication option when it sends **forcerenew** or **reconfigure** messages. If the service provider has previously configured the DHCP client with this token, then the client can compare that token against the newly received token, and reject the message if the tokens do not match. This functionality corresponds to RFC 3118, *Authentication for DHCP Messages*, section 4.

In the event of a RADIUS-initiated disconnect (RID), the client is deleted by default. You can configure the client to be reconfigured instead of deleted by including the **radius-disconnect** statement. The client is deleted if all attempts to reconfigure the client fail.

For the DHCPv6 server only, you can include the **strict** statement. By default, the server accepts solicit messages from clients that do not support server-initiated reconfiguration. Including this statement causes the server to discard solicit messages from nonsupporting clients; consequently the server does not bind these clients.

You can force the local server to initiate the reconfiguration process for clients by issuing the **request dhcp server reconfigure** command for DHCPv4 clients, and the **request dhcpv6 server reconfigure** command for DHCPv6 clients. Command options determine whether reconfiguration is then attempted for all clients or specified clients.

Events that take place while a reconfiguration is in process take precedence over the reconfiguration. [Table 37 on page 227](#) lists the actions taken in response to several different events.

**Table 37: Action Taken for Events That Occur During a Reconfiguration**

Event	Action
Server receives a discover (DHCPv4) or solicit (DHCPv6) message from the client.	Server drops packet and deletes client.
Server receives a request, renew, rebind, or init-reboot message from the client.	DHCPv4—Server sends NAK message and deletes client.  DHCPv6—Server drops packet and deletes client. Server replies to renew message with lease time of zero (0).
Server receives a release or decline message from the client.	Server deletes client.
The client lease times out.	Server deletes client.
The <b>clear dhcp server binding</b> command is issued.	Server deletes client.
The <b>request dhcp server reconfigure</b> (DHCPv4) or <b>request dhcpv6 server reconfigure</b> (DHCPv6) command is issued.	Command is ignored.
GRES or DHCP restart occurs.	Reconfiguration process is halted.

## Configuring Extended DHCP Local Server Dynamic Client Reconfiguration

The DHCP local server can initiate reconfiguration of its clients to avoid extended outages because of server configuration changes. In addition to requesting that the DHCP local server initiate reconfiguration, you can specify the reconfiguration behavior.

To configure dynamic reconfiguration of DHCP clients:

1. Enable dynamic reconfiguration with default values for all clients.

For DHCPv4:

```
[edit system services dhcp-local-server]
user@host# set reconfigure
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6]
user@host# set reconfigure
```

2. (Optional) Override the global configuration for a particular group of clients.

For DHCPv4:

```
[edit system services dhcp-local-server group-name]
user@host# set reconfigure
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6 group group-name]
user@host# set reconfigure
```

3. (Optional) Configure how the server attempts reconfiguration.

See [“Configuring Dynamic Reconfiguration Attempts for DHCP Clients” on page 229](#).

4. (Optional) Configure the response to a failed reconfiguration.

See [“Configuring Deletion of the Client When Dynamic Reconfiguration Fails” on page 230](#).

5. (Optional) Configure the behavior in response to a RADIUS-initiated disconnect.

See [“Configuring Reconfiguration of the Client on Receipt of RADIUS-Initiated Disconnect” on page 230](#).

6. (Optional) Configure a token for rudimentary server authentication.

See [“Configuring a Token for DHCP Local Server Authentication” on page 231](#).

7. (Optional) Initiate reconfiguration of some or all client bindings.

See [“Requesting DHCP Local Server to Initiate Reconfiguration of Client Bindings” on page 231](#).

8. (Optional) Prevent DHCPv6 clients from binding if they do not support reconfigure messages.

See [“Preventing Binding of Clients That Do Not Support Reconfigure Messages” on page 232](#).

## Configuring Dynamic Reconfiguration Attempts for DHCP Clients

You can configure how many attempts the local server makes to initiate reconfiguration of the DHCP client by sending `forcerenew` messages. You can also specify how long the server waits between attempts. By default, eight attempts are made and the initial interval is two seconds.

Each successive attempt doubles the interval between attempts. For example, if the first value is 2, the first retry is attempted 2 seconds after the first attempt fails. The second retry is attempted 4 seconds after the first retry fails. The third retry is attempted 8 seconds after the second retry fails, and so on. A group configuration takes precedence over a DHCP local server configuration.

(Optional) To configure DHCP local server reconfiguration behavior for all DHCP clients:

1. Specify the number of reconfiguration attempts.

For DHCPv4:

```
[edit system services dhcp-local-server reconfigure]
user@host# set attempts 5
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6 reconfigure]
user@host# set attempts 5
```

2. Specify the interval between reconfiguration attempts.

For DHCPv4:

```
[edit system services dhcp-local-server reconfigure]
user@host# set timeout 8
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6 reconfigure]
user@host# set timeout 8
```

To override the global configuration for a particular group of clients, include the statements at the `[edit system services dhcp-local-server group group-name reconfigure]` hierarchy level or the `[edit system services dhcpv6 dhcp-local-server group group-name reconfigure]` hierarchy level.

### Related Documentation

- [Configuring Extended DHCP Local Server Dynamic Client Reconfiguration on page 227](#)
- [attempts on page 1403](#)
- [timeout on page 1943](#)

## Configuring Deletion of the Client When Dynamic Reconfiguration Fails

---

You can configure the local server to delete the client when the maximum number of reconfiguration attempts has been made without success. By default, the client's original configuration is restored.

(Optional) To configure the DHCP local server to delete the client when reconfiguration is not successful, for all clients:

- Specify the client deletion.

For DHCPv4:

```
[edit system services dhcp-local-server reconfigure]
user@host# set clear-on-abort
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6 reconfigure]
user@host# set clear-on-abort
```

To override the global configuration for a particular group of clients, include the statement at the `[edit system services dhcp-local-server group group-name reconfigure]` hierarchy level or the `[edit system services dhcpv6 dhcp-local-server group group-name reconfigure]` hierarchy level.

### Related Documentation

- [Configuring Extended DHCP Local Server Dynamic Client Reconfiguration on page 227](#)
- [clear-on-abort on page 1440](#)

## Configuring Reconfiguration of the Client on Receipt of RADIUS-Initiated Disconnect

---

You can configure the local server to reconfigure the client when the client receives a RADIUS-initiated disconnect. By default, the client is deleted when a RADIUS-initiated disconnect is received.

(Optional) To configure the DHCP local server to reconfigure the client instead of deleting the client when a RADIUS-initiated disconnect is received, for all clients:

- Specify the RADIUS-initiated disconnect trigger.

For DHCPv4:

```
[edit system services dhcp-local-server reconfigure trigger]
user@host# set radius-disconnect
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6 reconfigure trigger]
user@host# set radius-disconnect
```

To override the global configuration for a particular group of clients, include the statement at the `[edit system services dhcp-local-server group group-name reconfigure trigger]`

hierarchy level or the `[edit system services dhcpv6 dhcp-local-server group group-name reconfigure trigger]` hierarchy level.

**Related  
Documentation**

- [Configuring Extended DHCP Local Server Dynamic Client Reconfiguration on page 227](#)
- [radius-disconnect on page 1842](#)
- [trigger on page 1978](#)

## Configuring a Token for DHCP Local Server Authentication

You can configure the local server to include a constant, unencoded token in the DHCP forcerenew message as part of the authentication option it sends to clients. The client compares the received token with a token already configured on the client. If the tokens do not match, the DHCP client discards the forcerenew message. Use of the token provides rudimentary protection against inadvertently instantiated DHCP servers.

(Optional) To configure the DHCP local server to include a token in the forcerenew message sent to the client, for all clients:

- Specify the token.

For DHCPv4:

```
[edit system services dhcp-local-server reconfigure]
user@host# set token 8ysIU9E32k8r
```

For DHCPv6:

```
[edit system services dhcp-local-server dhcpv6 reconfigure]
user@host# set token 8ysIU9E32k8r
```

To override the global configuration for a particular group of clients, include the statement at the `[edit system services dhcp-local-server group group-name reconfigure]` hierarchy level or the `[edit system services dhcpv6 dhcp-local-server group group-name reconfigure]` hierarchy level.

**Related  
Documentation**

- [Configuring Extended DHCP Local Server Dynamic Client Reconfiguration on page 227](#)
- [token on page 1946](#)

## Requesting DHCP Local Server to Initiate Reconfiguration of Client Bindings

You can request that the DHCP local server initiate reconfiguration of all of clients or only specified clients.

To request reconfiguration of all clients:

- Specify the **all** option.

For DHCPv4:

```
user@host> request dhcp server reconfigure all
```

For DHCPv6:

```
user@host> request dhcpv6 server reconfigure all
```

You can use any of the following methods to request reconfiguration of specific clients:

- Specify the IP address of the DHCP client.

For DHCPv4:

```
user@host> request dhcp server reconfigure 192.168.27.3
```

For DHCPv6:

```
user@host> request dhcpv6 server reconfigure 2001:bd8:1111:2222::
```

- Specify the client ID of a DHCPv6 client.

```
user@host> request dhcpv6 server reconfigure  
LL_TIME0x1-0x2e159c0-00:10:94:00:00:02
```

- Specify the session ID of a DHCPv6 client.

```
user@host> request dhcpv6 server reconfigure 5
```

- Specify the MAC address of a DHCPv4 client.

```
user@host> request dhcp server reconfigure 12:23:34:45:56:67
```

- Specify an interface; reconfiguration is attempted for all clients on this interface.

```
user@host> request dhcp server reconfigure interface fe-0/0/0.100
```

- Specify a logical system; reconfiguration is attempted for all clients or the specified clients in this logical system.

```
user@host> request dhcp server reconfigure all logical-system ls-bldg5
```

- Specify a routing instance; reconfiguration is attempted for all clients or the specified clients in this routing instance.

```
user@host> request dhcp server reconfigure all routing-instance ri-boston
```

**Related  
Documentation**

- [Configuring Extended DHCP Local Server Dynamic Client Reconfiguration on page 227](#)
- `request dhcp server reconfigure`

---

## Preventing Binding of Clients That Do Not Support Reconfigure Messages

The DHCPv6 client and server negotiate the use of reconfigure messages. When the client can accept reconfigure messages from the server, then the client includes the Reconfigure Accept option in both solicit and request messages sent to the server.

By default, the DHCPv6 server accepts solicit messages from clients regardless of whether they support reconfiguration. You can specify that the server require clients to accept reconfigure messages. In this case, the DHCPv6 server includes the Reconfigure Accept option in both advertise and reply messages when reconfiguration is configured for the client interface. Solicit messages from nonsupporting clients are discarded and the clients are not allowed to bind.

(Optional) To configure the DHCPv6 local server to require that all clients accept reconfiguration:

- Specify strict reconfiguration.

```
[edit system services dhcp-local-server dhcpv6 reconfigure]
user@host# set strict
```

To override the global configuration for a particular group of clients, include the statement at the `[edit system services dhcp-local-server dhcpv6 group group-name reconfigure]` hierarchy level.

The `show dhcpv6 server statistics` command displays a count of solicit messages that the server has discarded.

## DHCP Liveness Detection Overview

Unlike PPP, DHCP does not define a native keepalive mechanism as part of either the DHCPv4 or DHCPv6 protocols. Without a keepalive mechanism, DHCP local server, DHCP relay, or DHCP relay proxy is unable to quickly detect if it has lost connectivity with a subscriber and must rely on standard DHCP subscriber session termination messages.

DHCP clients often do not send DHCP release messages prior to exiting the network. The discovery of their absence is dependent on existing DHCP lease time and release request mechanisms. These mechanisms are often considered insufficient when serving as session health checks for clients in a DHCP subscriber access network. Because DHCP lease times are typically too long to provide an adequate response time for a session health failure, and configuring short DHCP lease times can pose an undue burden on control plane processing, implementing a DHCP liveness detection mechanism enables better monitoring of bound DHCP clients. When configured with a liveness detection protocol, if a given subscriber fails to respond to a configured number of consecutive liveness detection requests, the subscriber binding is deleted and its resources released.

DHCP liveness detection for DHCP subscriber IP sessions utilizes an active liveness detection protocol to institute liveness detection checks for relevant clients. Clients must respond to liveness detection requests within a specified amount of time. If the responses are not received within that time for a given number of consecutive attempts, then the liveness detection check fails and a failure action is implemented.

Using DHCP liveness detection, IP sessions are acted upon as soon as liveness detection checks fail. This faster response time serves to:

- Provide more accurate time-based accounting of subscriber sessions.
- Better preserve router resources.
- Help to reduce the window of vulnerability to some security attacks.

Examples of liveness detection protocols include Bidirectional Forwarding Detection (BFD) for both DHCPv4 and DHCPv6 subscribers, IPv4 Address Resolution Protocol (ARP) for DHCPv4 subscribers, and IPv6 Neighbor Unreachability Detection for DHCPv6 subscribers.

**NOTE:** This release supports only BFD for DHCPv4 and DHCPv6 liveness detection.

When configuring BFD liveness detection, keep the following in mind:

- You can configure DHCPv4 and DHCPv6 liveness detection either globally or per DHCPv4 or DHCPv6 group.
- DHCPv4 or DHCPv6 subscriber access clients that do not support BFD are not affected by the liveness detection configuration. These clients can continue to access the network (once validated) even if BFD liveness detection is enabled on the router.
- When configured, DHCPv4 or DHCPv6 initiates liveness detection checks for relevant clients (that is, clients that support BFD) when those clients enter a bound state.
- After protocol-specific messages are initiated for a BFD client, they are periodically sent to the subscriber IP address of the client and responses to those liveness detection requests are expected within a configured amount of time.
- If liveness detection responses are not received from clients that support BFD within the configured amount of time for a configured number of consecutive attempts, the liveness detection check is deemed to have failed and a configured failure action is implemented.

**Related  
Documentation**

---

## Configuring Detection of DHCP Local Server Client Connectivity

---

Liveness detection for DHCP subscriber IP sessions utilizes an active liveness detection protocol to institute liveness detection checks for relevant clients. Clients must respond to liveness detection requests within a specified amount of time. If the responses are not received within that time for a given number of consecutive attempts, then the liveness detection check fails and a failure action is implemented.

**NOTE:** You can also configure DHCP liveness detection for DHCP relay.

To configure liveness detection for DHCP local server:

1. Specify that you want to configure liveness detection.

- For DHCP global configuration:

```
[edit system services dhcp-local-server]
user@host# edit liveness-detection
```

- For DHCP group configuration:

```
[edit system services dhcp-local-server group group-name]
user@host# edit liveness-detection
```

**NOTE:** Liveness detection is also supported for DHCPv6 configurations. To configure DHCPv6 liveness detection, include the **liveness-detection** statement, and any subsequent configuration statements, at the `[edit system services dhcp-local-server dhcpv6]` or `[edit system services dhcp-local-server dhcpv6 group group-name]` hierarchy level.

2. Specify that you want to configure the liveness detection method.

- For DHCP global configuration:

```
[edit system services dhcp-local-server liveness-detection]
user@host# edit method
```

- For DHCP group configuration:

```
[edit system services dhcp-local-server group group-name liveness-detection]
user@host# edit method
```

3. Specify the liveness detection method that you want DHCP to use.

**NOTE:** In this release, the only method supported for liveness detection is Bidirectional Forwarding Detection (BFD).

- For DHCP global configuration:

```
[edit system services dhcp-local-server liveness-detection method]
user@host# edit bfd
```

- For DHCP group configuration:

```
[edit system services dhcp-local-server group group-name liveness-detection method]
user@host# edit bfd
```

4. Configure the liveness detection method as desired.

See [“Example: Configuring Group Liveness Detection for DHCP Local Server Clients” on page 251](#) for an example of how to configure DHCPv4 groups for DHCP local server liveness detection.

5. Configure the action the router takes when a liveness detection failure occurs.

- For DHCP global configuration:

```
[edit system services dhcp-local-server liveness-detection]
user@host# edit failure-action action
```

- For DHCP group configuration:

```
[edit system services dhcp-local-server group group-name liveness-detection]
user@host# edit failure-action action
```

## Verifying and Managing DHCP Local Server Configuration

**Purpose** View or clear information about client address bindings and statistics for the extended DHCP local server.

**Action** • To display the address bindings in the client table on the extended DHCP local server:

```
user@host> show dhcp server binding
```

- To display extended DHCP local server statistics:

```
user@host> show dhcp server statistics
```

- To clear the binding state of a DHCP client from the client table on the extended DHCP local server:

```
user@host> clear dhcp server binding
```

- To clear all extended DHCP local server statistics:

```
user@host> clear dhcp server statistics
```

**Related  
Documentation**

- [Junos OS Operational Mode Commands](#)

---

## Verifying and Managing DHCPv6 Local Server Configuration

**Purpose** View or clear information about client address bindings and statistics for the DHCPv6 local server.

**Action** • To display the address bindings in the client table on the DHCPv6 local server:

```
user@host> show dhcpv6 server binding
```

- To display DHCPv6 local server statistics:

```
user@host> show dhcpv6 server statistics
```

- To clear all DHCPv6 local server statistics:

```
user@host> clear dhcpv6 server binding
```

- To clear all DHCPv6 local server statistics:

```
user@host> clear dhcpv6 server statistics
```

**Related  
Documentation**

## Graceful Routing Engine Switchover

For EX Series switches, only extended DHCP local server maintains the state of active DHCP client leases. The DHCP local server supports the attachment of dynamic profiles and also interacts with the local AAA Service Framework to use back-end authentication servers, such as RADIUS, to provide subscriber authentication. You can configure dynamic profile and authentication support on a global basis or for a specific group of interfaces. The extended DHCP local server also supports the use of Junos address-assignment pools or external authorities, such as RADIUS, to provide the client address and configuration information.

For MX Series routers, the extended DHCP local server and the DHCP relay agent applications both maintain the state of active DHCP client leases in the session database. The extended DHCP application can recover this state if the DHCP process fails or is manually restarted, thus preventing the loss of active DHCP clients in either of these circumstances. However, the state of active DHCP client leases is lost if a power failure occurs or if the kernel stops operating (for example, when the router is reloaded) on a single Routing Engine.

You can enable graceful switchover support on both EX Series switches and MX Series routers. To enable graceful switchover support for the extended DHCP local server or extended DHCP relay agent on a switch, include the **graceful-switchover** statement at the **[edit chassis redundancy]** hierarchy level. To enable graceful Routing Engine switchover support on MX Series routers, include the **graceful-switchover** statement at the **[edit chassis redundancy]** hierarchy level. You cannot disable graceful Routing Engine switchover support for the extended DHCP application when the router is configured to support graceful Routing Engine switchover.

For more information about using graceful Routing Engine switchover, see the Junos OS High Availability Configuration Guide.

## Tracing Extended DHCP Operations

---

Both the extended DHCP local server and the extended DHCP relay agent support tracing operations. DHCP tracing operations track extended DHCP operations and record them in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

You can configure DHCP trace operations at the global level and at the interface level. Global DHCP tracing logs all DHCP-related events, whereas interface-level tracing logs only interface-specific DHCP events. If you configure interface-level trace operations, you can specify tracing for a range of interfaces or an individual interface. However, only a single interface-level log file is supported. That is, you cannot specify different interface-level log files for different interfaces or groups of interfaces.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

- Important events for both global and per-interface tracing are logged in a file located in the `/var/log` directory. By default, the router uses the filename, `jdhcpd`. You can specify a different filename, but you cannot change the directory in which trace files are located.
- When the trace log file *filename* reaches 128 kilobytes (KB), it is compressed and renamed *filename.0.gz*. Subsequent events are logged in a new file called *filename*, until it reaches capacity again. At this point, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)

- By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

To configure global DHCP tracing operations.

- Specify tracing operations for DHCP local server and DHCP relay:

```
[edit system processes dhcp-service]
user@host# edit traceoptions
```

The tracing configuration is applied globally to all DHCP applications in every LS:RI. Configuration of event tracing on a per-LS:RI basis is not supported. DHCP tracing is configurable only in the default LS:RI. However, DHCP applications (local server or relay) do not have to be configured in the default LS:RI. This behavior was different in software releases before Junos OS Release 11.4, where you had to configure a DHCP application in the default LS:RI in order to configure DHCP tracing, even when you wanted to run DHCP and trace its operations only in a nondefault LS:RI.

In the earlier software releases, you configured tracing statements at the **[edit system services dhcp-local-server]** and **[edit forwarding-options dhcp-relay]** hierarchy levels. These statements have been deprecated and hidden in favor of the statements at the **[edit system processes dhcp-service]** hierarchy level.

**NOTE:** The deprecated statements may be removed from a future release; we recommend that you transition to the new statements.

Because you can configure DHCP tracing at three different hierarchy levels (one new and recommended, two old and deprecated), the following rules apply to manage the interaction:

- When you configure a filename or any other options for the trace log file, the configuration at the **[edit system processes dhcp-service]** hierarchy level has the highest precedence, followed by the configuration at the **[edit system services dhcp-local-server]** hierarchy level, and finally with the lowest precedence, the configuration at the **[edit forwarding-options dhcp-relay]** hierarchy level.
- The flag configurations for multiple hierarchy levels are merged and applied to all trace log events.
- The deprecated statements do not support filtering the generation of DHCP trace log events by severity level. If you use these statements, trace logging operates with an implicit severity of **all**, regardless of the severity level configured at the **[edit system processes dhcp-service]** hierarchy level.

For information about configuring per-interface tracing options, see [“Tracing Extended DHCP Operations for Specific Interfaces” on page 243](#).

The extended DHCP traceoptions operations are described in the following sections:

- [Configuring the Extended DHCP Log Filename on page 239](#)
- [Configuring the Number and Size of Extended DHCP Log Files on page 240](#)
- [Configuring Access to the Extended DHCP Log File on page 240](#)
- [Configuring a Regular Expression for Extended DHCP Messages to Be Logged on page 241](#)
- [Configuring the Extended DHCP Tracing Flags on page 241](#)
- [Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged on page 242](#)
- [Tracing Extended DHCP Operations for Specific Interfaces on page 243](#)

## Configuring the Extended DHCP Log Filename

By default, the name of the file that records trace output is **jdhcpd**. You can specify a different name by including the **file** option. DHCP local server and DHCP relay agent both support the **file** option for the **traceoptions** statement and the **interface-traceoptions** statement.

To change the filename:

- Specify a filename for global tracing operations.

```
[edit system processes dhcp-service traceoptions]  
user@host# set file filename
```

- Specify a filename for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]  
user@host# set file filename
```

## Configuring the Number and Size of Extended DHCP Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format **.number.gz**. The newest archived file is **.0.gz** and the oldest archived file is **.(maximum number)-1.gz**. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, **filename**, reaches 2 MB, **filename** is compressed and renamed **filename.0.gz**, and a new file called **filename** is created. When the new **filename** reaches 2 MB, **filename.0.gz** is renamed **filename.1.gz** and **filename** is compressed and renamed **filename.0.gz**. This process repeats until there are 20 trace files. Then the oldest file, **filename.19.gz**, is simply overwritten when the next oldest file, **filename.18.gz** is compressed and renamed to **filename.19.gz**.

DHCP local server and DHCP relay agent both support the **files** and **size** options for the **traceoptions** statement and the **interface-traceoptions** statement. To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output for global tracing operations.

```
[edit system processes dhcp-service traceoptions]  
user@host# set file filename files number size maximum-file-size
```

- Specify the name, number, and size of the file used for the trace output for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]  
user@host# set file filename files number size maximum-file-size
```

## Configuring Access to the Extended DHCP Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

DHCP local server and DHCP relay agent both support the **world-readable** option and the **no-world-readable** option for the **traceoptions** statement and the **interface-traceoptions** statement. To specify that all users can read the log file:

- Configure the log file to be world-readable for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set file filename world-readable
```

- Configure the log file to be world-readable for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set file filename world-readable
```

To explicitly set the default behavior, in which the log file can only be read by the user who configured tracing:

- Configure the log file to be no-world-readable for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set file filename no-world-readable
```

- Configure the log file to be no-world-readable for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set file filename no-world-readable
```

## Configuring a Regular Expression for Extended DHCP Messages to Be Logged

By default, the trace operation output includes all messages relevant to the logged events. You can refine the output by including regular expressions to be matched.

DHCP local server and DHCP relay agent both support the **match** option for the **traceoptions** statement and the **interface-traceoptions** statement. To configure regular expressions to be matched:

- Specify the regular expression for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set file filename match regular-expression
```

- Specify the regular expression for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set file filename match regular-expression
```

## Configuring the Extended DHCP Tracing Flags

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

DHCP local server and DHCP relay agent both support the **flag** option for the **traceoptions** statement and the **interface-traceoptions** statement. A smaller set of flags is supported for interface-level tracing than for global tracing. To configure the flags for the events to be logged:

- Specify the flags for global tracing operations.

```
[edit system processes dhcp-service traceoptions]  
user@host# set flag flag
```

- Specify the flags for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]  
user@host# set flag flag
```

## Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged

The messages associated with a logged event are categorized according to severity level. You can use the severity level to determine which messages are logged for the event type. A low severity level is less restrictive—filters out fewer messages—than a higher level. When you configure a severity level, all messages at that level and all higher (more restrictive) levels are logged.

The following list presents severity levels in order from lowest (least restrictive) to highest (most restrictive). This order also represents the significance of the messages; for example, **error** messages are of greater concern than **info** messages.

- **verbose**
- **info**
- **notice**
- **warning**
- **error**

The severity level that you configure depends on the issue that you are trying to resolve. In some cases you might be interested in seeing all messages relevant to the logged event, so you specify **all**. You can also specify **verbose** with the same result, because **verbose** is the lowest (least restrictive) severity level; it has nothing to do with the terseness or verbosity of the messages. Either choice generates a large amount of output. You can specify a more restrictive severity level, such as **notice** or **info** to filter the messages. By default, the trace operation output includes only messages with a severity level of **error**.

DHCP local server and DHCP relay agent both support the **level** option for the **traceoptions** statement and the **interface-traceoptions** statement. To configure the flags for the events to be logged:

- Specify the severity level for global tracing operations.

```
[edit system processes dhcp-service traceoptions]  
user@host# set level severity
```

- Specify the severity level for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]  
user@host# set level severity
```

## Tracing Extended DHCP Operations for Specific Interfaces

In addition to the global DHCP tracing operations, subscriber management enables you to trace extended DHCP operations for a specific interface or for a range of interfaces.

Configuring per-interface tracing is a two-step procedure. In the first step, you specify the tracing options that you want to use, such as file information and flags. In the second step, you enable the tracing operation on the specific interfaces.

To configure per-interface tracing operations:

1. Specify the tracing options you want to use.

**NOTE:** Per-interface tracing uses the same default tracing behavior as the global extended DHCP tracing operation. The default behavior is described in [“Tracing Extended DHCP Operations” on page 238](#).

- a. Specify that you want to configure per-interface tracing options.
    - For DHCP local server, DHCPv6 local server, DHCP relay agent, and DHCPv6 relay agent:
 

```
[edit system processes dhcp-service]
user@host# edit interface-traceoptions
```
  - b. (Optional) Specify the tracing file options.
    - Configure the name for the file used for the trace output.  
See [“Configuring the Extended DHCP Log Filename” on page 239](#).
    - Configure the number and size of the log files.  
See [“Configuring the Number and Size of Extended DHCP Log Files” on page 240](#).
    - Configure access to the log file.  
See [“Configuring Access to the Extended DHCP Log File” on page 240](#).
    - Configure a regular expression to filter logging events.  
See [“Configuring a Regular Expression for Extended DHCP Messages to Be Logged” on page 241](#).
  - c. (Optional) Specify tracing flag options.  
See [“Configuring the Extended DHCP Tracing Flags” on page 241](#).
  - d. (Optional) Configure a severity level for messages to specify which event messages are logged.  
See [“Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged” on page 242](#).
2. Enable tracing on an interface or interface range.

The following examples show a DHCP local server configuration. You can also use the **trace** statement at the **[edit forwarding-options dhcp-relay]** hierarchy level and at the **[edit system services dhcp-local-server dhcpv6]** hierarchy level.

- Enable tracing on a specific interface.

```
[edit system services dhcp-local-server]
user@host# set group group-name interface interface-name trace
```

- Enable tracing on a range of interfaces.

```
[edit system services dhcp-local-server]
user@host# set group group-name interface interface-name upto interface
interface-name trace
```

## CHAPTER 8

# DHCP Local Server Examples

- [Example: Minimum Extended DHCP Local Server Configuration on page 245](#)
- [Example: Extended DHCP Local Server Configuration with Optional Pool Matching on page 245](#)
- [Example: Extended DHCPv6 Local Server Configuration on page 246](#)
- [Example: Configuring a DHCP Firewall Filter to Protect the Routing Engine on page 247](#)
- [Example: Configuring Group Liveness Detection for DHCP Local Server Clients on page 251](#)

### Example: Minimum Extended DHCP Local Server Configuration

---

This example shows the minimum configuration you need to use for the extended DHCP local server on the router:

```
[edit system services]
dhcp-local-server {
  group group_one {
    interface fe-0/0/2.0;
  }
}
```

This example creates the server group named **group\_one**, and specifies that the DHCP local server is enabled on interface **fe-0/0/2.0** within the group. The DHCP local server uses the default pool match configuration of **ip-address-first**.

#### Related Documentation

- [Extended DHCP Local Server Overview on page 186](#)

### Example: Extended DHCP Local Server Configuration with Optional Pool Matching

---

This example shows an extended DHCP local server configuration that includes optional IPv4 address-assignment pool matching and interface groups. For pool matching, this configuration specifies that the DHCP local server first check the response from an external authentication authority (for example, RADIUS) and use the Framed-IPv6-Pool attribute to determine the address-assignment pool to use for the client address. If no external authority match is found, the DHCP local server then uses ip-address-first matching together with the option 82 information to match the named address range

for client IPv4 address assignment. The option 82 matching must also be included in the address-assignment pool configuration.

```
[edit system services]
dhcp-local-server {
  group group_one {
    interface fe-0/0/2.0;
    interface fe-0/0/2.1;
  }
  group group_two {
    interface fe-0/0/3.0;
    interface fe-0/0/3.1;
  }
  pool-match-order {
    external-authority
    ip-address-first;
    option-82;
  }
}
```

- Related Documentation**
- [Extended DHCP Local Server Overview on page 186](#)
  - [Address-Assignment Pools Overview on page 155](#)

---

## Example: Extended DHCPv6 Local Server Configuration

This example shows a sample extended DHCPv6 local server configuration. The second part of the example shows a sample RADIUS authentication configuration—authentication must be configured for DHCPv6 local server operations.

```
[edit system services]
dhcp-local-server {
  dhcpv6 {
    authentication {
      password v679M8vt;
      username-include {
        user-prefix wallybrown;
        domain-name isp55.com;
      }
    }
    group group_two {
      authentication {
        password P$55qw4$$;
        username-include {
          user-prefix south5;
          domain-name isp55.com;
        }
      }
      interface ge-1/0/3.0;
    }
  }
}
```

The following is a sample RADIUS authentication configuration.

```
[edit access]
radius-server {
  192.168.1.250 {
    port 1812;
    secret &tIUeI*7688+;
  }
}
profile isp-bos-metro-fiber-basic {
  accounting-order radius;
  authentication-order radius;
  radius {
    authentication-server 192.168.1.250;
    accounting-server 192.168.1.250;
  }
  accounting {
    order radius;
    accounting-stop-on-failure;
    accounting-stop-on-access-deny;
    update-interval 10;
    statistics time;
  }
}
```

## Example: Configuring a DHCP Firewall Filter to Protect the Routing Engine

This example shows how to configure a firewall filter to ensure that proper DHCP packets can reach the Routing Engine on MX Series routers.

- [Requirements on page 247](#)
- [Overview on page 247](#)
- [Configuration on page 248](#)
- [Verification on page 250](#)

### Requirements

This configuration example applies only to routers where DHCP local server and DHCP relay agent services are provided by the `jdhcpd` process rather than the legacy `dhcpd` process or `fud` (UDP forwarding) process. MX Series routers, M120 routers, and M320 routers use `jdhcpd`. For DHCP relay, that means the configuration is required only at the **[edit forwarding-options dhcp-relay]** hierarchy level and not at the **[edit forwarding-options helpers bootp]** hierarchy level.

No special configuration beyond device initialization is required before you can configure this feature.

### Overview

Firewall filters that perform some action on DHCP packets at the Routing Engine, such as a filter to protect the Routing Engine by allowing only proper DHCP packets, require

that both port 67 (bootps) and port 68 (bootpc) are configured as both source and destination ports.

DHCP packets received on the line cards are encapsulated by `jdhcpd` with a new UDP header where their source and destination addresses are set to port 68 before being forwarded to the Routing Engine. For DHCP relay and DHCP proxy, packets sent to the DHCP server from the router have both the source and destination UDP ports set to 67. The DHCP server responds using the same ports. However, when the line card receives these DHCP response packets, it changes both port numbers from 67 to 68 before passing the packets to the Routing Engine. Consequently the filter needs to accept port 67 for packets relayed from the client to the server, and port 68 for packets relayed from the server to the client.

In this example, you configure two filter terms, **`dhcp-client-accept`** and **`dhcp-server-accept`**. The match conditions for **`dhcp-client-accept`** specify a source address and destination address for broadcast packets, the UDP protocol used for DHCP packets, and the bootpc (68) source port and bootps (67) destination port. Packets that match these conditions are counted and accepted.

The match conditions for **`dhcp-server-accept`** specify the UDP protocol used for DHCP packets, and both port 67 and 68 for both source port and destination port. Packets that match these conditions are counted and accepted.

**NOTE:** This example does not show all possible configuration choices, nor does it show how the filter is applied in your configuration. This example applies to both static application of the filter as well as dynamic application with a dynamic profile.

## Configuration

### CLI Quick Configuration

To quickly configure the sample Routing Engine DHCP filter, copy the following commands, paste them in a text file, remove any line breaks, and then copy and paste the commands into the CLI.

```
[edit]
edit firewall family inet filter RE-protect
edit term dhcp-client-accept
set from source-address 0.0.0.0/32
set from destination-address 255.255.255.255/32
set from protocol udp
set from source-port 68
set from destination-port 67
set then count dhcp-client-accept
set then accept
up
edit term dhcp-server-accept
set from protocol udp
set from source-port 67
set from source-port 68
set from destination-port 67
set from destination-port 68
```

```

set then count dhcp-server-accept
set then accept
top

```

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure a DHCP firewall filter to protect the Routing Engine:

1. Create or specify a firewall filter.

```

[edit firewall]
user@host# edit family inet filter RE-protect

```

2. Create a filter term for the client.

```

[edit firewall family inet filter RE-protect]
user@host# edit term dhcp-client-accept

```

3. Specify the match conditions for DHCP packets.

```

[edit firewall family inet filter RE-protect term dhcp-client-accept]
user@host# set from source-address 0.0.0.0/32
user@host# set from destination-address 255.255.255.255/32
user@host# set from protocol udp
user@host# set from source-port 68
user@host# set from destination-port 67

```

4. Specify the action to take for matched packets.

```

[edit firewall family inet filter RE-protect term dhcp-client-accept]
user@host# set then count dhcp-client-accept
user@host# set then accept

```

5. Create a filter term for the server.

```

[edit firewall family inet filter RE-protect]
user@host# edit term dhcp-server-accept

```

6. Specify the match conditions for DHCP packets.

```

[edit firewall family inet filter RE-protect term dhcp-server-accept]
user@host# set from protocol udp
user@host# set from source-port [67 68]
user@host# set from destination-port [67 68]

```

7. Specify the action to take for matched packets.

```

[edit firewall family inet filter RE-protect term dhcp-server-accept]
user@host# set then count dhcp-client-accept
user@host# set then accept

```

**Results** From configuration mode, confirm your configuration by entering the **show firewall** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show firewall
family inet {

```

```
filter RE-protect {
  term dhcp-client-accept {
    from {
      source-address {
        0.0.0.0/32;
      }
      destination-address {
        255.255.255.255/32;
      }
      protocol udp;
      source-port 68;
      destination-port 67;
    }
    then {
      count dhcp-client-accept;
      accept;
    }
  }
  term dhcp-server-accept {
    from {
      protocol udp;
      source-port [ 67 68 ];
      destination-port [ 67 68 ];
    }
    then {
      count dhcp-server-accept;
      accept;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the Routing Engine DHCP protection filter is properly passing DHCP packets, perform these tasks:

- [Verifying the DHCP Filter Operation on page 250](#)

---

### Verifying the DHCP Filter Operation

**Purpose** Verify that both counters increment as DHCP traffic passes to the Routing Engine.

**Action** From operational mode, enter the **show firewall family inet filter RE-protect** command.

```
user@host> show firewall family inet filter RE-protect
Filter: RE-protect
Counters:
Name                               Bytes      Packets
dhcp-client-accept                  328         1
dhcp-server-accept                  574         1

user@host> show firewall family inet filter RE-protect
Filter: RE-protect
Counters:
```

Name	Bytes	Packets
dhcp-client-accept	660	2
dhcp-server-accept	1152	2

**Meaning** The output lists both configured counters, dhcp-client-accept and dhcp-server-accept. By issuing the command more than once, you can see that the byte and packet fields both show that traffic is being accepted and counted.

## Example: Configuring Group Liveness Detection for DHCP Local Server Clients

This example shows how to configure group liveness detection for DHCP local server subscribers using Bidirectional Forwarding Detection (BFD) as the liveness detection method.

- [Requirements on page 251](#)
- [Overview on page 251](#)
- [Configuration on page 252](#)

### Requirements

- Juniper Networks MX Series routers.
- Junos OS Release 12.1R1 or later.
- Configure DHCP local server. See [“Extended DHCP Local Server Overview” on page 186](#).

### Overview

In this example, you configure group liveness detection for DHCP local server subscribers by completing the following operations:

1. Enable liveness detection for DHCP local server subscriber groups.
2. Specify BFD as the liveness detection method for all dynamically created DHCP local server subscribers.
3. Configure BFD-specific statements to define how the protocol behaves.
4. Configure the action the router takes when a liveness detection failure occurs.

**NOTE:** This example explains how to configure liveness detection for a DHCPv4 network. Liveness detection is also supported for DHCPv6 configurations. To configure DHCPv6 liveness detection, include the `liveness-detection` statement, and any subsequent configuration statements, at the `[edit system services dhcp-local-server dhcpv6]` or `[edit system services dhcp-local-server dhcpv6 group group-name]` hierarchy level.

## Configuration

### Step-by-Step Procedure

To configure group liveness detection for DHCP local server:

1. Specify that you want to configure liveness detection.  

```
[edit system services dhcp-local-server ]
user@host# edit liveness-detection
```
2. Specify that you want to configure liveness detection for a specific DHCP local server group.  

```
[edit system services dhcp-local-server liveness-detection]
user@host# edit group local_group_1
```
3. Specify that you want to configure the liveness detection method.  

```
[edit system services dhcp-local-server group local_group_1 liveness-detection]
user@host# edit method
```
4. Specify BFD as the liveness detection method that you want DHCP to use.  

```
[edit system services dhcp-local-server group local_group_1 liveness-detection
method]
user@host# edit bfd
```
5. Configure the detection time threshold (in milliseconds) at which a trap is produced.  

```
[edit system services dhcp-local-server group local_group_1 liveness-detection
method bfd]
user@host# set detection-time threshold 30000
```
6. Configure the time (in milliseconds) for which BFD holds a session up notification.  

```
[edit system services dhcp-local-server group local_group_1 liveness-detection
method bfd]
user@host# set holddown-interval 50
```
7. Configure the BFD minimum transmit and receive interval (in milliseconds).

**NOTE:** You do not need to configure the BFD minimum transmit and receive interval if you configure the `minimum-interval` for the BFD `transmit-interval` statement and the `minimum-receive-interval`.

```
[edit system services dhcp-local-servergroup local_group_1 liveness-detection method
bfd]
user@host# set minimum-interval 45000
```

8. Configure the minimum receive interval (in milliseconds).

**NOTE:** You do not need to configure the BFD minimum receive interval if you configure the BFD minimum transmit and receive interval.

```
[edit system services dhcp-local-server group local_group_1 liveness-detection
method bfd]
user@host# set minimum-receive-interval 60000
```

9. Configure a multiplier value for the detection time.

```
[edit system services dhcp-local-server group local_group_1 liveness-detection
method bfd]
user@host# set multiplier 100
```

10. Disable the ability for BFD interval timers to change or adapt to network situations.

```
[edit system services dhcp-local-server group local_group_1 liveness-detection
method bfd]
user@host# set no-adaptation
```

11. Configure the BFD session mode.

```
[edit system services dhcp-local-server group local_group_1 liveness-detection
method bfd]
user@host# set session-mode automatic
```

12. Configure the threshold and minimum interval for the BFD transmit interval.

**NOTE:** You do not need to configure the transmit interval values if you have already configured the minimum transmit and receive interval for BFD.

```
[edit system services dhcp-local-server group local_group_1 liveness-detection
method bfd]
user@host# set transmit-interval threshold 60000 minimum-interval 45000
```

13. Configure the BFD protocol version you want to detect.

```
[edit system services dhcp-local-server group local_group_1 liveness-detection
method bfd]
user@host# set version automatic
```

14. Configure the action the router takes when a liveness detection failure occurs. In this example, the failure action is to clear the client session only when a liveness detection failure occurs and the local interface is detected as being up.

```
[edit system services dhcp-local-server group local_group_1 liveness-detection]
user@host# edit failure-action action
```

**Results** From configuration mode, confirm your configuration by entering the **show system** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
regress@montag# show system
services {
  dhcp-local-server {
    group local_group_1 {
      liveness-detection {
        failure-action clear-binding-if-interface-up;
        method {
          bfd {
            version automatic;
            minimum-interval 45000;
            minimum-receive-interval 60000;
            multiplier 100;
            no-adaptation;
            transmit-interval {
              minimum-interval 45000;
              threshold 60000;
            }
            detection-time {
              threshold 30000;
            }
            session-mode automatic;
            holddown-interval 50;
          }
        }
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Extended DHCP Relay Agent Overview

---

You can configure extended DHCP relay options on the router and enable the router to function as a DHCP relay agent. A DHCP relay agent forwards DHCP request and reply packets between a DHCP client and a DHCP server.

DHCP relay supports the attachment of dynamic profiles and also interacts with the local AAA Service Framework to use back-end authentication servers, such as RADIUS, to provide subscriber authentication. You can attach dynamic profiles and configure authentication support on a global basis or for a specific group of interfaces.

**NOTE:** The PTX Series Packet Transport Switches do not support authentication for DHCP relay agents.

You can use DHCP relay in carrier edge applications such as video/IPTV to obtain configuration parameters, including an IP address, for your subscribers. For more information about how to use the DHCP relay agent in a video/IPTV application, see the Junos OS Feature Guides.

**NOTE:** The extended DHCP relay agent options configured with the `dhcp-relay` statement are incompatible with the DHCP/BOOTP relay agent options configured with the `bootp` statement. As a result, you cannot enable both the extended DHCP relay agent and the DHCP/BOOTP relay agent on the router at the same time.

For information about the DHCP/BOOTP relay agent, see the Routing Policy Configuration Guide.

You can also configure the extended DHCP relay agent to support IPv6 clients. See [“DHCPv6 Relay Agent Overview” on page 260](#) for information about the DHCPv6 relay agent feature.

To configure the extended DHCP relay agent on the router, include the `dhcp-relay` statement at the `[edit forwarding-options]` hierarchy level. See the [“`\[edit forwarding-options dhcp-relay\]` Hierarchy Level” on page 1339](#) for the complete DHCP relay agent syntax.

You can also include the `dhcp-relay` statement at the following hierarchy levels:

- `[edit logical-systems logical-system-name forwarding-options]`
- `[edit logical-systems logical-system-name routing-instances routing-instance-name forwarding-options]`
- `[edit routing-instances routing-instance-name forwarding-options]`

This overview covers:

- [Interaction Among the DHCP Relay Agent, DHCP Client, and DHCP Servers on page 259](#)
- [DHCP Liveness Detection on page 259](#)

## Interaction Among the DHCP Relay Agent, DHCP Client, and DHCP Servers

In a typical carrier edge network configuration, the DHCP client is on the subscriber's computer, and the DHCP relay agent is configured on the router between the DHCP client and one or more DHCP servers.

The following steps describe, at a high level, how the DHCP client, DHCP relay agent, and DHCP server interact in a configuration that includes two DHCP servers.

1. The DHCP client sends a discover packet to find a DHCP server in the network from which to obtain configuration parameters for the subscriber, including an IP address.
2. The DHCP relay agent receives the discover packet and forwards copies to each of the two DHCP servers. The DHCP relay agent then creates an entry in its internal client table to keep track of the client's state.
3. In response to receiving the discover packet, each DHCP server sends an offer packet to the client. The DHCP relay agent receives the offer packets and forwards them to the DHCP client.
4. On receipt of the offer packets, the DHCP client selects the DHCP server from which to obtain configuration information. Typically, the client selects the server that offers the longest lease time on the IP address.
5. The DHCP client sends a request packet that specifies the DHCP server from which to obtain configuration information.
6. The DHCP relay agent receives the request packet and forwards copies to each of the two DHCP servers.
7. The DHCP server requested by the client sends an acknowledgement (ACK) packet that contains the client's configuration parameters.
8. The DHCP relay agent receives the ACK packet and forwards it to the client.
9. The DHCP client receives the ACK packet and stores the configuration information.
10. If configured to do so, the DHCP relay agent installs a host route and Address Resolution Protocol (ARP) entry for this client.
11. After establishing the initial lease on the IP address, the DHCP client and the DHCP server use unicast transmission to negotiate lease renewal or release. The DHCP relay agent "snoops" on all of the packets unicast between the client and the server that pass through the router to determine when the lease for this client has expired or been released. This process is referred to as *lease shadowing* or *passive snooping*.

## DHCP Liveness Detection

Liveness detection for DHCP subscriber IP sessions utilizes an active liveness detection protocol to institute liveness detection checks for relevant clients. Clients are expected to respond to liveness detection requests within a specified amount of time. If the

responses are not received within that time for a given number of consecutive attempts, then the liveness detection check fails and a failure action is implemented.

**NOTE:** DHCP liveness detection either globally or per DHCP group.

## DHCPv6 Relay Agent Overview

The DHCPv6 relay agent enhances the extended DHCP relay agent by providing support in an IPv6 network. The DHCPv6 relay agent passes messages between the DHCPv6 client and the DHCPv6 server, similar to the way DHCP relay agent supports an IPv4 network.

When a DHCPv6 client logs in, the DHCPv6 relay agent uses the AAA service framework to interact with the RADIUS server to provide authentication and accounting. The RADIUS server, which is configured independently of DHCP, authenticates the client and supplies the IPv6 prefix and client configuration parameters, such as session timeout and the maximum number of clients allowed per interface.

**NOTE:** The PTX Series Packet Transport Switches do not support authentication for DHCPv6 relay agents.

The DHCPv6 relay agent is compatible with the extended DHCP local server and the extended DHCP relay agent, and can be enabled on the same interface as either the extended DHCP local server or DHCP relay agent.

To configure the DHCPv6 relay agent on the router, you include the **dhcpx6** statement at the **[edit forwarding-options dhcp-relay]** hierarchy level.

You can also include the **dhcpx6** statement at the following hierarchy levels:

- **[edit logical-systems *logical-system-name* forwarding-options dhcp-relay]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* forwarding-options dhcp-relay]**
- **[edit routing-instances *routing-instance-name* forwarding-options dhcp-relay]**

## DHCP Relay Proxy Overview

DHCP relay proxy mode is an enhancement to extended DHCP relay. DHCP relay proxy supports all DHCP relay features while providing additional features and benefits.

Normally, extended DHCP relay operates as a helper application for DHCP operations. Except for the ability to add DHCP relay agent options and the gateway address (giaddr) to DHCP packets, DHCP relay is transparent to DHCP clients and DHCP servers, and simply forwards messages between DHCP clients and servers.

When you configure DHCP relay to operate in proxy mode, the relay is no longer transparent. In proxy mode, DHCP relay conceals DHCP server details from DHCP clients, which interact with a DHCP relay in proxy mode as though it is the DHCP server. For DHCP servers there is no change, because proxy mode has no effect on how the DHCP server interacts with the DHCP relay.

DHCP relay proxy provides the following benefits:

- DHCP server isolation and DoS protection—DHCP clients are unable to detect the DHCP servers, learn DHCP server addresses, or determine the number of servers that are providing DHCP support. Server isolation also provides denial-of-service (DoS) protection for the DHCP servers.
- Multiple lease offer selection—DHCP relay proxy receives lease offers from multiple DHCP servers and selects a single offer to send to the DHCP client, thereby reducing traffic in the network. Currently, the DHCP relay proxy selects the first offer received.
- Support for both numbered and unnumbered Ethernet interfaces—For DHCP clients connected through Ethernet interfaces, when the DHCP client obtains an address, the DHCP relay proxy adds an access internal host route specifying that interface as the outbound interface. The route is automatically removed when the lease time expires or when the client releases the address.
- Logical system support—DHCP relay proxy can be configured in a logical system, whereas a non-proxy mode DHCP relay cannot.

**NOTE:** Extended DHCP relay proxy is not supported for the J Series Services Routers DHCP server. Also, you cannot configure both DHCP relay proxy and extended DHCP local server on the same interface.

---

## Interaction Among DHCP Relay Proxy, DHCP Client, and DHCP Servers

The DHCP relay agent is configured on the router, which operates between the DHCP client and one or more DHCP servers.

The following steps provide a high-level description of how DHCP relay proxy interacts with DHCP clients and DHCP servers.

1. The DHCP client sends a discover packet to locate a DHCP server in the network from which to obtain configuration parameters for the subscriber.
2. The DHCP relay proxy receives the discover packet from the DHCP client and forwards copies of the packet to each supporting DHCP server. The DHCP relay proxy then creates a client table entry to keep track of the client state.
3. In response to the discover packet, each DHCP server sends an offer packet to the client, which the DHCP relay proxy receives. The DHCP relay proxy does the following:
  - a. Selects the first offer received as the offer to sent to the client
  - b. Replaces the DHCP server address with the address of the DHCP relay proxy
  - c. Forwards the offer to the DHCP client.
4. The DHCP client receives the offer from the DHCP relay proxy.
5. The DHCP client sends a request packet that indicates the DHCP server from which to obtain configuration information—the request packet specifies the address of the DHCP relay proxy.

6. The DHCP relay proxy receives the request packet and forwards copies, which include the address of selected server, to all supporting DHCP servers.
7. The DHCP server requested by the client sends an acknowledgement (ACK) packet that contains the client configuration parameters.
8. The DHCP relay proxy receives the ACK packet, replaces the DHCP server address with its own address, and forwards the packet to the client.
9. The DHCP client receives the ACK packet and stores the configuration information.
10. If configured to do so, the DHCP relay proxy installs a host route and Address Resolution Protocol (ARP) entry for the DHCP client.
11. After the initial DHCP lease is established, the DHCP relay proxy receives all lease renewals and lease releases from the DHCP client and forwards them to the DHCP server.

## Dynamic Profile Attachment to DHCP Subscriber Interfaces Overview

The router's DHCP support enables you to attach a dynamic profile to a DHCP subscriber interface. When a DHCP subscriber logs in, the router instantiates the specified dynamic profile and then applies the services defined in the profile to the interface.

You can attach dynamic profiles to all interfaces or you can specify a particular group of interfaces to which the profile is attached. Both the DHCP local server and the DHCP relay agent support the attachment of dynamic profiles to interfaces.

You can enable the following optional features when the dynamic profile is attached. The two options cannot be used together.

- Enable multiple DHCP subscribers to share the same VLAN logical interface. The firewall filters, CoS schedulers, and IGMP configuration of the clients are merged.
- Specify the primary dynamic profile that is instantiated when the first subscriber logs in.

### Multiple DHCP Subscribers Sharing the Same VLAN Logical Interface

The **aggregate-clients** statement specifies that the router merge the firewall filters, CoS schedulers, and IGMP configuration of multiple DHCP clients that are on the same VLAN logical interface (for example, multiple clients belonging to the same household). You can configure the aggregate-clients support for all interfaces or for a group of interfaces. The **aggregate-clients** statement provides the option of either merging (chaining) or replacing software components for each client.

By default, the feature is disabled and a single DHCP client is allowed per VLAN when a dynamic profile is associated with the VLAN logical interface.

When you specify the **merge** option, the router aggregates the software components for multiple subscribers as follows:

- Firewall filters—The filters are chained together using the precedence as the order of execution. If the same firewall filter is attached multiple times, the filter is executed only once.
- CoS schedulers—The different CoS schedulers are merged as if the scheduler map has multiple schedulers. The merge operation for the individual traffic-control-profiles parameters (shaping-rate, delay-buffer-rate, guaranteed-rate) preserves the maximum value for each parameter.
- IGMP configuration—The current IGMP configuration is replaced with the configuration of the newest DHCP client.

When you specify the **replace** option, the entire logical interface is replaced whenever a new client logs in to the network using the same VLAN logical interface. For example, if a customer subscribes to voice, video, and data services on the network, when a voice client logs in, instead of applying a specific voice filter for only that service, the entire voice, video, and data filter chain is applied.

**NOTE:** You cannot use a dynamic demux interface to represent multiple subscribers in a dynamic profile attached to an interface. One dynamic demux interface represents one subscriber. Do not configure the **aggregate-clients** option when attaching a dynamic profile to a demux interface for DHCP.

---

## Primary Dynamic Profile

The **use-primary** option enables you to specify the primary dynamic profile that is instantiated when the first subscriber logs in. Subsequent subscribers are not assigned the primary dynamic profile; instead, they are assigned the dynamic profile specified for the interface. When the first subscriber logs out, the next subscriber that logs in is assigned the primary dynamic profile.

This feature can conserve logical interfaces in a network where dynamic IP demux interfaces are used to represent subscribers. To conserve interfaces, make sure the primary profile that you specify does not create a demux interface, but provides the initial policies for the primary interface subscriber.

## DHCP Duplicate Client Differentiation Using Client Subinterface Overview

---

In some network environments, client IDs and MAC addresses might not be unique, resulting in duplicate clients. For example, two network adapters might be manufactured with the same hardware address, resulting in a duplicate MAC address among the DHCP clients attached to the router. A duplicate DHCP client occurs when a client attempts to get a lease, and that client has the same client ID or the same MAC address as an existing DHCP client.

When DHCP server receives a request from a new client that has a duplicate ID or MAC address, DHCP server terminates the address lease for the existing client and returns the address to its original address pool. DHCP server then assigns a new address and lease to the new client.

By default, both DHCP local server and DHCP relay use the subnet information to differentiate between duplicate clients. However, in some cases, this level of differentiation is not adequate. For example, when multiple subinterfaces share the same underlying loopback interface with the same preferred source address, the interfaces appear to be on the same subnet. In this situation, the default configuration prevents duplicate clients.

You can provide greater differentiation between duplicate clients by configuring DHCP to consider the client subinterface when duplicate clients occur. In this optional configuration, DHCP uniquely identifies:

- The subnet on which the client resides
- The subinterface on which the client resides
- The client within the subnet

**Related  
Documentation**

- [Configuring DHCP Duplicate Client Support on page 198](#)
- [Guidelines for Configuring Support for DHCP Duplicate Clients on page 197](#)

## Guidelines for Configuring Support for DHCP Duplicate Clients

This topic describes the guidelines for configuring DHCP to include the client subinterface in order to distinguish between duplicate clients (clients with the same MAC address or client ID) in a subscriber access environment.

When configuring DHCP duplicate client support, consider the following guidelines:

- The optional DHCP duplicate client support feature is used for DHCPv4 clients. For DHCPv6, client identification is independent of MAC address.
- For DHCP relay agent configuration:
  - DHCP relay must be configured to insert option 82, regardless of whether or not the incoming packet has option 82.
  - Option 82 must include the Agent Circuit ID suboption (suboption 1).
  - Option 82 must be the interface name, not the interface description.
  - DHCP server must echo option 82 in the server's reply. This is required because of the following:
    - The giaddr inserted by DHCP relay is the same for duplicate clients on different subinterfaces. The DHCP local server uses option 82 when allocating the IP address.
    - DHCP relay uses the echoed option 82 to learn the client subinterface and to construct the client key.
- For the Layer 3 wholesale model:
  - The wholesaler and retailer logical system/routing instances must have the same **duplicate-clients-on-interface** statement configuration.
  - For DHCP relay, the wholesaler and the retailer routing contexts must both be configured with the Agent Circuit ID suboption (suboption 1) in option 82.

**Related  
Documentation**

- [DHCP Duplicate Client Differentiation Using Client Subinterface Overview on page 196](#)

## Configuring DHCP Duplicate Client Support

---

You can optionally configure DHCP local server and DHCP relay to include a client subinterface when distinguishing between two clients that have the same MAC address or client ID. The configuration is a global setting for each logical system/routing instance.

To configure DHCP local server to include the client subinterface:

1. Specify that you want to configure DHCP local server.

```
[edit system services]
user@host# edit dhcp-local-server
```

2. Configure the optional duplicate client support.

```
[edit system services dhcp-local-server]
user@host# set duplicate-clients-on-interface
```

To configure DHCP relay agent to include the client subinterface:

1. Specify that you want to configure DHCP relay agent.

```
[edit forwarding-options]
user@host# edit dhcp-relay
```

2. Configure the optional duplicate client support.

```
[edit system services dhcp-relay]
user@host# set duplicate-clients-on-interface
```

## Using External AAA Authentication Services with DHCP

---

The extended DHCP local server, including DHCPv6 local server, and the extended DHCP relay agent, including DHCPv6 relay agent, support the use of external AAA authentication services, such as RADIUS, to authenticate DHCP clients. When the extended DHCP local server or relay agent receives a discover PDU from a client, the extended DHCP application contacts the AAA server to authenticate the DHCP client. The extended DHCP application can obtain client addresses and DHCP configuration options from the external AAA authentication server.

**NOTE:** This section uses the term *extended DHCP application* to refer to both the extended DHCP local server and the extended DHCP relay agent.

---

The external authentication feature also supports AAA directed logout. If the external AAA service supports a user logout directive, the extended DHCP application honors the logout and responds as though it were requested by a CLI management command. All of the client state information and allocated resources are deleted at logout. The extended

DHCP application supports directed logout using the list of configured authentication servers you specify with the [authentication-server](#) statement at the **[edit access profile profile-name]** hierarchy level.

You can configure either global authentication support or group-specific support.

You must configure the **username-include** statement to enable the use of authentication. The **password** statement is not required and does not cause DHCP to use authentication if the **username-include** statement is not included.

To configure DHCP local server and DHCP relay agent authentication support:

1. Specify that you want to configure authentication options.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# edit authentication
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit authentication
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6]
user@host# edit authentication
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit authentication
```

2. (Optional) Configure a password that authenticates the username to the external authentication service.

See [“Configuring Passwords for Usernames”](#) on page 221.

3. (Optional) Configure optional features to create a unique username.

See [“Creating Unique Usernames for DHCP Clients”](#) on page 222.

#### Related Documentation

- [Extended DHCP Local Server Overview on page 186](#)

- [DHCPv6 Local Server Overview on page 190](#)
- [DHCPv6 Relay Agent Overview on page 260](#)

## Grouping Interfaces with Common DHCP Configurations

You use the group feature to group together a set of interfaces and then apply a common DHCP configuration to the named interface group. The extended DHCP local server, DHCPv6 local server, DHCP relay agent, and DHCPv6 relay agent all support interface groups.

The following steps create a DHCP local server group; the steps are similar for the DHCPv6 local server, DHCP relay agent, and DHCPv6 relay agent.

To configure a DHCP local server interface group:

1. Specify that you want to configure DHCP local server.

```
[edit system services]
user@host# edit dhcp-local-server
```

2. Create the group and assign a name.

```
[edit system services dhcp-local-server]
user@host# edit group boston
```

3. Specify the names of one or more interfaces on which the extended DHCP application is enabled. You can repeat the **interface interface-name** statement to specify multiple interfaces within the group, but you cannot use the same interface in more than one group.

```
[edit system services dhcp-local-server group boston]
user@host# set interface fe-1/0/1.1
user@host# set interface fe-1/0/1.2
```

4. (Optional) You can use the **upto** option to specify a range of interfaces for a group.

```
[edit system services dhcp-local-server group boston]
user@host# set interface fe-1/0/1.3 upto fe-1/0/1.9
```

5. (Optional) You can use the **exclude** option to exclude a specific interface or a specified range of interfaces from the group. For example:

```
[edit system services dhcp-local-server group boston]
user@host# set interface fe-1/0/1.1 upto fe-1/0/1.102
user@host# set interface fe-1/0/1.6 exclude
user@host# set interface fe-1/0/1.70 upto fe-1/0/1.80 exclude
```

---

## Guidelines for Configuring Interface Ranges

This topic describes guidelines to consider when configuring interface ranges for named interface groups for DHCP local server and DHCP relay. The guidelines refer to the following configuration statement:

```
user@host# set interface interface-name upto upto-interface-name
```

- The start subunit, **interface *interface-name***, serves as the key for the stanza. The remaining configuration settings are considered attributes.
- If the subunit is not included, an implicit **.0** subunit is enforced. The implicit subunit is applied to all interfaces when autoconfiguration is enabled. For example, **interface ge-2/2/2** is treated as **interface ge-2/2/2.0**.
- Ranged entries contain the **upto** option, and the configuration applies to all interfaces within the specified range. The start of a ranged entry must be less than the end of the range. Discrete entries apply to a single interface, except in the case of autoconfiguration, in which a **0** (zero) subunit acts as a wildcard.
- Interface stanzas defined within the same router context are dependent and can constrain each other—both DHCP local server and DHCP relay are considered. Interface stanzas defined across different router contexts are independent and do not constrain one another.
- Each interface stanza, whether discrete or ranged, has a unique start subunit across a given router context. For example, the following configuration is not allowed within the same group because **ge-1/0/0.10** is the start subunit for both.

```
interface ge-1/0/0.10 upto ge-1/0/0.30
interface ge-1/0/0.10
```

- Two groups cannot share interface space. For example, the following configuration is not allowed because the three stanzas share the same space and interfere with one another—interface **ge-1/0/0.26** is common to all three.

```
dhcp-relay group diamond interface ge-1/0/0.10 upto ge-1/0/0.30
dhcp-local-server group ruby interface ge-1/0/0.26
dhcp-relay group sapphire interface ge-1/0/0.25 upto ge-1/0/0.35
```

- Two ranges cannot overlap, either within a group or across groups. Overlapping occurs when two interface ranges share common subunit space but neither range is a proper subset of the other. The following ranges overlap:

```
interface ge-1/0/0.10 upto ge-1/0/0.30
interface ge-1/0/0.20 upto ge-1/0/0.40
```

- A range can contain multiple nested ranges. A nested range is a proper subset of another range. When ranges are nested, the smallest matching range applies.

In the following example, the three ranges nest properly:

```
interface ge-1/0/0.10 upto ge-1/0/0.30
interface ge-1/0/0.12 upto ge-1/0/0.15 exclude
interface ge-1/0/0.25 upto ge-1/0/0.29 exclude
```

- Discrete interfaces take precedence over ranges. In the following example, interface **ge-1/0/0.20** takes precedence and enforces an interface client limit of 5.

```
interface ge-1/0/0.10 upto ge-1/0/0.30
interface ge-1/0/0.15 upto ge-1/0/0.25 exclude
interface ge-1/0/0.20 overrides interface-client-limit 5
```

## Group-Specific DHCP Relay Options

---

You can include the following statements at the **[edit forwarding-options dhcp-relay group group-name]** hierarchy level to set group-specific DHCP relay agent configuration options. Group-specific statements apply only to the named group of interfaces, and override any global DHCP relay agent settings for the same statement.

Include the statements at the **[edit forwarding-options dhcp-relay dhcpv6 group group-name]** hierarchy level to configure group-specific options for DHCPv6 relay agent.

- **active-server-group**—Configure an active server group to apply a common DHCP relay agent configuration to a named group of DHCP server addresses. For information, see [“Configuring Active Server Groups” on page 308](#).
- **authentication**—Configure the parameters the router sends to the external AAA server.
- **dynamic-profile**—Specify the dynamic profile that is attached to a group of interfaces.
- **interface**—Specify one or more interfaces, or a range of interfaces, that are within the specified group.
- **liveness-detection**—Configure bidirectional failure detection timers and authentication criteria for static routes. For more information, see [“DHCP Liveness Detection Overview” on page 233](#).
- **overrides**—Override the default configuration settings for the extended DHCP relay agent. For information, see [“Overriding the Default DHCP Relay Configuration Settings” on page 273](#).
- **relay-agent-interface-id**—(DHCPv6 only) Insert the DHCPv6 Relay Agent Interface-ID option (option 18) in DHCPv6 packets destined for the DHCPv6 server.
- **relay-option**—Configure selective processing, which uses DHCP options in client packets to identify and filter client traffic, and to specify the action DHCP relay agent takes with the traffic. For more information, see [“Using DHCP Option Information to Selectively Process DHCP Client Traffic” on page 303](#).
- **relay-option-82**—(DHCPv4 only) Enable or disable the insertion of option 82 information in packets destined for a DHCP server. For information, see [“Enabling and Disabling Insertion of Option 82 Information” on page 305](#).
- **service-profile**—Specify the default subscriber service, which is activated when the subscriber logs in and no other service is activated by a RADIUS server or a provisioning server. For more information, see [“Default Subscriber Service Overview” on page 1071](#).

### Related Documentation

- [Grouping Interfaces with Common DHCP Configurations on page 201](#)

## Overriding the Default DHCP Relay Configuration Settings

Subscriber management enables you to override certain default DHCP and DHCPv6 relay agent configuration settings. You can override the settings at the global level, for a named group of interfaces, or for a specific interface within a named group.

- To override global default DHCP relay agent configuration options, include the **overrides** statement and its subordinate statements at the **[edit forwarding-options dhcp-relay]** hierarchy level.
- To override DHCP relay configuration options for a named group of interfaces, include the statements at the **[edit forwarding-options dhcp-relay group group-name]** hierarchy level.
- To override DHCP relay configuration options for a specific interface within a named group of interfaces, include the statements at the **[edit forwarding-options dhcp-relay group group-name interface]** hierarchy level.
- To configure overrides for DHCPv6 relay, use the supported statements at the **[edit forwarding-options dhcp-relay dhcpv6]** hierarchy level.

To override default DHCP relay agent configuration settings:

1. Specify that you want to configure override options.

Global override:

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

Group-level override:

```
[edit forwarding-options dhcp-relay]
user@host# edit group boston overrides
```

Per-interface override:

```
[edit forwarding-options dhcp-relay]
user@host# edit group boston interface fe-1/0/1.2 overrides
```

2. (DHCPv4 only) Enable DHCP relay proxy mode.

See [“Enabling DHCP Relay Proxy Mode” on page 309](#).

3. (DHCPv4 only) Overwrite the giaddr in DHCP packets that the DHCP relay agent forwards.

See [“Overwriting giaddr Information” on page 274](#).

4. (DHCPv4 only) Replace the IP source address in DHCP relay request and release packets with the gateway IP address (giaddr).

See [“Replacing the DHCP Relay Request and Release Packet Source Address” on page 275](#).

5. (DHCPv4 only) Override the DHCP relay agent information option (option 82) in DHCP packets.

See [“Overriding Option 82 Information” on page 275](#).

6. (DHCPv4 only) Override the setting of the broadcast bit in DHCP request packets and use the Layer 2 unicast transmission method.

See [“Using Layer 2 Unicast Transmission for DHCP Packets” on page 276](#).

7. (DHCPv4 only) Trust DHCP client packets that have a giaddr of 0 and that contain option 82 information.

See [“Trusting Option 82 Information” on page 276](#).

8. (DHCPv4 only) Override the ARP table population in distrusted environments.

See [“Disabling ARP Table Population” on page 206](#).

9. (DHCPv4 and DHCPv6) Override the maximum number of DHCP clients allowed per interface.

See [“Specifying the Maximum Number of DHCP Clients Per Interface” on page 205](#).

10. (DHCPv4 only) Configure client auto logout.

See [“DHCP Auto Logout Overview” on page 208](#).

11. (DHCPv4 and DHCPv6) Enable or disable support for DHCP snooped clients on interfaces.

See [“Enabling and Disabling DHCP Snooped Packets Support for DHCP Relay Agent” on page 281](#).

12. (DHCPv4 and DHCPv6) Send release messages to the DHCP server when clients are deleted.

See [“Sending Release Messages When Clients Are Deleted” on page 291](#).

13. (DHCPv4 only) Disable the DHCP relay agent on specific interfaces.

See [“Disabling DHCP Relay” on page 299](#).

14. (DHCPv4 and DHCPv6) Disable automatic binding of stray DHCP requests.

See [“Disabling Automatic Binding of Stray DHCP Requests” on page 299](#).

**Related  
Documentation**

- [Deleting DHCP Local Server and DHCP Relay Override Settings on page 213](#)

---

## Overwriting giaddr Information

You can configure the DHCP relay agent to change the gateway IP address (giaddr) field in packets that it forwards between a DHCP client and a DHCP server.

To overwrite the giaddr of every DHCP packet with the giaddr of the DHCP relay agent before forwarding the packet to the DHCP server:

1. Specify that you want to configure override options.

[edit forwarding-options dhcp-relay]

```
user@host# edit overrides
```

2. Specify that the giaddr of DHCP packets is overwritten.

```
[edit forwarding-options dhcp-relay overrides]
```

```
user@host# set always-write-giaddr
```

**Related  
Documentation**

- [Extended DHCP Relay Agent Overview on page 258](#)
- [Overriding the Default DHCP Relay Configuration Settings on page 273](#)

## Replacing the DHCP Relay Request and Release Packet Source Address

You can configure the DHCP relay agent to replace request and release packets with the gateway IP address (giaddr) before forwarding the packet to the DHCP server.

To replace the source address with giaddr:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]
```

```
user@host# edit overrides
```

2. Specify that you want to replace the IP source address in DHCP relay request and release packets with the gateway IP address (giaddr).

```
[edit forwarding-options dhcp-relay overrides]
```

```
user@host# set replace-ip-source-with giaddr
```

**Related  
Documentation**

- [Extended DHCP Relay Agent Overview on page 258](#)
- [Overriding the Default DHCP Relay Configuration Settings on page 273](#)

## Overriding Option 82 Information

You can configure the DHCP relay agent to add or remove the DHCP relay agent information option (option 82) in DHCP packets.

This feature causes the DHCP relay agent to perform one of the following actions, depending on the configuration:

- If the DHCP relay agent is configured to add option 82 information to DHCP packets, it clears the existing option 82 values from the DHCP packets and inserts the new values before forwarding the packets to the DHCP server.
- If the DHCP relay agent is not configured to add option 82 information to DHCP packets, it clears the existing option 82 values from the packets, but does not add any new values before forwarding the packets to the DHCP server.

To override the default option 82 information in DHCP packets destined for a DHCP server:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Specify that the option 82 information in DHCP packets is overwritten.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set always-write-option-82
```

**Related  
Documentation**

- [Extended DHCP Relay Agent Overview on page 258](#)
- [Overriding the Default DHCP Relay Configuration Settings on page 273](#)

---

## Using Layer 2 Unicast Transmission for DHCP Packets

You can configure the DHCP relay agent to override the setting of the broadcast bit in DHCP request packets. DHCP relay agent then instead uses the Layer 2 unicast transmission method to send DHCP Offer reply packets and DHCP ACK reply packets from the DHCP server to DHCP clients during the discovery process.

To override the default setting of the broadcast bit in DHCP request packets:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Specify that the DHCP relay agent uses the Layer 2 unicast transmission method.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set layer2-unicast-replies
```

**Related  
Documentation**

- [Extended DHCP Relay Agent Overview on page 258](#)
- [Overriding the Default DHCP Relay Configuration Settings on page 273](#)

---

## Trusting Option 82 Information

By default, the DHCP relay agent treats client packets with a giaddr of 0 (zero) and option 82 information as if the packets originated at an untrusted source, and drops them without further processing. You can override this behavior and specify that the DHCP relay agent process DHCP client packets that have a giaddr of 0 (zero) and contain option 82 information.

To configure DHCP relay agent to trust option 82 information:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Specify that the DHCP relay agent process DHCP client packets with a giaddr of 0 and that contain option 82 information.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set trust-option-82
```

- Related Documentation**
- [Extended DHCP Relay Agent Overview on page 258](#)
  - [Overriding the Default DHCP Relay Configuration Settings on page 273](#)

## Disabling ARP Table Population

By default, DHCP populates the ARP table with the MAC address of a client when the client binding is established. However, you may choose to use the DHCP **no-arp** statement to hide the subscriber MAC address information, as it appears in ARP table entries.

When running in a trusted environment (that is, when not using the **no-arp** statement), DHCP populates the ARP table with unique MAC addresses contained within the DHCP PDU for each DHCP client:

**Table 38: ARP Table in Trusted Environment**

IP Address	MAC Address
Client 1 IP Address	MAC A
Client 2 IP Address	MAC B
Client 3 IP Address	MAC C

In distrusted environments, you can specify the **no-arp** statement to hide the MAC addresses of clients. When you specify the **no-arp** statement, DHCP does not automatically populate the ARP table with MAC address information from the DHCP PDU for each client. Instead, the system performs an ARP to obtain the MAC address of each client and obtains the MAC address of the immediately attached device (for example, a DSLAM). DHCP populates the ARP table with the same interface MAC address (for example, MAC X from a DSLAM interface) for each client:

**Table 39: ARP Table in Distrusted Environment**

IP Address	MAC Address
Client 1 IP Address	MAC X
Client 2 IP Address	MAC X
Client 3 IP Address	MAC X

To disable ARP table population:

1. Specify that you want to configure override options.
  - For DHCP local server:
 

```
[edit system services dhcp-local-server]
user@host# edit overrides
```
  - For DHCP relay:

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Disable ARP table population with client-specific information. (DHCP local server and DHCP relay agent both support the **no-arp** statement.)

- For DHCP local server:

```
[edit system services dhcp-local-server overrides]
user@host# set no-arp
```

- For DHCP relay:

```
[edit forwarding-options dhcp-relay overrides]
user@host# set no-arp
```

---

## Specifying the Maximum Number of DHCP Clients Per Interface

By default, there is no limit to the number of DHCP local server or DHCP relay clients allowed on an interface. However, you can override the default setting and specify the maximum number of clients allowed per interface, in the range 1 through 500,000. When the number of clients on the interface reaches the specified limit, no additional DHCP Discover PDUs or DHCPv6 Solicit PDUs are accepted. When the number of clients subsequently drops below the limit, new clients are again accepted.

**NOTE:** The maximum number of DHCP (and DHCPv6) local server clients or DHCP (and DHCPv6) relay clients can also be specified by Juniper Networks VSA 26-143 during client login. The VSA-specified value always takes precedence if the `interface-client-limit` statement specifies a different number.

If the VSA-specified value differs with each client login, DHCP uses the largest limit set by the VSA until there are no clients on the interface.

---

To configure the maximum number of DHCP clients allowed per interface:

1. Specify that you want to configure override options.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# edit overrides
```

- For DHCPv6 local server:

```
[edit system services dhcp-local-server dhcpv6]
```

```
user@host# edit overrides
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
```

```
user@host# edit overrides
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6]
```

```
user@host# edit overrides
```

2. Configure the maximum number of clients allowed per interface. (DHCP local server, DHCPv6 local server, DHCP relay agent and DHCPv6 relay agent all support the **interface-client-limit** statement.)

```
[edit system services dhcp-local-server overrides]
```

```
user@host# set interface-client-limit number
```

## DHCP Snooping Support

DHCP snooping provides DHCP security on the router by filtering incoming messages. When DHCP snooping is enabled, the router differentiates between trusted and untrusted interfaces, and forwards messages from trusted sources while rejecting the untrusted messages.

In Junos OS, DHCP snooping is enabled in a routing instance when you configure either the **dhcp-relay** statement at the **[edit forwarding-options]** hierarchy level, or the **dhcp-local-server** statement at the **[edit system services]** hierarchy level in that routing instance. However, depending on the Junos OS release, the router processes the snooped packets differently, as described in the following list:

- In Junos OS Release 10.0 and earlier, the router processes snooped packets normally.
- In Junos OS Release 10.1 and later, the router discards snooped packets by default. To enable normal processing of snooped packets in Junos OS Release 10.1 and later, you must explicitly configure the **allow-snooped-clients** statement at the **[edit forwarding-options dhcp-relay]** hierarchy level.

You can configure DHCP snooping support for the following:

- DHCPv4 relay agent—Override the router's default snooping configuration and specify that DHCP snooping is enabled or disabled globally, for a named group of interfaces, or for a specific interface within a named group.

In a separate procedure, you can set a global configuration to specify whether the DHCPv4 relay agent forwards or drops snooped packets for all interfaces, only

configured interfaces, or only nonconfigured interfaces. The router also uses the global DHCP relay agent snooping configuration to determine whether to forward or drop snooped BOOTREPLY packets.

- DHCPv6 relay agent—As you can with snooping support for the DHCPv4 relay agent, you can override the default DHCPv6 relay agent snooping configuration on the router to explicitly enable or disable snooping support globally, for a named group of interfaces, or for a specific interface with a named group of interfaces.

In multi-relay topologies where more than one DHCPv6 relay agent is between the DHCPv6 client and the DHCPv6 server, snooping enables intervening DHCPv6 relay agents between the client and the server to correctly receive and process the unicast traffic from the client and forward it to the server. The DHCPv6 relay agent snoops incoming unicast DHCPv6 packets by setting up a filter with UDP port 547 (the DHCPv6 UDP server port) on a per-forwarding table basis. The DHCPv6 relay agent then processes the packets intercepted by the filter and forwards the packets to the DHCPv6 server.

Unlike the DHCPv4 relay agent, the DHCPv6 relay agent does not support global configuration of forwarding support for DHCPv6 snooped packets.

- DHCP local server—Configure whether DHCP local server forwards or drops snooped packets for all interfaces, only configured interfaces, or only nonconfigured interfaces.

**Related  
Documentation**

- [Configuring DHCP Snooping for DHCP Relay Agent on page 280](#)

- [Example: Configuring DHCP Snooping Support for DHCP Relay Agent on page 323](#)

---

## Configuring DHCP Snooping for DHCP Relay Agent

---

DHCP relay agent uses a two-part configuration to determine how to handle DHCP snooped packets. First, you enable or disable snooping support for DHCP relay agent and, optionally, override the default snooping configuration. Then you configure the forwarding action for snooped clients, which specifies whether DHCP relay agent forwards or drops snooped traffic.

To configure DHCP snooping for DHCP relay agent:

1. (DHCPv4 and DHCPv6) Enable or disable DHCP snooping. You can configure DHCP snooping globally, for a named group of interfaces, or for a specific interface.  
  
See [“Enabling and Disabling DHCP Snooped Packets Support for DHCP Relay Agent” on page 281](#).
2. (DHCPv4 only) Configure snooped packets forwarding support.  
  
See [“Configuring DHCP Snooped Packets Forwarding Support for DHCP Relay Agent” on page 286](#).

- Related Documentation**
- [DHCP Snooping Support on page 279](#)
  - [Enabling and Disabling DHCP Snooped Packets Support for DHCP Relay Agent on page 281](#)
  - [Configuring DHCP Snooped Packets Forwarding Support for DHCP Relay Agent on page 286](#)
  - [Example: Configuring DHCP Snooping Support for DHCP Relay Agent on page 323](#)

## Enabling and Disabling DHCP Snooped Packets Support for DHCP Relay Agent

DHCP relay agent uses a two-part configuration to determine how to handle DHCP snooped packets. This topic describes the first procedure, in which you configure DHCP relay to either enable or disable support for snooped packets.

The second procedure, which applies only to DHCPv4 relay agent, is described in “[Configuring DHCP Snooped Packets Forwarding Support for DHCP Relay Agent](#)” on [page 286](#), and configures the **forward-snooped-clients** statement, which determines whether the snooped packets are forwarded or dropped, depending on the type of interface.

**NOTE:** The router has a default global setting that specifies whether DHCP snooping support is enabled or disabled for DHCP relay. In Junos OS Release 10.0 and earlier, DHCP snooping is enabled by default. In Junos OS Release 10.1 and later, DHCP snooping is disabled by default.

You can override the default global DHCP snooping configuration and explicitly enable or disable DHCP snooping support. You can configure the explicit snooping support globally, for a group of interfaces, or for a specific interface in a group.

- To enable DHCP relay or DHCPv6 relay snooping support, include the **allow-snooped-clients** option in the **overrides** statement.
- To disable DHCP relay or DHCPv6 relay snooping support, include the **no-allow-snooped-clients** option in the **overrides** statement.

To enable or disable DHCP snooping support globally:

1. Specify that you want to configure DHCP relay agent.

- For DHCP relay agent:

```
[edit]
user@host# edit forwarding-options dhcp-relay
```

- For DHCPv6 relay agent:

```
[edit]
user@host# edit forwarding-options dhcp-relay dhcpv6
```

2. Specify that you want to override the default configuration.

- For DHCP relay agent:  
[edit forwarding-options dhcp-relay]  
user@host# edit overrides
  - For DHCPv6 relay agent:  
[edit forwarding-options dhcp-relay dhcpv6]  
user@host# edit overrides
3. Enable or disable DHCP snooping support.
- To enable DHCP snooping:
    - For DHCP relay agent:  
[edit forwarding-options dhcp-relay overrides]  
user@host# set allow-snooped-clients
    - For DHCPv6 relay agent:  
[edit forwarding-options dhcp-relay dhcpv6 overrides]  
user@host# set allow-snooped-clients
  - To disable DHCP snooping:
    - For DHCP relay agent:  
[edit forwarding-options dhcp-relay overrides]  
user@host# set no-allow-snooped-clients
    - For DHCPv6 relay agent:  
[edit forwarding-options dhcp-relay dhcpv6 overrides]  
user@host# set no-allow-snooped-clients

For example, to enable global DHCP snooping support :

```
forwarding-options {  
  dhcp-relay {  
    overrides {  
      allow-snooped-clients;  
    }  
  }  
}
```

To enable or disable DHCP snooping support for a group of interfaces:

1. Specify that you want to configure DHCP relay agent.
  - For DHCP relay agent:  
[edit]  
user@host# edit forwarding-options dhcp-relay
  - For DHCPv6 relay agent:  
[edit]  
user@host# edit forwarding-options dhcp-relay dhcpv6
2. Specify the named group.
  - For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit group group-name
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit group group-name
```

3. Specify that you want to override the default configuration.

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay group group-name]
user@host# edit overrides
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6 group group-name]
user@host# edit overrides
```

4. Enable or disable DHCP snooping support.

- To enable DHCP snooping:

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay group group-name overrides]
user@host# set allow-snooped-clients
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6 group group-name overrides]
user@host# set allow-snooped-clients
```

- To disable DHCP snooping:

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay group group-name overrides]
user@host# set no-allow-snooped-clients
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6 group group-name overrides]
user@host# set no-allow-snooped-clients
```

For example, to enable DHCP snooping support on all interfaces in group **boston**:

```
forwarding-options {
  dhcp-relay {
    group boston {
      overrides {
        allow-snooped-clients;
      }
    }
  }
}
```

To enable or disable DHCP snooping support on a specific interface:

1. Specify that you want to configure DHCP relay agent.

- For DHCP relay agent:

```
[edit]
user@host# edit forwarding-options dhcp-relay
```

- For DHCPv6 relay agent:

```
[edit]
user@host# edit forwarding-options dhcp-relay dhcpv6
```

2. Specify the named group containing the interface.

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit group group-name
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit group group-name
```

3. Specify the interface for which you want to configure DHCP snooping.

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay group group-name]
user@host# edit interface interface-name
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6 group group-name]
user@host# edit interface interface-name
```

4. Specify that you want to override the default configuration on the interface.

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay group group-name interface interface-name]
user@host# edit overrides
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6 group group-name interface
interface-name]
user@host# edit overrides
```

5. Enable or disable DHCP snooping support.

- To enable DHCP snooping:

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay group group-name interface interface-name
overrides]
user@host# set allow-snooped-clients
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6 group group-name interface
interface-name overrides]
```

```
user@host# set allow-snooped-clients
```

- To disable DHCP snooping:

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay group group-name interface interface-name
overrides]
```

```
user@host# set no-allow-snooped-clients
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6 group group-name interface
interface-name overrides]
```

```
user@host# set no-allow-snooped-clients
```

For example, to disable DHCP snooping support on interface **ge-2/1/8.0** in group **boston**:

```
forwarding-options {
  dhcp-relay {
    group boston {
      interface ge-2/1/8.0 {
        overrides {
          no-allow-snooped-clients;
        }
      }
    }
  }
}
```

To enable DHCPv6 snooping support on interface **ge-3/2/1.1** in group **sunnyvale**:

```
forwarding-options {
  dhcp-relay {
    dhcpv6 {
      group sunnyvale {
        interface ge-3/2/1.1 {
          overrides {
            allow-snooped-clients;
          }
        }
      }
    }
  }
}
```

#### Related Documentation

- [Configuring DHCP Snooped Packets Forwarding Support for DHCP Relay Agent on page 286](#)
- [DHCP Snooping Support on page 279](#)
- [Overriding the Default DHCP Relay Configuration Settings on page 273](#)

## Configuring DHCP Snooped Packets Forwarding Support for DHCP Relay Agent

You can configure how DHCP relay agent handles DHCP snooped packets. Depending on the configuration, DHCP relay agent either forwards or drops the snooped packets it receives.

DHCP relay uses a two-part configuration to determine how to handle DHCP snooped packets. This topic describes how you use the **forward-snooped-clients** statement to manage whether DHCP relay agent forwards or drops snooped packets, depending on the type of interface on which the packets are snooped. In the other part of the DHCP relay agent snooping configuration, which is described in “[Enabling and Disabling DHCP Snooped Packets Support for DHCP Relay Agent](#)” on page 281, you enable or disable the DHCP relay snooping feature.

[Table 40 on page 286](#) shows the action the router takes on snooped packets when DHCP snooping is enabled by the **allow-snooped-clients** statement. [Table 41 on page 287](#) shows the action the router takes on snooped packets when DHCP snooping is disabled by the **no-allow-snooped-clients** statement.

The router also uses the configuration of the DHCP relay agent forwarding support to determine how to handle snooped BOOTREPLY packets. [Table 42 on page 287](#) shows the action the router takes for the snooped BOOTREPLY packets.

**NOTE:** Configured interfaces have been configured with the **group** statement in the **[edit forwarding-options dhcp-relay]** hierarchy. Non-configured interfaces are in the logical system/routing instance but have not been configured by the **group** statement.

**Table 40: Actions for DHCP Relay Agent Snooped Packets When DHCP Snooping Is Enabled**

forward-snooped-clients Configuration	Action on Configured Interfaces	Action on Non-Configured Interfaces
<b>forward-snooped-clients</b> not configured	snooped packets result in subscriber creation	dropped
<b>all-interfaces</b>	forwarded	forwarded
<b>configured-interfaces</b>	forwarded	dropped
<b>non-configured-interfaces</b>	snooped packets result in subscriber creation	forwarded

Table 41: Actions for DHCP Relay Agent Snooped Packets When DHCP Snooping Is Disabled

forward-snooped-clients Configuration	Action on Configured Interfaces	Action on Non-Configured Interfaces
<b>forward-snooped-clients</b> not configured	dropped	dropped
<b>all-interfaces</b>	dropped	forwarded
<b>configured-interfaces</b>	dropped	dropped
<b>non-configured-interfaces</b>	dropped	forwarded

Table 42: Actions for Snooped BOOTREPLY Packets

forward-snooped-clients Configuration	Action
<b>forward-snooped-clients</b> not configured	snooped <b>BOOTREPLY</b> packets dropped if client is not found
<b>forward-snooped-clients</b> all configurations	snooped <b>BOOTREPLY</b> packets forwarded if client is not found

To configure DHCP snooped packet forwarding and BOOTREPLY snooped packet forwarding for DHCP relay agent:

1. Specify that you want to configure DHCP relay agent.

```
[edit]
user@host# edit forwarding-options dhcp-relay
```

2. Enable DHCP snooped packet forwarding.

```
[edit forwarding-options dhcp-relay]
user@host# edit forward-snooped-clients
```

3. Specify the interfaces that are supported for snooped packet forwarding.

```
[edit forwarding-options dhcp-relay forward-snooped-clients]
user@host# set (all-interfaces | configured-interfaces | non-configured-interfaces)
```

For example, to configure DHCP relay agent to forward DHCP snooped packets on only configured interfaces:

```
[edit]
forwarding-options {
  dhcp-relay {
    forward-snooped-clients configured-interfaces;
  }
}
```

## DHCP Auto Logout Overview

---

This topic provides an introduction to the optional DHCP auto logout feature and includes the following sections:

- [Auto Logout Overview on page 288](#)
- [How DHCP Identifies and Releases Clients on page 288](#)
- [Option 60 and Option 82 Requirements on page 289](#)

### Auto Logout Overview

Auto logout is an optional configuration for DHCP local server and DHCP relay agent that improves the efficiency of DHCP IP address assignment. Auto logout enables IP addresses to be immediately released and returned to the address pool when the addresses are no longer used by DHCP clients. DHCP can then assign the addresses to other clients. Without auto logout, an IP address is blocked for the entire lease period, and DHCP must wait until the address lease time expires before reusing the address.

Auto logout is particularly useful when DHCP uses long lease times for IP address assignments and to help avoid allocating duplicate IP addresses for a single client. For example, you might have an environment that includes set-top boxes (STB) that are often upgraded or replaced. Each time a STB is changed, the new STB repeats the DHCP discover process to obtain client configuration information and an IP address. DHCP views the new STB as a completely new client and assigns a new IP address—the previous IP address assigned to the client (the old STB) remains blocked and unavailable until the lease expires. If auto logout is configured in this situation, DHCP recognizes that the new STB is actually the same client and then immediately releases the original IP address. DHCP relay agent acts as a proxy client for auto logout and sends a DHCP release message to the DHCP server.

### How DHCP Identifies and Releases Clients

The auto logout feature requires that DHCP explicitly identify clients. By default, DHCP local server and DHCP relay agent identify clients based on MAC address or Client Identifier. However, in some cases this type of identification might not be sufficient. For example, in the previous STB example, each STB has a different MAC address, so DHCP incorrectly assumes that an upgraded or replacement STB is a new client.

In order to explicitly identify clients, auto logout uses a secondary identification method when the primary identification method is unsuccessful—the primary method is considered unsuccessful if the MAC address or Client Identifier does not match that of an existing client. The secondary identification method is based on the DHCP option 60 and option 82 information in DHCP discover messages.

Both the primary and secondary identification methods use subnet information to differentiate between clients. The primary identification method differentiates between

two clients with the same MAC address (or same Client Identifier) if the clients are on different subnets. Similarly, the secondary identification method considers two clients as different if they have the same option 60 and option 82 information, but different subnets.

DHCP local server and DHCP relay agent perform the following operations when auto logout is enabled and the secondary identification method identifies a duplicate client (that is, the discover packet is from an existing client).

- DHCP local server immediately releases the existing address.
- DHCP relay agent immediately releases the existing client and then sends a DHCP release packet to the DHCP server. Sending the release packet ensures that DHCP relay and the DHCP server are synchronized.

If the DHCP relay receives a DISCOVER message from an existing client, the DHCP relay forwards the DISCOVER message to the DHCP server. The DHCP relay preserves the binding if the client's existing IP address is returned by the DHCP server. This behavior is not applicable if the proxy-mode override or client-discover-match functionality are enabled.

**NOTE:** If the DHCP relay agent is in snoop mode, DHCP relay releases the client but does not send a release packet to the DHCP server if the discover packet is for a passive client (a client added as a result of snooped packets) or if the discover packet is a snooped packet.

## Option 60 and Option 82 Requirements

DHCP local server requires that the received discover packet include both DHCP option 60 and option 82. If either option is missing, DHCP local server cannot perform the secondary identification method and auto logout is not used.

DHCP relay agent requires that the received discover packet contain DHCP option 60. DHCP relay determines the option 82 value based on the guidelines provided in “[DHCP Relay Agent Option 82 Value for Auto Logout](#)” on page 289.

### Related Documentation

- [Automatically Logging Out DHCP Clients on page 210](#)
- [DHCP Relay Agent Option 82 Value for Auto Logout on page 289](#)
- [Clearing DHCP Bindings for Subscriber Access on page 217](#)

## DHCP Relay Agent Option 82 Value for Auto Logout

[Table 43 on page 290](#) indicates how the DHCP relay agent determines the option 82 value used for the client auto logout feature. Depending on the configuration settings, DHCP relay agent takes the action indicated in the right column.

Table 43: DHCP Relay Agent Option 82 Value for Auto Logout

DHCP Relay Agent Configuration Settings				giaddr in non-snooped packet	Action Taken
DHCP Relay Configured with Option 82	Discover Packet Contains Option 82	Override "trust-option-82"	Override "always-write-option-82"		
No	No	—	—	—	No secondary search performed
No	Yes	Yes	—	—	Use option 82 from packet
No	Yes	No	—	Zero	Drop packet
No	Yes	No	—	Non-zero	Use option 82 from packet
Yes	No	—	—	—	Use configured option 82
Yes	Yes	No	—	Zero	Drop packet
Yes	Yes	No	No	Non-zero	Use option 82 from packet
Yes	Yes	No	Yes	Non-zero	Overwrite the configured option 82
Yes	Yes	Yes	No	—	Use option 82 from packet
Yes	Yes	Yes	Yes	—	Overwrite the configured option 82

- Related Documentation**
- [DHCP Auto Logout Overview on page 208](#)
  - [Automatically Logging Out DHCP Clients on page 210](#)

## Automatically Logging Out DHCP Clients

You can configure the extended DHCP local server and extended DHCP relay to automatically log out DHCP clients. Auto logout immediately releases an existing client when DHCP receives a discover packet that has the same DHCP option 60 and DHCP option 82 information as the existing client. DHCP then releases the existing client IP address without waiting for the normal lease expiration.

**NOTE:** When the existing client is released, the new client undergoes the normal authentication process. The new client might not receive the same IP address as the original client.

To configure DHCP client auto logout:

1. Specify that you want to configure override options.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# edit overrides
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Enable auto logout. (DHCP local server and DHCP relay agent both support the **client-discover-match** statement.)

- For DHCP local server:

```
[edit system services dhcp-local-server overrides]
user@host# set client-discover-match
```

- For DHCP relay:

```
[edit forwarding-options dhcp-relay overrides]
user@host# set client-discover-match
```

**NOTE:** If you change the auto logout configuration, existing clients continue to use the auto logout setting that was configured when they logged in. New clients use the new setting.

- [Extended DHCP Relay Agent Overview on page 258](#)

## Sending Release Messages When Clients Are Deleted

By default, when DHCP relay and relay proxy delete a client, they do not send a release message to the DHCP server. You can override the default behavior and configure DHCP relay and relay proxy to send a release message whenever they delete a client. The release message sent by DHCP relay and relay proxy includes option 82 information.

**NOTE:** In Junos OS Release 10.1 and earlier, DHCP relay sends a release message to the DHCP server when the client-discover-match statement is included as a DHCP relay override. In Junos OS Release 10.2 and later, you must include the send-release-on-delete statement to configure DHCP relay and relay proxy to send the release message when the client-discover-match statement is included.

You can use the **[edit forwarding-options dhcp-relay dhcpv6]** hierarchy level to override the default behavior for DHCPv6 relay agent.

To send a release message:

1. Specify that you want to configure override options.

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

- For DHCPv6 relay agent:

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit overrides
```

2. Specify that you want DHCP relay and relay proxy (or DHCPv6 relay agent) to send a release message when clients are deleted.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set send-release-on-delete
```

## Subscriber Binding Retention During Interface Delete Events

You can configure the router to maintain DHCP subscribers when an event occurs that normally results in the router deleting the subscriber. For example, by default, the router logs out DHCP subscribers when an interface delete event occurs, such as a DPC reboot or failure. However, if you configure the router to maintain subscribers, the router identifies each subscriber that was on the deleted interface, and resumes normal packet processing for the subscriber when the interface is restored.

**NOTE:** Subscribers are logged off as usual when their lease expires, even if the router is configured to maintain subscribers and the subscriber is on a deleted interface that has not yet been restored.

You configure the router to maintain subscribers on a global basis— the configuration applies to DHCP local server, DHCPv6 local server, and DHCP relay clients in all logical

routers and routing instances. When you enable the maintain subscribers feature, the router applies the feature to existing subscribers as well as subscribers who later connect.

If the maintain subscribers feature is enabled on the router, you can explicitly delete a subscriber binding and log out the subscriber by either specifying a lease expiration timeout or using one of the following commands, as appropriate:

- `clear dhcp server binding`
- `clear dhcpv6 server binding`
- `clear dhcp relay binding`

**Related Documentation**

- [Configuring the Router to Maintain DHCP Subscribers During Interface Delete Events on page 216](#)
- [Verifying and Managing the DHCP Maintain Subscribers Feature on page 216](#)

## Configuring the Router to Maintain DHCP Subscribers During Interface Delete Events

You can specify a configuration in which the router does not log out a subscriber when the subscriber's interface is deleted.

To configure the router to maintain DHCP subscribers when the subscriber interface is deleted:

1. Specify that you want to configure subscriber management.

```
[edit system services]
user@host# edit subscriber-management
```

2. Configure the router to support the maintain-subscriber feature.

```
[edit system services subscriber-management]
user@host# edit maintain-subscriber
```

3. Configure the router to enable the maintain-subscriber feature when an interface-delete event occurs.

```
[edit system services subscriber-management maintain-subscriber]
user@host# set interface-delete
```

**Related Documentation**

- [Subscriber Binding Retention During Interface Delete Events on page 215](#)
- [Verifying and Managing the DHCP Maintain Subscribers Feature on page 216](#)

## Verifying and Managing the DHCP Maintain Subscribers Feature

**Purpose** Display information related to the DHCP maintain-subscribers feature and explicitly log out maintained clients.

**Action** • To display DHCP local server binding information for the DHCP maintain subscribers feature:

**user@host>show dhcp server binding detail**

- To display DHCPv6 local server binding information for the DHCP maintain subscribers feature:

**user@host>show dhcpv6 server binding detail**

- To display DHCP relay binding information for the DHCP maintain subscribers feature:

**user@host>show dhcp relay binding detail**

- To explicitly log out a DHCP local server subscriber when the maintain subscriber feature is enabled:

**user@host>clear dhcp server binding *binding-type***

- To explicitly log out a DHCPv6 local server subscriber when the maintain subscriber feature is enabled:

**user@host>clear dhcpv6 server binding *binding-type***

- To explicitly log out a DHCP relay subscriber when the maintain subscriber feature is enabled:

**user@host>clear dhcp relay binding *binding-type***

## Clearing DHCP Bindings for Subscriber Access

This topic provides the procedure you use to display current DHCP bindings, clear selected bindings, and verify that the specified bindings are successfully cleared.

Subscriber management enables you to clear DHCP bindings at several different levels for DHCP local server and DHCP relay agent. For example, you can clear the DHCP bindings on all interfaces, a group of interfaces, or a specific interface. You can also clear DHCP bindings based on IP address, MAC address, session-ID, DHCPv6 prefix, DHCPv6 Client ID, FPC, PIC, port, VLAN, or stacked VLAN (S-VLAN).

This topic includes examples to show several variations of the clear DHCP binding feature. The examples use DHCP local server commands; however, the procedure and commands are similar for DHCP relay agent, DHCPv6 local server, and DHCPv6 relay agent.

To clear bindings and verify the results for a specific IP address:

1. Display current bindings. Issue the appropriate variation of the **show dhcp server binding** command.

**user@host> show dhcp server binding**

2 clients, (2 bound, 0 selecting, 0 renewing, 0 rebinding)

IP address	Hardware address	Type	Lease expires at
192.168.32.1	90:00:00:01:00:01	active	2011-10-17 11:38:47 PST
192.168.32.3	90:00:00:02:00:01	active	2011-00-17 11:38:41 PST

2. Clear the binding you want to remove.

```
user@host> clear dhcp server binding 192.168.32.1
```

3. Verify that the binding has been cleared.

```
user@host> show dhcp server binding
1 clients, (1 bound, 0 selecting, 0 renewing, 0 rebinding)

IP address      Hardware address  Type    Lease expires at
192.168.32.3    90:00:00:02:00:01 active           2011-00-17 11:38:41 PST
```

The following examples show variations of the clear DHCP binding feature. The examples use the DHCP local server version of the commands.

**NOTE:** IP demux interfaces are not supported by the show and clear DHCP bindings commands for DHCP local server and DHCP relay agent.

To clear all bindings:

```
user@host> clear dhcp server binding all
```

To clear bindings on a specific interface:

```
user@host> clear dhcp server binding interface fe-0/0/2
```

To clear all bindings over an interface. This example uses the wildcard option.

```
user@host> clear dhcp server binding ge-1/0/0.*
```

To clear bindings on top of a specific VLAN. This example clears all bindings on top of VLAN 100.

```
user@host> clear dhcp server binding ge-1/0/0:100
```

To clear bindings for a specific S-VLAN. This example clears bindings on S-VLAN 100-200.

```
user@host> clear dhcp server binding ge-1/0/0:100-200
```

To clear all bindings on top of all demux VLANs:

```
user@host> clear dhcp server binding demux0
```

To clear all bindings on top of an underlying interface. This example clears the bindings on all demux VLANs on top of interface ae0:

```
user@host> clear dhcp server binding ae0
```

To clear PPP bindings. This example uses the wildcard feature and clears the PPP bindings over interface pp0.100 and pp0.200.

```
user@host> clear dhcp server binding pp0.*
```

To clear all bindings on an FPC. This example uses the wildcard feature and clears all DHCP bindings on FPC 1.

```
user@host> clear dhcp server binding ge-1/*
```

To clear all bindings on a PIC. This example uses the wildcard feature and clears all DHCP bindings on FPC 1, PIC 0.

```
user@host> clear dhcp server binding ge-1/0/*
```

To clear all bindings on a port. This example uses the wildcard feature and clears all DHCP bindings on FPC 1, PIC 0, port 0.

```
user@host> clear dhcp server binding ge-1/0/0.*
```

---

## DHCP Liveness Detection Overview

Unlike PPP, DHCP does not define a native keepalive mechanism as part of either the DHCPv4 or DHCPv6 protocols. Without a keepalive mechanism, DHCP local server, DHCP relay, or DHCP relay proxy is unable to quickly detect if it has lost connectivity with a subscriber and must rely on standard DHCP subscriber session termination messages.

DHCP clients often do not send DHCP release messages prior to exiting the network. The discovery of their absence is dependent on existing DHCP lease time and release request mechanisms. These mechanisms are often considered insufficient when serving as session health checks for clients in a DHCP subscriber access network. Because DHCP lease times are typically too long to provide an adequate response time for a session health failure, and configuring short DHCP lease times can pose an undue burden on control plane processing, implementing a DHCP liveness detection mechanism enables better monitoring of bound DHCP clients. When configured with a liveness detection protocol, if a given subscriber fails to respond to a configured number of consecutive liveness detection requests, the subscriber binding is deleted and its resources released.

DHCP liveness detection for DHCP subscriber IP sessions utilizes an active liveness detection protocol to institute liveness detection checks for relevant clients. Clients must respond to liveness detection requests within a specified amount of time. If the responses are not received within that time for a given number of consecutive attempts, then the liveness detection check fails and a failure action is implemented.

Using DHCP liveness detection, IP sessions are acted upon as soon as liveness detection checks fail. This faster response time serves to:

- Provide more accurate time-based accounting of subscriber sessions.
- Better preserve router resources.
- Help to reduce the window of vulnerability to some security attacks.

Examples of liveness detection protocols include Bidirectional Forwarding Detection (BFD) for both DHCPv4 and DHCPv6 subscribers, IPv4 Address Resolution Protocol (ARP) for DHCPv4 subscribers, and IPv6 Neighbor Unreachability Detection for DHCPv6 subscribers.

**NOTE:** This release supports only BFD for DHCPv4 and DHCPv6 liveness detection.

When configuring BFD liveness detection, keep the following in mind:

- You can configure DHCPv4 and DHCPv6 liveness detection either globally or per DHCPv4 or DHCPv6 group.
- DHCPv4 or DHCPv6 subscriber access clients that do not support BFD are not affected by the liveness detection configuration. These clients can continue to access the network (once validated) even if BFD liveness detection is enabled on the router.
- When configured, DHCPv4 or DHCPv6 initiates liveness detection checks for relevant clients (that is, clients that support BFD) when those clients enter a bound state.
- After protocol-specific messages are initiated for a BFD client, they are periodically sent to the subscriber IP address of the client and responses to those liveness detection requests are expected within a configured amount of time.
- If liveness detection responses are not received from clients that support BFD within the configured amount of time for a configured number of consecutive attempts, the liveness detection check is deemed to have failed and a configured failure action is implemented.

**Related  
Documentation**

- [Configuring Detection of DHCP Local Server Client Connectivity on page 234](#)
- [Configuring Detection of DHCP Relay or DHCP Relay Proxy Client Connectivity on page 297](#)

## Configuring Detection of DHCP Relay or DHCP Relay Proxy Client Connectivity

Liveness detection for DHCP subscriber IP sessions utilizes an active liveness detection protocol to institute liveness detection checks for relevant clients. Clients must respond to liveness detection requests within a specified amount of time. If the responses are not received within that time for a given number of consecutive attempts, then the liveness detection check fails and a failure action is implemented.

**NOTE:** You can also configure DHCP liveness detection for DHCP local server.

To configure liveness detection for DHCP relay:

1. Specify that you want to configure liveness detection.

- For DHCP global configuration:

```
[edit forwarding-options dhcp-relay]  
user@host# edit liveness-detection
```

- For DHCP group configuration:

```
[edit forwarding-options dhcp-relay group group-name]  
user@host# edit liveness-detection
```

**NOTE:** Liveness detection is also supported for DHCPv6 configurations. To configure DHCPv6 liveness detection, include the **liveness-detection** statement, and any subsequent configuration statements, at the [edit forwarding-options dhcp-relay dhcpv6] or [edit forwarding-options dhcp-relay dhcpv6 group *group-name*] hierarchy level.

2. (Optional) Specify that you want to use DHCP relay proxy mode.

```
[edit forwarding-options dhcp-relay group group-name]  
user@host# set overrides proxy-mode
```

3. Specify that you want to configure the liveness detection method.

- For DHCP global configuration:

```
[edit forwarding-options dhcp-relay liveness-detection]  
user@host# edit method
```

- For DHCP group configuration:

```
[edit forwarding-options dhcp-relay group group-name liveness-detection]  
user@host# edit method
```

4. Specify the liveness detection method that you want DHCP to use.

**NOTE:** In this release, the only method supported for liveness detection is Bidirectional Forwarding Detection (BFD).

- For DHCP global configuration:

```
[edit forwarding-options dhcp-relay liveness-detection method]  
user@host# edit bfd
```

- For DHCP group configuration:

```
[edit forwarding-options dhcp-relay group group-name liveness-detection method]  
user@host# edit bfd
```

5. Configure the liveness detection method as desired.

See [“Example: Configuring Global Liveness Detection for DHCP Relay Agent Clients” on page 337](#) for an example of how to globally configure DHCP relay liveness detection.

6. Configure the action the router takes when a liveness detection failure occurs.

- For DHCP global configuration:

```
[edit forwarding-options dhcp-relay liveness-detection]
user@host# edit failure-action action
```

- For DHCP group configuration:

```
[edit forwarding-options dhcp-relay group group-name liveness-detection]
user@host# edit failure-action action
```

## Disabling DHCP Relay

You can disable DHCP relay on all interfaces or a group of interfaces.

To disable DHCP relay agent:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Disable the DHCP relay agent.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set disable-relay
```

#### Related Documentation

## Disabling Automatic Binding of Stray DHCP Requests

DHCP requests that are received but have no entry in the database are known as stray requests. By default, DHCP relay, DHCP relay proxy, and DHCPv6 relay agent attempt to bind the requesting client by creating a database entry and forwarding the request to the DHCP server. If the server responds with an ACK, the client is bound and the ACK is forwarded to the client. If the server responds with a NAK, the database entry is deleted.

and the NAK is forwarded to the client. This behavior occurs regardless of whether authentication is configured.

You can override the default configuration at the global level, for a named group of interfaces, or for a specific interface within a named group. Overriding the default causes DHCP relay, DHCP relay proxy, and DHCPv6 relay agent to drop all stray requests instead of attempting to bind the clients.

**NOTE:** In Junos OS Release 10.4 and later, automatic binding of stray requests is enabled by default.

In Junos OS Release 10.3 and earlier releases, automatic binding of stray requests is disabled by default. In those releases, DHCP relay drops stray requests and forwards a NAK to the client when authentication is configured. Otherwise, DHCP relay attempts to bind the requesting client. In those releases, DHCP relay proxy always drops stray requests and forwards a NAK to the client, regardless of the authentication configuration.

- To disable automatic binding behavior, include the **no-bind-on-request** statement when you configure DHCP overrides at the global, group, or interface level.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set no-bind-on-request
```

- To override the default behavior for DHCPv6 relay agent, configure the override at the **[edit forwarding-options dhcp-relay dhcpv6]** hierarchy level.

```
[edit forwarding-options dhcp-relay dhcpv6 overrides]
user@host# set no-bind-on-request
```

The following two examples show a configuration that disables automatic binding of stray requests for a group of interfaces and a configuration that disables automatic binding on a specific interface.

To disable automatic binding of stray requests on a group of interfaces:

1. Specify the named group.

```
[edit forwarding-options dhcp-relay]
user@host# edit group boston
```

2. Specify that you want to configure overrides.

```
[edit forwarding-options dhcp-relay group boston]
user@host# edit overrides
```

3. Disable automatic binding for the group.

```
[edit forwarding-options dhcp-relay group boston overrides]
user@host# set no-bind-on-request
```

To disable automatic binding of stray requests on a specific interface:

1. Specify the named group of which the interface is a member.

```
[edit forwarding-options dhcp-relay]
user@host# edit group boston
```

2. Specify the interface on which you want to disable automatic binding.

```
[edit forwarding-options dhcp-relay group boston]
user@host# edit interface fe-1/0/1.2
```

3. Specify that you want to configure overrides.

```
[edit forwarding-options dhcp-relay group boston interface fe-1/0/1.2]
user@host# edit overrides
```

4. Disable automatic binding on the interface.

```
[edit forwarding-options dhcp-relay group boston interface fe-1/0/1.2 overrides]
user@host# set no-bind-on-request
```

## DHCP Options and Selective Traffic Processing Overview

Subscriber management enables you to provide selective traffic processing based on information that is provided in the DHCP and DHCPv6 options string included in the traffic. The selective traffic processing feature helps you manage multivendor networks by enabling the extended DHCP and DHCPv6 relay agent to compare option-specific strings received in DHCP client packets against a list of ASCII or hexadecimal strings that you configure on the router. Selective traffic processing allows you to identify traffic based on the option in the DHCP client packets, filter the traffic, and specify the action DHCP relay takes for the traffic. You can use DHCP options 60 and 77 and DHCPv6 options 15 and 16 to identify client traffic. You configure the action the router takes for the selected traffic, such as forwarding the traffic to a specific DHCP server, or dropping the traffic. DHCP relay agent selective traffic processing also allows you to specify a default action, which the router uses when no other action satisfies the configuration.

Using selective traffic processing is helpful in network environments where DHCP clients access services that are provided by multiple vendors and by multiple DHCP servers. For example, a DHCP client might gain Internet access from a particular DHCP server provided by one vendor, and access an IPTV service from a different DHCP server owned by a second vendor. Using the option-specific information in the DHCP client packets enables DHCP relay agent to differentiate between the two servers and to take the correct action for the subscriber.

You might also use selective processing to distinguish between services to different DHCP subscribers on the same interface. For example, a household might include two IP devices that obtain their IP addresses from the service provider's DHCP server. The service provider might want to bind one of the devices to the incoming interface, sharing that address with other households. At the same time the service provider might want the second device to have its own filter and CoS capabilities. For this second device, the service provider can use selective processing to create a dynamic IP demux interface.

You can configure selective processing support globally or for a named group of interfaces. You can also configure the support for the extended DHCP relay agent on a per logical system and per routing instance basis.

To configure selective processing, you specify the DHCP or DHCPv6 option attribute that identifies the traffic, the match criteria used to filter the traffic, and the action to perform with the filtered traffic.

You can use the following DHCP options to selectively process client traffic:

- DHCPv4 option 60 (Vendor Class Identifier)
- DHCPv4 option 77 (User Class Identifier)
- DHCPv6 option 15 (User Class Option)
- DHCPv6 option 16 (Vendor Class Option)

You can configure exact match or partial match criteria to filter client traffic, and specify either the **ascii** option (to define a nonempty ASCII string of 1 through 255 alphanumeric characters) or the **hexadecimal** option (to define a hexadecimal string of 1 through 255 hexadecimal characters [0 through 9, a through f, and A through F]).

**BEST PRACTICE:** Because of the format of DHCP option 77 and DHCPv6 option 16, we recommend you configure hexadecimal matching only with these two options instead of ASCII matching.

You can configure an unlimited number of match strings. If you configure a string as both exact match (**equals**) and a partial match (**starts-with**) criteria, the exact match takes precedence. Wildcard characters are not supported in exact match or partial match strings.

Use the following match criteria to filter client traffic:

- **equals**—Your specified string is an exact match to the option string in client traffic.
- **starts-with**—Your specified string is a subset of the option string in client traffic, starting with the left-most character. For example, your configuration of the string “test” is a subset of “test123” in the client’s option string, and matches the **starts-with** criteria.
- **default-action**—The option string in client traffic does not satisfy any match criteria, or no match criteria are configured.

**NOTE:** The **default-action** is optional. If the match criteria are not satisfied or not configured and there is no **default-action** configured, DHCP relay processes the traffic in the normal manner.

You can specify the following actions for the filtered client traffic:

- **drop**—Discard the traffic.
- **forward-only**—Forward the traffic, without creating a new subscriber session.

**NOTE:** When you use the **forward-only** action, the only configured **overrides** operation supported is the **trust-option-82** option. DHCP relay agent ignores all other **overrides** options that are configured.

- **local-server-group**—Forward the traffic to the specified group of DHCP local servers that provides the requested client service. This option is not supported for DHCPv6 relay agent.
- **relay-server-group**—Forward the traffic to the specified group of DHCP servers that provides the requested client service.

- [Example: Configuring DHCP and DHCPv6 Relay Agent Group-Level Selective Traffic Processing on page 333](#)

## Using DHCP Option Information to Selectively Process DHCP Client Traffic

The following procedure describes the steps you use to configure DHCP relay agent to selectively process client traffic—selective processing uses DHCP or DHCPv6 option information to identify, filter, and process client traffic. To configure DHCPv6 support you use the procedure at the **[edit forwarding-options dhcp-relay dhcpv6]** hierarchy level.

To configure DHCP relay agent to use option information to selectively process DHCP client traffic:

1. Specify that you want to configure DHCP relay agent support.

```
[edit forwarding-options]
user@host# edit dhcp-relay
```

2. Specify that you want to use the DHCP option feature to selectively process incoming DHCP traffic.

```
[edit forwarding-options dhcp-relay]
user@host# edit relay-option
```

3. Specify the DHCP or DHCPv6 option number DHCP relay uses to identify and process the client traffic. You can specify options 60 and 77 for DHCP relay agent, and options 15 and 16 for DHCPv6 relay agent.

```
[edit forwarding-options dhcp-relay relay-option]
user@host# set option-number option-number
```

For example, to identify traffic that has DHCP option 60 information:

```
[edit forwarding-options dhcp-relay relay-option]
user@host# set option-number 60
```

4. (Optional) Configure the default action that DHCP relay uses when the incoming client traffic does not satisfy any configured match or partial match criteria.

For example, to configure DHCP relay to drop traffic by default:

```
[edit forwarding-options dhcp-relay relay-option]
user@host# set default-action drop
```

5. (Optional) Configure an exact match condition that filters the client traffic and specifies the associated action for DHCP relay agent to take.

For example, to select traffic that has an option 60 (configured in the previous step) ASCII string of **video25**, and then forward that traffic to a named local server group:

```
[edit forwarding-options dhcp-relay relay-option]
user@host# set equals ascii video25 local-server-group servergroup-east-video
```

6. (Optional) Configure a partial match condition that filters the client traffic and specifies the associated action.

For example, to select traffic that has an option 60 hexadecimal string that starts with **766964656F** (left to right), and then forward that traffic without creating a new session:

```
[edit forwarding-options dhcp-relay relay-option]
user@host# edit starts-with hexadecimal 766964656F forward-only
```

## Enabling and Disabling Insertion of Option 82 Information

You can enable or disable support for the DHCP relay agent information option (option 82) in packets destined for a DHCP server. You can configure option 82 support globally or for a named group of interfaces.

To restore the default behavior (option 82 information is not inserted into DHCP packets), you use the **delete relay-option-82** statement.

To configure support for the DHCP relay agent information option 82, you use the **relay-option-82** statement.

The following sections describe the option 82 operations you can configure:

- [Configuring Agent Circuit ID Information on page 305](#)
- [Configuring an Option 82 Prefix on page 306](#)
- [Using a Textual Description in Option 82 on page 307](#)

## Configuring Agent Circuit ID Information

You use the **relay-option-82** statement to enable insertion of option 82 information in DHCP packets. You must also specify at least the **circuit-id** statement to include the Agent Circuit ID suboption (suboption 1) of the DHCP relay agent information option.

If you specify the **circuit-id** statement, the format of the Agent Circuit ID information for Fast Ethernet (**fe**) or Gigabit Ethernet (**ge**) interfaces is one of the following, depending on your network configuration:

- For Fast Ethernet or Gigabit Ethernet interfaces that do not use virtual local area networks (VLANs) or stacked VLANs (S-VLANs):

*(fe | ge)-fpc/pic/port*

- For Fast Ethernet or Gigabit Ethernet interfaces that use VLANs:

*(fe | ge)-fpc/pic/port:vlan-id*

- For Fast Ethernet or Gigabit Ethernet interfaces that use S-VLANs:

*(fe | ge)-fpc/pic/port:svlan-id-vlan-id*

To enable insertion of option 82 information:

1. Specify that you want to configure option 82 support.

```
[edit forwarding-options dhcp-relay]
user@host# edit relay-option-82
```

2. Specify insertion of the Agent Circuit ID suboption.

```
[edit forwarding-options dhcp-relay relay-option-82]
user@host# set circuit-id
```

## Configuring an Option 82 Prefix

You can include an optional prefix to the base option 82 information in DHCP packets destined for a DHCP server.

The prefix is separated from the option 82 Agent Circuit ID information by a colon (:), and can include any combination of the **host-name**, **logical-system-name**, and **routing-instance-name** options. The DHCP relay agent obtains the values for the **host-name**, **logical-system-name**, and **routing-instance-name** as follows:

- If you include the **host-name** option, the DHCP relay agent uses the hostname of the router configured with the **host-name** statement at the **[edit system]** hierarchy level.
- If you include the **logical-system-name** option, the DHCP relay agent uses the logical system name configured with the **logical-system** statement at the **[edit logical-system]** hierarchy level.
- If you include the **routing-instance-name** option, the DHCP relay agent uses the routing instance name configured with the **routing-instance** statement at the **[edit routing-instances]** hierarchy level or at the **[edit logical-system logical-system-name routing-instances]** hierarchy level.

If you include the hostname and either or both of the logical system name and the routing instance name in the prefix, the hostname is followed by a forward slash (/). If you include both the logical system name and the routing instance name in the prefix, these values are separated by a semicolon (;).

The following examples show several possible formats for the Agent Circuit ID information when you specify the **prefix** statement for Fast Ethernet (**fe**) or Gigabit Ethernet (**ge**) interfaces with S-VLANs.

- If you include only the hostname in the prefix for Fast Ethernet or Gigabit Ethernet interfaces with S-VLANs:

*hostname:(fe | ge)-fpc/pic/port:svlan-id-vlan-id*

- If you include only the logical system name in the prefix for Fast Ethernet or Gigabit Ethernet interfaces with S-VLANs:

*logical-system-name:(fe | ge)-fpc/pic/port:svlan-id-vlan-id*

- If you include only the routing instance name in the prefix for Fast Ethernet or Gigabit Ethernet interfaces with S-VLANs:

*routing-instance-name:(fe | ge)-fpc/pic/port:svlan-id-vlan-id*

- If you include both the hostname and the logical system name in the prefix for Fast Ethernet or Gigabit Ethernet interfaces with S-VLANs:

*host-name/logical-system-name:(fe | ge)-fpc/pic/port:svlan-id-vlan-id*

- If you include both the logical system name and the routing instance name in the prefix for Fast Ethernet or Gigabit Ethernet interfaces with S-VLANs:

*logical-system-name;routing-instance-name:(fe | ge)-fpc/pic/port:svlan-id-vlan-id*

- If you include the hostname, logical system name, and routing instance name in the prefix for Fast Ethernet or Gigabit Ethernet interfaces with S-VLANs:

```
host-name/logical-system-name;routing-instance-name:(fe |
ge)-fpc/pic/port:svlan-id-vlan-id
```

For Fast Ethernet or Gigabit Ethernet interfaces that use VLANs but not S-VLANs, only the **vlan-id** value appears in the Agent Circuit ID format. For Fast Ethernet or Gigabit Ethernet interfaces that do not use VLANs or S-VLANs, neither the **vlan-id** value nor the **svlan-id** value appears.

To configure an optional prefix with the option 82 information:

1. Specify that you want to configure option 82 support.

```
[edit forwarding-options dhcp-relay]
user@host# edit relay-option-82
```

2. Specify insertion of the Agent Circuit ID information.

```
[edit forwarding-options dhcp-relay relay-option-82]
user@host# edit circuit-id
```

3. Specify that the prefix is included in the option 82 information. In this example, the prefix includes the hostname and logical system name

```
[edit forwarding-options dhcp-relay relay-option-82 circuit-id]
user@host# set prefix host-name logical-system-name
```

## Using a Textual Description in Option 82

By default, when DHCP option 82 is inserted into client packets, the Agent Circuit ID suboption includes the interface identifier. You can optionally configure that the Agent Circuit ID suboption include the textual description that is configured for the interface instead of the interface identifier. You can use the textual description for either the logical interface or the device interface.

You can include the textual interface description in the Agent Circuit ID suboption for static interfaces. The textual description is configured using the **description** statement at the **[edit interfaces interface-name]** hierarchy level. If you specify that the textual description is used and no description is configured for the interface, DHCP relay defaults to using the interface identifier.

To configure the DHCP relay option 82 suboption to include the textual interface description:

1. Specify that you want to configure option 82 support.

```
[edit forwarding-options dhcp-relay]
user@host# edit relay-option-82
```

2. Specify insertion of the Agent Circuit ID information.

```
[edit forwarding-options dhcp-relay relay-option-82]
user@host# edit circuit-id
```

3. Specify that the textual description is included in the option 82 information. In this example, the option 82 information includes the description used for the device interface.

```
[edit forwarding-options dhcp-relay relay-option-82 circuit-id]
user@host# set use-interface-description device
```

---

## Configuring Server Groups

You can configure a named group of DHCP servers for use by the extended DHCP relay agent on the router.

You specify the name of the DHCP server group and the IP addresses of one or more DHCP servers that belong to this group. You can configure a maximum of five IP addresses per named server group.

To configure a named server group:

1. Specify the name of the server group.

```
[edit forwarding-options dhcp-relay]
user@host# set server-group myServerGroup
```

2. Add the IP addresses of the DHCP servers belonging to the group.

```
[edit forwarding-options dhcp-relay server-group myServerGroup]
user@host# set 192.168.100.50
user@host# set 192.168.100.75
```

**Related Documentation**

- [Extended DHCP Relay Agent Overview on page 258](#)

---

## Configuring Active Server Groups

You can configure an active server group. Using an active server group enables you to apply a common DHCP relay agent configuration to a named group of DHCP server addresses.

Use the statement at the **[edit ... dhcpv6]** hierarchy levels to configure DHCPv6 support.

To configure an active server group:

- Specify the name of the active server group.

```
[edit forwarding-options dhcp-relay]
user@host# set active-server-group myServerGroup
```

To create an active server group as a global DHCP relay agent configuration option, include the **active-server-group** statement at the **[edit forwarding-options dhcp-relay]** hierarchy level. To have the group apply only to a named group of interfaces, include the **active-server-group** statement at the **[edit forwarding-options dhcp-relay group group-name]** hierarchy level.

Including the **active-server-group** statement at the **[edit forwarding-options dhcp-relay group group-name]** hierarchy level (as a group-specific option) overrides the effect of including the **active-server-group** statement at the **[edit forwarding-options dhcp-relay]** hierarchy level as a global option.

- Related Documentation**
- [Extended DHCP Relay Agent Overview on page 258](#)
  - [Grouping Interfaces with Common DHCP Configurations on page 201](#)

## Enabling DHCP Relay Proxy Mode

You can enable DHCP relay proxy mode on all interfaces or a group of interfaces.

To enable DHCP relay proxy mode:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]
user@host# edit overrides
```

2. Enable DHCP relay proxy mode.

```
[edit forwarding-options dhcp-relay overrides]
user@host# set proxy-mode
```

- Related Documentation**
- [DHCP Relay Proxy Overview on page 261](#)
  - [Overriding the Default DHCP Relay Configuration Settings on page 273](#)

## Inserting DHCPv6 Interface-ID Option (Option 18) In DHCPv6 Packets

You can configure DHCPv6 relay agent to insert the DHCPv6 Interface-ID (Option 18) in the packets that the relay sends to a DHCPv6 server. You can optionally include a prefix, which can include any combination of hostname, logical system name, and routing instance name. You can also specify that the packets include the textual interface description instead of the interface identifier.

**NOTE:** If you configure the optional Steps 2 or 3, and the specified information does not exist (for example, there is no interface description), DHCPv6 relay ignores the optional configuration and inserts the interface identifier in the packets.

To insert the DHCPv6 Interface-ID option (Option 18) in DHCPv6 packets :

1. Configure the DHCPv6 relay to include Option 18.

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit relay-agent-interface-id
```

2. (Optional) Specify the prefix to include in Option 18.

```
[edit forwarding-options dhcp-relay dhcpv6 relay-agent-interface-id]
```

```
user@host# set prefix prefix
```

3. (Optional) Specify that the Option 18 include the textual description of the interface. You can specify either the **logical** interface description or the **device** interface description.

```
[edit forwarding-options dhcp-relay dhcpv6 relay-agent-interface-id]  
user@host# set use-interface-description (logical | device)
```

#### Related Documentation

## Attaching Dynamic Profiles to DHCP Subscriber Interfaces

This topic describes how to attach a dynamic profile to a DHCP subscriber interface. When a DHCP subscriber logs in, the specified dynamic profile is instantiated and the services defined in the profile are applied to the interface.

This topic contains the following sections:

- [Attaching a Dynamic Profile to All DHCP Subscriber Interfaces on page 310](#)
- [Attaching a Dynamic Profile to a Group of DHCP Subscriber Interfaces on page 311](#)

### Attaching a Dynamic Profile to All DHCP Subscriber Interfaces

To attach a dynamic profile to all DHCP subscriber interfaces:

1. At the DHCP configuration hierarchy, use the **dynamic-profile** statement to specify the name of the dynamic profile to attach to all interfaces.

- For DHCP local server:

```
[edit system services dhcp-local-server]  
user@host# set dynamic-profile vod-profile-22
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]  
user@host# set dynamic-profile vod-profile-west
```

2. Optionally, you can configure the attribute to use when attaching the specified profile.

You can include either the **aggregate-clients** option to enable multiple DHCP subscribers to share the same VLAN logical interface, or the **use-primary** option to specify that the primary dynamic profile is used. The **aggregate-clients** option does not apply to demux subscriber interfaces. The two options are mutually exclusive.

- To enable multiple subscribers to share the same VLAN logical interface:

```
[edit system services dhcp-local-server dynamic-profile]  
user@host# set aggregate-clients merge
```

- To use the primary dynamic profile:

```
[edit forwarding-options dhcp-relay dynamic-profile]  
user@host# set use-primary subscriber_profile
```

## Attaching a Dynamic Profile to a Group of DHCP Subscriber Interfaces

Before you begin:

- Configure the interface group.

See [“Grouping Interfaces with Common DHCP Configurations”](#) on page 201.

To attach a dynamic profile to a group of interfaces:

1. At the DHCP configuration hierarchy, specify the name of the interface group and the dynamic profile to attach to the group.

- For DHCP local server:

```
[edit system services dhcp-local-server]
user@host# set group boston dynamic-profile vod-profile-42
```

- For DHCP relay agent:

```
[edit forwarding-options dhcp-relay]
user@host# set group quebec dynamic-profile vod-profile-east
```

2. Optionally, you can configure the attribute to use when attaching the specified profile.

You can include either the **aggregate-clients** option to enable multiple DHCP subscribers to share the same VLAN logical interface, or the **use-primary** option to specify that the primary dynamic profile is used. The **aggregate-clients** option does not apply to demux subscriber interfaces. The two options are mutually exclusive.

- To enable multiple subscribers to share the same VLAN logical interface:

```
[edit system services dhcp-local-server dynamic-profile]
user@host# set aggregate-clients merge
```

- To use the primary dynamic profile:

```
[edit forwarding-options dhcp-relay dynamic-profile]
user@host# set use-primary subscriber_profile
```

## Tracing Extended DHCP Operations

Both the extended DHCP local server and the extended DHCP relay agent support tracing operations. DHCP tracing operations track extended DHCP operations and record them in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

You can configure DHCP trace operations at the global level and at the interface level. Global DHCP tracing logs all DHCP-related events, whereas interface-level tracing logs only interface-specific DHCP events. If you configure interface-level trace operations, you can specify tracing for a range of interfaces or an individual interface. However, only a single interface-level log file is supported. That is, you cannot specify different interface-level log files for different interfaces or groups of interfaces.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

- Important events for both global and per-interface tracing are logged in a file located in the **/var/log** directory. By default, the router uses the filename, **jdhcpd**. You can specify a different filename, but you cannot change the directory in which trace files are located.

- When the trace log file **filename** reaches 128 kilobytes (KB), it is compressed and renamed **filename.0.gz**. Subsequent events are logged in a new file called **filename**, until it reaches capacity again. At this point, **filename.0.gz** is renamed **filename.1.gz** and **filename** is compressed and renamed **filename.0.gz**. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)

- By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

To configure global DHCP tracing operations.

- Specify tracing operations for DHCP local server and DHCP relay:

```
[edit system processes dhcp-service]
user@host# edit traceoptions
```

The tracing configuration is applied globally to all DHCP applications in every LS:RI. Configuration of event tracing on a per-LS:RI basis is not supported. DHCP tracing is configurable only in the default LS:RI. However, DHCP applications (local server or relay) do not have to be configured in the default LS:RI. This behavior was different in software releases before Junos OS Release 11.4, where you had to configure a DHCP application in the default LS:RI in order to configure DHCP tracing, even when you wanted to run DHCP and trace its operations only in a nondefault LS:RI.

In the earlier software releases, you configured tracing statements at the **[edit system services dhcp-local-server]** and **[edit forwarding-options dhcp-relay]** hierarchy levels. These statements have been deprecated and hidden in favor of the statements at the **[edit system processes dhcp-service]** hierarchy level.

**NOTE:** The deprecated statements may be removed from a future release; we recommend that you transition to the new statements.

Because you can configure DHCP tracing at three different hierarchy levels (one new and recommended, two old and deprecated), the following rules apply to manage the interaction:

- When you configure a filename or any other options for the trace log file, the configuration at the **[edit system processes dhcp-service]** hierarchy level has the highest precedence, followed by the configuration at the **[edit system services dhcp-local-server]** hierarchy level, and finally with the lowest precedence, the configuration at the **[edit forwarding-options dhcp-relay]** hierarchy level.
- The flag configurations for multiple hierarchy levels are merged and applied to all trace log events.

- The deprecated statements do not support filtering the generation of DHCP trace log events by severity level. If you use these statements, trace logging operates with an implicit severity of **all**, regardless of the severity level configured at the **[edit system processes dhcp-service]** hierarchy level.

For information about configuring per-interface tracing options, see [“Tracing Extended DHCP Operations for Specific Interfaces” on page 243](#).

The extended DHCP traceoptions operations are described in the following sections:

- [Configuring the Extended DHCP Log Filename on page 314](#)
- [Configuring the Number and Size of Extended DHCP Log Files on page 314](#)
- [Configuring Access to the Extended DHCP Log File on page 315](#)
- [Configuring a Regular Expression for Extended DHCP Messages to Be Logged on page 316](#)
- [Configuring the Extended DHCP Tracing Flags on page 316](#)
- [Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged on page 316](#)
- [Tracing Extended DHCP Operations for Specific Interfaces on page 317](#)

## Configuring the Extended DHCP Log Filename

By default, the name of the file that records trace output is **jdhcpd**. You can specify a different name by including the **file** option. DHCP local server and DHCP relay agent both support the **file** option for the **traceoptions** statement and the **interface-traceoptions** statement.

To change the filename:

- Specify a filename for global tracing operations.

```
[edit system processes dhcp-service traceoptions]  
user@host# set file filename
```

- Specify a filename for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]  
user@host# set file filename
```

## Configuring the Number and Size of Extended DHCP Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format **.number.gz**. The newest archived file is **.0.gz** and the oldest archived file is **.(maximum number)-1.gz**. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, *filename*, reaches 2 MB, *filename* is compressed and renamed *filename.0.gz*, and a new file called *filename* is created. When the new *filename* reaches 2 MB, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until there are 20 trace files. Then the oldest file, *filename.19.gz*, is simply overwritten when the next oldest file, *filename.18.gz* is compressed and renamed to *filename.19.gz*.

DHCP local server and DHCP relay agent both support the **files** and **size** options for the **traceoptions** statement and the **interface-traceoptions** statement. To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set file filename files number size maximum-file-size
```

- Specify the name, number, and size of the file used for the trace output for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set file filename files number size maximum-file-size
```

## Configuring Access to the Extended DHCP Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

DHCP local server and DHCP relay agent both support the **world-readable** option and the **no-world-readable** option for the **traceoptions** statement and the **interface-traceoptions** statement. To specify that all users can read the log file:

- Configure the log file to be world-readable for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set file filename world-readable
```

- Configure the log file to be world-readable for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set file filename world-readable
```

To explicitly set the default behavior, in which the log file can only be read by the user who configured tracing:

- Configure the log file to be no-world-readable for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set file filename no-world-readable
```

- Configure the log file to be no-world-readable for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set file filename no-world-readable
```

## Configuring a Regular Expression for Extended DHCP Messages to Be Logged

By default, the trace operation output includes all messages relevant to the logged events. You can refine the output by including regular expressions to be matched.

DHCP local server and DHCP relay agent both support the **match** option for the **traceoptions** statement and the **interface-traceoptions** statement. To configure regular expressions to be matched:

- Specify the regular expression for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set file filename match regular-expression
```

- Specify the regular expression for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set file filename match regular-expression
```

## Configuring the Extended DHCP Tracing Flags

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

DHCP local server and DHCP relay agent both support the **flag** option for the **traceoptions** statement and the **interface-traceoptions** statement. A smaller set of flags is supported for interface-level tracing than for global tracing. To configure the flags for the events to be logged:

- Specify the flags for global tracing operations.

```
[edit system processes dhcp-service traceoptions]
user@host# set flag flag
```

- Specify the flags for per-interface tracing operations.

```
[edit system processes dhcp-service interface-traceoptions]
user@host# set flag flag
```

## Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged

The messages associated with a logged event are categorized according to severity level. You can use the severity level to determine which messages are logged for the event type. A low severity level is less restrictive—filters out fewer messages—than a higher level. When you configure a severity level, all messages at that level and all higher (more restrictive) levels are logged.

The following list presents severity levels in order from lowest (least restrictive) to highest (most restrictive). This order also represents the significance of the messages; for example, **error** messages are of greater concern than **info** messages.

- verbose**
- info**

- **notice**
- **warning**
- **error**

The severity level that you configure depends on the issue that you are trying to resolve. In some cases you might be interested in seeing all messages relevant to the logged event, so you specify **all**. You can also specify **verbose** with the same result, because **verbose** is the lowest (least restrictive) severity level; it has nothing to do with the terseness or verbosity of the messages. Either choice generates a large amount of output. You can specify a more restrictive severity level, such as **notice** or **info** to filter the messages. By default, the trace operation output includes only messages with a severity level of **error**.

DHCP local server and DHCP relay agent both support the **level** option for the **traceoptions** statement and the **interface-traceoptions** statement. To configure the flags for the events to be logged:

- Specify the severity level for global tracing operations.  
[edit system processes dhcp-service **traceoptions**]  
user@host# **set level severity**
- Specify the severity level for per-interface tracing operations.  
[edit system processes dhcp-service **interface-traceoptions**]  
user@host# **set level severity**

## Tracing Extended DHCP Operations for Specific Interfaces

In addition to the global DHCP tracing operations, subscriber management enables you to trace extended DHCP operations for a specific interface or for a range of interfaces.

Configuring per-interface tracing is a two-step procedure. In the first step, you specify the tracing options that you want to use, such as file information and flags. In the second step, you enable the tracing operation on the specific interfaces.

To configure per-interface tracing operations:

1. Specify the tracing options you want to use.

**NOTE:** Per-interface tracing uses the same default tracing behavior as the global extended DHCP tracing operation. The default behavior is described in [“Tracing Extended DHCP Operations” on page 238](#).

- a. Specify that you want to configure per-interface tracing options.

- For DHCP local server, DHCPv6 local server, DHCP relay agent, and DHCPv6 relay agent:

```
[edit system processes dhcp-service]
user@host# edit interface-traceoptions
```

- b. (Optional) Specify the tracing file options.

- Configure the name for the file used for the trace output.

See [“Configuring the Extended DHCP Log Filename” on page 239](#).

- Configure the number and size of the log files.

See [“Configuring the Number and Size of Extended DHCP Log Files” on page 240](#).

- Configure access to the log file.

See [“Configuring Access to the Extended DHCP Log File” on page 240](#).

- Configure a regular expression to filter logging events.

See [“Configuring a Regular Expression for Extended DHCP Messages to Be Logged” on page 241](#).

- c. (Optional) Specify tracing flag options.

See [“Configuring the Extended DHCP Tracing Flags” on page 241](#).

- d. (Optional) Configure a severity level for messages to specify which event messages are logged.

See [“Configuring the Severity Level to Filter Which Extended DHCP Messages Are Logged” on page 242](#).

2. Enable tracing on an interface or interface range.

The following examples show a DHCP local server configuration. You can also use the **trace** statement at the **[edit forwarding-options dhcp-relay]** hierarchy level and at the **[edit system services dhcp-local-server dhcpv6]** hierarchy level.

- Enable tracing on a specific interface.

```
[edit system services dhcp-local-server]
user@host# set group group-name interface interface-name trace
```

- Enable tracing on a range of interfaces.

```
[edit system services dhcp-local-server]
user@host# set group group-name interface interface-name upto interface
interface-name trace
```

## Disabling DHCP Relay

---

You can disable DHCP relay on all interfaces or a group of interfaces.

To disable DHCP relay agent:

1. Specify that you want to configure override options.

```
[edit forwarding-options dhcp-relay]  
user@host# edit overrides
```

2. Disable the DHCP relay agent.

```
[edit forwarding-options dhcp-relay overrides]  
user@host# set disable-relay
```

- [Example: Configuring Global Liveness Detection for DHCP Relay Agent Clients on page 337](#)

### Example: Minimum DHCP Relay Agent Configuration

---

This example shows the minimum configuration you need to use the extended DHCP relay agent on the router:

```
[edit forwarding-options]
dhcp-relay {
  server-group {
    test 10.0.2.1;
  }
  active-server-group test;
  group all {
    interface fe-0/0/2.0;
  }
}
```

This example creates a server group and an active server group named **test** with IP address 10.0.2.1. The DHCP relay agent configuration is applied to a group named **all**. Within this group, the DHCP relay agent is enabled on interface fe-0/0/2.0.

#### Related Documentation

- [Extended DHCP Relay Agent Overview on page 258](#)

## Example: DHCP Relay Agent Configuration with Multiple Clients and Servers

---

This example shows an extended DHCP relay agent configuration for a network that includes multiple DHCP clients and DHCP servers. Additional details follow the example.

```
[edit forwarding-options]
dhcp-relay {
  server-group {
    sp-1 {
      10.0.2.1;
      10.0.2.2;
    }
    sp-2 {
      10.33.2.1;
      10.33.2.2;
      10.33.2.3;
    }
  }
  active-server-group sp-1;
  overrides layer2-unicast-replies;
  group clients_a {
    relay-option-82 circuit-id;
    interface fe-1/0/1.1;
    interface fe-1/0/1.2;
    interface fe-1/0/1.3;
  }
  group clients_b {
    relay-option-82 {
      circuit-id {
        prefix routing-instance-name;
      }
    }
    interface fe-1/0/1.4;
    interface fe-1/0/1.5;
    interface fe-1/0/1.6;
  }
  group eth_dslam_relay {
    active-server-group sp-2;
    overrides {
      trust-option-82;
      layer2-unicast-replies;
    }
    interface fe-1/0/1.7;
    interface fe-1/0/1.8;
    interface fe-1/0/1.9;
  }
}
```

This example creates two server-groups: **sp-1**, which includes DHCP server addresses 10.0.2.1 and 10.0.2.2, and **sp-2**, which includes DHCP server addresses 10.33.2.1, 10.33.2.2, and 10.33.2.3. The active server group to which the DHCP relay agent configuration applies is **sp-1**. A global override is set that causes the DHCP relay agent to use Layer 2 unicast transmission to send DHCP reply packets from the DHCP server to DHCP clients during the discovery process.

The example also creates three groups of subscribers and their associated Fast Ethernet interfaces: **clients\_a**, **clients\_b**, and **eth\_dslam\_relay**. These groups are configured to meet different needs, as follows:

- The **clients\_a** and **clients\_b** groups consist of basic subscribers. The service provider for these groups inserts option 82 information in the DHCP packets that are destined for the DHCP server.
- The subscribers in **eth\_dslam\_relay** are connected to an Ethernet digital subscriber line access multiplexer (DSLAM) that functions as a Layer 2 DHCP relay agent. The active server group for **eth\_dslam\_relay** is **sp-2**. Overrides are set for the **eth\_dslam\_relay** group that enable the DHCP relay agent to trust option 82 information and to use Layer 2 unicast transmission to send DHCP reply packets to DHCP clients during discovery.

#### Related Documentation

- [Extended DHCP Relay Agent Overview on page 258](#)

## Example: Configuring DHCP Snooping Support for DHCP Relay Agent

This example shows how to configure DHCP snooping support for DHCP relay agent.

- [Requirements on page 323](#)
- [Overview on page 323](#)
- [Configuration on page 323](#)

### Requirements

- Configure DHCP relay agent. See “[Extended DHCP Relay Agent Overview](#)” on page 258.

### Overview

In this example, you configure DHCP snooping support for DHCP relay agent by completing the following operations:

- Override the default DHCP snooping configuration and enable DHCP snooping support for the interfaces in group **frankfurt**.
- Configure DHCP relay agent to forward snooped packets to only configured interfaces.

**NOTE:** By default, DHCP snooping is enabled globally in Junos OS Release 10.0 and earlier and disabled globally in Junos OS Release 10.1 and later.

### Configuration

#### Step-by-Step Procedure

To configure DHCP relay support for DHCP snooping:

1. Specify that you want to configure DHCP relay agent.

[edit]

user@host# edit forwarding-options **dhcp-relay**

2. Specify the named group of interfaces on which DHCP snooping is supported.  

```
[edit forwarding-options dhcp-relay]
user@host# edit group frankfurt
```
3. Specify the interfaces that you want to include in the group. DHCP relay agent considers these as the configured interfaces when determining whether to forward or drop traffic.  

```
[edit forwarding-options dhcp-relay group frankfurt]
user@host# set interface fe-1/0/1.3 upto fe-1/0/1.9
```
4. Specify that you want to override the default configuration for the group.  

```
[edit forwarding-options dhcp-relay group frankfurt]
user@host# edit overrides
```
5. Enable DHCP snooping support for the group.  

```
[edit forwarding-options dhcp-relay group frankfurt overrides]
user@host# set allow-snooped-clients
```
6. Return to the `[edit forwarding-options dhcp-relay]` hierarchy level to configure the forwarding action and specify that DHCP relay agent forward snooped packets on only configured interfaces:  

```
[edit forwarding-options dhcp-relay group frankfurt overrides]
user@host# up 2
```
7. Enable DHCP snooped packet forwarding for DHCP relay agent.  

```
[edit forwarding-options dhcp-relay]
user@host# edit forward-snooped-clients
```
8. Specify that snooped packets are forwarded on only configured interfaces (the interfaces in group `frankfurt`).  

```
[edit forwarding-options dhcp-relay forward-snooped-clients]
user@host# set configured-interfaces
```

**Results** From configuration mode, confirm your configuration by entering the **show forwarding-options** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it. The following output also shows a range of configured interfaces in group `frankfurt`.

```
[edit]
regress@montag# show forwarding-options
dhcp-relay {
  forward-snooped-clients configured-interfaces;
  group frankfurt {
    overrides {
      allow-snooped-clients;
    }
    interface fe-1/0/1.3 {
      upto fe-1/0/1.9;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

- [DHCP Snooping Support on page 279](#)
  - [Configuring DHCP Snooping for DHCP Relay Agent on page 280](#)

## Example: Enabling DHCP Snooping Support for DHCPv6 Relay Agent

Snooping support for DHCPv6 relay agent is disabled on the router by default. This example shows how to override the default DHCPv6 relay agent snooping configuration to explicitly enable DHCPv6 snooping for a named group of interfaces and for a specific interface within a different named group.

**NOTE:** You can also enable DHCPv6 snooping support globally by using the `allow-snooped-clients` statement at the `[edit forwarding-options dhcp-relay dhcpv6 overrides]` hierarchy level.

- [Requirements on page 325](#)
- [Overview on page 325](#)
- [Configuration on page 326](#)
- [Verification on page 328](#)

### Requirements

This example uses the following hardware and software components:

- MX Series 3D Universal Edge Routers
- Junos OS Release 12.1

Before you begin:

- Configure DHCPv6 relay agent.  
See [“DHCPv6 Relay Agent Overview” on page 260](#)
- Configure named DHCPv6 relay agent interface groups to which you want to apply a common DHCP configuration.  
See [“Grouping Interfaces with Common DHCP Configurations” on page 201](#)

### Overview

In this example, you override the default DHCPv6 relay agent snooping configuration to explicitly enable DHCP snooping for both of the following:

- All of the interfaces in the group named **boston**
- Interface **ge-3/2/1.1** in the group named **sunnyvale**

## Configuration

To override the default DHCPv6 relay agent snooping configuration to explicitly enable DHCPv6 snooping for a named group of interfaces and for a specific interface within a named group, perform these tasks:

- [Enabling DHCPv6 Snooping Support for a Named Group of Interfaces on page 326](#)
- [Enabling DHCPv6 Snooping Support for a Specific Interface in a Named Group on page 327](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set forwarding-options dhcp-relay dhcpv6 group boston overrides allow-snooped-clients
set forwarding-options dhcp-relay dhcpv6 group sunnyvale interface ge-3/2/1.1 overrides
allow-snooped-clients
```

---

### Enabling DHCPv6 Snooping Support for a Named Group of Interfaces

---

### Step-by-Step Procedure

To enable DHCPv6 snooping support for a named group of interfaces:

1. Specify that you want to configure DHCPv6 relay agent.  

```
[edit]
user@host# edit forwarding-options dhcp-relay dhcpv6
```
2. Specify the named group of interfaces for which you want to enable DHCPv6 snooping.  

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit group boston
```
3. Specify that you want to override the default DHCPv6 configuration for the interfaces in that group.  

```
[edit forwarding-options dhcp-relay dhcpv6 group boston]
user@host# edit overrides
```
4. Enable DHCPv6 snooping support for all interfaces in group **boston**.  

```
[edit forwarding-options dhcp-relay dhcpv6 group boston overrides]
user@host# set allow-snooped-clients
```

### Results

From configuration mode, confirm the results of your configuration by issuing the **show** statement at the **[edit forwarding-options dhcp-relay]** hierarchy level. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit forwarding-options dhcp-relay]
user@host# show
dhcpv6 {
  group boston {
    overrides {
```

```

        allow-snooped-clients;
    }
}

```

If you are done configuring the router, enter **commit** from configuration mode.

### Enabling DHCPv6 Snooping Support for a Specific Interface in a Named Group

- Step-by-Step Procedure** To enable DHCPv6 snooping support for a specific interface within a named group of interfaces:
- Return to the **[edit forwarding-options dhcp-relay dhcpv6]** hierarchy level to specify that you want to configure DHCPv6 relay agent.
 

```
[edit forwarding-options dhcp-relay dhcpv6 group boston overrides]
user@host# up 2
```
  - Specify the named group containing the interface.
 

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit group sunnyvale
```
  - Specify the interface in group **sunnyvale** for which you want to enable DHCPv6 snooping.
 

```
[edit forwarding-options dhcp-relay dhcpv6 group sunnyvale]
user@host# edit interface ge-3/2/1.1
```
  - Specify that you want to override the default DHCPv6 configuration for interface **ge-3/2/1.1** in group **sunnyvale**.
 

```
[edit forwarding-options dhcp-relay dhcpv6 group sunnyvale interface ge-3/2/1.1]
user@host# edit overrides
```
  - Enable DHCPv6 snooping support for interface **ge-3/2/1.1** in group **sunnyvale**.
 

```
[edit forwarding-options dhcp-relay dhcpv6 group sunnyvale interface ge-3/2/1.1
overrides]
user@host# set allow-snooped-clients
```
- Results** From configuration mode, confirm the results of your configuration by issuing the **show** statement at the **[edit forwarding-options dhcp-relay]** hierarchy level. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit forwarding-options dhcp-relay]
user@host# show
dhcpv6 {
  group boston {
    overrides {
      allow-snooped-clients;
    }
  }
  group sunnyvale {
    interface ge-3/2/1.1 {
      overrides {
        allow-snooped-clients;
      }
    }
  }
}

```

```
    }  
  }  
}
```

If you are done configuring the router, enter **commit** from configuration mode.

## Verification

To verify the DHCPv6 configuration in a multi-relay topology, perform this task:

- [Verifying the Address Bindings for DHCPv6 Relay Agent Clients on page 328](#)

### Verifying the Address Bindings for DHCPv6 Relay Agent Clients

**Purpose** Verify the DHCPv6 address bindings in the Dynamic Host Configuration Protocol (DHCP) client table.

**Action** Display detailed information about address bindings for DHCPv6 relay agent clients.

```
user@host > show dhcpv6 relay binding detail
```

```
Session Id: 13  
  Client IPv6 Prefix: 3000:0:0:8001::5/128  
  Client DUID: LL0x1-00:00:65:03:01:02  
  State: BOUND(DHCPV6_RELAY_STATE_BOUND)  
  Lease Expires: 2011-11-21 06:14:50 PST  
  Lease Expires in: 293 seconds  
  Lease Start: 2011-11-21 06:09:50 PST  
  Incoming Client Interface: ge-3/2/1.1  
  Server Address: unknown  
  Next Hop Server Facing Relay: 4000::2  
  Server Interface: none  
  Client Id Length: 10  
  Client Id: /0x00030001/0x00006503/0x0102
```

**Meaning** The **Server Address** field in the **show dhcpv6 relay binding detail** command output typically displays the IP address of the DHCPv6 server. In this example, the value **unknown** in the **Server Address** field indicates that this is a multi-relay topology in which the DHCPv6 relay agent is not directly adjacent to the DHCPv6 server, and does not detect the IP address of the server.

In that case, the output instead includes the **Next Hop Server Facing Relay** field, which displays the next-hop address in the direction of the DHCPv6 server.

- Related Documentation**
- [DHCPv6 Relay Agent Overview on page 260](#)
  - [DHCP Snooping Support on page 279](#)

  - [Enabling and Disabling DHCP Snooped Packets Support for DHCP Relay Agent on page 281](#)

---

## Example: Configuring DHCP Relay Agent Selective Traffic Processing Based on DHCP Option Strings

---

This example shows how to configure DHCP relay agent to use DHCP option strings to selectively identify, filter, and process client traffic.

- [Requirements on page 329](#)
- [Overview on page 329](#)
- [Configuration on page 330](#)
- [Verification on page 331](#)

### Requirements

This example uses the following hardware and software components:

- MX Series 3D Universal Edge Routers
- Junos OS Release 12.3 or later.

Before you configure DHCP relay agent selective processing support, be sure you:

- Configure DHCP relay agent.

See [“Extended DHCP Relay Agent Overview” on page 258](#).

- (Optional) Configure a named DHCP local server group if you want to forward client traffic to a server group.

See [“Grouping Interfaces with Common DHCP Configurations” on page 201](#).

### Overview

In this example, you configure DHCP relay agent to use DHCP option strings in client packets to selectively identify, filter, and process client traffic. To configure selective processing, you perform the following procedures:

1. Identify the client traffic—Specify the DHCP option that DHCP relay agent uses to identify the client traffic you want to process. The option you specify matches the option in the client traffic.
2. Configure a default action—Specify the default processing action, which DHCP relay uses for identified client traffic that does not satisfy any configured match criteria.
3. Create match filters and associate an action with each filter—Specify match criteria that filter the client traffic. The criteria can be an exact match or a partial match with the option string in the client traffic. Associate a processing action with each match criterion.

## Configuration

To configure DHCP relay agent selective processing based on DHCP option information, perform these tasks:

- [Configuring DHCP Relay Agent To Selectively Process Client Traffic Based on DHCP Option Strings on page 330](#)
- [Results on page 331](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the command into the CLI at the **[edit]** hierarchy level.

```
set forwarding-options dhcp-relay relay-option option-number 60
set forwarding-options dhcp-relay relay-option equals ascii video-gold forward-only
set forwarding-options dhcp-relay relay-option equals ascii video-bronze local-server-group
  servergroup-15
set forwarding-options dhcp-relay relay-option starts-with hexadecimal ffff
  local-server-group servergroup-east
set forwarding-options dhcp-relay relay-option default-action drop
```

---

### Configuring DHCP Relay Agent To Selectively Process Client Traffic Based on DHCP Option Strings

---

### Step-by-Step Procedure

To configure DHCP relay selective processing:

1. Specify that you want to configure DHCP relay agent support.  

```
[edit forwarding-options]
user@host# edit dhcp-relay
```
2. Specify the DHCP option that DHCP relay agent uses to identify incoming client traffic.  

```
[edit forwarding-options dhcp-relay]
user@host# set relay-option option-number 60
```
3. Configure a default action, which DHCP relay agent uses when the incoming client traffic does not satisfy any configured match criteria.  

```
[edit forwarding-options dhcp-relay]
user@host# set relay-option default-action drop
```
4. Configure an exact match condition and associated action that DHCP relay uses to process the identified client traffic.  

```
[edit forwarding-options dhcp-relay]
user@host# set relay-option equals ascii video-gold forward-only
```
5. Configure a second exact match condition and associated action that DHCP relay uses to process client traffic.  

```
[edit forwarding-options dhcp-relay]
user@host# set relay-option equals ascii video-bronze local-server-group
  servergroup-15
```

6. Configure a partial match criteria and associated action that DHCP relay uses to process client traffic.

```
[edit forwarding-options dhcp-relay]
user@host# set relay-option starts-with hexadecimal ffff local-server-group
servergroup-east
```

## Results

From configuration mode, confirm the results of your configuration by issuing the **show** statement at the **[edit forwarding-options]** hierarchy level. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit forwarding-options]
user@host# show
dhcp-relay {
  relay-option {
    option-number 60;
    equals {
      ascii video-gold {
        forward-only;
      }
    }
    equals {
      ascii video-bronze {
        local-server-group servergroup-15;
      }
    }
    default-action {
      drop;
    }
    starts-with {
      hexadecimal ffff {
        local-server-group servergroup-east;
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To verify the status of DHCP relay agent selective traffic processing, perform this task:

- [Verifying the Status of DHCP Relay Agent Selective Traffic Processing on page 331](#)

### Verifying the Status of DHCP Relay Agent Selective Traffic Processing

**Purpose** Verify the DHCP relay agent selective traffic processing status.

**Action** Display statistics for DHCP relay agent.

```
user@host> show dhcp relay statistics
Packets dropped:
  Total                30
  Bad hardware address  1
  Bad opcode            1
  Bad options           3
  Invalid server address 5
  No available addresses 1
  No interface match    2
  No routing instance match 9
  No valid local address 4
  Packet too short      2
  Read error            1
  Send error            1
  Option 60             1
  Option 82             2

Messages received:
  BOOTREQUEST          116
  DHCPDECLINE           0
  DHCPDISCOVER         11
  DHCPINFORM           0
  DHCPRELEASE          0
  DHCPREQUEST         105

Messages sent:
  BOOTREPLY            0
  DHCPOFFER            2
  DHCPACK              1
  DHCPNAK              0
  DHCPFORCERENEW       0

Packets forwarded:
  Total                4
  BOOTREQUEST          2
  BOOTREPLY            2
```

**Meaning** The **Packets forwarded** field in the **show dhcp relay statistics** command output displays the number of client packets that have been forwarded as a result of the selective traffic processing configuration. In this example, the output indicates the total number of packets that DHCP relay agent has forwarded, as well as a breakdown for the number of **BOOTREQUEST** and **BOOTREPLY** packets forwarded.

  - [Displaying a Count of DHCP Packets That Are Dropped or Forwarded During Selective Processing That Is Based on DHCP Option Strings on page 304](#)
  - [Example: Configuring DHCP and DHCPv6 Relay Agent Group-Level Selective Traffic Processing on page 333](#)

## Example: Configuring DHCP and DHCPv6 Relay Agent Group-Level Selective Traffic Processing

This example shows how to configure named interface group-based support for DHCPv6 relay agent selective processing, which uses DHCP option strings to identify, filter, and process client traffic.

This example describes DHCPv6 relay agent configuration—you can configure the related procedure for DHCP relay agent groups at the **[edit forwarding-options dhcp-relay]** hierarchy level. DHCPv6 selective processing supports DHCPv6 options 15 and 16. DHCP selective processing supports option 60 (MX Series routers only) and option 77.

- [Requirements on page 333](#)
- [Overview on page 333](#)
- [Configuration on page 334](#)
- [Verification on page 336](#)

### Requirements

This example uses the following hardware and software components:

- MX Series 3D Universal Edge Routers or PTX Series Packet Transport Switches
- Junos OS Release 12.3 or later.

Before you configure DHCPv6 relay agent selective processing support, be sure you:

- Configure DHCPv6 relay agent.

See [“Extended DHCP Relay Agent Overview” on page 258](#) and [“DHCPv6 Relay Agent Overview” on page 260](#).

- Configure the DHCPv6 named interface groups used for the configuration.

See [“Grouping Interfaces with Common DHCP Configurations” on page 201](#).

- Configure the DHCPv6 server groups used for the processing actions.

See [“Grouping Interfaces with Common DHCP Configurations” on page 201](#).

### Overview

In this example, you configure group-level DHCPv6 relay agent named interface support for selective processing of client packets based on DHCPv6 option strings. To configure selective processing, you perform the following procedures:

1. Identify the client traffic—Specify the DHCPv6 option that DHCPv6 relay agent uses to identify the client traffic you want to process. The DHCPv6 option you specify matches the option in the client traffic.
2. Configure the default action—Specify the default processing action, which DHCPv6 relay uses for identified client traffic that does not satisfy any configured match criteria.

3. Create match filters and associate an action with each filter—Specify match criteria that filters the client traffic. The criteria can be an exact match or a partial match with the DHCPv6 option string in the client traffic. Associate a processing action with each match criteria.

## Configuration

To configure group-level DHCPv6 relay agent selective processing based on DHCPv6 option information, perform these tasks:

- [Configuring a DHCPv6 Relay Agent Named Interface Group To Selectively Process Client Traffic Based on DHCPv6 Option Strings on page 334](#)
- [Results on page 335](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the command into the CLI at the **[edit]** hierarchy level. The quick configuration assumes that the named interface group and the DHCP server groups have been previously configured.

```
set forwarding-options dhcp-relay dhcpv6 group groupv6-east-27
set forwarding-options dhcp-relay dhcpv6 relay-option option-number 15
set forwarding-options dhcp-relay dhcpv6 relay-option equals ascii triple-gold
  relay-server-group relayserver-triple-8
set forwarding-options dhcp-relay dhcpv6 relay-option equals ascii triple-silver
  relay-server-group relayserver-triple-23
set forwarding-options dhcp-relay dhcpv6 relay-option starts-with ascii single
  relay-server-group relayserver-1-aa
set forwarding-options dhcp-relay dhcpv6 relay-option default-action drop
```

### Configuring a DHCPv6 Relay Agent Named Interface Group To Selectively Process Client Traffic Based on DHCPv6 Option Strings

---

### Step-by-Step Procedure

This procedure assumes that you have previously created the named interface group and the DHCPv6 server groups. To configure DHCPv6 relay group-level selective processing:

1. Specify that you want to configure DHCPv6 relay agent support.  

```
[edit forwarding-options]
user@host# edit dhcp-relay dhcpv6
```
2. Specify that you want to configure group-level DHCPv6 relay agent support.  

```
[edit forwarding-options dhcp-relay dhcpv6]
user@host# edit group groupv6-east-27
```
3. Specify the DHCPv6 option number that DHCPv6 relay agent uses to identify incoming client traffic.  

```
[edit forwarding-options dhcp-relay dhcpv6 group groupv6-east-27]
user@host# set relay-option option-number 15
```
4. Configure the default action, which DHCPv6 relay agent uses when the incoming client traffic does not satisfy any configured match criteria.

```
[edit forwarding-options dhcp-relay dhcpv6 group groupv6-east-27]
user@host# set relay-option default-action relay-server-group relayserver-def-4
```

5. Configure an exact match condition and associated action that DHCPv6 relay uses to process the identified client traffic.

```
[edit forwarding-options dhcp-relay dhcpv6 group groupv6-east-27]
user@host# set relay-option equals ascii triple-gold relay-server-group
relayserver-triple-8
```

6. Configure a second exact match condition and associated action that DHCPv6 relay uses to process client traffic.

```
[edit forwarding-options dhcp-relay dhcpv6 group groupv6-east-27]
user@host# set relay-option equals ascii triple-silver relay-server-group
relayserver-triple-23
```

7. Configure a partial match criteria and associated action that DHCPv6 relay uses to process client traffic.

```
[edit forwarding-options dhcp-relay dhcpv6 group groupv6-east-27]
user@host# set relay-option starts-with ascii single relay-server-group
relayserver-1-aa
```

## Results

From configuration mode, confirm the results of your configuration by issuing the **show** statement at the **[edit forwarding-options dhcp]** hierarchy level. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
dhcpv6 {
  group test-1 {
    relay-option {
      option-number 15;
      equals {
        ascii triple-gold {
          relay-server-group relayserver-triple-8;
        }
        ascii triple-silver {
          relay-server-group relayserver-triple-23;
        }
      }
      default-action {
        relay-server-group relayserver-def-4;
      }
      starts-with {
        ascii single {
          relay-server-group relayserver-1-aa;
        }
      }
    }
  }
  interface ge-1/0/0.0 upto ge-1/1/0.0;
}
server-group {
  relayserver-1-aa;
  relayserver-triple-8;
```

```
        relayserver-triple-23;  
        relayserver-def-4;  
    }  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To verify the status of DHCPv6 relay agent selective traffic processing, perform this task:

- [Verifying the Status of DHCPv6 Relay Agent Selective Traffic Processing on page 336](#)

### Verifying the Status of DHCPv6 Relay Agent Selective Traffic Processing

**Purpose** Verify the DHCPv6 relay agent selective traffic processing status.

**Action** Display statistics for DHCPv6 relay agent.

```
user@host> show dhcpv6 relay statistics
```

```
DHCPv6 Packets dropped:  
Total 0
```

```
Messages received:  
DHCPV6_DECLINE 0  
DHCPV6_SOLICIT 10  
DHCPV6_INFORMATION_REQUEST 0  
DHCPV6_RELEASE 0  
DHCPV6_REQUEST 10  
DHCPV6_CONFIRM 0  
DHCPV6_RENEW 0  
DHCPV6_REBIND 0  
DHCPV6_RELAY_REPL 0
```

```
Messages sent:  
DHCPV6_ADVERTISE 0  
DHCPV6_REPLY 0  
DHCPV6_RECONFIGURE 0  
DHCPV6_RELAY_FORW 0
```

```
Packets forwarded:  
Total 4  
FWD REQUEST 2  
FWD REPLY 2
```

**Meaning** The **Packets forwarded** field in the **show dhcpv6 relay statistics** command output displays the number of client packets that have been forwarded as a result of the selective traffic processing configuration. In this example, the output indicates the total number of packets that DHCPv6 relay agent has forwarded, as well as a breakdown for the number of **FWD REQUEST** and **FWD REPLY** packets forwarded.

## Example: Configuring Global Liveness Detection for DHCP Relay Agent Clients

This example shows how to configure liveness detection for DHCP relay agent subscribers using Bidirectional Forwarding Detection (BFD) as the liveness detection method.

- [Requirements on page 337](#)
- [Overview on page 337](#)
- [Configuration on page 338](#)

### Requirements

- Juniper Networks MX Series routers.
- Junos OS Release 12.1R1 or later.
- Configure DHCP relay agent. See “[Extended DHCP Relay Agent Overview](#)” on page 258.

### Overview

In this example, you configure liveness detection for DHCP relay agent subscribers by completing the following operations:

1. Enable liveness detection globally for DHCP relay subscribers.
2. Specify BFD as the liveness detection method for all dynamically created DHCP relay subscribers.
3. Configure BFD-specific statements to define how the protocol behaves.
4. Configure the action the router takes when a liveness detection failure occurs.

**NOTE:** This example explains how to configure liveness detection for a DHCPv4 network. Liveness detection is also supported for DHCPv6 configurations. To configure DHCPv6 liveness detection, include the [liveness-detection](#) statement, and any subsequent configuration statements, at the [edit forwarding-options dhcp-relay dhcpv6] or [edit forwarding-options dhcp-relay dhcpv6 group *group-name*] hierarchy level.

## Configuration

### Step-by-Step Procedure

To configure liveness detection for DHCP relay:

1. Specify that you want to configure liveness detection.  

```
[edit forwarding-options dhcp-relay]  
user@host# edit liveness-detection
```
2. Specify that you want to configure the liveness detection method.  

```
[edit forwarding-options dhcp-relay liveness-detection]  
user@host# edit method
```
3. Specify BFD as the liveness detection method that you want DHCP to use.  

```
[edit forwarding-options dhcp-relay liveness-detection method]  
user@host# edit bfd
```
4. Configure the detection time threshold (in milliseconds) at which a trap is produced.  

```
[edit forwarding-options dhcp-relay liveness-detection method bfd]  
user@host# set detection-time threshold 50000
```
5. Configure the time (in milliseconds) for which BFD holds a session up notification.  

```
[edit forwarding-options dhcp-relay liveness-detection method bfd]  
user@host# set holddown-interval 50
```
6. Configure the BFD minimum transmit and receive interval (in milliseconds).  

```
[edit forwarding-options dhcp-relay liveness-detection method bfd]  
user@host# set minimum-interval 45000
```
7. Configure the minimum receive interval (in milliseconds).  

```
[edit forwarding-options dhcp-relay liveness-detection method bfd]  
user@host# set minimum-receive-interval 60000
```
8. Configure a multiplier value for the detection time.  

```
[edit forwarding-options dhcp-relay liveness-detection method bfd]  
user@host# set multiplier 100
```
9. Disable the ability for BFD interval timers to change or adapt to network situations.  

```
[edit forwarding-options dhcp-relay liveness-detection method bfd]  
user@host# set no-adaptation
```
10. Configure the BFD session mode.  

```
[edit forwarding-options dhcp-relay liveness-detection method bfd]  
user@host# set session-mode automatic
```
11. Configure the threshold and minimum interval for the BFD transmit interval.  

```
[edit forwarding-options dhcp-relay liveness-detection method bfd]  
user@host# set transmit-interval threshold 60000 minimum-interval 45000
```
12. Configure the BFD protocol version you want to detect.  

```
[edit forwarding-options dhcp-relay liveness-detection method bfd]  
user@host# set version automatic
```

13. Configure the action the router takes when a liveness detection failure occurs. In this example, the failure action is to clear the client session only when a liveness detection failure occurs and the local interface is detected as being up.

```
[edit forwarding-options dhcp-relay liveness-detection]
user@host# edit failure-action action
```

**Results** From configuration mode, confirm your configuration by entering the **show forwarding-options** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it. The following output also shows a range of configured interfaces in group frankfurt.

```
[edit]
regress@montag# show forwarding-options
dhcp-relay {
  liveness-detection {
    failure-action clear-binding-if-interface-up;
    method {
      bfd {
        version automatic;
        minimum-interval 45000;
        minimum-receive-interval 60000;
        multiplier 100;
        no-adaptation;
        transmit-interval {
          minimum-interval 45000;
          threshold 60000;
        }
        detection-time {
          threshold 50000;
        }
        session-mode automatic;
        holddown-interval 50;
      }
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Dynamic Profiles for PPP Subscriber Interfaces Overview

---

Subscriber management PPP support enables you to create and attach dynamic profiles for PPP subscriber interfaces. When the PPP subscriber logs in, the router instantiates the specified dynamic profile and then applies the attributes defined in the profile to the interface.

Dynamic profiles are used for both static and dynamic PPP interfaces. For static PPP interfaces, you use the CLI to attach dynamic profiles, which specify PPP options. For dynamic PPP interfaces, the dynamic profile creates the interface, including the PPP options.

**NOTE:** Dynamically created interfaces are supported only on PPPoE interfaces.

Unlike traditional PPP support, subscriber management does not allow bi-directional PPP authentication—authentication is performed only by the router, never by the remote peer. The router's AAA process manages authentication and address assignment for subscriber management. When you configure PPP options for a dynamic profile, you can configure either Challenge Handshake Authentication Protocol (CHAP) or Password Authentication Protocol (PAP) authentication, and you can control the order in which the router negotiates the CHAP and PAP protocols. In addition, for CHAP authentication, you can modify the default length of the CHAP challenge message. Other PPP options, which are either commonly used or mandatory for a traditional PPP interface configuration, are not supported in subscriber management dynamic profiles.

## Configuring Dynamic Authentication for PPP Subscribers

---

You can configure a dynamic profile that includes PPP authentication that enables PPP clients to dynamically access the network. You can specify either CHAP or PAP authentication. Optionally, you can also control the order in which the router negotiates the CHAP and PAP protocols.

For dynamic interfaces, the router supports unidirectional authentication only—the router always functions as the authenticator. When you configure PPP authentication in a dynamic profile, CHAP authentication supports the **challenge-length** option, which enables you to configure the minimum length and maximum length of the CHAP challenge message. Neither CHAP authentication nor PAP authentication supports any other configuration options, including the **passive** statement.

**NOTE:** Dynamic profiles for PPP subscribers are supported only on PPPoE interfaces.

To configure authentication in a dynamic profile for PPP subscriber interfaces:

1. Name the dynamic profile.

[edit]

user@host# edit **dynamic-profiles vod-profile-25**

2. Configure the interfaces and unit for the dynamic profile. Use **pp0** for the interface type and the Junos predefined variable for the unit.

[edit dynamic-profiles vod-profile-25]

```
user@host# edit interfaces pp0 unit $junos-interface-unit
```

3. Configure PPP options.

```
[edit dynamic-profiles vod-profile-25 interfaces pp0 unit "$junos-interface-unit"]
```

```
user@host# edit ppp-options
```

4. Specify the authentication protocol used in the dynamic profile. You can configure either CHAP or PAP. There are no additional options for either authentication protocol.

```
[edit dynamic-profiles vod-profile-25 interfaces pp0 unit "$junos-interface-unit"  
  ppp-options]
```

```
user@host# set chap
```

5. (Optional) Configure the minimum length and maximum length of the CHAP challenge message.

See [“Modifying the CHAP Challenge Length” on page 349](#).

6. (Optional) Configure the order in which the router negotiates the CHAP and PAP authentication protocols.

See [“Controlling the Negotiation Order of PPP Authentication Protocols” on page 347](#).

## Controlling the Negotiation Order of PPP Authentication Protocols

You can control the order in which the router tries to negotiate PPP authentication protocols when it verifies that a PPP client can access the network. By default, the router first tries to negotiate Challenge Handshake Authentication Protocol (CHAP) authentication. If the attempt to negotiate CHAP authentication is unsuccessful, the router then tries to negotiate Password Authentication Protocol (PAP) authentication.

You can modify this default negotiation order in any of the following ways:

- Specify that the router negotiate PAP authentication first, followed by CHAP authentication if PAP negotiation is unsuccessful.

When you specify both authentication protocols in either order, you must enclose the set of protocol names in square brackets ([ ]).

- Specify that the router negotiate only CHAP authentication.
- Specify that the router negotiate only PAP authentication.

Before you begin:

- Configure the CHAP or PAP protocol on the interface.
  - For dynamic PPP subscriber interfaces, see [“Configuring Dynamic Authentication for PPP Subscribers” on page 345](#).
  - For CHAP on static interfaces with PPP encapsulation, see [Configuring the PPP Challenge Handshake Authentication Protocol](#).
  - For PAP on static interfaces with PPP encapsulation, see [Configuring the PPP Password Authentication Protocol](#).

To control the order in which the router negotiates PPP authentication protocols:

1. Specify that you want to configure PPP options.
  - For dynamic PPP subscriber interfaces:
 

```
[edit dynamic-profiles profile-name interfaces pp0 unit "$junos-interface-unit"]
user@host# edit ppp-options
```
  - For static interfaces with PPP encapsulation:
 

```
[edit interfaces pp0 unit logical-unit-number]
user@host# edit ppp-options
```
2. Specify the negotiation order for PPP authentication protocols on the router.
  - For dynamic PPP subscriber interfaces:
 

```
[edit dynamic-profiles profile-name interfaces pp0 unit "$junos-interface-unit"
  ppp-options]
user@host# set authentication [authentication-protocols]
```
  - For static interfaces with PPP encapsulation:
 

```
[edit interfaces pp0 unit logical-unit-number ppp-options]
```

```
user@host# set authentication [authentication-protocols]
```

The following sample **authentication** statements in a dynamic profile named `pppoe-client-profile` show the different ways you can configure the negotiation order for PPP authentication protocols. (The **authentication** statements for configuring static interfaces are identical.)

- To specify that the router negotiate PAP authentication first, followed by CHAP authentication:

```
[edit dynamic-profiles pppoe-client-profile interfaces pp0 unit "$junos-interface-unit"
 ppp-options]
user@host# set authentication [pap chap]
```

- To specify that the router negotiate only CHAP authentication:

```
[edit dynamic-profiles pppoe-client-profile interfaces pp0 unit "$junos-interface-unit"
 ppp-options]
user@host# set authentication chap
```

- To specify that the router negotiate only PAP authentication:

```
[edit dynamic-profiles pppoe-client-profile interfaces pp0 unit "$junos-interface-unit"
 ppp-options]
user@host# set authentication pap
```

- To restore the default negotiation order for PPP authentication protocols after you have modified it:

```
[edit dynamic-profiles pppoe-client-profile interfaces pp0 unit "$junos-interface-unit"
 ppp-options]
user@host# set authentication [chap pap]
```

- [Configuring the PPP Password Authentication Protocol](#)

## Modifying the CHAP Challenge Length

You can modify the default minimum length and maximum length of the Challenge Handshake Authentication Protocol (CHAP) challenge message that the router sends to a PPP client. The CHAP challenge message, which contains information that is unique to a particular PPP subscriber session, is used as part of the authentication mechanism between the router and the client to verify the identity of the client for access to the router.

By default, the minimum length of the CHAP challenge is 16 bytes, and the maximum length is 32 bytes. You can override this default to configure the CHAP challenge minimum length and maximum length in the range 8 bytes through 63 bytes.

**BEST PRACTICE:** We recommend that you configure both the minimum length and the maximum length of the CHAP challenge to at least 16 bytes.

Before you begin:

- Configure the CHAP protocol on the interface.
  - For dynamic PPP subscriber interfaces, see [“Configuring Dynamic Authentication for PPP Subscribers” on page 345](#).
  - For static interfaces with PPP encapsulation, see [Configuring the PPP Challenge Handshake Authentication Protocol](#).

To configure the minimum and maximum length of the CHAP challenge message:

1. Specify that you want to configure PPP options.
  - For dynamic PPP subscriber interfaces:
 

```
[edit dynamic-profiles profile-name interfaces pp0 unit "$junos-interface-unit"]
user@host# edit ppp-options
```
  - For static interfaces with PPP encapsulation:
 

```
[edit interfaces pp0 unit logical-unit-number]
user@host# edit ppp-options
```
2. Specify that you want to configure CHAP options.
  - For dynamic PPP subscriber interfaces:
 

```
[edit dynamic-profiles profile-name interfaces pp0 unit "$junos-interface-unit"
  ppp-options]
user@host# edit chap
```
  - For static interfaces with PPP encapsulation:
 

```
[edit interfaces pp0 unit logical-unit-number ppp-options]
user@host# edit chap
```
3. Specify the minimum length and maximum length of the CHAP challenge.

- For dynamic PPP subscriber interfaces:

```
[edit dynamic-profiles profile-name interfaces pp0 unit "$junos-interface-unit"  
  ppp-options chap]  
user@host# set challenge-length minimum minimum-length maximum  
  maximum-length
```

- For static interfaces with PPP encapsulation:

```
[edit interfaces pp0 unit logical-unit-number ppp-options chap]  
user@host# set challenge-length minimum minimum-length maximum  
  maximum-length
```

For example, the following **challenge-length** statement in a dynamic profile named pppoe-client-profile sets the minimum length of the CHAP challenge to 20 bytes, and the maximum length to 40 bytes.

```
[edit dynamic-profiles pppoe-client-profile interfaces pp0 unit "$junos-interface-unit"  
  ppp-options chap]  
user@host# set challenge-length minimum 20 maximum 40
```

## Attaching Dynamic Profiles to Static PPP Subscriber Interfaces

---

You can attach a dynamic profile to a static PPP subscriber interface. When a PPP subscriber logs in, the specified dynamic profile is instantiated and the services defined in the profile are applied to the interface.

To attach a dynamic profile to a static PPP subscriber interface:

1. Specify that you want to configure PPP options.

```
[edit interfaces pp0 unit 0]  
user@host# edit ppp-options
```

2. Specify the dynamic profile you want to associate with the interface.

```
[edit interfaces pp0 unit 0 ppp-options]  
user@host# set dynamic-profile vod-profile-50
```

## Understanding How the Router Processes Subscriber-Initiated PPP Fast Keepalive Requests

---

On MX Series routers with Modular Port Concentrators/Modular Interface Cards (MPCs/MICs), the Packet Forwarding Engine on an MPC/MIC processes and responds to Link Control Protocol (LCP) Echo-Request packets that the PPP subscriber (client) initiates and sends to the router. LCP Echo-Request packets and LCP Echo-Reply packets are part of the PPP keepalive mechanism that helps determine whether a link is functioning properly.

Previously, LCP Echo-Request packets and LCP Echo-Reply packets were handled on an MX Series router by the Routing Engine. Support for the PPP fast keepalive feature enables the Packet Forwarding Engine on the MPC/MIC to receive LCP Echo-Request packets from the PPP subscriber and transmit LCP Echo-Reply packets in response, without having to send the LCP packets to the Routing Engine for processing. The mechanism by which LCP Echo-Request packets are processed by the Packet Forwarding Engine instead of by the Routing Engine is referred to as *PPP fast keepalive*.

Relieving the Routing Engine of having to process LCP Echo-Request packets provides increased bandwidth on the router to support a larger number of subscribers with improved performance.

- [How PPP Fast Keepalive Processing Works on page 351](#)
- [Statistics Display for PPP Fast Keepalive on page 352](#)
- [Effect of Changing the Forwarding Class Configuration on page 352](#)

### How PPP Fast Keepalive Processing Works

You do not need any special configuration on an MX Series router with MPCs/MICs to enable processing of PPP fast keepalive requests on the Packet Forwarding Engine. The feature is enabled by default, and cannot be disabled.

The following sequence describes how an MX Series router processes LCP Echo-Request packets and LCP Echo-Reply packets on the Packet Forwarding Engine on the MPC/MIC:

1. The Routing Engine notifies the Packet Forwarding Engine when transmission of keepalive requests is enabled on a PPP logical interface. The notification includes the magic numbers of both the server and the remote client.
2. The Packet Forwarding Engine receives the LCP Echo-Request packet initiated by the PPP subscriber (client).
3. The Packet Forwarding Engine validates the peer magic number in the LCP Echo-Request packet, and transmits the corresponding LCP Echo-Reply packet containing the magic number negotiated by the router.
4. If the Packet Forwarding Engine detects a loop condition in the link, it sends the LCP Echo-Request packet to the Routing Engine for further processing.

The Routing Engine continues to process LCP Echo-Request packets until the loop condition is cleared.

Transmission of keepalive requests from the Packet Forwarding Engine on the router is not currently enabled.

### Statistics Display for PPP Fast Keepalive

When an MX Series router with MPCs/MICs is using PPP fast keepalive for a PPP link, the **Keepalive statistics** field in the output of the **show interfaces pp0.logical statistics** operational command does not include statistics for the number of keepalive packets received or sent, or the amount of time since the router received or sent the last keepalive packet.

### Effect of Changing the Forwarding Class Configuration

To change the default queue assignment (forwarding class) for outbound traffic generated by the Routing Engine, you can include the **forwarding-class class-name** statement at the **[edit class-of-service host-outbound-traffic]** hierarchy level.

For PPP fast (inline) keepalive LCP Echo-Request and LCP Echo-Reply packets transmitted between an MX Series router with MPCs/MICs and a PPP client, changing the forwarding class configuration takes effect immediately for both new PPP-over-Ethernet (PPPoE), PPP-over-ATM (PPPoA), and L2TP network server (LNS) subscriber sessions created after the configuration change, and for existing PPPoE, PPPoA, and LNS subscriber sessions established before the configuration change.

# Configuring Subscriber Services for MLPPP Interfaces

- [Dynamic PPP Subscriber Services for Static MLPPP Interfaces on page 353](#)
- [Hardware Requirements for PPP Subscriber Services on Non-Ethernet Interfaces on page 354](#)
- [Configuring PPP Subscriber Services for MLPPP Bundles on page 354](#)
- [Enabling PPP Subscriber Services for Static Non-Ethernet Interfaces on page 355](#)
- [Attaching Dynamic Profiles to MLPPP Bundles on page 355](#)

## Dynamic PPP Subscriber Services for Static MLPPP Interfaces

---

Dynamic subscriber services are supported for MLPPP bundle interfaces, with certain interface and hardware restrictions. See [“Hardware Requirements for PPP Subscriber Services on Non-Ethernet Interfaces” on page 354](#). Multiclass MLPPP (MCML) enables the relative prioritization of up to eight classes of traffic over an MLPPP bundle, but only on link services intelligent queuing (IQ) (LSQ) interfaces.

RADIUS previously supported only authentication for MLPPP. Address management, service deactivation, and dynamic selection of subscriber properties based on RADIUS user ID are now also supported.

RADIUS can dynamically allocate IPv4 addresses for MLPPP connections. When the first subscriber logs in, an address is allocated. The same address is allocated to all links in a bundle. Any other address provided for any of the links is ignored. The IP address is released for re-allocation when the last member link in a bundle logs out. Similar to the address allocation, the services configured for the first subscriber to log in are configured for all subsequent subscribers in the bundle.

The Acct-Multi-Session-Id [50] attribute enables RADIUS to link multiple related sessions into a single log file. RADIUS uses the session database (SDB) bundle session ID for the value of Acct-Multi-Session-Id. This bundle ID enables RADIUS to initiate a disconnect for an entire bundle. By tracking the member link sessions, RADIUS is also able to disconnect the individual member links in a bundle.

The Acct-Link-Count [51] attribute records the number of links present in a multilink session at the time the accounting record is generated.

---

## Hardware Requirements for PPP Subscriber Services on Non-Ethernet Interfaces

PPP subscriber services are supported for MLPPP bundle interfaces. These services require the following hardware:

- M120 router or M320 router
- Channelized DS3/E3 Enhanced IP PIC (PB-4CHDS3-E3-IQE-BNC) to support MLPPP subscriber access
- An Adaptive Services PIC or Multiservices PIC to support subscriber services on LSQ MLPPP bundle interfaces

Subscriber services are not supported for single-link PPP interfaces with this hardware.

- Related Documentation**
- [Dynamic PPP Subscriber Services for Static MLPPP Interfaces on page 353](#)

---

## Configuring PPP Subscriber Services for MLPPP Bundles

You can configure PPP subscriber services for static LSQ MLPPP bundle interfaces.

To configure PPP subscriber services for static LSQ MLPPP bundle interfaces:

1. Enable PPP subscriber services for the interfaces.  
[See “Enabling PPP Subscriber Services for Static Non-Ethernet Interfaces” on page 355.](#)
2. Attach a dynamic profile to the MLPPP bundle interface.  
[See “Attaching Dynamic Profiles to MLPPP Bundles” on page 355.](#)

- Related Documentation**
- [Hardware Requirements for PPP Subscriber Services on Non-Ethernet Interfaces on page 354](#)
  - [Example: Minimum MLPPP Dynamic Profile on page 656](#)
  - [Example: Configuring CoS on Static LSQ MLPPP Bundle Interfaces on page 768](#)

## Enabling PPP Subscriber Services for Static Non-Ethernet Interfaces

You can enable PPP subscriber services for certain non-Ethernet interface types on particular associated PICs. Supported interfaces are listed in [“Hardware Requirements for PPP Subscriber Services on Non-Ethernet Interfaces” on page 354](#).

To enable PPP subscriber services on supported non-Ethernet interfaces:

- Configure PPP subscriber services.

```
[edit chassis]
user@host# set ppp-subscriber-services enable
```

To disable PPP subscriber services on supported non-Ethernet interfaces:

- Disable PPP subscriber services.

```
[edit chassis]
user@host# set ppp-subscriber-services disable
```

### Related Documentation

- For hardware requirements, see [Hardware Requirements for PPP Subscriber Services on Non-Ethernet Interfaces on page 354](#)
- [Configuring PPP Subscriber Services for MLPPP Bundles on page 354](#)

## Attaching Dynamic Profiles to MLPPP Bundles

You can attach a dynamic profile to a static MLPPP bundle interface. When a PPP subscriber logs in on a member link, the specified dynamic profile is instantiated and the services defined in the profile are applied to the LSQ bundle interface.

To attach a dynamic profile to a static LSQ MLPPP bundle interface:

1. Specify that you want to configure PPP options.

```
[edit interfaces lsq-3/3/0 unit 0]
user@host# edit ppp-options
```

2. Specify the dynamic profile you want to associate with the interface.

```
[edit interfaces lsq-3/3/0 unit 0 ppp-options]
user@host# set dynamic-profile vod-profile-50
```

## L2TP for Subscriber Access Overview

The Layer 2 Tunneling Protocol (L2TP) is a client-server protocol that allows the Point-to-Point Protocol (PPP) to be tunneled across a network. L2TP encapsulates Layer 2 packets, such as PPP, for transmission across a network. An L2TP access concentrator (LAC), configured on an access device, receives packets from a remote client and forwards them to an L2TP network server (LNS) on a remote network. The LNS functions as the logical termination point of the PPP session tunneled by the LAC from the remote client. [Figure 6 on page 359](#) shows a simple L2TP topology.

**Figure 6: Typical L2TP Topology**

L2TP separates the termination of access technologies, such as cable or xDSL, from the termination of PPP and subsequent access to a network. This separation enables public ISPs to outsource their access technologies to competitive local exchange carriers

(CLECs). L2TP provides ISPs the capability to supply VPN service; private enterprises can reduce or avoid investment in access technologies for remote workers.

You can configure your router to act as the LAC in PPP pass-through mode in which the LAC receives packets from a remote client and then forwards them at Layer 2 directly to the LNS. The PPP session is terminated on the LNS. This LAC implementation supports only Point-to-Point Protocol over Ethernet (PPPoE) subscribers over dynamic or static logical interfaces. [Figure 7 on page 360](#) shows the protocol layer stacking for an L2TP pass-through connection.

**Figure 7: Protocol Stacking for L2TP Subscribers in Pass-Through Mode**

**NOTE:** On MX Series routers, L2TP is supported only on MX240, MX480, and MX960 routers. It is not supported on MX80 routers.

On MX Series routers, the LAC and LNS functions are supported only on MPCs; they are not supported on any services PIC or MS-DPC. For details about MPC support for L2TP, see the [MX Series 3D Universal Edge Routers Line Card Guide](#)

Certain M Series routers support LNS functions on services PICs. For more information about the L2TP implementation on M Series routers, see the Junos Services Interfaces Configuration Release 12.3.

The LAC dynamically creates tunnels based on AAA authentication parameters and transmits L2TP packets to the LNS by means of the IP/User Datagram Protocol (UDP). Traffic travels in an L2TP *session*; a tunnel is an aggregation of one or more sessions. You can also provision a domain map that is used by AAA to determine whether to tunnel or terminate the PPPoE subscriber on the LAC. A one-to-one mapping exists between each PPP subscriber tunneled to the LNS and an L2TP session.

When the LNS is an MX Series router, a LAC-facing peer interface on an MPC provides an IP address for the exchange of IP packets between the tunnel endpoints; the Routing Engine maintains the L2TP tunnels. The Packet Forwarding Engine hosts one or more inline services (*si*) interfaces. These interfaces function like a virtual physical interface and *anchor* the L2TP sessions on the LNS. The *si* interface enables L2TP services without requiring a special services PIC. Finally, another interface is used to transmit the subscriber data to and from the Internet.

The characteristics of the tunnel can originate either from a tunnel profile that you configure or from RADIUS tunnel attributes and vendor-specific attributes (VSAs) from the AAA server accessible at the LAC. You can include a tunnel profile in a domain map,

which applies the tunnel profile before RADIUS authentication takes place. You can use RADIUS standard attributes and VSAs to override any or all characteristics configured by the tunnel profile in a domain map. Alternatively, RADIUS can itself apply a tunnel profile when the RADIUS Tunnel-Group VSA [26-64] is specified in the RADIUS login.

The Virtual-Router VSA [26-1] in the subscriber profile on the service provider AAA server (accessible from the LNS) determines the routing instance in which the L2TP session is brought up on the LNS. When this VSA is not present, the subscriber session comes up in the same routing instance as the tunnel, because the AAA server can be accessed only from the routing instance in which the tunnel terminates on the LNS.

This behavior is different than for DHCP and non-tunneled PPPoE subscribers, which come up in the default routing instance in the absence of the Virtual-Router VSA. For L2TP subscribers, you must include this VSA in the subscriber profile when you want the subscriber session to come up in a different routing instance than the tunnel routing instance.

The LAC supports RADIUS-initiated mirroring, which creates secure policies based on certain RADIUS VSAs, and uses RADIUS attributes to identify a subscriber whose traffic is to be mirrored. (This feature is not supported for an LNS configured on an MX Series router.)

The LAC supports unified ISSU. When an upgrade is initiated, the LAC completes any L2TP negotiations that are in progress but rejects any new negotiations until the upgrade has completed. No new tunnels or sessions are established during the upgrade. Subscriber logouts are recorded during the upgrade and are completed after the upgrade has completed. The LNS does not support unified ISSU. When LNS destinations exist, the LNS gracefully rejects the upgrade and the unified ISSU does not proceed.

## L2TP Terminology

Table 44 on page 361 describes the basic terms for L2TP.

**Table 44: L2TP Terms**

Term	Description
AVP	Attribute value pair (AVP)—Combination of a unique attribute—represented by an integer—and a value containing the actual value identified by the attribute.

Table 44: L2TP Terms (*continued*)

Term	Description
Call	A connection (or attempted connection) between a remote system and the LAC.
LAC	L2TP access concentrator (LAC)—A node that acts as one side of an L2TP tunnel endpoint and is a peer to the LNS. The LAC sits between an LNS and a remote system and forwards packets to and from each.
LNS	L2TP network server (LNS)—A node that acts as one side of an L2TP tunnel endpoint and is a peer to the LAC. The LNS is the logical termination point of a PPP connection that is being tunneled from the remote system by the LAC.
Peer	In the L2TP context, either the LAC or LNS. The LAC's peer is an LNS, and vice versa.
Proxy authentication	PPP pre-authentication performed by the LAC on behalf of the LNS. The proxy data is sent by the LAC to the LNS containing attributes such as authentication type, authentication name, and authentication challenge. The LNS responds with the authentication results.
Proxy LCP	Link Control Protocol (LCP) negotiation that is performed by the LAC on behalf of the LNS. The proxy is sent by the LAC to the LNS containing attributes such as the last configuration attributes sent and received from the client.
Remote system	An end system or router attached to a remote access network, which is either the initiator or recipient of a call.
Session	A logical connection created between the LAC and the LNS when an end-to-end PPP connection is established between a remote system and the LNS.  <b>NOTE:</b> There is a one-to-one relationship between established L2TP sessions and their associated PPP connections.
Tunnel	A connection between the LAC-LNS pair consisting of a control connection and 0 or more L2TP sessions.

**Related Documentation**

- [L2TP for Subscriber Access Overview on page 359](#)

## L2TP Implementation

L2TP is implemented on four levels:

- Source—The local router acting as the LAC.
- Destination—The remote router acting as the LNS.
- Tunnel—A direct path between the LAC and the LNS.
- Session—A PPP connection in a tunnel.

When the router has established destinations, tunnels, and sessions, you can control the L2TP traffic. Making a change to a destination affects all tunnels and sessions to that destination; making a change to a tunnel affects all sessions in that tunnel. For example, closing a destination closes all tunnels and sessions to that destination.

## Sequence of Events on the LAC

The router acting as the LAC creates destinations, tunnels, and sessions dynamically, as follows:

1. The client initiates a PPP connection with the router.
2. The router and the client exchange Link Control Protocol (LCP) packets. The LAC negotiates on behalf of the LNS; this is known as *proxy LCP*.
3. The LAC authenticates the client on behalf of the LNS; this is known as *proxy authentication*. By using either a local database related to the domain name or RADIUS authentication, the router determines either to terminate or to tunnel the PPP connection.
4. If the router discovers that it should tunnel the session, it does the following:
  - a. Sets up a new destination or selects an existing destination.
  - b. Sets up a new tunnel or selects an existing tunnel.

When a shared secret is configured in either the tunnel profile or the RADIUS attribute Tunnel-Password [69]—depending on which method is used to configure the tunnel—the secret is used to authenticate the tunnel during the establishment phase. The LAC includes the Challenge AVP in the SCCRP message sent to the LNS. The LNS returns the Challenge Response AVP in the SCCRP message. If the response from the LNS does not match the value expected by the LAC, then tunnel authentication fails and the tunnel is not established.

- c. Opens a new session.
5. The router forwards the results of the LCP negotiations and authentication to the LNS.

A PPP connection now exists between the client and the LNS.

**NOTE:** The router discards received packets if the size of the variable-length, optional offset pad field in the L2TP header is too large. The router always supports packets that have an offset pad field of up to 16 bytes, and may support larger offset pad fields, depending on other information in the header. This restriction is a possible, although unlikely, cause of excessive discarding of L2TP packets.

## Sequence of Events on the LNS

A router acting as an LNS might be set up as follows:

1. The LAC initiates a tunnel with the router acting as the LNS.
2. The LNS verifies that a tunnel with this LAC is valid: the destination is configured, the hostname and the tunnel password are correct.
3. The LNS completes the tunnel setup with the LAC.
4. The LAC sets up a session and initiates a session request to the LNS.
5. The LNS uses a static interface or creates a dynamic interface to anchor the PPP session.
6. If they are enabled and present, the LNS accepts the proxy LCP and the proxy authentication data and passes them to PPP.
7. PPP processes the proxy LCP, if it is present, and, if the proxy LCP is acceptable, places LCP on the LNS in opened state without renegotiation of LCP.
8. PPP processes the proxy authentication data, if it is present, and passes the data to AAA for verification. (If the data is not present, PPP requests the data from the peer.)

**NOTE:** When the proxy LCP is not present or not acceptable, the LNS negotiates LCP with the peer. When LCP renegotiation is enabled on the LNS, the LNS ignores any pre-negotiated LCP parameters and renegotiates both the LCP parameters and PPP authentication with the PPP client.

9. The LNS passes the authentication results to the peer.

---

## LAC Tunnel Selection Overview

L2TP enables you to specify:

- Up to 31 destinations for a domain.
- Up to eight levels of preference. Preference indicates the order in which the router attempts to connect to the destinations specified for a domain. Zero (0) is the highest level of preference.
- Up to 31 destinations for a single preference level.

When the LAC determines that a PPP session should be tunneled, it selects a tunnel from a set of tunnels associated with either the PPP user or the PPP user's domain. The router provides the following methods for selecting tunnels:

- Tunnel selection failover between preference levels (the default behavior)
- Tunnel selection failover within a preference level
- Maximum sessions per tunnel
- Weighted load balancing

### Tunnel Selection Failover Between Preference Levels

When a user tries to log in to a domain, in the default method, the router attempts to connect to a destination in that domain by means of the associated tunnel with the highest preference level. If more than one destination is considered reachable by a tunnel in the preference level, the router randomly selects a destination and attempts to contact it through its associated tunnel at that level. If the router is unsuccessful, it marks the destination as unreachable and does not try to connect to that destination for five minutes. The router then moves to the next lower preference level and repeats the process.

For example, suppose that there are three destinations for a domain and a tunnel has been defined for each destination: A, B, and C. All destinations are considered reachable, and the preference levels for the tunnels are assigned as follows:

- A at preference 0
- B at preference 1
- C at preference 2

When a PPP user tries to connect to the domain, the router initially attempts to reach a destination by a tunnel at preference level 0. In this example, that is destination A. If this connection attempt fails, the router excludes destination A for five minutes and goes to the next level (preference 1) to reach a destination for the domain. At level 1, it attempts to connect to destination B. If the second connection attempt also fails, the router excludes destination B in addition to the already excluded destination A. The router goes to the next level (preference 2), and attempts to connect to destination C, the only destination in the domain that is still available. If that attempt also fails, the router has attempted to connect to every tunnel available for the domain. When the exclusion period for destination A expires, the router can attempt again to connect to destination A, and so on.

Although the five-minute timer typically prevents an unreachable destination from being tried until the timer expires, the timer is ignored in some circumstances. For example, if all destinations at a preference level are marked as unreachable when a user tries to log in to a domain, the router chooses and attempts to connect to the destination that failed first and therefore has the shortest time remaining until the timer expires. The key is to understand that the router always chooses a single destination at each level of preference, even if all destinations have recently failed.

If more than one destination for the domain is present at a preference level, the router randomly selects among them. If the router fails to connect to a destination at all preference levels with destinations for the domain, it cycles back to the highest level that still has a destination not excluded by an attempt.

For example, suppose that again there are three destinations for a domain and a tunnel has been defined for each destination: A, B, and C. All destinations are considered reachable, but the tunnels are distributed among the preference levels as follows:

- A and B at preference 0
- C at preference 1

If a PPP user tries to connect to the domain, the router randomly selects between A and B at level 0. Suppose it selects B, but the connection attempt fails. The router excludes destination B for five minutes and goes to the next level (preference 1) to reach a destination for the domain. At level 1, it attempts to connect to destination C. If the second connection attempt also fails, the router excludes destination C in addition to the already excluded destination B. The router cycles back to preference level 0. If destination B is still excluded, it attempts to connect to destination A. If the exclusion period for destination B has expired, then the router once again randomly selects between A and B to attempt a connection.

### Tunnel Selection Failover Within a Preference Level

When tunnel selection failover within a preference level is configured, if the router tries to connect to a destination and is unsuccessful, it selects a new destination at the same preference level. If all destinations at a preference level are marked as unreachable, the router does not attempt to connect to a destination at that level. It drops to the next lower preference level to select a destination.

If all destinations at all preference levels are marked as unreachable, the router chooses the destination that failed first and tries to make a connection. If the connection fails, the router rejects the PPP user session without attempting to contact the remote router.

For example, suppose that there are four destinations for a domain and a tunnel has been defined for each destination: A, B, C, and D. All destinations are considered reachable, and the preference levels for the tunnels are assigned as follows:

- A and B at preference 0
- C and D at preference 1

When the router attempts to connect to the domain, suppose it randomly selects tunnel B from preference 0. If it fails to connect to the destination, the router excludes tunnel B for five minutes and attempts to connect to a destination with tunnel A. If this attempt also fails, the router drops to preference level 1. Then suppose the router randomly selects tunnel C. If it also fails to connect to a destination with tunnel C, the router excludes tunnel C for five minutes and attempts to connect with tunnel D. If this connection attempt fails, then the router attempts to use tunnel B again, the original selection. If that attempt fails, the user session is rejected.

## Tunnel Selection and Maximum Sessions per Tunnel

When the maximum number of sessions allowed per tunnel is configured, the router takes that setting into consideration during the tunnel selection process. The maximum number of sessions per tunnel can be configured through a RADIUS Tunnel-Max-Sessions VSA [26-64] or by including the **max-sessions** statement in a tunnel profile.

If a randomly selected tunnel has a current session count equal to its maximum session count, the router does not attempt to connect to a destination with that tunnel. Instead, it selects an alternate tunnel from the set of reachable tunnels at the same preference level. If no additional reachable tunnels exist at the current preference level, the router drops to the next lower preference level to make the selection. This process is consistent, regardless of which fail-over scheme is currently running on the router.

If the maximum number of sessions is not configured for a tunnel, then that tunnel has no upper limit on the number of sessions it can support. By default, the maximum sessions value is 0 (zero), which allows unlimited sessions in the tunnel.

## Tunnel Selection with Weighted Load Balancing

The maximum sessions value for a tunnel is used for weighted load balancing to select among multiple tunnels with the same preference level.

The weight of a tunnel is determined by the tunnel's maximum session limit and the maximum session limits of the other tunnels at the same preference level. The tunnel with the largest maximum session value has the largest weight. The tunnel with the next largest maximum session value has the next largest weight, and so on. The tunnel with the smallest maximum session value has the smallest weight.

## L2TP Failover and Peer Resynchronization

L2TP failover enables a failed L2TP endpoint to resynchronize with its nonfailed peer during recovery and restart of the L2TP protocol on the failed endpoint. L2TP failover is enabled by default.

The failover and L2TP peer resynchronization process does all of the following:

- Prevents the nonfailed endpoint from prematurely terminating a tunnel while the failed endpoint is recovering.
- Reestablishes the sequence numbers required for the operation of the L2TP control protocol.
- Resolves inconsistencies in the tunnel and session databases of the failed endpoint and the nonfailed endpoint.

The router supports both the L2TP failover protocol method (described in *RFC 4951, Fail Over Extensions for Layer 2 Tunneling Protocol (L2TP) "failover"*) and the L2TP silent failover method. The differences between these two methods are as follows:

- With the L2TP failover protocol method, both endpoints must support the method or recovery always fails. The L2TP failover protocol method also requires a nonfailed endpoint to wait an additional recovery time period while the failed endpoint is recovering to prevent the nonfailed endpoint from prematurely disconnecting the tunnel. The additional recovery period delays the detection of tunnel keepalive failures.
- Silent failover operates entirely within the failed endpoint and does not require nonfailed endpoint support—this improves interoperability between peers. Silent failover does not require additional recovery time by the nonfailed endpoint, which also eliminates the potential for degraded responsiveness to the loss of tunnel connectivity.

The default resynchronization method in Junos OS is *failover-protocol-fall-back-to-silent-failover*. The recovery method used depends on the results of the failover capability negotiation that takes place between L2TP peers when they establish a tunnel, which works as follows:

- L2TP on the LAC by default attempts to negotiate the L2TP failover protocol first. When L2TP determines that the remote peer supports the L2TP failover protocol, then the L2TP failover protocol method is used.
- When L2TP determines that the remote peer does not support the L2TP failover protocol, then the L2TP silent failover method is used. Falling back on this secondary method prevents the failover from forcing a disconnection of the tunnel to the peer and all its sessions.

You can change the default behavior by including the [disable-failover-protocol](#) statement at the **[edit services l2tp]** hierarchy level. This statement forces the LAC to operate only in silent failover mode. This configuration can be useful when routers that act as the LNS either are configured for silent failover or incorrectly negotiate use of the failover protocol even though they do not support it. However, when you issue this statement and the LNS supports only failover protocol, then the LAC cannot negotiate failover protocol, and recovery (failover protocol recovery initiated by the LNS) always fails.

- [L2TP for Subscriber Access Overview on page 359](#)

## L2TP and Graceful Routing Engine Switchover

Graceful Routing Engine switchover (GRES) is supported on MX Series routers acting as either the L2TP LAC or LNS. In the event that L2TP (the l2tp-universal-edge process) restarts or that the router fails over from the active routing engine (RE) to the standby RE, L2TP graceful Routing Engine switchover ensures that the following occurs:

- The LAC and the LNS recover destinations, tunnels, and sessions that were already established at the time of the failure or restart.
- The LAC and the LNS respond to tunnel keepalive requests received during the switchover for established tunnels, but do not generate any keepalives until the switchover is complete.
- The LAC and the LNS delete all the tunnels and sessions that are not in the Established state.
- The LAC and the LNS reject requests to create new tunnels and sessions.
- The LAC and the LNS send another disconnect notification to the peer for sessions and tunnels that are already in the Disconnecting state at the time of the failure or restart. For sessions and tunnels that were coming up at that time, the LAC and LNS send a disconnect notification to the peer.
- The LAC and the LNS restart timers for the full timeout period for recovered L2TP destinations, tunnels, and sessions.

**NOTE:** Graceful Routing Engine switchover is supported only by L2TP LAC and LNS on MX Series routers. It is not supported by L2TP LNS on M Series routers.

## IP Packet Fragment Reassembly for L2TP Overview

You can configure the service interfaces on the MX Series routers with modular port concentrators (MPCs) to support reassemble fragmented IP packets for an L2TP connection. When packets are transmitted over an L2TP connection, the packets may be fragmented during transmission and need to be reassembled before they are processed further. Efficient reassembly is important for network throughput, scalability, and graceful response to congestion.

Fragmentation of IP packets for transmission and the need to reassemble the IP packets at a destination is a feature of how Layer 2 (the frame layer) and Layer 3 (the packet layer) operate. The maximum size of a frame, set by the Maximum Transmission Unit (MTU) value, and the maximum size of a packet are determined independently. Typically the packet size can far exceed the MTU size defined for the outgoing connection. If the

packet size (data plus IP and other headers) exceeds the configured frame size (usually set by the transport medium limits), the packet must be fragmented and split across multiple frames for transmission. Frames are always processed immediately, when they arrive (if error-free), but packet fragments cannot be processed until the whole packet has been reassembled. Each packet fragment inside a frame series, except the last packet fragment, has the more fragments (MF) IP header bit set, indicating that this packet is part of a whole. The last packet fragment inside a frame does not have this MF bit set and therefore ends the fragment sequence. After all of the fragments of a packet have arrived, the entire packet can be reassembled.

In an L2TP connection, packets are transmitted between the L2TP Access Concentrator (LAC) and the L2TP Network Server (LNS). For an IP packet being transmitted over an L2TP connection, the packet is fragmented at the LAC, at an LNS, or at any intermediate router. IP reassembly parameters configured on the service interfaces of the LAC and the LNS determine how the fragments are reassembled at the service interfaces to ensure efficient reassembly over an L2TP connection.

## Transmission of Tx Connect-Speed and Rx Connect-Speed AVPs from LAC to LNS

---

An L2TP access concentrator (LAC) uses Incoming-Call-Connected (ICCN) messages to send the attribute-value pair (AVP) 24 (which represents the transmit connect speed) and the AVP 38 (which represents the receive connect speed) to the L2TP network server (LNS).

The value of speed in AVP 24 and AVP 38 is typically not greater than the value that is enforced by CoS on the LAC side of the network. Any difference between the speed reported in these AVPs and that enforced by CoS can occur because of differences between the CoS configuration (of the source that is used to enforce a downstream speed) and the transmit connect speed method used to establish these AVPs.

When you include the **tx-connect-speed-method** statement at the **[edit services l2tp]** hierarchy level, the transmit connect speed method selected for the downstream speed, AVP 24, also applies to the selection of the upstream speed, AVP 38. You can configure the transmit and receive connect speeds to be derived from Point-to-Point Protocol over Ethernet (PPPoE) intermediate agent tags that are sent from the digital subscriber line access multiplexer (DSLAM) to the LAC, the Access Node Control Protocol (ANCP) settings of the underlying interface, or the recommended (advisory) shaping rate. When the method you specify as ANCP, PPPoE intermediate agent tags (PPPoE IA tags), or advisory shaping rate does not support an upstream speed, the static or advisory speed is used.

A fallback method is adopted to derive the transmit and receive connect speed values when these values cannot be determined from any of the configured methods, such as

from the ANCP settings, the PPPoE IA tags, or the advisory shaping rate, or if the speed value is determined to be 0 from any of the configured methods.

If you configure the ANCP method to calculate the connect speed, the following sequence of events takes place:

1. The upstream and downstream connect speed values are derived from ANCP.
2. If the values cannot be derived from ANCP, the PPPoE IA tags are used to determine the values. If the PPPoE IA tags are present for either or both transmit and receive connect speeds, these values are used.
3. If the values cannot be derived from the PPPoE IA tags, the recommended (advisory) shaping rate configured on the PPPoE logical interface is used. If the advisory shaping rate is present for either or both transmit and receive connect speeds, these values are used.
4. If the values cannot be derived from the advisory shaping rate, the configured or default port speed is used for transmit and receive connect speeds.

If you configure the PPPoE IA tags method to calculate the connect speed, the following sequence of events takes place:

1. The upstream and downstream connect speed values are derived from PPPoE IA tags.
2. If the values cannot be derived from the PPPoE IA tags, the recommended (advisory) shaping rate configured on the PPPoE logical interface is used. If the advisory shaping rate is present for either or both transmit and receive connect speeds, these values are used.
3. If the values cannot be derived from the advisory shaping rate, the configured or default port speed is used for transmit and receive connect speeds.

If you configure the static or advisory downstream shaping rate method to calculate the connect speed, the following sequence of events takes place:

1. The upstream and downstream connect speed values are derived from the advisory shaping rate.
2. If the values cannot be derived from the advisory shaping rate, the default port speed is used for transmit and receive connect speeds.

The transmit connect speed, AVP 24, is set in the ICCN messages on the basis of the method for determining the transmit connect speed configured using the **tx-connect-speed-method** statement at the **[edit services l2tp]** hierarchy level. You can configure the method for determining the transmit connect speed in the following order of precedence:

1. **ancp**—The speed is derived from the configured ANCP value for the underlying interface. You can change this speed after a subscriber has logged in, but those changes do not affect the actual speed used by the LNS.

2. **pppoe-ia-tags**—PPPoE IA tags sent from the DSLAM to the LAC. This speed value is transmitted when a subscriber logs in and it cannot be subsequently changed. This value is used when the **ancp** value is not available. This speed does not apply to the subscribers that are already logged in; it is effective only for subscribers that log in after this setting has been saved.
3. **static**—The speed is derived from the recommended (advisory) shaping rate configured on the PPPoE logical interface underlying the subscriber interface. If the advisory shaping rate is not configured on the underlying interface, then the actual port speed is used.

If you do not configure the transmit connect speed using the CLI interface, and if the advisory speed is also not available, then the actual port speed is used. For ge and xe interfaces, the speed value is set to 10,000,000 and for ae interfaces, the speed value is set to 0 and sent in both AVP 24 and AVP 38.

## Configuring an L2TP LAC

---

To configure an L2TP LAC:

1. Configure a tunnel profile to apply to subscribers.  
[See “Configuring a Tunnel Profile for Subscriber Access” on page 375.](#)
2. (Optional) Configure the method used for selecting among multiple tunnels.
  - [See “Configuring the L2TP LAC Tunnel Selection Parameters” on page 377.](#)
  - [See “Configuring Weighted Load Balancing for LAC Tunnel Sessions” on page 378.](#)
  - [See “Configuring LAC Tunnel Selection Failover Within a Preference Level” on page 377.](#)
3. (Optional) Configure the LAC to not send Calling Number AVP 22 to the LNS.  
[See “Preventing the LAC from Sending Calling Number AVP 22 to the LNS” on page 379.](#)
4. (Optional) Specify the method for setting the transmit and receive connect speeds.  
[See “Configuring the Method to Set the LAC Connection Speeds to the LNS” on page 379.](#)
5. (Optional) Disable negotiation of the L2TP failover protocol to force use of only the silent failover resynchronization mechanism.  
[See “Preventing the LAC From Negotiating L2TP Failover Protocol” on page 381.](#)
6. (Optional) Specify the format for the tunnel name.  
[“Setting the Format for the Tunnel Name” on page 381.](#)
7. (Optional) Specify how many times L2TP retransmits unacknowledged control messages.  
[See “Configuring the Number of L2TP Control Message Retransmissions” on page 382.](#)
8. (Optional) Specify how long a tunnel can remain idle before being torn down.  
[See “Setting the L2TP Tunnel Idle Timeout” on page 383.](#)

9. (Optional) Specify how long the L2TP retains information about terminated dynamic tunnels, sessions, and destinations.  
See [“Setting the L2TP Destruct Timeout” on page 384](#).
10. (Optional) Configure trace options for troubleshooting the configuration.  
See [“Tracing L2TP Operations for Subscriber Access” on page 399](#)

## Configuring a Tunnel Profile for Subscriber Access

The tunnel profile specifies a set of attributes to characterize the tunnel. The profile can be applied by a domain map or automatically when the tunnel is created.

**NOTE:** RADIUS attributes and VSAs can override the values you configured by a tunnel profile in a domain map. In the absence of a domain map, RADIUS can supply all the characteristics of a tunnel. The steps in the following procedure list the corresponding standard RADIUS attribute or VSA that you can configure on your RADIUS server to modify or configure the tunnel profile.

RADIUS-supplied attributes are associated with a tunnel by a tag carried in the attribute, which matches the tunnel identifier. A tag of 0 indicates the tag is not used. If L2TP receives a RADIUS attribute with a tag of 0, the attribute cannot be merged with the tunnel profile configuration corresponding to the subscriber domain because a tunnel profile cannot provide a tunnel tag (tunnel identifier) of 0. Only tags in the range of 1 through 31 are supported.

To configure a tunnel definition for a tunnel profile:

1. Specify the tunnel profile for which you are defining a tunnel. (Tunnel-Group [26-64])  
[edit access]  
user@host# **set** **tunnel-profile** *profile-name*
2. Specify an identifier (name) for the L2TP control connection for the tunnel.  
[edit access tunnel-profile *profile-name*]  
user@host# **set** **tunnel** *tunnel-id*
3. Configure the IP address of the local L2TP tunnel endpoint, the LAC. (Tunnel-Client-Endpoint [66])  
[edit access tunnel-profile *profile-name* tunnel *tunnel-id*]  
user@host# **set** **source-gateway** *address* *client-ip-address*
4. Configure the IP address of the remote L2TP tunnel endpoint, the LNS. (Tunnel-Server-Endpoint [67])  
[edit access tunnel-profile *profile-name* tunnel *tunnel-id*]  
user@host# **set** **remote-gateway** *address* *server-ip-address*
5. (Optional) Configure the preference level for the tunnel. (Tunnel-Preference [83])  
[edit access tunnel-profile *profile-name* tunnel *tunnel-id*]

```
user@host# set preference number
```

6. (Optional) Configure the hostname of the local client (LAC). (Tunnel-Client-Auth-Id [90])

```
[edit access tunnel-profile profile-name tunnel tunnel-id]
user@host# set source-gateway gateway-name client-name
```

7. (Optional) Configure the hostname of the remote server (LNS). (Tunnel-Server-Auth-Id [91])

```
[edit access tunnel-profile profile-name tunnel tunnel-id]
user@host# set remote-gateway gateway-name server-name
```

8. (Optional) Specify the medium (network) type for the tunnel. (Tunnel-Medium-Type [65])

```
[edit access tunnel-profile profile-name tunnel tunnel-id]
user@host# set medium type
```

9. (Optional) Specify the protocol type for the tunnel. (Tunnel-Type [64])

```
[edit access tunnel-profile profile-name tunnel tunnel-id]
user@host# set type tunnel-type
```

10. (Optional) Configure the assignment ID for the tunnel. (Tunnel-Assignment-Id [82])

```
[edit access tunnel-profile profile-name tunnel tunnel-id]
user@host# set identification name
```

11. (Optional) Configure the maximum number of sessions allowed in the tunnel. (Tunnel-Max-Sessions [26-33])

```
[edit access tunnel-profile profile-name tunnel tunnel-id]
user@host# set max-sessions number
```

12. (Optional) Configure the password for remote server authentication. (Standard RADIUS attribute Tunnel-Password [69] or VSA Tunnel-Password [26-9])

```
[edit access tunnel-profile profile-name tunnel tunnel-id]
user@host# set secret password
```

13. (Optional) Configure the logical system to use for the tunnel.

If you configure a logical system, you must also configure a routing instance.

```
[edit access tunnel-profile profile-name tunnel tunnel-id]
user@host# set logical-system logical-system-name
```

14. (Optional) Configure the routing instance to use for the tunnel. (Tunnel-Virtual-Router [26-8])

If you configure a routing instance, configuring a logical system is optional.

```
[edit access tunnel-profile profile-name tunnel tunnel-id]
user@host# set routing-instance routing-instance-name
```

The following example shows a complete configuration for a tunnel profile:

```
tunnel-profile marketing {
  tunnel 1 {
    preference 5;
```

```

remote-gateway {
    address 172.16.98.4;
    gateway-name work;
}
source-gateway {
    address 192.168.4.10;
    gateway-name local;
}
secret mk5Sn$3k%V;
logical-system bos-metro-5;
routing-instance rox-12-32;
medium ipv4;
type l2tp;
identification tunnel_to_work;
max-sessions 32;
}

```

**Related Documentation** • [Domain Mapping Overview on page 168](#)

## Configuring the L2TP LAC Tunnel Selection Parameters

When the LAC determines that a PPP session should be tunneled, it selects a tunnel from the set of tunnels associated with either the PPP user or the PPP user's domain. You can configure how a tunnel is selected and whether certain information is sent by the LAC to the LNS.

To configure tunnel selection parameters:

1. (Optional) Configure how a tunnel is selected when a connection attempt fails.  
See [“Configuring LAC Tunnel Selection Failover Within a Preference Level” on page 377](#).
2. (Optional) Configure how sessions are load-balanced among tunnels.  
See [“Configuring Weighted Load Balancing for LAC Tunnel Sessions” on page 378](#).

**Related Documentation** • [LAC Tunnel Selection Overview on page 364](#)

## Configuring LAC Tunnel Selection Failover Within a Preference Level

You can configure how LAC tunnel selection continues in the event of a failure to connect. By default, when the router is unable to connect to a destination at a given preference level, it attempts to connect at the next lower level. You can specify that the router instead attempt to connect to another destination at the same level as the failed attempt.

If all destinations at a preference level are marked as unreachable, the router does not attempt to connect to a destination at that level. It drops to the next lower preference level to select a destination.

If all destinations at all preference levels are marked as unreachable, the router chooses the destination that failed first and tries to make a connection. If the connection fails, the router rejects the PPP user session without attempting to contact the remote router.

For example, suppose there are four tunnels for a domain: A, B, C, and D. All tunnels are considered reachable, and the preference levels are assigned as follows:

- A and B at preference 0
- C and D at preference 1

When the router attempts to connect to the domain, suppose it randomly selects tunnel B from preference 0. If it fails to connect to tunnel B, the router excludes tunnel B for five minutes and attempts to connect to tunnel A. If this attempt also fails, the router drops to preference 1. Then suppose the router selects tunnel C. If it also fails to connect to tunnel C, the router excludes tunnel C for five minutes and attempts to connect to tunnel D.

You configure the preference level used for this tunnel selection method in the tunnel profile or the RADIUS Tunnel-Preference [83] attribute.

To enable tunnel selection failover within a preference level:

- Specify failover within preference.

```
[edit services l2tp]
user@host# set fail-over-within-preference
```

---

## Configuring Weighted Load Balancing for LAC Tunnel Sessions

---

You can configure how L2TP LAC sessions are distributed across tunnels. You can specify that the router uses the maximum sessions per tunnel to choose among multiple tunnels that share the same preference level.

The weight of a tunnel is proportional to its maximum session limit and the maximum session limits of the other tunnels at the same preference level. The tunnel with the largest maximum session value has the highest weight. The tunnel with the next larger maximum session value has the next higher weight, and so on. The tunnel with the smallest maximum session value has the lowest weight.

When you configure weighted load balancing, the tunnel with the highest weight in the preference level is selected until the maximum number of sessions for the tunnel is reached. Then the router selects the tunnel with the next higher weight to establish connections until that tunnel's maximum session limit is reached, and so on.

To configure weighted load balancing:

- Specify load balancing.

```
[edit services l2tp]
user@host# set weighted-load-balancing
```

- Related Documentation**

## Preventing the LAC from Sending Calling Number AVP 22 to the LNS

Calling Number AVP 22 typically identifies the interface that is connected to the customer in the access network. When RADIUS includes the Calling-Station-Id in the Access-Accept message, that value is used for the Calling Number AVP. Otherwise, the underlying interface (for example, the S-VLAN IFL) on which the PPPoE session is established is used for the Calling Number AVP value.

By default, the LAC includes this AVP in the incoming-call request (ICRQ) packets that it sends to the LNS. However, you may wish to hide your network access interface information. To do so, you can configure the tunnel so that the LAC does not send the Calling Number AVP to the LNS.

To disable sending the Calling Number AVP:

- Configure disabling.

```
[edit services l2tp]
user@host# set disable-calling-number-avp
```

- Related Documentation**
- [LAC Tunnel Selection Overview on page 364](#)

## Configuring the Method to Set the LAC Connection Speeds to the LNS

During the establishment of an L2TP tunnel session, the LAC sends the L2TP transmit connect speed in bits per second (BPS) using AVP 24 to the LNS in Incoming-Call-Connected (ICCN) messages. AVP 24 conveys the transmit connect speed of the subscriber's access interface; that is, it represents the speed of the connection from the LAC to the LNS, from the perspective of the LAC. The L2TP receive connect speed, which is represented by AVP 38, is included in the message when the receive connect speed is different from the transmit connect speed. AVP 38 conveys the receive connect speed of the connection from the LNS to the LAC, again from the perspective of the LAC. When AVP 38 is not sent, it means that the connection speed is the same in both directions; the LNS uses the value in AVP 24 for both transmit and receive connect speeds.

You can configure what the LAC uses as a resource for setting these speeds. To use the recommended (advisory) downstream shaping rate for AVP 24 and the recommended upstream shaping rate for AVP 38, include the **tx-connect-speed-method static** statement

at the **[edit services l2tp]** hierarchy level. You configure the advisory rates under the PPPoE logical interface underlying the subscriber interface with the **advisory-options** statement at the **[edit interfaces interface-name unit logical-unit-number]** hierarchy level. When the advisory speed is not configured on the underlying interface, the **tx-connect-speed-method advisory** statement automatically sets the speed to 1 Gbps and sends this value in both AVP 24 and AVP 38.

To derive the speeds from the PPPoE IA tags, use the **tx-connect-speed-method pppoe-ia-tags** statement. In this case, AVP 24 is the value of Actual-Data-Rate-Downstream (VSA 26-129). AVP 38 is the value of Actual-Data-Rate-Upstream (VSA 26-130), and is sent only when the VSA values differ.

To derive the speeds from the ANCP value configured on the PPPoE interface underlying the subscriber interface, use the **tx-connect-speed-method ancp** statement.

To set the method for calculating the transmit connect speed:

- Configure the ANCP method to use the values derived from the configured ANCP value for the underlying interface.

```
[edit services l2tp]
user@host# set tx-connect-speed-method ancp
```

- Configure the PPPoE IA tags method to use the values provided in the PPPoE IA tags.

```
[edit services l2tp]
user@host# set tx-connect-speed-method pppoe-ia-tags
```

- Configure the static (advisory downstream shaping rate) method to use the underlying interface's recommended shaping rates.

```
[edit services l2tp]
user@host# set tx-connect-speed-method static
```

## Transmission of the Receive Connect Speed AVP When Transmit and Receive Connect Speeds are Equal

---

The L2TP Rx Connect Speed (in bits per second) AVP, which is represented by AVP 38, is included in the ICCN message when the receive connect speed is different from the transmit connect speed. By default, when the connection speed is the same in both directions, AVP 38 is not sent; the LNS uses the value in AVP 24 for both transmit and receive connect speeds.

AVP 38 is generated when the receive connect speed of the access interface is set equal to the calculated transmit connect speed by issuing the **rx-connect-speed-when-equal** statement at the **[edit services l2tp]** hierarchy level. In this scenario, the LAC transmits the same value for transmit and receive connect speeds that are sent to the LNS through the AVP 24 and AVP 38 in the ICCN message.

To configure the sending of AVP 38 when the connection speeds are the same in both the downstream and upstream directions:

- Configure the transmission of the receive connect speed, AVP 38, when the receive connect speed is set equal to the calculated transmit connect speed.

```
[edit services l2tp]
user@host# set rx-connect-speed-when-equal
```

#### Related Documentation

## Preventing the LAC From Negotiating L2TP Failover Protocol

The L2TP LAC implementation on MX Series routers supports L2TP failover and peer resynchronization with a failed remote endpoint. The LAC supports both the L2TP failover protocol method and the L2TP silent failover method. By default, L2TP on the LAC attempts to negotiate the L2TP failover protocol with the LNS. When negotiation determines that the LNS supports this method, then the LAC uses L2TP failover protocol if the LNS fails. When the LNS does not support L2TP failover protocol, then the LAC uses silent failover in the event of an LNS failure. The ability to fall back on silent failover prevents the failover from forcing a disconnection of the tunnel to the peer and all the associated sessions.

You can disable the default behavior to force the LAC to operate only in silent failover mode. This configuration can be useful when routers that act as the LNS either are configured for silent failover or incorrectly negotiate use of the failover protocol even though they do not support it. However, when you issue this statement and the LNS supports only failover protocol, then the LAC cannot negotiate failover protocol, and recovery (failover protocol recovery initiated by the LNS) always fails.

To disable negotiation of the L2TP failover protocol:

- Configure disabling.

```
[edit services l2tp]
user@host# set disable-failover-protocol
```

#### Related Documentation

- [Configuring an L2TP LAC on page 374](#)

## Setting the Format for the Tunnel Name

By default, the name of a tunnel corresponds to the Tunnel-Assignment-Id [82] returned by the AAA server. You can optionally configure the LAC to use more elements in the construction of a tunnel name by including the **assignment-id-format client-server-id** statement at the **[edit services l2tp tunnel]** hierarchy level. This format uses three

attributes: Tunnel-Client-Auth-Id [90], Tunnel-Server-Endpoint [67], and Tunnel-Assignment-Id [82]. These attributes correspond, respectively, to the values configured in the tunnel profile for the LAC (source gateway) name, the tunnel endpoint (remote gateway) address on the LNS, and the tunnel ID.

A consequence of the **client-server-id** format is that the LAC automatically creates a new tunnel when the AAA server returns a different Tunnel-Client-Auth-Id than previously returned.

**NOTE:** Before you downgrade to a Junos OS Release that does not support this statement, we recommend that you explicitly unconfigure the feature by including the **no assignment-id-format assignment-id** statement at the **[edit services l2tp tunnel]** hierarchy level.

To change how the tunnel name is formatted:

- Configure the format.

```
[edit services l2tp tunnel]
user@host# set assignment-id-format client-server-id
```

**Related  
Documentation**

- [Configuring an L2TP LAC on page 374](#)

---

## Configuring the Number of L2TP Control Message Retransmissions

---

L2TP peers maintain a queue of control messages that must be sent to the peer device. After a message is sent, the local peer waits for a response from the remote peer. If a response is not received, the local peer retransmits the message. You can configure how many times an unacknowledged message is retransmitted by the LAC or the LNS. For tunnels that have been established, include the **retransmission-count-established** statement at the **[edit services l2tp tunnel]** hierarchy level. For tunnels that are not yet established, include the **retransmission-count-not-established** statement.

The local peer waits one second for the first response to a control message. The retransmit timer then doubles the interval between each successive retransmission, up to a maximum interval of 16 seconds. This behavior allows the remote peer more time to respond. If the maximum retransmission count is reached and no response has been received, the tunnel and all its sessions are cleared.

**BEST PRACTICE:** Before you downgrade to a Junos OS release that does not support these statements, we recommend that you explicitly unconfigure the feature by including the **no retransmission-count-established** statement and the **no retransmission-count-non-established** statement at the **[edit services l2tp tunnel]** hierarchy level.

**BEST PRACTICE:** During a unified in-service software upgrade (unified ISSU) on an MX Series router configured as the LAC, the LAC does not respond to control messages from the LNS. This can result in dropping LAC L2TP sessions. You can avoid this situation by ensuring that the maximum retransmission count on the LNS is set to 16 or higher.

To set the maximum retransmission count for established tunnels:

- Configure the count.

```
[edit services l2tp tunnel]
user@host# set retransmission-count-established count
```

To set the maximum retransmission count for non-established tunnels:

- Configure the count.

```
[edit services l2tp tunnel]
user@host# set retransmission-count-not-established count
```

- [Configuring an L2TP LNS with Inline Service Interfaces on page 384](#)

## Setting the L2TP Tunnel Idle Timeout

You can configure the LAC or the LNS to specify how long a tunnel without any sessions remains active. The idle timer starts when the last session on the tunnel is terminated. When the timer expires the tunnel is disconnected. This idle timeout frees up resources otherwise consumed by inactive tunnels.

If you set the idle timeout value to zero, the tunnel is forced to remain active indefinitely after the last session is terminated until one of the following occurs:

- You issue the **clear services l2tp tunnel** command.
- The remote peer disconnects the tunnel.

**BEST PRACTICE:** Before you downgrade to a Junos OS Release that does not support this statement, we recommend that you explicitly unconfigure the feature by including the **no idle-timeout** statement at the **[edit services l2tp tunnel]** hierarchy level.

To set the tunnel idle timeout:

- Configure the timeout period.

```
[edit services l2tp tunnel]
user@host# set idle-timeout seconds
```

- Related Documentation**
- [Configuring an L2TP LAC on page 374](#)
  - [Configuring an L2TP LNS with Inline Service Interfaces on page 384](#)

---

## Setting the L2TP Destruct Timeout

You can configure the LAC or the LNS to specify how long the router attempts to maintain dynamic destinations, tunnels, and sessions after they have been destroyed. This destruct timeout aids debugging and other analysis by saving underlying memory structures after the destination, tunnel, or session is terminated. Any specific dynamic destination, tunnel, or session may not be maintained for this entire time period if the resources must be reclaimed early to allow new tunnels to be established.

**BEST PRACTICE:** Before you downgrade to a Junos OS Release that does not support this statement, we recommend that you explicitly unconfigure the feature by including the `no destruct-timeout` statement at the `[edit services l2tp]` hierarchy level.

To set the L2TP destruct timeout:

- Configure the timeout period.

```
[edit services l2tp]  
user@host# set destruct-timeout seconds
```

- Related Documentation**

## Configuring an L2TP LNS with Inline Service Interfaces

In addition to performing the specific LNS configuration procedure that follows, you must also configure a RADIUS server and optionally configure an address pool on the local routing instance to be used by RADIUS to assign addresses to PPP subscribers at login.

The L2TP LNS feature license must be installed before you begin the configuration. Else, a warning message is displayed when the configuration is committed.

To configure an L2TP LNS with inline service interfaces:

1. (Optional) Configure a user group profile that defines the PPP configuration for tunnel subscribers.

See [“Applying PPP Attributes to L2TP LNS Subscribers with a User Group Profile” on page 386](#).

2. (Optional) Configure PPP attributes for subscribers on inline service interfaces.

See [“Applying PPP Attributes to L2TP LNS Subscribers Per Inline Service Interface” on page 387](#).

3. Configure an L2TP access profile that defines the L2TP parameters for each LNS client (LAC).  
See [“Configuring an L2TP Access Profile on the LNS” on page 390.](#)
4. (Optional) Configure a AAA access profile to override the access profile configured under the routing instance.  
See [“Configuring a AAA Local Access Profile on the LNS” on page 391.](#)
5. Configure a pool of addresses to be dynamically assigned to tunneled PPP subscribers.  
See [“Configuring an Address-Assignment Pool for L2TP LNS with Inline Services” on page 392.](#)
6. Configure the peer interface to terminate the tunnel and the PPP server-side IPCP address.  
See [“Configuring the L2TP LNS Peer Interface” on page 393.](#)
7. Enable inline service interfaces on an MPC.  
See [“Enabling Inline Service Interfaces” on page 394.](#)
8. Configure a service interface.  
See [“Configuring an Inline Service Interface for L2TP LNS” on page 394.](#)
9. Configure options for each inline service logical interface.  
See [“Configuring Options for the LNS Inline Services Logical Interface” on page 395.](#)
10. Configure the L2TP tunnel group.  
See [“Configuring an L2TP Tunnel Group for LNS Sessions with Inline Services Interfaces” on page 396.](#)
11. (Optional) Configure a dynamic profile that dynamically creates L2TP logical interfaces.  
See [“Configuring a Dynamic Profile for Dynamic LNS Sessions” on page 398](#)
12. (Optional) Configure a service interface pool for dynamic LNS sessions.  
See [“Configuring a Pool of Inline Services Interfaces for Dynamic LNS Sessions” on page 397.](#)
13. (Optional) Specify how many times L2TP retransmits unacknowledged control messages.  
See [“Configuring the Number of L2TP Control Message Retransmissions” on page 382.](#)
14. (Optional) Specify how long a tunnel can remain idle before being torn down.  
See [“Setting the L2TP Tunnel Idle Timeout” on page 383.](#)
15. (Optional) Specify how long the L2TP retains information about terminated dynamic tunnels, sessions, and destinations.  
See [“Setting the L2TP Destruct Timeout” on page 384.](#)
16. (Optional) Configure trace options for troubleshooting the configuration.

See [“Tracing L2TP Operations for Subscriber Access” on page 399](#)

You also need to configure CoS for LNS sessions. For more information, see [“Configuring Dynamic CoS for an L2TP LNS Inline Service” on page 972](#).

**Related  
Documentation**

- [L2TP for Subscriber Access Overview on page 359](#)

---

## Applying PPP Attributes to L2TP LNS Subscribers with a User Group Profile

---

You can configure a user group profile that enables the LNS to apply PPP attributes to the PPP subscribers tunneled from the LAC. The user group profile is associated with clients (LACs) in the L2TP access profile. Consequently all subscribers handled by a given client share the same PPP attributes.

To configure a user group profile:

1. Create the profile.

```
[edit access]
user@host# edit group-profile profile-name
```

2. Configure the interval between PPP keepalive messages for the L2TP tunnel terminating on the LNS.

```
[edit access group-profile profile-name]
user@host# set ppp keepalive seconds
```

**NOTE:** Changes to the keepalive interval in a user group profile affect only new L2TP sessions that come up after the change. Existing sessions are not affected.

3. Configure PPP authentication methods that apply to tunneled PPP subscribers at the LNS.

```
[edit access group-profile profile-name]
user@host# set ppp ppp-options chap
user@host# set ppp ppp-options pap
```

4. Configure how long the PPP subscriber session can be idle before it is considered to have timed out.

```
[edit access group-profile profile-name]
user@host# set ppp idle-timeout 200
```

**NOTE:** You can also configure PPP attributes on a per-interface basis. See [“Applying PPP Attributes to L2TP LNS Subscribers Per Inline Service Interface” on page 387](#) for more information. When you configure the PPP attributes for L2TP LNS subscribers both on the si interface and in user group profiles, the inline service interface configuration takes precedence over the user group profile configuration.

- Related Documentation**
- [Configuring an L2TP Access Profile on the LNS on page 390](#)
  - [Configuring an L2TP LNS with Inline Service Interfaces on page 384](#)

## Applying PPP Attributes to L2TP LNS Subscribers Per Inline Service Interface

You can configure PPP attributes that are applied by the LNS on the inline service (si) interface to the PPP subscribers tunneled from the LAC. Because you are configuring the attributes per interface rather than with a user group profile, the attributes for subscribers can be varied with a finer granularity. This configuration matches that used for terminated PPPoE subscribers.

To configure the PPP attributes for dynamically created si interfaces:

1. Specify the predefined dynamic interface and logical interface variables in the dynamic profile.

```
[edit dynamic-profiles profile-name]
user@host# edit interfaces "$junos-interface-ifd-name" unit "$junos-interface-unit"
```

2. Configure the interval between PPP keepalive messages for the L2TP tunnel terminating on the LNS.

```
[edit dynamic-profiles profile-name interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set keepalives interval seconds
```

3. Configure PPP authentication methods that apply to tunneled PPP subscribers at the LNS.

```
[edit dynamic-profiles profile-name interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set ppp-options chap
user@host# set ppp-options pap
```

To configure the PPP attributes for statically created si interfaces:

1. Specify the logical inline service interface.

```
[edit interfaces si-slot/pic/port]
user@host# edit unit logical-unit-number
```

2. Configure the interval between PPP keepalive messages for the L2TP tunnel terminating on the LNS.

```
[edit interfaces si-slot/pic/port unit logical-unit-number]
user@host# set keepalives interval seconds
```

3. Configure the number of keepalive packets a destination must fail to receive before the network takes down a link.

```
[edit interfaces si-slot/pic/port unit logical-unit-number]
user@host# set keepalives down-count number
```

**NOTE:** The `keepalives up-count` option is typically not used for subscriber management.

4. Configure PPP authentication methods that apply to tunneled PPP subscribers at the LNS.

```
[edit interfaces si-slot/pic/port unit logical-unit-number]
```

```
user@host# set ppp-options chap
```

```
user@host# set ppp-options pap
```

**BEST PRACTICE:** Although all other statements subordinate to `ppp-options`—including those subordinate to `chap` and `pap`—are supported, they are typically not used for subscriber management. We recommend that you leave these other statements at their default values.

**NOTE:** You can also configure PPP attributes with a user group profile that applies the attributes to all subscribers with that profile on a LAC client. See [“Applying PPP Attributes to L2TP LNS Subscribers with a User Group Profile” on page 386](#) for more information. When you configure the PPP attributes for L2TP LNS subscribers both on the `si` interface and in user group profiles, the inline service interface configuration takes precedence over the user group profile configuration.

## Configuring IP Inline Reassembly for L2TP

This procedure shows how to configure a service interface on a LAC or LNS to reassembly fragmented IP packets. This example creates a service set that configures the IP reassembly parameters for L2TP fragments. The service set is then associated with the L2TP service.

Before you configure inline IP reassembly, be sure you have:

- Configured L2TP.
- Configured a valid service interface on the LAC or LNS.

To configure inline IP reassembly:

1. Configure the chassis-level bandwidth used by the inline services interface on the FPC and PIC slot for inline IP fragment reassembly.

```
[edit chassis]
```

```
user@host# set fpc 2 pic 1 inline-services bandwidth 10g
```

2. Configure the interface-level logical unit used by the inline services (si-) interface on the FPC and PIC slot for inline IP fragment reassembly.

```
[edit interfaces]
user@host# set si-2/1/0 unit 0 family inet
user@host# set si-2/1/0 unit 0 service-domain inside
```

**NOTE:** This configuration is not unique to L2TP. However, you must configure the family (inet) and service domain (inside) as shown.

3. Configure the service set (set1) for IP reassembly in the input match direction. (The local option loops the reassembled packets back to the local interface.)

```
[edit services]
user@host# set service-set set1

[edit services service set ip-reassembly-set]
user@host# set ip-reassembly-rules ipr_rule1
user@host# set next-hop-service inside-service-interface si-9/1/0.0
user@host# set next-hop-service outside-service-interface-type local
```

**NOTE:** You must configure both inside (si- interface) and outside type (local) service interfaces statements. The reassembly rule is not formulated outside of the service set; this statement simply initiates the reassembly process.

4. Configure the IP reassembly rule parameter

```
[edit services ip-reassembly]
user@host# set rule ipr_rule1 match-direction input;
```

5. Configure the service set (set1) for IP reassembly to bind to the L2TP service.

**NOTE:**

- The service set must be defined at the [edit services] hierarchy level.
- You cannot delete a service set instance if it is associated with an L2TP service.

```
[edit services l2tp]
user@host# set ip-reassembly service-set set1
```

## Configuring an L2TP Access Profile on the LNS

Access profiles define how to validate Layer 2 Tunneling Protocol (L2TP) connections and session requests. Within each L2TP access profile, you configure one or more clients (LACs). The client characteristics are used to authenticate LACs with matching passwords, and to establish attributes of the client tunnel and session. You can configure multiple access profiles and multiple clients within each profile.

To configure an L2TP access profile:

1. Create the access profile.

```
[edit access]
user@host# edit profile access-profile-name
```

2. Configure characteristics for one or more clients (LACs).

```
[edit access profile access-profile-name]
user@host# client client-name
```

**NOTE:** Except for the special case of the default client, the LAC client name that you configure in the access profile must match the hostname of the LAC. In the case of a Juniper Networks router acting as the LAC, the hostname is configured in the LAC tunnel profile with the gateway gateway-name statement at the [edit access tunnel-profile profile-name tunnel tunnel-id source-gateway] hierarchy level. Alternatively, the client name can be returned from RADIUS in the attribute, Tunnel-Client-Auth-Id [90].

**NOTE:** Use default as the client name when you want to define a default tunnel client. The default client enables the authentication of multiple LACs with the same secret and L2TP attributes. This behavior is useful when, for example, many new LACs are added to the network, because it enables the LACs to be used without additional LNS profile configuration.

Use default only on MX Series routers. The equivalent client name on M Series routers is \*.

3. (Optional) Specify a local access profile that overrides the global access profile and the tunnel group AAA access profile to configure RADIUS server settings for the client.

```
[edit access profile access-profile-name client client-name]
user@host# set l2tp aaa-access-profile
```

4. Configure the LNS to renegotiate the link control protocol (LCP) with the PPP client tunneled from the client.

```
[edit access profile access-profile-name client client-name]
user@host# set l2tp lcp-renegotiation
```

5. Configure the maximum number of sessions allowed in a tunnel from the client (LAC).

```
[edit access profile access-profile-name client client-name]
user@host# set l2tp maximum-sessions-per-tunnel number
```

6. Configure the tunnel password used to authenticate the client (LAC).

```
[edit access profile access-profile-name client client-name]
user@host# set l2tp shared-secret shared-secret
```

7. (Optional) Associate a group profile containing PPP attributes to apply for the PPP sessions being tunneled from this LAC client.

```
[edit access profile access-profile-name client client-name]
user@host# set user-group-profile group-profile-name
```

**Related  
Documentation**

- [Configuring an L2TP LNS with Inline Service Interfaces on page 384](#)
- [Configuring an L2TP Tunnel Group for LNS Sessions with Inline Services Interfaces on page 396](#)

## Configuring a AAA Local Access Profile on the LNS

For some LNS tunnels, you might wish to override the access profile configured at the routing instance that hosts the tunnel with a particular RADIUS server configuration. You can configure a local access profile to do so. You can subsequently use the **aaa-access-profile** statement to apply the local access profile to a tunnel group or LAC client.

A local access profile applied to a client overrides a local access profile applied to a tunnel group, which in turn overrides the access profile for the routing instance.

To configure a AAA local access profile:

1. Create the access profile.

```
[edit access]
user@host# edit profile local-aaa-profile-name
```

2. Configure the order of AAA authentication methods.

```
[edit access profile local-aaa-profile-name]
user@host# set authentication-order radius
```

3. Configure the RADIUS server attributes, such as the authentication password.

```
[edit access profile local-aaa-profile-name]
user@host# set radius-server server-address secret password
```

**Related  
Documentation**

- [Configuring an L2TP LNS with Inline Service Interfaces on page 384](#)

## Configuring an Address-Assignment Pool for L2TP LNS with Inline Services

You can configure pools of addresses that can be dynamically assigned to the tunneled PPP subscribers. The pools must be local to the routing instance where the subscriber comes up. The configured pools are supplied in the RADIUS Framed-Pool and Framed-IPv6-Pool attributes. Pools are optional when Framed-IP-Address is sent by RADIUS.

To configure an address-assignment pool, you must specify the name of the pool and configure the addresses for the pool.

You can optionally configure multiple named ranges, or subsets, of addresses within an address-assignment pool. During dynamic address assignment, a client can be assigned an address from a specific named range. To create a named range, you specify a name for the range and define the address range.

**NOTE:** Be sure to use the address-assignment pools (**address-assignment**) statement rather than the address pools (**address-pool**) statement.

To configure an IPv4 address-assignment pool for L2TP LNS:

1. Configure the name of the pool and specify the IPv4 family.

```
[edit access]
user@host# edit address-assignment pool pool-name family inet
```

2. Configure the network address and the prefix length of the addresses in the pool.

```
[edit access address-assignment pool pool-name family inet]
user@host# set network ip-prefix/<prefix-length>
```

3. Configure the name of the range and the lower and upper boundaries of the addresses in the range.

```
[edit access address-assignment pool pool-name family inet]
user@host# set range range-name low lower-limit high upper-limit
```

For example, to configure an IPv4 address-assignment pool:

```
[edit access]
user@host# edit address-assignment pool lns-v4-pool family inet
[edit access address-assignment pool lns-v4-pool family inet]
user@host# set network 192.168.1.1/16
[edit access address-assignment pool lns-v4-pool family inet]
user@host# set range lns-v4-pool-range low 192.168.1.1 high 192.168.255.255
```

**NOTE:** Dual-stack (IPv4/IPv6) LNS is supported, but IPv6-only subscribers are not supported.

To configure an IPv6 address-assignment pool for L2TP LNS:

1. Configure the name of the pool and specify the IPv6 family.

```
[edit access]
user@host# edit address-assignment pool pool-name family inet6
```

2. Configure the IPv6 network prefix for the address pool. The prefix specification is required when you configure an IPv6 address-assignment pool.

```
[edit access address-assignment pool pool-name family inet6]
user@host# set prefix ipv6-prefix
```

3. Configure the name of the range and define the range. You can define the range based on the lower and upper boundaries of the prefixes in the range, or based on the length of the prefixes in the range.

```
[edit access address-assignment pool pool-name family inet6]
user@host# set range range-name low lower-limit high upper-limit
```

For example, to configure an IPv6 address-assignment pool:

```
[edit access]
user@host# edit address-assignment pool lns-v6-pool family inet6
[edit access address-assignment pool lns-v6-pool family inet6]
user@host# set prefix 2010:9999::/32
[edit access address-assignment pool lns-v6-pool family inet6]
user@host# set range lns-v6-pool-range low 2010:9999:1::/48 high 2010:9999::ffff::/48
```

## Configuring the L2TP LNS Peer Interface

The peer interface connects the LNS to the cloud towards the LACs so that IP packets can be exchanged between the tunnel endpoints. MPLS and aggregated Ethernet can also be used to reach the LACs.

**NOTE:** On MX Series routers, you must configure the peer interface on an MPC.

To configure the LNS peer interface:

1. Specify the interface name.

```
[edit interfaces]
user@host# edit interface-name
```

2. Enable VLANs.

```
[edit interfaces interface-name]
user@host# set vlan-tagging
```

3. Specify the logical interface, bind a VLAN tag ID to the interface, and configure the address family and the IP address for the logical interface.

```
[edit interfaces interface-name]  
user@host# edit unit logical-unit-number  
[edit interfaces interface-name unit logical-unit-number]  
user@host# set vlan-id number  
user@host# set family family address ip-address
```

**NOTE:** The IPv6 address family is not supported as a tunnel endpoint.

**Related  
Documentation**

- [Configuring an L2TP LNS with Inline Service Interfaces on page 384](#)

---

## Enabling Inline Service Interfaces

The inline service interface is a virtual physical interface that resides on the Packet Forwarding Engine. This *si* interface, referred to as an *anchor* interface, makes it possible to provide L2TP services without a special services PIC. The inline service interface is supported only by MPCs on MX Series routers. Four inline service interfaces are configurable per MPC-occupied chassis slot.

**NOTE:** On MX80 routers, you can configure only four inline services physical interfaces as anchor interfaces for L2TP LNS sessions: si-1/0/0, si-1/1/0, si-1/2/0, and si-1/3/0. You cannot configure si-0/0/0 for this purpose on MX80 routers.

To enable inline service interfaces:

1. Access an MPC-occupied slot and the PIC where the interface is to be enabled.

```
[edit chassis]  
user@host# edit fpc slot-number pic number
```

2. Enable the interface and specify the amount of bandwidth reserved on each Packet Forwarding Engine for tunnel traffic using inline services.

```
[edit chassis fpc slot-number pic number]  
user@host# set inline-services bandwidth (1g | 10g)
```

**Related  
Documentation**

- [Configuring an L2TP LNS with Inline Service Interfaces on page 384](#)

---

## Configuring an Inline Service Interface for L2TP LNS

The inline service interface is a virtual physical service interface that resides on the Packet Forwarding Engine. This *si* interface, referred to as an *anchor* interface, makes it possible to provide L2TP services without a special services PIC. The inline service interface is

supported only by MPCs on MX Series routers. Four inline service interfaces are configurable per MPC-occupied chassis slot.

You can maximize the number of sessions that can be shaped in one service interface by setting the maximum number of hierarchy levels to two. In this case, each LNS session consumes one L3 node in the scheduler hierarchy for shaping.

If you do not specify the number of levels (two is the only option), then the number of LNS sessions that can be shaped on the service interface is limited to the number of L2 nodes, or 4096 sessions. Additional sessions still come up, but they are not shaped.

To configure an inline service interface:

1. Access the service interface.

```
[edit interfaces]
user@host# edit si-slot/pic/port
```

2. (Optional; for per-session shaping only) Enable the inline service interface for hierarchical schedulers and limit the number of scheduler levels to two.

```
[edit interfaces si-slot/pic/port]
user@host# set hierarchical-scheduler maximum-hierarchy-levels 2
```

3. (Optional; for per-session shaping only) Configure services encapsulation for inline service interface.

```
[edit interfaces si-slot/pic/port]
user@host# set encapsulation generic-services
```

4. Configure the IPv4 family on the reserved unit 0 logical interface.

```
[edit interfaces si-slot/pic/port]
user@host# set unit 0 family inet
```

## Configuring Options for the LNS Inline Services Logical Interface

You must specify characteristics—**dial-options**—for each of the inline services logical interfaces that you configure for the LNS. LNS on MX Series routers supports only one session per logical interface, so you must configure it as a **dedicated** interface; the **shared** option is not supported. (LNS on M Series routers supports **dedicated** and **shared** options.) You also configure an identifying name for the logical interface that matches the name you specify in the access profile.

To configure the logical interface options:

1. Access the inline services logical interface.

```
[edit]
user@host# edit interfaces si-fpc/pic/port unit logical-unit-number
```

2. Specify an identifier for the logical interface.

```
[edit interfaces si-fpc/pic/port unit logical-unit-number]
```

```
user@host# set dial-options l2tp-interface-id name
```

3. Configure the logical interface to be used for only one session at a time.

```
[edit interfaces si-fpc/pic/port unit logical-unit-number]
```

```
user@host# set dial-options dedicated
```

4. Configure the address family for each logical interface and enable the local address on the LNS that provides local termination for the L2TP tunnel to be derived from the specified interface name.

```
[edit interfaces si-fpc/pic/port unit logical-unit-number]
```

```
user@host# set family inet unnumbered-address lo0.0
```

## Configuring an L2TP Tunnel Group for LNS Sessions with Inline Services Interfaces

The L2TP tunnel group specifies attributes that apply to L2TP tunnels and sessions from a group of LAC clients. These attributes include the access profile used to validate L2TP connection requests made to the LNS on the local gateway address, a local access profile that overrides the global access profile, the keepalive timer, and whether the IP ToS value is reflected.

**NOTE:** If you delete a tunnel group, all L2TP sessions in that tunnel group are terminated. If you change the value of the `local-gateway-address`, `service-device-pool`, or `service-interface` statements, all L2TP sessions using those settings are terminated. If you change or delete other statements at the `[edit services l2tp tunnel-group name]` hierarchy level, new tunnels you establish use the updated values but existing tunnels and sessions are not affected.

To configure the LNS tunnel group:

1. Create the tunnel group.

```
[edit services l2tp]
```

```
user@host# edit tunnel-group name
```

2. Specify the service anchor interface responsible for L2TP processing on the LNS.

```
[edit services l2tp tunnel-group name]
```

```
user@host# set service-interface interface-name
```

This service anchor interface is required for static LNS sessions, and for dynamic LNS sessions that do not balance traffic across a pool of anchor interfaces. The interface is configured at the `[edit interfaces]` hierarchy level.

3. (Optional; for load-balancing dynamic LNS sessions only) Specify a pool of inline service anchor interfaces to enable load-balancing of L2TP traffic across the interfaces.

```
[edit services l2tp tunnel-group name]
```

```
user@host# set service-device-pool pool-name
```

The pool is defined at the **[edit services service-device-pools]** hierarchy level.

4. (For dynamic LNS sessions only) Specify the name of the dynamic profile that defines and instantiates inline service interfaces for L2TP tunnels

```
[edit services l2tp tunnel-group name]
user@host# set dynamic-profile profile-name
```

The profile is defined at the **[edit dynamic-profiles]** hierarchy level.

5. Specify the access profile that validates all L2TP connection requests to the local gateway address.

```
[edit services l2tp tunnel-group name]
user@host# set l2tp-access-profile profile-name
```

6. Configure the local gateway address on the LNS; corresponds to the IP address that is used by LACs to identify the LNS.

```
[edit services l2tp tunnel-group name]
user@host# set local-gateway address address
```

7. (Optional) Configure the interval at which the LNS sends hello messages if it has received no messages from the LAC.

```
[edit services l2tp tunnel-group name]
user@host# set hello-interval seconds
```

8. (Optional) Specify a local access profile that overrides the global access profile to configure RADIUS server settings for the tunnel group.

```
[edit services l2tp tunnel-group name]
user@host# set aaa-access-profile profile-name
```

This local profile is configured at the **[edit access profile]** hierarchy level.

9. (Optional) Configure the LNS to reflect the IP ToS value from the inner IP header to the outer IP header (applies to CoS configurations).

```
[edit services l2tp tunnel-group name]
user@host# set tos-reflect
```

  - [Configuring an L2TP Access Profile on the LNS on page 390](#)

## Configuring a Pool of Inline Services Interfaces for Dynamic LNS Sessions

You can create a pool of inline service interfaces, also known as a *service device pool*, to enable load-balancing of L2TP traffic across the interfaces. The pool is supported for dynamic LNS configurations, where it provides a set of logical interfaces that can be dynamically created and allocated to L2TP sessions on the LNS. The pool is assigned to an LNS tunnel group. L2TP maintains the state of each inline service interface and uses a round-robin method to evenly distribute the load among available interfaces when new session requests are accepted.

**NOTE:** Load balancing is available only for dynamically created subscriber interfaces.

LNS sessions anchored on an MPC are not affected by a MIC failure as long as some other path to the peer LACs exists. If the MPC hosting the peer interface fails and there is no path to peer LACs, the failure initiates termination and clean-up of all the sessions on the MPC.

If the MPC anchoring the LNS sessions itself fails, the Routing Engine does not relocate sessions to another slot and all sessions are terminated immediately. New sessions can come up on another available interface when the client retries.

To configure the service device pool:

1. Create the pool.

```
[edit services service-device-pools]
user@host# edit pool pool-name
```

2. Specify the inline service interfaces that make up the pool.

```
[edit services service-device-pools pool pool-name]
user@host# set interface service-interface-name
user@host# set interface service-interface-name
```

---

## Configuring a Dynamic Profile for Dynamic LNS Sessions

You can configure L2TP to dynamically assign inline service interfaces for L2TP tunnels. You must define one or more dynamic profiles and assign a profile to each tunnel group. Both IPv4-only and dual-stack IPv4/IPv6 interfaces are supported.

To configure the L2TP dynamic profile:

1. Create the dynamic profile.

```
[edit]
user@host# edit dynamic-profiles profile-name
```

2. Configure the interface to be dynamically assigned to the routing instance used by the tunneled PPP clients.

```
[edit dynamic-profiles profile-name routing-instances "$junos-routing-instance"]
user@host# set interface $junos-interface-name
```

3. Configure the routing options for access routes in the routing instance.

```
[edit dynamic-profiles profile-name routing-instances "$junos-routing-instance"
routing-options access]
user@host# set route next-hop $junos-framed-route-nexthop
```

```
user@host# set route metric $junos-framed-route-cost
user@host# set route preference $junos-framed-route-distance
```

4. Configure the routing options for access-internal routes in the routing instance.

```
[edit dynamic-profiles profile-name routing-instances "$junos-routing-instance"
 routing-options access-internal]
user@host# set route $junos-subscriber-ip-address
```

5. Define the interfaces used by the dynamic profile. The variable is dynamically replaced by one of the configured inline service interfaces.

```
[edit dynamic-profiles profile-name]
user@host# set interfaces $junos-interface-ifd-name
```

6. Configure the inline services logical interfaces to be dynamically instantiated.

```
[edit dynamic-profiles profile-name interfaces "$junos-interface-ifd-name"]
user@host# set unit $junos-interface-unit
```

7. Specify an identifier for the logical interfaces.

```
[edit dynamic-profiles profile-name interfaces "$junos-interface-ifd-name" unit
 "$junos-interface-unit"]
user@host# set dial-options l2tp-interface-id name
```

8. Configure each logical interface to be used for only one session at a time.

```
[edit dynamic-profiles profile-name interfaces "$junos-interface-ifd-name" unit
 "$junos-interface-unit"]
user@host# set dial-options dedicated
```

9. Configure the address family for the logical interfaces and enable the local address on the LNS that provides local termination for the L2TP tunnel to be derived from the specified interface name.

```
[edit dynamic-profiles profile-name interfaces "$junos-interface-ifd-name" unit
 "$junos-interface-unit"]
user@host# set family inet unnumbered-address $junos-loopback-interface
```

## Tracing L2TP Operations for Subscriber Access

The Junos OS trace feature tracks L2TP operations and records events in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

**NOTE:** This topic refers to tracing L2TP operations on MX Series routers. To trace L2TP operations on M Series routers, see [Tracing L2TP Operations](#).

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

1. Important events are logged in a file located in the `/var/log` directory. By default, the router uses the filename `jl2tpd`. You can specify a different filename, but you cannot change the directory in which trace files are located.
2. When the trace log file *filename* reaches 128 kilobytes (KB), it is compressed and renamed *filename.0.gz*. Subsequent events are logged in a new file called *filename*, until it reaches capacity again. At this point, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)

By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

To configure L2TP tracing operations:

1. (Optional) Configure a trace log filename.  
See [“Configuring the L2TP Trace Log Filename” on page 400](#).
2. (Optional) Configure the number and size of trace logs.  
See [“Configuring the Number and Size of L2TP Log Files” on page 401](#).
3. (Optional) Configure user access to trace logs.  
See [“Configuring Access to the L2TP Log File” on page 401](#).
4. (Optional) Configure a regular expression to filter the information to be included in the trace log.  
See [“Configuring a Regular Expression for L2TP Messages to Be Logged” on page 402](#).
5. (Optional) Configure flags to specify which events are logged.  
See [“Configuring the L2TP Tracing Flags” on page 402](#).
6. (Optional) Configure a severity level for messages to specify which event messages are logged.  
See [“Configuring the Severity Level to Filter Which L2TP Messages Are Logged” on page 402](#).

---

## Configuring the L2TP Trace Log Filename

---

By default, the name of the file that records trace output for L2TP is `jl2tpd`. You can specify a different name with the `file` option.

To configure the filename for L2TP tracing operations:

- Specify the name of the file used for the trace output.

```
[edit services l2tp traceoptions]
user@host# set file l2tp_logfile_1
```

**Related  
Documentation**

- [Tracing L2TP Operations for Subscriber Access on page 399](#)

## Configuring the Number and Size of L2TP Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format *.number.gz*. The newest archived file is *.0.gz* and the oldest archived file is *.(maximum number)-1.gz*. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, *filename*, reaches 2 MB, *filename* is compressed and renamed *filename.0.gz*, and a new file called *filename* is created. When the new *filename* reaches 2 MB, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until there are 20 trace files. Then the oldest file, *filename.19.gz*, is simply overwritten when the next oldest file, *filename.18.gz* is compressed and renamed to *filename.19.gz*.

To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output.

```
[edit services l2tp traceoptions]
user@host# set file l2tp_1_logfile_1 files 20 size 2097152
```

**Related  
Documentation**

- [Tracing L2TP Operations for Subscriber Access on page 399](#)

## Configuring Access to the L2TP Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

To specify that all users can read the log file:

- Configure the log file to be world-readable.

```
[edit services l2tp traceoptions]
user@host# set file l2tp_1_logfile_1 world-readable
```

To explicitly set the default behavior, only the user who configured tracing can read the log file:

- Configure the log file to be no-world-readable.

```
[edit services l2tp traceoptions]  
user@host# set file l2tp_1_logfile_1 no-world-readable
```

**Related  
Documentation**

- [Tracing L2TP Operations for Subscriber Access on page 399](#)

---

## Configuring a Regular Expression for L2TP Messages to Be Logged

By default, the trace operation output includes all lines relevant to the logged events.

You can refine the output by including regular expressions to be matched.

To configure regular expressions to be matched:

- Configure the regular expression.

```
[edit services l2tp traceoptions]  
user@host# set file l2tp_1_logfile_1 match regex
```

**Related  
Documentation**

- [Tracing L2TP Operations for Subscriber Access on page 399](#)

---

## Configuring the L2TP Tracing Flags

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

To configure the flags for the events to be logged:

- Configure the flags.

```
[edit services l2tp traceoptions]  
user@host# set flag flag
```

**Related  
Documentation**

- [Tracing L2TP Operations for Subscriber Access on page 399](#)

---

## Configuring the Severity Level to Filter Which L2TP Messages Are Logged

The messages associated with a logged event are categorized according to severity level. You can use the severity level to determine which messages are logged for the event type. A low severity level is less restrictive—filters out fewer messages—than a higher level. When you configure a severity level, all messages at that level and all higher (more restrictive) levels are logged.

The following list presents severity levels in order from lowest (least restrictive) to highest (most restrictive). This order also represents the significance of the messages; for example, **error** messages are of greater concern than **info** messages.

- **verbose**
- **info**
- **notice**
- **warning**
- **error**

The severity level that you configure depends on the issue that you are trying to resolve. In some cases you might be interested in seeing all messages relevant to the logged event, so you specify **all**. You can also specify **verbose** with the same result, because **verbose** is the lowest (least restrictive) severity level; it has nothing to do with the terseness or verbosity of the messages. Either choice generates a large amount of output. You can specify a more restrictive severity level, such as **notice** or **info** to filter the messages. By default, the trace operation output includes only messages with a severity level of **error**.

To configure the type of messages to be logged:

- Configure the message severity level.

```
[edit services l2tp traceoptions]
user@host# set level severity
```

## Verifying and Managing L2TP for Subscriber Access

<b>Purpose</b>	View or clear information about L2TP tunnels and sessions.
<b>Action</b>	<ul style="list-style-type: none"> <li>• To display a summary of L2TP tunnels, sessions, errors, and control and data packets:  <pre>user@host&gt; show services l2tp summary</pre> </li> <li>• To display the L2TP destinations:  <pre>user@host&gt; show services l2tp destination</pre> </li> <li>• To clear all L2TP destinations:  <pre>user@host&gt; clear services l2tp destination all</pre> </li> <li>• To clear statistics for all L2TP tunnels belonging to a destination, tunnels belonging to a specified local-gateway address, and tunnels belonging to a specified peer-gateway address:  <pre>user@host&gt;clear services l2tp destination statistics all user@host&gt;clear services l2tp destination local-gateway 10.1.1.2</pre> </li> <li>• To display the L2TP sessions:</li> </ul>

**user@host> show services l2tp session**

- To clear all L2TP sessions, the session with a specified local session ID, or sessions associated with the local gateway specified by an IP address or name:

```
user@host>clear services l2tp session all
user@host>clear services l2tp session local-session-id 40553
user@host>clear services l2tp session local-gateway 10.1.1.2
user@host>clear services l2tp session local-gateway-name lns-mx960
```

- To clear statistics for all L2TP sessions, the session with a specified local session ID, or sessions associated with the local gateway specified by an IP address or name:

```
user@host>clear services l2tp session statistics all
user@host>clear services l2tp session statistics local-session-id 17967
user@host>clear services l2tp session statistics local-gateway 10.1.1.2
user@host>clear services l2tp session statistics local-gateway-name lns-mx960
```

- To display the L2TP tunnels:

**user@host> show services l2tp tunnel**

- To clear all L2TP tunnels, the tunnel with a specified local tunnel ID, or tunnels associated with the local gateway specified by an IP address or name:

```
user@host> clear services l2tp tunnel all
user@host>clear services l2tp tunnel local-tunnel-id 40553
user@host>clear services l2tp tunnel local-gateway 10.1.1.2
user@host>clear services l2tp tunnel local-gateway-name lns-mx960
```

- To clear statistics for all L2TP tunnels, the tunnel with a specified local tunnel ID, or tunnels associated with the local gateway specified by an IP address or name:

```
user@host> clear services l2tp tunnel statistics all
user@host>clear services l2tp tunnel statistics local-tunnel-id 40553
user@host>clear services l2tp tunnel statistics local-gateway 10.1.1.2
user@host>clear services l2tp tunnel statistics local-gateway-name lns-mx960
```

- Junos OS Operational Mode Commands.

---

## Testing L2TP Tunnel Configurations from the LAC

You can test L2TP tunnel configurations on the LAC and successful subscriber authentication and tunneling without bringing up a PPP user and an associated tunnel.

Issue the **test services l2tp tunnel** command from CLI operational mode to map a subscriber to an L2TP tunnel, verify the L2TP tunnel configuration (both locally on the LAC and on a back-end server such as a RADIUS server), and verify that L2TP tunnels from the LAC can be established with the remote LNS.

The Junos OS LAC implementation enables you to configure multiple tunnels from which one tunnel is chosen for tunneling a PPP subscriber. You can use the **test services l2tp**

**tunnel** command to test all possible tunnel configurations to verify that each can be established. Alternatively, you can test only a specific tunnel for the subscriber.

You must specify a configured subscriber username when you issue the command. The test generates a dummy password—*testpass*—for the subscriber, or you can optionally specify the password. The test verifies whether the subscriber identified by that username can be tunneled according to the tunnel configuration. If the subscriber can be tunneled, then the test verifies whether the L2TP tunnel can be established with the LNS according to the L2TP configuration.

You can optionally specify a tunnel ID, in which case only that tunnel is tested; the tunnel must be already configured for that username. If you omit this option, the test is applied to the full set of tunnel configurations that are returned for the username. The tunnel ID you specify is the same as that used by Tunnel-Assignment-Id (RADIUS attribute 82) and specified by the **identification** statement in the tunnel profile.

To test subscriber authentication and tunnel configuration:

- Specify only the username.

Example 1:

```
user@host> test services l2tp tunnel user test-user1@example.com
Subscriber: test-user1@example.com, authentication failed
```

The user failed authentication with the generated password and consequently was not tunneled.

Example 2:

```
user@host> test services l2tp tunnel user user23@example.com
Subscriber: user23@example.com, authentication success, l2tp tunneled
  Tunnel-name  Tunnel-peer  Logical-System  Routing-Instance  Status
  test1tunnel  192.168.2.3   default         default           Up
  test2tunnel  172.24.3.3    default         default           Peer
unresponsive
  test3tunnel  172.24.5.1    default         test              Up
```

This user was authenticated with the generated password and successfully tunneled. A set of tunnels was found to be associated with that username and the entire set was tested.

- Specify the username and the user's configured password.

```
user@host> test services l2tp tunnel user test-user1@example.com password grZ98#jW
Subscriber: test-user1@example.com, authentication success, locally terminated
```

The subscriber was authenticated. However, the user was terminated locally rather than tunneled; this means that no tunnel was found to be associated with the user.

- Specify the username and a particular tunnel for the subscriber.

```
user@host> test services l2tp tunnel user rx37w@example.com tunnel-name ce-lac
Subscriber: rx37w@example.com, authentication success, l2tp tunneled
  Tunnel-name  Tunnel-peer  Logical-System  Routing-Instance  Status
  ce-lac       192.168.5.10  default         default           Up
```

The subscriber was authenticated and tunneled. The specified tunnel was found for the subscriber and the tunnel was established, confirming the tunnel configuration.

- Specify the username, the user's configured password, and a tunnel.

```
user@host> test services l2tp tunnel user fanta4-mfg-fan@example.com password dieda499
tunnel-name tunnel5
```

```
Subscriber: fanta4-mfg-fan@example.com, authentication success, l2tp tunneled
```

The subscriber was authenticated and tunneled. The absence of tunnel information in the output indicates that the specified tunnel configuration does not exist.

## Example: Configuring an L2TP LNS

This example shows how you can configure an L2TP LNS on an MX Series router to provide tunnel endpoints for an L2TP LAC in your network. This configuration includes a dynamic profile for dual-stack subscribers.

- [Requirements on page 406](#)
- [Overview on page 407](#)
- [Configuration on page 409](#)

## Requirements

L2TP LNS requires the following hardware and software:

- MX Series 3D Universal Edge Router
- One or more MPCs
- Junos OS Release 11.4 or later

No special configuration beyond device initialization is required before you can configure this feature.

You must configure certain standard RADIUS attributes and Juniper Networks VSAs in the attribute return list on the AAA server associated with the LNS for this example to work. [Table 45 on page 406](#) lists the attributes with their required order setting and values. We recommend that you use the most current Juniper Networks RADIUS dictionary, available in the *Downloads* box on the *Junos OS Subscriber Management* page for the current release at

[http://www.juniper.net/techpubs/en\\_US/junos/information-products/pathway-pages/subscriber-access/index.html](http://www.juniper.net/techpubs/en_US/junos/information-products/pathway-pages/subscriber-access/index.html).

**Table 45: VSA and Standard RADIUS Attribute Names, Order, and Values Required for Example**

VSA Name [Number]	Order	Value
CoS-Parameter-Type [26–108]	1	T01 Multiplay
CoS-Parameter-Type [26–108]	2	T02 10m
CoS-Parameter-Type [26–108]	3	T08 -36

**Table 45: VSA and Standard RADIUS Attribute Names, Order, and Values Required for Example (*continued*)**

VSA Name [Number]	Order	Value
CoS-Parameter-Type [26–108]	4	T07 cell-mode
Framed-IPv6-Pool [100]	0	jnpr_ipv6_pool
Framed-Pool [88]	0	jnpr_pool
Egress-Policy-Name [26-11]	0	classify
Ingress-Policy-Name [26-10]	0	classify
Virtual-Router [26-1]	0	default

## Overview

The LNS employs user group profiles to apply PPP attributes to the PPP subscribers that are tunneled from the LAC. LACs in the network are clients of the LNS. The clients are associated with user group profiles in the L2TP access profile configured on the LNS. In this example, the user group profile **ce-l2tp-group-profile** specifies the following PPP attributes:

- A 30-second interval between PPP keepalive messages for L2TP tunnels from the client LAC terminating on the LNS.
- A 200-second interval that defines how long the PPP subscriber session can be idle before it is considered to have timed out.
- Both PAP and CHAP as the PPP authentication methods that apply to tunneled PPP subscribers at the LNS.

The L2TP access profile **ce-l2tp-profile** defines a set of L2TP parameters for each client LAC. In this example, the user group profile **ce-l2tp-group-profile** is associated with both clients, **lac1** and **lac2**. Both clients are configured to have the LNS renegotiate the link control protocol (LCP) with the PPP client rather than accepting the pre-negotiated LCP parameters that the LACs pass to the LNS. LCP renegotiation also causes authentication to be renegotiated by the LNS; the authentication method is specified in the user group profile. The maximum number of sessions allowed per tunnel is set to 1000 for **lac1** and to 4000 for **lac2**. A different password is configured for each LAC.

A local AAA access profile, **aaa-profile**, enables you to override the global AAA access profile, so that you can specify an authentication order, a RADIUS server that you want to use for L2TP, and a password for the server.

In this example, an address pool defines a range of IP addresses that the LNS allocates to the tunneled PPP sessions. This example defines ranges of IPv4 and IPv6 addresses.

Two inline service interfaces are enabled on the MPC located in slot 5 of the router. For each interface, 10 Gbps of bandwidth is reserved for tunnel traffic on the interface's

associated PFE. These *anchor* interfaces serve as the underlying physical interface. To enable CoS queue support on the individual logical inline service interfaces, you must configure both services encapsulation (**generic-services**) and hierarchical scheduling support on the anchors. The IPv4 address family is configured for both anchor interfaces. Both anchor interfaces are specified in the **lns\_p1** service device pool. The LNS can balance traffic loads across the two anchor interfaces when the tunnel group includes the pool.

This example uses the dynamic profile **dyn-lns-profile2** to specify characteristics of the L2TP sessions that are created or assigned dynamically when a subscriber is tunneled to the LNS. For many of the characteristics, a predefined variable is set; the variables are dynamically replaced with the appropriate values when a subscriber is tunneled to the LNS.

The interface to which the tunneled PPP client connects (**\$junos-interface-name**) is dynamically created in the routing instance (**\$junos-routing-instance**) assigned to the subscriber. Routing options for access routes include the route's next hop address (**\$junos-framed-route-nexthop**), metric (**\$junos-framed-route-cost**), and preference (**\$junos-framed-route-distance**). For access-internal routes, a dynamic IP address variable (**\$junos-subscriber-ip-address**) is set.

The logical inline service interfaces are defined by the name of a configured anchor interface (**\$junos-interface-ifd-name**) and a logical unit number (**\$junos-interface-unit**). The profile assigns **l2tp-encapsulation** as the identifier for the logical interface and specifies that each interface can be used for only a single session at a time.

The IPv4 address is set to a value returned from the AAA server. For IPv4 traffic an input firewall filter **\$junos-input-filter** and an output firewall filter **\$junos-output-filter** are attached to the interface. The loopback variable (**\$junos-loopback-interface**) derives an IP address from a loopback interface (**lo**) configured in the routing instance and uses it in IPCP negotiation as the PPP server address. Because this is a dual-stack configuration, the IPv6 address family is also set, with the addresses provided by the **\$junos-ipv6-address** variable.

The **\$junos-ipv6-address** variable is used because Router Advertisement Protocol is also configured. This variable enables AAA to allocate the first address in the prefix to be reserved as the local address for the interface. The minimal configuration for the Router Advertisement Protocol in the dynamic profile specifies the **\$junos-interface-name** and **\$junos-ipv6-ndra-prefix** variables to dynamically assign a prefix value in IPv6 neighbor discovery router advertisements.

The dynamic profile also includes the class of service configuration that is applied to the tunnel traffic. The traffic control profile (**tc-profile**) includes variables for the scheduler map (**\$junos-cos-scheduler-map**), shaping rate (**\$junos-cos-shaping-rate**), overhead accounting (**\$junos-cos-shaping-mode**), and byte adjustment **\$junos-cos-byte-adjust**. The dynamic profile applies the CoS configuration—including the forwarding class, the output traffic control profile, and the rewrite rules—to the dynamic service interfaces.

The **tg-dynamic** tunnel group configuration specifies the access profile **ce-l2tp-profile**, the local AAA profile **aaa-profile**, and the dynamic profile **dyn-lns-profile2** that are used to dynamically create LNS sessions and define the characteristics of the sessions. The **lns\_p1** service device pool associates a pool of service interfaces with the group to enable

LNS to balance traffic across the interfaces. The local gateway address 11.1.1.2 corresponds to the remote gateway address that is configured on the LAC.

**NOTE:** This example does not show all possible configuration choices.

## Configuration

**CLI Quick Configuration** To quickly configure an L2TP LNS, copy the following commands, paste them in a text file, remove any line breaks, and then copy and paste the commands into the CLI.

```
[edit]
edit access group-profile ce-l2tp-group-profile
set ppp idle-timeout 200
set ppp ppp-options pap
set ppp ppp-options chap

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure an L2TP LNS with inline service interfaces:

1. Configure a user group profile that defines the PPP configuration for tunnel subscribers.

```
[edit access]
user@host# edit group-profile ce-l2tp-group-profile
[edit access group-profile ce-l2tp-group-profile]
user@host# set ppp keepalive 30
user@host# set ppp idle-timeout 200
user@host# set ppp ppp-options chap
user@host# set ppp ppp-options pap
```

2. Configure an L2TP access profile that defines the L2TP parameters for each client LAC. This includes associating a user group profile with the client and specifying the identifier for the inline services logical interface that represents an L2TP session on the LNS.

```
[edit access profile ce-l2tp-profile client lac1]
user@host# set l2tp interface-id l2tp-encapsulation
user@host# set l2tp maximum-sessions-per-tunnel 1000
user@host# set l2tp shared-secret "lac1-secret"
user@host# set l2tp lcp-renegotiation
user@host# set user-group-profile ce-l2tp-group-profile
[edit access profile ce-l2tp-profile client lac2]
user@host# set l2tp interface-id interface-id
user@host# set l2tp maximum-sessions-per-tunnel 4000
user@host# set l2tp shared-secret "lac2-secret"
user@host# set l2tp lcp-renegotiation
user@host# set user-group-profile ce-l2tp-group-profile
```

3. Configure a AAA access profile to override the global access profile for the order of AAA authentication methods and server attributes.

```
[edit access profile aaa-profile]
user@host# set authentication-order radius
user@host# set radius-server 172.21.146.93 secret "aaa-secret"
```

4. Configure IPv4 and IPv6 address-assignment pools to allocate addresses for the clients (LACs).

```
[edit access address-assignment pool client-pool1 family inet]
user@host# set network 192.168.1.1/16
user@host# set range lns-v4-pool-range low 192.168.1.1 high 192.168.255.255
[edit access address-assignment pool client-ipv6-pool2 family inet6]
user@host# set prefix 2010:DB8::/32
user@host# set range lns-v6-pool-range low 2010:DB8:1::/48
user@host# set range lns-v6-pool-range high 2010:DB8:ffff::/48
```

5. Configure the peer interface to terminate the tunnel and the PPP server-side IPCP address (loopback address).

```
[edit interfaces ge-5/0/1
```

```
user@host# set vlan-tagging
user@host# set unit 11
[edit interfaces ge-5/0/1.11]
user@host# set vlan-id 11
user@host# set family inet address 11.1.1.2/24
[edit interfaces lo0]
user@host# set unit 0 family inet address 127.0.0.1/32
```

6. Enable inline service interfaces on an MPC.

```
[edit chassis fpc 5]
user@host# set pic 0 inline-services bandwidth 10g
user@host# set pic 2 inline-services bandwidth 10g
```

7. Configure the anchor service interfaces with services encapsulation, hierarchical scheduling, and the address family.

```
[edit interfaces si-5/0/0]
user@host# set hierarchical-scheduler maximum hierarchy-levels 2
user@host# set encapsulation generic-services
user@host# set unit 0 family inet
[edit interfaces si-5/2/0]
user@host# set hierarchical-scheduler maximum hierarchy-levels 2
user@host# set encapsulation generic-services
user@host# set unit 0 family inet
```

8. Configure a pool of service interfaces for dynamic LNS sessions.

```
[edit services service-device-pools pool lns_p1]
user@host# set interface si-5/0/0
user@host# set interface si-5/2/0
```

9. Configure a dynamic profile that dynamically creates L2TP logical interfaces for dual-stack subscribers.

```
[edit dynamic-profiles dyn-lns-profile2]
user@host# edit routing-instances $junos-routing-instance
user@host# set interface $junos-interface-name
[edit dynamic-profiles dyn-lns-profile2 routing-instances "$junos-routing-instance"]
user@host# edit routing-options access route $junos-framed-route-ip-address-prefix
[edit dynamic-profiles dyn-lns-profile2 routing-instances "$junos-routing-instance"
 routing-options access route "$junos-framed-route-ip-address-prefix"]
user@host# set next-hop $junos-framed-route-nexthop
user@host# set metric $junos-framed-route-cost
user@host# set preference $junos-framed-route-distance
[edit dynamic-profiles dyn-lns-profile2 routing-instances "$junos-routing-instance"
 routing-options access-internal]
user@host# set route $junos-subscriber-ip-address qualified-next-hop
 $junos-interface-name
[edit dynamic-profiles dyn-lns-profile2 interfaces "$junos-interface-ifd-name" unit
 "$junos-interface-unit"]
user@host# set dial-options l2tp-interface-id l2tp-encapsulation
user@host# set dial-options dedicated
user@host# set family inet unnumbered-address $junos-loopback-interface
user@host# set family inet filter input $junos-input-filter
user@host# set family inet filter output $junos-output-filter
user@host# set family inet6 address $junos-ipv6-address
set family inet6 filter input $junos-input-ipv6-filter
```

- ```

set family inet6 filter output $junos-output-ipv6-filter
[edit dynamic-profiles dyn-lns-profile2 protocols router-advertisement]
user@host# set interface $junos-interface-name prefix $junos-ipv6-ndra-prefix

```
10. Configure shaping, scheduling, and rewrite rules, and apply in the dynamic profile to tunnel traffic.
 

```

[edit class-of-service]
user@host# edit rewrite-rules dscp rewriteDSCP forwarding-class
    expedited-forwarding
user@host# set loss-priority high code-point af11
user@host# set loss-priority high code-point af12
[edit dynamic-profiles dyn-lns-profile2 class-of-service traffic-control-profiles
    tc-profile]
user@host# set scheduler-map $junos-cos-scheduler-map
user@host# set shaping-rate $junos-cos-shaping-rate
user@host# set overhead-accounting $junos-cos-shaping-mode
user@host# set overhead-accounting bytes $junos-cos-byte-adjust
[edit dynamic-profiles dyn-lns-profile2 class-of-service interfaces
    "$junos-interface-ifd-name" unit "$junos-interface-unit"]
user@host# set forwarding-class expedited-forwarding
user@host# set output-traffic-control-profile tc-profile
user@host# set rewrite-rules dscp rewriteDSCP
[edit class-of-service interfaces si-5/0/0]
user@host# set output-traffic-control-profile-remaining tc-profile

```
  11. Configure the L2TP tunnel group to bring up dynamic LNS sessions using the pool of inline service interfaces to enable load-balancing.
 

```

[edit services l2tp tunnel-group tg-dynamic]
user@host# set l2tp-access-profile ce-l2tp-profile
user@host# set local-gateway address 11.1.1.2
user@host# set aaa-access-profile aaa-profile
user@host# set dynamic-profile dyn-lns-profile2
user@host# set service-device-pool lns_pl

```

**Results** From configuration mode, confirm the access profile, group profile, AAA profile, and address-assignment pools configuration by entering the **show access** command. Confirm the inline services configuration by entering the **show chassis** command. Confirm the interface configuration by entering the **show interfaces** command. Confirm the dynamic profile configuration by entering the **show dynamic-profiles** command. Confirm the tunnel group configuration by entering the **show services l2tp** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

## Diameter Base Protocol Overview

---

The Diameter protocol is defined in *RFC 3588, Diameter Base Protocol*, and provides an alternative to RADIUS that is more flexible and extensible. The Diameter base protocol provides basic services to one or more applications (also called functions) that each runs in a different Diameter instance. The individual application provides the extended AAA functionality. Applications that use Diameter include Gx-Plus, JSRC, and PTSP.

Diameter peers communicate over a reliable TCP transport layer connection by exchanging Diameter messages that convey status, requests, and acknowledgments by means of standard Diameter AVPs and application-specific AVPs. The Diameter transport layer configuration is based on Diameter network elements (DNEs); multiple DNEs per Diameter instance are supported. Currently only the predefined *master* Diameter instance is supported, but you can configure alternative values for many of the master Diameter instance values.

Each DNE consists of a prioritized list of peers and a set of routes that define how traffic is forwarded. Each route associates a destination with a function, a function partition, and a metric. When an application sends a message to a routed destination, all routes within the Diameter instance are examined for a match. When the best route to the destination has been selected, the message is forwarded by means of the DNE that includes that route.

Multiple routes to the same destination can exist within a given DNE and in different DNEs. In the case of multiple routes that match a request for forwarding, the best route is selected as follows:

1. The route with the lowest metric is selected.
2. In the event of a tie, the route with the highest specification score is selected.

3. In the event of another tie, then the names of the DNEs are compared in lexicographical order. The route in the DNE with the lowest value is selected. For example, `dne-austin` has a lower value than `dne-boston`.
4. If the routes are tied within the same DNE, then the route names are compared in lexicographical order. The route with the lowest value is selected.

The specification score of a route is 0 by default. Points are added to the score as follows:

- If the destination realm matches the request, add 1.
- If the destination host matches the request, add 2.
- If the function matches the request, add 3.
- If the function partition matches the request, add 4.

When the state of any DNE changes, the route lookup for all destinations is reevaluated. All outstanding messages to routed destinations are rerouted as needed, or discarded.

To configure a Diameter network element, include the **network-element** statement at the **[edit diameter]** hierarchy level. Include the **route** statement at the **[edit diameter network-element element-name forwarding]** hierarchy level.

To configure a route for the DNE, include the **destination** (optional), **function** (optional), and **metric** statements at the **[edit diameter network-element element-name forwarding route dne-route-name]** hierarchy level.

Specify the Diameter peers associated with the DNE by including one or more **peer** statements at the **[edit diameter network-element element-name]** hierarchy level.

Set the priority for each peer with the **priority** statement at the **[edit diameter network-element element-name peer peer-name]** hierarchy level.

Diameter requires you to configure information about the origin node; this is the endpoint node that originates Diameter for the Diameter instance. Include the **host** and **realm** statements at the **[edit diameter]** hierarchy level to configure the Diameter origin.

You can optionally configure one or more *transports* to specify the source (local) address of the transport layer connection. To configure a Diameter transport, include the **transport** statement at the **[edit diameter]** hierarchy level. Then include the **address** statement at the **[edit diameter transport transport-name]** hierarchy level.

You can optionally specify a logical system and routing instance for the connection by including the **logical-system** and **routing-instance** statements at the **[edit diameter transport transport-name]** hierarchy level. By default, Diameter uses the *default* logical system and *master* routing instance. The logical system and routing instance for the transport connection must match that for the peer, or a configuration error is reported.

Each Diameter peer is specified by a name. Peer attributes include address and the destination TCP port used by active connections to this peer. To configure a Diameter peer, include the **peer** statement at the **[edit diameter]** hierarchy level, and then include the **address** and **connect-actively** statements at the **[edit diameter peer peer-name]** hierarchy level.

To configure the active connection, include the **port** and **transport** statements at the **[edit diameter peer *peer-name* connect-actively]** hierarchy level. The assigned transport identifies the transport layer source address used to establish active connections to the peers. **transport** statements.

## Messages Used by Diameter Applications

The following Diameter applications are supported by Junos OS:

- JSRC—A Juniper Networks Diameter application registered with the IANA (<http://www.iana.org>) as Juniper Policy-Control-JSRC, with an ID of 16777244. Communicates with the SAE (remote SRC peer).
- PTSP—A Juniper Networks Diameter application registered with the IANA (<http://www.iana.org>) as Juniper JGx, with an ID of 16777273. Communicates with the SAE (remote SRC peer).
- Gx-Plus—An application that extends the 3GPP Gx interface for wireline use cases. 3GPP Gx is registered with the IANA (<http://www.iana.org>). Communicates with a PCRF.

If data for a particular AVP included in a message is not available to the router, Gx-Plus simply omits the AVP from the message it sends to the PCRF. If the PCRF determines it has insufficient information to make a decision, it may deny the request. The Diameter answer messages include the Result-Code AVP (AVP 268); the values of this AVP convey success, failure, or errors to the requestor.

Juniper Networks has also registered the Juniper-Session-Recovery application (16777296) and two new command codes (8388628 for Juniper-Session-Events and 8388629 for Juniper-Session-Discovery) with the IANA (<http://www.iana.org>).

[Table 46 on page 423](#) describes Diameter messages the applications use.

**Table 46: Diameter Messages and Diameter Applications**

| Diameter Message | Code | Application | Description                                                                                                                                                                                                        |
|------------------|------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AA-Request (AAR) | 265  | JSRC, PTSP  | Request from the application to the SAE at new subscriber login or during SAE-application synchronization. The request can be one of three types: address-authorization, provisioning-request, or synchronization. |

**Table 46: Diameter Messages and Diameter Applications (*continued*)**

| Diameter Message            | Code | Application | Description                                                                                                                                                                                                                                     |
|-----------------------------|------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AA-Answer (AAA)             | 265  | JSRC, PTSP  | Response from the SAE to the application's AA-Request message.                                                                                                                                                                                  |
| Abort-Session-Request (ASR) | 274  | JSRC, PTSP  | Request from the SAE to the application to log out a provisioned subscriber.                                                                                                                                                                    |
| Abort-Session-Answer (ASA)  | 274  | JSRC, PTSP  | Response from the application to the SAE's ASR message. If the application sends the logout request to AAA, the ASA message includes a success notification (ACK). If the logout failed, the ASA message includes a failure notification (NAK). |
| Accounting-Request (ACR)    | 271  | JSRC, PTSP  | Request from the SAE to the application or from the application to the SAE for statistics.                                                                                                                                                      |
| Accounting-Answer (ACA)     | 271  | JSRC, PTSP  | Response to the ACR message to provide statistics for each installed policy (service).                                                                                                                                                          |

Table 46: Diameter Messages and Diameter Applications (*continued*)

| Diameter Message             | Code | Application | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------------------|------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Credit-Control-Request (CCR) | 272  | Gx-Plus     | <p>Request from Gx-Plus to the PCRF at subscriber login, logout, or update.</p> <p>An initial request (CCR-I) is sent when a subscriber logs in and AAA is requested to activate the subscriber's session. Gx-Plus retries the CCR-I message if a CCA-I message is not received from the PCRF within 10 seconds. The CCR-I message is retried up to 3 times.</p> <p>If no CCA-I is received after the 4 CCR-I messages have been sent—the first message plus 3 retries—then Gx-Plus starts sending CCR-N messages. CCR-N messages are retried forever until a success or failure response is received from the PCRF. CCR-N messages include the Juniper-Provisioning-Source AVP (AVP code 2101) set to local to notify the PCRF that the router has the authority to make a local decision regarding subscriber service activation.</p> <p>An update request (CCR-U) message is sent when a usage threshold is reached. The CCR-U reports the actual usage for all statistics. The PCRF may return a CCA-U message that includes new monitoring thresholds, service activations, service deactivations.</p> <p>A CCR-U is also sent to report the status of service activation or deactivation.</p> <p>A termination request (CCR-T) is sent at subscriber logout to inform the PCRF that a provisioned subscriber session is being terminated. CCR-T messages are retried forever until a success response is received from the PCRF.</p> |

Table 46: Diameter Messages and Diameter Applications (*continued*)

| Diameter Message                         | Code    | Application | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------|---------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Credit-Control-Answer (CCA)              | 272     | Gx-Plus     | <p>Reply from the PCRF to a CCR message.</p> <p>In response to a CCR-I, the PCRF returns a CCA-I message that indicates success (DIAMETER_SUCCESS) or failure (DIAMETER_AUTHORIZATION_REJECTED) depending on whether the subscriber has sufficient credit for the requested services. All other responses are ignored and the CCR-I is retried.</p> <p>In response to a CCR-T, the PCRF returns a CCA-T message that indicates a successful termination with a value of 2001 (DIAMETER_SUCCESS) in the Result-Code AVP. All other responses are ignored and the CCR-T is retried.</p> <p>A CCA-N is a response to a CCR-N.</p> |
| Juniper-Session-Discovery-Request (JSDR) | 8388629 | Gx-Plus     | Discovery request from the PCRF to Gx-Plus to discover subscriber sessions on the router.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Juniper-Session-Discovery-Answer (JSDA)  | 8388629 | Gx-Plus     | <p>Reply from router to a JSDR message; describes session information. The Result-Code AVP includes one of the following values, or an error value:</p> <ul style="list-style-type: none"> <li>• 2001—DIAMETER_SUCCESS; the end of the database was reached, meaning all information has been sent.</li> <li>• 2002—DIAMETER_LIMITED_SUCCESS; some of the session information was sent, but more remains to be sent.</li> </ul>                                                                                                                                                                                                |
| Juniper-Session-Event-Request (JSER)     | 8388628 | Gx-Plus     | Request from router to PCRF regarding events that take place on the router. Notifies the PCRF of certain events on the router by including the Juniper-Event-Type AVP (AVP code 2103). Events reported include cold or warm boots, explicit discovery requests, substantial configuration changes, non-response or error response from PCRF, and exhaustion of fault-tolerant resources.                                                                                                                                                                                                                                       |
| Juniper-Session-Event-Answer (JSEA)      | 8388628 | Gx-Plus     | Reply from PCRF to a JSER message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Push-Profile-Request (PPR)               | 288     | JSRC, PTSP  | Request from the SAE to the router to activate or deactivate services for a subscriber.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Table 46: Diameter Messages and Diameter Applications (*continued*)

| Diameter Message                  | Code | Application | Description                                                                                                                                                             |
|-----------------------------------|------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Push-Profile-Answer (PPA)         | 288  | JSRC, PTSP  | Response from the router to the SAE's PPR message. Includes success or failure notification for each of the service activation or deactivation commands in the request. |
| Session-Resource-Query (SRQ)      | 277  | JSRC, PTSP  | Request from the router to the SAE or from the SAE to the router to initiate synchronization between router and the SAE.                                                |
| Session-Resource-Reply (SRR)      | 277  | JSRC, PTSP  | Response to the SRQ message to begin synchronization.                                                                                                                   |
| Session-Termination-Request (STR) | 275  | JSRC, PTSP  | Notification from the router to the SAE that a provisioned subscriber has logged out.                                                                                   |
| Session-Termination-Answer (STA)  | 275  | JSRC, PTSP  | Response from the SAE to the router's STR message. Includes success or failure notification.                                                                            |

## Diameter AVPs and Diameter Applications

Diameter conveys information by including various attribute-value pairs (AVPs) in Diameter messages. [Table 47 on page 428](#) lists the standard Diameter AVPs used in interactions with the supported Diameter applications. Diameter reserves AVP code numbers 0 through 255 for RADIUS AVPs that are implemented in Diameter.

Table 47: Standard Diameter AVPs

| Attribute Number | Diameter AVP          | Application         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Type        |
|------------------|-----------------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 1                | User-Name             | Gx-Plus, JSRC       | Specifies the username. For a subscriber managed by AAA, the value is the subscriber's login name. For a static interface, the value is the interface name, which is used as the subscriber's login name.                                                                                                                                                                                                                                                                                                                                                                                                      | UTF8String  |
| 8                | Framed-IP-Address     | Gx-Plus, JSRC, PTSP | Identifies the IPv4 address configured for the subscriber. This is the same value as for RADIUS Framed-IP-Address attribute [8].                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | OctetString |
| 55               | Event-Timestamp       | Gx-Plus, JSRC, PTSP | Specifies the time of the event that triggered the message in which this AVP is included. Time is indicated in seconds since January 1, 1900, 00:00 UTC.                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Time        |
| 85               | Acct-Interim-Interval | JSRC, PTSP          | <p>Number of seconds between each interim accounting update for this session.</p> <p>The router uses the following guidelines for interim accounting:</p> <ul style="list-style-type: none"> <li>Attribute value is within the acceptable range (600 through 86,400 seconds)—Accounting is updated at the specified interval.</li> <li>Attribute value is less than the minimum acceptable value—Accounting is updated at the minimum interval (600 seconds).</li> <li>Attribute value is greater than the maximum acceptable value—Accounting is updated at the maximum interval (86,400 seconds).</li> </ul> | Unsigned32  |
| 87               | NAS-Port-Id           | Gx-Plus, JSRC, PTSP | Identifies the port of the NAS that authenticates the user. This is the same value as for RADIUS NAS-Port-Id attribute [87].                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | UTF8String  |
| 263              | Session-ID            | Gx-Plus, JSRC, PTSP | Specifies the subscriber session identifier. The router assigns the value to uniquely identify a subscriber session.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | UTF8String  |

Table 47: Standard Diameter AVPs (*continued*)

| Attribute Number | Diameter AVP | Application         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Type       |
|------------------|--------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| 268              | Result-Code  | Gx-Plus, JSRC, PTSP | <p>Indicates whether a request completed successfully. Provides an error code if the request failed.</p> <p>The following classes are recognized by Diameter:</p> <ul style="list-style-type: none"> <li>• 1xxx—Informational</li> <li>• 2xxx—Success</li> <li>• 3xxx—Protocol errors</li> <li>• 4xxx—Transient errors</li> <li>• 5xxx—Permanent failures</li> </ul> <p>Unrecognized classes, which begin with numerals 6–9 or 0, are handled as permanent failures.</p> <p>JSRC and PTSP support the following values; all non-success values are treated as permanent failures:</p> <ul style="list-style-type: none"> <li>• 1001—DIAMETER MULTI ROUND AUTH</li> <li>• 2001—DIAMETER SUCCESS</li> <li>• 5002—DIAMETER UNKNOWN SESSION ID</li> <li>• 5012—DIAMETER UNABLE TO COMPLY</li> </ul> <p>JSRC also supports the following value, which is treated as a permanent failure:</p> <ul style="list-style-type: none"> <li>• 3004—DIAMETER TOO BUSY; this is a transient condition, typically when the router already has a request in process for a specified subscriber.</li> </ul> <p>Gx-Plus supports the following values for errors in a PCRF response; when these values are received or the response is malformed or unrecognizable, the request is retried.</p> <ul style="list-style-type: none"> <li>• 3001—DIAMETER COMMAND NOT SUPPORTED; the application is not running or the command is not recognized.</li> <li>• 3004—DIAMETER TOO BUSY; the received message is above either the quota of downstream transactions or the outstanding message memory limit for messages from the network.</li> <li>• 5012—DIAMETER UNABLE TO COMPLY; the received message is greater than the local limit.</li> </ul> | Unsigned32 |

Table 47: Standard Diameter AVPs (*continued*)

| Attribute Number | Diameter AVP         | Application | Description                                                                                                                                                                                                                                                                                                                                                                                | Type       |
|------------------|----------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| 277              | Auth-Session-State   | JSRC, PTSP  | Indicates whether AAA session state is maintained. <ul style="list-style-type: none"> <li>0—STATE MAINTAINED</li> <li>1—NO STATE MAINTAINED</li> </ul>                                                                                                                                                                                                                                     | Enumerated |
| 295              | Termination-Cause    | JSRC, PTSP  | Indicates the reason why a session was terminated on the access device. <ul style="list-style-type: none"> <li>1—DIAMETER LOGOUT</li> <li>2—DIAMETER SERVICE NOT PROVIDED</li> <li>3—DIAMETER BAD ANSWER</li> <li>4—DIAMETER ADMINISTRATIVE</li> <li>5—DIAMETER LINK BROKEN</li> <li>6—DIAMETER AUTH EXPIRED</li> <li>7—DIAMETER USER MOVED</li> <li>8—DIAMETER SESSION TIMEOUT</li> </ul> | Enumerated |
| 415              | CC-Request-Number    | Gx-Plus     | Identifies a request within a session. The combination of Session-Id and CC-Request-Type is globally unique. The number is incremented for each request during the course of a session. The number is reset when a router high availability event takes place.                                                                                                                             | Unsigned32 |
| 416              | CC-Request-Type      | Gx-Plus     | Specifies the type of credit control request: <ul style="list-style-type: none"> <li>INITIAL REQUEST (1)</li> <li>UPDATE REQUEST (2)</li> <li>TERMINATION_REQUEST (3)</li> <li>EVENT REQUEST (4)</li> </ul>                                                                                                                                                                                | Enumerated |
| 431              | Granted-Service-Unit | Gx-Plus     | Contains the amount that can be provided of one or more of the following requested units specified by the client: CC-Input-Octets, CC-Output-Octets, CC-Time, or CC-Total-Octets. Included in CCA-I messages, and may be included in CCA-U messages.                                                                                                                                       | Grouped    |
| 446              | Used-Service-Unit    | Gx-Plus     | Contains the amount of the requested units that have been actually used; measured from 4 when the service is activated. The units are one or more of the following requested units specified by the client: CC-Input-Octets, CC-Output-Octets, CC-Time, or CC-Total-Octets. Included in CCR-U messages.                                                                                    | Grouped    |

Table 47: Standard Diameter AVPs (*continued*)

| Attribute Number | Diameter AVP                 | Application | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Type        |
|------------------|------------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 480              | Accounting-Record-Type       | JSRC, PTSP  | <p>Specifies the type of account record for service accounting:</p> <ul style="list-style-type: none"> <li>• <b>INTERIM_RECORD</b>—Accounting record sent between the start and stop records, at intervals specified by the Acct-Interim-Interval AVP (AVP code 85). It contains cumulative accounting data for the existing accounting session.</li> <li>• <b>START_RECORD</b>—Accounting record sent when the service is activated to initiate the accounting session. It contains accounting data relevant to the initiation of that session.</li> <li>• <b>STOP_RECORD</b>—Accounting record sent when the service is deactivated to terminate the accounting session. It contains cumulative data relevant to that session.</li> </ul> | Enumerated  |
| 1001             | Charging-Rule-Install        | Gx-Plus     | Requests the installation of the rule (activation of the service) designated by the included Charging-Rule-Name AVP (1005). This AVP has a vendor ID of 10415 (3GPP).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Grouped     |
| 1002             | Charging-Rule-Remove         | Gx-Plus     | Requests the removal of the rule (deactivation of the service) designated by the included Charging-Rule-Name AVP (1005). This AVP has a vendor ID of 10415 (3GPP).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Grouped     |
| 1005             | Charging-Rule-Name           | Gx-Plus     | Name of a specific rule that has been installed, modified, or removed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | OctetString |
| 1066             | Monitoring-Key               | Gx-Plus     | Specifies which of the monitoring structures to use. Included in Charging-Rule-Install AVP (1001). The MX router does not support aggregation of statistics across services, so the value of this AVP must be different for each service. This AVP has a vendor ID of 10415 (3GPP).                                                                                                                                                                                                                                                                                                                                                                                                                                                         | OctetString |
| 1067             | Usage-Monitoring-Information | Gx-Plus     | Sets monitoring thresholds. When service statistics match at least one of the granted service values, the router sends a CCR-U report with the current statistics to the PCRF. Includes the Monitoring-Key AVP (1066) and the Granted-Service-Unit AVP (431). This AVP has a vendor ID of 10415 (3GPP).                                                                                                                                                                                                                                                                                                                                                                                                                                     | Grouped     |

Juniper Networks AVPs are used in addition to the standard Diameter AVPs. These AVPs have an enterprise number of 2636. [Table 48 on page 432](#) lists the Juniper Networks AVPs that the supported Diameter applications use.

**Table 48: Juniper Networks Diameter AVPs**

| Attribute Number | Diameter AVP               | Application | Description                                                                                                                                   | Type        |
|------------------|----------------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| 2004             | Juniper-Service-Bundle     | JSRC        | Specifies the name of the service bundle.                                                                                                     | OctetString |
| 2010             | Juniper-DHCP-Options       | JSRC        | Specifies the client's DHCP options.                                                                                                          | OctetString |
| 2011             | Juniper-DHCP-GI-Address    | JSRC        | Specifies the DHCP relay agent's IP address.                                                                                                  | OctetString |
| 2020             | Juniper-Policy-Install     | JSRC, PTSP  | Specifies policies to be activated for the subscriber. Includes Juniper-Policy-Name and Juniper-Policy-Definition                             | Grouped     |
| 2021             | Juniper-Policy-Name        | JSRC, PTSP  | Defines the name of a policy decision.                                                                                                        | OctetString |
| 2022             | Juniper-Policy-Definition  | JSRC, PTSP  | Defines a policy decision. Includes Juniper-Policy-Name, Juniper-Template-Name, and Juniper-Substitution.                                     | Grouped     |
| 2023             | Juniper-Template-Name      | JSRC, PTSP  | Profile name defined by the router. PTSP supports only the <code>__svc_rule__</code> policy template.                                         | UTF8String  |
| 2024             | Juniper-Substitution       | JSRC, PTSP  | Defines the substitution attributes. Includes Juniper-Substitution-Name and Juniper-Substitution-Value.                                       | OctetString |
| 2025             | Juniper-Substitution-Name  | JSRC, PTSP  | Defines the name of the variable to be replaced.                                                                                              | OctetString |
| 2026             | Juniper-Substitution-Value | JSRC, PTSP  | Defines the value of the variable to be replaced.                                                                                             | OctetString |
| 2027             | Juniper-Policy-Remove      | JSRC, PTSP  | Specifies policies to be deactivated for the subscriber. Includes Juniper-Policy-Name.                                                        | Grouped     |
| 2035             | Juniper-Policy-Failed      | JSRC, PTSP  | Specifies the name of the policy activation or deactivation that failed.                                                                      | OctetString |
| 2038             | Juniper-Policy-Success     | JSRC, PTSP  | Specifies the name of the policy activation or deactivation that succeeded.                                                                   | OctetString |
| 2046             | Juniper-Logical-System     | JSRC, PTSP  | Specifies the logical system.                                                                                                                 | UTF8String  |
| 2047             | Juniper-Routing-Instance   | JSRC, PTSP  | Specifies the routing instance.                                                                                                               | UTF8String  |
| 2048             | Juniper-Jsrc-Partition     | JSRC, PTSP  | Specifies the logical system and routing instance for the subscriber or request. Includes Juniper-Logical-System and Juniper-Routing-Instance | Grouped     |

Table 48: Juniper Networks Diameter AVPs (*continued*)

| Attribute Number | Diameter AVP                 | Application   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Type       |

| 2050             | Juniper-Request-Type         | JSRC, PTSP    | Describes the type of request: <ul style="list-style-type: none"> <li>1—ADDRESS_AUTHORIZATION</li> <li>2—PROVISIONING_REQUEST</li> <li>3—SYNCHRONIZATION</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Enumerated |
| 2051             | Juniper-Synchronization-Type | JSRC, PTSP    | Describes the type of synchronization: <ul style="list-style-type: none"> <li>1—FULL-SYNC</li> <li>2—FAST-SYNC</li> <li>3—NO-STATE-TO-SYNC</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Enumerated |
| 2052             | Juniper-Synchronization      | JSRC, PTSP    | Describes the state of synchronization: <ul style="list-style-type: none"> <li>1—NO-SYNC; this is the default state</li> <li>2—SYNC-IN-PROGRESS</li> <li>3—SYNC-COMPLETE</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Enumerated |
| 2053             | Juniper-Acct-Record          | JSRC, PTSP    | Statistics data for each policy installed for this subscriber. Includes Juniper-Policy-Name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Grouped    |
| 2054             | Juniper-Acct-Collect         | JSRC, PTSP    | Specifies whether to collect accounting data for the installed policy (service) when included in the Juniper-Policy-Install AVP: <ul style="list-style-type: none"> <li>1—COLLECT_ACCT</li> <li>2—NOT_COLLECT_ACCT</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Enumerated |
| 2058             | Juniper-State-ID             | JSRC, PTSP    | Specifies the value assigned to each synchronization cycle for the purpose of identifying which messages to discard. All solicited requests containing the same <b>Juniper-State-ID</b> belong to the same Session-Resource-Query (SRQ) synchronization cycle. Messages from a previous synchronization cycle are discarded. When a new cycle begins, the value of the <b>Juniper-State-ID</b> AVP is increased by 1.<br><br><b>NOTE:</b> For solicited synchronization requests, the SRQ message contains the incremented <b>Juniper-State-ID</b> value. For unsolicited synchronization requests, the Session-Resource-Reply (SRR) message contains the incremented <b>Juniper-State-ID</b> value. | Unsigned32 |
| 2100             | Juniper-Virtual-Router       | Gx-Plus, JSRC | Specifies the name of the virtual router associated with the session.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | UTF8String |

Table 48: Juniper Networks Diameter AVPs (*continued*)

| Attribute Number | Diameter AVP                    | Application | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Type       |
|------------------|---------------------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| 2101             | Juniper-Provisioning-Source     | Gx-Plus     | Specifies the provisioning source for the session in CCR-N and JSDA messages: <ul style="list-style-type: none"> <li>1—Local</li> <li>2—Remote</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Enumerated |
| 2102             | Juniper-Provisioning-Descriptor | Gx-Plus     | Defines the group used in JSDA messages that includes the session ID, and optionally Juniper-Provisioning-Source and subscriber data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | Grouped    |
| 2103             | Juniper-Event-Type              | Gx-Plus     | Communicates the event type in JSER messages: <ul style="list-style-type: none"> <li>1—Cold boot; all sessions are lost</li> <li>2—Warm boot; sessions are preserved</li> <li>3—Discovery requested by the operator</li> <li>4—<i>Are you there?</i> (AYT); application level ping sent when the notification is due to no response or an erroneous response from the PCRF, or due to a configuration change.</li> <li>5—AWD; application-level watchdog sent by the router when there has been no other activity for 15 seconds. The watchdog is sent every 5 seconds unless preempted by higher-priority synchronization event.</li> </ul> | Enumerated |
| 2104             | Juniper-Discovery-Descriptor    | Gx-Plus     | Defines the group used in JSDR and JSDA messages that includes parameters of a discovery request: discovery type, request string, verbosity, max results.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Grouped    |
| 2105             | Juniper-Discovery-Type          | Gx-Plus     | Specifies the discovery subcommand for JSDR and JSDA messages: <ul style="list-style-type: none"> <li>1—Exact: look up the data for the specified session.</li> <li>2—Bulk: Provide get-bulk kinds of information after the specified string.</li> <li>3—Done: Stop retries for all sessions up to the specified session.</li> </ul>                                                                                                                                                                                                                                                                                                         | Enumerated |

Table 48: Juniper Networks Diameter AVPs (*continued*)

| Attribute Number | Diameter AVP            | Application | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Type       |
|------------------|-------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| 2106             | Juniper-Verbosity-Level | Gx-Plus     | Specifies the verbosity level for JSDR and JSDA messages: <ul style="list-style-type: none"> <li>1—Summary; include only the Session-Id AVP.</li> <li>2—Brief; include the Session-Id, Juniper-Virtual-Router, and Framed-IP-Address AVPs.</li> <li>3—Detail; include the Session-Id, Juniper-Provisioning-Source, Juniper-Virtual-Router, Framed-IP-Address, and Event-Timestamp AVPs.</li> <li>4—Extensive; include all available session information.</li> </ul> | Enumerated |
| 2107             | Juniper-String-A        | Gx-Plus     | Specifies a generic string that is interpreted according to the context.                                                                                                                                                                                                                                                                                                                                                                                            | UTF8String |
| 2108             | Juniper-String-B        | Gx-Plus     | Specifies a generic string that is interpreted according to the context.                                                                                                                                                                                                                                                                                                                                                                                            | UTF8String |

| 2110             | Juniper-Unsigned32-A    | Gx-Plus     | Specifies a generic, unsigned 32-bit integer that is interpreted according to the context.                                                                                                                                                                                                                                                                                                                                                                          | Unsigned32 |
| 2111             | Juniper-Unsigned32-B    | Gx-Plus     | Specifies a generic, unsigned 32-bit integer that is interpreted according to the context.                                                                                                                                                                                                                                                                                                                                                                          | Unsigned32 |
| 2112             | Juniper-Unsigned32-C    | Gx-Plus     | Specifies a generic, unsigned 32-bit integer that is interpreted according to the context.                                                                                                                                                                                                                                                                                                                                                                          | Unsigned32 |

Tekelec AVPs are used only for Gx-Plus. These AVPs have an enterprise number of 21274. [Table 49 on page 435](#) lists the Tekelec AVPs. These four variables are used to provide substitution values for user-defined CoS service variables.

Table 49: Tekelec Diameter AVPs

| Attribute Number | Diameter AVP                         | Application | Description                                               | Type        |
|------------------|--------------------------------------|-------------|-----------------------------------------------------------|-------------|
| 5555             | Tekelec-Charging-Rule-Argument-Name  | Gx-Plus     | Defines the name of the service variable to be replaced.  | OctetString |
| 5556             | Tekelec-Charging-Rule-Argument-Value | Gx-Plus     | Defines the value of the service variable to be replaced. | OctetString |

Table 49: Tekelec Diameter AVPs (*continued*)

| Attribute Number | Diameter AVP                         | Application | Description                                                                                                                                                                                                                                             | Type    |
|------------------|--------------------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| 5557             | Tekelec-Charging-Rule-Argument       | Gx-Plus     | Defines the substitution attributes used to replace service variables. Includes Tekelec-Charging-Rule-Argument-Name AVP (5555) and Tekelec-Charging-Rule-Argument-Value AVP (5556).                                                                     | Grouped |
| 5558             | Tekelec-Charging-Rule-With-Arguments | Gx-Plus     | Requests the installation of the rule (activation of the service) designated by the included Charging-Rule-Name AVP (1005). Requested service variable substitutions are provided by the optionally included Tekelec-Charging-Rule-Argument AVP (5557). | Grouped |

## Configuring Diameter

---

You configure Diameter by specifying the endpoint origin, the remote peers, the transport layer connection, and network elements that associate routes with peers. Only the master Diameter instance is currently supported. You can configure alternative values for the master instance only in the context of the master routing instance

To configure Diameter base protocol:

1. Configure the origin realm and origin host of the Diameter master instance.  
See [“Configuring the Origin Attributes of the Diameter Instance” on page 438](#)
2. Configure the Diameter peers.  
See [“Configuring Diameter Peers” on page 439](#)
3. (Optional) Configure the Diameter transport layer elements.  
See [“Configuring the Diameter Transport” on page 440](#)
4. (Optional) Configure the Diameter network elements.  
See [“Configuring Diameter Network Elements” on page 439](#)
5. (Optional) Configure trace options for troubleshooting the configuration.  
See [“Tracing Diameter Base Protocol Processes for Subscriber Access” on page 441](#).

**Related  
Documentation**

- [Diameter Base Protocol Overview on page 421](#)

---

## Configuring the Origin Attributes of the Diameter Instance

---

You can configure the identifying characteristics of the endpoint node that originates Diameter messages for the Diameter instance. The hostname is supplied as the value for the Origin-Host AVP by the Diameter instance. The realm is supplied as the value for the Origin-Realm AVP by the Diameter instance.

To configure the origin attributes for a Diameter instance:

1. Specify the name of the host that originates the Diameter message.  

```
[edit diameter origin]  
user@host# set host host14
```
2. Specify the realm of the host that originates the Diameter message.  

```
[edit diameter origin]  
user@host# set realm example.com
```

**Related  
Documentation**

- [Configuring Diameter on page 437](#)
- [origin on page 1762](#)

## Configuring Diameter Peers

You can configure the peers to which Diameter sends messages. By default, logical system *default* and routing instance *master* are used. Port 3868 is used for active connections to peers by default.

To configure a remote peer for a Diameter instance:

1. Specify the name of the Diameter peer.

```
[edit diameter]
user@host# set peer p3
```

2. Specify the address of the Diameter peer.

```
[edit diameter peer p3]
user@host# set address 192.168.23.10
```

3. (Optional) Specify a routing instance, a logical system, or a logical system and routing instance for the Diameter peer.

```
[edit diameter peer p3]
user@host# set routing-instance ri8
```

```
[edit diameter peer p3]
user@host# set logical-system ls10
```

```
[edit diameter peer p3]
user@host# set logical-system ls10 routing-instance ri8
```

4. (Optional) Specify the port that Diameter uses for active connections to the peer.

```
[edit diameter peer p3]
user@host# set connect-actively port 49152
```

5. Specify the transport that Diameter uses for active connections to the peer.

```
[edit diameter peer p3]
user@host# set connect-actively transport t6
```

**Related Documentation**

- [Configuring Diameter on page 437](#)

## Configuring Diameter Network Elements

A Diameter network element (DNE) consists of associated functions, a list of prioritized peers, and a set of forwarding rules. The forwarding rules define individual routes through a set of associated destinations, functions, and metrics.

Before you configure Diameter network elements, perform the following task:

- Define the Diameter peers. See “[Configuring Diameter Peers](#)” on page 439.

To configure a Diameter network element:

1. Specify the name of the network element.

```
[edit diameter]
user@host# set network-element dne25
```

2. (Optional) Associate one or more functions with the network element. All functions are associated by default.

```
[edit diameter network-element dne25]
user@host# set function jsrc
```

3. Associate a Diameter peer with the network element and set the priority for the peer.

```
[edit diameter network-element dne25]
user@host# set peer peer1 priority 1
```

4. Specify a route that is reachable through the network element based on the forwarding rules that you define.

```
[edit diameter network-element dne25]
user@host# set forwarding route dne-route2
```

5. Specify a metric for the route.

```
[edit diameter network-element dne25 forwarding route dne-route2]
user@host# set metric 15
```

6. (Optional) Associate the route with a destination host and realm.

```
[edit diameter network-element dne25 forwarding route dne-route2]
user@host# set destination host host5 realm example.com
```

7. (Optional) Specify a function (application) associated with the route.

```
[edit diameter network-element dne25 forwarding route dne-route2]
user@host# set function jsrc
```

**Related Documentation** • [Configuring Diameter on page 437](#)

---

## Configuring the Diameter Transport

You can configure one or more transports for a Diameter instance to set the IP address for the local connection, and optionally configure a logical system or routing instance context. By default, the logical system *default* and the routing instance *master* are used. The logical system and routing instance for the transport connection must match that for the peer, or a configuration error is reported. Multiple peers can share the same transport.

To configure a transport for a Diameter instance:

1. Configure the transport name.

```
[edit diameter]
user@host# set transport t1
```

2. Configure the local IP address for the Diameter local transport connection.

```
[edit diameter transport t1]
user@host# set address 10.9.20.0
```

3. (Optional) Configure a logical system and optionally a routing instance for the transport.

```
[edit diameter transport t1]
user@host# set logical-system ls5
```

4. (Optional) Configure a routing instance for the transport.

```
[edit diameter transport t1]
user@host# set routing-instance ri10
```

**Related Documentation**

## Tracing Diameter Base Protocol Processes for Subscriber Access

The Junos OS trace feature tracks Diameter base protocol operations and records events in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

1. Important events are logged in a file located in the `/var/log` directory. By default, the router uses the filename `jdiameterd`. You can specify a different filename, but you cannot change the directory in which trace files are located.
2. When the trace log file *filename* reaches 128 kilobytes (KB), it is compressed and renamed *filename.0.gz*. Subsequent events are logged in a new file called *filename*, until it reaches capacity again. At this point, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). For more information about how log files are created, see the *Junos OS System Log Messages Reference*.

By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

To configure Diameter base protocol tracing operations:

1. (Optional) Configure a trace log filename.  
See [“Configuring the Diameter Base Protocol Trace Log Filename” on page 442](#).
2. (Optional) Configure the number and size of trace logs.  
See [“Configuring the Number and Size of Diameter Base Protocol Log Files” on page 442](#).
3. (Optional) Configure user access to trace logs.  
See [“Configuring Access to the Diameter Base Protocol Log File” on page 443](#).

4. (Optional) Configure a regular expression to filter the information to be included in the trace log.

See “Configuring a Regular Expression for Diameter Base Protocol Messages to Be Logged” on page 443.

5. (Optional) Configure flags to specify which events are logged.

See “Configuring the Diameter Base Protocol Tracing Flags” on page 444.

6. (Optional) Configure a severity level for messages to specify which event messages are logged.

See “Configuring the Severity Level to Filter Which Diameter Base Protocol Messages Are Logged” on page 444.

---

## Configuring the Diameter Base Protocol Trace Log Filename

By default, the name of the file that records trace output for Diameter base protocol is **jdiameterd**. You can specify a different name with the **file** option.

To configure the filename for Diameter base protocol tracing operations:

- Specify the name of the file used for the trace output.

```
[edit system processes diameter-service traceoptions]  
user@host# set file diam_logfile_1
```

### Related Documentation

- [Tracing Diameter Base Protocol Processes for Subscriber Access on page 441](#)

---

## Configuring the Number and Size of Diameter Base Protocol Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format **.number.gz**. The newest archived file is **.0.gz** and the oldest archived file is **.(maximum number)-1.gz**. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, **filename**, reaches 2 MB, **filename** is compressed and renamed **filename.0.gz**, and a new file called **filename** is created. When the new **filename** reaches 2 MB, **filename.0.gz** is renamed **filename.1.gz** and **filename** is compressed and renamed **filename.0.gz**. This process repeats until there are 20 trace files. Then the oldest file, **filename.19.gz**, is simply overwritten when the next oldest file, **filename.18.gz** is compressed and renamed to **filename.19.gz**.

To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output. (Diameter base protocol supports the **files** and **size** options for the **traceoptions** statement.)

```
[edit system processes diameter-service traceoptions]
user@host# set file diam_1 _logfile_1 files 20 size 2097152
```

**Related  
Documentation**

- [Tracing Diameter Base Protocol Processes for Subscriber Access on page 441](#)

## Configuring Access to the Diameter Base Protocol Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

To specify that all users can read the log file:

- Configure the log file to be world-readable.

```
[edit system processes diameter-service traceoptions]
user@host# set file diam_1 _logfile_1 world-readable
```

To explicitly set the default behavior, only the user who configured tracing can read the log file:

- Configure the log file to be no-world-readable.

```
[edit system processes diameter-service traceoptions]
user@host# set file diam_1 _logfile_1 no-world-readable
```

**Related  
Documentation**

- [Tracing Diameter Base Protocol Processes for Subscriber Access on page 441](#)

## Configuring a Regular Expression for Diameter Base Protocol Messages to Be Logged

By default, the trace operation output includes all messages relevant to the logged events.

You can refine the output by including regular expressions to be matched.

To configure regular expressions to be matched:

- Configure the regular expression.

```
[edit system processes diameter-service traceoptions]
user@host# set file diam_1 _logfile_1 match regex
```

**Related  
Documentation**

- [Tracing Diameter Base Protocol Processes for Subscriber Access on page 441](#)

## Configuring the Diameter Base Protocol Tracing Flags

---

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

To configure the flags for the events to be logged:

- Configure the flags.

```
[edit system processes diameter-service traceoptions]  
user@host# set flag dne
```

**Related Documentation** • [Tracing Diameter Base Protocol Processes for Subscriber Access on page 441](#)

## Configuring the Severity Level to Filter Which Diameter Base Protocol Messages Are Logged

---

The messages associated with a logged event are categorized according to severity level. You can use the severity level to determine which messages are logged for the event type. The severity level that you configure depends on the issue that you are trying to resolve. In some cases you might be interested in seeing all messages relevant to the logged event, so you specify **all** or **verbose**. Either choice generates a large amount of output. You can specify a more restrictive severity level, such as **notice** or **info** to filter the messages. By default, the trace operation output includes only messages with a severity level of **error**.

To configure the type of messages to be logged:

- Configure the message severity level.

```
[edit system processes diameter-service traceoptions]  
user@host# set level severity
```

**Related Documentation** • [Tracing Diameter Base Protocol Processes for Subscriber Access on page 441](#)

## Verifying Diameter Node, Instance, and Route Information

---

**Purpose** View Diameter node information:

**Action** • To display summary information about all Diameter nodes:

```
user@host> show diameter
```

- To display summary information about all Diameter nodes and add information about Diameter functions, instances, network elements, and peers:

```
user@host> show diameter brief
```

- To display brief information about all Diameter nodes and add information about Diameter routes:

**user@host> show diameter detail**

- To display summary information about all Diameter instances:

**user@host> show diameter instance**

- To display detailed information about all Diameter instances:

**user@host> show diameter instance detail**

- To display information about a specific Diameter instance, add the instance name to the command:

**user@host> show diameter instance master**

**user@host> show diameter instance detail master**

- To display summary information about all Diameter routes:

**user@host> show diameter route**

- To display detailed information about all Diameter routes:

**user@host> show diameter route detail**

- To display information about a specific Diameter route, add the route name to the command:

**user@host> show diameter route dne-route2**

**user@host> show diameter route detail dne-route2**

## Verifying and Managing Diameter Function Information

**Purpose** View or clear Diameter function information:

**Action** • To display summary information about all functions associated with Diameter:

**user@host> show diameter function**

- To display detailed information about all functions associated with Diameter:

**user@host> show diameter function detail**

- To display information about a specific function associated with Diameter, add the function name to the command:

**user@host> show diameter function jsrsc**

**user@host> show diameter function detail ptsp**

- To display summary statistics about all functions associated with Diameter:

**user@host> show diameter function statistics**

- To display detailed statistics about all functions associated with Diameter:

**user@host> show diameter function statistics detail**

- To display statistics about a specific function associated with Diameter, add the function name to the command:

**user@host> show diameter function statistics gx-plus**

**user@host> show diameter function statistics detail jsrsc**

- To delete current statistics for all functions associated with Diameter:

**user@host>clear diameter function statistics**

- To delete current statistics for a specific function associated with Diameter:

**user@host>clear diameter function gx-plus statistics**

- Related Documentation**

---

## Verifying and Managing Diameter Peer Information

---

**Purpose** View or clear Diameter peer information:

- Action**
- To display summary information about all Diameter peers:

**user@host> show diameter peer**

- To display detailed information about all Diameter peers:

**user@host> show diameter peer detail**

- To display information about a specific Diameter peer, add the peer name to the command:

**user@host> show diameter peer peer235**

**user@host> show diameter peer detail peer235**

- To display summary information about Diameter peer-to-network-element mapping for all peers:

**user@host> show diameter peer map**

- To display detailed information about Diameter peer-to-network-element mapping for all peers:

**user@host> show diameter peer map detail**

- To display information about Diameter peer-to-network-element mapping for a specified peer, add the peer name to the command:

**user@host> show diameter peer map peer235**

**user@host> show diameter peer map detail peer235**

- To display summary statistics about all Diameter peers:

**user@host> show diameter peer statistics**

- To display detailed statistics about all Diameter peers:  
`user@host> show diameter peer statistics detail`
- To display summary statistics about a specified Diameter peer:  
`user@host> show diameter peer statistics peer235`
- To display detailed statistics about a specified Diameter peer:  
`user@host> show diameter peer statistics detail peer235`
- To delete the specified Diameter peer and all of its statistics.  
`user@host>clear diameter peer peer5 connection`
- To delete the specified Diameter peer and its current statistics:  
`user@host>clear diameter peer peer5 statistics`

- Related Documentation**

## Verifying Diameter Network Element Information

**Purpose** View Diameter network element information:

- Action**
- To display summary information about Diameter network elements:  
`user@host> show diameter network-element`
  - To display detailed information about Diameter network elements:  
`user@host> show diameter network-element detail`
  - To display information about Diameter network elements for a specified network element, include the element name in the command:  
`user@host> show diameter network-element dne-1`  
`user@host> show diameter network-element detail dne-1`
  - To display summary information about Diameter network-element-to-peer mapping for all network elements:  
`user@host> show diameter network-element map`
  - To display detailed information about Diameter network-element-to-peer mapping for all network elements:  
`user@host> show diameter network-element map detail`

- Related Documentation**
- [Configuring Diameter on page 437](#)

## Troubleshooting Diameter Network Configuration

---

**Problem** A misconfiguration of the network can prevent Diameter from functioning properly. Configuration options for the Diameter base protocol are simple in the current release, simplifying discovery of a misconfiguration.

The output of the **show diameter peer** command indicates a peer is in the no-activation state. In this case issue the **show diameter peer map** and **show diameter network-element map** commands to determine which network elements use the peer. The output of these commands can indicate why the peer is not activated. For example, all the associated network elements might have higher-priority peers in the open state.

The failed-to-forward counters are increasing in the output of the **show diameter function statistics detail** command. This can indicate that the routes to the peer are incorrectly configured. Check the network connectivity, then use the **show diameter routes** command to determine whether application traffic is being correctly forwarded.

**Cause** Typical misconfigurations appear in the routes, peers, and network element configurations.

**Solution** Use the appropriate statements to correct the misconfiguration.

**Related Documentation**

- show diameter function statistics
- show diameter network-element map
- show diameter peer
- show diameter peer map
- show diameter route

## Troubleshooting Diameter Network Connectivity

---

**Problem** In some circumstances, problems can arise with network connectivity to Diameter peers. The problem may originate with the peer or the peer host.

The output of the **show diameter peer** command indicates a peer is in the suspended, rejected, or bad-peer state.

**Cause** The suspended state indicates that the peer is not responding or has some other malfunction, or the network path to the peer does not exist.

The rejected state indicates that the network connection has been rejected by the peer.

The bad-peer state indicates that the network connection has been rejected by the router on which the peer resides.

**Solution** Determine how persistent the problem is by issuing the **show diameter peer statistics peer-name brief** command to check the connectivity statistics.

# JSRC and Juniper Networks Session Resource Control (SRC) Overview

- [Juniper Networks Session and Resource Control \(SRC\) and JSRC Overview on page 451](#)
- [Service Accounting with JSRC on page 452](#)
- [Understanding JSRC-SAE Interactions on page 454](#)

## Juniper Networks Session and Resource Control (SRC) and JSRC Overview

The Juniper Networks Session and Resource Control (SRC) environment provides a central administrative point for managing subscribers and their services. The SRC software runs on Juniper Networks C Series Controllers. The SRC software uses the Diameter protocol for communications between the local SRC peer on a Juniper Networks routing platform and the remote SRC peer on a C Series Controller. The local SRC peer is known as JSRC and is part of the AAA application. The remote SRC peer is the service activation engine (SAE); the SAE acts as the controlling agent in the SRC environment. JSRC and the SAE jointly provide the remote control enforcement functionality (RCEF).

JSRC has the following responsibilities:

- Request address authorization from the SAE.
- Request service activations from the SAE.
- Activate and deactivate services as specified by the SAE. JSRC can activate multiple policies with the same service (dynamic profile) name.
- Optionally report volume statistics for service accounting.
- Log out subscribers as specified by the SAE.
- Update the SAE with status of new service activations and deactivations.
- Synchronize subscriber state and service information with the SAE.
- Notify the SAE when subscribers log out.

The SRC software enables the SAE to activate and deactivate subscriber services (described by SRC policies) and log out subscribers. The SAE can control only those resources that have been provisioned through SAE. Therefore, the SAE receives information about only those subscribers for whom JSRC has requested provisioning

from the SAE. For example, when a subscriber logs in, but the configuration did not require the session activation path to include SAE provisioning, the SAE does not receive information about this subscriber and cannot control the subscriber session.

Similarly, the SAE can control only the subscriber services that it has activated. When a service is not activated from the SAE—a RADIUS-activated service, for example—the SAE receives no information about the service and has no control over it.

The SAE can also direct JSRC to collect accounting statistics per service session.

**NOTE:** More than one Diameter-based application (function) can run on a router simultaneously.

---

## Hardware Requirements for JSRC for Subscriber Access

JSRC is supported on Juniper Networks MX Series 3D Universal Edge Routers. JSRC currently supports subscriber sessions on static and dynamic interfaces.

### Related Documentation

- [Understanding JSRC-SAE Interactions on page 454](#)
- [Messages Used by Diameter Applications on page 423](#)
- [Diameter AVPs and Diameter Applications on page 427](#)
- [Configuring JSRC on page 457](#)

## Service Accounting with JSRC

---

A service session represents a service for a specific subscriber. Service sessions exist in the context of a subscriber session. JSRC activates and deactivates services as specified by the SAE (remote SRC peer). JSRC can collect and report service accounting data by volume. JSRC accounting requires that either classic firewall filters or fast update firewall filters be configured to count service packets—the service packet information provides the volume statistics.

**NOTE:** JSRC supports only volume statistics accounting for service sessions. Time statistics and subscriber accounting are not supported.

---

JSRC service accounting supports both accounting based on service activation/deactivation and interim accounting.

- **Service activation/deactivation accounting**—When accounting is enabled, JSRC sends an accounting start message to the SAE when it activates a service and an accounting stop message when it deactivates the service. The start message initiates the accounting session and provides initial information about the service session. The stop message terminates the accounting session and reports the final (cumulative) accounting data.

- Interim accounting—When interim accounting is enabled for a service session, JSRC sends interim accounting messages to the SAE at a specified interval to report the cumulative accounting information available at that time. Interim accounting is ignored when accounting is not enabled for the corresponding service session.

JSRC accounting for a service begins when the service is activated, and remains in effect while the service is active. The SAE specifies the service (policy) to be activated for the subscriber with the Juniper-Policy-Install AVP (AVP code 2020). When this AVP includes the Juniper-Acct-Collect AVP (AVP code 2054), JSRC initiates service activation/deactivation accounting for the service.

JSRC initiates interim accounting when the Juniper-Policy-Install AVP includes the Acct-Interim-Interval AVP (AVP code 85). In this case, JSRC updates the accounting values at the interval specified in the AVP— in the range 600 through 86,400 seconds. Aggregate counters are reported for the dual stack case.

JSRC and the SAE exchange Diameter Accounting-Request (ACR) and Accounting-Answer (ACA) messages to communicate accounting data. Both messages include the Juniper-Acct-Record AVP (AVP code 2053) to identify the service for which accounting information is requested.

JSRC sends ACR messages to report accounting data to the SAE. The ACR message includes the Accounting-Record-Type AVP (AVP code 480) to specify the kind of accounting record that it is sending. When a service is activated, this AVP has a value of START\_RECORD. When a service is deactivated, it has a value of STOP\_RECORD. For interim accounting, ACR messages are sent at the specified accounting interval and the AVP has a value of INTERIM\_RECORD.

In addition to specifying the accounting record type, the ACR messages include standard RADIUS attributes to specify the desired statistics: Acct-Input-Octets [42], Acct-Output-Octets [43], Acct-Input-Packets [47], Acct-Output-Packets [48], and Acct-Session-Time [46].

The SAE returns ACA messages to the JSRC to acknowledge receipt of the ACR messages.

An access profile specifies subscriber access authentication and accounting parameters. When a service is activated through JSRC, the accounting reports can be sent either to the SAE or to RADIUS. The default configuration sends the reports to the SAE; you can also configure this by including the **service accounting-order activation-protocol** statement in the access profile. To send the reports instead to the RADIUS server, include the **service accounting-order radius** statement in the access profile.

When a service is activated through RADIUS rather than through JSRC, the accounting reports of the service session are sent to the RADIUS server.

## Understanding JSRC-SAE Interactions

---

This topic describes the sequences of Diameter messages exchanged between JSRC (the local SRC peer) and the SAE (the remote SRC peer) as they interact to perform the following tasks for subscriber access:

- Subscriber login
- Service activation
- Service deactivation
- Resynchronization
- SAE-initiated subscriber logout
- Statistics collection and reporting
- Subscriber-initiated logout

### Subscriber Login

JSRC authorization is enabled for DHCP subscribers when you include the **authorization-order jsrc** statement at the **[edit access profile *profile-name*]** hierarchy level. This setting causes AAA to ignore the authentication order setting in the access profile. As a result, AAA does not authenticate the DHCP subscribers. For non-DHCP subscribers, AAA ignores the **authorization-order** statement.

When a DHCP subscriber attempts to log in, DHCP sends an authentication request to AAA. In turn, JSRC sends a Diameter AA-Request message to the SAE. SAE returns a Diameter AA-Answer message that can include the Framed-IP-Address attribute and the Juniper-DHCP-Options AVP (AVP code 2010). JSRC ignores any other optional AVPs included in this AA-Answer message.

JSRC provisioning is enabled for DHCP (and SSC) subscribers when you include the **provisioning-order** statement at the **[edit access profile *profile-name*]** hierarchy level. When the application requests AAA to activate the subscriber's session, JSRC sends an AA-Request message that includes the Juniper-Request-Type AVP (AVP code 2050) with a value that indicates service provisioning is requested from the SAE.

The SAE returns a AA-Answer message that contains an ACK if the request is accepted or a NAK if the request is denied. If the request is accepted, the AA-Answer message includes the Juniper-Policy-Install AVP (AVP code 2020), which is used to specify the service to attach to the subscriber's interface. When this AVP is included, the SAE sets the Result-Code AVP to 1001 (DIAMETER\_MULTI\_ROUND\_AUTH). This code means that the JSRC must send another AA-Request message to the SAE to report the success or failure of the policy instantiation (service activation) by AAA. JSRC ignores any other optional AVPs included in this AA-Answer message. The SAE returns an AA-Answer message to acknowledge this second AA-Request message.

## Subscriber Service Activation and Deactivation

SAE policies provision subscriber services. After a subscriber is logged in, the SAE can send a PPR message to JSRC to activate or deactivate services. A given PPR can include the Juniper-Policy-Install AVP (AVP code 2020) to activate a service, the Juniper-Policy-Remove AVP (AVP code 2027) to deactivate a service, or both (for different services). A PPR can include no more than three of these AVPs (install, remove, or mixed).

JSRC sends a PPA message to the SAE when it has completed the tasks requested in the PPR. The PPA indicates the success or failure of the actions requested in the PPR.

**NOTE:** If you use RADIUS or the CLI to deactivate a service that the SAE, the SAE becomes unsynchronized with the state of subscribers on the routing engine.

## Subscriber Resynchronization

During resynchronization, JSRC informs the SAE about the services that are active for the provisioned subscribers. Either JSRC or the SAE initiates the resynchronization.

- The SAE initiates resynchronization at startup or when a backup SAE takes over session control due to resource limits or conditions on the primary SAE. The SAE clears its database of all entries in preparation for the synchronization.
- JSRC initiates resynchronization at JSRC startup, such as when AAA starts or restarts.

JSRC can also initiate resynchronization in another circumstance. When an SAE in a multi-SAE environment becomes active, it must send an SRQ to JSRC as its first message. JSRC then locks the Origin-Host AVP of the active SAE. JSRC subsequently triggers resynchronization if it receives a message from any other SAE as indicated by the Origin-Host AVP. Such an incident can occur if communication between the active SAE and a standby SAE is interrupted.

Both entities initiate a resynchronization by sending an SRQ message. The recipient responds with an SRR message. After the SRR is sent, regardless of whether the SAE or JSRC initiates the synchronization, JSRC sends an AA-Request message to the SAE for each provisioned subscriber present in the session database. The AA-Request message includes a Juniper-Policy-Install AVP for the active services. The SAE returns an AA-Answer message with an ACK to acknowledge receipt.

## Subscriber Session Terminated by the SAE

When the SAE terminates a subscriber session, it sends an ASR message to JSRC. JSRC causes AAA to send a logout request to the DHCP (or SSC) client application. When the DHCP client application accepts the logout request, JSRC includes an ACK in the ASR message it sends to the SAE to signify success. If the DHCP client application does not accept the request, then JSRC includes a NAK in the ASR to signify failure. The DHCP client application is responsible for initiating the actual logout sequence with AAA.

## Statistics Collection and Reporting per Service Rule

Statistics information can be sent from the router to the SAE or from the SAE to the router. Both the Diameter Accounting-Request (ACR) and Accounting-Answer (ACA) messages include the Juniper-Acct-Record AVP (AVP code 2053), which identifies the policy (service) for which accounting information is requested.

## Subscriber Logout

When the DHCP (or SSC) client application sends a subscriber logout notice to AAA, JSRC sends an STR message to notify the SAE that the provisioned subscriber session is being terminated. The SAE returns an STA message to JSRC, and JSRC notifies DHCP that the logout is complete.

## Configuring JSRC

---

You can configure the JSRC client application to work with Session and Resource Control (SRC) to centrally manage subscribers and services. JSRC requests address and service authorizations from the remote SRC peer (the SAE), activates and deactivates services as specified by the SAE, logs out subscribers as specified by the SAE, and synchronizes subscriber state and service information with the SAE.

To configure JSRC:

1. Configure the JSRC partition.  
[See “Configuring the JSRC Partition” on page 458.](#)
2. Assign the JSRC partition.  
[See “Assigning a Partition to JSRC” on page 459.](#)
3. Configure JSRC authorization for subscribers.  
[See “Authorizing Subscribers with JSRC” on page 459.](#)
4. Configure JSRC provisioning for subscribers.  
[See “Provisioning Subscribers with JSRC” on page 460.](#)
5. Configure service accounting by JSRC.  
[See “Configuring Service Accounting with JSRC” on page 460.](#)
6. Configure JSRC event tracing as part of general authentication service tracing operations.  
[See “Tracing General Authentication Service Processes” on page 163.](#)

- Related Documentation**
- [Juniper Networks Session and Resource Control \(SRC\) and JSRC Overview on page 451](#)

## Configuring the JSRC Partition

---

JSRC works within a specific logical system: routing instance context, called a partition.

**NOTE:** Currently, only a single partition is supported; you must configure it within the default logical system: routing instance context.

Before you configure the JSRC partition, perform the following task:

- Configure the Diameter instance at the **[edit diameter]** hierarchy level. See [“Configuring Diameter” on page 437](#).

Configuration for the JSRC partition consists of naming the partition and then associating a Diameter instance, the SAE hostname, and the SAE realm with the partition.

To configure the JSRC partition:

1. Create the partition.

```
[edit jsrc]
user@host# set partition partition1
```

2. Specify the Diameter instance for the JSRC partition.

**NOTE:** Currently, only the default Diameter instance, *master*, is supported.

```
[edit jsrc partition partition1]
user@host# set diameter-instance master
```

3. Configure the destination host for the JSRC partition.

```
[edit jsrc partition partition1]
user@host# set destination-host sae1
```

4. Configure the destination realm for the JSRC partition.

```
[edit jsrc partition partition1]
user@host# set destination-realm generic.example.com
```

- Related Documentation**
- [Configuring JSRC on page 457](#)

---

## Assigning a Partition to JSRC

---

You must associate a configured JSRC partition with the JSRC instance that you are configuring.

Before you assign a partition to JSRC, perform the following task:

- Configure the JSRC partition. See [“Configuring the JSRC Partition” on page 458](#)

To assign the JSRC partition:

- Specify the partition name.

```
[edit jsrc]  
user@host# set jsrc-partition partition1
```

### Related Documentation

- [Configuring JSRC on page 457](#)

---

## Authorizing Subscribers with JSRC

---

You can configure AAA to use JSRC in an SRC environment to request authorization from the SAE when AAA is verifying whether a DHCP subscriber can access the router. When JSRC authorization is configured, AAA ignores any configured authentication order settings.

Before you configure JSRC authorization, perform the following tasks:

- Create the subscriber access profile at the **[edit access profile]** hierarchy level.
- Define the subscriber username with the **username-include** statement in the authentication configuration for DHCP local server or DHCP relay.

To configure JSRC authorization:

- Specify **jsrc** as the authorization method in the profile.

```
[edit access profile dhcpsub1]  
user@host# set authorization-order jsrc
```

### Related Documentation

- [Creating Unique Usernames for DHCP Clients on page 222](#)
- [profile on page 1823](#)

## Provisioning Subscribers with JSRC

---

You can configure AAA to use JSRC in an SRC environment to request provisioning from the SAE to instantiate services for an authenticated subscriber.

Before you configure JSRC provisioning for subscribers, perform the following task:

- Create the subscriber access profile at the **[edit access profile]** hierarchy level.

To configure JSRC provisioning:

- Specify **jsrc** as the provisioning method in the profile.

```
[edit access profile dhcpsub1]  
user@host# set provisioning-order jsrc
```

**Related  
Documentation**

- [Configuring JSRC on page 457](#)

## Configuring Service Accounting with JSRC

---

You can configure JSRC to report accounting statistics for service sessions.

In addition to the configuration shown here, the network context for JSRC service accounting includes the configuration of firewall filters to count the statistics, Diameter, JSRC, the subscriber services, RADIUS, and the SRC.

To configure service accounting by JSRC:

1. Configure JSRC to provision subscriber services.

```
[edit access profile profile-name]  
user@host# set provisioning-order jsrc
```

2. Configure service accounting to be provided by the application that provisions the service—JSRC.

```
[edit access profile profile-name service]  
user@host# set accounting-order activation-protocol
```

**Related  
Documentation**

- [Service Accounting with JSRC on page 452](#)

# Subscribers on Static Interfaces

- [Subscribers on Static Interfaces Overview on page 461](#)

## Subscribers on Static Interfaces Overview

---

You can associate subscribers with statically configured interfaces and provide dynamic service activation and activation for these subscribers. When the static interface comes up, the event is treated as a subscriber login. When the interface goes down, it is treated as a subscriber logout. After the subscribers are present in the session database (SDB), JSRC can report the subscribers to the SAE so that the SRC software can subsequently manage the subscribers.

Alternatively, you can configure the static subscribers to be authenticated and authorized by means of RADIUS. In this case, RADIUS can then activate and deactivate services with change of authorization (CoA) messages. However, this configuration does not prevent the interface from coming up and forwarding traffic. Further, authorization parameters are not imposed on the subscriber interface.

Currently, only Ethernet interfaces support static subscribers. Only one static subscriber can exist over a given interface. An interface cannot appear in more than one group. Static subscribers cannot be created over dynamic interfaces.

Static subscribers are intended to work with JSRC. Include the **provisioning-order jsrc** statement at the **[edit access profile *profile-name*]** hierarchy level to enable JSRC to handle the subscribers at the direction of the SRC software.

If the authentication request fails for a static subscriber, a 60-minute, nonconfigurable timer begins counting down. The request is reissued when the timer expires. This action repeats for as long as the interface is operationally up.

You can force a logout of the static subscriber by issuing the **request services static-subscribers logout interface *interface-name*** command. A static subscriber can also be logged out by AAA or an external policy manager. In both cases, no subsequent logins can take place on the underlying interface until you reset the state by issuing the **request services static-subscribers login interface *interface-name*** command or the router or process reboots.

You can log out an interface group by issuing the **request services static-subscriber logout group group-name** command. You can subsequently log in a group of interfaces by issuing the **request services static-subscriber login group group-name** command.

No new CLI statements are required to configure the dynamic profile for static subscribers. The dynamic profile can be very simple; it is activated at login and deactivated at logout. If you do not configure a profile, then the *junos-default-profile* is automatically activated.

During a graceful Routing Engine switchover (GRES) event, active static subscribers are recovered, inactive subscribers are cleaned up, and logout continues for subscribers that were in the process of logging out.

Include the **static-subscribers** statement at the **[edit system services]** hierarchy level to configure static subscribers. Include the **traceoptions** statement at the **[edit system processes static-subscribers]** hierarchy level to configure tracing operations for static subscribers.

You can configure the access profile, dynamic profile, and authentication parameters for all static subscribers or for a particular group of static subscribers:

- To configure the access profile that triggers AAA services for the static subscriber for all static subscribers, include the **access-profile** statement at the **[edit system services static-subscribers]** hierarchy level. Alternatively, include this statement at the **[edit system services static-subscribers group group-name]** hierarchy level to apply the profile to a specific group and override a top-level configuration.
- To configure the dynamic profile that is instantiated when the static subscriber logs in for all static subscribers, include the **dynamic-profile** statement at the **[edit system services static-subscribers]** hierarchy level. Alternatively, include this statement at the **[edit system services static-subscribers group group-name]** hierarchy level to apply the profile to a specific group and override a top-level configuration. Do not specify a dynamic profile that creates a dynamic interface.
- To configure the authentication parameters that trigger an Access-Request message to AAA for all static subscribers, include the **authentication** statement at the **[edit system services static-subscribers]** hierarchy level. Alternatively, include the statement at the **[edit system services static-subscribers group group-name]** hierarchy level to configure authentication for a specific group and override a top-level configuration. If you do not configure authentication, then by default the interface name is modified and used as the default username for the subscriber session and the authentication request.

The configurable authentication parameters include the password and details of how the username is formed. Include the **password** statement at the **[edit system services static-subscribers authentication]** hierarchy level to configure the authentication password for all static subscribers. Alternatively, include the statement at the **[edit system services static-subscribers group group-name authentication]** hierarchy level to configure authentication for a specific group and override a top-level configuration.

The username that is sent to AAA for authentication must include at least one of the following attributes:

- Domain name
- User prefix
- Interface name
- Logical system name
- Routing instance name

To configure how the username is formed for all static subscribers, include the desired statements at the **[edit system services static-subscribers authentication]** hierarchy level: **domain-name**, **user-prefix**, **logical-system-name**, or **routing-instance-name**. Alternatively, include the desired statements at the **[edit system services static-subscribers group group-name authentication]** hierarchy level to configure the username for a specific group and override a top-level configuration.

If you change the authentication configuration for an existing group or for static subscribers globally, the change has no effect on existing static subscribers. The changes are applied only to any new logins that are attempted after you commit the changes.

A group configuration must specify all the interfaces that you expect to support static subscribers. Include the **interface** statement at the **[edit system services static-subscribers group group-name]** hierarchy level to specify the interfaces. This statement enables you to specify a single interface or a range of interfaces.

You must also statically configure these interfaces before any static subscribers can be supported on them. You must configure the static interfaces in the same logical system and routing instance as the group that includes the interfaces.

If you change the interfaces that are included in an existing interface group, existing static subscribers are automatically logged out and then back in when you commit the changes. However, changes made to the configuration of the interface itself have no effect on the login or logout state of the static subscriber associated with that interface.

By default, multiple subscribers are not supported on top of the same VLAN logical interface. If you want to support this behavior, then you can manage multiple subscribers on a single logical interface in one of two ways. You can either merge attributes such as firewall filters and CoS attributes for the multiple subscribers, or you can replace the current attributes with those of a new subscriber whenever a new subscriber logs into the underlying VLAN logical interface.

- To enable attribute merging for all static interfaces, include the **aggregate-clients merge** statement at the **[edit system services static-subscribers]** hierarchy level. Alternatively, include this statement at the **[edit system services static-subscribers group group-name]** hierarchy level to enable attribute merging for a specific group of static interfaces and override a top-level configuration.
- To enable attribute replacement for all static interfaces, include the **aggregate-clients replace** statement at the **[edit system services static-subscribers]** hierarchy level.

Alternatively, include this statement at the **[edit system services static-subscribers group *group-name*]** hierarchy level to enable attribute replacement for a specific group of static interfaces and override a top-level configuration.

## **Configuring Subscribers over Static Interfaces**

---

This topic describes the procedure for configuring subscribers over static interfaces (static subscribers).

Before you configure subscribers over static interfaces, perform the following tasks:

- Configure the static interfaces on which you want to create and manage subscribers.
- Create an access profile to trigger AAA services for static subscribers.
- Create a dynamic profile that is instantiated when static subscribers log in.

To configure static subscribers:

1. Specify the global access profile that triggers AAA services for static subscribers.  
[See “Specifying the Static Subscriber Global Access Profile” on page 467.](#)
2. Specify the global dynamic profile that is instantiated when static subscribers log in.  
[See “Specifying the Static Subscriber Global Dynamic Profile” on page 468.](#)
3. Configure global method to handle multiple subscribers on a VLAN Logical Interface.  
[See “Enabling Multiple Subscribers on a VLAN Logical Interface for All Static Subscribers” on page 468](#)
4. Configure the global authentication password for static subscribers.  
[See “Configuring the Static Subscriber Global Authentication Password” on page 469.](#)
5. Configure the global username for static subscribers.  
[See “Configuring the Static Subscriber Global Username” on page 469.](#)
6. Configure a group of subscribers to share values different from the global configuration.  
[See “Creating a Static Subscriber Group” on page 470.](#)
7. Specify the access profile for the static subscriber group.  
[See “Specifying the Static Subscriber Group Access Profile” on page 471.](#)
8. Specify the dynamic profile for the static subscriber group.  
[See “Specifying the Static Subscriber Group Dynamic Profile” on page 471.](#)
9. Configure method to handle multiple subscribers on a VLAN Logical Interface for a static subscriber group.  
[See “Enabling Multiple Subscribers on a VLAN Logical Interface for a Static Subscriber Group” on page 472.](#)
10. Configure the authentication password for the static subscriber group.

See [“Configuring the Static Subscriber Group Authentication Password” on page 472.](#)

11. Configure the username for the static subscriber group.

See [“Configuring the Static Subscriber Group Username” on page 473.](#)

12. (Optional) Force a static subscriber to be logged out from an interface.

See [“Forcing a Static Subscriber to Be Logged Out” on page 474.](#)

13. (Optional) Enable an interface to accept static subscriber logins.

See [“Resetting the State of an Interface for Static Subscriber Login” on page 474.](#)

14. (Optional) Force static subscribers to be logged out from a group of interfaces.

See [“Forcing a Group of Static Subscribers to Be Logged Out” on page 474.](#)

15. (Optional) Enable a group of interfaces to accept static subscriber logins.

See [“Resetting the State of an Interface Group for Static Subscriber Login” on page 474.](#)

16. Configure trace options for troubleshooting the configuration.

See [“Tracing Static Subscriber Operations” on page 475.](#)

## Specifying the Static Subscriber Global Access Profile

You specify a previously created access profile that triggers AAA services for all static subscribers. This value can be overridden for a group of static subscribers when a different profile is configured for that group.

To specify the access profile used for all static subscribers:

- Specify the profile name.  
  
[edit system services static-subscribers]  
user@host# set [access-profile](#) access5

**Related  
Documentation**

- [Configuring Subscribers over Static Interfaces on page 466](#)
- [Specifying the Static Subscriber Group Access Profile on page 471](#)
- [profile on page 1823](#)

## Specifying the Static Subscriber Global Dynamic Profile

---

You specify a previously created dynamic profile that is instantiated when a static subscriber logs in. This profile is used for all static subscribers. This value can be overridden for a group of static subscribers when a different profile is configured for that group.

To specify the dynamic profile used for all static subscribers:

- Specify the profile name.

```
[edit system services static-subscribers]
user@host# set dynamic-profile dyn-profile-1
```

## Enabling Multiple Subscribers on a VLAN Logical Interface for All Static Subscribers

---

For a given interface, only a single static subscriber (or group) is logged in. Although we do not recommend this practice, you might have other kinds of subscribers configured on the same interface, such as a DHCP subscriber managed by the DHCP application. You can use the **aggregate-clients** statement to extend the dynamic profile for all static subscribers to enable multiple subscribers to share the same VLAN logical interface.

You can specify that attributes (such as CoS or firewall) for the multiple subscribers are merged for the logical interface. That is, the profiles for multiple subscribers of different types are instantiated on the interface, but the profile attributes of each are merged together. Alternatively, you can specify that the instantiated profile for the current subscriber is replaced by the profile of a new subscriber that logs in using the same logical interface. This configuration can be overridden for a group of static subscribers when a different configuration is applied for that group.

To enable multiple subscribers to share the same VLAN logical interface for all static subscribers, do one of the following:

- Specify that the multiple subscriber attributes are merged for the logical interface.

```
[edit system services static-subscribers dynamic-profile dyn-profile-1]
user@host# set aggregate-clients merge
```

- Specify that the entire logical interface is replaced when a new subscriber logs into the network using the same VLAN logical interface.

```
[edit system services static-subscribers dynamic-profile dyn-profile-3]
user@host# set aggregate-clients replace
```

## Configuring the Static Subscriber Global Authentication Password

You configure a password that is included in the Access-Request message sent to AAA to authenticate all static subscribers. This value can be overridden for a group of static subscribers when a different password is configured for that group.

To specify the authentication password used for all static subscribers:

- Specify the password.

```
[edit system services static-subscribers authentication]
user@host# set password Gj85*3mS
```

### Related Documentation

- [Configuring Subscribers over Static Interfaces on page 466](#)
- [Configuring the Static Subscriber Group Authentication Password on page 472](#)
- [authentication on page 1409](#)

## Configuring the Static Subscriber Global Username

You configure how the username is formed. The username serves as the username for all static subscribers that are created and is included in the Access-Request message sent to AAA to authenticate all static subscribers. This value can be overridden for a group of static subscribers when a different username is configured for that group.

The username must include at least one of the five possible elements. The value of each element is concatenated in a specific order; the resulting string is the username. If you specify their inclusion, the interface name, logical system name, and routing instance name are derived from the configuration context. The elements are ordered as follows:

***user-prefix.interface.logical-system-name.routing-instance-name@domain-name***

To configure the username for all static subscribers:

1. (Optional) Specify a prefix for the username.

```
[edit system services static-subscribers authentication username-include]
user@host# set user-prefix Building5
```

2. (Optional) Specify that the interface name is included in the username.

```
[edit system services static-subscribers authentication username-include]
user@host# set interface
```

3. (Optional) Specify that the logical system name is included in the username.

```
[edit system services static-subscribers authentication username-include]
user@host# set logical-system-name
```

4. Specify that the routing instance name is included in the username.

```
[edit system services static-subscribers authentication username-include]
```

```
user@host# set routing-instance-name
```

5. Specify the domain name included in the username.

```
[edit system services static-subscribers authentication username-include]
```

```
user@host# set domain-name campus.example.com
```

Configured in the default logical system and master routing instance for interface ge-0/1/1.100, this sample configuration generates the following username:

```
Building5.ge-0-1-1-100.default.master.campus.example.com
```

---

## Creating a Static Subscriber Group

You can override the configuration that is applied globally to static subscribers by creating a static subscriber group that consists of a set of statically configured interfaces. You can then apply a common configuration for the group with values different from the global values for access and dynamic profiles, password, and username.

To configure an interface group for static subscribers:

1. Access the **[edit system services static-subscribers]** hierarchy level.
2. Create the group and assign the name.

```
[edit system services static-subscribers]
```

```
user@host# edit group boston
```

3. Specify the names of one or more interfaces on which static subscribers can be created. You can repeat the **interface interface-name** statement to specify multiple interfaces within the group, but you cannot use the same interface in more than one group.

```
[edit system services static-subscribers group boston]
```

```
user@host# set interface ge-1/0/1.1
```

```
user@host# set interface ge-1/0/1.2
```

4. (Optional) You can use the **upto upto-interface-name** option to specify a range of interfaces for a group.

```
[edit system services static-subscribers group boston]
```

```
user@host# set interface ge-1/0/1.3 upto ge-1/0/1.9
```

5. (Optional) You can use the **exclude** option to exclude a specific interface or a specified range of interfaces from the group. For example:

```
[edit system services static-subscribers group boston]
```

```
user@host# set interface ge-1/0/1.1 upto ge-1/0/1.102
```

```
user@host# set interface ge-1/0/1.6 exclude
```

```
user@host# set interface ge-1/0/1.70 upto ge-1/0/1.80 exclude
```

---

## Specifying the Static Subscriber Group Access Profile

You can override the configured global access profile by specifying a different profile for a group of static subscribers. The access profile triggers AAA services for that group of static subscribers.

To specify the access profile used for a group of static subscribers:

- Specify the profile name.  

```
[edit system services static-subscribers group boston]  
user@host# set access-profile boston-acs
```

- Related Documentation**
- [Configuring Subscribers over Static Interfaces on page 466](#)
  - [profile on page 1823](#)

---

## Specifying the Static Subscriber Group Dynamic Profile

You can override the configured global dynamic profile by specifying a different profile for a group of static subscribers. The dynamic profile is instantiated when any static subscriber in the group logs in.

To specify the dynamic profile used for a group of static subscribers:

- Specify the profile name.  

```
[edit system services static-subscribers group boston]  
user@host# set dynamic-profile dyn-profile-2
```

- Related Documentation**

## Enabling Multiple Subscribers on a VLAN Logical Interface for a Static Subscriber Group

For a given interface, only a single static subscriber group (or static subscriber) is logged in. Although we do not recommend this practice, you might have other kinds of subscribers configured on the same interface, such as a DHCP subscriber managed by the DHCP application. You can use the **aggregate-clients** statement to extend the dynamic profile for a static subscriber group to enable multiple subscribers to share the same VLAN logical interface.

You can specify that attributes (such as CoS or firewall) for the multiple subscribers are merged for the logical interface. That is, the profiles for multiple subscribers of different types are instantiated on the interface, but the profile attributes of each are merged together. Alternatively, you can specify that the instantiated profile for the current subscriber group is replaced by the profile of a new subscriber that logs in using the same logical interface. This configuration overrides the configuration applied to all static subscribers that are not members of the group.

To enable multiple subscribers to share the same VLAN logical interface for a static subscriber group, do one of the following:

- Specify that the multiple subscriber attributes are merged for the logical interface.

```
[edit system services static-subscribers group boston dynamic-profile dyn-profile-2]  
user@host# set aggregate-clients merge
```

- Specify that the entire logical interface is replaced when a new subscriber logs into the network using the same VLAN logical interface.

```
[edit system services static-subscribers group boston dynamic-profile dyn-profile-4]  
user@host# set aggregate-clients replace
```

### Related Documentation

## Configuring the Static Subscriber Group Authentication Password

You can override the configured global authentication password by specifying a different password for a group of static subscribers. This password is included in the Access-Request message sent to AAA to authenticate all static subscribers in the group.

To specify the authentication password used for a group of static subscribers:

- Specify the password.

```
[edit system services static-subscribers group boston authentication]  
user@host# set password knTS$$k2
```

### Related Documentation

- [Configuring Subscribers over Static Interfaces on page 466](#)

- [Configuring the Static Subscriber Global Authentication Password on page 469](#)
- [authentication on page 1409](#)

## Configuring the Static Subscriber Group Username

You can override the configured global username by specifying a different username for a group of static subscribers. The username serves as the username for a group of static subscribers that is created and is included in the Access-Request message sent to AAA to authenticate that group.

The username must include at least one of the five possible elements. The value of each element is concatenated in a specific order; the resulting string is the username. If you specify their inclusion, the interface name, logical system name, and routing instance name are derived from the configuration context. The elements are ordered as follows:

***user-prefix.interface.logical-system-name.routing-instance-name@domain-name***

To configure the username for a group of static subscribers:

1. (Optional) Specify a prefix for the username.

```
[edit system services static-subscribers group boston authentication username-include]
user@host# set user-prefix 2ndFloor
```

2. (Optional) Specify that the interface name is included in the username.

```
[edit system services static-subscribers group boston authentication username-include]
user@host# set interface
```

3. (Optional) Specify that the logical system name is included in the username.

```
[edit system services static-subscribers group boston authentication username-include]
user@host# set logical-system-name
```

4. Specify that the routing instance name is included in the username.

```
[edit system services static-subscribers group boston authentication username-include]
user@host# set routing-instance-name
```

5. Specify the domain name included in the username.

```
[edit system services static-subscribers group boston authentication username-include]
user@host# set domain-name building5.example.com
```

Configured in the default logical system and master routing instance for interface ge-0/1/2.50, this sample configuration generates the following username:

**2ndfloor.ge-0-1-2-50.default.master.building5.example.com**

## Verifying Information about Subscriber Sessions on Static Interfaces

**Purpose** View information about subscriber sessions on static interfaces:

**Action** • To display information about all static subscriber sessions:

```
user@host> show static-subscribers sessions
```

- To display information about the subscriber sessions for the specified group of static interfaces:

```
user@host> show static-subscribers sessions group boston
```

- To display information about the subscriber session for the specified interface:

```
user@host> show static-subscribers sessions interface ge-0/0/1.1
```

**Related  
Documentation**

- For more information, see the Junos OS Operational Mode Commands

## Tracing Static Subscriber Operations

The Junos OS trace feature tracks static subscriber operations and records events in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

1. Important events are logged in a file located in the `/var/log` directory. By default, the router uses the filename `jsscd`. You can specify a different filename, but you cannot change the directory in which trace files are located.
2. When the trace log file *filename* reaches 128 kilobytes (KB), it is compressed and renamed *filename.0.gz*. Subsequent events are logged in a new file called *filename*, until it reaches capacity again. At this point, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)

By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

To configure static subscriber tracing operations:

1. (Optional) Configure a trace log filename.  
See [“Configuring the Static Subscribers Trace Log Filename” on page 476](#).
2. (Optional) Configure the number and size of trace logs.  
See [“Configuring the Number and Size of Static Subscribers Log Files” on page 476](#).
3. (Optional) Configure user access to trace logs.  
See [“Configuring Access to the Static Subscribers Log File” on page 477](#).
4. (Optional) Configure a regular expression to filter the information to be included in the trace log.  
See [“Configuring a Regular Expression for Static Subscriber Messages to Be Logged” on page 477](#).
5. (Optional) Configure flags to specify which events are logged.  
See [“Configuring the Static Subscribers Tracing Flags” on page 478](#).
6. (Optional) Configure a severity level for messages to specify which event messages are logged.  
See [“Configuring the Severity Level to Filter Which Static Subscriber Messages Are Logged” on page 478](#).

---

## Configuring the Static Subscribers Trace Log Filename

By default, the name of the file that records trace output for static subscribers is **jsscd**. You can specify a different name with the **file** option.

To configure the filename for static subscribers tracing operations:

- Specify the name of the file used for the trace output.  

```
[edit system processes static-subscribers traceoptions]  
user@host# set file stat-subs_1
```

**Related Documentation** • [Tracing Static Subscriber Operations on page 475](#)

---

## Configuring the Number and Size of Static Subscribers Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format **.number.gz**. The newest archived file is **.0.gz** and the oldest archived file is **.(maximum number)-1.gz**. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, *filename*, reaches 2 MB, *filename* is compressed and renamed *filename.0.gz*, and a new file called *filename* is created. When the new *filename* reaches 2 MB, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until there are 20 trace files. Then the oldest file, *filename.19.gz*, is simply overwritten when the next oldest file, *filename.18.gz* is compressed and renamed to *filename.19.gz*.

To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output.

```
[edit system processes static-subscribers traceoptions]
user@host# set file stat-subs_1 _logfile_1 files 20 size 2097152
```

#### Related Documentation

- [Tracing Static Subscriber Operations on page 475](#)

## Configuring Access to the Static Subscribers Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

To specify that all users can read the log file:

- Configure the log file to be world-readable.

```
[edit system processes static-subscribers traceoptions]
user@host# set file stat-subs_1 _logfile_1 world-readable
```

To explicitly set the default behavior, only the user who configured tracing can read the log file:

- Configure the log file to be no-world-readable.

```
[edit system processes static-subscribers traceoptions]
user@host# set file stat-subs_1 _logfile_1 no-world-readable
```

#### Related Documentation

- [Tracing Static Subscriber Operations on page 475](#)

## Configuring a Regular Expression for Static Subscriber Messages to Be Logged

By default, the trace operation output includes all messages relevant to the logged events.

You can refine the output by including regular expressions to be matched.

To configure regular expressions to be matched:

- Configure the regular expression.

```
[edit system processes static-subscribers traceoptions]
```

```
user@host# set file stat-subs_1_logfile match regex
```

**Related Documentation** • [Tracing Static Subscriber Operations on page 475](#)

---

## Configuring the Static Subscribers Tracing Flags

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

To configure the flags for the events to be logged:

- Configure the flags.

```
[edit system processes static-subscribers traceoptions]  
user@host# set flag authentication
```

**Related Documentation** • [Tracing Static Subscriber Operations on page 475](#)

---

## Configuring the Severity Level to Filter Which Static Subscriber Messages Are Logged

The messages associated with a logged event are categorized according to severity level. You can use the severity level to determine which messages are logged for the event type. The severity level that you configure depends on the issue that you are trying to resolve. In some cases you might be interested in seeing all messages relevant to the logged event, so you specify **all** or **verbose**. Either choice generates a large amount of output. You can specify a more restrictive severity level, such as **notice** or **info** to filter the messages. By default, the trace operation output includes only messages with a severity level of **error**.

To configure the type of messages to be logged:

- Configure the message severity level.

```
[edit system processes static-subscribers traceoptions]  
user@host# set level severity
```

**Related Documentation** • [Tracing Static Subscriber Operations on page 475](#)

---

## Example: Configuring Static Subscribers for Subscriber Access

This example shows a static subscriber configuration.

1. Configure the access profile to be used for static subscribers.

```
access {  
  profile access5 {  
    provisioning-order jsr;  
    accounting {  
      order radius;  
    }  
  }  
}
```

```

    }
    authentication {
        order radius;
    }
}

```

2. Configure the dynamic profile to be used for static subscribers.

If you do not configure this profile, the default profile, `junos-default-profile`, is used.

3. Configure the static interfaces on which to layer the static subscribers.
4. Configure the parameters that apply globally to all static subscribers in the configuration context.

```

static-subscribers {
    access-profile access5;
    dynamic-profile dyn-profile-1;
    authentication {
        password Gj85*3mS;
        username-include {
            user-prefix Building5;
            interface;
            logical-system-name;
            routing-instance-name;
            domain-name example.com;
        }
    }
}

```

5. If you want to override the global parameters for certain static subscribers, create a group of static interfaces for those subscribers and configure parameters to apply to that group. Repeat this step for as many groups as you need.

```

static-subscribers {
    group boston {
        interface ge-1/0/1.1 upto ge-1/0/1.102
        interface ge-1/0/1.6 exclude
        interface ge-1/0/1.70 upto ge-1/0/1.80 exclude
        access-profile boston-acs;
        dynamic-profile dyn-profile-2;
        authentication {
            password knTS$$k2;
            username-include {
                user-prefix 2ndFloor;
                interface;
                logical-system-name;
                routing-instance-name;
                domain-name example.net;
            }
        }
    }
}

```

6. Configure tracing options for static subscriber events.

```

static-subscribers {

```

```
traceoptions {  
  file filename <files number> <match regular-expression > <size maximum-file-size>  
    <world-readable | no-world-readable>;  
  flag flag;  
  level (all | error | info | notice | verbose | warning);  
  no-remote-trace;  
}
```

## PTSP Overview

---

The packet-triggered subscribers and policy control (PTSP) feature allows the application of policies to individual source IP addresses flowing through a given interface. A subscriber context is created for each distinct source IP address seen in a given underlying interface. This feature can be used to support dynamic subscribers that are controlled by a subscriber termination device, such as a B-RAS or GGSN device, that is connected to an MX Series 3D Universal Edge Router.

PTSP has the following responsibilities:

- Create a subscriber context for each distinct IPv4 address on a given interface (subscriber context).
- Apply policies to or remove policies from the subscriber context.
- Collect statistics and report for each individual policy for each subscriber context.
- Derive information about subscribers.

You can associate specific subscriber contexts based on IPv4 addresses and provide service activation and deactivation for these subscribers. The Multiservices DPC (MS-DPC) maintains a table of addresses for each subscriber and any corresponding policies. If an address is not found in the subscriber table, then a new subscriber context is created. All policies are defined on a per-subscriber basis. Once the subscribers are present in the subscriber table, PSTP enforces the policies active for the subscriber context. PTSP can report the subscribers to the SAE using the Diameter protocol so that the SRC software can manage the subscribers and services with dynamic policies. You can also configure static policies, but dynamic policies take precedence over static policies. When you download a new dynamic policy, it takes effect only for new flows. All new flows and

TCP connections use the new dynamic policy. Existing flows are not affected by the new policy unless they timeout, after which they are considered a new flow.

Statistics collection that is aggregated on a service rule basis is also shared with the SAE using the Diameter application. These statistics are not written to a flat file. Statistics collection that is aggregated on an application or application group basis is written to a flat file. These statistics are not shared with the SAE using the Diameter protocol.

## Hardware Requirements for PTSP for Subscriber Access

PTSP is supported on Juniper Networks MX Series 3D Universal Edge Routers. You must have a Multiservices DPC (MS-DPC) on the MX Series router.

---

## Juniper Networks Session and Resource Control (SRC) and PTSP Overview

The Juniper Networks Session and Resource Control (SRC) environment provides a central administrative point for managing subscribers and their services. The SRC software runs on Juniper Networks C Series Controllers. The SRC software uses the Diameter protocol for communications between the local peer on a Juniper Networks routing platform and the remote SRC peer on a C Series Controller. The local peer is known as PTSP and is part of the AAA application. The remote SRC peer is the service activation engine (SAE); the SAE acts as the controlling agent in the SRC environment.

The SRC software enables the SAE to activate and deactivate subscriber services (described by SRC policies). The SAE installs or removes policies using a service rule policy template called `__svc_rule__`. This policy template indicates which policy is applied to a new subscriber session. Additional policies are bound to new sessions; they do not affect existing sessions. Note that policy name must be unique between PPR requests. You can use the same rule name within a single request, but you cannot use the same name again in a separate request.

Statistics collection that is aggregated on a service rule basis is also shared with the SAE using the Diameter protocol.

**NOTE:** More than one Diameter-based application (function) can run on a router simultaneously.

---

**NOTE:** When the SRC software downloads PTSP policies, it matches all the application groups defined in the rule of the PTSP policy if the **application-group-any** keyword is used in the policy. The **application-group-any** keyword is not configured on the router although the application group name is defined in the application identification configuration database on the router to process application-aware access list (AACL) rules for accepting or discarding packets. The keyword is considered as an exception because the application group is defined in the application identification database.

## Understanding PTSP-SAE Interactions

This topic describes the sequences of Diameter messages exchanged between PTSP and the SAE as they interact to perform the following tasks for subscriber access:

- Subscriber login

When a packet-triggered subscriber logs in, PTSP sends a Diameter AA-Request message to request service provisioning from the SAE that includes the Session-Id attribute for the new subscriber. If the AA-Request fails, then the subscriber is not considered logged in and the subscriber session is not managed by the SAE. Only the static PTSP rules apply to the subscriber.

The SAE returns a Diameter AA-Answer message with the Result-Code. The AA-Answer message can include the Juniper-Policy-Install AVP (AVP code 2020), which is used to specify a service to attach to the subscriber's IP address.

PTSP can send an AA-Request message to the SAE to confirm activation. The SAE returns a AA-Answer message in acknowledgment. If the AA-Request message fails or the SAE does not respond with an AA-Answer message, the subscriber session is managed by the SAE.

- Service activation and deactivation

The SAE policies provision subscriber services. After a packet-triggered subscriber is logged in, the SAE can send a PPR message to PTSP to activate or deactivate services. A given PPR can include the Juniper-Policy-Install AVP (AVP code 2020) to activate a service or the Juniper-Policy-Remove AVP (AVP code 2027) to deactivate a service.

PTSP sends a PPA message to the SAE when it has completed the tasks requested in the PPR. The PPA indicates the success or failure of the actions requested in the PPR.

- Resynchronization

Either PTSP or the SAE initiates the resynchronization.

The SAE initiates resynchronization at startup or when a backup SAE takes over session control due to resource limits or conditions on the primary SAE. The SAE clears its database of all entries in preparation for the synchronization.

PTSP initiates resynchronization at startup, such as when AAA starts or restarts. PTSP uses the Juniper-Last-Origin-Host AVP (AVP code 2055) to keep track of the active SAE host in a multi-SAE environment. When an SAE in a multi-SAE environment becomes active, it must send an SRQ to PTSP as its first message. PTSP initiates a synchronization when it receives any other message type from an SAE that is different from the SAE indicated in the Juniper-Last-Origin-Host AVP.

Both entities initiate a resynchronization by sending an SRQ message. The recipient responds with an SRR message.

- Statistics collection and reporting per service rule

Statistics information can be sent from the router to the SAE or from the SAE to the router. Both the Diameter Accounting-Request and Accounting-Answer messages include the Juniper-Acct-Record AVP (AVP code 2053) which identifies the policy for which accounting information is requested.

- Subscriber logout

PTSP can determine when there is a logout request for a packet-triggered subscriber in two ways:

- The SAE terminates a subscriber session by sending an ASR message to PTSP.
- PTSP monitors a subscriber session and starts the logout process after 30 minutes of inactivity.

The subscriber logout triggers the final statistics aggregation for all policies and the removal of any policies installed by the SAE. PTSP sends an STR message that indicates the logout event to the SAE.

## Packet-Triggered Subscribers Services Overview

---

The packet-triggered subscribers and policy control (PTSP) feature allows the application of policies to dynamic subscribers that are controlled by a subscriber termination device. You can associate specific subscriber contexts based on IPv4 addresses and provide dynamic service activation and deactivation for these subscribers. Once the subscribers

are present in the subscriber database on the router, PSTP can report the subscribers to the SAE using the PTSP application so that the SRC software can manage the subscribers and services.

PTSP policies can be downloaded dynamically from the external policy manager (such as SRC) or configured statically on the router. The PTSP policies can be configured for each distinct IPv4 source address for a given interface on which the service is configured. Each distinct IPv4 address is considered a subscriber and all PTSP policies are applied on a per-subscriber basis. Dynamic policies, which are always specific to a subscriber, take precedence over static policies.

You can set up PTSP policies to:

- Manage traffic by configuring filtering, rate-limiting, and QoS enforcement in the rules.
- Steer traffic by specifying the forwarding instance in the forward rule.
- Collect accounting information by service rule or by application.

When you configure PTSP policies, you must specify the type of statistics collection (**count**) and the IP address used to identify the packet-triggered subscriber (**demux**) in the service rule. All service rules attached to a given service set must have the same settings for these options.

For the statistics collection type, terms and rules also cannot mix and match the following styles:

- rule—Statistics are aggregated in one bucket for the service rule and Diameter is used to report the statistics.
- application—Statistics are aggregated by application for a specific application, for a specific application group, or in one bucket. The statistics are reported in a flat file.

Subscriber instantiation is triggered for ingress packets by the IP address. When source address is specified, the source IP address of the ingress packets is used to establish the subscriber context. When destination address is specified, the destination IP address of the ingress packets is used to establish the subscriber context. If the IP address does not correspond to a known subscriber, then a new subscriber context is created to log in the packet-triggered subscriber.

The match conditions include local address, local port, remote address, and remote port. The following table describes how the **demux** value changes the IP address or port used for these terms.

| Match Conditions      | demux source-address |                     | demux destination-address |                     |
|-----------------------|----------------------|---------------------|---------------------------|---------------------|
|                       | Ingress Flows        | Egress Flows        | Ingress Flows             | Egress Flows        |
| <b>local-address</b>  | Source address       | Destination address | Destination address       | Source address      |
| <b>remote-address</b> | Destination address  | Source address      | Source address            | Destination address |
| <b>local-port</b>     | Source port          | Destination port    | Destination port          | Source port         |

| Match Conditions   | demux source-address |              | demux destination-address |                  |
|--------------------|----------------------|--------------|---------------------------|------------------|
|                    | Ingress Flows        | Egress Flows | Ingress Flows             | Egress Flows     |
| <b>remote-port</b> | Destination port     | Source port  | Source port               | Destination port |

## Subscriber Identification Method for PTSP Partition

The PSTP functionality uses RADIUS attributes, such as *User-Name* to identify subscribers in a RADIUS partition. If a service provider uses a different RADIUS attribute other than *User-Name*, the authentication of subscribers and establishment of client sessions fail. To enable service providers to use a subscriber-identification method that suits their network needs, you can add flexible configurations in the packet-triggered subscriber process.

The PTSP configurable user-identification feature allows you to do the following:

- Configure the subscriber identification method for PTSP partitions, based on the network topology and the service provider requirements.
- Insert subscriber-specific tags for the subscriber's HTTP traffic for which the reference to subscriber-specific tagging is provided using subscriber identification.

The PTSP application generates the subscriber-identification parameter as a text-string by combining the RADIUS attribute value and the internal attribute value of the PTSP partition. The text-string is generated in the same order as the attributes that are configured in the PTSP partition.

**NOTE:** Only RADIUS partitions support user-identification to configure the subscriber-identification method for PTSP partitions.

## PTSP Services on Aggregated and Redundant Services PICs

The packet-triggered subscribers and policy control (PTSP) feature supports both Aggregated Multiservices (AMS) and Redundant Multiservices (RMS) PICs. RMS services interfaces support 1:1 redundancy between two logical PICs and in an active or standby model. AMS services interfaces support load sharing and N:1 redundancy between N logical PICs.

**NOTE:** The PTSP services do not support load balancing on AMS.

In 1:1 redundancy, if services PIC fails:

- The subscriber is logged out, the traffic is switched to the redundant services PIC, and the subscriber receives a new session ID to log in with.
- The subscriber's last configured accounting data is retrieved as the latest interim accounting record.

In AMS, the PTSP subscriber's traffic is redistributed to other services PIC and the same subscriber may appear on different services PICs. The subscriber with no new data flow is logged out after idle timeout with the complete accounting data. The following example depicts the AMS scenario:

```
ams0 {
  load-balancing-options {
    member-interface mams-4/0/0;
    member-interface mams-4/1/0;
    member-interface mams-5/0/0;
    member-failure-options {
      redistribute-all-traffic;
    }
  }
  unit 1 {
    family inet;
  }
}
```

The traffic on ms-4/0/0 is redistributed to ms-4/1/0 only after ms-5/0/0 has failed. In this example, there are two subscribers: s1 on ms-4/0/0 and s2 on ms-4/1/0. The two subscribers have the same source IP address. If there is no new traffic, s1 is eventually logged out after idle timeout.

**NOTE:** PTSP does not support any type of hash key for traffic sharing among logical PICs configured with the same PTSP service set. For PTSP to work, all traffic for any given subscriber needs to reach the same logical PIC within an AMS container. For this to happen, the AMS hashing algorithm needs to align with the PTSP demux type, as follows:

- If PTSP is configured for source-demux, then the AMS hashing algorithm must be based on the source-ip-address only.
- If PTSP is configured for destination-demux, then the AMS hashing algorithm must be based on the destination-ip-address only.
- No other type of AMS hashing algorithm is compatible with PTSP.

**NOTE:** The packet level idle timeout for every packet is assigned from a given subscriber transiting the router. If the timeout limit sets in, the subscriber is logged out. The valid range for the subscriber packet idle timeout is 15 to 1440 minutes.

## Understanding the Subscriber Profiles for Client Sessions per PSTP Partition

Subscriber profiles for service activation enables you to specify which service plug-ins become activated on a per-subscriber basis. Previously, the only control mechanism for specifying service activation was to attach a service-set configuration to a selected interface or route. The new utility allows you to enable or disable services based on the subscriber associated with every data flow. As a result, you can apply differentiated services to different sets of subscribers. You can exercise the control mechanism in one of two ways: by using a CLI operational command or a RADIUS attribute.

**NOTE:** This feature applies only to MP-SDK services and does not depend on the specific services enabled or disabled, except that PTSP must be included in the chain.

The procedure consists of three steps:

1. Configure a service set that includes all the services to be applied to flows. You can include a default subscriber profile that controls which services are and are not active by default. The default profile applies to all subscribers until overridden for a specific subscriber. In the absence of a default subscriber profile, all services specified in the service set are applied by default. You can also include one or more alternative subscriber profiles that can be implemented to override the default profile. The following sample configuration illustrates these components:

```
services {
  service-set ssl {
    application-identification-profile appidr1;
    idp-profile idpr1;
    aacl-rules aaclr1;
    hcm_rules hcmr1;
    sfw_rules sfwr1;
    subscriber-profile {
      sp1;
    }
    interface-service {
      service-interface ms-3/0/0.0;
    }
  }
}
subscriber-profile sp1 {
  disable HCM;
  enable IDP {
    concurrent-data-sessions 10;
  }
  disable AACL;
  max-data-sessions-per-subscriber {
    limit 10;
    exceed-action [ syslog drop ];
  }
}
subscriber-profile sp2 {
```

```

enable HCM;
disable IDP;
enable ACL,
max-data-sessions-per-subscriber {
    limit 100;
    exceed-action [ syslog ];
}
}

```

Initially, all traffic reaching the service plane under service set `ss1` receives all the services configured in service set `ss1` that are enabled by the default subscriber profile `sp1` applied to it. In the example, APPID, stateful firewall, and IDP are enabled, whereas HCM and ACL are disabled. However IDP is enabled for only at most 10 sessions concurrently. Beyond that threshold, IDP is also disabled. Also, because of the `max-data-sessions-per-subscriber` setting, any subscriber is allowed a maximum of ten concurrent data sessions. Beyond that threshold, data sessions are logged and dropped.

2. There are two ways to dynamically override the default subscriber profile associated with a particular PTSP subscriber:
  - CLI operational command
  - RADIUS attribute or VSA in an access-accept message.

From the previous example, assume that the subscriber profile for subscriber X is dynamically set to `sp2`. After that, any new data session associated with subscriber X has a different set of services applied to it. In the example, it would be APPID, stateful firewall, HCM, and ACL. Also, because the `max-data-sessions-per-subscriber` setting changes to 100, subscriber X now has no upper limit on the number of concurrent data sessions, although if that number crosses the 100 threshold, the threshold-crossing event is logged.

The following examples illustrate the dynamic override settings:

Operational command

```

user@router>request services subscriber clear subscriber-profile
client-id client-id

```

```

user@router>request services subscriber set subscriber-profile
subscriber-profile-name client-id client-id

```

RADIUS configuration

```

user@router# set system services packet-triggered-subscribers
partition-radius foo subscriber-service-profile attribute-26.4874.31

```

3. Processing of a new data session at the service plane takes place as follows, with respect to subscriber profiles:
  1. A new flow starts. MP-SDK sends a SESSION-INTEREST event to the service plug-ins. The first plug-in in the chain is the subscribers (PTSP) plug-in.
  2. The subscribers plug-in matches the flow to its subscriber by searching its database. It sets the subscriber ID in the session metadata.

3. The subscriber plug-in checks for the corresponding subscriber profile and which services are enabled. It then sets the services mask of enabled and disabled services in the session metadata.
4. MP-SDK or JSF invokes only the services that are enabled per the services mask. The other services are skipped, even if configured in the service set.

.....

**NOTE:** : Subscriber-profile changes affect only the upcoming flows. Existing flows remain unaffected.

.....

# Configuring the PTSP Application

- [Configuring the PTSP Application on page 491](#)
- [Configuring the PTSP Partition on page 492](#)
- [Assigning the PTSP Partition on page 492](#)
- [Tracing Packet-Triggered Subscriber Operations on page 493](#)

## Configuring the PTSP Application

---

You can configure the PTSP client application to work with the Session and Resource Control (SRC) peer to centrally manage packet-triggered subscribers and services. PTSP requests address and service authorizations from the remote SRC peer (the SAE), activates and deactivates services as specified by the SAE, logs out subscribers as specified by the SAE, and synchronizes subscriber state and service information with the SAE. The PTSP application also performs statistics collection and reporting.

To configure the PTSP application:

1. Configure the PTSP partition.  
[See “Configuring the PTSP Partition” on page 492.](#)
2. Assign the PTSP partition.  
[See “Assigning the PTSP Partition” on page 492.](#)
3. Configure statistics collection and reporting.  
[See “Tracing Packet-Triggered Subscriber Operations” on page 493.](#)

**Related  
Documentation**

- [Juniper Networks Session and Resource Control \(SRC\) and PTSP Overview on page 482](#)

## Configuring the PTSP Partition

---

PTSP works within a specific logical system:routing instance context, called a partition. The partition is configured to connect to the external policy manager.

**NOTE:** Currently, only a single partition is supported; you must configure it within the default logical system:routing instance context.

Before you configure the PTSP partition to connect to the external policy manager, perform the following task:

- Configure the Diameter instance for the remote SRC peer at the **[edit diameter]** hierarchy level. See [“Configuring Diameter” on page 437](#).

Configuration for the PTSP partition consists of naming the partition and then associating a Diameter instance, the SAE hostname, and the SAE realm with the partition.

To configure the PTSP partition:

1. Create the partition at the **[edit system services packet-triggered-subscribers]** hierarchy level.

```
[edit system services packet-triggered-subscribers]
user@host# edit partition ptsp-default
```

2. Specify the Diameter instance for the PTSP partition.

```
[edit system services packet-triggered-subscribers partition ptsp-default]
user@host# set diameter-instance master
```

3. Configure the destination host for the PTSP partition.

```
[edit system services packet-triggered-subscribers partition ptsp-default]
user@host# set destination-host sae1
```

4. Configure the destination realm for the PTSP partition.

```
[edit system services packet-triggered-subscribers partition ptsp-default]
user@host# set destination-realm generic.example.com
```

5. Configure the subscriber ID for the PTSP partition.

```
[edit system services packet-triggered-subscribers partition-radius
  radius-partition-name]
user@host# set subscriber-identification
```

**Related Documentation**

- [Configuring the PTSP Application on page 491](#)

## Assigning the PTSP Partition

---

You must associate the PTSP partition with the logical system:routing instance.

**NOTE:** Currently, only the global logical system:routing instance, *master* logical system and default routing instance, is supported.

Before you assign the PTSP partition, perform the following task:

- Configure the PTSP partition. See [“Configuring the PTSP Partition” on page 492](#).

To assign the PTSP partition:

- Specify the partition name at the **[edit system]** hierarchy level.

```
[edit system]
```

```
user@host# set packet-triggered-subscribers-partition ptsp-default
```

#### Related Documentation

- [Configuring the PTSP Application on page 491](#)

## Tracing Packet-Triggered Subscriber Operations

Packet-triggered subscriber tracing operations track packet-triggered subscriber operations and record them in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

All log files are located in the `/var/log` directory. You cannot change the directory (`/var/log`) in which trace files are located. When the trace file reaches its maximum size, a `.0` is appended to the filename, then a new file is created with a `.1`, and finally a `.2`. When the maximum number of trace files is reached, the oldest trace file is overwritten.

To configure packet-triggered subscriber tracing operations:

1. Specify that you want to configure tracing options.

```
[edit system services packet-triggered-subscribers]
```

```
user@host# edit traceoptions
```

2. (Optional) Configure the name for the file used for the trace output.
3. (Optional) Configure the number and size of the log files.
4. (Optional) Configure flags to filter the operations to be logged.

The packet-triggered subscriber traceoptions operations are described in the following sections:

- [Configuring the Packet-Triggered Subscribers Trace Log Filename on page 494](#)
- [Configuring the Size of Packet-Triggered Subscribers Log Files on page 494](#)
- [Configuring the Packet-Triggered Subscribers Tracing Flags on page 494](#)

## Configuring the Packet-Triggered Subscribers Trace Log Filename

By default, the name of the file that records trace output for packet-triggered subscribers is **jptspd**. You can specify a different name with the **file** option.

To configure the filename for packet-triggered subscribers tracing operations:

- Specify the name of the file used for the trace output.

```
[edit system services packet-triggered-subscribers traceoptions]
user@host# set file ptsp-subsys_1
```

## Configuring the Size of Packet-Triggered Subscribers Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format **.number.gz**. The newest archived file is **.0.gz** and the oldest archived file is **.(maximum number)-1.gz**. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, **filename**, reaches 2 MB, **filename** is compressed and renamed **filename.0.gz**, and a new file called **filename** is created. When the new **filename** reaches 2 MB, **filename.0.gz** is renamed **filename.1.gz** and **filename** is compressed and renamed **filename.0.gz**. This process repeats until there are 20 trace files. Then the oldest file, **filename.19.gz**, is simply overwritten when the next oldest file, **filename.18.gz** is compressed and renamed to **filename.19.gz**.

To configure the size of trace files:

- Specify the name and size of the file used for the trace output.

```
[edit system services packet-triggered-subscribers traceoptions]
user@host# set file ptsp-subsys_1_logfile_1 size 2097152
```

## Configuring the Packet-Triggered Subscribers Tracing Flags

To configure the flags for the events to be logged:

- Configure the flags.

```
[edit system services packet-triggered-subscribers traceoptions]
user@host# set flag peer
user@host# set flag session
```

## Configuring PTSP

---

You can configure the packet-triggered subscribers and policy control (PTSP) feature on MX Series routers to allow the application of policies to dynamic subscribers that are controlled by a subscriber termination device, such as a B-RAS or GGSN device, connected to an MX Series router. The subscribers are associated by their IPv4 address and dynamic or static policies can be applied. Dynamic policies take precedence over static policies. When you download a new dynamic policy, it takes effect only for new flows. All new flows and TCP connections use the new dynamic policy. Existing flows are not affected by the new policy unless they timeout, after which they are considered a new flow.

To configure PTSP services on the MX Series router:

1. Configure the Multiservices DPC.  
[See “Configuring the Multiservices DPC for PTSP” on page 496.](#)
2. Configure the Diameter application to support the download of dynamic PTSP policies from the external policy manager (such as SRC). The PTSP application also provides statistics collection and reporting.  
[See “Configuring the PTSP Application” on page 491.](#)

3. Configure the static PTSP service rules.

See [“Configuring Static PTSP Rules” on page 497](#).

4. Configure statistics collection and reporting in a flat file.

See [“Configuring a Statistics Profile for PTSP” on page 502](#) and [“Tracing PTSP Operations” on page 504](#).

**Related  
Documentation**

- [PTSP Overview on page 481](#)

---

## Configuring the Multiservices DPC for PTSP

To configure the Multiservices Dense Port Concentrator (MS-DPC) to support PTSP services, perform the following tasks:

- [Enabling the PTSP Service Package on the Multiservices DPC on page 496](#)
- [Configuring Services Interface for PTSP on page 496](#)

### Enabling the PTSP Service Package on the Multiservices DPC

The PTSP feature runs on the Multiservices DPC, you must enable the PTSP service package on the Multiservices DPC before you can configure the PTSP software. The name of the PTSP service package is **jservices-ptsp**.

To enable the PTSP service package:

1. Determine the FPC slot number and the PIC number of the MS-DPC on which you want to enable the PTSP service package.

```
user@host> show chassis hardware
```

In this example, the FPC slot number is 3 and the PIC number is 0.

2. Enable the jservices-ptsp package on the Multiservices DPC.

```
[edit chassis]
```

```
user@host# set fpc 3 pic 0 adaptive-services service-package extension-provider  
package jservices-ptsp
```

### Configuring Services Interface for PTSP

**NOTE:** ams- interfaces and rms- interfaces can be configured for PTSP.

---

To configure the services interface for PTSP:

1. Enter edit mode for the interface.

```
[edit]
```

```
user@host# edit interfaces ms-3/0/0
```

2. Configure a logical unit and specify the protocol family.

```
[edit interfaces ms-3/0/0]
```

```
user@host# set unit 0 family inet
```

## Configuring PTSP Service Rules

PTSP policies can be downloaded dynamically from the external policy manager (such as SRC) or configured statically on the router. The PTSP policies can be configured for each distinct IPv4 source address for a given interface on which the service is configured. Each distinct IPv4 address is considered a subscriber and all PTSP policies are applied on a per-subscriber basis.

Dynamic policies, which are always specific to a subscriber, take precedence over static policies. When you download a new dynamic policy, it takes effect only for new flows. All new flows and TCP connections use the new dynamic policy. Existing flows are not affected by the new policy unless they timeout, after which they are considered a new flow.

To configure the PTSP policies, perform these tasks:

- To download dynamic policies and to collect statistics with Diameter, configure the Diameter application for PTSP. See [“Configuring the PTSP Application” on page 491](#).
- To configure static policies, see [“Configuring Static PTSP Rules” on page 497](#). To collect statistics in a flat file, see [“Configuring a Statistics Profile for PTSP” on page 502](#).

- Related Documentation**

---

## Configuring Static PTSP Rules

You can configure the static PTSP policies on the router. If the PTSP service is configured on the underlying interface, the PTSP service enforces the policies associated with the subscriber context.

To configure static PTSP rules:

1. Specify the rule that you want to configure.  

```
[edit services ptsp]  
user@host# edit rule ptspRule1
```
2. Specify the direction in which the rule match is applied.  

```
[edit services ptsp rule ptspRule1]  
user@host# set match-direction input
```

- Specify the IP address used for the subscriber context. Subscriber instantiation is always triggered for ingress packets, so this value indicates which IP address in the ingress packets for the flow is used.

```
[edit services ptsp rule ptspRule1]
user@host# set demux source-address
```

- Specify the statistics aggregation, collection, and reporting style. Terms and rules cannot mix and match different styles.

```
[edit services ptsp rule ptspRule1]
user@host# set count-type rule
```

If you specify the rule style, statistics collection is performed by the Diameter application. If you specify the application style, statistics collection is in a flat file controlled by the local policy decision function (L-PDF).

- (Optional) Specify the forward rule used for forwarding packets. See [“Configuring the PTSP Forwarding Instance” on page 500](#).

```
[edit services ptsp rule ptspRule1]
user@host# set forward-rule forward-rule-name
```

- Configure the term precedence for the rule.

```
[edit services ptsp rule ptspRule1]
user@host# edit term 1
```

- Configure the match conditions for the term. See [Table 50 on page 498](#).

```
[edit services ptsp rule ptspRule1 term 1]
user@host# set from remote-address-range low 203.0.0.2 high 203.0.0.100
user@host# set from remote-address-range low 204.0.0.2 high 204.0.0.253
```

- (Optional) Specify the action taken when the match conditions are met. See [Table 51 on page 499](#).

```
[edit services ptsp rule ptspRule1 term 1]
user@host# set then count rule
user@host# set then accept
```

[Table 50 on page 498](#) describes the match conditions for PTSP rules.

**Table 50: PTSP Match Conditions**

| Match Condition                                                     | Description                                                                     |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------|
| <b>application-group-any</b>                                        | Application group name defined in the application identification configuration. |
| <b>application-groups</b> [ <i>application-group-name</i> ]         | Application group name defined in the application identification configuration. |
| <b>applications</b>                                                 | Application name defined in the application identification configuration.       |
| <b>local-port-range</b> low <i>low-value</i> high <i>high-value</i> | Local port range.                                                               |
| <b>local-ports</b> <i>value-list</i>                                | Local ports.                                                                    |

Table 50: PTSP Match Conditions (*continued*)

| Match Condition                                                           | Description                      |
|---------------------------------------------------------------------------|----------------------------------|
| <b>protocol</b> <i>protocol-number</i>                                    | IP protocol number.              |
| <b>remote-address</b> ( <i>address</i>   any-unicast)                     | Remote IP address. IPv4 only.    |
| <b>remote-address-range</b> low <i>low-value</i><br>high <i>low-value</i> | Remote address range. IPv4 only. |
| <b>remote-port-range</b> low <i>low-value</i> high<br><i>high-value</i>   | Remote port range.               |
| <b>remote-ports</b> <i>value-list</i>                                     | Remote ports.                    |
| <b>remote-prefix-list</b> <i>prefix-list-name</i>                         | Prefixes in the specified list.  |

Table 51 on page 499 describes the actions for PTSP rules.

Table 51: PTSP Actions

| Action or Action Modifier | Description                                              |
|---------------------------|----------------------------------------------------------|
| accept                    | Accept the packet.                                       |
| count                     | Increment the specified counter.                         |
| discard                   | Drop the packet.                                         |
| forwarding-class          | Classify the packet into the specified forwarding class. |
| police                    | Rate-limit packets based on the specified policer.       |

## Configuring PTSP Rule Sets

You can define a collection of PTSP rules to determine the actions performed on packets.

To configure static PTSP rule sets:

1. Specify the rule set that you want to configure.

[edit services ptsp]

```
user@host# edit rule-set ptspRules
```

2. Specify the rules in the order that you want them processed.

```
[edit services ptsp rule-set ptspRules]
user@host# set rule ptspRule1
user@host# set rule ptspRule2
```

**Related Documentation**

- [Configuring Static PTSP Rules on page 497](#)

---

## Configuring PTSP Service Sets

To configure the service set for the PTSP application:

1. Configure the service set that you want to contain the PTSP service.

```
[edit services service-set ptspServiceSet]
user@host# set service-set ptspServiceSet
```

2. Specify the PTSP rules that constitute the service set that is applied to the services interface.

```
[edit services service-set ptspServiceSet]
user@host# set ptsp-rules ptsp-rule1
user@host# set ptsp-rules ptsp-rule2
```

3. Configure the services interface.

**NOTE:** ams- interfaces and rms- interfaces are supported for PTSP.

```
[edit services service-set ptspServiceSet]
user@host# set interface-service service-interface ms-3/0/0.0
```

4. Associate the service set with the underlying interface from which the subscribers originate. The service set must be applied to the interface facing the subscriber, that is, the interface with the IP address of the subscriber.

```
[edit interfaces ge-4/0/0 unit 0 family inet service]
user@host# set input service-set ptspServiceSet
user@host# set output service-set ptspServiceSet
```

**Related Documentation**

## Configuring the PTSP Forwarding Instance

Before you can forward PTSP traffic, perform these tasks for each forwarding instance:

1. Configure each PTSP forwarding instance as a routing instance type of forwarding.
2. Configure a firewall filter with an action that specifies the routing instance configured in Step 1.

3. Configure the unit number for the Multiservices interface that specifies the filter configured in Step 2 as the input filter.

**NOTE:** To avoid service set dependency on specific unit numbers, use the same unit number across all Multiservices interfaces where PTSP services are applied.

4. Configure the PTSP forward rule to specify the forwarding instance.

**NOTE:** When the forwarding instance action is performed on the flow, any postservice filters are not applied to the underlying interface.

If you want to forward traffic for PTSP subscribers, you must specify the forwarding instance for specific subscribers based on IP address, network, or prefix list. The match direction for forward rules is always input.

To configure the PTSP forwarding instance:

1. Specify the PTSP forward rule that you want to use when configuring a PTSP forwarding instance.

```
[edit services ptsp]
user@host# edit forward-rule ptspForward
```

2. Set the term precedence for the forward rule. Term with lowest precedence is evaluated first.

```
[edit services ptsp forward-rule ptspForward]
user@host# edit term 5
```

3. Configure the match conditions for the IP address, address range, or prefix list. See [Table 52 on page 501](#).

```
[edit services ptsp forward-rule ptspForward term 5]
user@host# set from local-address 200.0.0.1
```

**Table 52: PTSP Forward Rule Match Conditions**

| Match Condition                                                 | Description                                                                     |
|-----------------------------------------------------------------|---------------------------------------------------------------------------------|
| <b>application-groups</b><br>[ <i>application-group-name</i> ]  | Application group name defined in the application identification configuration. |
| <b>applications</b>                                             | Application name defined in the application identification configuration.       |
| <b>local-address</b> ( <i>address</i>   <i>any-unicast</i> )    | Local IP address. IPv4 only.                                                    |
| <b>local-address-range</b> <i>low low-value high high-value</i> | Local address range. IPv4 only.                                                 |
| <b>local-prefix-list</b> <i>prefix-list-name</i>                | Prefixes in the specified list.                                                 |

**NOTE:** You can specify match conditions for applications or application groups that support application identification (APPID) services, but we do not recommend specifying the forwarding instance action when you are using these match conditions in PTSP policies. In this situation, some network topologies may route packets in a manner that causes the flow to be dropped. For example, the APPID services might forward some packets on the default routing instance while the PTSP services forward other packets in the same flow to another routing instance.

4. Configure the forwarding instance action with the routing instance name and the unit number.

```
[edit services ptsp forward-rule ptspForward term 5]  
user@host# set then forwarding-instance less-effort-ri 144
```

**NOTE:** When the forwarding instance action is performed on the flow, any postservice filters are not applied to the underlying interface.

**Related  
Documentation**

- For information about forwarding instances, see the Junos OS Routing Protocols Configuration Guide

---

## Configuring a Statistics Profile for PTSP

The local policy decision function (L-PDF) enables you to configure properties for statistics output by creating a statistics profile. The statistics profile configures the files to which statistics records are exported and the format that is exported. You configure the statistics profile so that the statistics records are exported to a flat file. Flat files contain statistics that are collected for each subscriber by application or application group. The statistics in a flat file are not transmitted to the external policy manager using Diameter.

To configure a statistics profile for PTSP:

1. Specify that you want to configure a statistics profile.

```
[edit system services local-policy-decision-function]  
user@host# edit statistics
```

2. Configure the file properties used for the trace output.
3. Configure the profile properties.
4. Specify the record type.

Tasks to configure a statistics profile for PTSP are:

- [Configuring the File Properties for Statistics Data Output on page 503](#)
- [Configuring the Profile Properties for Statistics Data Output on page 503](#)
- [Configuring the Record Type for Statistics Data on page 504](#)

## Configuring the File Properties for Statistics Data Output

You configure a file to which the statistics data output is exported in a specified format.

To configure the file properties:

1. Specify the unique filename for receiving statistics data output.

```
[edit system services local-policy-decision-function statistics]
user@host# edit file ptsp
```

2. (Optional) Specify the maximum number of files that are maintained at one time and the maximum size of each file. If you configure one of these options, you also must set the other option.

```
[edit system services local-policy-decision-function statistics file ptsp]
user@host# set files 10 size 1g
```

3. Specify the interval for transferring files to archive sites.

```
[edit system services local-policy-decision-function statistics file ptsp]
user@host# set transfer-interval 60
```

4. Specify one or more URLs for archiving the files. Archiving can be done by using FTP or SCP.

```
[edit system services local-policy-decision-function statistics file ptsp]
user@host# set archive-sites "ftp://anonymous@10.227.1.114"
```

## Configuring the Profile Properties for Statistics Data Output

You can create an AACL statistics profile, which configures the statistics to collect and write to a file in the `/var/stats/aacl` directory.

To configure the profile properties:

1. Specify the name of the profile.

```
[edit system services local-policy-decision-function statistics]
user@host# edit aacl-statistics-profile ptsp
```

2. (Optional) Specify the file in the `/var/stats/aacl` directory in which statistics are collected. Enclose the name within quotation marks.

```
[edit system services local-policy-decision-function statistics aacl-statistics-profile
ptsp]
user@host# set file "pstp"
```

3. Set the interval for reporting statistics.

```
[edit system services local-policy-decision-function statistics aacl-statistics-profile
ptsp]
```

```
user@host# set report-interval 5
```

4. Set the **interim-active-only** mode for reporting statistics. This mode reports only statistics that have changed in the past report interval.

```
[edit system services local-policy-decision-function statistics aacl-statistics-profile  
ptsp]
```

```
user@host# set record-mode interim-active-only
```

5. Specify the statistics to be collected in the log file.

```
[edit system services local-policy-decision-function statistics aacl-statistics-profile  
ptsp]
```

```
user@host# set aacl-fields all-fields
```

## Configuring the Record Type for Statistics Data

You must configure the interim record type for recording the AACL statistics.

To configure the record type:

- Specify interim as the record type.

```
[edit system services local-policy-decision-function statistics]  
user@host# set record-type interim
```

  - [Configuring PTSP on page 495](#)

---

## Tracing PTSP Operations

Tracing operations track L-PDF operations and record them in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

By default, no events are traced. When you enable the tracing operation, the default tracing behavior is as follows:

1. Important events are logged in a file located in the **/var/log** directory. By default, the router uses the filename, **ptspd**. You can specify a different filename, but you cannot change the directory in which trace files are located.
2. When the trace log file **filename** reaches 128 kilobytes (KB), it is compressed and renamed **filename.0.gz**. Subsequent events are logged in a new file called **filename**, until it reaches capacity again. At this point, **filename.0.gz** is renamed **filename.1.gz** and **filename** is compressed and renamed **filename.0.gz**. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally configure the maximum file size to be from 10 KB through 1 gigabyte (GB). You can also specify the number of trace files to be from 2 through 1000. (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)

To customize trace file settings:

1. Specify that you want to configure tracing options.

```
[edit system services local-policy-decision-function]
user@host# edit traceoptions
```

2. Configure the filename used for the trace output.

```
[edit system services local-policy-decision-function traceoptions]
user@host# set file lpdfd
```

3. (Optional) Configure the maximum number and size of the log files. If you configure one of these options, you also must set the other option.

```
[edit system services local-policy-decision-function traceoptions]
user@host# set files 10 size 1g
```

4. (Optional) Specify flags to filter the operations to be logged. To specify more than one flag, include multiple **flag** statements.

```
[edit system services local-policy-decision-function traceoptions]
user@host# set flag ptsp-statistics
```

The following table describes the flags that you can include.

| Flag                   | Description                 |
|------------------------|-----------------------------|
| <b>configuration</b>   | Trace configuration events  |
| <b>database</b>        | Trace database events       |
| <b>general</b>         | Trace general flow          |
| <b>ptsp-statistics</b> | Trace PTSP events           |
| <b>rtsock</b>          | Trace routing socket events |
| <b>statistics</b>      | Trace statistics events     |
| <b>subscriber</b>      | Trace subscriber events     |

## Verifying and Managing PTSP Configuration

**Purpose** Display and clear information about packet-triggered subscribers and PTSP services.

- Action**
- To display bandwidth information about subscribers:
 

```
user@host> show services subscriber bandwidth
```
  - To display information about the active dynamic policies applied to a subscriber:

**user@host> show services subscriber dynamic-policies client-id *client-id***

- To display information about the data flows associated with a subscriber:

**user@host> show services subscriber flows client-id *client-id***

- To display information about the active packet-triggered subscriber sessions on the router:

**user@host> show services subscriber sessions**

- To display information about the data traffic statistics for the packet-triggered subscriber:

**user@host> show services subscriber statistics client-id *client-id***

- To clear the active packet-triggered subscriber session on the router and log out the subscriber:

**user@host> clear services subscriber sessions client-id *client-id***

# Gx-Plus Overview

- [Gx-Plus for Provisioning Subscribers Overview on page 507](#)
- [Understanding Gx-Plus Interactions Between the Router and the PCRF on page 509](#)

## Gx-Plus for Provisioning Subscribers Overview

Gx-Plus is a Diameter-based application that extends the capability of the Gx interface. The 3rd Generation Partnership Project (3GPP) defined Gx as the online policy interface between the Policy Control and Charging Rules Function (PCRF) and the Policy and Charging Enforcement Function (PCEF), to provide control over policy and flow-based charges for subscribers. The PCRF is a centralized policy decision point that deploys business policy rules to allocate broadband network resources and manages flow-based charges for subscribers and services. The router functions as the PCEF in this environment.

Gx-Plus provides provisioning, activation, and deactivation of services; threshold triggers for service statistics processing; service accounting; subscriber session termination; fault recovery; and event (subscriber login and logout) notifications. The terminology typically used for PCRFs varies slightly from standard Junos OS terminology. The terms listed in [Table 53 on page 507](#) are interchangeable.

Table 53: Differences Between Gx-Plus and Junos OS Terminology

| Gx-Plus                      | Junos OS                            |
|------------------------------|-------------------------------------|
| policy                       | service                             |
| rule                         | service                             |
| rule install or installation | service activation or instantiation |
| rule uninstall               | service deactivation                |
| usage monitoring             | service accounting                  |

Gx-Plus enables the router acting as a PCEF to exchange Diameter Credit-Control Application (DCCA) messages with a PCRF residing on a server to request credit authorization and service provisioning for authenticated subscribers. When an application requests AAA to activate a subscriber's session, the router sends a Credit-Control-Request

(CCR) message to determine whether the subscriber has credit for the desired services and to request provisioning of those services from the PCRF policy manager.

The PCRF responds with a Credit-Control-Answer (CCA) message that indicates success or failure for credit authorization. If the subscriber has sufficient credit for the requested services, credit is authorized. If the subscriber has insufficient credit for the services, credit authorization fails.

The CCA can include services to be activated for the subscriber. If the response times out, the subscriber is logged in but only default services—if present—are activated for the subscriber. The router interprets the omission of the Result-Code AVP from the CCA as a provisioning authorization failure and does not allow the subscriber to log in.

When a subscriber client application, such as DHCP, sends a subscriber logout notice to AAA, the router in turn sends a CCR message to the PCRF to request subscriber termination. The PCRF acknowledges the logout with a CCA message.

Different Diameter message types exchanged by the router and the PCRF contain different sets of attribute-value pairs (AVPs). If data for an AVP is not available for a request to the PCRF, that AVP is omitted from the message. If the PCRF subsequently has insufficient information to decide on the request, it may deny the request.

Gx-Plus establishes sessions that correspond to IPv4 DHCP sessions on dual-stack IPv6/IPv4 or IPv4-only subscriber interfaces, depending on the access profile. By default, IPv6 information is not communicated to the PCRF. You must explicitly configure Gx-Plus to include IPv6 information. When you do so, Gx-Plus can establish sessions that correspond to DHCPv6 sessions on IPv6-enabled subscriber interfaces and on dual-stack IPv6/IPv4-enabled interfaces.

For dual-stack DHCP subscribers (DHCPv4 and DHCPv6 on the same VLAN), each DHCP session is treated as a separate Gx-Plus session. However, only a single Gx-Plus session exists for dual-stack PPP sessions.

Gx-Plus includes the following fault tolerance and recovery capabilities:

- Unlimited retries of unacknowledged provisioning requests
- Unlimited retries of logout requests
- Router event notification
- Router discovery

**NOTE:** More than one Diameter-based application (function), such as Gx-Plus or JSRC, can run on a router simultaneously.

---

**Related  
Documentation**

- [Messages Used by Diameter Applications on page 423](#)
- [Diameter AVPs and Diameter Applications on page 427](#)
- [Understanding Gx-Plus Interactions Between the Router and the PCRF on page 509](#)

- [Configuring Gx-Plus on page 515](#)

## Understanding Gx-Plus Interactions Between the Router and the PCRF

This topic describes the sequences of Diameter messages exchanged by means of Gx-Plus between the Policy Control and Rules Charging Function (PCRF) and the router acting as a Policy and Charging Enforcement Function (PCEF) as they interact to perform the following tasks for subscriber access:

- Subscriber login
- Fault tolerance and event notification
- Subscriber audit
- Subscriber logout

### Subscriber Login

Gx-Plus provisioning is enabled for subscribers when you include the **provisioning-order gx-plus** statement at the **[edit access profile *profile-name*]** hierarchy level. When an application requests AAA to activate the subscriber's session, the router sends a CCR-I message to the PCRF to request provisioning for the subscriber session. The CCR-I message must include the Juniper-Virtual-Router, Framed-IP-Address, and NAS-Port-ID AVPs. The request is not generated when no IPv4 address has been assigned to the subscriber, when IPv6 is enabled and an IPv6 address has been assigned, or when the NAS-Port-ID is unknown.

The PCRF returns a CCA-I message that includes the Result-Code AVP (AVP code 268). The router considers a CCA-I that does not include the Result-Code AVP as a failed response. The CCA-I can return the Charging-Rule-Install AVP (AVP code 1001), which identifies services to be activated.

If the Result-Code value is `DIAMETER_SUCCESS` (2001), the router communicates to AAA that the requested service is activated. If the Result-Code value is `DIAMETER_AUTHORIZATION_REJECTED`, the router communicates to AAA that the service activation is not permitted. If the Result-Code AVP has any other value, or is missing, the request is retried. A total of three CCR-I messages can be sent.

If the PCRF does not indicate success or failure, then by default the router continues to send requests, but the retry requests are CCR-N messages (no-response notifications) that include the Juniper-Provisioning-Source AVP (AVP code 2101). This AVP indicates that the router has local decision-making authority to provision services in the absence of a PCRF response to the CCR-I. This AVP is not present in the CCR-I message.

A subscriber login initiates the following sequence of events:

1. A client application—such as DHCP, PPP, or static subscriber sessions—requests AAA to authenticate the subscriber.
2. Authentication begins if the subscriber access profile specifies RADIUS authentication. Login continues when the authentication is successful. Login fails when the

**authentication-order** statement in the profile does not specify RADIUS authentication or no authentication. Login fails unless the **authentication-order** statement in the profile specifies RADIUS authentication or no authentication. Login also fails when authentication fails.

3. Default services are activated for the subscriber. Any services that the authentication server includes in the authentication grant are activated. Additionally, a default service may have been configured for the client application.
4. If the subscriber access profile specifies Gx-Plus provisioning, the router initiates the Gx-Plus message exchange by sending a CCR-I message to the PCRF. The router waits for the PCRF to respond with a CCA-I message within a non-configurable timeout period.

When the PCRF responds within the timeout period and includes the Charging-Rule-Install AVP in the CCA-I message, subscriber login is delayed while the router deactivates any default services and attempts to activate the specified services.

- If all the specified services are activated, then the login completes.
- If any of the services cannot be activated, the router sends the PCRF a CCR-U message with the status of the services (a rule report). The PCRF responds to this message with a CCA-U that can contain a new set of services for activation.
- The router ignores any default services, even if the CCA-I message does not include any services. In this circumstance, no services are activated.

If the PCRF does not return a CCA-I within the timeout period, subscriber login completes.

- The router searches first for services returned from the authentication server and activates any it finds. If no such services are found, then the router activates any locally configured default services. Subscriber login completes when default service activation is successful, but fails when any default service fails to activate. Because default services are not required to be present, login also completes when no default services are found.
  - If login completes (with or without a default service), the router periodically resends the CCR-I message to the PCRF. If the PCRF subsequently returns a CCA-I, the router deactivates the default service, if any, and then activates any services included in the CCA-I. If the message does not include any services, then no services are activated, not even a default service.
  - If any of the services contained in the CCA-I cannot be activated, the router sends the PCRF a CCR-U message with the status of the services (a rule report). The PCRF responds to this message with a CCA-U that can contain a new set of services for activation.
5. The router begins to monitor session accounting statistics if the CCA-I message includes any threshold triggers for usage monitoring. The Usage-Monitoring-Information AVP (AVP code 1067) contains the threshold triggers in the Granted-Service-Unit AVP (AVP code 431). The triggers are the values granted by the PCRF for the following statistics: duration of the session, input octets count, output octets count, and total octets count.

- a. If the service statistics meet or exceed any of these trigger thresholds during the session, the router sends a CCR-U message to the PCRF with accounting information in the Usage-Monitoring-Information AVP (AVP code 1067). The AVP now contains the Used-Service-Unit AVP (AVP code 446) to report the current values for all four statistics.
- b. In response, the PCRF may return a CCA-U message with the Usage-Monitoring-Information AVP, which can include any of the following: the Granted-Service-Unit AVP with new threshold triggers (absolute values rather than increments to the previous thresholds), the Charging-Rule-Install AVP (AVP code 1001) for service activations, or the Charging-Rule-Remove AVP (AVP code 1002) for service deactivations.

**NOTE:** The router does not aggregate statistics across services.

6. When the subscriber logs out, the router sends a CCR-T message (termination notice) to the PCRF, which responds with a CCA-T message.

## Fault Tolerance and Event Notification

Although the probability is low, the PCRF and the router can have different values for the number of subscribers. This error can arise from the following scenarios:

- CCA-I loss: if no CCA-I is delivered to the router, then the PCRF considers a subscriber as provisioned whereas the router considers it not provisioned.
- CCR-T loss: if no CCR-T is delivered to the PCRF, then the PCRF considers a subscriber to be provisioned whereas the router considers the subscriber not provisioned (logged out).

Loss of messages can be greater during cold boots and high availability events. Unacknowledged CCR-I and CCR-T requests are retransmitted forever until a satisfactory response is received to reduce the incidence of failure, and significant events are reported to Gx-Plus. By default, the number of outstanding requests is limited to 40 to avoid overloading the PCRF. This limit reduces the possibility of losing requests. You can modify this number by including the **max-outstanding-requests** statement at the **[edit access-gx-plus global]** hierarchy level.

Gx-Plus does not rely on the connection state between devices to detect router or PCRF outages, because some events do not affect the connection state and others are not detected when there is a Diameter relay or proxy between the devices. Event notifications (JSER messages) are sent when certain events take place on the router. The Juniper-Event-Type AVP (AVP code 2103) in the message describes the event.

Event notifications are retried until Gx-Plus returns a JSEA message with a Result-Code value of **DIAMETER\_SUCCESS** (2001) to acknowledge receipt of the event notification. When retrying notifications, one notification is sent for each outstanding event. No other request are sent as long as there is any outstanding event other than an application watch dog (AWD).

Table 54 on page 512 lists router events and the subsequent router and PCRF actions.

**Table 54: Router Events, Router Actions, and PCRF Actions**

| Router Event                                                                                                                                                                                                            | Router Action            | PCRF Action                                           |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|-------------------------------------------------------|
| The router receives no response from the PCRF or an error response.                                                                                                                                                     | Send event notification. | Respond to event notification.                        |
| The configuration changes.<br><br>Significant changes such as the origin host or realm and the Gx-Plus partition destination host or realm also increment the value of the Origin-State-Id AVP.                         | Send event notification. | Respond to event notification and perform discovery.  |
| The router receives an explicit discovery request from the PCRF.                                                                                                                                                        | Send event notification. | Respond to event notification.                        |
| The router undergoes a cold boot and all sessions are lost. This can result from a catastrophic failure or power cycle.                                                                                                 | Send event notification. | Respond to event notification and clear the database. |
| The router undergoes a warm boot.                                                                                                                                                                                       | Send event notification. | Respond to event notification and clear the database. |
| Recovery resources that are needed to continuously retry unacknowledged requests (CCR-N and CCR-T messages) are exhausted. The value of the Origin-State-Id AVP is incremented.<br><br>This event is unlikely to occur. | Send event notification. | Respond to event notification and perform discovery.  |

An important aspect of Gx-Plus fault tolerance is that subscriber login and termination requests are retried (replayed) forever until a satisfactory response is received from the PCRF. In rare circumstances, this can result in a stack of pending requests being replayed over and over.

You can issue the **clear network-access gx-plus replay** command to clear all pending requests. This command causes Gx-Plus to send a JSER message to PCRF that includes the Juniper-Event-Type AVP (AVP code 2103) with a value of 3 indicating a discovery request. The PCRF then returns a JDER message to initiate discovery of all subscribers. When this discovery completes, all pending subscriber requests are cleared.

## PCRF-Generated Discovery

The PCRF runs a discovery process in response to data loss, exhaustion of router resources, operator request, or router request. The JSER message specifies the level of verbosity desired in the reply from Gx-Plus. The message also specifies whether the request is for data about a particular session or information similar to an SNMP Get-Bulk for all sessions. Gx-Plus returns a JSDA message that indicates complete success, limited success, or an error. In the event of success, the requested data is also returned.

## Subscriber Accounting

When the PCRF returns a CCA-I message to the router, the message may contain thresholds for any of several usage statistics for a subscriber service: Duration, input data, output data, or total data for the service session. Upon receipt of a threshold, the router begins monitoring the subscriber's service session activity for that statistic. When the usage statistic reaches the threshold, it triggers the router to send a Gx-Plus usage notification message (CCR-U) to the PCRF. In response, the PCRF may send a CCA-U message to specify a new threshold, activate new services, or deactivate current services.

The PCRF can also send a CCR-U message that explicitly requests usage monitoring for statistics at different levels. The router can monitor usage at the subscriber level or at the service level. The Granted-Service-Unit AVP in the message specifies one or more of the following the statistics:

- CC-Input-Octets
- CC-Output-Octets
- CC-Total-Octets
- CC-Time

If any other statistics are specified, the router sends the PCRF a CCA message indicating that incorrect statistics were requested. When the specified threshold for a monitored statistic is reached, the router sends a CCR-U that contains the usage report for the statistics. In response, the PCRF sends another CCA-R with new thresholds or a request to activate or deactivate services.

## Subscriber Logout

When the client application sends a subscriber logout notice to AAA, Gx-Plus sends a CCR-T message to notify the PCRF that the provisioned subscriber session is being terminated. The PCRF returns a CCA-T message that includes the Result-Code AVP. If the Result-Code value is DIAMETER\_SUCCESS, Gx-Plus notifies AAA, and AAA notifies the application that the logout is complete. If Gx-Plus does not receive a CCA-T message, or if the Result-Code AVP has any other value or is missing, then the termination request is retried until the CCA-T message is returned with DIAMETER\_SUCCESS.

## Configuring Gx-Plus

---

You can configure the Gx-Plus client application to work with a PCRF policy manager residing on a server. The PCRF is a centralized policy decision point that deploys business rules to allocate broadband network resources and manage subscribers and services. AAA on the router (acting as the PCEF) uses Gx-Plus to request service provisioning from the PCRF.

**NOTE:** Contact the Juniper Networks Technical Assistance Center (JTAC) for information on supported PCRFs.

To configure Gx-Plus:

1. Configure the Gx-Plus partition.  
[See “Configuring the Gx-Plus Partition” on page 516.](#)
2. Configure Gx-Plus global attributes: the number of outstanding requests permitted and the inclusion of IPv6 subscribers.  
[See “Configuring Gx-Plus Global Attributes” on page 517.](#)
3. Configure Gx-Plus provisioning for subscribers.  
[See “Provisioning Subscribers with Gx-Plus” on page 518.](#)
4. (Optional) Override PCRF control of a subscriber session to correct services or troubleshoot a problem.  
[See “Disabling PCRF Control of a Subscriber Session” on page 518.](#)
5. (Optional) Configure Gx-Plus event tracing as part of general authentication service tracing operations.

See [“Tracing General Authentication Service Processes”](#) on page 163.

**Related Documentation**

- [Gx-Plus for Provisioning Subscribers Overview](#) on page 507

## Configuring the Gx-Plus Partition

Gx-Plus works within a specific logical system: routing instance context, called a partition.

**NOTE:** Currently, only a single partition is supported; you must configure it within the default logical system: routing instance context.

Before you configure the Gx-Plus partition, perform the following task:

- Configure the Diameter instance at the **[edit diameter]** hierarchy level. See [“Configuring Diameter”](#) on page 437.

Configuration for the Gx-Plus partition consists of naming the partition and then associating a Diameter instance, the PCRF hostname, and the PCRF realm with the partition.

To configure the Gx-Plus partition:

1. Create the partition or specify the name of an existing partition.

```
[edit access gx-plus]
user@host# set partition partition-name
```

2. Specify the Diameter instance for the Gx-Plus partition.

**NOTE:** Currently, only the default Diameter instance, *master*, is supported.

```
[edit access gx-plus partition partition-name]
user@host# set diameter-instance instance-name
```

3. (Optional) Configure the destination host for the Gx-Plus partition.

```
[edit access gx-plus partition partition-name]
user@host# set destination-host hostname
```

4. Configure the destination realm for the Gx-Plus partition.

```
[edit access gx-plus partition partition-name]
user@host# set destination-realm realm
```

The following example shows a Gx-Plus partition configuration.

```
gx-plus {
  partition partition1 {
    diameter-instance master;
    destination-host pcrf1;
    destination-realm generic.example.com;
  }
}
```

}

## Configuring Gx-Plus Global Attributes

---

You can configure attributes that apply to all Gx-Plus partitions globally.

When a request from Gx-Plus to the PCRF is not answered or is improperly answered, Gx-Plus keeps retrying the request until it receives an appropriate answer. If the number of requests grows too large, the PCRF can become overloaded and messages can be lost. To reduce this risk, you can set a limit on the number of outstanding requests to the PCRF that Gx-Plus can retry.

By default, Gx-Plus does not include IPv6 subscribers in Gx-Plus provisioning requests to the PCRF. Instead, Gx-Plus only establishes sessions that correspond to IPv4 DHCP sessions on dual-stack IPv6/IPv4 or IPv4-only subscriber interfaces. You must explicitly configure Gx-Plus to include IPv6 information. When you do so, Gx-Plus can establish sessions that correspond to DHCPv6 sessions on IPv6-enabled subscriber interfaces and on dual-stack IPv6/IPv4-enabled interfaces.

To configure Gx-Plus global attributes:

1. (Optional) Set a limit on the number of outstanding requests.

```
[edit access gx-plus global]
user@host# set max-outstanding-requests number
```

2. (Optional) Include IPv6 subscribers in provisioning requests.

```
[edit access gx-plus global]
user@host# set include-ipv6
```

For example to limit the number of outstanding requests to 30 and to include IPv6 subscribers:

```
[edit access gx-plus global]
user@host# set max-outstanding-requests 30
user@host# set include-ipv6
```

## Provisioning Subscribers with Gx-Plus

---

You can configure AAA to use Gx-Plus to request provisioning from a PCRF to instantiate services for an authenticated subscriber.

Before you configure Gx-Plus provisioning for subscribers, perform the following task:

- Create the subscriber access profile at the **[edit access profile]** hierarchy level. See [“Configuring an Access Profile for Subscriber Management” on page 137](#).

To configure Gx-Plus provisioning:

- Specify **gx-plus** as the provisioning method in the profile.

```
[edit access profile profile-name]
user@host# set provisioning-order gx-plus
```

## Disabling PCRF Control of a Subscriber Session

---

When a subscriber has been provisioned with Gx-Plus, services for that subscriber can be activated and deactivated only by the PCRF. Accordingly, AAA rejects any RADIUS CoA requests for subscribers provisioned by Gx-Plus. Similarly, CLI-based service activation and deactivation do not work while a subscriber is remotely provisioned.

Network administrators without PCRF access or authority may need to override PCRF control on a particular subscriber session to troubleshoot the session or correct the subscriber services. You can disable PCRF control by issuing the **request network-access aaa subscriber set session-id** command. In response, the router sends a termination notice to the PCRF, but does not actually log out the subscriber.

When you have confirmed that provisioning is disabled, you can then activate or deactivate subscriber services for that session with the **request network-access aaa subscriber add session-id** and **request network-access aaa subscriber delete session-id** commands, respectively. These commands fail if provisioning is still enabled.

Another consequence of disabling provisioning for a subscriber session is that RADIUS change of authorization (CoA) messages can modify the session.

Before you begin, determine or verify the ID for the session by displaying the session IDs of all current subscribers with the **show subscribers detail** or **show network-access aaa subscribers** command.

To disable control by the PCRF over a subscriber session:

1. Disable provisioning for the specified subscriber session ID.

```
user@host> request network-access aaa subscriber set session-id subscriber-session-id
provisioning-state none
```

2. (Optional) Verify that provisioning is disabled for the session.

```
user@host> show network-access aaa subscribers session-id subscriber-session-id
detail
```

For example, to disable provisioning for subscriber larry:

```
user@host> show network-access aaa subscribers
Username      Logical system/Routing instance  Client type  Session-ID
...
larry         default:default                  dhcp         55
...

user@host> request network-access aaa subscriber set session-id 55 provisioning-state none
user@host> show network-access aaa subscribers session-id 55 detail
Type: dhcp
Username: larry@isp5.net
Stripped username: larry
AAA Logical system/Routing instance: default:default
Target Logical system/Routing instance: default:retail-onlinecompany-ca
Access-profile:retailer-onlinecompany-sjc
Session ID: 55
Accounting Session ID: 55
Multi Accounting Session ID: 0
IP Address: 192.168.44.104
Authentication State: AuthStateActive
Accounting State: Acc-Start-Send
Provisioning-type: none
Service name: basic-service
Service State: SvcActive
Session ID: 56
Session uptime: 00:01:45
```

## Mobile IP Home Agent Elements and Behavior

---

Mobile IP is a tunneling-based solution that enhances the utility of Junos routing platforms at the edge of the network between fixed wire and wireless network domains. This tunneling-based solution enables a router on a user's home subnet to intercept and forward IP packets to users who roam beyond traditional network boundaries. Mobile IP is useful in environments where mobility is desired and the traditional land line dial-in model does not provide an adequate solution, and in environments where a wireless technology is used.

You configure Mobile IP home agent parameters in the **[edit services mobile-ip]** hierarchy level, the **[edit logical-systems *logical-system-name*]** hierarchy level, and the **[edit routing-instances *routing-instances-name*]** hierarchy level.

**NOTE:** Currently, Junos OS does not support configuration of the Mobile IP foreign agent.

Traditionally, IP addresses are associated with a fixed network location. To achieve mobility, the mobile node assumes a secondary IP address that matches the new network and redirects the traffic bound to the primary or home address to the mobile node's new network. In the Mobile IP architecture, the two agents that accomplish this task are the home agent and the foreign agent.

When a mobile node roams into a new, foreign network, it negotiates with the foreign agent to get a secondary IP address, which is referred to as the care-of address. The mobile node registers this care-of address with the home agent. The home agent then establishes a tunnel to the care-of address if the tunnel is not established earlier.

**NOTE:** You need to establish only one tunnel between the home agent and the care-of address. Demultiplexing of the traffic is done through IP address inspection.

Packets sent to the home address of the mobile node are redirected by the home agent through the tunnel to the care-of address at the foreign agent. The foreign agent routes the packets to the mobile node's home address. [Figure 8 on page 524](#) illustrates this forwarding and routing process behavior. Although the traffic to the correspondent node comes from the foreign agent, to the correspondent node the traffic appears to come from the mobile node's home network.

**Figure 8: Mobile IP Network Without Reverse Tunneling**

If the mobile node's home address is a private address or if the foreign agent implements ingress filtering, a reverse tunnel from the care-of address to the home agent is required. This reverse tunnel capability is negotiated between the foreign agent and the home agent when the mobile node requests registration. Traffic from a correspondent node to the mobile node is forwarded by the home agent through the foreign agent as in the other scenario. [Figure 9 on page 525](#) shows how traffic from the mobile node to a correspondent node is tunneled from the foreign agent to the home agent and then routed to the correspondent node by the home agent.

Figure 9: Mobile IP Network with Reverse Tunneling

Mobile nodes typically belong to a virtual network, which is an address range or subnet that is not directly served by any physical, routed interface on the home network. These mobile nodes never return home to attach to a physical interface on the home agent. Traffic destined for the mobile node can be forwarded over any interface.

You can use the Mobile IP home agent feature to configure the home agent within the default router context with either local or AAA authentication. When you configure local authentication, you can also configure Mobile IP independently in any named routing instance in any configured logical router. When you configure AAA as the authentication method, you can configure Mobile IP only in the default router context.

The Mobile IP home agent can also receive, process, and send Worldwide Interoperability for Microwave Access (WiMAX) vendor-specific RADIUS attributes (VSAs). This feature enables Mobile IP home agent to work in a WiMAX home connectivity services network (H-CSN), to provide for mobility management at the IP layer.

The home agent handles the following tasks:

- Registration of mobile nodes
- Routing and forwarding of mobile node traffic

## Mobile IP Registration

---

The home agent receives the registration requests (RRQs) on UDP port 434. The registration request contains the home agent IP address. The home agent can support static home address allocation and dynamic home address allocation. The home agent can revoke a mobile node's registration. When this happens, the mobility binding is removed and the foreign agent is informed of the revocation so it can free up its resources. The foreign agent can send a registration revocation request to the home agent when the mobile node roams to another area. The revocation request can include a revocation support extension to indicate that it supports the revocation mechanism.

## Home Address Assignment

The mobile node's home address can either be preconfigured, or dynamically allocated by the Mobile IP home agent. If a nonzero home address is preconfigured, the home agent processes the registration request using the home address and NAI (if the NAI is present).

If the home address is dynamically allocated, the mobile node submits a zero home address and requests the home agent to assign an IP address. The mobile node then uses the address provided by the home agent for subsequent registration requests, until the mobile node is rebooted or the registration expires.

Home address allocation is done by one of the existing authentication, authorization, and accounting (AAA) server back-end address mechanisms, such as:

- By RADIUS, in the Framed-IP-Address attribute
- From a local address pool returned by RADIUS in the Framed-Pool attribute

## Authentication

The home agent authenticates the requests based on RFC 3344—IP Mobility Support for IPv4 (August 2002). By default, a AAA server is used for authentication; alternatively, you can configure local authentication parameters on the home agent. The mobile node authentication is verified and the authentication algorithm and key are retrieved by checking the security association indexed by the security parameter index (SPI) value. This verification results in the key and the authentication algorithm with which to compute an MD-5 message digest over the registration request. The Mobile IP home agent supports both HMAC-MD5 and keyed-MD5 authentication algorithms. When the result of this computation matches the authenticator, the mobile-home extension is authenticated. For local authentication, the key is limited to a maximum of 128 bits. For AAA authentication, the key can be longer depending on the maximum length configured on the AAA server.

When HA receives the access accept from the AAA, it extracts the MN-HA key from the response. The home agent does the MN-HA authentication extension processing based on the MN-HA key by running authentication algorithm (HMAC-MD5 or Keyed-MD5) on the message to compute a hash (authenticator), which is compared with the hash value in the MN-HA extension. If the hash value matches, the RRQ is considered authenticated.

If a security association is configured for the foreign agent, the foreign-home authentication extension is verified; otherwise, authentication success is based only on the mobile-home authenticator.

The home agent checks the identification (ID) field to verify that a registration message has been freshly generated by the mobile node, and is not simply being replayed by an attacker from some previous registration. The ID field represents a 64-bit Network Time Protocol (NTP)-formatted time value. The configured replay timestamp defines the tolerance time window in seconds by which a registration request timestamp and the local time of the HA can differ. By default, the timestamp must be within 7 seconds of the replay tolerance configured for the mobile node or, if that is configured, the timestamp tolerance of the home agent itself.

## Reauthentication

Reauthentication is not currently supported by the authentication process. Mobile IP caches a security association for each mobile node, which helps overcome this limitation. When a mobile node requests re-registration or de-registration, Mobile IP refers to the cached security association for that mobile node and performs MD5 message authentication.

When the security association for the mobile node changes after the node is authenticated, the cache entry is not invalidated. Consequently, the mobile node's RRQ is rejected. In this case you must clear the binding with the mobile node so that it can de-register and then log in.

RADIUS server configuration changes relating to the subscriber do not propagate to the cache. In this case you must clear the binding with the mobile node so that it can de-register and then log in.

## AAA Authentication

You can store the security associations and configuration information remotely on a RADIUS server. The home agent applies the authentication algorithm and security key to the mobile node's message. The AAA server uses Juniper Networks vendor-specific attributes (VSAs; vendor ID 4874) listed in [Table 55 on page 527](#). These VSAs are mandatory in the reply to provide the appropriate authentication algorithm and the secure key for the authentication request. If the security parameters are not retrieved, then the request for mobility service is rejected, a security violation error is logged, and no registration reply is generated.

**Table 55: Juniper Networks VSAs Used by Mobile IP**

| Attribute Number | Attribute Name      | Description                                              | Value            |
|------------------|---------------------|----------------------------------------------------------|------------------|
| 26–84            | Mobile-IP-Algorithm | Authentication algorithm used for Mobile-IP registration | integer: 4-octet |
| 26–85            | Mobile-IP-SPI       | Security parameter index for Mobile IP registration      | integer: 4-octet |

Table 55: Juniper Networks VSAs Used by Mobile IP (*continued*)

| Attribute Number | Attribute Name     | Description                                             | Value            |
|------------------|--------------------|---------------------------------------------------------|------------------|
| 26–86            | Mobile-IP-Key      | Security association MD5 key for Mobile IP registration | string: key      |
| 26–87            | Mobile-IP-Replay   | Replay timestamp for Mobile IP registration             | integer: 4-octet |
| 26–89            | Mobile-IP-Lifetime | Registration lifetime for Mobile IP registration        | integer: 4-octet |

AAA authentication is accomplished by generating a AAA access-request to a AAA server. This is the default authentication mode, but you can include the **authenticate order aaa** statement at the **[edit services mobile-ip]** hierarchy level to explicitly configure AAA authentication. You cannot configure a fallback mechanism for AAA authentication. If the AAA request times out, the home agent does not fall back on the local router to determine the authentication parameters. The registration request is rejected. When the message is authenticated, the AAA server always returns either the Framed-IP-Address or Framed-Pool attribute for the user.

The presence of the mobile node's NAI and home IP address in the authentication request that the home agent sends to the AAA server is determined by their presence in the mobile node RRQ received by the home agent:

- When both the NAI and home IP address of the mobile node are present in the registration request, then the authentication request from Mobile IP to AAA has the NAI as the user name.
- When only the NAI is present in the registration request, then the NAI is used as the user name.
- When only the IP address (home address) is present in the registration request, then the IP address is used as the user name.
- When both the NAI address and the IP address are missing from the registration request, then the registration request is rejected.

## Local Authentication

As an alternative to the default authentication by AAA server, you can store the security associations and configuration information locally on the router hosting the home agent. Local authentication is accomplished by querying the locally configured security parameters for the mobile node. The home agent applies the authentication algorithm and security key to the mobile node's message. If the security parameters are not available or do not match the RRQ, then the request for mobility service is rejected, a security violation error is logged, and no registration reply is generated.

For local authentication, include the **authenticate order local** statement at the **[edit services mobile-ip]** hierarchy level. You cannot configure a fallback mechanism for local

authentication. If the local authentication fails, the home agent does not fall back on the AAA server to determine the authentication parameters. The registration request is rejected. Include the **peer** statement at the **[edit services mobile-ip]** hierarchy level to configure the authentication attributes on the home agent for a user identified by IP address or network address identifier (NAI). This user can be a mobile node or a foreign agent.

The authentication attributes include a security parameter index (SPI) to identify a particular security context between the home agent and the mobile node or foreign agent among the contexts available in the mobility security association. Associated with each SPI is the MD5 algorithm and key used to authenticate messages from the mobile node or foreign agent. You can also configure the replay timestamp tolerance for the mobile node or foreign agent.

When local authentication is configured, you can configure Mobile IP independently in any named routing instance in any configured logical router. All Mobile IP statements are available in those contexts, except for the **order aaa** statement at the **[edit services mobile-ip authenticate]** hierarchy level.

## Accounting

The Junos Mobile IP home agent application supports time-based accounting for Mobile IP subscribers. Include the **statistics time** statement in the subscriber access profile at the **[edit access profile profile-name accounting]** hierarchy level. Time-based accounting for Mobile IP subscribers also requires that you include the **authenticate order aaa** statement at the **[edit services mobile-ip]** hierarchy level. Accounting begins when the Mobile IP home agent registers the mobile node and creates a binding with the mobile node.

Accounting stops when the binding is deleted. Any of the following actions can cause the binding to be deleted:

- The mobile user logs off.
- The binding lifetime expires.
- The mobile node is deregistered for any reason.
- The foreign agent sends a revocation message.

The Acct-Start message the home agent sends to the AAA server includes the network address identifier (NAI) in the User-Name attribute and the home address of the mobile IP node in the Framed-IP-Address attribute. The Acct-Stop message additionally includes the Acct-Session-Id and Acct-Session-Time attributes.

You cannot currently configure time-based accounting for only the Mobile IP service in a given logical router or routing instance. Enabling time-based accounting for Mobile IP also enables time-based accounting for all other services that are configured in that logical router or routing instance. If you do not want time-based accounting to apply to other services, then you must configure those services in a different logical router or routing instance.

## Mobile IP Routing and Forwarding

Mobile IP employs a care-of address to process traffic for the mobile node.

The mobile node acquires the a care-of address from the foreign agent. The care-of address is reachable from the mobile node, and routable from the home agent. The mobile node includes the care-of address in its registration request to the home agent. After AAA or local authentication successfully processes and authenticates the RRQ and provides both the authorization parameters for the mobile node and an IP address, the home agent then sets up the data path for the mobile node and sends back a registration reply (RRP) confirming successful registration of the mobile node.

When the foreign agent receives the successful RRP from the home agent, the foreign agent sets up the data path for the mobile node. Then it sends the RRP to the mobile node to acknowledge that the mobile node is now successfully registered and the data path between the home agent and the mobile node is in place.

The home agent supports generic routing encapsulation (GRE) and IP-in-IP tunnel encapsulation for forward and reverse tunneling. The tunnels must be statically configured. When packets destined for the mobile node reach a home agent, the home agent encapsulates the packets and tunnels them to the care-of address. Packets that exceed the maximum transmission unit (MTU) value of the tunnel are dropped and an ICMP error message is sent to the source IP address. Packets without an access route are returned to the source with an ICMP destination unreachable error message. For reverse tunnels, packets are de-tunneled and forwarded towards the next hop to the destination address.

Mobile IP does not support graceful Routing Engine switchover (GRES). It handles the rebooting of processes in the following ways:

- Mobile IP process—After Mobile IP completes a restart, it removes the Mobile IP subscriber entries from AAA and the session database. When that is complete, Mobile IP can process new mobile node registration requests.
- AAA process—After AAA completes a restart, Mobile IP removes all subscriber data held internally by AAA and all corresponding session database entries.
- Routing protocol process—When the connection between the routing protocol process and Mobile IP is lost, Mobile IP responds by clearing the mobile node bindings that are associated with the logical system in which the routing protocol process restarted. The

routing protocol process maintains routes to mobile nodes during the restart. The routing protocol process flushes these routes if they are not reinstalled after the restart completes and before the stale route timer expires.

## Mobile IP in the WiMAX Environment

Worldwide Interoperability for Microwave Access (WiMAX) is the international standard for wide area radio access networks. It provides a framework for networks that are implemented in different ways to successfully interoperate with mobile subscribers that roam among the networks. This interoperability enables the subscribers to be authenticated by their home network wherever they roam, and to receive the services for which they are authorized.

The Mobile IP home agent can operate in either of two access modes, generic and WiMAX. The generic access type is appropriate when the home agent is deployed in a generic Mobile IP home network. When deployed as a home agent in a WiMAX home connectivity services network (H-CSN), you must configure the WiMAX access type. The WiMAX access type enables the Mobile IP home agent to receive, process, and send WiMAX vendor-specific attributes (VSAs) that are used by AAA and the RADIUS server to authenticate the mobile subscriber. When the access type is generic, the Mobile IP home agent cannot handle these VSAs.

**NOTE:** The Mobile IP configuration for WiMAX requires that AAA be used for the authentication method. For that reason, WiMAX is available only in the default router context.

A WiMAX H-CSN is analogous to the Mobile IP home network for non-WiMAX implementations. When WiMAX is enabled for the Mobile IP home agent in an H-CSN, the Mobile IP home agent triggers subscriber authentication when the agent receives the registration request. The home agent stores WiMAX Forum (vendor ID 24757) vendor-specific attributes (VSAs) listed in [Table 56 on page 532](#) in the session database based on the registration request.

Table 56: WiMAX Forum VSAs used by Mobile IP

| Attribute Number | Attribute Name   | Description                                                                                                                                                                                                                         | Value                                                                |
|------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| 26-1             | WiMAX-Capability | Identifies the WiMAX capabilities supported by the home agent (sent in the Access-Request message). In an Access-Accept message, identifies the capabilities selected by the RADIUS server (returned in the Access-Accept message). | string or integer                                                    |
| 26-6             | hHA-IP-MIP4      | IP address of the home agent (hHA) making the request                                                                                                                                                                               | octet string: IP address                                             |
| 26-10            | MN-HA-MIP4-KEY   | MN-hHA key sent by the RADIUS server for validation by the home agent                                                                                                                                                               | integer: 2-octet salt followed by 16-octet encrypted MN-hHA hash key |
| 26-11            | MN-HA-MIP4-SPI   | Security parameter index (SPI) associated with the MN-HA-MIP4 key                                                                                                                                                                   | integer: 4-octet                                                     |
| 26-15            | hHA-RK-KEY       | Key used by the NAS to generate FA-HA keys                                                                                                                                                                                          | integer: 2-octet salt followed by 16-octet encrypted MN-hHA hash key |
| 26-16            | hHA-RK-SPI       | SPI associated with the hHA-RK key                                                                                                                                                                                                  | integer: 4-octet                                                     |
| 26-17            | HA-RK-Lifetime   | Lifetime of the hHA-RK key and derived keys                                                                                                                                                                                         | integer: 4-octet                                                     |
| 26-18            | RRQ-HA-IP        | IP address of the home agent contained in the Mobile IP registration request or the binding update                                                                                                                                  | octet string: IP address                                             |

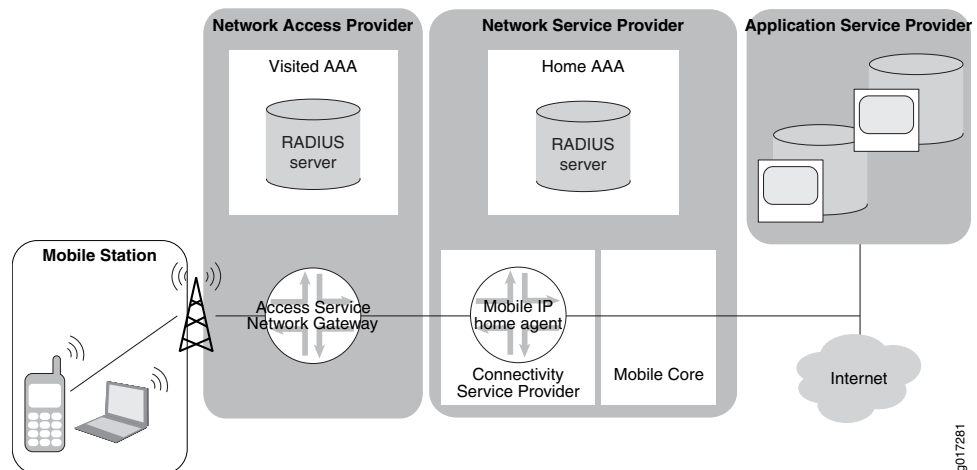

Table 56: WiMAX Forum VSAs used by Mobile IP (*continued*)

| Attribute Number | Attribute Name | Description                                                                                                                                                   | Value                                                                |
|------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| 26–19            | RRQ-MN-HA-KEY  | The MN-HA key bound to the home agent IP address as reported by the RRQ-HA-IP attribute. Used to validate the MN-HA-AE of the Mobile IP registration request. | integer: 2-octet salt followed by 16-octet encrypted MN-hHA hash key |

The home agent requests AAA to fetch the corresponding WiMAX-related information from the RADIUS server. The AAA client sends an Access-Request message to the server. The RADIUS server responds with the necessary WiMAX information, such as the MN-HA key and the HA-RK key, and then the AAA client passes the response to the home agent. The Mobile IP home agent verifies the response received from AAA, processes the registration request, and then grants, extends, or denies subscriber registration.

Figure 10 on page 533 shows the elements of a sample WiMAX topology.

Figure 10: Sample Mobile IP WiMAX Topology

The Mobile IP subscriber registration flow is a four-step process.

1. The access service network gateway (ASN-GW) sends the subscriber registration request from the mobile node to the Mobile IP home agent. The registration request is protected by the MN-HA authentication extension and the FA-HA authentication extension.
2. The home agent requests that the RADIUS server send the cryptographic keys for the Mobile IP session identified by user@realm. The home agent notifies the RADIUS server that it seeks to source IP session-based accounting messages.

3. The RADIUS server agrees to use IP session-based accounting, provides the requested cryptographic keys, and sends the AAA-Session-ID for this session.
4. The home agent replies to the Mobile IP registration request.

Reauthentication of WiMAX subscribers is not currently supported.

You can configure the Mobile IP home agent for WiMAX access by including the **wimax** statement at the **[edit services mobile-ip access-type]** hierarchy level. You can prevent the Mobile IP home agent from being able to process WiMAX VSAs by either removing the **wimax** statement at the **[edit services mobile-ip access-type]** hierarchy level or by including the **generic** statement at the **[edit services mobile-ip access-type]** hierarchy level. The default access type for Mobile IP home agent is generic.

## Configuring Mobile IP

---

You can configure Mobile IP to provide mobility for subscribers in IP networks. The Mobile IP home agent authenticates registration requests from mobile users and forward traffic to them at their care-of address without having to advertise that address to the wider network.

To configure Mobile IP for mobile subscriber access:

1. Configure the authentication method for registration requests, local or AAA.  
[See “Configuring the Mobile IP Authentication Method” on page 536.](#)
2. Configure the Mobile IP home agent.  
[See “Configuring the Mobile IP Home Agent” on page 536.](#)
3. Configure the authentication attributes for the mobile node.  
[See “Configuring the Local Authentication Attributes for the Mobile Node” on page 537.](#)

4. Configure accounting for Mobile IP subscribers.  
See [“Configuring Accounting for Mobile IP Subscribers” on page 538](#)
5. Configure the dynamic reassignment of the mobile node to another home agent.  
See [“Configuring Dynamic Home Assignment for the Mobile Node” on page 538](#).
6. Configure the access type for Mobile IP.  
See [“Configuring the Access Type for Mobile IP” on page 539](#).
7. Configure trace options for troubleshooting the configuration.  
See [“Tracing Mobile IP Operations for Subscriber Access” on page 539](#).

---

## Configuring the Mobile IP Authentication Method

You can configure Mobile IP to authenticate registration requests from mobile nodes by either the locally configured attributes or a AAA server. AAA server authentication is the default method.

**NOTE:** AAA server authentication is available only in the default router context. Local authentication is available in both default and nondefault router contexts.

To configure the Mobile IP authentication method:

- Specify either local or AAA authentication.  

```
[edit services mobile-ip]  
user@host# set authenticate order local
```

**Related  
Documentation**

- [Configuring Mobile IP on page 535](#)

---

## Configuring the Mobile IP Home Agent

To configure the home agent for a Mobile IP virtual network:

1. Configure the loopback IP address that is used as the home agent IP address.  

```
[edit services mobile-ip home-agent virtual-network]  
user@host# set home-agent-address 10.5.5.0
```
2. (Optional) Configure the maximum lifetime that the home agent accepts in any registration request from a mobile node.  

```
[edit services mobile-ip home-agent virtual-network]  
user@host# set home-agent-address 10.5.5.0 registration-lifetime 100
```
3. (Optional) Configure a timestamp tolerance for registration replay protection.  

```
[edit services mobile-ip home-agent virtual-network]  
user@host# set home-agent-address 10.5.5.0 timestamp-tolerance 200
```

4. Configure whether the home agent can revoke a mobile node's registration to deactivate the node.

```
[edit services mobile-ip home-agent virtual-network]
user@host# set home-agent-address 10.5.5.0 revocation-required
```

5. Specify the interfaces on which the home agent accepts registration requests.

```
[edit services mobile-ip home-agent]
user@host# set enable-service ge-0/0/1.0
user@host# set enable-service ge-0/0/2.0
user@host# set enable-service ge-0/0/3.0
user@host# set enable-service ge-0/0/4.0
```

**Related Documentation**

- [Configuring Mobile IP on page 535](#)

## Configuring the Local Authentication Attributes for the Mobile Node

You specify for each mobile node several attributes that enable authentication of registration requests from the node. These attributes include security association context for the peering relationship, the entity type of the node, the encryption algorithm and key used to authenticate the request, and replay protection.

To configure authentication attributes for the mobile node:

1. Configure the peer entity for the security parameter.

```
[edit services mobile-ip]
user@host# set peer ip-address 10.4.2.20 spi 500 entity-type mobility-agent
```

2. Configure the algorithm used for authenticating Mobile IP messages. By default, the hmac-md5 algorithm is used.

```
[edit services mobile-ip]
user@host# set peer ip-address 10.4.2.20 spi 500 algorithm md5
```

3. Configure the authentication key for the security association, in either HEX or ASCII format.

```
[edit services mobile-ip]
user@host# set peer ip-address 10.4.2.20 spi 500 key ascii xf125j9m
```

4. Configure a timestamp tolerance for registration replay protection or specify that the timestamp tolerance be taken from the value configured on the home agent.

```
[edit services mobile-ip]
user@host# set peer ip-address 10.4.2.20 spi 500 replay-method timestamp tolerance 250
```

**Related Documentation**

- [Configuring Mobile IP on page 535](#)

## Configuring Accounting for Mobile IP Subscribers

---

You can configure time-based accounting to track the subscriber sessions of Mobile IP subscribers.

To configure Mobile IP accounting:

1. Configure the IP address for the RADIUS accounting server.

```
[edit access profile mip-win4]
user@host# set radius accounting-server 192.168.20.5
```

2. Specify RADIUS as the accounting method for Mobile IP subscribers.

```
[edit access profile mip-win4 accounting]
user@host# set order radius
```

3. Specify time-based accounting for the access profile used for the subscriber.

```
[edit access profile mip-win4 accounting]
user@host# set statistics time
```

## Configuring Dynamic Home Assignment for the Mobile Node

---

The mobile node can request that the home agent dynamically assign an IP address for the home agent. The mobile node uses this address for the home agent in all subsequent registration requests until the registration expires or the mobile node is rebooted.

To configure the IP address to be used by the mobile node for the home agent:

- Configure the IP address for the specified mobile node.

```
[edit services mobile-ip]
user@host# set dynamic-home-assignment home-agent nai bws@example.com
home-agent 192.168.4.5
```

### Related Documentation

- [Configuring Mobile IP on page 535](#)

## Configuring the Access Type for Mobile IP

You can configure the Mobile IP home agent to operate in a Worldwide Interoperability for Microwave Access (WiMAX) home connectivity services network (H-CSN). This configuration enables the home agent to receive, process, and send WiMAX VSAs for subscriber authentication and registration. By default, Mobile IP cannot process the WiMAX VSAs. For operation in non-WiMAX environments, you can return it to this mode by configuring the **generic** access type.

**NOTE:** The Mobile IP configuration for WiMAX requires that AAA be used for the authentication method. For that reason, WiMAX is available only in the default router context.

To configure the access type, do one of the following:

- Configure generic operation.  

```
[edit services mobile-ip]
user@host# set access-type generic
```
- Configure WiMAX operation.  

```
[edit services mobile-ip]
user@host# set access-type wimax
```

## Tracing Mobile IP Operations for Subscriber Access

The Junos OS trace feature tracks Mobile IP operations and records events in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

Trace-related configurations are independent for each logical system and routing instance in which Mobile IP is configured. Mobile IP can generate two types of log messages:

- Trace messages common to all logical systems and routing instances in which Mobile IP is configured. Examples of this global message type are the messages generated by Mobile IP during initialization after it starts up. These trace messages are stored in the default trace file, `/var/log/mipd`. You cannot configure Mobile IP to save global messages in a different file. Mobile IP traces global messages by default.
- Trace messages specific to a logical system or routing instance in which Mobile IP is configured. An example of this message type is the message generated by Mobile IP when it receives a registration request. These trace messages are stored in the trace file configured for that logical system or routing instance. These messages cannot be saved in `/var/log/mipd`.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

1. Important events are logged in a file located in the `/var/log` directory. By default, the router uses the filename `mipd` for global tracing. You can specify a different filename, but you cannot change the directory in which trace files are located. Logical system and routing instance messages are logged in a file that you must configure separately from `mipd` in the `/var/log` directory.
2. When the trace log file *filename* reaches 128 kilobytes (KB), it is compressed and renamed *filename.0.gz*. Subsequent events are logged in a new file called *filename*, until it reaches capacity again. At this point, *filename.0.gz* is renamed *filename.1.gz* and *filename* is compressed and renamed *filename.0.gz*. This process repeats until the number of archived files reaches the maximum file number. Then the oldest trace file—the one with the highest number—is overwritten.

You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). (For more information about how log files are created, see the *Junos OS System Log Messages Reference*.)

By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

To configure Mobile IP tracing operations:

1. (Optional) Configure a trace log filename.  
See [“Configuring the Mobile IP Trace Log Filename” on page 541](#).
2. (Optional) Configure the number and size of trace logs.  
See [“Configuring the Number and Size of Mobile IP Log Files” on page 541](#).
3. (Optional) Configure user access to trace logs.  
See [“Configuring Access to the Mobile IP Log File” on page 542](#).
4. (Optional) Configure a regular expression to filter the information to be included in the trace log.  
See [“Configuring a Regular Expression for Mobile IP Messages to Be Logged” on page 542](#).
5. (Optional) Configure flags to specify which events are logged.  
See [“Configuring the Mobile IP Tracing Flags” on page 542](#).
6. (Optional) Configure a severity level for messages to specify which event messages are logged.  
See [“Configuring the Severity Level to Filter Which Mobile IP Messages Are Logged” on page 543](#).

## Configuring the Mobile IP Trace Log Filename

Global messages common to all Mobile IP logical systems and routing instances are recorded only in `/var/log/mipd`. Mobile IP automatically creates this file if it is not present when Mobile IP starts. You cannot configure global messages to be recorded in any other file.

You must specify a different name with the `file` option for messages that are specific to a logical system or routing instance in which Mobile IP is configured. Ensure that filenames are unique for each logical system or routing instance in which Mobile IP is configured. If you do not configure a trace filename for a logical system or routing instance, then nothing is traced for that entity.

To configure the filename for Mobile IP tracing operations for a logical system or routing instance:

- Specify the name of the file used for the trace output.

```
[edit logical-systems lr1 services mobile-ip traceoptions]
user@host# set file mip-lr1_1
```

### Related Documentation

- Tracing Mobile IP Operations for Subscriber Access on page 539

## Configuring the Number and Size of Mobile IP Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format `.number.gz`. The newest archived file is `.0.gz` and the oldest archived file is `.(maximum number)-1.gz`. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, `filename`, reaches 2 MB, `filename` is compressed and renamed `filename.0.gz`, and a new file called `filename` is created. When the new `filename` reaches 2 MB, `filename.0.gz` is renamed `filename.1.gz` and `filename` is compressed and renamed `filename.0.gz`. This process repeats until there are 20 trace files. Then the oldest file, `filename.19.gz`, is simply overwritten when the next oldest file, `filename.18.gz` is compressed and renamed to `filename.19.gz`.

To configure the number and size of trace files:

- Specify the name, number, and size of the file used for the trace output. (Mobile IP supports the `files` and `size` options for the `traceoptions` statement.)

```
[edit services mobile-ip traceoptions]
user@host# set file mip_1 _logfile_1 files 20 size 2097152
```

- Related Documentation**
- [Tracing Mobile IP Operations for Subscriber Access on page 539](#)

---

## Configuring Access to the Mobile IP Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

To specify that all users can read the log file:

- Configure the log file to be world-readable.

```
[edit services mobile-ip traceoptions]  
user@host# set file mip_1_logfile_1 world-readable
```

To explicitly set the default behavior, only the user who configured tracing can read the log file:

- Configure the log file to be no-world-readable.

```
[edit services mobile-ip traceoptions]  
user@host# set file mip_1_logfile_1 no-world-readable
```

- Related Documentation**
- [Tracing Mobile IP Operations for Subscriber Access on page 539](#)

---

## Configuring a Regular Expression for Mobile IP Messages to Be Logged

By default, the trace operation output includes all messages relevant to the logged events.

You can refine the output by including regular expressions that will be matched.

To configure regular expressions to be matched:

- Configure the regular expression.

```
[edit services mobile-ip traceoptions]  
user@host# set file mip_1_logfile_1 match regex
```

- Related Documentation**
- [Tracing Mobile IP Operations for Subscriber Access on page 539](#)

---

## Configuring the Mobile IP Tracing Flags

By default, only important events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

To configure the flags for the events to be logged:

- Configure the flags.

```
[edit services mobile-ip traceoptions]
```

```
user@host# set flag home-agent
```

**Related Documentation**

- [Tracing Mobile IP Operations for Subscriber Access on page 539](#)

---

## Configuring the Severity Level to Filter Which Mobile IP Messages Are Logged

---

The messages associated with a logged event are categorized according to severity level. You can use the severity level to determine which messages are logged for the event type. The severity level that you configure depends on the issue that you are trying to resolve. In some cases you might be interested in seeing all messages relevant to the logged event, so you specify **all** or **verbose**. Either choice generates a large amount of output. You can specify a more restrictive severity level, such as **notice** or **info** to filter the messages. By default, the trace operation output includes only messages with a severity level of **error**.

To configure the type of messages to be logged:

- Configure the message severity level.  

```
[edit services mobile-ip traceoptions]  
user@host# set level severity
```

## ATM for Subscriber Access Overview

---

By using the ATM Modular Interface Card (MIC) with small form-factor pluggable transceiver (SFP) and a supported Modular Port Concentrator (MPC), you can configure the MX Series router to support configurations that enable subscribers to access the router over an ATM network using ATM Adaptation Layer 5 (AAL5) permanent virtual connections (PVCs). Using these configurations enables the delivery of subscriber-based services, such as class of service (CoS) and firewall filters, for subscribers accessing the router over an ATM network.

This overview describes the following topics about configuring ATM interfaces for subscriber access:

- [Supported Configurations for ATM Subscriber Access on page 547](#)
- [PPP-over-Ethernet-over-ATM Configurations on page 548](#)
- [Routed IP-over-ATM Configurations on page 548](#)
- [Bridged IP-over-Ethernet-over-ATM Configurations on page 549](#)
- [PPP-over-ATM Configurations on page 549](#)
- [Configuration and Encapsulation Types for ATM Subscriber Access on page 550](#)

## Supported Configurations for ATM Subscriber Access

On MX Series routers with MPC/MIC interfaces that use the ATM MIC with SFP (Model Number MIC-3D-8OC3-2OC12-ATM), you can create the following configurations to enable subscribers to access the router over an ATM network using ATM Adaptation Layer 5 (AAL5) permanent virtual connections (PVCs):

- PPP-over-Ethernet-over-ATM
- Routed IP-over-ATM
- Bridged IP-over-Ethernet-over-ATM
- PPP-over-ATM

The following sections briefly describe each supported ATM subscriber access configuration.

## PPP-over-Ethernet-over-ATM Configurations

PPP-over-Ethernet-over-ATM (PPPoE-over-ATM) configurations support both statically created and dynamically created PPPoE (**pp0**) logical subscriber interfaces over static ATM underlying interfaces. Most PPPoE and subscriber services features supported on terminated connections and tunneled (L2TP access concentrator, or LAC) connections are also supported for access to an MX Series router over an ATM network.

PPPoE-over-ATM configurations require static configuration of the underlying ATM physical interface and ATM logical interface. You can configure the PPPoE (**pp0**) subscriber interface either dynamically, by means of a dynamic profile, or statically at the **[edit interfaces pp0 unit logical-unit-number]** hierarchy level.

For PPPoE-over-ATM configurations on an MX Series router, you must configure the ATM underlying interface with PPPoE-over-ATM logical link control (LLC) encapsulation. To do so, include the **encapsulation ppp-over-ether-over-atm-llc** statement at the **[edit interfaces interface-name unit logical-unit-number]** hierarchy level.

Using dynamic PPPoE-over-ATM configurations for ATM subscriber access enables you to configure an MX Series router to dynamically create PPPoE logical subscriber interfaces over static ATM underlying interfaces only when needed; that is, when a subscriber logs in on the associated underlying interface. Dynamic PPPoE over static ATM configurations are *not* supported on M Series routers and T Series routers.

Optionally, you can dynamically or statically apply subscriber services such as class of service (CoS) and firewall filters to the PPPoE (**pp0**) subscriber interface. For PPPoE-over-ATM configurations that create a dynamic PPPoE subscriber interface, you can configure CoS attributes and firewall filters in the dynamic profile that defines the **pp0** subscriber interface. For PPPoE-over-ATM configurations that create a static PPPoE subscriber interface, you can statically configure CoS attributes and firewall filters as you would for any static interface configured on an MX Series router.

## Routed IP-over-ATM Configurations

Routed IP-over-ATM (IPoA) configurations support statically created IPv4 and IPv6 logical subscriber interfaces over static ATM underlying interfaces. IPoA configurations are typically used to implement business digital subscriber line (DSL) connections that do not require connection negotiation for address assignment.

IPoA configurations on MX Series routers require static configuration of the ATM underlying interface, IPv4 interface, IPv6 interface, CoS attributes, and firewall filters. Dynamic configuration of these components is not supported.

To configure IPoA subscriber access on MX Series routers, you must configure either of the following encapsulation types on the ATM underlying interface:

- For IPoA encapsulation with logical link control (LLC), configure ATM subnetwork attachment point (SNAP) encapsulation by including the **encapsulation atm-snap**

statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

- For IPoA encapsulation with virtual circuit (VC) multiplexing, configure ATM VC multiplex encapsulation by including the **encapsulation atm-vc-mux** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

Optionally, you can statically configure subscriber services such as CoS and firewall filters and apply them to the IPv4 or IPv6 interface; you *cannot* use a dynamic profile for this purpose.

## Bridged IP-over-Ethernet-over-ATM Configurations

Bridged IP-over-Ethernet-over-ATM (IPoE-over-ATM) configurations support statically created IPv4 and IPv6 logical subscriber interfaces over static ATM underlying interfaces. Like IPoA configurations, IPoE-over-ATM configurations are typically used in topologies that do not require connection negotiation for address assignment.

IPoE-over-ATM configurations on MX Series routers require static configuration of the ATM underlying interface, IP interface, CoS attributes, and firewall filters. Dynamic configuration of these components is not supported.

For bridged IP-over-Ethernet-over-ATM configurations on an MX Series router, you must configure the ATM underlying interface with Ethernet-over-ATM LLC encapsulation. To do so, include the **encapsulation ether-over-atm-llc** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

Optionally, you can statically configure subscriber services such as class of service (CoS) and firewall filters and apply them to the IPv4 or IPv6 interface; you *cannot* use a dynamic profile for this purpose.

## PPP-over-ATM Configurations

PPP-over-ATM (PPPoA) configurations support statically created PPP logical subscriber interfaces over static ATM underlying interfaces. Most features supported for PPPoE configurations are also supported for PPP access to an MX Series router over an ATM network.

PPPoA configurations on MX Series routers require static configuration of the ATM underlying interface and PPP subscriber interface.

To configure PPPoA subscriber access on MX Series routers, you must configure either of the following encapsulation types on each PPP logical subscriber interface:

- For PPPoA encapsulation with logical link control (LLC), configure PPP-over-AAL5 LLC encapsulation by including the **encapsulation atm-ppp-llc** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.
- For PPPoA encapsulation with virtual circuit (VC) multiplexing, configure PPP-over-AAL5 multiplex encapsulation by including the **encapsulation atm-ppp-vc-mux** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

Optionally, you can use dynamic profiles to dynamically or statically apply subscriber services, such as CoS attributes and firewall filters, to the static PPP subscriber interface. Configuring CoS and firewall filters in this manner enables you to efficiently and economically provide these services to PPP subscribers accessing the router over an ATM network.

## Configuration and Encapsulation Types for ATM Subscriber Access

You use the same basic statements, commands, and procedures to create, verify, and manage PPPoE-over-ATM, IPoA, IPoE-over-ATM, and PPPoA configurations as the statements, commands, and procedures you use for static configurations on M Series routers and T Series routers, and for dynamic PPPoE configurations on MX Series routers.

A critical element of configuring ATM subscriber access is ensuring that you specify the correct encapsulation type for the ATM logical interface. The encapsulation type you use depends on the supported configuration and, for IPoA and PPPoA configurations, whether you want to configure an encapsulation type that uses logical link control (LLC) or virtual circuit (VC) multiplexing.

## ATM for Subscriber Access Encapsulation Types Overview

To enable subscriber access to an MX Series router over an ATM network, you can create any of the following configurations on Modular Port Concentrator/Modular Interface Card (MPC/MIC) interfaces that use the ATM MIC with SFP:

- PPP-over-Ethernet-over-ATM (PPPoE-over ATM) with a dynamic or static PPPoE (**pp0**) subscriber interface over a static ATM underlying interface
- Routed IP-over-ATM (IPoA) with a static IPv4 or IPv6 subscriber interface over a static ATM underlying interface
- Bridged IP-over-Ethernet-over-ATM (IPoE-over-ATM) with a static IPv4 or IPv6 subscriber interface over a static ATM underlying interface
- PPP-over-ATM (PPPoA) with a static PPP subscriber interface over a static ATM underlying interface

As part of the configuration procedure, you must specify the appropriate encapsulation type for your configuration on the ATM logical interface.

[Table 57 on page 551](#) lists and describes the encapsulation type you must specify as part of the **encapsulation** statement when you configure the ATM logical interface for each supported configuration.

**Table 57: Encapsulation Types for Supported ATM Subscriber Access Configurations**

| ATM Subscriber Access Configuration                         | Encapsulation Type                 | Description                                                                    |
|-------------------------------------------------------------|------------------------------------|--------------------------------------------------------------------------------|
| PPPoE-over-ATM with dynamic <b>pp0</b> subscriber interface | <b>ppp-over-ether-over-atm-llc</b> | PPPoE-over-ATM encapsulation with logical link control (LLC)                   |
| PPPoE-over-ATM with static <b>pp0</b> subscriber interface  | <b>ppp-over-ether-over-atm-llc</b> | PPPoE-over-ATM encapsulation with LLC                                          |
| IP-over-ATM (IPoA)                                          | <b>atm-snap</b>                    | ATM subnetwork attachment point (SNAP) encapsulation for IPoA with LLC         |
|                                                             | <b>atm-vc-mux</b>                  | ATM VC multiplex encapsulation for IPoA with virtual circuit (VC) multiplexing |
| IP-over-Ethernet-over-ATM (IPoE-over-ATM)                   | <b>ether-over-atm-llc</b>          | Ethernet-over-ATM encapsulation with LLC                                       |

**Table 57: Encapsulation Types for Supported ATM Subscriber Access Configurations (*continued*)**

| ATM Subscriber Access Configuration | Encapsulation Type                                                  | Description                                      |
|-------------------------------------|---------------------------------------------------------------------|--------------------------------------------------|
| PPP-over-ATM (PPPoA)                | <b>atm-ppp-llc</b> (for PPPoA with logical link control)            | PPP-over-AAL5 encapsulation with LLC             |
|                                     | <b>atm-ppp-vc-mux</b> (for PPPoA with virtual circuit multiplexing) | PPP-over-AAL5 encapsulation with VC multiplexing |

- [Verifying and Managing ATM Configurations for Subscriber Access on page 556](#)

## Configuring ATM for Subscriber Access

---

On MX Series routers with MPC/MIC interfaces that use the ATM MIC with SFP, you can create the following configurations to enable subscribers to access the router over an ATM network using ATM Adaptation Layer 5 (AAL5) permanent virtual connections (PVCs):

- PPP-over-Ethernet-over-ATM (PPPoE-over ATM) with a dynamic PPPoE (**pp0**) subscriber interface over a static ATM underlying interface
- PPP-over-Ethernet-over-ATM (PPPoE-over ATM) with a static PPPoE (**pp0**) subscriber interface over a static ATM underlying interface
- Routed IP-over-ATM (IPoA) with a static IPv4 or IPv6 subscriber interface over a static ATM underlying interface
- Bridged IP-over-Ethernet-over-ATM with a static IPv4 or IPv6 subscriber interface over a static ATM underlying interface
- PPP-over-ATM (PPPoA) with a static PPP subscriber interface over a static ATM underlying interface

Before you begin:

1. Make sure the MX Series router you are using has Modular Port Concentrator/Modular Interface Card (MPC/MIC) interfaces and an ATM MIC with SFP (Model Number MIC-3D-8OC3-2OC12-ATM) installed and operational.
  - For information about compatible MPCs for the ATM MIC with SFP, see the [MX Series 3D Universal Edge Routers Line Card Guide](#).
  - For information about installing MPCs and MICs in an MX Series router, see the *Hardware Guide* for your MX Series router model.
2. Make sure you understand how to configure and use static ATM interfaces.

See ATM Interfaces Overview.

3. If your configuration includes dynamic profiles for PPPoE, class of service (CoS) attributes, or standard firewall filters, make sure you understand how to configure these attributes and apply them to the subscriber interface.
  - For PPPoE dynamic profiles, see [“Configuring Dynamic PPPoE Subscriber Interfaces Using Dynamic Profiles” on page 857](#)
  - For CoS configuration, see [“Configuring Traffic Scheduling and Shaping for Subscriber Access” on page 919](#)
  - For standard firewall filter configuration, see [Guidelines for Configuring Standard Firewall Filters](#) and [Guidelines for Applying Standard Firewall Filters](#)

To configure ATM for subscriber access on an MX Series router:

1. For a PPPoE-over-ATM configuration with a dynamic PPPoE (**pp0**) subscriber interface, create a dynamic profile that defines the **pp0** subscriber interface.

See [“Example: Configuring a Dynamic PPPoE Subscriber Interface over ATM” on page 557](#).

2. Configure one or more virtual path identifiers (VPIs) on the ATM physical interface.
3. Configure the ATM logical subscriber interface.

- a. Configure the appropriate encapsulation type for your configuration.

See [“ATM for Subscriber Access Encapsulation Types Overview” on page 551](#).

- b. Configure a virtual circuit identifier (VCI) for each VPI configured on the ATM logical interface.

- c. Configure other interface-specific properties as needed for your configuration.

See [“Guidelines for Configuring ATM for Subscriber Access” on page 555](#).

4. For static PPPoE-over-ATM configurations, define the static PPPoE (**pp0**) subscriber interface at the **[edit interfaces pp0 unit *logical-unit-number*]** hierarchy level.

See [“Example: Configuring a Static PPPoE Subscriber Interface over ATM” on page 566](#).

5. (Optional) Verify the configuration for ATM subscriber access.

See [“Verifying and Managing ATM Configurations for Subscriber Access” on page 556](#).

## Guidelines for Configuring ATM for Subscriber Access

The following guidelines apply when you configure PPP-over-Ethernet-over-ATM (PPPoE-over-ATM), IP-over-ATM (IPoA), IP-over-Ethernet-over-ATM (IPoE-over-ATM), or PPP-over-ATM (PPPoA) configurations for ATM subscriber access. You can create these configurations on MX Series routers with Modular Port Concentrator/Modular Interface Card (MPC/MIC) interfaces that use the ATM MIC with SFP.

For all supported ATM subscriber access configurations:

- Make sure you specify the correct encapsulation type on the ATM logical interface for your configuration, as described in [“ATM for Subscriber Access Encapsulation Types Overview” on page 551](#).

For PPPoE-over-ATM configurations:

- For dynamic or static PPPoE-over-ATM configurations, specify PPPoE-specific options at the **[edit interfaces *interface-name* unit *logical-unit-number* family pppoe]** hierarchy level. Specifying PPPoE-specific options at the **[edit interfaces *interface-name* unit *logical-unit-number* pppoe-underlying-options]** hierarchy level is not supported for these configurations.
- For dynamic or static PPPoE-over-ATM configurations, you must configure the router to act as a PPPoE server (also known as a *remote access concentrator*). Configuring the router to act as a PPPoE client is not supported in these configurations.
- For dynamic PPPoE-over-ATM configurations, issue the **dynamic-profile *profile-name*** statement at the **[edit interfaces *interface-name* unit *logical-unit-number* family pppoe]** hierarchy level to associate the ATM logical interface with the dynamic profile that defines the PPPoE subscriber interface.

For static IPoA and IPoE-over-ATM configurations:

- Specify interface-specific options at the **[edit interfaces *interface-name* unit *logical-unit-number* family inet]** hierarchy level (for IPv4) or at the **[edit interfaces *interface-name* unit *logical-unit-number* family inet6]** hierarchy level (for IPv6).

For static PPPoA configurations:

- Specify PPP-specific options at the **[edit interfaces *interface-name* unit *logical-unit-number* ppp-options]** hierarchy level.

## Verifying and Managing ATM Configurations for Subscriber Access

---

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>               | View information about the static or dynamic subscriber interfaces configured over a static ATM underlying interface on an MX Series router with MPC/MIC interfaces and an ATM MIC with SFP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Action</b>                | <ul style="list-style-type: none"><li>• To display information about the ATM physical interface to ensure that it is properly configured for use with ATM PVCs:<br/><br/>user@host&gt; <b>show interfaces at-<i>fpc/pic/port</i></b></li><li>• To display information about the ATM logical interface to ensure that it is properly configured as a dynamic or static subscriber interface:<br/><br/>user@host&gt; <b>show interfaces at-<i>fpc/pic/port</i>.logical-unit-number</b></li><li>• To display information about all static PPPoE (<b>pp0</b>) subscriber interfaces for static PPPoE-over-ATM configurations:<br/><br/>user@host&gt; <b>show interfaces pp0</b></li><li>• To display information about a specified static PPPoE (<b>pp0</b>) subscriber interface for static PPPoE-over-ATM configurations:<br/><br/>user@host&gt; <b>show interfaces pp0.logical-unit-number</b></li><li>• To display detailed information about the PPPoE underlying interface for dynamic or static PPPoE-over-ATM configurations:<br/><br/>user@host&gt; <b>show pppoe underlying-interfaces at-<i>fpc/pic/port</i>.logical-unit-number detail</b></li><li>• To display extensive information, including packet statistics and lockout time settings, about the PPPoE underlying interface for dynamic or static PPPoE-over-ATM configurations:<br/><br/>user@host&gt; <b>show pppoe underlying-interfaces at-<i>fpc/pic/port</i>.logical-unit-number extensive</b></li></ul> |

## Example: Configuring a Dynamic PPPoE Subscriber Interface over ATM

---

This example illustrates a Point-to-Point Protocol over Ethernet (PPPoE) over ATM configuration that creates a dynamic PPPoE (**pp0**) subscriber interface over a static ATM underlying interface on an MX Series router. The router must have Module Port Concentrator/Modular Interface Card (MPC/MIC) interfaces that use an ATM MIC with small form-factor pluggable transceiver (SFP).

**NOTE:** You can also configure a *static* PPPoE interface over a static ATM underlying interface on an MX Series router with an ATM MIC with SFP installed. For information, see [“Example: Configuring a Static PPPoE Subscriber Interface over ATM” on page 566](#).

- [Requirements on page 557](#)
- [Overview on page 558](#)
- [Configuration on page 559](#)
- [Verification on page 564](#)

## Requirements

This example uses the following software and hardware components:

- Junos OS Release 12.2
- MX Series 3D Universal Edge Router
- ATM MIC with SFP (Model Number MIC-3D-8OC3-2OC12-ATM) and compatible MPC1 or MPC2

Before you begin:

1. Make sure the MX Series router you are using has an ATM MIC with SFP installed and operational.
  - For information about compatible MPCs for the ATM MIC with SFP, see the [MX Series 3D Universal Edge Routers Line Card Guide](#).
  - For information about installing MPCs and MICs in an MX Series router, see the *Hardware Guide* for your MX Series router model.
2. Make sure you understand how to configure and use static ATM interfaces.

See ATM Interfaces Overview.
3. Make sure you understand how to configure and use dynamic PPPoE subscriber interfaces.
  - For overview information, see “Subscriber Interfaces and PPPoE Overview” on [page 841](#)
  - For configuration instructions, see “Configuring Dynamic PPPoE Subscriber Interfaces Using Dynamic Profiles” on [page 857](#)

## Overview

By using the ATM MIC with SFP and a supported MPC, you can configure an MX Series router to support dynamic PPPoE subscriber access over an ATM network. PPPoE-over-ATM configurations on MX Series routers consist of one or more dynamically created PPPoE (**pp0**) subscriber interfaces over a static ATM underlying interface. Most PPPoE and subscriber services features supported on terminated connections and tunneled (L2TP access concentrator, or LAC) connections are also supported for PPPoE-over-ATM connections on an MX Series router.

Optionally, you can dynamically apply subscriber services such as class of service (CoS) and firewall filters to the PPPoE subscriber interface by configuring these services in the dynamic profile that creates the **pp0** subscriber interface. In this example, the PPPoE dynamic profile (ppoe-profile) applies CoS traffic shaping parameters to the dynamic **pp0** subscriber interface. Configuring CoS and firewall filters in this manner enables you to efficiently and economically provide these services to PPPoE subscribers accessing the router over an ATM network using ATM Adaptation Layer 5 (AAL5) permanent virtual connections (PVCs).

This example includes the following basic steps to configure dynamic PPPoE-over-ATM subscriber access on an MX Series router:

1. Create a PPPoE dynamic profile named pppoe-profile for the **pp0** subscriber interface that includes all of the following:
  - The logical unit number, represented by the **\$junos-interface-unit** predefined dynamic variable
  - The name of the underlying ATM interface, represented by the **\$junos-underlying-interface** predefined dynamic variable

- The **server** statement, which configures the router to act as a PPPoE server

**NOTE:** Configuring the router to act as a PPPoE client is not supported.

- The unnumbered address (lo0.0) for the IPv4 (**inet**) protocol family
  - CoS traffic shaping parameters
2. Statically configure the ATM physical interface at-1/0/0 with virtual path identifier (VPI) 3.
  3. Statically configure logical unit 2 on the ATM physical interface (at-1/0/0.2) with at least the following properties:
    - PPPoE-over-ATM logical link control (LLC) encapsulation (**ppp-over-ether-over-atm-llc**)
    - Virtual circuit identifier (VCI) 2 on VPI 3. The combination of VPIs and VCIs provisions the ATM AAL5 PVC for access over the ATM network.
    - PPPoE-specific options at the **[edit interfaces interface-name unit logical-unit-number family pppoe]** hierarchy level, including at least the name of the associated PPPoE dynamic profile (pppoe-profile) that creates the pp0 dynamic subscriber interface

In dynamic PPPoE-over-ATM configurations, each **pp0** interface defined in the dynamic profile corresponds to a dynamic PPPoE subscriber interface.

**NOTE:** For dynamic or static PPPoE-over-ATM configurations on MX Series routers, You must specify PPPoE-specific options in the family **pppoe** stanza at the **[edit interfaces interface-name unit logical-unit-number]** hierarchy level. Specifying PPPoE-specific options in the **pppoe-underlying-options** stanza at the **[edit interfaces interface-name unit logical-unit-number]** hierarchy level is not supported for these configurations.

## Configuration

To configure a dynamic PPPoE subscriber interface over an underlying ATM interface, perform these tasks:

- [Configuring the PPPoE Dynamic Profile on page 560](#)
- [Configuring the ATM Physical Interface on page 562](#)
- [Configuring the Dynamic PPPoE Subscriber Interface on Logical Unit 2 on page 563](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
# PPPoE Dynamic Profile
```

```

set dynamic-profiles pppoe-profile interfaces pp0 unit "$junos-interface-unit" ppp-options
chap
set dynamic-profiles pppoe-profile interfaces pp0 unit "$junos-interface-unit"
  pppoe-options underlying-interface "$junos-underlying-interface"
set dynamic-profiles pppoe-profile interfaces pp0 unit "$junos-interface-unit"
  pppoe-options server
set dynamic-profiles pppoe-profile interfaces pp0 unit "$junos-interface-unit"
  no-keepalives
set dynamic-profiles pppoe-profile interfaces pp0 unit "$junos-interface-unit" family
inet unnumbered-address lo0.0
set dynamic-profiles pppoe-profile class-of-service traffic-control-profiles tcp-test
shaping-rate 10m
set dynamic-profiles pppoe-profile class-of-service interfaces pp0 unit
"$junos-interface-unit" output-traffic-control-profile tcp-test
#
# ATM Physical Interface
set interfaces at-1/0/0 atm-options vpi 3
#
# Logical Unit 2
set interfaces at-1/0/0 atm-options vpi 3
set interfaces at-1/0/0 unit 2 encapsulation ppp-over-ether-over-atm-llc
set interfaces at-1/0/0 unit 2 vci 3.2
set interfaces at-1/0/0 unit 2 family pppoe access-concentrator ac-pppoeoa
set interfaces at-1/0/0 unit 2 family pppoe duplicate-protection
set interfaces at-1/0/0 unit 2 family pppoe dynamic-profile pppoe-profile
set interfaces at-1/0/0 unit 2 family pppoe max-sessions 3
set interfaces at-1/0/0 unit 2 family pppoe short-cycle-protection

```

### Configuring the PPPoE Dynamic Profile

#### Step-by-Step Procedure

To configure the PPPoE dynamic profile for the **pp0** subscriber interface:

1. Name the dynamic profile.  

```
[edit]
user@host# edit dynamic-profiles pppoe-profile
```
2. Specify that you want to configure the **pp0** (PPPoE) interface.  

```
[edit dynamic-profiles pppoe-profile]
user@host# edit interfaces pp0
```
3. Specify that you want to configure the logical unit represented by the **\$junos-interface-unit** predefined variable.  

```
[edit dynamic-profiles pppoe-profile interfaces pp0]
user@host# edit unit $junos-interface-unit
```

The **\$junos-interface-unit** variable is dynamically replaced with the actual unit number supplied by the network when the subscriber logs in.

4. Configure PPPoE-specific options for the **pp0** interface.
  - a. Configure the ATM underlying interface represented by the **\$junos-underlying-interface** predefined variable.  

```
[edit dynamic-profiles pppoe-profile interfaces pp0 unit "$junos-interface-unit"]
user@host# set pppoe-options underlying-interface $junos-underlying-interface
```

The `$junos-underlying-interface` variable is dynamically replaced with the actual name of the underlying interface supplied by the network when the subscriber logs in.

- b. Configure the router to act as a PPPoE server, also known as a remote access concentrator.

```
[edit dynamic-profiles pppoe-profile interfaces pp0 unit "$junos-interface-unit"]
user@host# set pppoe-options server
```

5. Configure Challenge Handshake Authentication Protocol (CHAP) authentication for the `pp0` interface.

```
[edit dynamic-profiles pppoe-profile interfaces pp0 unit "$junos-interface-unit"]
user@host# set ppp-options chap
```

6. Disable sending keepalive messages on the interface.

```
[edit dynamic-profiles pppoe-profile interfaces pp0 unit "$junos-interface-unit"]
user@host# set no-keepalives
```

7. Configure the protocol family for the `pp0` interface.

- a. Specify that you want to configure the IPv4 (`inet`) protocol family.

```
[edit dynamic-profiles pppoe-profile interfaces pp0 unit "$junos-interface-unit"]
user@host# edit family inet
```

- b. Configure the unnumbered address for the protocol family.

```
[edit dynamic-profiles pppoe-profile interfaces pp0 unit "$junos-interface-unit"
family inet]
user@host# set unnumbered-address lo0.0
user@host# up 4
```

8. Configure CoS traffic shaping parameters in the dynamic profile for the `pp0` subscriber interface.

- a. Specify that you want to configure CoS traffic shaping parameters.

```
[edit dynamic-profiles pppoe-profile]
user@host# edit class-of-service
```

- b. Create a traffic control profile.

```
[edit dynamic-profiles pppoe-profile class-of-service]
user@host# edit traffic-control-profiles tcp-test
```

- c. Configure the traffic shaping rate.

```
[edit dynamic-profiles pppoe-profile class-of-service traffic-control-profiles
tcp-test]
user@host# set shaping-rate 10m
user@host# up 2
```

- d. Apply the traffic shaping parameters to the `pp0` dynamic subscriber interface.

```
[edit dynamic-profiles pppoe-profile class-of-service]
user@host# edit interfaces pp0 unit $junos-interface-unit
```

- e. Apply the output traffic scheduling and shaping profile to the interface.

```
[edit dynamic-profiles pppoe-profile class-of-service interfaces pp0 unit
"$junos-interface-unit"]
user@host# set output-traffic-control-profile tcp-test
```

**Results** From the **[edit]** hierarchy level in configuration mode, confirm the results of the PPPoE dynamic profile configuration by issuing the **show dynamic-profiles pppoe-profile** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
user@host# show dynamic-profiles pppoe-profile
interfaces {
  pp0 {
    unit "$junos-interface-unit" {
      ppp-options {
        chap;
      }
      pppoe-options {
        underlying-interface "$junos-underlying-interface";
        server;
      }
      no-keepalives;
      family inet {
        unnumbered-address lo0.0;
      }
    }
  }
}
class-of-service {
  traffic-control-profiles {
    tcp-test {
      shaping-rate 10m;
    }
  }
  interfaces {
    pp0 {
      unit "$junos-interface-unit" {
        output-traffic-control-profile tcp-test;
      }
    }
  }
}
```

If you are done configuring the dynamic profile, enter **commit** from configuration mode.

---

### Configuring the ATM Physical Interface

---

#### Step-by-Step Procedure

To configure the ATM physical interface:

1. Specify that you want to configure ATM-specific options on the physical interface.  

```
[edit interfaces at-1/0/0]
user@host# edit atm-options
```
2. Configure one or more VPIs on the physical interface.

```
[edit interfaces at-1/0/0 atm-options]
user@host# set vpi 3
```

**Results** From the **[edit]** hierarchy level in configuration mode, confirm the results of the ATM physical interface configuration by issuing the **show interfaces at-1/0/0** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
user@host# show interfaces at-1/0/0
atm-options {
  vpi 3;
}
```

If you are done configuring the ATM physical interface, enter **commit** from configuration mode.

### Configuring the Dynamic PPPoE Subscriber Interface on Logical Unit 2

**Step-by-Step Procedure** To configure the dynamic PPPoE subscriber interface on logical unit 2:

1. Configure PPPoE-over-ATM LLC encapsulation on the interface.

```
[edit interfaces at-1/0/0 unit 2]
user@host# set encapsulation ppp-over-ether-over-atm-llc
```

2. Configure the VCI for the logical interface.

```
[edit interfaces at-1/0/0 unit 2]
user@host# set vci 3.2
```

This statement configures VCI 2 on VPI 3.

3. Specify that you want to configure the PPPoE protocol family.

```
[edit interfaces at-1/0/0 unit 2]
user@host# edit family pppoe
```

4. Associate the interface with the dynamic profile that creates the dynamic PPPoE subscriber interface.

```
[edit interfaces at-1/0/0 unit 2 family pppoe]
user@host# set dynamic-profile pppoe-profile
```

5. Configure additional PPPoE-specific options for the dynamic subscriber interface.

```
[edit interfaces at-1/0/0 unit 2 family pppoe]
user@host# set max-sessions 3
user@host# set duplicate-protection
user@host# set short-cycle-protection
user@host# set access-concentrator ac-pppoeoa
```

**Results** From the **[edit]** hierarchy level in configuration mode, confirm the results of the dynamic PPPoE subscriber interface configuration on logical unit 2 by issuing the **show interfaces at-1/0/0.2** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
user@host# show interfaces at-1/0/0.2
encapsulation ppp-over-ether-over-atm-llc;
vci 3.2;
family pppoe {
    access-concentrator ac-pppoeoa;
    duplicate-protection;
    dynamic-profile pppoe-profile;
    max-sessions 3;
    short-cycle-protection;
}
```

If you are done configuring the dynamic PPPoE subscriber interface on logical unit 2, enter **commit** from configuration mode.

## Verification

To confirm that the dynamic PPPoE subscriber interface is properly configured on ATM interface at-1/0/0.2, perform the following tasks:

- [Verifying the ATM Physical Interface Configuration on page 564](#)
- [Verifying the Dynamic PPPoE Subscriber Interface Configuration on Logical Unit 2 on page 565](#)
- [Verifying the PPPoE Underlying Interface Configuration on page 565](#)

---

### Verifying the ATM Physical Interface Configuration

**Purpose** Verify that ATM physical interface at-1/0/0 is properly configured for use with ATM PVCs.

**Action** From operational mode, issue the **show interfaces at-1/0/0** command.

For brevity, this **show** command output includes only the configuration that is relevant to the at-1/0/0 physical interface. Any other configuration on the system has been replaced with ellipses (...).

```
user@host> show interfaces at-1/0/0
Physical interface: at-1/0/0, Enabled, Physical link is Up
  Interface index: 173, SNMP ifIndex: 592
  Link-level type: ATM-PVC, MTU: 2048, Clocking: Internal, SDH mode, Speed: OC3,
  Loopback: None, Payload scrambler: Enabled
  Device flags   : Present Running
  Link flags     : None
  CoS queues     : 8 supported, 8 maximum usable queues
  Schedulers    : 0
  Current address: 00:1f:12:bc:4a:95
  Last flapped   : 2012-09-17 07:21:19 PDT (08:26:16 ago)
  Input rate     : 0 bps (0 pps)
  Output rate    : 0 bps (0 pps)
  SDH alarms    : None
  SDH defects    : None
  VPI 3
    Flags: Active
    Total down time: 0 sec, Last down: Never
  Traffic statistics:
    Input packets:                                0
```

```

Output packets: 0
...

```

**Meaning** ATM-PVC in the Link-level Type field indicates that encapsulation for ATM permanent virtual circuits is being used on ATM physical interface at-1/0/0. The **Active** flag for VPI 3 indicates that the virtual path is up and operational.

### Verifying the Dynamic PPPoE Subscriber Interface Configuration on Logical Unit 2

**Purpose** Verify that the dynamic PPPoE subscriber interface is properly configured on logical unit 2 (at-1/0/0.2).

**Action** From operational mode, issue the **show interfaces at-1/0/0.2** command.

```

user@host> show interfaces at-1/0/0.2
Logical interface at-1/0/0.2 (Index 350) (SNMP ifIndex 1701)
  Flags: Point-To-Point SNMP-Traps 0x4000 Encapsulation: PPPoE-over-ATM-LLC
  Input packets : 0
  Output packets: 0
  Protocol pppoe
    Dynamic Profile: pppoe-profile,
    Service Name Table: None,
    Max Sessions: 3, Max Sessions VSA Ignore: Off,
    Duplicate Protection: On, Short Cycle Protection: mac-address,
    AC Name: ac-pppoeoa
  VCI 3.2
    Flags: Active
    Total down time: 0 sec, Last down: Never
    Input packets : 0
    Output packets: 0

```

**Meaning** PPPoE-over-ATM-LLC in the Encapsulation field indicates that logical interface at-1/0/0.2 is properly configured for PPPoE-over-ATM LLC encapsulation. **Protocol pppoe** indicates that the PPPoE protocol family has been properly configured on the logical interface. The Dynamic Profile field indicates that dynamic profile **pppoe-profile** creates the dynamic PPPoE subscriber interface. The **Active** flag for VCI 3.2 indicates that VCI 2 on VPI 3 is up and operational.

### Verifying the PPPoE Underlying Interface Configuration

**Purpose** Verify that the underlying interface is properly configured for dynamic PPPoE-over-ATM subscriber access.

**Action** From operational mode, issue the **show pppoe underlying-interfaces at-1/0/0.2** command.

```

user@host> show pppoe underlying-interfaces at-1/0/0.2 detail
at-1/0/0.2 Index 350
  State: Static, Dynamic Profile: pppoe-profile,
  Max Sessions: 3, Max Sessions VSA Ignore: Off,
  Active Sessions: 0,
  Service Name Table: None,
  Duplicate Protection: On, Short Cycle Protection: mac-address,
  AC Name: ac-pppoeoa,

```

**Meaning** This command indicates that ATM logical interface at-1/0/0.2 is properly configured as the PPPoE underlying interface. **Static** in the State field indicates that at-1/0/0.2 is statically configured. The Dynamic Profile field indicates that **pppoe-profile** is the name of the dynamic profile used to create this interface. The remaining fields display information about the PPPoE-specific interface options configured for the PPPoE underlying interface at the **[edit interfaces at-1/0/0 unit 2 family pppoe]** hierarchy level.

## Example: Configuring a Static PPPoE Subscriber Interface over ATM

---

This example illustrates a Point-to-Point Protocol over Ethernet (PPPoE) over ATM configuration that creates a static PPPoE (**pp0**) subscriber interface over a static ATM underlying interface on an MX Series router. The router must have Module Port Concentrator/Modular Interface Card (MPC/MIC) interfaces that use an ATM MIC with small form-factor pluggable transceiver (SFP).

NOTE: You can also configure a *dynamic* PPPoE interface over a static ATM underlying interface on an MX Series router with an ATM MIC with SFP installed. For information, see [“Example: Configuring a Dynamic PPPoE Subscriber Interface over ATM” on page 557](#).

- [Requirements on page 566](#)
- [Overview on page 567](#)
- [Configuration on page 568](#)
- [Verification on page 571](#)

## Requirements

This example uses the following software and hardware components:

- Junos OS Release 12.2
- MX Series 3D Universal Edge Router
- ATM MIC with SFP (Model Number MIC-3D-8OC3-2OC12-ATM) and compatible MPC1 or MPC2

Before you begin:

1. Make sure the MX Series router you are using has an ATM MIC with SFP installed and operational.
  - For information about compatible MPCs for the ATM MIC with SFP, see the [MX Series 3D Universal Edge Routers Line Card Guide](#).
  - For information about installing MPCs and MICs in an MX Series router, see the [Hardware Guide](#) for your MX Series router model.
2. Make sure you understand how to configure and use static ATM interfaces.

See ATM Interfaces Overview.

## Overview

By using the ATM MIC with SFP and a supported MPC, you can configure an MX Series router to support static PPPoE subscriber access over an ATM network using ATM Adaptation Layer 5 (AAL5) permanent virtual connections (PVCs). PPPoE-over-ATM configurations on MX Series routers consist of one or more statically created PPPoE (**pp0**) logical subscriber interfaces over a static ATM underlying interface. Most PPPoE and subscriber services features supported on terminated connections and tunneled (L2TP access concentrator, or LAC) connections are also supported for PPPoE-over-ATM connections on an MX Series router.

This example include the following basic steps to configure static PPPoE-over-ATM subscriber access on an MX Series router:

1. Statically configure ATM physical interface at-1/0/6 with virtual path identifier (VPI) 6.
2. Statically configure logical unit 2 on the ATM physical interface (at-1/0/6.2) with the following properties:
  - PPPoE-over-ATM logical link control (LLC) encapsulation (**ppp-over-ether-over-atm-llc**)
  - Virtual circuit identifier (VCI) 2 on VPI 6. The combination of VPIs and VCIs provisions the ATM AAL5 PVC for access over the ATM network.
  - (Optional) PPPoE-specific options at the **[edit interfaces *interface-name* unit *logical-unit-number* family pppoe]** hierarchy level

**NOTE:** For dynamic or static PPPoE-over-ATM configurations on MX Series routers, You must specify PPPoE-specific options in the family **pppoe** stanza at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level. Specifying PPPoE-specific options in the **pppoe-underlying-options** stanza at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level is not supported for these configurations.

3. Statically configure the **pp0** logical subscriber interface (pp0.2) with at least the following properties:
  - The name of the underlying ATM interface (at-1/0/6.2)
  - The **server** statement, which configures the router to act as a PPPoE server
  - The unnumbered address (lo0.0) for the **inet** (IPv4) or **inet6** (IPv6) protocol family

In static PPPoE-over-ATM configurations, each **pp0** logical interface configured at the **[edit interfaces pp0 unit *logical-unit-number*]** hierarchy level corresponds to a static PPPoE subscriber interface.

## Configuration

To configure a static PPPoE subscriber interface over an underlying ATM interface, perform these tasks:

- [Configuring the ATM Physical Interface on page 568](#)
- [Configuring Encapsulation, VCI, and PPPoE Options on Logical Unit 2 on page 569](#)
- [Configuring the Static PPPoE Subscriber Interface on page 570](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
# ATM Physical Interface
set interfaces at-1/0/6 atm-options vpi 6
#
# Logical Unit 2
set interfaces at-1/0/6 unit 2 encapsulation ppp-over-ether-over-atm-llc
set interfaces at-1/0/6 unit 2 vci 6.2
set interfaces at-1/0/6 unit 2 family pppoe access-concentrator ac-pppoeoa
set interfaces at-1/0/6 unit 2 family pppoe duplicate-protection
set interfaces at-1/0/6 unit 2 family pppoe max-sessions 3
set interfaces at-1/0/6 unit 2 family pppoe max-sessions-vsa-ignore
set interfaces at-1/0/6 unit 2 family pppoe short-cycle-protection lockout-time-min 120
set interfaces at-1/0/6 unit 2 family pppoe short-cycle-protection lockout-time-max 240
#
# Static PPPoE Subscriber Interface
set interfaces pp0 unit 2 ppp-options chap
set interfaces pp0 unit 2 pppoe-options underlying-interface at-1/0/6.2
set interfaces pp0 unit 2 pppoe-options server
set interfaces pp0 unit 2 keepalives interval 10
set interfaces pp0 unit 2 family inet unnumbered-address lo0.0
```

---

### Configuring the ATM Physical Interface

#### Step-by-Step Procedure

To configure the ATM physical interface:

1. Specify that you want to configure ATM-specific options on the physical interface.

```
[edit interfaces at-1/0/6]
user@host# edit atm-options
```

2. Configure one or more VPIs on the physical interface.

```
[edit interfaces at-1/0/6 atm-options]
user@host# set vpi 6
```

**Results** From the **[edit]** hierarchy level in configuration mode, confirm the results of the ATM physical interface configuration by issuing the **show interfaces at-1/0/6** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
user@host# show interfaces at-1/0/6
atm-options {
  vpi 6;
}
```

If you are done configuring the ATM physical interface, enter **commit** from configuration mode.

### Configuring Encapsulation, VCI, and PPPoE Options on Logical Unit 2

#### Step-by-Step Procedure

To configure encapsulation, VCI, and PPPoE options on logical unit 2:

1. Configure PPPoE-over-ATM LLC encapsulation on the interface.

```
[edit interfaces at-1/0/6 unit 2]
user@host# set encapsulation ppp-over-ether-over-atm-llc
```

2. Configure the VCI for the logical interface.

```
[edit interfaces at-1/0/6 unit 2]
user@host# set vci 6.2
```

This statement configures VCI 2 on VPI 6.

3. Specify that you want to configure the PPPoE protocol family.

```
[edit interfaces at-1/0/6 unit 2]
user@host# edit family pppoe
```

4. Configure additional PPPoE-specific options for the dynamic subscriber interface.

```
[edit interfaces at-1/0/6 unit 2 family pppoe]
user@host# set duplicate-protection
user@host# set short-cycle-protection lockout-time-min 120 lockout-time-max
240
user@host# set max-sessions 3
user@host# set max-sessions-vsa-ignore
user@host# set access-concentrator ac-pppoea
```

**Results** From the **[edit]** hierarchy level in configuration mode, confirm the results of the configuration on logical unit 2 by issuing the **show interfaces at-1/0/6.2** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
user@host# show interfaces at-1/0/6.2
```

```
encapsulation ppp-over-ether-over-atm-llc;
vci 6.2;
family pppoe {
  access-concentrator ac-pppoeoa;
  duplicate-protection;
  max-sessions 3;
  max-sessions-vsa-ignore;
  short-cycle-protection {
    lockout-time-min 120;
    lockout-time-max 240;
  }
}
```

If you are done configuring logical unit 2, enter **commit** from configuration mode.

---

### Configuring the Static PPPoE Subscriber Interface

---

#### Step-by-Step Procedure

To configure the static PPPoE subscriber interface:

1. Specify that you want to configure the **pp0** subscriber interface on logical unit 2.  

```
[edit]
user@host# edit interfaces pp0 unit 2
```
2. Specify that you want to configure PPP options for the subscriber interface.  

```
[edit interfaces pp0 unit 2]
user@host# edit ppp-options
```
3. Configure Challenge Handshake Authentication Protocol (CHAP) authentication for the subscriber interface.  

```
[edit interfaces pp0 unit 2 ppp-options]
user@host# set chap
user@host# up
```
4. Specify that you want to configure PPPoE-specific options.  

```
[edit interfaces pp0 unit 2]
user@host# edit pppoe-options
```
5. Associate the PPPoE subscriber interface with the underlying ATM interface.  

```
[edit interfaces pp0 unit 2 pppoe-options]
user@host# set underlying-interface at-1/0/6.2
```
6. Configure the router to act as a PPPoE server, also known as a remote access concentrator.  

```
[edit interfaces pp0 unit 2 pppoe-options]
user@host# set server
user@host# up
```
7. Configure the interval for sending keepalive requests.  

```
[edit interfaces pp0 unit 2]
user@host# set keepalives interval 10
```
8. Specify that you want to configure the IPv4 (**inet**) protocol family.  

```
[edit interfaces pp0 unit 2]
```

```
user@host# edit family inet
```

9. Configure the unnumbered address for the protocol family.

```
[edit interfaces pp0 unit 2 family inet]
user@host# set unnumbered-address lo0.0
```

**Results** From the **[edit]** hierarchy level in configuration mode, confirm the results of the static PPPoE subscriber interface configuration by issuing the **show interfaces pp0** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
user@host# show interfaces pp0
unit 2 {
  ppp-options {
    chap;
  }
  pppoe-options {
    underlying-interface at-1/0/6.2;
    server;
  }
  keepalives interval 10;
  family inet {
    unnumbered-address lo0.0;
  }
}
```

If you are done configuring the static PPPoE subscriber interface, enter **commit** from configuration mode.

## Verification

To confirm that the static PPPoE subscriber interface pp0.2 is properly configured on ATM underlying interface at-1/0/6.2, perform the following tasks:

- [Verifying the ATM Physical Interface Configuration on page 571](#)
- [Verifying the Encapsulation, VCI, and PPPoE Options Configuration on Logical Unit 2 on page 572](#)
- [Verifying the Static PPPoE Subscriber Interface Configuration on page 573](#)
- [Verifying the PPPoE Underlying Interface Configuration on page 573](#)

### Verifying the ATM Physical Interface Configuration

**Purpose** Verify that ATM physical interface at-1/0/6 is properly configured for use with ATM PVCs.

**Action** From operational mode, issue the **show interfaces at-1/0/6** command.

For brevity, this **show** command output includes only the configuration that is relevant to the at-1/0/6 physical interface. Any other configuration on the system has been replaced with ellipses (...).

```
user@host> show interfaces at-1/0/6
```

```
Physical interface: at-1/0/6, Enabled, Physical link is Down
  Interface index: 179, SNMP ifIndex: 598
  Link-level type: ATM-PVC, MTU: 2048, Clocking: Internal, SDH mode, Speed: OC3,
  Loopback: None, Payload scrambler: Enabled
  Device flags   : Present Running Down
  Link flags     : None
  CoS queues    : 8 supported, 8 maximum usable queues
  Schedulers    : 0
  Current address: 00:1f:12:bc:4a:9b
  Last flapped  : 2012-09-19 07:57:59 PDT (07:46:56 ago)
  Input rate    : 0 bps (0 pps)
  Output rate   : 0 bps (0 pps)
  SDH alarms    : LOL, LOS
  SDH defects   : LOL, LOS, LOP, BERR-SF, HP-FERF
  VPI 6
    Flags: Active
    Total down time: 0 sec, Last down: Never
  Traffic statistics:
    Input packets: 0
    Output packets: 0
  ...
```

**Meaning** **ATM-PVC** in the Link-level Type field indicates that encapsulation for ATM permanent virtual circuits is being used on ATM physical interface at-1/0/6. The **Active** flag for VPI 6 indicates that the virtual path is up and operational.

### Verifying the Encapsulation, VCI, and PPPoE Options Configuration on Logical Unit 2

---

**Purpose** Verify that the encapsulation, VCI, and PPPoE settings have been properly configured on logical unit 2 (at-1/0/6.2).

**Action** From operational mode, issue the **show interfaces at-1/0/6.2** command.

```
user@host> show interfaces at-1/0/6.2
  Logical interface at-1/0/6.2 (Index 345) (SNMP ifIndex 1990)
  Flags: Device-Down Point-To-Point SNMP-Traps 0x4000 Encapsulation:
  PPPoE-over-ATM-LLC
    Input packets : 0
    Output packets: 0
  Protocol pppoe
    Dynamic Profile: None,
    Service Name Table: None,
    Max Sessions: 3, Max Sessions VSA Ignore: On,
    Duplicate Protection: On, Short Cycle Protection: mac-address,
    AC Name: ac-pppoeoa
  VCI 6.2
    Flags: Active
    Total down time: 0 sec, Last down: Never
    Input packets : 0
    Output packets: 0
```

**Meaning** **PPPoE-over-ATM-LLC** in the Encapsulation field indicates that logical interface at-1/0/6.2 is properly configured for PPPoE-over-ATM LLC encapsulation. **Protocol pppoe** indicates that the PPPoE protocol family has been properly configured on the logical interface. The **Active** flag for VCI 6.2 indicates that VCI 2 on VPI 6 is up and operational.

### Verifying the Static PPPoE Subscriber Interface Configuration

**Purpose** Verify that the static PPPoE subscriber interface (pp0.2) is properly configured.

**Action** From operational mode, issue the **show interfaces pp0** command.

```
user@host> show interfaces pp0
Physical interface: pp0, Enabled, Physical link is Up
  Interface index: 131, SNMP ifIndex: 505
  Type: PPPoE, Link-level type: PPPoE, MTU: 1532
  Device flags   : Present Running
  Interface flags: Point-To-Point SNMP-Traps
  Link type      : Full-Duplex
  Link flags     : None

Logical interface pp0.2 (Index 360) (SNMP ifIndex 1991)
  Flags: Hardware-Down Point-To-Point SNMP-Traps 0x4000 Encapsulation: PPPoE
  PPPoE:
    State: SessionDown, Session ID: None,
    Underlying interface: at-1/0/6.2 (Index 345)
    Input packets : 0
    Output packets: 0
  Keepalive settings: Interval 10 seconds, Up-count 1, Down-count 3
  LCP state: Not-configured
  NCP state: inet: Not-configured, inet6: Not-configured, iso: Not-configured,
  mp1s: Not-configured
  CHAP state: Closed
  PAP state: Closed
  Protocol inet, MTU: 1492
    Flags: Sendbcst-pkt-to-re, Protocol-Down
    Addresses, Flags: Dest-route-down Is-Preferred Is-Primary
    Destination: 100.0.0/24, Local: 100.0.0.1
```

**Meaning** PPPoE in the Link-level type field indicates that PPPoE encapsulation is in use on the pp0 physical interface. PPPoE in the Encapsulation field indicates that PPPoE encapsulation is also in use on the pp0.2 logical subscriber interface. The Underlying interface field indicates that at-1/0/6.2 is properly configured as the underlying interface for the static PPPoE subscriber interface. Protocol inet indicates that the IPv4 protocol family is properly configured on the pp0.2 logical subscriber interface.

### Verifying the PPPoE Underlying Interface Configuration

**Purpose** Verify that the underlying interface is properly configured for static PPPoE-over-ATM subscriber access.

**Action** From operational mode, issue the **show pppoe underlying-interfaces at-1/0/6.2 extensive** command.

```
user@host> show pppoe underlying-interfaces at-1/0/6.2 extensive
at-1/0/6.2 Index 345
  State: Static, Dynamic Profile: None,
  Max Sessions: 3, Max Sessions VSA Ignore: On,
  Active Sessions: 0,
  Service Name Table: None,
  Duplicate Protection: On, Short Cycle Protection: mac-address,
  AC Name: ac-pppoeoa,
```

| PacketType                                    | Sent | Received |
|-----------------------------------------------|------|----------|
| PADI                                          | 0    | 0        |
| PADO                                          | 0    | 0        |
| PADR                                          | 0    | 0        |
| PADS                                          | 0    | 0        |
| PADT                                          | 0    | 0        |
| Service name error                            | 0    | 0        |
| AC system error                               | 0    | 0        |
| Generic error                                 | 0    | 0        |
| Malformed packets                             | 0    | 0        |
| Unknown packets                               | 0    | 0        |
| <b>Lockout Time (sec): Min: 120, Max: 240</b> |      |          |
| Total clients in lockout: 0                   |      |          |
| Total clients in lockout grace period: 0      |      |          |

**Meaning** This command indicates that ATM logical interface at-1/0/6.2 is properly configured as the PPPoE underlying interface. **Static** in the State field indicates that at-1/0/0/2 is statically configured. The remaining fields display information about the PPPoE-specific interface options configured for the PPPoE underlying interface at the **[edit interfaces at-1/0/6 unit 2 family pppoe]** hierarchy level. The Lockout Time fields, which appear in this command only when you display the **extensive** level of output, show the minimum lockout time (120 seconds) and maximum lockout time (240 seconds) configured for the PPPoE underlying interface.

## Example: Configuring a Static Subscriber Interface for IP Access over ATM

---

This example illustrates a routed IP-over-ATM (IPoA) configuration that creates a subscriber interface for a static IPv4 interface over a static ATM interface on an MX Series router. The router must have Module Port Concentrator/Modular Interface Card (MPC/MIC) interfaces that use an ATM MIC with small form-factor pluggable transceiver (SFP).

- [Requirements on page 575](#)
- [Overview on page 575](#)
- [Configuration on page 576](#)
- [Verification on page 579](#)

## Requirements

This example uses the following software and hardware components:

- Junos OS Release 12.2
- MX Series 3D Universal Edge Router
- ATM MIC with SFP (Model Number MIC-3D-8OC3-2OC12-ATM) and compatible MPC1 or MPC2

Before you begin:

1. Make sure the MX Series router you are using has an ATM MIC with SFP installed and operational.
  - For information about compatible MPCs for the ATM MIC with SFP, see the [MX Series 3D Universal Edge Routers Line Card Guide](#).
  - For information about installing MPCs and MICs in an MX Series router, see the *Hardware Guide* for your MX Series router model.
2. Make sure you understand how to configure and use static ATM interfaces.  
See ATM Interfaces Overview.
3. Define the static standard firewall filters (biz-customer-in-filter and biz-customer-out-filter) referenced in the configuration.
  - For information about creating standard firewall filters, see Guidelines for Configuring Standard Firewall Filters.
  - For information about applying a firewall filter to an interface, see Guidelines for Applying Standard Firewall Filters.

## Overview

By using the ATM MIC with SFP and a supported MPC, you can configure the MX Series router to support subscriber access for a statically created IPv4 or IPv6 interface over a static ATM underlying interface. An IPoA configuration enables you to provide access to subscribers on static IPv4 or IPv6 interfaces over an ATM network using ATM Adaptation Layer 5 (AAL5) permanent virtual circuits (PVCs).

**NOTE:** IPoA configurations on MX Series routers require static configuration of the IPv4 interface, IPv6 interface, CoS attributes, and firewall filters. Dynamic configuration is not supported.

To configure IPoA subscriber access on MX Series routers, you must configure the correct encapsulation type: **atm-snap** for IPoA encapsulation with logical link control (LLC), or **atm-vc-mux** for IPoA encapsulation with virtual circuit (VC) multiplexing. This example configures **atm-vc-mux** as the encapsulation type on the ATM logical interface.

To provision the ATM AAL5 PVCs for access over the ATM network, you must also configure the virtual path identifiers (VPIs) on the ATM physical interface, and one or more virtual circuit identifiers (VCIs) for each VPI.

In IPoA configurations, the subscriber interfaces correspond to the IPv4 or IPv6 addresses that are on the same network as the statically configured ATM underlying interface. In this IPoA example, the IPv4 address 1.0.0.2 represents the subscriber interface. You can configure the destination address with the **set address 1.0.0.2.254/32 destination 1.0.0.2** statement at the **[edit interfaces at-1/0/3 unit 0 family inet]** hierarchy level.

This example includes the following basic steps to statically configure a single IPv4 subscriber interface over an ATM underlying interface:

1. Configure VPI 0 on ATM physical interface at-1/0/3.
2. Configure ATM VC multiplex encapsulation, VCI 0.39 (VCI 39 on VPI 0), and the following IPv4 (**inet**) protocol family characteristics on logical interface at-1/0/3.0 :
  - IP source address validation (**rpf-check**)
  - Standard input (biz-customer-in-filter) and output (biz-customer-out-filter) firewall filters
  - Interface address 1.0.0.254/32 with destination address 1.0.0.2
3. Configure static access route 200.10.10.0/24 with qualified-next-hop address at-1/0/0.0.

## Configuration

To configure a static IPv4 subscriber interface over a static ATM underlying interface, perform these tasks:

- [Configuring the ATM Physical Interface on page 577](#)
- [Configuring the Static IPv4 Subscriber Interface on Logical Unit 0 on page 577](#)
- [Configuring Routing Properties on page 578](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
# ATM Physical Interface
set interfaces at-1/0/3 atm-options vpi 0
#
# Logical Unit 0
set interfaces at-1/0/3 unit 0 encapsulation atm-vc-mux
set interfaces at-1/0/3 unit 0 vci 0.39
set interfaces at-1/0/3 unit 0 family inet rpf-check
set interfaces at-1/0/3 unit 0 family inet filter input biz-customer-in-filter
set interfaces at-1/0/3 unit 0 family inet filter output biz-customer-out-filter
set interfaces at-1/0/3 unit 0 family inet address 1.0.0.254/32 destination 1.0.0.2
#
# Routing Properties
```

```
set routing-options access route 200.10.10.0/24 qualified-next-hop at-1/0/0.0
```

### Configuring the ATM Physical Interface

#### Step-by-Step Procedure

To configure the ATM physical interface:

1. Specify that you want to configure ATM-specific options on the physical interface.

```
[edit interfaces at-1/0/3]
user@host# edit atm-options
```

2. Configure one or more VPIs on the physical interface.

```
[edit interfaces at-1/0/3 atm-options]
user@host# set vpi 0
```

#### Results

From the **[edit]** hierarchy level in configuration mode, confirm the results of the ATM physical interface configuration by issuing the **show interfaces at-1/0/3** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
user@host# show interfaces at-1/0/3
atm-options {
  vpi 0;
}
```

If you are done configuring the ATM physical interface, enter **commit** from configuration mode.

### Configuring the Static IPv4 Subscriber Interface on Logical Unit 0

#### Step-by-Step Procedure

To configure the static IPv4 subscriber interface on logical unit 0:

1. Configure ATM VC multiplex encapsulation on the logical interface.

```
[edit interfaces at-1/0/3 unit 0]
user@host# set encapsulation atm-vc-mux
```

2. Configure the VCI for the logical interface.

```
[edit interfaces at-1/0/3 unit 0]
user@host# set vci 0.39
```

3. Configure the IPv4 (**inet**) protocol family, IPv4 address, and remote (destination) address of the connection.

```
[edit interfaces at-1/0/3 unit 0]
user@host# set family inet address 1.0.0.254/32 destination 1.0.0.2
```

4. Specify that you want to configure additional attributes for the IPv4 protocol family.

```
[edit interfaces at-1/0/3 unit 0]
user@host# edit family inet
```

5. Enable IP source address validation, which checks whether traffic is arriving at the router on an expected path.

```
[edit interfaces at-1/0/3 unit 0 family inet]
```

```
user@host# set rpf-check
```

6. Apply the previously defined standard firewall filters to the logical interface.

```
[edit interfaces at-1/0/3 unit 0 family inet]
user@host# set filter input biz-customer-in-filter
user@host# set filter output biz-customer-out-filter
```

**Results** From the **[edit]** hierarchy level in configuration mode, confirm the results of the static subscriber interface configuration on logical unit 0 by issuing the **show interfaces at-1/0/3.0** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
user@host# show interfaces at-1/0/3.0
encapsulation atm-vc-mux;
vci 0.39;
family inet {
  rpf-check;
  filter {
    input biz-customer-in-filter;
    output biz-customer-out-filter;
  }
  address 1.0.0.254/32 {
    destination 1.0.0.2;
  }
}
```

If you are done configuring the static subscriber interface on logical unit 0, enter **commit** from configuration mode.

---

### Configuring Routing Properties

**Step-by-Step Procedure** To configure static routing properties:

1. Specify that you want to configure protocol-independent routing properties.  

```
[edit]
user@host# edit routing-options
```
2. Configure a static access route for routing downstream traffic from the router, and a qualified-next-hop address for routing upstream traffic to the router.  

```
[edit routing-options]
user@host# set access route 200.10.10.0/24 qualified-next-hop at-1/0/0.0
```

**Results** From the **[edit]** hierarchy level in configuration mode, confirm the results of the static routing properties configuration by issuing the **show routing-options** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
user@host# show routing-options
access {
  route 200.10.10.0/24 {
```

```

        qualified-next-hop at-1/0/0.0;
    }
}

```

If you are done configuring the static routing properties, enter **commit** from configuration mode.

## Verification

To confirm that the IPoA configuration is working properly, perform the following tasks:

- [Verifying the ATM Physical Interface Configuration on page 579](#)
- [Verifying the Static Subscriber Interface Configuration on Logical Unit 0 on page 580](#)

### Verifying the ATM Physical Interface Configuration

**Purpose** Verify that the at-1/0/3 physical interface is properly configured for use with ATM PVCs.

**Action** From operational mode, issue the **show interfaces at-1/0/3** command.

For brevity, this **show** command output includes only the configuration that is relevant to the at-1/0/3 physical interface. Any other configuration on the system has been replaced with ellipses (...).

```

user@host> show interfaces at-1/0/3
Physical interface: at-1/0/3, Enabled, Physical link is Down
  Interface index: 168, SNMP ifIndex: 595
  Link-level type: ATM-PVC, MTU: 2048, Clocking: Internal, SONET mode, Speed:
OC3, Loopback: None,
  Payload scrambler: Enabled
  Device flags   : Present Running Down
  Link flags     : None
  CoS queues    : 8 supported, 8 maximum usable queues
  Schedulers    : 0
  Current address: 00:1f:12:bc:4a:98
  Last flapped  : 2012-08-28 07:14:48 PDT (08:28:47 ago)
  Input rate    : 0 bps (0 pps)
  Output rate   : 0 bps (0 pps)
  SONET alarms  : LOL, LOS
  SONET defects : LOL, LOS, LOP, BERR-SF, RDI-P
  VPI 0
    Flags: Active
    Total down time: 0 sec, Last down: Never
  Traffic statistics:
    Input  packets:          0
    Output packets:          0
  ...

```

**Meaning** **ATM-PVC** in the Link-level Type field indicates that encapsulation for ATM permanent virtual circuits is being used on ATM physical interface at-1/0/3. The **Active** flag for VPI 0 indicates that the virtual path is up and operational.

### Verifying the Static Subscriber Interface Configuration on Logical Unit 0

---

**Purpose** Verify that the static subscriber interface on logical unit 0 is properly configured for IPv4 access over ATM.

**Action** From operational mode, issue the **show interfaces at-1/0/3.0** command.

```
user@host> show interfaces at-1/0/3.0
Logical interface at-1/0/3.0 (Index 341) (SNMP ifIndex 1984)
  Flags: Device-Down Point-To-Point SNMP-Traps 0x4000 Encapsulation: ATM-VCMUX

  Input packets : 0
  Output packets: 0
  Protocol inet, MTU: 2040
    Flags: Sendbcst-pkt-to-re, uRPF
    Addresses, Flags: Dest-route-down Is-Preferred Is-Primary
      Destination: 1.0.0.2, Local: 1.0.0.254
  VCI 0.39
    Flags: Active
    Total down time: 0 sec, Last down: Never
    Input packets : 0
    Output packets: 0
```

**Meaning** **ATM-VCMUX** in the Encapsulation field indicates that the logical interface at-1/0/3.0 is properly configured for IPoA encapsulation with VC multiplexing. **Protocol inet** indicates that the IPv4 protocol family has been properly configured on the logical interface. The local address 1.0.0.254 is the IPv4 address of the logical interface. The destination address 1.0.0.2, which is in the same network as the local address, is the IPv4 address of the remote side of the connection and represents the static subscriber interface. The **Active** flag for VCI 0.39 indicates that virtual circuit identifier (VCI) 39 on VPI 0 is up and operational.

### Example: Configuring a Static Subscriber Interface for IP Access over Ethernet over ATM

---

This example illustrates a bridged IP-over-Ethernet-over-ATM (IPoE-over-ATM) configuration that creates a subscriber interface for IPv4 access over a static ATM interface on an MX Series router. The router must have Module Port Concentrator/Modular

Interface Card (MPC/MIC) interfaces that use an ATM MIC with small form-factor pluggable transceiver (SFP).

- [Requirements on page 581](#)
- [Overview on page 581](#)
- [Configuration on page 582](#)
- [Verification on page 585](#)

## Requirements

This example uses the following software and hardware components:

- Junos OS Release 12.2
- MX Series 3D Universal Edge Router
- ATM MIC with SFP (Model Number MIC-3D-8OC3-2OC12-ATM) and compatible MPC1 or MPC2

Before you begin:

1. Make sure the MX Series router you are using has an ATM MIC with SFP installed and operational.
  - For information about compatible MPCs for the ATM MIC with SFP, see the [MX Series 3D Universal Edge Routers Line Card Guide](#).
  - For information about installing MPCs and MICs in an MX Series router, see the *Hardware Guide* for your MX Series router model.
2. Make sure you understand how to configure and use static ATM interfaces.

See ATM Interfaces Overview.
3. Define the static standard firewall filters (biz-customer-in-filter and biz-customer-out-filter) referenced in the configuration.
  - For information about creating standard firewall filters, see *Guidelines for Configuring Standard Firewall Filters*.
  - For information about applying a firewall filter to an interface, see *Guidelines for Applying Standard Firewall Filters*.

## Overview

By using the ATM MIC with SFP and a supported MPC, you can configure the MX Series router to support subscriber access for a statically created IPv4 or IPv6 interface over a static ATM underlying interface. An IPoE-over-ATM configuration enables you to provide access to subscribers on static IPv4 or IPv6 interfaces over an underlying ATM interface on an ATM network using ATM Adaptation Layer 5 (AAL5) permanent virtual circuits (PVCs).

**NOTE:** IPoE-over-ATM configurations on MX Series routers require static configuration of the IP interface, ATM interface, CoS attributes, and firewall filters. Dynamic configuration is not supported.

To configure bridged IPoE-over-ATM subscriber access on MX Series routers, you must configure Ethernet-over-ATM logical link control (LLC) encapsulation on the ATM underlying interface by including the **encapsulation ether-over-atm-llc** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

To provision the ATM AAL5 PVCs for access over the ATM network, you must also configure the virtual path identifiers (VPIs) on the ATM physical interface, and one or more virtual circuit identifiers (VCIs) for each VPI.

In IPoE-over-ATM configurations, the subscriber interfaces are associated with IPv4 or IPv6 addresses that are mapped to media access control (MAC) addresses. To statically configure Address Resolution Protocol (ARP) table entries that map IP address to MAC addresses, use the **arp** statement at the **[edit interfaces *interface-name* unit *logical-unit-number* family inet address *address*]** hierarchy level. In this example, the IPv4 address 1.0.50.2, configured with the **set arp 1.0.50.2 mac 00:00:01:02:04:ff publish** statement at the **[edit interfaces *at-1/0/2* unit 0 family inet address 1.0.50.254/24]** hierarchy level, represents the subscriber interface.

This example includes the following basic steps to statically configure a single IPv4 subscriber interface over an ATM underlying interface:

1. Configure VPI 0 on ATM physical interface *at-1/0/2*.
2. Configure Ethernet-over-ATM LLC encapsulation, VCI 0.39 (VCI 39 on VPI 0), and the following IPv4 (**inet**) protocol family characteristics on logical interface *at-1/0/2.0* :
  - IPv4 subscriber interface address 1.0.50.254/24
  - Static Address Resolution Protocol (ARP) table entries that provide explicit mappings between IP addresses and MAC addresses
  - IP source address validation (**rpf-check**)
  - Standard input (*biz-customer-in-filter*) and output (*biz-customer-out-filter*) firewall filters
3. Configure static access route 200.10.10.0/24 with qualified-next-hop address *at-1/0/0.0*.

## Configuration

To configure a static IPv4 subscriber interface over a static ATM underlying interface, perform these tasks:

- [Configuring the ATM Physical Interface on page 583](#)
- [Configuring the Static IPv4 Subscriber Interface on Logical Unit 0 on page 583](#)
- [Configuring Routing Properties on page 585](#)

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
# ATM Physical Interface
set interfaces at-1/0/2 atm-options vpi 0
#
# Logical Unit 0
set interfaces at-1/0/2 unit 0 encapsulation ether-over-atm-llc
set interfaces at-1/0/2 unit 0 vci 0.39
set interfaces at-1/0/2 unit 0 family inet rpf-check
set interfaces at-1/0/2 unit 0 family inet filter input biz-customer-in-filter
set interfaces at-1/0/2 unit 0 family inet filter output biz-customer-out-filter
set interfaces at-1/0/2 unit 0 family inet address 1.0.50.254/24 arp 1.0.50.2 mac
00:00:01:02:04:ff
set interfaces at-1/0/2 unit 0 family inet address 1.0.50.254/24 arp 1.0.50.2 publish
#
# Routing Properties
set routing-options access route 200.10.10.0/24 qualified-next-hop at-1/0/0.0
```

### Configuring the ATM Physical Interface

**Step-by-Step Procedure** To configure the ATM physical interface:

1. Specify that you want to configure ATM-specific options on the physical interface.  

```
[edit interfaces at-1/0/2]
user@host# edit atm-options
```
2. Configure one or more VPIs on the physical interface.  

```
[edit interfaces at-1/0/2 atm-options]
user@host# set vpi 0
```

**Results** From the **[edit]** hierarchy level in configuration mode, confirm the results of the ATM physical interface configuration by issuing the **show interfaces at-1/0/2** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
user@host# show interfaces at-1/0/2
atm-options {
  vpi 0;
}
```

If you are done configuring the ATM physical interface, enter **commit** from configuration mode.

### Configuring the Static IPv4 Subscriber Interface on Logical Unit 0

**Step-by-Step Procedure** To configure the static IPv4 subscriber interface on logical unit 0:

1. Configure Ethernet-over-ATM LLC encapsulation on the logical interface.

- ```
[edit interfaces at-1/0/2 unit 0]
user@host# set encapsulation ether-over-atm-llc
```
2. Configure the VCI for the logical interface.  

```
[edit interfaces at-1/0/2 unit 0]
user@host# set vci 0.39
```
  3. Configure the IPv4 (**inet**) protocol family and address.  

```
[edit interfaces at-1/0/2 unit 0]
user@host# set family inet address 1.0.50.254/24
```
  4. Specify that you want to configure static ARP table entries to map between IP addresses and MAC addresses.  

```
[edit interfaces at-1/0/2 unit 0 family inet]
user@host# edit family inet address 1.0.50.254/24
```
  5. Configure IP address 1.0.50.2, which maps to the MAC address, and MAC address 00:00:01:02:04:ff, which maps to the IP address. Include the **publish** option to specify that the router reply to ARP requests for the specified IP address.  

```
[edit interfaces at-1/0/2 unit 0 family inet address 1.0.50.254/24]
user@host# set arp 1.0.50.2 mac 00:00:01:02:04:ff publish
user@host# up
```
  6. Enable IP source address validation, which checks whether traffic is arriving at the router on an expected path.  

```
[edit interfaces at-1/0/2 unit 0 family inet]
user@host# set rpf-check
```
  7. Apply the previously defined standard firewall filters to the logical interface.  

```
[edit interfaces at-1/0/2 unit 0 family inet]
user@host# set filter input biz-customer-in-filter
user@host# set filter output biz-customer-out-filter
```

**Results** From the **[edit]** hierarchy level in configuration mode, confirm the results of the static subscriber interface configuration on logical unit 0 by issuing the **show interfaces at-1/0/2.0** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
user@host# show interfaces at-1/0/2.0
encapsulation ether-over-atm-llc;
vci 0.39;
family inet {
  rpf-check;
  filter {
    input biz-customer-in-filter;
    output biz-customer-out-filter;
  }
  address 1.0.50.254/24 {
    arp 1.0.50.2 mac 00:00:01:02:04:ff publish;
  }
}
```

If you are done configuring the static subscriber interface on logical unit 0, enter **commit** from configuration mode.

### Configuring Routing Properties

#### Step-by-Step Procedure

To configure static routing properties:

1. Specify that you want to configure protocol-independent routing properties.  

```
[edit]
user@host# edit routing-options
```
2. Configure a static access route for routing downstream traffic from the router, and a qualified-next-hop address for routing upstream traffic to the router.  

```
[edit routing-options]
user@host# set access route 200.10.10.0/24 qualified-next-hop at-1/0/0.0
```

**Results** From the **[edit]** hierarchy level in configuration mode, confirm the results of the static routing properties configuration by issuing the **show routing-options** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
user@host# show routing-options
access {
  route 200.10.10.0/24 {
    qualified-next-hop at-1/0/0.0;
  }
}
```

If you are done configuring the static routing properties, enter **commit** from configuration mode.

### Verification

To confirm that the IPoE-over-ATM configuration is working properly, perform the following tasks:

- [Verifying the ATM Physical Interface Configuration on page 585](#)
- [Verifying the Static Subscriber Interface Configuration on Logical Unit 0 on page 586](#)

### Verifying the ATM Physical Interface Configuration

**Purpose** Verify that the at-1/0/2 physical interface is properly configured for use with ATM PVCs.

**Action** From operational mode, issue the **show interfaces at-1/0/2** command.

For brevity, this **show** command output includes only the configuration that is relevant to the at-1/0/2 physical interface. Any other configuration on the system has been replaced with ellipses (...).

```
user@host> show interfaces at-1/0/2
```

```

Physical interface: at-1/0/2, Enabled, Physical link is Down
  Interface index: 175, SNMP ifIndex: 594
  Link-level type: ATM-PVC, MTU: 2048, Clocking: Internal, SDH mode, Speed: OC3,
  Loopback: None,
  Payload scrambler: Enabled
  Device flags   : Present Running Down
  Link flags     : None
  CoS queues     : 8 supported, 8 maximum usable queues
  Schedulers     : 0
  Current address: 00:1f:12:bc:4a:97
  Last flapped   : 2012-09-06 12:11:39 PDT (05:45:45 ago)
  Input rate     : 0 bps (0 pps)
  Output rate    : 0 bps (0 pps)
  SDH alarms     : LOL, LOS
  SDH defects    : LOL, LOS, LOP, BERR-SF, HP-FERF
  VPI 0
    Flags: Active
    Total down time: 0 sec, Last down: Never
  Traffic statistics:
    Input packets: 0
    Output packets: 0
  ...

```

**Meaning** **ATM-PVC** in the Link-level Type field indicates that encapsulation for ATM permanent virtual circuits is being used on ATM physical interface at-1/0/2. The **Active** flag for VPI 0 indicates that the virtual path is up and operational.

### Verifying the Static Subscriber Interface Configuration on Logical Unit 0

**Purpose** Verify that the static subscriber interface on logical unit 0 is properly configured for IPoE-over-ATM access.

**Action** From operational mode, issue the **show interfaces at-1/0/2.0** command.

```

user@host> show interfaces at-1/0/2.0
Logical interface at-1/0/2.0 (Index 336) (SNMP ifIndex 1983)
  Flags: Device-Down Point-To-Multipoint SNMP-Traps 0x4000 Encapsulation:
Ether-over-ATM-LLC
  Input packets : 0
  Output packets: 0
  Protocol inet, MTU: 2016
  Flags: Sendbcast-pkt-to-re, uRPF
  Addresses, Flags: Dest-route-down Is-Preferred Is-Primary
    Destination: 1.0.50/24, Local: 1.0.50.254, Broadcast: 1.0.50.255
  VCI 0.39
    Flags: Active, Multicast
    Total down time: 0 sec, Last down: Never
    Input packets : 0
    Output packets: 0

```

**Meaning** **Ether-over-ATM-LLC** in the Encapsulation field indicates that logical interface at-1/0/2.0 is properly configured for Ethernet-over-ATM encapsulation with LLC. **Protocol inet** indicates that the IPv4 protocol family has been properly configured on the logical interface. The destination address 1.0.50/24 identifies the network in which the subscriber interface (1.0.50.2) resides. The **Active** flag for VCI 0.39 indicates that virtual circuit identifier (VCI) 39 on VPI 0 is up and operational.

- Related Documentation**
- [ATM for Subscriber Access Overview on page 547](#)
  - [Configuring ATM for Subscriber Access on page 553](#)
  - [Example: Configuring a Dynamic PPPoE Subscriber Interface over ATM on page 557](#)
  - [Example: Configuring a Static PPPoE Subscriber Interface over ATM on page 566](#)

## Example: Configuring a Static PPP Subscriber Interface over ATM

This example illustrates a PPP-over-ATM (PPPoA) configuration that creates three static PPP logical subscriber interfaces over a static ATM underlying interface on an MX Series router. The router must have Module Port Concentrator/Modular Interface Card (MPC/MIC) interfaces that use an ATM MIC with small form-factor pluggable transceiver (SFP).

- [Requirements on page 587](#)
- [Overview on page 588](#)
- [Configuration on page 589](#)
- [Verification on page 593](#)

## Requirements

This example uses the following software and hardware components:

- Junos OS Release 12.2
- MX Series 3D Universal Edge Router
- ATM MIC with SFP (Model Number MIC-3D-8OC3-2OC12-ATM) and compatible MPC1 or MPC2

Before you begin:

1. Make sure the MX Series router you are using has an ATM MIC with SFP installed and operational.
  - For information about compatible MPCs for the ATM MIC with SFP, see the [MX Series 3D Universal Edge Routers Line Card Guide](#).
  - For information about installing MPCs and MICs in an MX Series router, see the [Hardware Guide](#) for your MX Series router model.
2. Make sure you understand how to configure and use static ATM interfaces.  
See [ATM Interfaces Overview](#).
3. Create the dynamic profile (pppoa-cos-profile) and access profile (pe-B-ppp-clients) referenced in the configuration.

- For information about creating a basic dynamic profile, see [“Configuring a Basic Dynamic Profile” on page 633](#).
- For information about creating a dynamic profile for class of service (CoS) attributes, see [“Configuring Traffic Scheduling and Shaping for Subscriber Access” on page 919](#).
- For information about creating an access profile for PPP Challenge Handshake Authentication Protocol (CHAP) authentication, see [Configuring the PPP Challenge Handshake Authentication Protocol](#).

## Overview

By using the ATM MIC with SFP and a supported MPC, you can configure an MX Series router to support PPP subscriber access over an ATM network. PPPoA configurations on MX Series routers consist of one or more statically created PPP logical subscriber interfaces over a static ATM underlying interface.

Optionally, you can use dynamic profiles to dynamically or statically apply subscriber services, such as CoS and firewall filters, to the static PPP logical interface. Configuring CoS and firewall filters in this manner enables you to efficiently and economically provide these services to PPP subscribers accessing the router over an ATM network using ATM Adaptation Layer 5 (AAL5) permanent virtual connections (PVCs). This example uses a previously configured dynamic profile named `pppoa-cos-profile` to apply traffic scheduling and shaping parameters to logical interface `at-1/0/1.2`.

To configure PPPoA subscriber access on MX Series routers, you must configure the correct encapsulation type: **`atm-ppp-llc`** for PPPoA encapsulation with logical link control (LLC), or **`atm-ppp-vc-mux`** for PPPoA encapsulation with virtual circuit (VC) multiplexing. This example configures **`atm-ppp-llc`** as the encapsulation type on logical interface `at-1/0/1.0`, and **`atm-ppp-vc-mux`** as the encapsulation type on logical interfaces `at-1/0/1.1` and `at-1/0/1.2`.

To provision the ATM AAL5 PVCs for access over the ATM network, you must also configure the virtual path identifiers (VPIs) on the ATM physical interface, and one or more virtual circuit identifiers (VCIs) for each VPI.

In PPPoA configurations, each statically configured logical interface (for example, `at-1/0/1.0`) corresponds to a PPP logical subscriber interface. This example configures three PPP logical subscriber interfaces over an ATM interface, as follows:

- The ATM physical interface (`at-1/0/1`) is statically configured with VPI 0 and VPI 2.
- Logical interface `at-1/0/1.0` (logical unit 0) is configured with PPP-over AAL5 LLC encapsulation, VCI 0.120 (VCI 120 on VPI 0), PPP-specific options, and the IPv4 protocol family and address.
- Logical interface `at-1/0/1.1` (logical unit 1) is configured with PPP-over-AAL5 VC multiplexing encapsulation, VCI 2.120 (VCI 120 on VPI 2), PPP-specific options, and the IPv4 protocol family and address.
- Logical interface `at-1/0/1.2` (logical unit 2) is configured with PPP-over-AAL5 VC multiplexing encapsulation, VCI 2.121 (VCI 121 on VPI 2), PPP-specific options, and the

IPv4 protocol family and address. The PPP-specific options include applying a dynamic profile named pppoa-cos-profile to the static PPP interface. The pppoa-cos-profile dynamic profile applies traffic scheduling and shaping parameters to the PPP logical subscriber interface.

## Configuration

To configure static PPP logical subscriber interfaces over an ATM interface, perform these tasks:

- [Configuring the ATM Physical Interface on page 590](#)
- [Configuring the Static PPP Subscriber Interface on Logical Unit 0 on page 590](#)
- [Configuring the Static PPP Subscriber Interface on Logical Unit 1 on page 591](#)
- [Configuring the Static PPP Subscriber Interface on Logical Unit 2 on page 592](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them in a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
# ATM Physical Interface
set interfaces at-1/0/1 atm-options vpi 0
set interfaces at-1/0/1 atm-options vpi 2
#
# Logical Unit 0
set interfaces at-1/0/1 unit 0 encapsulation atm-ppp-llc
set interfaces at-1/0/1 unit 0 vci 0.120
set interfaces at-1/0/1 unit 0 ppp-options chap access-profile pe-B-ppp-clients
set interfaces at-1/0/1 unit 0 ppp-options chap local-name pe-A-at-1/0/1
set interfaces at-1/0/1 unit 0 keepalives interval 5
set interfaces at-1/0/1 unit 0 keepalives up-count 6
set interfaces at-1/0/1 unit 0 keepalives down-count 4
set interfaces at-1/0/1 unit 0 family inet address 192.122.13.13/30
#
# Logical Unit 1
set interfaces at-1/0/1 unit 1 encapsulation atm-ppp-vc-mux
set interfaces at-1/0/1 unit 1 vci 2.120
set interfaces at-1/0/1 unit 1 keepalives interval 6
set interfaces at-1/0/1 unit 1 keepalives up-count 6
set interfaces at-1/0/1 unit 1 keepalives down-count 4
set interfaces at-1/0/1 unit 1 family inet address 192.122.14.13/30
#
# Logical Unit 2
set interfaces at-1/0/1 unit 2 encapsulation atm-ppp-vc-mux
set interfaces at-1/0/1 unit 2 vci 2.121
set interfaces at-1/0/1 unit 2 ppp-options chap access-profile pe-A-ppp-clients
set interfaces at-1/0/1 unit 2 ppp-options chap local-name pe-A-at-1/0/1
set interfaces at-1/0/1 unit 2 ppp-options chap passive
set interfaces at-1/0/1 unit 2 ppp-options dynamic-profile pppoa-cos-profile
set interfaces at-1/0/1 unit 2 keepalives interval 5
set interfaces at-1/0/1 unit 2 keepalives up-count 6
set interfaces at-1/0/1 unit 2 keepalives down-count 4
set interfaces at-1/0/1 unit 2 family inet address 192.122.15.13/30
```

### Configuring the ATM Physical Interface

---

#### Step-by-Step Procedure

To configure the ATM physical interface:

1. Specify that you want to configure ATM-specific options on the physical interface.  

```
[edit interfaces at-1/0/1]  
user@host# edit atm-options
```
2. Configure one or more VPIs on the physical interface.  

```
[edit interfaces at-1/0/1 atm-options]  
user@host# set vpi 0  
user@host# set vpi 2
```

#### Results

From the **[edit]** hierarchy level in configuration mode, confirm the results of the ATM physical interface configuration by issuing the **show interfaces at-1/0/1** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]  
user@host# show interfaces at-1/0/1  
atm-options {  
  vpi 0;  
  vpi 2;  
}
```

If you are done configuring the ATM physical interface, enter **commit** from configuration mode.

### Configuring the Static PPP Subscriber Interface on Logical Unit 0

---

#### Step-by-Step Procedure

To configure the static PPP subscriber interface on logical unit 0:

1. Configure PPP-over AAL5 LLC encapsulation on the logical interface.  

```
[edit interfaces at-1/0/1 unit 0]  
user@host# set encapsulation atm-ppc-llc
```
2. Configure the VCI for the logical interface.  

```
[edit interfaces at-1/0/1 unit 0]  
user@host# set vci 0.120
```
3. Specify that you want to configure options for PPP CHAP on the logical interface.  

```
[edit interfaces at-1/0/1 unit 0]  
user@host# edit ppp-options chap
```
4. Assign the previously configured pe-B-ppp-clients access profile to the PPP logical subscriber interface.  

```
[edit interfaces at-1/0/1 unit 0 ppp-options chap]  
user@host# set access-profile pe-B-ppp-clients
```
5. Configure the local name used by the interface in CHAP challenge and response packets.

```
[edit interfaces at-1/0/1 unit 0 ppp-options chap]
user@host# set local-name "pe-A-at-1/0/1"
user@host# up 2
```

6. Configure the transmission of keepalive messages on the logical interface.

```
[edit interfaces at-1/0/1 unit 0]
user@host# set keepalives interval 5
user@host# set keepalives up-count 6
user@host# set keepalives down-count 4
```

7. Configure the IPv4 (inet) protocol family and IP address.

```
[edit interfaces at-1/0/1 unit 0]
user@host# set family inet address 192.122.13.13/30
```

**Results** From the **[edit]** hierarchy level in configuration mode, confirm the results of the static PPP subscriber interface configuration on logical unit 0 by issuing the **show interfaces at-1/0/1.0** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
user@host# show interfaces at-1/0/1.0
encapsulation atm-ppp-llc;
vci 0.120;
ppp-options {
  chap {
    access-profile pe-B-ppp-clients;
    local-name pe-A-at-1/0/1;
  }
}
keepalives interval 5 up-count 6 down-count 4;
family inet {
  address 192.122.13.13/30;
}
```

If you are done configuring the PPP logical subscriber interface on logical unit 0, enter **commit** from configuration mode.

### Configuring the Static PPP Subscriber Interface on Logical Unit 1

#### Step-by-Step Procedure

To configure the static PPP subscriber interface on logical unit 1:

1. Configure PPP-over-AAL5 VC multiplexing encapsulation on the logical interface.

```
[edit interfaces at-1/0/1 unit 1]
user@host# set encapsulation atm-ppc-vc-mux
```

2. Configure the VCI for the logical interface.

```
[edit interfaces at-1/0/1 unit 1]
user@host# set vci 2.120
```

3. Configure the transmission of keepalive messages on the logical interface.

```
[edit interfaces at-1/0/1 unit 1]
user@host# set keepalives interval 6
user@host# set keepalives up-count 6
```

```
user@host# set keepalives down-count 4
```

4. Configure the IPv4 (inet) protocol family and IP address.

```
[edit interfaces at-1/0/1 unit 1]  
user@host# set family inet address 192.122.14.13/30
```

**Results** From the **[edit]** hierarchy level in configuration mode, confirm the results of the static PPP subscriber interface configuration on logical unit 1 by issuing the **show interfaces at-1/0/1.1** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]  
user@host# show interfaces at-1/0/1.1  
encapsulation atm-ppp-vc-mux;  
vci 2.120;  
keepalives interval 6 up-count 6 down-count 4;  
family inet {  
    address 192.122.14.13/30;  
}
```

If you are done configuring the PPP logical subscriber interface on logical unit 1, enter **commit** from configuration mode.

---

### Configuring the Static PPP Subscriber Interface on Logical Unit 2

#### Step-by-Step Procedure

To configure the static PPP subscriber interface on logical unit 2:

1. Configure PPP-over-AAL5 VC multiplex encapsulation on the logical interface.  

```
[edit interfaces at-1/0/1 unit 2]  
user@host# set encapsulation atm-ppc-vc-mux
```
2. Configure the VCI for the logical interface.  

```
[edit interfaces at-1/0/1 unit 2]  
user@host# set vci 2.121
```
3. Specify that you want to configure options for PPP CHAP on the logical interface.  

```
[edit interfaces at-1/0/1 unit 2]  
user@host# edit ppp-options chap
```
4. Assign the previously configured pe-A-ppp-clients access profile to the PPP logical subscriber interface.  

```
[edit interfaces at-1/0/1 unit 2 ppp-options chap]  
user@host# set access-profile pe-A-ppp-clients
```
5. Configure the local name used by the interface in CHAP challenge and response packets.  

```
[edit interfaces at-1/0/1 unit 2 ppp-options chap]  
user@host# set local-name "pe-A-at-1/0/1"
```
6. Configure passive mode for CHAP authentication.  

```
[edit interfaces at-1/0/1 unit 2 ppp-options chap]  
user@host# set passive
```

```
user@host# up
```

7. Apply the previously configured pppoa-cos-profile dynamic profile to the PPP logical subscriber interface.

```
[edit interfaces at-1/0/1 unit 2 ppp-options]
user@host# set dynamic-profile pppoa-cos-profile
user@host# up
```

8. Configure the transmission of keepalive messages on the logical interface.

```
[edit interfaces at-1/0/1 unit 2]
user@host# set keepalives interval 5
user@host# set keepalives up-count 6
user@host# set keepalives down-count 4
```

9. Configure the IPv4 (inet) protocol family and IP address.

```
[edit interfaces at-1/0/1 unit 2]
user@host# set family inet address 192.122.15.13/30
```

**Results** From the **[edit]** hierarchy level in configuration mode, confirm the results of the static PPP subscriber interface configuration on logical unit 2 by issuing the **show interfaces at-1/0/1.2** command. If the output does not display the intended configuration, repeat the instructions in this example to correct it.

```
[edit]
user@host# show interfaces at-1/0/1.2
encapsulation atm-ppp-vc-mux;
vci 2.121;
ppp-options {
  chap {
    access-profile pe-A-ppp-clients;
    local-name pe-A-at-1/0/1;
    passive;
  }
  dynamic-profile pppoa-cos-profile;
}
keepalives interval 5 up-count 6 down-count 4;
family inet {
  address 192.122.15.13/30;
}
```

If you are done configuring the PPP logical subscriber interface on logical unit 2, enter **commit** from configuration mode.

## Verification

To confirm that the PPPoA configuration is working properly, perform the following tasks:

- [Verifying the ATM Physical Interface Configuration on page 594](#)
- [Verifying the Static PPPoA Configuration on Logical Unit 0 on page 594](#)
- [Verifying the Static PPPoA Configuration on Logical Unit 1 on page 595](#)
- [Verifying the Static PPPoA Configuration on Logical Unit 2 on page 596](#)

### Verifying the ATM Physical Interface Configuration

---

**Purpose** Verify that the at-1/0/1 physical interface is properly configured for use with ATM PVCs.

**Action** From operational mode, issue the **show interfaces at-1/0/1** command.

For brevity, this **show** command output includes only the configuration that is relevant to the at-1/0/1 physical interface. Any other configuration on the system has been replaced with ellipses (...).

```
user@host> show interfaces at-1/0/1
Physical interface: at-1/0/1, Enabled, Physical link is Down
  Interface index: 166, SNMP ifIndex: 593
  Link-level type: ATM-PVC, MTU: 2048, Clocking: Internal, SONET mode, Speed:
OC3, Loopback: None, Payload scrambler: Enabled
  Device flags   : Present Running Down
  Link flags     : None
  CoS queues    : 8 supported, 8 maximum usable queues
  Schedulers    : 0
  Current address: 00:1f:12:bc:4a:96
  Last flapped  : 2012-06-29 15:35:29 PDT (2d 16:24 ago)
  Input rate    : 0 bps (0 pps)
  Output rate   : 0 bps (0 pps)
  SONET alarms  : LOL, LOS
  SONET defects : LOL, LOS, LOP, BERR-SF, RDI-P
  VPI 0
    Flags: Active
    Total down time: 0 sec, Last down: Never
  Traffic statistics:
    Input packets: 0
    Output packets: 0
  VPI 2
    Flags: Active
    Total down time: 0 sec, Last down: Never
  Traffic statistics:
    Input packets: 0
    Output packets: 0
  ...
```

**Meaning** **ATM-PVC** in the Link-level Type field indicates that encapsulation for ATM permanent virtual circuits is being used on ATM physical interface at-1/0/1. The **Active** flag for VPI 0 and VPI 2 indicates that these virtual paths are up and operational.

### Verifying the Static PPPoA Configuration on Logical Unit 0

---

**Purpose** Verify that the static PPP subscriber interface is properly configured on logical unit 0 (at-1/0/1.0).

**Action** From operational mode, issue the **show interfaces at-1/0/1.0** command.

```
user@host> show interfaces at-1/0/1.0
Logical interface at-1/0/1.0 (Index 337) (SNMP ifIndex 1979)
  Flags: Device-Down Point-To-Point Inverse-ARP SNMP-Traps 0x4000 Encapsulation:
ATM-PPP-LLC
  Input packets : 0
```

```

Output packets: 0
Keepalive settings: Interval 5 seconds, Up-count 6, Down-count 4
Keepalive: Input: 0 (never), Output: 0 (never)
LCP state: Down
NCP state: inet: Not-configured, inet6: Not-configured, iso: Not-configured,
mpls: Not-configured
CHAP state: Closed
PAP state: Closed
Protocol inet, MTU: 2034
  Flags: Sendbcst-pkt-to-re, Protocol-Down
  Addresses, Flags: Dest-route-down Is-Preferred Is-Primary
    Destination: 192.122.13.12/30, Local: 192.122.13.13, Broadcast:
192.122.13.15
VCI 0.120
  Flags: Active, Inverse-ARP
  Total down time: 0 sec, Last down: Never
  ARP statistics
    Received: 0, Sent: 0, Denied: 0, Operation not supported: 0,
    Bad packet length: 0, Bad protocol: 0, Bad protocol length: 0,
    Bad hardware length: 0, Dropped: 0
    Last received: Never, Last sent: Never
    Input packets : 0
    Output packets: 0

```

**Meaning** **ATM-PPP-LLC** in the Encapsulation field indicates that logical interface at-1/0/1.0 is properly configured for PPP-over-AAL5 logical link control (LLC) encapsulation. **Protocol inet** indicates that the IPv4 protocol family has been properly configured on the logical interface. The **Active** flag for VCI 0.120 indicates that virtual circuit identifier (VCI) 120 on VPI 0 is up and operational.

### Verifying the Static PPPoA Configuration on Logical Unit 1

**Purpose** Verify that the static PPP subscriber interface is properly configured on logical unit 1 (at-1/0/1.1).

**Action** From operational mode, issue the **show interfaces at-1/0/1.1** command.

```
user@host> show interfaces at-1/0/1.1
```

```

Logical interface at-1/0/1.1 (Index 338) (SNMP ifIndex 1980)
  Flags: Device-Down Point-To-Point SNMP-Traps 0x4000 Encapsulation:
ATM-PPP-VCMUX
  Input packets : 0
  Output packets: 0
  Keepalive settings: Interval 6 seconds, Up-count 6, Down-count 4
  Keepalive: Input: 0 (never), Output: 0 (never)
  LCP state: Down
  NCP state: inet: Not-configured, inet6: Not-configured, iso: Not-configured,
mpls: Not-configured
  CHAP state: Closed
  PAP state: Closed
  Protocol inet, MTU: 2038
    Flags: Sendbcst-pkt-to-re, Protocol-Down
    Addresses, Flags: Dest-route-down Is-Preferred Is-Primary
      Destination: 192.122.14.12/30, Local: 192.122.14.13, Broadcast:
192.122.14.15
  VCI 2.120
    Flags: Active, Inverse-ARP

```

```

Total down time: 0 sec, Last down: Never
ARP statistics
Received: 0, Sent: 0, Denied: 0, Operation not supported: 0,
Bad packet length: 0, Bad protocol: 0, Bad protocol length: 0,
Bad hardware length: 0, Dropped: 0
Last received: Never, Last sent: Never
Input packets : 0
Output packets: 0

```

**Meaning** **ATM-PPP-VCMUX** in the Encapsulation field indicates that the logical interface at-1/0/1.1 is properly configured for PPP-over-AAL5 VC multiplexing encapsulation. **Protocol inet** indicates that the IPv4 protocol family has been properly configured on the logical interface. The **Active** flag for VCI 2.120 indicates that virtual circuit identifier (VCI) 120 on VPI 2 is up and operational.

### Verifying the Static PPPoA Configuration on Logical Unit 2

**Purpose** Verify that the static PPP subscriber interface is properly configured on logical unit 2 (at-1/0/1.2).

**Action** From operational mode, issue the **show interfaces at-1/0/1.2** command.

```

user@host> show interfaces at-1/0/1.2
Logical interface at-1/0/1.2 (Index 339) (SNMP ifIndex 1981)
  Flags: Device-Down Point-To-Point SNMP-Traps 0x4000 Encapsulation:
ATM-PPP-VCMUX
  Input packets : 0
  Output packets: 0
  Keepalive settings: Interval 5 seconds, Up-count 6, Down-count 4
  Keepalive: Input: 0 (never), Output: 0 (never)
  LCP state: Down
  NCP state: inet: Not-configured, inet6: Not-configured, iso: Not-configured,
mp1s: Not-configured
  CHAP state: Closed
  PAP state: Closed
  Protocol inet, MTU: 2038
    Flags: Sendbcst-pkt-to-re, Protocol-Down
    Addresses, Flags: Dest-route-down Is-Preferred Is-Primary
      Destination: 192.122.15.12/30, Local: 192.122.15.13, Broadcast:
192.122.15.15
  VCI 2.121
    Flags: Active
    Total down time: 0 sec, Last down: Never
    Input packets : 0
    Output packets: 0

```

**Meaning** **ATM-PPP-VCMUX** in the Encapsulation field indicates that the logical interface at-1/0/1.2 is properly configured for PPP-over-AAL5 VC multiplexing encapsulation. **Protocol inet** indicates that the IPv4 protocol family has been properly configured on the logical interface. The **Active** flag for VCI 2.121 indicates that virtual circuit identifier 121 on VPI 2 is up and operational.

## Dynamic Profiles Overview

---

A dynamic profile is a set of characteristics, defined in a type of template, that you can use to provide dynamic subscriber access and services for broadband applications. These services are assigned dynamically to interfaces. The **dynamic-profiles** hierarchy appears at the top level of the CLI hierarchy and contains many Juniper Networks configuration statements that you normally define statically.

Dynamic profile statements appear in the following subhierarchies within the **[edit dynamic-profiles]** hierarchy:

- **class-of-service**
- **firewall**
- **interfaces**
- **predefined-variable-defaults**
- **protocols**
- **routing-instances**
- **routing-options**
- **variables**

This topic covers:

- [Dynamic Profile Interface Support on page 602](#)
- [What Dynamic Profiles Do on page 602](#)
- [How Dynamic Profiles Work on page 603](#)
- [Dynamic Profile Version Creation on page 603](#)
- [Dynamic Profile Semantic Checking on page 604](#)

### Dynamic Profile Interface Support

You can identify subscribers statically or dynamically. To identify subscribers statically, you can reference a static VLAN interface in a dynamic profile. To identify subscribers dynamically, you create variables for demux interfaces that are dynamically created when subscribers log in.

### What Dynamic Profiles Do

A dynamic profile acts as a kind of template that enables you to create, update, or remove a configuration that includes client access (for example, interface or protocol) or service (for example, class of service (CoS)) attributes or objects that are created dynamically (for example pseudowire). Using these profiles enables you to consolidate all of the common attributes of a client (and eventually a group of clients) and apply the attributes or dynamically created objects simultaneously.

## How Dynamic Profiles Work

After profiles are created, they reside on the router in a profile library. These profiles can contain various configurations. For example, you can create a client network access configuration, a services activation configuration, or both. When a router interface receives a join message from a client, the router applies the values configured in the specified dynamic profile to that router interface. The profile can contain interface, CoS, and protocol values that are applied directly to the interface. In addition, the dynamic profile can call input or output firewall filters that reside outside of the dynamic profiles hierarchy.

## Dynamic Profile Version Creation

You can create new versions of dynamic profiles that are currently in use by subscribers. Dynamic profile version creation is enabled at the **[edit system]** hierarchy level. When enabled, you can create multiple versions of any dynamic profiles on the router. Any subscriber that logs in following a dynamic profile modification uses the latest version of the dynamic profile. Subscribers that are already active continue to use the older version of the dynamic profile until they log out or their session terminates.

When creating versions of dynamic profiles, keep the following in mind:

- You must enable or disable dynamic profile version creation before creating or using any dynamic profiles on the router. Enabling or disabling dynamic profile version creation after dynamic profiles are configured is not supported.

**NOTE:** Before you can enable or disable dynamic profile version creation for a router on which any dynamic profiles are configured, you must first remove all dynamic profiles from the router configuration.

- Each version of a dynamic profile is stored in the profile database as a new profile.
- The name of the new profile version is derived by appending a string to the original base dynamic profile name. This string contains two dollar sign (\$) characters to identify the version field of the profile name. These two characters are followed by numerical characters that represent the “version number” of the dynamic profile (for example, 01).
- The version number of the dynamic profile is automatically generated by the system.
- The dynamic profile that you modify is always stored as the latest version. You cannot create a modified dynamic profile and save it as an earlier version. For example, if you modify version three of a dynamic profile while it is in use, the dynamic profile is saved as version four.
- You can only modify the latest version of a dynamic profile.
- The maximum value for the version number is 99999. However, for each profile, only 10 active versions are supported at a time.
- If the dynamic profile version that you modify is not in use by any subscriber, the profile is overwritten with committed changes without creating a new version.

- After reaching the 99999th modified version of a dynamic profile, any further modifications to the dynamic profile result in overwriting that final version. If the final version is in use, any modification attempts fail upon commit.
- You can delete a dynamic profile only when none of its versions are in use.
- The dynamic profile version feature supports graceful restart and unified ISSU.

## Dynamic Profile Semantic Checking

Variables are applied to dynamic profiles dynamically and cannot be checked with existing CLI commands. Semantic checking validates some variables in dynamic profiles to help identify potential configuration errors.

Semantic checks are performed during commit and during profile instantiation. Commit time checks ensure that variables appear in the correct location within the dynamic profile. Checks performed before profile instantiation ensure that the values that replace the variables are correct. The checks performed on the values include the following:

- Range validation
- Variable type validation
- Existence of variables where they are mandatory
- Variable matching to regular expressions

A commit time check failure results in an error message being displayed and logged in the `/var/log/messages` file and the commit failing. An instantiation failure results in an error being logged in the `/var/log/messages` file and the profile instantiation failing.

## Dynamic Variables Overview

---

Variables constitute the dynamic component of a dynamic profile. You use variables in dynamic profiles as placeholders for dynamically obtained or dynamically generated information that the dynamic profiles use to configure subscriber interfaces.

- [How Dynamic Variables Work on page 605](#)
- [Default Values for Predefined Variables on page 605](#)
- [Unique Identifier \(UID\) for Parameterized Filters on page 606](#)

### How Dynamic Variables Work

Dynamic variables are data placeholders that you define and place in dynamic profiles. When a particular event occurs on an interface (for example, a DHCP client accesses the interface), the dynamic profiles obtain data to fill these placeholders from one of three possible sources—the interface receiving an incoming client data packet, an externally configured server (for example, RADIUS), or a value associated with each user-configurable variable.

For your convenience, Junos OS provides several predefined variables that you can use within a dynamic profile. Most of these variables relate to interface-specific data obtained directly from the interface that receives an incoming client data packets (for example, interface name, interface unit value, and so on). When a client accesses the interface, the router software extracts the necessary interface data, propagates this data to the dynamic profile, and then uses the dynamic profile to configure the interface for the accessing client.

You define user-defined variables for individual dynamic profiles at the **[dynamic-profiles profile-name variables]** hierarchy level. At this hierarchy level, you create an association between a variable value (for example, `$junos-igmp-version`) that appears in the body of the dynamic profile and data associated with that call value that is managed in an externally configured server (for example, a RADIUS VSA managed on a RADIUS server) or defined as a value in the **variables** stanza. When an event occurs on an interface to trigger the instantiation of a dynamic profile for the interface, Junos OS obtains values for each variable from an external server (for example, from RADIUS authentication and authorization VSAs) during the subscriber authentication process. At run time, the variables are replaced by these actual values and are used to configure the subscriber interface.

### Default Values for Predefined Variables

You can optionally configure default values for many of the predefined variables. If the external RADIUS server is not available or the VSA does not contain a value for the predefined variable, Junos OS uses the default values.

When a default value is configured for a variable and RADIUS also returns a value, the system uses the value from RADIUS instead.

## Unique Identifier (UID) for Parameterized Filters

You can optionally configure a unique identifier (UID) for parameterized filters in dynamic profiles created for services. The generated UIDs enable you to identify and configure separate parameter values for filters with the same variable name. In addition, assigning a UID improves performance of the router.

For service profiles, you can request the generation of an UID for a user-defined variable by including the **uid** statement at the **[dynamic-profiles profile-name variables]** hierarchy level. You then reference the variable name in the filter. To enable selection of a particular filter in a dynamic profile that contains multiple variables of the same parameter and criteria type, you must indicate that the variable refers to a UID. To configure, include the **uid-reference** statement at the **[dynamic-profiles profile-name variables]** hierarchy level. For example, if the variable **\$in-filter** receives the value of “filter1” from RADIUS, the filter definition named **\$filter** is used.

## Junos OS Predefined Variables

Junos OS contains several predefined variables. The dynamic profile obtains and replaces data for these variables from an incoming client data packet and configuration (local and RADIUS). These variables are predefined—you use them in the body of a dynamic profile without first having to define the variables at the **[dynamic-profiles profile-name variables]** hierarchy level. [Table 58 on page 607](#) provides a list of predefined variables, their descriptions, and where in the Junos OS hierarchy you can configure them.

Table 58: Junos OS Predefined Variables and Definitions

Variable	Definition
<b>Access and Access-Internal Routes</b>	
\$junos-framed-route-cost	Cost metric of an access route. You specify this variable at the <b>[edit dynamic-profiles profile-name routing-options access route address]</b> hierarchy level for the <b>metric</b> statement.
\$junos-framed-route-distance	Distance of an access route. You specify this variable at the <b>[edit dynamic-profiles profile-name routing-options access route address]</b> hierarchy level for the <b>preference</b> statement.
\$junos-framed-route-ip-address-prefix	Route prefix of an access route. You specify this variable at the <b>[edit dynamic-profiles profile-name routing-options access]</b> hierarchy level for the <b>route</b> statement.
\$junos-framed-route-ipv6-address-prefix	IPv6 route prefix of an access route. You specify this variable at the <b>[edit dynamic-profiles profile-name routing-options access]</b> hierarchy level for the <b>route</b> statement.
\$junos-framed-route-ipv6-nexthop	IPv6 next-hop address of an access route. You specify this variable at the <b>[edit dynamic-profiles profile-name routing-options access route address]</b> hierarchy level for the <b>next-hop</b> statement.
\$junos-framed-route-nexthop	Next-hop address of an access route. You specify this variable at the <b>[edit dynamic-profiles profile-name routing-options access route address]</b> hierarchy level for the <b>next-hop</b> statement.
\$junos-framed-route-tag	Tag value of an access route. You specify this variable at the <b>[edit dynamic-profiles profile-name routing-options access route address]</b> hierarchy level for the <b>tag</b> statement.
\$junos-interface-name	<p>Logical interface of an access-internal route. DHCP or PPP supplies this information when the subscriber logs in. You specify this variable at the <b>[edit dynamic-profiles profile-name routing-options access-internal route address]</b> hierarchy level for the <b>qualified-next-hop</b> statement.</p> <p>This variable is also used for creating dynamic IP demux interfaces.</p>

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
\$junos-subscriber-ip-address	<p>IP address of a subscriber identified in an access-internal route. You specify this variable at the <b>[edit dynamic-profiles <i>profile-name</i> routing-options access-internal]</b> hierarchy level for the <b>route</b> statement.</p> <p>This variable is also used for creating dynamic IP demux interfaces.</p>
\$junos-subscriber-mac-address	<p>MAC address for a subscriber identified in an access-internal route. You specify this variable at the <b>[edit dynamic-profiles <i>profile-name</i> routing-options access-internal route address qualified-next hop <i>underlying-interface</i>]</b> hierarchy level for the <b>mac-address</b> statement.</p>
<b>Dynamic Protocols</b>	
\$junos-igmp-access-group-name	Specifies the access list to use for the source (S) filter.
\$junos-igmp-access-source-group-name	Specifies the access list to use for the source-group (S,G) filter.
\$junos-igmp-enable	<p>Ensures that IGMP is not disabled on the interface by an AAA-based authentication and management method (for example, RADIUS). You specify this variable at the <b>[dynamic-profiles <i>profile-name</i> protocols igmp]</b> hierarchy level for the <b>interface</b> statement.</p>
\$junos-igmp-immediate-leave	<p>Enables IGMP immediate leave on the interface. You specify this variable at the <b>[dynamic-profiles <i>profile-name</i> protocols igmp]</b> hierarchy level for the <b>interface</b> statement.</p>
\$junos-igmp-version	<p>IGMP version configured in a client access profile. Junos OS obtains this information from the RADIUS server when a subscriber accesses the router. The version is applied to the accessing subscriber when the profile is instantiated. You specify this variable at the <b>[dynamic-profiles <i>profile-name</i> protocols igmp]</b> hierarchy level for the <b>interface</b> statement.</p>

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
\$junos-interface-name	<p>Name of the dynamic interface to which the subscriber access client connects. Its use is in dynamically enabling IGMP on the subscriber interface. You specify this variable at the <b>[dynamic-profiles profile-name protocols igmp]</b> hierarchy level for the <b>interface</b> statement.</p> <p>The interface name is derived from concatenating the <b>\$junos-interface-ifd-name</b> and the <b>\$junos-underlying-interface-unit</b> variables obtained when a subscriber is created dynamically at the <b>[dynamic-profiles profile-name interfaces]</b> hierarchy level.</p>
\$junos-ipv6-ndra-prefix	<p>Prefix value for the router advertisement interface. Junos OS obtains this information from the RADIUS server when a subscriber accesses the router. The prefix value is applied to the accessing subscriber when the profile is instantiated. You specify this variable at the <b>[dynamic-profiles profile-name protocols router-advertisement interface \$junos-interface-name]</b> hierarchy level.</p>
\$junos-mld-access-group-name	Specifies the access list to use for the group (G) filter.
\$junos-mld-access-source-group-name	Specifies the access list to use for the source-group (S,G) filter.
\$junos-mld-enable	<p>Ensures that MLD is not disabled on the interface by an AAA-based authentication and management method (for example, RADIUS). You specify this variable at the <b>[dynamic-profiles profile-name protocols mld]</b> hierarchy level for the <b>interface</b> statement.</p>
\$junos-mld-immediate-leave	<p>Enables MLD immediate leave on the interface. You specify this variable at the <b>[dynamic-profiles profile-name protocols mld]</b> hierarchy level for the <b>interface</b> statement.</p>
\$junos-mld-version	<p>MLD version configured in a client access profile. Junos OS obtains this information from the RADIUS server when a subscriber accesses the router. The version is applied to the accessing subscriber when the profile is instantiated. You specify this variable at the <b>[dynamic-profiles profile-name protocols mld]</b> hierarchy level for the <b>interface</b> statement.</p>

---

Dynamic CoS — Traffic-Control Profile Parameters

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
\$junos-cos-adjust-minimum	<p>Minimum adjusted shaping rate configured in a traffic-control profile in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>adjust-minimum</b> statement at the <b>[edit dynamic-profiles <i>profile-name</i> class-of-service traffic-control-profiles <i>profile-name</i>]</b> hierarchy level.</p>
\$junos-cos-byte-adjust	<p>Byte adjustment value configured in a traffic-control profile in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>bytes</b> option with the <b>overhead-accounting</b> statement at the <b>[edit dynamic-profiles <i>profile-name</i> class-of-service traffic-control-profiles <i>profile-name</i>]</b> hierarchy level.</p>
\$junos-cos-delay-buffer-rate	<p>Delay-buffer rate configured in a traffic-control profile in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>delay-buffer-rate</b> statement at the <b>[edit dynamic-profiles <i>profile-name</i> class-of-service traffic-control-profiles <i>profile-name</i>]</b> hierarchy level.</p>
\$junos-cos-excess-rate	<p>Excess rate configured in a traffic-control profile in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>excess-rate</b> statement at the <b>[edit dynamic-profiles <i>profile-name</i> class-of-service traffic-control-profiles <i>profile-name</i>]</b> hierarchy level.</p>

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
\$junos-cos-excess-rate-high	<p>Rate configured for excess high-priority traffic in a traffic-control profile in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>excess-rate-high</b> statement at the <b>[edit dynamic-profiles <i>profile-name</i> class-of-service traffic-control-profiles <i>profile-name</i>]</b> hierarchy level.</p>
\$junos-cos-excess-rate-low	<p>Rate configured for excess low-priority traffic in a traffic-control profile in a dynamic profile for subscriber access. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>excess-rate-low</b> statement at the <b>[edit dynamic-profiles <i>profile-name</i> class-of-service traffic-control-profiles <i>profile-name</i>]</b> hierarchy level.</p>
\$junos-cos-guaranteed-rate	<p>Guaranteed rate configured in a traffic-control profile in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>guaranteed-rate</b> statement at the <b>[edit dynamic-profiles <i>profile-name</i> class-of-service traffic-control-profiles <i>profile-name</i>]</b> hierarchy level.</p>
\$junos-cos-guaranteed-rate-burst	<p>Burst size for the guaranteed rate that is configured in a traffic-control profile in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable with the <b>burst-size</b> option in the <b>guaranteed-rate</b> statement at the <b>[edit dynamic-profiles <i>profile-name</i> class-of-service traffic-control-profiles <i>profile-name</i>]</b> hierarchy level.</p>

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
\$junos-cos-scheduler-map	<p>Scheduler-map name configured in a traffic-control profile in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>scheduler-map</b> statement at the <b>[edit dynamic-profiles profile-name class-of-service traffic-control-profiles profile-name]</b> hierarchy level.</p> <p><b>NOTE:</b> The scheduler map can be defined dynamically (at the <b>[edit dynamic-profiles profile-name class-of-service scheduler-maps]</b> hierarchy level) or statically (at the <b>[edit class-of-service scheduler-maps]</b> hierarchy level).</p>
\$junos-cos-shaping-mode	<p>Shaping mode configured in a traffic-control profile in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>overhead-accounting</b> statement at the <b>[edit dynamic-profiles profile-name class-of-service traffic-control-profiles profile-name]</b> hierarchy level.</p>
\$junos-cos-shaping-rate	<p>Shaping rate configured in a traffic-control profile in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>shaping-rate</b> statement at the <b>[edit dynamic-profiles profile-name class-of-service traffic-control-profiles profile-name]</b> hierarchy level.</p>

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
\$junos-cos-shaping-rate-burst	<p>Burst size for the shaping rate configured in a traffic-control profile in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable with the <b>burst-size</b> option in the <b>shaping-rate</b> statement at the <b>[edit dynamic-profiles <i>profile-name</i> class-of-service traffic-control-profiles <i>profile-name</i>]</b> hierarchy level.</p>
\$junos-cos-traffic-control-profile	<p>Traffic-control profile configured in a dynamic profile for subscriber access. The Junos OS obtains the profile information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>traffic-control-profiles</b> statement at the <b>[edit dynamic-profiles <i>profile-name</i> class-of-service]</b> hierarchy level.</p>
<b>Dynamic CoS — Scheduler Parameters</b>	
\$junos-cos-scheduler	<p>Name of a scheduler configured in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable at the <b>[edit dynamic-profiles <i>profile-name</i> class-of-service schedulers]</b> hierarchy level.</p>
\$junos-cos-scheduler-bs	<p>Buffer size as a percentage of total buffer, specified for a scheduler configured in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>buffer-size</b> statement with the <b>percent</b> option at the <b>[edit dynamic-profiles <i>profile-name</i> class-of-service schedulers <i>scheduler-name</i>]</b> hierarchy level.</p>

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
\$junos-cos-scheduler-pri	<p>Packet-scheduling priority value specified for a scheduler configured in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>priority</b> statement at the <b>[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]</b> hierarchy level.</p>
\$junos-cos-scheduler-dropfile-any	<p>Name of the drop profile for random early detection (RED) for loss-priority level <b>any</b> specified for a scheduler configured in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>drop-profile</b> statement at the <b>[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name drop-profile-map loss-priority any protocol any]</b> hierarchy level.</p> <p><b>NOTE:</b> The drop profile must be configured statically (at the <b>[edit class-of-service drop-profiles]</b> hierarchy level).</p>
\$junos-cos-scheduler-dropfile-high	<p>Name of the drop profile for random early detection (RED) for loss-priority level <b>high</b> specified for a scheduler configured in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>drop-profile</b> statement at the <b>[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name drop-profile-map loss-priority high protocol any]</b> hierarchy level.</p> <p><b>NOTE:</b> The drop profile must be configured statically (at the <b>[edit class-of-service drop-profiles]</b> hierarchy level).</p>

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
<code>\$junos-cos-scheduler-dropfile-low</code>	<p>Name of the drop profile for random early detection (RED) for loss-priority level <b>low</b> specified for a scheduler configured in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>drop-profile</b> statement at the <b>[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name drop-profile-map loss-priority low protocol any]</b> hierarchy level.</p> <p><b>NOTE:</b> The drop profile must be configured statically (at the <b>[edit class-of-service drop-profiles]</b> hierarchy level) for loss-priority <b>low</b>.</p>
<code>\$junos-cos-scheduler-dropfile-medium-high</code>	<p>Name of the drop profile for random early detection (RED) for loss-priority level <b>medium-high</b> specified for a scheduler configured in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>drop-profile</b> statement at the <b>[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name drop-profile-map loss-priority medium-high protocol any]</b> hierarchy level.</p> <p><b>NOTE:</b> The drop profile must be configured statically (at the <b>[edit class-of-service drop-profiles]</b> hierarchy level).</p>

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
\$junos-cos-scheduler-dropfile-medium-low	<p>Name of the drop profile for random early detection (RED) for loss-priority level <b>medium-low</b> specified for a scheduler configured in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>drop-profile</b> statement at the <b>[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name drop-profile-map loss-priority medium-low protocol any]</b> hierarchy level.</p> <p><b>NOTE:</b> The drop profile must be configured statically (at the <b>[edit class-of-service drop-profiles]</b> hierarchy level).</p>
\$junos-cos-scheduler-excess-priority	<p>Priority value of the excess rate specified for a scheduler configured in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>excess-priority</b> statement at the <b>[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]</b> hierarchy level.</p>
\$junos-cos-scheduler-excess-rate	<p>Value of the excess rate specified for a scheduler configured in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>excess-rate</b> statement at the <b>[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]</b> hierarchy level.</p>
\$junos-cos-scheduler-shaping-rate	<p>Value of the shaping rate specified for a scheduler configured in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>shaping-rate</b> statement at the <b>[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]</b> hierarchy level.</p>

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
\$junos-cos-scheduler-tx	<p>Transmit rate specified for a scheduler configured in a dynamic profile. Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the dynamic profile is attached.</p> <p>You reference this variable in the <b>transmit-rate</b> statement at the <b>[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]</b> hierarchy level.</p>
<b>Dynamic Connectivity Fault Management Parameters</b>	
\$junos-action-profile	Name of the action profile configured in a dynamic profile.
\$junos-ccm-interval	Continuity check interval time configured in a dynamic profile.
\$junos-loss-threshold	The number of continuity check messages lost before marking the remote MEP as down, configured in a dynamic profile.
\$junos-ma-name-format	Name of the maintenance association name format configured in a dynamic profile.
\$junos-md-name-format	Name of the maintenance domain format configured in a dynamic profile.
\$junos-ma-name	Name of the maintenance association configured in a dynamic profile.
\$junos-md-level	Value of 'Level', configured in a dynamic profile.
\$junos-md-name	Name of the maintenance domain configured in a dynamic profile.
\$junos-mep-id	The 'MEP' value configured in the dynamic profile.
\$junos-remote-mep-id	The 'Remote MEP' value configured in the dynamic profile.
<b>Filters — RADIUS-obtained Policies</b>	
\$junos-input-filter	Attaches a filter based on RADIUS VSA 26-10 (Ingress-Policy-Name) or RADIUS attribute 11 (Filter-ID) to the interface.
\$junos-input-ipv6-filter	Attaches a filter based on RADIUS VSA 26-106 (IPv6-Ingress-Policy-Name) to the interface.

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
\$junos-output-filter	Attaches a filter based on RADIUS VSA 26-11 (Egress-Policy-Name) to the interface.
\$junos-output-ipv6-filter	Attaches a filter based on RADIUS VSA 26-107 (IPv6-Egress-Policy-Name) to the interface.
<b>Subscriber Interfaces — Dynamic Demux Interfaces</b>	
\$junos-interface-ifd-name	<p>Name of the device to which the subscriber access client connects. All interfaces are created on this device. Its primary use is in creating single or multiple subscribers on a statically created interface. You specify this variable at the <b>[dynamic-profiles <i>profile-name</i> interfaces]</b> hierarchy level.</p> <p>When creating a logical underlying interface for a dynamic VLAN demux interface, you must also specify this variable at the <b>[dynamic-profiles <i>profile-name</i> interfaces <i>demux0</i> unit <i>\$junos-interface-unit</i> demux-options underlying-interface]</b> hierarchy level.</p>
\$junos-interface-unit	Creates a unit number assigned to the logical interface. The router supplies this information when the subscriber accesses the network. You specify this variable at the <b>[dynamic-profiles <i>profile-name</i> interfaces <i>interface-name</i>]</b> hierarchy level for the <b>unit</b> statement.
\$junos-ipv6-address	Selects the IPv6 address of the interface the subscriber uses. You specify this variable at the <b>[edit dynamic-profiles <i>profile-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i>]</b> , <b>[edit dynamic-profiles <i>profile-name</i> interfaces <i>demux0</i> unit <i>logical-unit-number</i> family <i>family</i>]</b> , <b>[edit dynamic-profiles <i>profile-name</i> interfaces <i>pp0</i> unit "<i>\$junos-interface-unit</i>" family <i>family</i>]</b> , and <b>[edit logical-systems <i>logical-system-name</i> interfaces <i>interface-name</i> unit <i>logical-unit-number</i> family <i>family</i>]</b> hierarchy level for the <b>address</b> statement.
\$junos-loopback-interface	Selects the loopback interface the subscriber uses. You specify this variable at the <b>[dynamic-profiles <i>profile-name</i> interfaces <i>demux0</i> unit "<i>\$junos-interface-unit</i>" family <i>inet</i>]</b> hierarchy level for the <b>unnumbered-address</b> statement.

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
<code>\$junos-preferred-source-address</code>	<p>Selects the preferred source address associated with the loopback address used for the subscriber. You specify this variable at the <b>[dynamic profiles <i>profile-name</i> interfaces demux0 unit "<i>\$junos-interface-unit</i>" family inet unnumbered-address "<i>\$junos-loopback-interface</i>"]</b> hierarchy level for the <b>preferred-source-address</b> statement.</p>
<code>\$junos-subscriber-ip-address</code>	<p>IP address of the subscriber. You specify this variable at the <b>[dynamic-profiles <i>profile-name</i> interfaces demux0 unit family inet demux-source]</b> hierarchy level.</p> <p>This variable is also used for creating access-internal routes.</p>
<code>\$junos-subscriber-ipv6-address</code>	<p>IPv6 address for subscriber. You specify this variable at the <b>[dynamic-profiles <i>profile-name</i> interfaces interface-name unit logical-unit-number family inet6 demux-source]</b> hierarchy level.</p>
<code>\$junos-subscriber-ipv6-multi-address</code>	<p>Expands the <b>demux-source</b> into multiple addresses; for example, the IPv6 prefix and /128 address for the subscriber.</p> <p>You specify this variable at the <b>[dynamic-profiles <i>profile-name</i> interfaces interface-name unit logical-unit-number family inet6 demux-source]</b> hierarchy level.</p>
<code>\$junos-underlying-interface</code>	<p>Creates a logical underlying interface for a dynamic IP demux interface. The client logs in on this interface. You specify this variable at the <b>[dynamic profiles <i>profile-name</i> interfaces demux0 unit "<i>\$junos-interface-unit</i>" demux-options]</b> hierarchy level for the <b>underlying-interface</b> statement.</p> <p>When configured, the underlying interface is used to determine the <b><i>\$junos-underlying-interface</i></b>, <b><i>\$junos-underlying-interface-unit</i></b>, and <b><i>\$junos-ifd-name</i></b> variables. For example, if the receiving logical interface is ge-0/0/0.1, the <b><i>\$junos-underlying-interface</i></b> variable is set to ge-0/0/0 and the <b><i>\$junos-underlying-interface-unit</i></b> variable is set to 1.</p> <p>This variable is also used for creating access-internal routes.</p>

---

#### Subscriber Interfaces — Static VLAN Interfaces

---

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
<code>\$junos-interface-ifd-name</code>	Name of the device to which the subscriber access client connects. All interfaces are created on this device. Its primary use is in creating single or multiple subscribers on a statically created interface. You specify this variable at the <b>[dynamic-profiles <i>profile-name</i> interfaces]</b> hierarchy level.
<code>\$junos-underlying-interface-unit</code>	Obtains the unit number for the underlying interface. It specifies the use of the underlying interface for the subscriber. You specify this variable at the <b>[dynamic-profiles <i>profile-name</i> interfaces <i>\$junos-interface-ifd-name</i>]</b> hierarchy for the <b>unit</b> statement.

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
<b>Subscriber Interfaces — Dynamic PPPoE Interfaces</b>	
<code>\$junos-interface-unit</code>	Specifies the logical unit number when the router dynamically creates a PPPoE logical interface. The <code>\$junos-interface-unit</code> predefined variable is dynamically replaced with the unit number supplied by the network when the PPPoE subscriber logs in. You specify this variable at the <code>[edit dynamic-profiles profile-name interfaces pp0]</code> hierarchy level for the <code>unit</code> statement.
<code>\$junos-underlying-interface</code>	Specifies the name of the underlying Ethernet interface on which the router dynamically creates the PPPoE logical interface. The <code>\$junos-underlying-interface</code> predefined variable is dynamically replaced with the name of the underlying interface supplied by the network when the PPPoE subscriber logs in. You specify this variable at the <code>[edit dynamic-profiles profile-name interfaces pp0 unit "\$junos-interface-unit" pppoe-options]</code> hierarchy level for the <code>underlying-interface</code> statement.
<b>Subscriber Interfaces — Dynamic Interface Sets</b>	
<code>\$junos-interface-set-name</code>	Name of an interface set configured in a dynamic profile. To represent the name of a dynamically created agent circuit identifier (ACI) interface set, use the <code>\$junos-interface-set-name</code> predefined variable in the <code>interface-set</code> statement at the <code>[edit dynamic-profiles profile-name interfaces]</code> hierarchy level.
<code>\$junos-svlan-interface-set-name</code>	Locally generated interface set name for use by dual-tagged VLAN interfaces based on the outer tag of the dual-tagged VLAN. The format of the generated variable is <code>physical_interface_name - outer_VLAN_tag</code> .
<b>Wholesale Networking</b>	

Table 58: Junos OS Predefined Variables and Definitions (*continued*)

Variable	Definition
\$junos-interface-name	<p>Name of the dynamic interface to which the subscriber access client connects. Its use is in identifying the subscriber interface. You specify this variable at the <b>[dynamic-profiles profile-name routing-instance \$junos-routing-instance]</b> hierarchy level for the <b>interface</b> statement.</p> <p>The interface name is derived from concatenating the <b>\$junos-interface-ifs-name</b> and the <b>\$junos-underlying-interface-unit</b> variables obtained when a subscriber is created dynamically at the <b>[dynamic-profiles profile-name routing-instance \$junos-routing-instance interface]</b> hierarchy level.</p>
\$junos-routing-instance	<p>Name of the routing instance to which the subscriber is assigned. This variable triggers a return value from the RADIUS server for Virtual-Router (VSA 26–1).</p> <p>You reference this variable in the statement at the <b>[dynamic-profiles profile-name]</b> hierarchy level for the <b>routing-instance</b> statement.</p>

## Junos OS Predefined Variables That Correspond to RADIUS Attributes and VSAs

Table 59 on page 622 lists the RADIUS attributes and Juniper Networks VSAs and their corresponding Junos OS predefined variables that are used in dynamic profiles. When the router instantiates a dynamic profile following subscriber access, the Junos OS uses the predefined variable to specify the RADIUS attribute or VSA for the information obtained from the RADIUS server.

Table 59: RADIUS Attributes and Corresponding Junos OS Predefined Variables

RADIUS Attribute or VSA	Junos OS Predefined Variable	Description	Default Value Support for Junos OS Predefined Variable
<b>RADIUS Attribute</b>			
Framed-IP-Address (8)	\$junos-framed-route-ip-address	Address for the client	No

Table 59: RADIUS Attributes and Corresponding Junos OS Predefined Variables (*continued*)

RADIUS Attribute or VSA	Junos OS Predefined Variable	Description	Default Value Support for Junos OS Predefined Variable
Filter-ID (11)	\$junos-input-filter  <b>NOTE:</b> Variable is also used for VSA 26–10.	Input filter to apply to client IPv4 interface	Yes
Framed-Route (22)	\$junos-framed-route-ip-address-prefix	(Subattribute 1): Route prefix for access route	No
	\$junos-framed-route-nexthop	(Subattribute 2): Next hop address for access route	No
	\$junos-framed-route-cost	(Subattribute 3): Metric for access route	No
	\$junos-framed-route-distance	(Subattribute 5): Preference for access route	No
	\$junos-framed-route-tag	(Subattribute 6): Tag for access route	No
Framed-IPv6-Prefix (97)	\$junos-ipv6-ndra-prefix	Prefix value in IPv6 Neighbor Discovery route advertisements	No
Framed-IPv6-Route (99)	\$junos-framed-route-ipv6-address-prefix	(Subattribute 1): Framed IPv6 route prefix configured for the client	No
	\$junos-framed-route-ipv6-nexthop	(Subattribute 2): IPv6 routing information configured for the client	No
<b>Juniper Networks VSA</b>			
Virtual-Router (26–1)	\$junos-routing-instance	Routing instance to which subscriber is assigned	No
Ingress-Policy-Name (26–10)	\$junos-input-filter  <b>NOTE:</b> Variable is also used for RADIUS attribute 11.	Input filter to apply to client IPv4 interface	Yes
Egress-Policy-Name (26–11)	\$junos-output-filter	Output filter to apply to client IPv4 interface	Yes
IGMP-Enable (26–23)	\$junos-igmp-enable	Enable or disable IGMP on client interface	Yes

Table 59: RADIUS Attributes and Corresponding Junos OS Predefined Variables (*continued*)

RADIUS Attribute or VSA	Junos OS Predefined Variable	Description	Default Value Support for Junos OS Predefined Variable
IGMP-Access-Name (26–71)	\$junos-igmp-access-group-name	Access list to use for the group (G) filter	Yes
IGMP-Access-Src-Name (26–72)	\$junos-igmp-access-source-group-name	Access List to use for the source group (S,G) filter	Yes
MLD-Access-Name (26–74)	\$junos-mld-access-group-name	Access list to use for the group (G) filter	Yes
MLD-Access-Src-Name (26–75)	\$junos-mld-access-source-group-name	Access List to use for the source group (S,G) filter	Yes
MLD-Version (26–77)	\$junos-mld-version	MLD protocol version	Yes
IGMP-Version (26–78)	\$junos-igmp-version	IGMP protocol version	Yes
IGMP-Immediate-Leave (26–97)	\$junos-igmp-immediate-leave	IGMP immediate leave	Yes
MLD-Immediate-Leave (26–100)	\$junos-mld-immediate-leave	MLD immediate leave	Yes
IPv6-Ingress-Policy-Name (26–106)	\$junos-input-ipv6-filter	Input filter to apply to client IPv6 interface	Yes
IPv6-Egress-Policy-Name (26–107)	\$junos-output-ipv6-filter	Output filter to apply to client IPv6 interface	Yes
CoS Traffic Control Profile Parameters (26–108)	\$junos-cos-scheduler-map	(T01: Scheduler-map name) Name of scheduler map configured in traffic-control profile	Yes
	\$junos-cos-shaping-rate	(T02: Shaping rate) Shaping rate configured in traffic-control profile	Yes
	\$junos-cos-guaranteed-rate	(T03: Guaranteed rate) Guaranteed rate configured in traffic-control profile	Yes
	\$junos-cos-delay-buffer-rate	(T04: Delay-buffer rate) Delay-buffer rate configured in traffic-control profile	Yes

Table 59: RADIUS Attributes and Corresponding Junos OS Predefined Variables (*continued*)

RADIUS Attribute or VSA	Junos OS Predefined Variable	Description	Default Value Support for Junos OS Predefined Variable
	\$junos-cos-excess-rate	(T05; Excess rate) Excess rate configured in traffic-control profile	Yes
	\$junos-cos-traffic-control-profile	(T06; Traffic-control profile) Name of the traffic-control profile configured in a dynamic profile	Yes
	\$junos-cos-shaping-mode	(T07; Shaping mode) CoS shaping mode configured in a dynamic profile	Yes
	\$junos-cos-byte-adjust	(T08; Byte adjust) Byte adjustments configured for the shaping mode in a dynamic profile	Yes
	\$junos-cos-adjust-minimum	(T09; Adjust minimum) Minimum adjusted value allowed for the shaping rate in a dynamic profile	Yes
	\$junos-cos-excess-rate-high	(T10; Excess rate high) Excess rate configured for high-priority traffic in a dynamic profile	Yes
	\$junos-cos-excess-rate-low	(T11; Excess rate low) Excess rate configured for low-priority traffic in a dynamic profile	Yes
	\$junos-cos-shaping-rate-burst	(T12; Shaping rate burst) Burst size configured for the shaping rate in a dynamic profile	Yes
	\$junos-cos-guaranteed-rate-burst	(T13; Guaranteed rate burst) Burst size configured for the guaranteed rate in a dynamic profile	Yes
Qos-Set-Name (26–130)	\$junos-interface-set-name	Name of an interface set configured in a dynamic profile	Yes

Table 59: RADIUS Attributes and Corresponding Junos OS Predefined Variables (*continued*)

RADIUS Attribute or VSA	Junos OS Predefined Variable	Description	Default Value Support for Junos OS Predefined Variable
CoS-Scheduler-Pmt-Type (26–146)	\$junos-cos-scheduler	(Null: Scheduler name) Name of scheduler configured in a dynamic profile	Yes
	\$junos-cos-scheduler-tx	(T01: CoS scheduler transmit rate) Transmit rate for scheduler configured in a dynamic profile	Yes  Available for multiple parameters: <ul style="list-style-type: none"> <li>• Percent</li> <li>• Rate</li> </ul>
	\$junos-cos-scheduler-bs	(T02: CoS scheduler buffer size) Buffer size for scheduler configured in a dynamic profile	Yes  Available for multiple parameters: <ul style="list-style-type: none"> <li>• Percent</li> <li>• Temporal</li> </ul>
	\$junos-cos-scheduler-pri	(T03: CoS scheduler priority) Packet-scheduling priority for scheduler configured in a dynamic profile	Yes
	\$junos-cos-scheduler-dropfile-low	(T04: CoS scheduler drop-profile low) Name of drop profile for RED loss-priority level <b>low</b> for scheduler configured in a dynamic profile	Yes
	\$junos-cos-scheduler-dropfile-medium-low	(T05: CoS scheduler drop-profile medium-low) Name of drop profile for RED loss-priority level <b>medium-low</b> for scheduler configured in a dynamic profile	Yes

Table 59: RADIUS Attributes and Corresponding Junos OS Predefined Variables (*continued*)

RADIUS Attribute or VSA	Junos OS Predefined Variable	Description	Default Value Support for Junos OS Predefined Variable
	\$junos-cos-scheduler-dropfile-medium-high	(T06: CoS scheduler drop-profile medium-high) Name of drop profile for RED loss-priority level <b>medium-high</b> for scheduler configured in a dynamic profile	Yes
	\$junos-cos-scheduler-dropfile-high	(T07: CoS scheduler drop-profile high) Name of drop profile for RED loss-priority level <b>high</b> for scheduler configured in a dynamic profile	Yes
	\$junos-cos-scheduler-dropfile-any	(T08: CoS scheduler drop-profile any) Name of drop profile for RED loss-priority level <b>any</b> for scheduler configured in a dynamic profile	Yes
	\$junos-cos-scheduler-excess-rate	(T09: CoS scheduler excess rate) Excess rate configured for a scheduler in a dynamic profile	Yes  Available for multiple parameters: <ul style="list-style-type: none"> <li>• Percent</li> <li>• Proportion</li> </ul>
	\$junos-cos-scheduler-shaping-rate	(T10: CoS scheduler shaping rate) Shaping rate configured for a scheduler in a dynamic profile	Yes  Available for multiple parameters: <ul style="list-style-type: none"> <li>• Percent</li> <li>• Rate</li> </ul>
	\$junos-cos-scheduler-excess-priority	(T11: CoS scheduler excess priority) Excess priority configured for a scheduler in a dynamic profile	Yes

## User-Defined Variables

---

In service profiles, the Junos OS enables you to configure custom variables at the **[dynamic-profiles *profile-name* variables]** hierarchy level and associate those variables with supported RADIUS VSAs. The dynamic profile obtains and replaces data for these variables from an external server (for example, from RADIUS authentication and authorization VSAs) during the subscriber authentication process. At run time, the variables are replaced by these actual values (obtained from default information on the router or from the RADIUS server) and are used to configure the subscriber interface.

For a complete list of supported RADIUS VSAs for which you can create variable associations, see [“RADIUS Attributes and Juniper Networks VSAs Supported by the AAA Service Framework” on page 81](#).

You can also configure the user-defined variables with a default value. The default value provides a standalone configuration for the associated statement or a backup for the statement configuration if the RADIUS server is inaccessible or the VSA attribute does not contain a value.

## Variable Expressions Overview

---

Junos OS enables you to create expressions—groups of arithmetic operators, string operators, and operands—for use as variables within dynamic profiles. You configure variable expressions at the **[dynamic-profiles *profile-name* variables]** hierarchy level. At run time, the variable expressions are calculated and used as variable values to configure dynamic subscriber interfaces.

When configuring expressions in dynamic profiles, you must adhere to the following rules:

- You can configure expressions only within a variable stanza of a dynamic profile.
- Dynamic profiles that contain expressions must be used only for service activation.
- You can assign expressions only to user-defined variables. You cannot assign expressions to internal variables or predefined variables.
- Expression values are given precedence over default values.
- Entire expressions must be contained within quotation marks (“ ”).
- Strings within the expressions must be quoted within single quotation marks (‘ ’) and the single quotation marks can contain only strings.

- White space is treated as a delimiter for all operands and operators. Strings containing spaces that you create within expressions are treated as single strings and include any leading or trailing white space. For example:

```
dynamic-profiles {
  service profile {
    variables {
      scheduler-name;
      video-filter equals " ' Filter 1 ' " # Everything within the single quotation marks is
      considered a string, including the leading and trailing white space
    }
  }
}
```

- The expression must be either all arithmetic operators or all string operators; mixing arithmetic operators and string operators is not allowed unless properly converted to the correct type.
- Expressions can refer to other system predefined variables or other user-defined variables. However, no circular referencing between variables is allowed. For example, the following reference is incorrect:

```
dynamic-profiles {
  Service_Profile_1 {
    variables {
      scheduler-name;
      transmit-rate2 equals " ( $transmit-rate1 * 2)/3" # refers to transmit-rate1
      transmit-rate1 equals " ( $transmit-rate2 * 2)/3" # refers to transmit-rate2
    }
  }
}
```

- Any mandatory variable that does not contain a “default” value or an “equals” expression must contain a value as a part of service activation. For example, a RADIUS service VSA like “service-video( value1, value2)” that contains two or fewer mandatory variables in the dynamic service profile definition “service-video” succeeds. The service activation fails if at least one mandatory variable does not have any value associated with it, either through default or equals attribute evaluation.

Table 60 on page 629 lists supported operators and functions you can use to create expressions.

NOTE: Precedence 5 is the highest level.

Table 60: Operators and Functions

Operation	Operator	Associativity	Precedence	Action
Arithmetic Addition	+	Left	1	Adds the elements to the right and left of the operator together.
Arithmetic Subtraction	-	Left	1	Subtracts the element to the right of the operator from the element to the left of the operator.

Table 60: Operators and Functions (*continued*)

Operation	Operator	Associativity	Precedence	Action
Arithmetic Multiplication	*	Left	2	Multiplies the element to the left of the operator by the element to the right of the operator.
Arithmetic Division	/	Left	2	Divides the element to the left of the operator by the element to the right of the operator.
Arithmetic Modulo	%	Left	2	Divides the element to the left of the operator by the element to the right of the operator and returns the integer remainder. If the element to the left of the operator is less than the element to the right of the operator, the result is the element to the left of the operator.
Concatenation	##	Left	3	Creates a new string by joining the string values to the left of the operator and the values to the right of the operator together.
Maximum	max(param1,param2)	Left	4	Takes the maximum of the two values passed as parameters.
Minimum	min(param1,param2)	Left	4	Takes the minimum of the two values passed as parameters.
Round	round(param1)	-	4	Rounds the value to the nearest integer.
Truncate	trunc(param1)	-	4	Truncates a non-integer value to the value left of the decimal point.
Convert to String	toStr(param1)	-	4	Converts the variable inside the parentheses to a null terminated string.
Convert to Integer	toInt(param1)	-	4	Converts the parameter to an integer. A single string or variable is allowed as a parameter.
Random	rand()	-	4	Generates a random numerical value.
Parentheses	( )	-	5	Groups operands and operators to achieve results different from simple precedence; effectively has the highest precedence.

Expressions are evaluated after variables are populated with values. The evaluation is conducted immediately before profile instantiation and includes value checking. If the computed values are not acceptable, or rules governing expression syntax are broken, the expression evaluation fails, profile instantiation does not occur, and messages are logged to describe the errors.

[Table 61 on page 631](#) lists the possible expression error scenarios and the action taken by the router software.

Table 61: Expression Errors and Actions

Error	Occurance	Action	Variable Value
Parsing error	Commit check phase	Commit fails	not applicable
Circular variable dependency error	Commit check phase	Commit fails	not applicable
Variables inside the expressions are not defined	Commit check phase	Commit fails	not applicable
Divide by zero	Profile Instantiation	Profile instantiation fails	Zero (0)
Adding string to a number	Profile Instantiation	Profile instantiation fails	Zero (0)
Overflow error	Profile Instantiation	Profile instantiation fails	Undefined
Underflow error	Profile Instantiation	Profile instantiation fails	Undefined

You can also configure the user-defined variables with a default value. The default value provides a standalone configuration for the associated statement or a backup for the statement configuration if the RADIUS server is inaccessible or the VSA attribute does not contain a value.

## Access Profiles and Service Profiles Overview

Dynamic profiles enable you to configure parameters that enable access and services to subscribers.

*Access profiles*, also known as client profiles, contain the parameters to grant access and provide basic service to a subscriber during initial login. By configuring the access profile with Junos OS predefined variables, you also enable the service to be activated for those subscribers at login. The RADIUS variables in an access profile map to one or more VSAs.

*Service profiles* contain parameters that activate or deactivate services for a subscriber. You can apply a service profile with an access profile at login, or apply the service profile separately to modify a service. A service profile maps to a Service VSA.

## Functionality Supported in Access and Service Profiles

The types of variables, expressions, and default values that you can use depends on the type of dynamic profile.

[Table 62 on page 632](#) lists the types of variables supported by access profiles and service profiles.

**Table 62: Types of Variables Supported in Dynamic Profiles**

Type of Dynamic Profile	Junos OS Predefined Variable (Local)	Junos OS Predefined Variable (RADIUS)	User-Defined Variable
Access Profile	Yes	Yes	Yes
Service Profile	Yes	No	Yes

[Table 63 on page 632](#) lists the default values, expressions, and unique identifiers supported by access profiles and service profiles.

**Table 63: Default Values and Expressions Supported in Dynamic Profiles**

Type of Dynamic Profile	Default Values	Expressions	Unique Identifiers
Access Profile	Yes (RADIUS predefined variables only)	No	Yes (Schedulers and Scheduler maps only)
Service Profile	Yes (User-defined variables only)	Yes (Service activation only)	Yes (Firewall filters only)

## Configuring a Basic Dynamic Profile

---

This topic describes how to create a basic dynamic profile. A basic profile must contain a profile name and have both an interface variable name (such as `$junos-interface-ifd-name`) included at the `[edit dynamic-profiles profile-name interfaces` hierarchy level and logical interface variable name (such as `$junos-underlying-interface-unit` or `$junos-interface-unit`) at the `[edit dynamic-profiles profile-name interfaces variable-interface-name unit]` hierarchy level.

Before you configure dynamic profiles for initial client access:

1. Configure the necessary router interfaces that you want DHCP clients to use when accessing the network.  
  
See [“Subscriber Interface Overview” on page 715](#) for information about the types of interfaces you can use with dynamic profiles and how to configure them.
2. Configure all RADIUS values that you want the profiles to use when validating DHCP clients for access to the multicast network.

See [“Configuring RADIUS Server Parameters for Subscriber Access” on page 35](#)

To configure a basic dynamic profile:

1. Name the profile.

```
[edit]
user@host# edit dynamic-profiles basic-profile
```

2. Define the **interface-name** statement with the internal **\$junos-interface-ifd-name** variable used by the router to match the interface name of the receiving interface.

```
[edit dynamic-profiles basic-profile]
user@host# edit interfaces $junos-interface-ifd-name
```

3. Define the **unit** statement with the internal variable:
  - When referencing an existing interface, specify the **\$junos-underlying-interface-unit** variable used by the router to match the unit value of the receiving interface.
  - When creating dynamic interfaces, specify the **\$junos-interface-unit** variable used by the router to generate a unit value for the interface.

```
[edit dynamic-profiles basic-profile interfaces "$junos-interface-ifd-name"]
user@host# set unit $junos-underlying-interface-unit
```

or

```
[edit dynamic-profiles basic-profile interfaces "$junos-interface-ifd-name"]
user@host# set unit $junos-interface-unit
```

4. If you are using interface sets, you must apply the traffic-control profile to the interface set in the static **[edit class-of-service]** hierarchy. The interface set name must be explicitly referenced in the CoS configuration as part of the static configuration outside of the dynamic profile. The CoS configuration is static and the interface set name must be statically referenced.

This rule applies to all interface sets except ACI sets.

## Configuring Predefined Dynamic Variables in Dynamic Profiles

This topic discusses how to configure predefined variables in a dynamic profile. The dynamic profile obtains and replaces data for these variables from an incoming client data packet. You can specify these variables in the body of a dynamic profile without having to first define the variables at the **[edit dynamic-profiles profile-name variables]** hierarchy level.

Before you configure dynamic variables:

1. Create a basic dynamic profile.  
See [“Configuring a Basic Dynamic Profile” on page 633](#).
2. Ensure that the router hardware is configured in the network to accept subscriber access.

To configure predefined variables in a dynamic profile:

1. Access the desired dynamic profile.

```
[edit]
user@host# edit dynamic-profiles igmpProfile1
[edit dynamic-profiles igmpProfile1]
```

2. Configure the necessary variables.

```
[edit dynamic-profiles igmpProfile1]
user@host# set protocols igmp interface $junos-interface-name
```

For a complete list of supported predefined variables, see [“Junos OS Predefined Variables” on page 606](#).

## Configuring Default Values for Predefined Variables in a Dynamic Profile

You can configure default values for the predefined variables that are configured in a dynamic profile. These default values are used when RADIUS does not supply a value.

To configure default values for Junos predefined variables:

1. Specify that you want to configure the dynamic profile.

```
[edit]
user@host# edit dynamic-profile profile-name
```

2. Configure the default value for a specific option within a predefined variable.

```
[edit dynamic-profiles profile-name]
user@host# set predefined-variable-defaults predefined-variable variable-option
default-value
```

**NOTE:** Do not use the “junos-” prefix when specifying the *predefined-variable*.

#### Related Documentation

---

## Configuring User-Defined Dynamic Variables in Dynamic Profiles

This topic discusses how to configure the user-defined dynamic variables in a dynamic profile. You define user-defined variables for individual dynamic profiles at the **[edit dynamic-profiles *profile-name* variables]** hierarchy level. At this hierarchy level, you create an association between a variable call value (for example, **\$junos-igmp-version**) that appears in the body of the dynamic profile and data associated with that call value that is managed in an externally configured server (for example, a RADIUS VSA managed on a RADIUS server) or defined as a default value in the **variables** stanza.

Before you configure dynamic variables:

1. Create a basic dynamic profile.  
See [“Configuring a Basic Dynamic Profile” on page 633](#).
2. Ensure that the router is configured to enable communication between the client and the RADIUS server.  
See [“Specifying the Authentication and Accounting Methods for Subscriber Access” on page 24](#).
3. Configure all RADIUS values that you want the profiles to use when validating subscribers.  
See [“Configuring RADIUS Server Parameters for Subscriber Access” on page 35](#)

To configure variables in a dynamic profile:

1. Access the **variables** stanza in the desired dynamic profile.

```
user@host# edit dynamic-profiles profile1 variables
[edit dynamic-profiles profile1 variables]
```

2. Specify a name to identify the variable.

The variable name can be any alphanumeric value. The name is an association to a variable in the dynamic profile configuration. For example, if you specify a variable name of “**igmp-version**” as the variable name, you must specify the call variable “**\$igmp-version**” in the dynamic profile configuration for the statement you want the variable to define.

```
[edit dynamic-profiles igmpProfile1 variables]
user@host# set igmp-version
```

3. Configure the variable using one (or both) of the following methods:

- Specify a RADIUS attribute and RADIUS tag (when required) for the variable.

```
[edit dynamic-profiles igmpProfile1 variables]
user@host# set igmp-version radius vendor-id 4874 attribute 78
```

- Configure a default value for the variable.

```
[edit dynamic-profiles igmpProfile1 variables]
user@host# set igmp-version default-value 3
```

**NOTE:** You can configure variables by using the RADIUS method, the default value method, or both. If you choose to configure both a RADIUS attribute and a default value for the variable, the RADIUS attribute takes precedence over the default value. However, the dynamic profile applies the default value if the router cannot contact the RADIUS server or if the RADIUS server does not contain a value for the assigned attribute.

4. Configure the call variable in the dynamic profile.

```
[edit dynamic-profiles igmpProfile1]
user@host# set protocols igmp interface demux0 version $igmp-version
```

**NOTE:** The call variable must match the name of the variable that you configured in the variables stanza.

## Configuring Variable Expressions in Dynamic Profiles

You can create expressions—groups of arithmetic operators, string operators, and operands—for use as variables within dynamic profiles. These expressions are used as variable values to configure dynamic subscriber interfaces.

To configure dynamic profile variable expressions:

1. Access the dynamic profile for which you want to create variable expressions.

```
[edit]
user@host# edit dynamic-profiles profile-name
```

2. Access the **variables** hierarchy for the dynamic profile.

```
[edit dynamic-profiles profile-name]
user@host# edit variables
```

3. Define the variable using the expression operators and operands described in [“Variable Expressions Overview” on page 628](#).

```
[edit dynamic-profiles profile-name variables]
user@host# set expression
```

[Table 64 on page 638](#) provides several examples of expressions that you can create using the supported operators and functions.

**Table 64: Expression Examples**

Example	Description
video-filter equals “ Filter1”	Assigns the string “ Filter1” to the dynamic \$video-filter variable.
video-filter2 equals “\$video-filter ## ‘ Filter2’ ”	Converts dynamic variable “\$video-filter” to a string and concatenates the new string with the string “ Filter2”. The result is the string “\$video-filter Filter2” assigned to the \$video-filter2 variable.
tempvar equals “120”	Converts “120” to an integer and assigns the integer to the \$tempvar variable.
transmit-rate2 equals “ ( \$transmit-rate1 * 2)/3 + \$tempvar)”	Multiplies the “transmit-rate1” variable by 2 and divides that value by the sum of 3 and the value of “\$tempvar”. The result is assigned to the \$transmit-rate2 variable.
host-ip equals “ ‘10.0.0.2’ ”	Assigns the string “10.0.02” to the \$host-ip variable.
max-val “max(\$max1,\$max2)”	Assigns the greater of value “max1” or “max2” to the \$max-val variable.
min-val “\$min(\$var1,30)”	Assign the smaller of value “var1” and “30” to the \$min-val variable.
rounded-var equals “round(\$var1 )”	Rounds off the value of the variable “\$var1” to the nearest integer and assigns the value to the \$rounded-var variable.
trunc-var equals “trunc(1234.5)”	Truncates the value in parentheses to the left side of the decimal and assigns the resulting value to the \$trunc-var variable.

Table 64: Expression Examples (*continued*)

Example	Description
bwg-shaping-rate equals "\$anqp-downstream - (\$anqp-downstream % 2 * (1 - \$sp-qos-cell-mode))"	Evaluates the expression as per the precedence set in the parentheses.
temp-filter1 equals "'Filter1' ## toStr(\$filter)"	Converts the "\$filter" variable to a string value and concatenates the converted string to the string "Filter1". The resulting combined string is assigned to the \$temp-filter1 variable.

## Configuring a Dynamic Profile for Client Access

This topic describes how to create a basic dynamic profile that enables DHCP clients to dynamically access the multicast network.

Before you configure dynamic profiles for initial client access:

1. Create a basic dynamic profile.  
See ["Configuring a Basic Dynamic Profile" on page 633](#).
2. Configure the necessary router interfaces that you want accessing DHCP clients to use.  
See ["Subscriber Interface Overview" on page 715](#) for information about the types of interfaces you can use with dynamic profiles and how to configure them.
3. Ensure that the router is configured to enable communication between the client and the RADIUS server.  
See ["Specifying the Authentication and Accounting Methods for Subscriber Access" on page 24](#).
4. Configure all RADIUS values that you want the profiles to use when validating DHCP clients for access to the multicast network.  
See ["Configuring RADIUS Server Parameters for Subscriber Access" on page 35](#)

To configure an initial client access dynamic profile:

1. Access an IGMP access profile.  

```

user@host# edit dynamic-profiles access-profile
[edit dynamic-profiles access-profile]
user@host#

```
2. Define the IGMP interface with the interface variable.

**NOTE:** The variable value is replaced by the name of the interface over which the router received the DHCP message.

```
[edit dynamic-profiles access-profile]
user@host# set protocols igmp interface $junos-interface-name
```

3. (Optional) Enable or disable accounting on the IGMP interface.

```
[edit dynamic-profiles access-profile protocols igmp interface "$junos-interface-name"]
user@host# set accounting
```

or

```
[edit dynamic-profiles access-profile protocols igmp interface "$junos-interface-name"]
user@host# set no-accounting
```

**NOTE:** This statement enables you to override the accounting setting at the IGMP protocol level. For example, if IGMP accounting is enabled at the [edit protocols igmp interface *interface-name*] hierarchy level, you can use the no-accounting statement to disable accounting for any IGMP interfaces that are dynamically created by the dynamic profile. If IGMP accounting is not enabled at the [edit protocols igmp interface *interface-name*] hierarchy level, you can use the accounting statement to enable accounting for any IGMP interfaces that are dynamically created by the dynamic profile.

4. Set the IGMP interface to remain enabled.

```
[edit dynamic-profiles access-profile protocols igmp interface "$junos-interface-name"]
user@host# set disable:$junos-igmp-enable
```

**NOTE:** RADIUS is capable of disabling IGMP. By assigning the enable variable to the disable statement, you can ensure that IGMP remains enabled.

5. (Optional) Specify a group policy for the IGMP interface.

```
[edit dynamic-profiles access-profile protocols igmp interface "$junos-interface-name"]
user@host# set group-policy report-reject-policy
```

6. (Optional) Enable immediate leave on the IGMP interface.

```
[edit dynamic-profiles access-profile protocols igmp interface "$junos-interface-name"]
user@host# set immediate-leave:$junos-igmp-immediate-leave
```

7. (Optional) Set the IGMP interface to obtain the IGMP version from RADIUS.

```
[edit dynamic-profiles access-profile protocols igmp interface "$junos-interface-name"]
user@host# set version $junos-igmp-version
```

## Configuring a Dynamic Profile for Various Levels of Services

This topic discusses how to create dynamic profiles to define various levels of service for DHCP clients.

Before you configure dynamic profiles for client services:

1. Create a basic dynamic profile.  
See [“Configuring a Basic Dynamic Profile” on page 633](#).
2. Configure a dynamic profile that enables DHCP clients access to the network.  
See [“Configuring a Dynamic Profile for Client Access” on page 639](#)

**NOTE:** You can create a basic dynamic profile that contains both access configuration and some level of basic service.

3. Ensure that the router is configured to enable communication between the client and the RADIUS server.  
See [“Specifying the Authentication and Accounting Methods for Subscriber Access” on page 24](#).
4. Configure all RADIUS values that you want the profiles to use when validating DHCP clients.  
See [“Configuring RADIUS Server Parameters for Subscriber Access” on page 35](#)

To configure an initial client access dynamic profile:

1. Access the desired service profile.  
**user@host# set dynamic-profiles basic-service-profile**
2. (Optional) Define any IGMP protocols values as described for creating a basic access profile to combine a basic service with access in a profile.  
See [“Configuring a Dynamic Profile for Client Access” on page 639](#).
3. (Optional) Specify any filters for the interface.  
See [“Dynamically Attaching Statically Created Filters for Any Interface Type” on page 1114](#), [“Dynamically Attaching Statically Created Filters for a Specific Interface Family Type” on page 1113](#), or [“Dynamically Attaching Filters Using RADIUS Variables” on page 1115](#).
4. Define any CoS values for the service level you want this profile to configure on the interface.

## Configuring Unique Identifiers for Parameterized Filters in Dynamic Profiles

---

This topic discusses how to configure unique identifiers (UID) for parameterized filters in a dynamic profile. The dynamic profile obtains and replaces data for these variables from an incoming client data packet. You can specify these variables in the body of a dynamic profile without having to first define the variables at the **[edit dynamic-profiles profile-name variables]** hierarchy level.

Before you configure dynamic variables:

1. Create a basic dynamic profile.  
[See “Configuring a Basic Dynamic Profile” on page 633.](#)
2. Ensure that the router hardware is configured in the network to accept subscriber access.

To configure unique identifiers for parameterized filters in a dynamic profile:

1. Access the desired dynamic profile.

```
[edit]
user@host# edit dynamic-profiles Profile1
[edit dynamic-profiles Profile1]
```

2. Configure the necessary variables.

```
[edit dynamic-profiles service-profile]
user@host# set variable policer1 uid

[edit dynamic-profiles service-profile]
user@host# set variables in-filter uid-reference
```

Example of a dynamic-profile for parameterized filters:

```
dynamic profile {
  service-profile {
    variable {
      in-filter {
        default-value filter1;
        mandatory;
        uid-reference;
      }
      policer1 {
        uid;
      }
      filter1 {
        uid;
      }
      policer2 {
        uid;
      }
      filter2 {
        uid;
      }
    }
  }
}
```

```
}
}
```

## Enabling Dynamic Profiles to use Multiple Versions

You can create new versions of dynamic profiles that are currently in use by subscribers. Any subscriber that logs in following a dynamic profile modification uses the latest version of the dynamic profile. Subscribers that are already active continue to use the older version of the dynamic profile until they log out or their session terminates.

**NOTE:** You must enable or disable dynamic profile version creation before creating or using any dynamic profiles on the router. Enabling or disabling dynamic profile version creation after dynamic profiles are configured is not supported.

To configure versioning for dynamic profiles:

1. Access the router system hierarchy level.

```
[edit]
user@host# edit system
```

2. Access the global dynamic profile options.

```
[edit system]
user@host# edit dynamic-profile-options
```

3. Enable version creation for dynamic profiles on the router.

```
[edit system dynamic-profile-options]
user@host# set versioning
```

#### Related Documentation

## Modifying Dynamic Profiles with Versioning Disabled

---

You use dynamic profiles to configure large groups of subscribers. However, after you have configured and applied dynamic profiles, be cautious when modifying any dynamic profiles that are in use by active subscribers on the router if you have not enabled the router to use dynamic profile versioning. This section provides guidelines and procedures for modifying existing profiles and applying them to subscriber interfaces if dynamic profile versioning is not enabled on the router.

When modifying dynamic profiles, keep the following considerations in mind:

- Do not modify a dynamic profile when dynamic profile versioning is disabled and the dynamic profile is in use by active subscribers.
- Modifying a dynamic profile when dynamic profile versioning is disabled and when the dynamic profile is in use by active subscribers can lead to unpredictable behavior.

When a dynamic profile is modified and committed when dynamic profile versioning is not enabled, the router:

1. Logs a warning that the profiles are being modified and committed.
2. Determines whether the profile is currently being use by any subscriber.
3. If the profile is in use by a subscriber, the commit fails and the router logs errors to report the conflict.

Juniper Networks recommends that you only modify dynamic profiles when you have enabled dynamic profile versioning on the router. However, to properly modify a dynamic profile when dynamic profile versioning is disabled on the router:

1. Ensure that no subscribers are using the dynamic profile.
2. Create a new dynamic profile with a different name that contains the desired changes:

### Original Profile

```
profile1 {
  interfaces {
    "$junos-interface-ifd-name" {
      unit "$junos-underlying-interface-unit" {
        family inet {
          filter {
            input "$junos-input-filter";
          }
        }
      }
    }
  }
}
```

### Original DHCP Configuration

```
forwarding-options {
  dhcp-relay {
    traceoptions {
```

```

        flag all;
    }
    .....
    dynamic-profile profile1;
    .....
}

```

#### New Profile

```

profile2 {
  interfaces {
    "$junos-interface-ifd-name" {
      unit "$junos-underlying-interface-unit" {
        family inet {
          filter {
            input "$junos-input-filter";
            output "$junos-output-filter; /* added output filter variable */";
          }
        }
      }
    }
  }
}

```

#### Modified DHCP Configuration

```

forwarding-options {
  dhcp-relay {
    traceoptions {
      flag all;
    }
    .....
    dynamic-profile profile2; /* Name changed from profile1 */
    .....
  }
}

```

3. Commit the configuration containing the modified profile.

The modified profile is used for any new subscribers that access the router.

- [Verifying the Configuration of Access and Access-Internal Routes for Subscriber Management on page 653](#)

## Access and Access-Internal Routes for Subscriber Management

---

The DHCP and PPP applications on the router use both access routes and access-internal routes to represent either the end users or the networks behind the attached router. An access route represents a network behind an attached router, and is set to a preference of 13. An access-internal route is a /32 route that represents a directly attached end user, and is set to a preference of 12.

Access routes typically are used to apply the values of the RADIUS Framed-Route attribute [22] for IPv4 routes and the Framed-IPv6-Route attribute [99] for IPv6 routes. A framed route consists of a prefix that represents a public network behind the CPE, a next-hop gateway, and optional route attributes consisting of a combination of metric, preference, and tag. The only mandatory component of the framed route is the prefix. The next-hop gateway can be specified explicitly in the framed route. Alternatively, the absence of the gateway address implies address 0.0.0.0, which the must resolve using the CPE's IP address. In either case, the convention is that the next-hop gateway is the CPE IP address.

You can configure a dynamic profile to use predefined variables to dynamically configure access routes using the values specified in the RADIUS attribute. To configure access routes include the **access** stanza at the **edit dynamic-profiles *profile-name* routing-options**] hierarchy level. To configure access-internal routes, include the **access-internal** stanza at the same hierarchy level.

Consider the following rules for resolving the next-hop gateway to determine when each stanza is required:

- If the RADIUS framed route always specifies the next-hop gateway, only the **access** stanza is required in the dynamic profile. The **access-internal** stanza is not required.
- If the RADIUS framed route does not specify the next-hop gateway—as is more common—the variable representing the next-hop, `$junos-framed-route-nexthop`, defaults to 0.0.0.0. This value implies that the CPE IP address is to be used. For this case, the **access-internal** stanza is required to resolve `$junos-framed-route-nexthop` to the CPE IP address (represented in the **access-internal** stanza by `$junos-subscriber-ip-address`) and the logical interface (represented as a qualified next-hop by `$junos-interface-name`).

**BEST PRACTICE:** We recommend that you always include the **access-internal** stanza in the dynamic-profile when the **access** stanza is present for framed route support.

---

---

## Overview of Access Routes and Access-Internal Routes Removal After Graceful Routing Engine Switchover

---

For a subscriber network configured with either nonstop active routing (NSR) or graceful restart, you can configure the router to wait 180 seconds (3 minutes) before removing access routes and access-internal routes for DHCP and PPP subscriber management after a graceful Routing Engine switchover (GRES) takes place.

- [Benefits of Delaying Removal of Access Routes and Access-Internal Routes on page 649](#)
- [Graceful Restart and Delayed Removal of Access Routes and Access-Internal Routes on page 649](#)
- [Nonstop Active Routing and Delayed Removal of Access Routes and Access-Internal Routes on page 649](#)

## Benefits of Delaying Removal of Access Routes and Access-Internal Routes

The 3-minute delay in removing access routes and access-internal routes after a graceful Routing Engine switchover provides sufficient time for the DHCP client process (jdhcpcd), PPP client process (jpppcd), or routing protocol process (rpd) to reinstall the access routes and access-internal routes before the router removes the stale routes from the forwarding table. As a result, the risk of traffic loss is minimized because the router always has available subscriber routes for DHCP subscribers and PPP subscribers.

Configuring the router to delay removal of access routes and access-internal routes after a graceful Routing Engine switchover has the following benefits:

- Provides sufficient time to reinstall subscriber routes from the previously active Routing Engine
- Prevents loss of subscriber traffic due to unavailable routes

## Graceful Restart and Delayed Removal of Access Routes and Access-Internal Routes

In subscriber networks with graceful restart and routing protocols such as BGP and OSPF configured, the router purges any remaining stale access routes and access-internal routes as soon as the graceful restart operation completes, which can occur very soon after completion of the graceful Routing Engine switchover.

Configuring the delay in removing access and access-internal routes after a graceful Routing Engine switchover causes the router to retain the stale routes for a full 180 seconds, which provides sufficient time for the jdhcpcd or jpppcd client process to reinstall all of the subscriber routes.

## Nonstop Active Routing and Delayed Removal of Access Routes and Access-Internal Routes

In subscriber networks with nonstop active routing and routing protocols such as BGP and OSPF configured, the routing protocol process (rpd) immediately purges the stale access routes and access-internal routes that correspond to subscriber routes. This removal results in a loss of subscriber traffic.

Configuring the delay in removing access and access-internal routes after a graceful Routing Engine switchover causes the router to retain the stale routes for a full 180 seconds, which prevents potential traffic loss due to unavailable routes.

- For information about configuring static routes, see the Junos OS Routing Protocols Configuration Guide

## Configuring Dynamic Access Routes for Subscriber Management

---

You can dynamically configure access routes for DHCP and PPP subscribers based on the values specified in the following RADIUS attributes:

- For IPv4 access routes, use the variable, **\$junos-framed-route-ip-address-prefix**. The route prefix variable is dynamically replaced with the value in Framed-Route RADIUS attribute [22].
- For IPv6 access routes, use the variable, **\$junos-framed-route-ipv6-address-prefix**. The variable is dynamically replaced with the value in Framed-IPv6-Route RADIUS attribute [99].

To dynamically configure access routes:

1. Configure the route prefix for the access route as a variable.

For IPv4:

```
[edit dynamic-profiles profile-name routing-options]
user@host# edit access route $junos-framed-route-ip-address-prefix
```

For IPv6:

```
[edit dynamic-profiles profile-name routing-options]
user@host# edit access route $junos-framed-route-ipv6-address-prefix
```

2. Configure the next-hop address as a variable.

For IPv4:

```
[edit dynamic-profiles profile-name routing-options access route
"$junos-framed-route-ip-address-prefix"]
user@host# set next-hop $junos-framed-route-nexthop
```

For IPv6:

```
[edit dynamic-profiles profile-name routing-options access route
"$junos-framed-route-ipv6-address-prefix"]
user@host# set next-hop $junos-framed-route-ipv6-nexthop
```

3. Configure the metric as a variable (IPv4 only).

```
[edit dynamic-profiles profile-name routing-options access route
"$junos-framed-route-ip-address-prefix"]
user@host# set metric $junos-framed-route-cost
```

4. Configure the preference as a variable (IPv4 only).

```
[edit dynamic-profiles profile-name routing-options access route
"$junos-framed-route-ip-address-prefix"]
user@host# set preference $junos-framed-route-distance
```

5. Configure the tag as a variable (IPv4 only).

```
[edit dynamic-profiles profile-name routing-options access route
"$junos-framed-route-ip-address-prefix"]
user@host# set tag $junos-framed-route-tag
```

**BEST PRACTICE:** We recommend that you always include the `access-internal` stanza in the dynamic-profile when the `access` stanza is present for framed route support.

#### Related Documentation

- [Access and Access-Internal Routes for Subscriber Management on page 647](#)
- [Configuring Dynamic Access-Internal Routes for DHCP Subscriber Management on page 651](#)
- [Configuring Dynamic Access-Internal Routes for PPP Subscriber Management on page 652](#)
- [Verifying the Configuration of Access and Access-Internal Routes for Subscriber Management on page 653](#)
- [RADIUS IETF Attributes Supported by the AAA Service Framework on page 82](#)

## Configuring Dynamic Access-Internal Routes for DHCP Subscriber Management

You can dynamically configure access-internal routes. Configuring support for access-internal variables is optional, but it ensures that values from the access-internal variables are used if the next-hop value is missing in the relevant RADIUS attribute—Framed-Route [22] for IPv4 and Framed-IPv6-Route [99] for IPv6.

**BEST PRACTICE:** We recommend that you always include the `access-internal` stanza in the dynamic-profile when the `access` stanza is present for framed route support.

DHCP subscriber interfaces require the qualified-next-hop to identify the interface and the MAC address.

To dynamically configure access-internal routes:

1. Specify that you want to configure the access-internal route.

```
user@host# edit dynamic-profiles profile-name routing-options
```

2. Configure the IP address and the qualified next-hop address as variables.

```
[edit dynamic-profiles profile-name routing-options]
```

```
user@host# edit access-internal route $junos-subscriber-ip-address qualified-next-hop
$junos-interface-name
```

**NOTE:** Prior to Junos OS Release 10.0, the variable used for qualified-next-hop was `$junos-underlying-interface`. It is now `$junos-interface-name`.

3. Configure the MAC address for the qualified next-hop as a variable.

```
[edit dynamic-profiles profile-name routing-options access-internal route
$junos-subscriber-ip-address qualified-next-hop $junos-underlying-interface]
user@host# set mac-address $junos-subscriber-mac-address
```

**Related  
Documentation**

- [Access and Access-Internal Routes for Subscriber Management on page 647](#)
- [Configuring Dynamic Access Routes for Subscriber Management on page 650](#)
- [Verifying the Configuration of Access and Access-Internal Routes for Subscriber Management on page 653](#)

---

## Configuring Dynamic Access-Internal Routes for PPP Subscriber Management

---

You can dynamically configure access-internal routes for PPP subscribers. Configuring support for access-internal variables is optional, but it ensures that values from the access-internal variables are used if the next-hop value is missing in the relevant RADIUS attribute—Framed-Route [22] for IPv4 and Framed-IPv6-Route [99] for IPv6.

**BEST PRACTICE:** We recommend that you always include the `access-internal` stanza in the dynamic-profile when the `access` stanza is present for framed route support.

For PPP subscriber interfaces, you do not need to specify the MAC address for access-internal routes.

To dynamically configure access-internal routes for PPP:

1. Specify that you want to configure the access-internal route.

```
user@host# edit dynamic-profiles profile-name routing-options
```

2. Specify the IP address as a variable.

```
[edit dynamic-profiles profile-name routing-options]
user@host# edit access-internal route $junos-subscriber-ip-address
```

3. Specify the qualified-next-hop as a variable.

```
[edit dynamic-profiles profile-name routing-options access-internal route
$junos-subscriber-ip-address]
user@host# set qualified-next-hop $junos-interface-name
```

**Related  
Documentation**

- [Access and Access-Internal Routes for Subscriber Management on page 647](#)

- [Verifying the Configuration of Access and Access-Internal Routes for Subscriber Management on page 653](#)

## Delaying Removal of Access Routes and Access-Internal Routes After Graceful Routing Engine Switchover

---

In subscriber networks configured with either nonstop active routing (NSR) or graceful restart, you can configure the router to delay for 180 seconds (3 minutes) before removing access routes and access-internal routes for DHCP and PPP subscriber management after a graceful Routing Engine switchover takes place.

To configure the router to delay removal (flushing) of access-routes and access-internal routes after a graceful Routing Engine switchover:

1. Specify that you want to configure subscriber management.

```
[edit system services]
user@host# edit subscriber-management
```

2. Configure the router to wait 180 seconds before removing access-routes and access-internal routes after a graceful Routing Engine switchover.

```
[edit system services subscriber-management]
user@host# set gres-route-flush-delay
```

# Dynamic Profile Examples

- [Example: IGMP Dynamic Profile on page 655](#)
- [Example: Firewall Dynamic Profile on page 656](#)
- [Example: Minimum MLPPP Dynamic Profile on page 656](#)
- [Example: Minimum PPPoE Dynamic Profile on page 657](#)
- [Example: Subscriber Secure Policy Dynamic Profile on page 657](#)

## Example: IGMP Dynamic Profile

In this example, IGMP is configured for subscriber access using Junos OS predefined variables.

The predefined variables equate to RADIUS settings as follows:

Junos OS Predefined Variable	RADIUS VSA Name	RADIUS Attribute Number
<code>\$var-igmp-version</code>	IGMP-Version	26–78
<code>\$var-igmp-access-grp</code>	IGMP-Access-Name	26–71
<code>\$var-igmp-access-src-grp</code>	IGMP-Access-Src-Name	26–72

```
[edit dynamic-profiles profile-name]  
interfaces {  
  demux0 {  
    unit "$junos-interface-unit" {  
      demux-options {  
        underlying-interface "$junos-underlying-interface";  
      }  
      family inet {  
        demux-source {  
          "$junos-subscriber-ip-address";  
        }  
        unnumbered-address lo0.0 preferred-source-address 20.21.0.1;  
      }  
    }  
  }  
}  
protocols {
```

```

igmp {
  interface "$junos-interface-name" {
    version "$var-igmp-version";
    group-policy [ "$var-igmp-access-grp" "$var-igmp-access-src-grp" ];
  }
}

```

**NOTE:** You must also configure any global IGMP parameters.

## Example: Firewall Dynamic Profile

In this example, dynamic firewall is configured for subscriber access using Junos IPv4 predefined variables.

The predefined variables equate to RADIUS settings as follows:

Junos OS Predefined Variable	RADIUS VSA Name	RADIUS Attribute Number
\$junos-input-filter	Ingress-Policy-Name	26–10
\$junos-output-filter	Egress-Policy-Name	26–11

```

dynamic-profiles {
  DynamicFilterProfile {
    interfaces {
      "$junos-interface-ifd-name" {
        unit "$junos-underlying-interface-unit" {
          family inet {
            filter {
              input "$junos-input-filter";
              output "$junos-output-filter";
            }
          }
        }
      }
    }
  }
}

```

**NOTE:** You must also configure any global firewall parameters.

## Example: Minimum MLPPP Dynamic Profile

This example shows the minimum configuration for a dynamic profile that is used for static LSQ MLPPP bundle interfaces.

```

dynamic-profiles {
  mlppp-profile-1 {

```

```

    interfaces {
        "$junos-interface-ifd-name" {
            unit "$junos-underlying-interface-unit";
        }
    }
}

```

- Related Documentation**
- [Dynamic Profiles for PPP Subscriber Interfaces Overview on page 343](#)
  - [Attaching Dynamic Profiles to MLPPP Bundles on page 355](#)

## Example: Minimum PPPoE Dynamic Profile

This example shows the minimum configuration for a dynamic profile that is used for static PPPoE interfaces. The configuration must include the **interfaces pp0** stanza.

```

dynamic-profiles {
  ppp-profile-1 {
    interfaces {
      pp0 {
        unit "$junos-interface-unit";
      }
    }
  }
}

```

- Related Documentation**

  - [Configuring Dynamic Authentication for PPP Subscribers on page 345](#)
  - [Attaching Dynamic Profiles to Static PPP Subscriber Interfaces on page 350](#)

## Example: Subscriber Secure Policy Dynamic Profile

In this example, subscriber secure policy mirroring is configured for subscriber access using user-defined variables and Junos OS predefined variables. This example is for the flow-tap service configured on a router without a Tunnel Services PIC.

The user-defined variables equate to RADIUS settings as follows:

User-Defined Variable Name	Junos OS Variable	RADIUS VSA Name	RADIUS Attribute Number	Example RADIUS Setting
ssp-intercept-id	\$ssp-intercept-id	Med-Dev-Handle	26-59	subscriber-bg-2350
ssp-destination-addr	\$ssp-destination-addr	Med-IP-Address	26-60	192.163.100.22
ssp-destination-port	\$ssp-destination-port	Med-Port-Number	26-61	2222

```

variables {
  var ssp-intercept-id;
}

```

```
var ssp-destination-addr;
var ssp-destination-port;
}
interfaces {
  <*> {
    unit <*> {
      family inet {
        filter {
          input ssp;
          output ssp;
        }
      }
    }
  }
}
firewall {
  family inet {
    filter ssp {
      term $ssp-id {
        from {
          # optional classifiers.
        }
        then {
          flowtap-destination-address $ssp-destination-addr;
          flowtap-destination-port $ssp-destination-port;
          flowtap;
        }
      }
    }
  }
}
```

## Dynamic 802.1Q VLAN Overview

---

You can identify VLANs statically or dynamically. You can also configure a mix of static and dynamic VLANs on the same underlying interface.

For Ethernet, Fast Ethernet, Tri-Rate Ethernet copper, Gigabit Ethernet, 10-Gigabit Ethernet, and aggregated Ethernet interfaces supporting VPLS, the Junos OS supports a subset of the IEEE 802.1Q standard for channelizing an Ethernet interface into multiple logical interfaces. Many hosts can be connected to the same Gigabit Ethernet switch, but they cannot be in the same routing or bridging domain.

To identify VLANs statically, you can reference a static VLAN interface in a dynamic profile. To identify subscribers dynamically, you use a variable to specify an 802.1Q VLAN that is dynamically created when a subscriber accesses the network.

## Static VLAN Configuration

Static VLAN configuration is not described in this guide. For information about how to statically configure VLANs and stacked VLANs, see the Junos® OS Network Interfaces. For an example of how to configure static VLANs in a subscriber access network, see the Junos OS Subscriber Management, Release 12.3.

## Dynamic VLAN Configuration

You can configure the router to dynamically create VLANs when a client accesses an interface and requests a VLAN ID that does not yet exist. When a client accesses a particular interface, the router instantiates a VLAN dynamic profile that you have associated with the interface. Using the settings in the dynamic profile, the router extracts

information about the client from the incoming packet (for example, the interface and unit values), saves this information in the routing table, and creates a VLAN or stacked VLAN ID for the client from a range of VLAN IDs that you configure for the interface.

**NOTE:** Dynamic VLAN configuration supports the creation of IPv4 (inet), DHCPv4, IPv6 (inet6), and DHCPv6 VLANs.

Dynamically configuring VLANs or stacked VLANs requires the following general steps:

1. Configure a dynamic profile for dynamic VLAN or dynamic stacked VLAN creation.  
See [“Configuring VLAN Dynamic Profiles” on page 673](#).
2. Associate the VLAN or stacked VLAN dynamic profile with the interface.  
See [“Configuring VLAN Interfaces to Use Dynamic Profiles” on page 680](#).
3. Specify the Ethernet packet type that the VLAN dynamic profile accepts.  
See [“Configuring Which VLAN Ethernet Packet Types Dynamic Profiles Can Accept” on page 681](#).
4. Define VLAN ranges for use by the dynamic profile when creating VLAN IDs.  
See [“Configuring VLAN Ranges for Use with Dynamic Profiles” on page 684](#).

---

## Agent Circuit Identifier-Based Dynamic VLANs Overview

You can configure the router to create dynamic virtual LAN (VLAN) subscriber interfaces for Dynamic Host Configuration Protocol (DHCP) and Point-to-Point Protocol over Ethernet (PPPoE) subscribers based on agent circuit identifier (ACI) information. To use ACI-based dynamic VLAN subscriber interfaces, you must configure them on Modular Port Concentrators/Modular Interface Cards (MPCs/MICs) that face the access side of the network in an MX Series router.

This overview covers the following topics:

- [VLAN Architectures and Subscriber Identification on page 662](#)
- [ACI-Based Dynamic VLANs and Agent Circuit Identifier Interface Sets on page 663](#)

### VLAN Architectures and Subscriber Identification

The following VLAN architectures defined in the DSL Forum Technical Report (TR)-101, Migration to Ethernet-Based DSL Aggregation (April 2006), use different methods to uniquely identify subscribers in Ethernet-based subscriber access networks:

- 1:1 access model using customer VLANs

Configurations that use the 1:1 access model uniquely identify subscribers by means of VLAN encapsulation; that is, by using the VLAN ID and stacked VLAN (S-VLAN) ID. Subscriber packets received from the access node (such as a digital subscriber line access multiplexer, or DSLAM) that are either single-tagged with a VLAN ID or double-tagged with both an S-VLAN ID and a VLAN ID are examples of 1:1 VLAN

configurations because they provide a one-to-one correspondence between an individual subscriber and the VLAN encapsulation.

In the 1:1 VLAN architecture, each customer premises equipment (CPE) or subscriber network has its own dedicated Layer 2 path to the router. Each subscriber network is separated by a customer VLAN (C-VLAN) that is dedicated to a particular customer. The services for each customer are transmitted from the router to the access node by means of that customer's C-VLAN.

The ability to uniquely identify subscribers by means of VLAN encapsulation facilitates delivery of services such as authentication, authorization, and accounting (AAA); class of service (CoS); and filters (policers) to subscribers in a 1:1 VLAN configuration.

- N:1 access model using service VLANs

Configurations that use the N:1 access model do not uniquely identify subscribers by means of VLAN encapsulation. Instead, these configurations identify subscribers by means of the agent circuit identifier (ACI) information present in DHCP and PPPoE control packets. Subscriber packets received from the access node that are either single-tagged with the same VLAN ID for a group of subscribers or untagged are examples of N:1 VLAN configurations because they provide a many-to-one correspondence between individual subscribers and the VLAN encapsulation.

In the N:1 VLAN architecture, a service such as video, voice, or data is typically routed to a particular VLAN instead of having multiple services share a single VLAN, as is the case with the 1:1 VLAN architecture. Such VLANs, often referred to as service VLANs, enable service providers to route different services to different routers to functionally separate network services and reduce network complexity.

Because a VLAN in an N:1 configuration corresponds to a service rather than an individual subscriber, the router uses ACI information in DHCP and PPPoE control packets instead of VLAN encapsulation to uniquely identify subscribers and facilitate application of subscriber-based services.

## ACI-Based Dynamic VLANs and Agent Circuit Identifier Interface Sets

For single-tagged, double-tagged, or untagged N:1 configurations that do not use VLAN encapsulation to uniquely identify subscribers, you can configure the router to create dynamic VLAN subscriber interfaces for DHCP and PPPoE subscribers based on ACI information. ACI-based dynamic VLANs uniquely identify subscribers on the router and facilitate application of subscriber-based services, such as CoS and interface-shared filters, to all subscribers that originate from a single household and share the same ACI information.

When you configure an ACI-based dynamic VLAN, the router examines the DHCP and PPPoE control packets to extract the ACI information in order to build a unique dynamic VLAN subscriber interface. The agent-circuit-identifier value is a string that uniquely identifies the subscriber's access node and the digital subscriber line (DSL) on the access node. For DHCP traffic, the agent-circuit-identifier string is in the DHCP option 82 field of DHCP messages. For PPPoE traffic, the agent-circuit-identifier string is in the DSL Forum Agent-Circuit-ID VSA [26-1] of PPPoE Active Discovery Initiation (PADI) and PPPoE Active Discovery Request (PADR) control packets.

Configuring ACI-based dynamic VLAN subscriber interfaces is particularly useful in configurations with multiple DHCP and PPPoE subscriber sessions per household. Because DHCP and PPPoE control traffic sent to the router from the same household has the same unique agent-circuit-identifier string, the router groups these DHCP and PPPoE subscriber interfaces in the same ACI interface set. An *ACI interface set* is a logical collection of subscriber interfaces that originate at the same household or on the same access-loop port. Grouping subscriber interfaces into ACI interface sets enables unique subscriber identification and facilitates application of subscriber-based services, such as class of service (CoS) and interface-shared filters, on a per-household basis.

---

## Agent Circuit Identifier-Based Dynamic VLANs Components Overview

You can configure ACI-based dynamic VLAN subscriber interfaces on Modular Port Concentrators/Modular Interface Cards (MPCs/MICs) that face the access side of the network in an MX Series router.

This overview describes the components of an ACI-based dynamic VLAN configuration, from top to bottom of the interface stack:

- [ACI-Based Dynamic Subscriber Interface on page 664](#)
- [Dynamic ACI Interface Set on page 664](#)
- [Dynamic or Static Underlying VLAN Interface on page 665](#)
- [Static Physical Interface on page 665](#)

### ACI-Based Dynamic Subscriber Interface

You must create a dynamic profile to define either a dynamic PPPoE subscriber interface for PPPoE subscriber sessions, or a dynamic IP demultiplexer (IP demux) subscriber interface for DHCP subscriber sessions. The router automatically creates (instantiates) the subscriber interface when a DHCP or PPPoE subscriber logs in on the associated underlying VLAN interface associated with the dynamic profile that defines the ACI interface set.

### Dynamic ACI Interface Set

The dynamic ACI interface set, which is the primary component of an ACI-based dynamic VLAN configuration, groups the DHCP and PPPoE subscriber sessions that belong to a particular household and share a common unique agent-circuit-identifier value. The router creates one ACI interface set per household to facilitate application of subscriber-based services, such as CoS and interface-shared filters, to all subscribers in the household.

You must create a dynamic profile to define the ACI interface set, which is represented in the profile by the Junos OS predefined dynamic variable `$junos-interface-set-name`. When a DHCP or PPPoE subscriber accesses the router on a particular interface, the router obtains the agent-circuit-identifier information from the DHCP or PPPoE control packets transmitted on that interface and dynamically creates the ACI interface set when the first subscriber from that household logs in.

## Dynamic or Static Underlying VLAN Interface

After you define the ACI interface set, you must configure the underlying VLAN interface to enable creation of dynamic VLAN subscriber interfaces based on ACI information. You can configure the underlying VLAN interface either dynamically (with a dynamic profile) or statically.

ACI-based dynamic VLAN configurations support the following underlying VLAN interface types:

- Gigabit Ethernet
- 10-Gigabit Ethernet
- VLAN demux (demux0)

**NOTE:** When you configure an underlying VLAN interface to support creation of ACI-based dynamic VLANs, we recommend that you use this underlying interface only for subscriber interfaces that contain agent-circuit-identifier information in their DHCP or PPPoE control packets. If the router receives DHCP or PPPoE control packets without agent-circuit-identifier information on an underlying VLAN interface configured for ACI-based dynamic VLANs, the associated subscriber interfaces might not instantiate successfully.

## Static Physical Interface

ACI-based dynamic VLAN configurations support the following physical interface types:

- Gigabit Ethernet
- 10-Gigabit Ethernet
- Aggregated Ethernet

- [Clearing Agent Circuit Identifier Interface Sets on page 707](#)

## Agent Circuit Identifier-Based Dynamic VLANs Bandwidth Management Overview

A router in a subscriber access network ensures class of service (CoS) for dynamic subscriber interfaces. An MX Series router with Modular Port Concentrator/Modular Interface Card (MPC/MIC) interfaces ensures that subscribers receive an adequate minimum bandwidth, referred to as the *guaranteed rate*, and maximum bandwidth, referred to as the *shaping rate*. For dynamic VLAN subscriber interfaces based on agent circuit identifier (ACI) information, you can shape the bandwidth either at a per-household level for a dynamic ACI interface set, or at a per-subscriber level for a dynamic VLAN subscriber interface associated with an ACI interface set.

To help you manage bandwidth more efficiently and economically for ACI-based dynamic VLAN subscriber interfaces for PPPoE subscribers, you can configure the router to use specific PPPoE vendor-specific attributes (VSAs) found in PPPoE control packets to adjust the CoS shaping-rate and overhead-accounting attributes for dynamic ACI interface sets and their associated ACI-based dynamic VLAN subscriber interfaces.

This overview covers the following topics:

- [CoS Shaping Rate Adjustment on page 666](#)
- [CoS Overhead Accounting Adjustment on page 667](#)
- [Dynamic Profiles and Adjustment of CoS Shaping Rate and Overhead Accounting on page 667](#)
- [Guidelines for Configuring Adjustment of CoS Shaping Rate and Overhead Accounting on page 668](#)

### CoS Shaping Rate Adjustment

The CoS shaping rate adjustment is based on the value of the Actual-Data-Rate-Downstream DSL Forum VSA [26-130] found in PPPoE Active Discovery Initiation (PADI) and PPPoE Active Discovery Request (PADR) control packets for PPPoE traffic. The Actual-Data-Rate-Downstream VSA contains the actual downstream data rate, in bits per second, of the subscriber's synchronized digital subscriber line (DSL) link.

To configure the router to use the Actual-Data-Rate-Downstream VSA to adjust the CoS shaping-rate attribute, include the **vendor-specific-tags** statement with the **actual-data-rate-downstream** option at the **[edit dynamic-profiles profile-name class-of-service dynamic-class-of-service-options]** hierarchy level in either the dynamic profile that defines the ACI interface set or the dynamic profile that configures the associated dynamic PPPoE (**pp0**) subscriber interface.

When you enable this feature, the value of the Actual-Data-Rate-Downstream VSA overrides the **shaping-rate** value configured at the **[edit dynamic-profiles profile-name class-of-service traffic-control-profiles]** hierarchy level only if the Actual-Data-Rate-Downstream VSA value is less than the **shaping-rate** value configured with the CLI.

## CoS Overhead Accounting Adjustment

The CoS overhead accounting adjustment is based on the value of the Access-Loop-Encapsulation DSL Forum VSA [26-144] found in PADI and PADR control packets for PPPoE traffic. The Access-Loop-Encapsulation VSA identifies the encapsulation used by the subscriber associated with the digital subscriber line access multiplexer (DSLAM) access loop from which requests are initiated.

The value of the Data Link subfield in the Access-Loop-Encapsulation VSA determines the overhead accounting mode in use on the access loop. If the Data Link subfield value is 0 (ATM Adaptation Layer 5, or AAL5), the access loop uses cell-mode encapsulation. If the Data Link subfield value is 1 (Ethernet), the access loop uses frame-mode encapsulation.

In subscriber access networks where the router passes downstream ATM traffic to Ethernet interfaces, the different Layer 2 encapsulations between the router and the PPPoE Intermediate Agent on the DSLAM make managing the bandwidth of downstream ATM traffic difficult. Using the Access-Loop-Encapsulation VSA to shape traffic based on frames or cells enables the router to adjust the overhead-accounting attribute in order to apply the correct downstream rate for the subscriber.

To configure the router to use the Access-Loop-Encapsulation VSA to adjust the CoS overhead-accounting attribute, include the **vendor-specific-tags** statement with the **access-loop-encapsulation** option at the **[edit dynamic-profiles *profile-name* class-of-service dynamic-class-of-service-options]** hierarchy level in either the dynamic profile that defines the ACI interface set or the dynamic profile that configures the associated dynamic PPPoE (**pp0**) subscriber interface.

When you enable this feature, the value of the Access-Loop-Encapsulation VSA always overrides the **overhead-accounting** value configured at the **[edit dynamic-profiles *profile-name* class-of-service traffic-control-profiles]** hierarchy level.

## Dynamic Profiles and Adjustment of CoS Shaping Rate and Overhead Accounting

When you configure the router to use one or both of the Actual-Data-Rate-Downstream VSA value and Access-Loop-Encapsulation VSA value to adjust the CoS shaping rate and overhead accounting attributes, respectively, the router adjusts these attributes when the dynamic ACI interface set is created and the router receives the PADI and PADR packets from the first subscriber interface belonging to the ACI interface set.

You can configure CoS adjustment based on either or both VSAs in either or both of the following dynamic profiles:

- To configure adjustment of the CoS shaping rate and overhead accounting on a per-household basis, use the dynamic profile that defines the dynamic ACI interface set.
- To configure adjustment of the CoS shaping rate and overhead accounting on a per-subscriber basis, use the dynamic profile that defines the ACI-based dynamic PPPoE (**pp0**) subscriber interface associated with the ACI interface set.

[Table 65 on page 668](#) summarizes how the dynamic profile in which you configure CoS adjustment for ACI-based dynamic VLANs using one or both VSAs affects the router behavior.

**Table 65: CoS Adjustment in Dynamic Profiles for ACI Interface Sets and ACI-Based Subscriber Interfaces**

VSA's Specified in ACI Interface Set Dynamic Profile	VSA's Specified in PPPoE Subscriber Interface Dynamic Profile	Result
Yes	No	Router adjusts specified CoS attributes only for dynamic ACI interface set
No	Yes	Router adjusts specified CoS attributes only for ACI-based dynamic PPPoE subscriber interface
Yes	Yes	Router adjusts specified CoS attributes for both dynamic ACI interface set and ACI-based dynamic PPPoE subscriber interface
No	No	Router does not adjust CoS attributes for either the dynamic ACI interface set or the ACI-based dynamic PPPoE subscriber interface

## Guidelines for Configuring Adjustment of CoS Shaping Rate and Overhead Accounting

You can also configure the router to use the Actual-Data-Rate-Downstream VSA and Access-Loop-Encapsulation VSA values in PPPoE control packets to adjust the CoS shaping rate and overhead accounting attributes, respectively, for dynamic subscriber interfaces *not* associated with dynamic ACI interface sets.

With the exception of the constraints described in [“Restrictions for Configuring Adjustment of CoS Shaping Rate and Overhead Accounting for Dynamic ACI Interface Sets” on page 669](#), most of the guidelines and restrictions that apply to this feature for use with non-ACI-based dynamic subscriber interfaces also apply to its use for dynamic ACI interface sets and their associated ACI-based dynamic VLAN subscriber interfaces.

### Related Documentation

- [Setting Class-of-Service Parameters Using PPPoE Vendor-Specific Tags on page 1020](#)
- [Adjusting the CoS Shaping Rate and Overhead Accounting Parameters for Agent Circuit Identifier-Based Dynamic VLANs on page 701](#)
- [Restrictions for Configuring Adjustment of CoS Shaping Rate and Overhead Accounting for Dynamic ACI Interface Sets on page 669](#)

## Restrictions for Configuring Adjustment of CoS Shaping Rate and Overhead Accounting for Dynamic ACI Interface Sets

The following restrictions apply when you configure the router to use the Actual-Data-Rate-Downstream VSA and Access-Loop-Encapsulation vendor-specific attribute (VSA) values in PPPoE control packets to adjust the CoS shaping rate and overhead accounting attributes, respectively, for dynamic ACI interface sets and their associated agent circuit identifier (ACI)-based dynamic VLAN subscriber interfaces:

- You cannot configure adjustment of CoS shaping rate and overhead accounting attributes based on Actual-Data-Rate-Downstream VSA and Access-Loop-Encapsulation VSA values that the router receives from the following sources:
  - RADIUS servers
  - Access Node Control Protocol (ANCP) access loop information
  - Dynamic Host Configuration Protocol (DHCP) discovery packets
- You cannot use this feature to report information about the PPPoE VSA values to RADIUS.
- You cannot use this feature to configure CoS adjustment of upstream data traffic on a dynamic ACI interface set.

## Ethernet OAM Support for Service VLANs Overview

You can enable propagation of the Ethernet IEEE 802.1ag Operation, Administration, and Maintenance (OAM) state of a static single-tagged service VLAN (S-VLAN) to a dynamic or static double-tagged customer VLAN (C-VLAN) and, by extension, to the subscriber interfaces configured on the C-VLAN. The static S-VLAN logical interface must be configured on a Gigabit Ethernet, 10-Gigabit Ethernet, or aggregated Ethernet physical interface.

Propagation of the S-VLAN OAM state to associated C-VLANs ensures that when the OAM state of the S-VLAN link is down, the associated C-VLANs and all subscriber interfaces configured on the C-VLANs are brought down as well.

- [Ethernet OAM Support for Service VLANs Terms and Acronyms on page 670](#)
- [Components of Ethernet OAM Support for Service VLANs on page 670](#)

- [How Ethernet OAM Support for Service VLANs Works on page 671](#)
- [Restrictions for Using Ethernet OAM Support for Service VLANs on page 672](#)

## Ethernet OAM Support for Service VLANs Terms and Acronyms

[Table 66 on page 670](#) defines the basic terms and acronyms used in this discussion of Ethernet OAM support for service VLANs.

**Table 66: Ethernet OAM Support for Service VLANs Terms and Acronyms**

Term	Definition
CFM	Connectivity fault management. Provides end-to-end monitoring of an Ethernet network that can be made up of one or more service instances. Junos OS supports Ethernet IEEE 802.1ag CFM.
Continuity check protocol	A feature of Ethernet IEEE 802.1ag CFM that provides fault detection within a maintenance association.
C-VLAN	Customer VLAN. A dynamic or static double-tagged logical interface that has both an outer VLAN tag (corresponding to the S-VLAN) and an inner VLAN tag (corresponding to the C-VLAN). In a 1:1 subscriber network access model, dedicated C-VLANs provide a one-to-one correspondence between an individual subscriber and the VLAN encapsulation.
OAM	Operation, Administration, and Maintenance. A set of Ethernet connectivity specifications and functions providing connectivity monitoring, fault detection and notification, fault verification, fault isolation, loopback, and remote defect identification. Ethernet interfaces on MX Series routers support the IEEE 802.1ag standard for OAM.
S-VLAN	Service VLAN. A static single-tagged logical interface that has only one outer VLAN tag (corresponding to the S-VLAN). In an N:1 subscriber network access model, S-VLANs are dedicated to a particular service, such as video, voice, or data, instead of to a particular subscriber. Because an S-VLAN is typically shared by many subscribers within the same household or in different households, it provides a many-to-one correspondence between individual subscribers and the VLAN encapsulation.
VLAN	Virtual local area network. A logical group of network devices that appear to be on the same local area network, regardless of their physical location.

## Components of Ethernet OAM Support for Service VLANs

Ethernet OAM support for S-VLANs involves the following components:

- **Physical interface**—On MX Series routers with Modular Port Concentrator/Modular Interface Card (MPC/MIC) interfaces, you can enable propagation of the S-VLAN OAM state to a C-VLAN on Gigabit Ethernet, 10-Gigabit Ethernet, or aggregated Ethernet physical interfaces.
- **S-VLAN**—To enable propagation of the S-VLAN Ethernet OAM state to associated C-VLANs and subscriber interfaces, you must configure the static single-tagged S-VLAN logical interface to run the Ethernet IEEE 802.1ag CFM continuity check protocol.

- **C-VLAN**—The C-VLAN is a dynamic or static double-tagged logical interface that has the same S-VLAN (outer) tag as the static single-tagged S-VLAN logical interface. If propagation of the S-VLAN OAM state to the C-VLAN is enabled on the physical interface, the router brings down the C-VLAN and its associated subscriber interfaces when the CFM continuity check protocol detects that the OAM state of the underlying S-VLAN is down.
- **Subscriber interfaces**—Propagation of the S-VLAN Ethernet OAM state to associated C-VLANs and subscriber interfaces applies to all dynamic or static DHCP, IP demultiplexing (IP demux), and PPPoE subscriber interfaces configured on the C-VLAN.

## How Ethernet OAM Support for Service VLANs Works

To enable propagation of the Ethernet OAM state of the S-VLAN to associated C-VLANs and subscriber interfaces, use the **oam-on-svlan** statement when you configure a Gigabit Ethernet (ge), 10-Gigabit Ethernet (xe), or aggregated Ethernet (ae) physical interface.

If Ethernet IEEE 802.1ag CFM is properly configured on the S-VLAN logical interface, including the **oam-on-svlan** statement for these Ethernet interfaces causes the router to bring down both of the following when the CFM continuity check protocol detects that the OAM state of the S-VLAN logical interface is down:

- All dynamic or static double-tagged C-VLAN logical interfaces that have the same S-VLAN (outer) tag as the S-VLAN logical interface on which they are configured.
- All dynamic or static DHCP, IP demux, and PPPoE logical subscriber interfaces configured on the associated C-VLANs.

To illustrate how Ethernet OAM support for S-VLANs works, consider the following sample configuration on a Gigabit Ethernet physical interface:

- Gigabit Ethernet physical interface ge-1/0/3 configured with the **svlan-on-oam** statement.
- Static single-tagged S-VLAN logical interface ge-1/0/3.0, which has a single S-VLAN outer tag, VLAN ID 600.
- Ethernet OAM CFM protocol configured on the static S-VLAN logical interface. The CFM configuration includes an action profile with the **interface-down** default action to bring down the C-VLAN and dynamic subscriber interfaces when the continuity check protocol detects that the Ethernet OAM state of S-VLAN interface ge-1/0/3.0 is down.
- Static double-tagged C-VLAN logical interface ge-1/0/3.100, which has an S-VLAN outer tag, VLAN ID 600, and a C-VLAN inner tag, VLAN ID 1.
- Static PPPoE subscriber interfaces configured on C-VLAN interface ge-1/0/3.100.

Because the S-VLAN and C-VLAN logical interfaces in this example have the same S-VLAN outer tag (VLAN ID 600), the router brings down the C-VLAN interface and the PPPoE logical subscriber interfaces when the CFM continuity check detects that the OAM status of S-VLAN interface ge-1/0/3.0 is down.

## Restrictions for Using Ethernet OAM Support for Service VLANs

Ethernet OAM support for S-VLANs is *not currently supported* for use with any of the following:

- Dynamically configured S-VLAN logical interfaces
- S-VLAN trunk interfaces
- C-VLAN trunk interfaces

## Configuring VLAN Dynamic Profiles

---

Creating dynamic single-tag VLANs or stacked (dual-tag) VLANs requires the use of dynamic profiles. The dynamic profile automatically references the VLAN interface and

creates the interface unit and the necessary VLAN IDs for each new single-tag VLAN or stacked VLAN.

**NOTE:** VLAN dynamic profiles do not support user-defined variables. Use only Junos VLAN predefined variables when configuring VLAN dynamic profiles. See [“Dynamic Variables Overview” on page 605](#) for information about dynamic variables.

- [Configuring a VLAN Dynamic Profile for Creating Single-Tag VLANs Using Standard TPID Values on page 674](#)
- [Configuring a VLAN Dynamic Profile for Creating Single-Tag VLANs Using Any TPID Values on page 676](#)
- [Configuring a Stacked VLAN Dynamic Profile on page 677](#)
- [Configuring a VLAN Dynamic Profile That Associates VLAN Interfaces with Separate Routing Instances on page 678](#)

## Configuring a VLAN Dynamic Profile for Creating Single-Tag VLANs Using Standard TPID Values

You can configure a VLAN dynamic profile to create single-tag VLANs that accept only standard TPID values (a TPID value of 0x8100) by using the **vlan-id** statement and the **\$junos-vlan-id** variable.

**NOTE:** This procedure configures a dynamic profile that accepts only TPID values of 0x8100. To configure a VLAN dynamic profile for creating VLANs using any TPID values, see [“Configuring a VLAN Dynamic Profile for Creating Single-Tag VLANs Using Any TPID Values” on page 676](#).

Before you begin:

- Configure the dynamic profile.  
See [“Configuring a Basic Dynamic Profile” on page 633](#).

To configure a dynamic VLAN profile:

1. Ensure that the VLAN dynamic profile uses the **\$junos-interface-ifd-name** variable for the dynamic interface and the **\$junos-interface-unit** variable for the interface unit.
2. (Optional) To support dynamic demux interfaces, enable them using the **demux-source** statement.
  - a. For IPv4 demux interfaces, specify **inet** as the source type.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit "$junos-interface-unit"]
user@host# set demux-source inet
```
  - b. For IPv6 demux interfaces, specify **inet6** as the source type.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set demux-source inet6
```

3. (Optional) To configure the router to respond to any ARP request, specify the **proxy-arp** statement.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set proxy-arp
```

4. Specify that you want to use dynamic VLAN IDs in the dynamic profile.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set vlan-id $junos-vlan-id
```

When the dynamic profile is instantiated, the variable is dynamically replaced with a VLAN ID within the VLAN range specified at the **[interfaces]** hierarchy level.

5. Define the unit family type.

- a. For IPv4 interfaces, specify the **inet** family type.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set family inet
```

- b. For IPv6 interfaces, specify the **inet6** family type.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set family inet6
```

6. (Optional) Enable IP and MAC address validation for dynamic demux interfaces in a dynamic profile.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit" family inet]
user@host# set mac-validate loose
```

7. Specify the unnumbered address and preferred source address.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit" family inet]
user@host# set unnumbered-address lo.0 preferred-source-address 192.0.16.1
```

## Configuring a VLAN Dynamic Profile for Creating Single-Tag VLANs Using Any TPID Values

You can configure a VLAN dynamic profile to create single-tag VLANs that accept any TPID values by configuring the **vlan-tags** statement and the **\$junos-vlan-id** variable.

**NOTE:** For procedures to configure a VLAN dynamic profile for creating single-tag VLANs that use only standard TPID values (a TPID value of 0x8100), see “[Configuring a VLAN Dynamic Profile for Creating Single-Tag VLANs Using Standard TPID Values](#)” on page 674.

Before you begin:

- Configure the dynamic profile.

See “[Configuring a Basic Dynamic Profile](#)” on page 633.

To configure a dynamic VLAN profile:

1. Ensure that the VLAN dynamic profile uses the **\$junos-interface-ifd-name** variable for the dynamic interface and the **\$junos-interface-unit** variable for the interface unit.
2. (Optional) To support dynamic demux interfaces, enable them using the **demux-source** statement.

- a. For IPv4 demux interfaces, specify **inet** as the source type.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit  
"$junos-interface-unit"]  
user@host# set demux-source inet
```

- b. For IPv6 demux interfaces, specify **inet6** as the source type.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit  
"$junos-interface-unit"]  
user@host# set demux-source inet6
```

3. (Optional) To configure the router to respond to any ARP request, specify the **proxy-arp** statement.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit  
"$junos-interface-unit"]  
user@host# set proxy-arp
```

4. Specify that you want to use dynamic VLAN IDs in the dynamic profile.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit  
"$junos-interface-unit"]  
user@host# set vlan-tags outer $junos-vlan-id
```

The variable is dynamically replaced with both the TPID value and a VLAN ID within the VLAN range specified at the **[interfaces]** hierarchy level.

5. Define the unit family type.
  - a. For IPv4 interfaces, specify the **inet** family type.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set family inet
```

- b. For IPv6 interfaces, specify the **inet6** family type.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set family inet6
```

6. (Optional) Enable IP and MAC address validation for dynamic demux interfaces in a dynamic profile.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit" family inet]
user@host# set mac-validate loose
```

7. Specify the unnumbered address and preferred source address.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit" family inet]
user@host# set unnumbered-address lo.0 preferred-source-address 192.0.16.1
```

## Configuring a Stacked VLAN Dynamic Profile

You can configure a dynamic profile for creating stacked 802.1Q VLANs.

Before you begin:

- Configure the dynamic profile.

See [“Configuring a Basic Dynamic Profile” on page 633](#).

To configure a stacked VLAN dynamic profile:

1. Ensure that the VLAN dynamic profile uses the **\$junos-interface-ifd-name** variable for the dynamic interface and the **\$junos-interface-unit** variable for the interface unit.
2. (Optional) To support dynamic demux interfaces, enable them using the **demux-source** statement.

- a. For IPv4 demux interfaces, specify **inet** as the source type.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set demux-source inet
```

- b. For IPv6 demux interfaces, specify **inet6** as the source type.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set demux-source inet6
```

3. (Optional) To configure the router to respond to any ARP request, specify the **proxy-arp** statement.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set proxy-arp
```

4. Specify the outer VLAN ID variable.

```
[edit dynamic-profiles STACKED-VLAN-PROF1 interfaces "$junos-interface-ifd-name"
  unit "$junos-interface-unit"]
user@host# set vlan-tags outer $junos-stacked-vlan-id
```

The variable is dynamically replaced with an outer VLAN ID within the VLAN range specified at the **[interfaces]** hierarchy level.

5. Specify the inner VLAN ID variable.

```
[edit dynamic-profiles STACKED-VLAN-PROF1 interfaces "$junos-interface-ifd-name"
  unit "$junos-interface-unit"]
user@host# set vlan-tags inner $junos-vlan-id
```

The variable is dynamically replaced with an inner VLAN ID within the VLAN range specified at the **[interfaces]** hierarchy level.

6. Define the unit family type.

- a. For IPv4 interfaces, specify the **inet** family type.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
  "$junos-interface-unit"]
user@host# set family inet
```

- b. For IPv6 interfaces, specify the **inet6** family type.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
  "$junos-interface-unit"]
user@host# set family inet6
```

7. (Optional) Enable IP and MAC address validation for dynamic demux interfaces in a dynamic profile.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
  "$junos-interface-unit" family inet]
user@host# set mac-validate loose
```

8. Specify the unnumbered address and preferred source address.

```
[edit dynamic-profiles VLAN-PROF1 interfaces "$junos-interface-ifd-name" unit
  "$junos-interface-unit" family inet]
user@host# set unnumbered-address lo.0 preferred-source-address 192.0.16.1
```

## Configuring a VLAN Dynamic Profile That Associates VLAN Interfaces with Separate Routing Instances

You can configure a VLAN dynamic profile that dynamically creates underlying VLAN interfaces and associates these interfaces with dynamically created routing instances. The VLAN interface is created in the default logical system (LS) for a specific routing instance as defined by VSA 26–1 (Virtual-Router) on the AAA server (for example, RADIUS server).

To configure a dynamic VLAN profile using routing instances:

1. Name the profile.

```
[edit]
```

```
user@host# edit dynamic-profiles VLAN_PROFILE_RI
```

2. Specify that you want to dynamically create routing instances on the default logical system.

```
[edit dynamic-profiles VLAN_PROFILE_RI]
user@host# edit routing-instances $junos-routing-instance
```

3. Define the routing instance **interface** statement with the internal **\$junos-interface-name** variable used by the router to match the interface name of the receiving interface.

```
[edit dynamic-profiles VLAN_PROFILE_RI routing-instances "$junos-routing-instance"]
user@host# set interface $junos-interface-name
```

4. Define the dynamic profile **interfaces** statement with the internal **\$junos-interface-ifd-name** variable.

```
[edit dynamic-profiles VLAN_PROFILE_RI]
user@host# edit interfaces $junos-interface-ifd-name
```

5. Define the **unit** statement with the internal **\$junos-interface-unit** variable used by the router to generate a unit value for the interface.

```
[edit dynamic-profiles VLAN_PROFILE_RI interfaces "$junos-interface-ifd-name"]
user@host# edit unit $junos-interface-unit
```

6. To support dynamic demux interfaces, enable them using the **demux-source** statement.
  - a. For IPv4 demux interfaces, specify **inet** as the source type.

```
[edit dynamic-profiles VLAN_PROFILE_RI interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set demux-source inet
```

- b. For IPv6 demux interfaces, specify **inet6** as the source type.

```
[edit dynamic-profiles VLAN_PROFILE_RI interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set demux-source inet6
```

7. (Optional) To configure the router to respond to any ARP request, specify the **proxy-arp** statement.

```
[edit dynamic-profiles VLAN_PROFILE_RI interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set proxy-arp
```

8. Specify that you want to use dynamic VLAN IDs in the dynamic profile.

```
[edit dynamic-profiles VLAN_PROFILE_RI interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
user@host# set vlan-id $junos-vlan-id
```

The variable is dynamically replaced with both the TPID value and a VLAN ID within the VLAN range specified at the **[interfaces]** hierarchy level.

9. Define the unit family type.

- a. For IPv4 interfaces, specify the **inet** family type.

```
[edit dynamic-profiles VLAN_PROFILE_RI interfaces "$junos-interface-ifd-name" unit
"$junos-interface-unit"]
```

```
user@host# set family inet
```

- b. For IPv6 interfaces, specify the **inet6** family type.

```
[edit dynamic-profiles VLAN-PROFILE interfaces "$junos-interface-ifd-name" unit  
"$junos-interface-unit"]  
user@host# set family inet6
```

10. (Optional) Enable IP and MAC address validation for dynamic demux interfaces in a dynamic profile.

```
[edit dynamic-profiles VLAN_PROFILE_RI interfaces "$junos-interface-ifd-name" unit  
"$junos-interface-unit" family inet]  
user@host# set mac-validate loose
```

11. Specify the unnumbered address to dynamically create loopback interfaces.

**NOTE:** You can optionally specify the preferred source address. This option is included in the step.

```
[edit dynamic-profiles VLAN_PROFILE_RI interfaces "$junos-interface-ifd-name" unit  
"$junos-interface-unit" family inet]  
user@host# set unnumbered-address $junos-loopback-interface  
preferred-source-address 192.0.16.1
```

---

## Configuring VLAN Interfaces to Use Dynamic Profiles

You can configure an interface to use a single-tag VLAN or stacked (dual-tag) VLAN dynamic profile when creating dynamic VLANs. The dynamic profile assigns a VLAN ID to each VLAN dynamically created over the interface by using the single-tag VLAN and stacked VLAN ranges configured for the VLAN interface. You can configure VLAN interfaces to use dynamic profiles in the following ways:

- [Associating a Single-Tag VLAN Dynamic Profile with an Interface on page 680](#)
- [Associating a Stacked VLAN Dynamic Profile with an Interface on page 681](#)

### Associating a Single-Tag VLAN Dynamic Profile with an Interface

Before you begin:

- Configure the VLAN dynamic profile.

See “[Configuring a Basic Dynamic Profile](#)” on page 633.

To associate a single-tag VLAN dynamic profile with an interface:

1. Access the interface that you want to use for creating VLANs.

```
[edit]  
user@host# edit interfaces ge-1/0/0
```

2. Edit the **auto-configure** stanza to automatically configure VLANs.

```
[edit interfaces ge-1/0/0]  
user@host# edit auto-configure
```

3. Edit the **vlan-ranges** stanza.

```
[edit interfaces ge-1/0/0 auto-configure]
user@host# edit vlan-ranges
```

4. Specify the dynamic VLAN profile that you want the interface to use.

```
[edit interfaces ge-1/0/0 auto-configure vlan-ranges]
user@host# set dynamic-profile VLAN-PROF1
```

## Associating a Stacked VLAN Dynamic Profile with an Interface

To associate a stacked (dual-tag) VLAN dynamic profile with an interface:

1. Access the interface that you want to use for creating VLANs.

```
[edit interfaces]
user@host# edit interfaces ge-1/0/0
```

2. Edit the **auto-configure** stanza to automatically configure the stacked VLANs.

```
[edit interfaces ge-1/0/0]
user@host# edit auto-configure
```

3. Edit the **stacked-vlan-ranges** stanza.

```
[edit interfaces ge-1/0/0 auto-configure]
user@host# edit stacked-vlan-ranges
```

4. Specify the dynamic VLAN profile that you want the interface to use.

```
[edit interfaces ge-1/0/0 auto-configure stacked-vlan-ranges]
user@host# set dynamic-profile STACKED-VLAN-PROF1
```

## Configuring Which VLAN Ethernet Packet Types Dynamic Profiles Can Accept

To create dynamic single-tag VLANs and dynamic stacked (dual-tag) VLANs, you must specify what Ethernet packet type you want the single-tag VLAN or stacked VLAN dynamic profile to accept. You can configure which VLAN Ethernet packet types a dynamic profile accepts in the following ways:

- [Configuring the VLAN Ethernet Packet Type for Single-Tag VLAN Dynamic Profiles on page 681](#)
- [Configuring the VLAN Ethernet Packet Type for Stacked VLAN Dynamic Profiles on page 682](#)

## Configuring the VLAN Ethernet Packet Type for Single-Tag VLAN Dynamic Profiles

To configure the VLAN Ethernet packet type the VLAN dynamic profile can accept:

1. Access the interface over which you want to create dynamic VLANs.

```
user@host# edit interfaces ge-0/0/0
```

2. Edit the VLAN **auto-configure** stanza.

```
[edit interfaces ge-0/0/0]
user@host# edit auto-configure
```

3. Edit the **vlan-ranges** stanza.

```
[edit interfaces ge-0/0/0 auto-configure]
user@host# edit vlan-ranges
```

4. Access the VLAN dynamic profile for which you want to configure VLAN ranges.

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]
user@host# edit dynamic-profile VLAN-PROF1
```

5. Specify what VLAN Ethernet packet type the VLAN or stacked VLAN dynamic profile accepts.

**NOTE:** This release supports **inet** and **dhcp-v4** for IPv4 packets, **inet6** and **dhcp-v6** for IPv6 packets, and **pppoe** for PPP packets.

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges dynamic-profile VLAN-PROF1]
user@host# set accept inet
```

## Configuring the VLAN Ethernet Packet Type for Stacked VLAN Dynamic Profiles

To configure the VLAN Ethernet packet type the stacked VLAN dynamic profile can accept:

1. Access the interface over which you want to create dynamic VLANs.

```
user@host# edit interfaces ge-0/0/0
```

2. Edit the VLAN **auto-configure** stanza.

```
[edit interfaces ge-0/0/0]
user@host# edit auto-configure
```

3. Edit the **stacked-vlan-ranges** stanza.

```
[edit interfaces ge-0/0/0 auto-configure]
user@host# edit stacked-vlan-ranges
```

4. Access the VLAN dynamic profile for which you want to configure VLAN ranges.

```
[edit interfaces ge-0/0/0 auto-configure stacked-vlan-ranges]
user@host# edit dynamic-profile STACKED-VLAN-PROF1
```

5. Specify what VLAN Ethernet packet type the stacked VLAN dynamic profile accepts.

**NOTE:** This release supports **inet** and **dhcp-v4** for IPv4 packets, **inet6** and **dhcp-v6** for IPv6 packets, and **pppoe** for PPP packets.

```
[edit interfaces ge-0/0/0 auto-configure stacked-vlan-ranges dynamic-profile
STACKED-VLAN-PROF1]
user@host# set accept inet
```

## Configuring an Authentication Password for VLAN or Stacked VLAN Ranges

You can specify an authentication password for dynamically created VLAN or stacked VLAN interfaces at the **[edit interfaces *interface-name* auto-configure vlan-ranges authentication]** or **[edit interfaces *interface-name* auto-configure stacked-vlan-ranges authentication]** hierarchy level. This password is sent to the external AAA authentication server for subscriber authentication.

**NOTE:** You must configure the `username-include` statement to enable the use of authentication. The `password (Interfaces)` statement is not required and does not cause the interface to use authentication if the `username-include` statement is not included.

To configure an authentication password:

1. Access the interface over which you want to create dynamic VLANs.

```
user@host# edit interfaces ge-0/0/0
```

2. Edit the VLAN `auto-configure` stanza.

```
[edit interfaces ge-0/0/0]
user@host# edit auto-configure
```

3. Edit the `vlan-ranges` or `stacked-vlan-ranges` stanza.

```
[edit interfaces ge-0/0/0 auto-configure]
user@host# edit vlan-ranges
```

or

```
[edit interfaces ge-0/0/0 auto-configure]
user@host# edit stacked-vlan-ranges
```

4. Edit the VLAN `authentication` stanza.

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]
user@host# edit authentication
```

5. Specify a password that is sent to the external AAA authentication server for subscriber authentication.

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]
user@host# set password (Interfaces) PSSWD1
```

**Related  
Documentation**

## Configuring VLAN Ranges for Use with Dynamic Profiles

---

You define dynamic VLAN ranges under the **[edit interfaces]** hierarchy. You can configure VLAN ranges in the following ways for use with dynamic profiles:

- [Configuring Single-Level VLAN Ranges for Use with VLAN Dynamic Profiles on page 684](#)
- [Configuring Stacked VLAN Ranges for Use with Stacked VLAN Dynamic Profiles on page 685](#)
- [Configuring Dynamic Mixed VLAN Ranges on page 686](#)
- [Configuring VLAN Dynamic Profile Override on page 687](#)

### Configuring Single-Level VLAN Ranges for Use with VLAN Dynamic Profiles

You configure VLAN ranges at the **[edit interfaces]** hierarchy level by specifying the **vlan-tagging** statement for the interface and defining up to 32 VLAN ranges for use with a VLAN dynamic profile.

To configure a VLAN range:

1. Access the interface over which you want to create dynamic VLANs.

```
user@host# edit interfaces ge-0/0/0
```

2. Specify the **vlan-tagging** statement to indicate that this interface is for use with stacked VLAN ranges.

```
[edit interfaces ge-0/0/0]  
user@host# set vlan-tagging
```

3. Access the VLAN **[auto-configure]** hierarchy level.

```
[edit interfaces ge-0/0/0]  
user@host# edit auto-configure
```

4. Access the **[vlan-ranges]** hierarchy level.

```
[edit interfaces ge-0/0/0 auto-configure]  
user@host# edit vlan-ranges
```

5. Access the VLAN dynamic profile for which you want to configure VLAN ranges.

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]  
user@host# edit dynamic-profile VLAN-PROFI
```

6. Specify the VLAN ranges that you want the dynamic profile to use. The following example specifies a lower VLAN ID limit of 3000 and any upper VLAN ID limit (a range from 1 through 4094).

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]  
user@host# set ranges 3000-any
```

**NOTE:** You can configure multiple VLAN range groups (up to 32 total) on the same physical interface that use different VLAN dynamic profiles.

---

7. (Optional) Access another VLAN dynamic profile for which you want to configure VLAN ranges.

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]
user@host# edit dynamic-profile VLAN-PROF2
```

8. (Optional) Specify the VLAN ranges that you want the dynamic profile to use. The following example specifies a lower VLAN ID limit of 5000 and any upper VLAN ID limit (a range from 1 through 4094).

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]
user@host# set ranges 5000-any
```

## Configuring Stacked VLAN Ranges for Use with Stacked VLAN Dynamic Profiles

You configure stacked VLAN ranges at the **[edit interfaces]** hierarchy level by specifying the **stacked-vlan-tagging** statement for the interface and defining up to 32 stacked VLAN ranges for use with a stacked VLAN dynamic profile.

To configure a VLAN range:

1. Access the interface over which you want to create dynamic VLANs.

```
user@host# edit interfaces ge-0/0/0
```

2. Specify the **stacked-vlan-tagging** statement to indicate that this interface is for use with stacked VLAN ranges.

```
[edit interfaces ge-0/0/0]
user@host# set stacked-vlan-tagging
```

3. Access the VLAN **[auto-configure]** hierarchy level.

```
[edit interfaces ge-0/0/0]
user@host# edit auto-configure
```

4. Access the **[stacked-vlan-ranges]** hierarchy level.

```
[edit interfaces ge-0/0/0 auto-configure]
user@host# edit stacked-vlan-ranges
```

5. Access the VLAN dynamic profile for which you want to configure VLAN ranges.

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]
user@host# edit dynamic-profile VLAN-PROF1
```

6. Specify the outer and inner stacked VLAN ranges that you want the dynamic profile to use. The following example specifies an outer stacked VLAN ID range from 2000 through 4000 and an inner stacked VLAN ID range of **any** (enabling a range from 1 through 4094 for the inner stacked VLAN ID).

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]
user@host# set ranges 2000-4000,any
```

**NOTE:** You can configure multiple dynamic profile associations (up to 32) with different VLAN range groups on each physical interface.

7. (Optional) Access another VLAN dynamic profile for which you want to configure VLAN ranges.

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]
user@host# edit dynamic-profile VLAN-PROF2
```

8. (Optional) Specify the outer and inner stacked VLAN ranges that you want the dynamic profile to use. The following example specifies an outer stacked VLAN ID range from 4001 through 6000 and an inner stacked VLAN ID range of **any** (enabling a range from 1 through 4094 for the inner stacked VLAN ID).

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]
user@host# set ranges 4001-6000,any
```

## Configuring Dynamic Mixed VLAN Ranges

Dynamic VLAN and dynamic stacked VLAN configuration supports mixed (or flexible) VLAN ranges. You configure mixed VLAN ranges at the **[edit interfaces]** hierarchy level by specifying the **flexible-vlan-tagging** statement for the interface and defining up to 32 VLAN and stacked VLAN range groups for use with different VLAN or stacked VLAN dynamic profiles.

**NOTE:** Junos VLAN IDs for single-tag VLANs are equivalent to the outer tags used for stacked (dual-tag) VLANs. When configuring mixed (flexible) VLANs, any overlap on single-tag VLAN IDs and stacked VLAN outer tag values is supported only for dynamic VLANs on MPC line cards. When configuring mixed (flexible) VLANs on DPCE line cards, overlapping single-tag VLAN IDs and stacked VLAN outer tag values is not supported. This means that a dynamically created single-tagged VLAN interface prevents any overlapping stacked VLAN interfaces from being created or a dynamically created stacked VLAN interface prevents any overlapping single-tagged VLAN interfaces from being created.

To configure both VLAN and stacked VLAN ranges:

1. Access the interface over which you want to create dynamic VLANs.

```
user@host# edit interfaces ge-0/0/0
```

2. Specify the **flexible-vlan-tagging** statement to indicate that this interface is for use with both VLAN and stacked VLAN ranges.

```
[edit interfaces ge-0/0/0]
user@host# set flexible-vlan-tagging
```

3. Define interface automatic configuration values.

```
[edit interfaces ge-0/0/0]
user@host# edit auto-configure
```

4. Specify that you want to modify VLAN ranges.

```
[edit interfaces ge-0/0/0 auto-configure]
user@host# edit vlan-ranges
```

5. Access the VLAN dynamic profile for which you want to configure VLAN ranges.

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]
user@host# edit dynamic-profile VLAN-PROF1
```

6. Specify the VLAN ranges that you want the dynamic profile to use. The following example specifies a lower VLAN ID limit of 2000 and an upper VLAN ID limit of 3000.

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]
user@host# set ranges 2000-3000
```

**NOTE:** You can configure multiple dynamic profile associations (up to 32) with different VLAN range groups on each physical interface.

7. Specify that you want to modify stacked VLAN ranges.

```
[edit interfaces ge-0/0/0 auto-configure]
user@host# edit stacked-vlan-ranges
```

8. Access the VLAN dynamic profile for which you want to configure VLAN ranges.

```
[edit interfaces ge-0/0/0 auto-configure stacked-vlan-ranges]
user@host# edit dynamic-profile VLAN-PROF2
```

9. Specify the outer and inner stacked VLAN ranges that you want the dynamic profile to use. The following example specifies an outer stacked VLAN ID range from 3001 through 4000 (to avoid overlapping VLAN IDs with single-tag VLANs) and an inner stacked VLAN ID range of **any** (enabling a range from 1 through 4094 for the inner stacked VLAN ID).

```
[edit interfaces ge-0/0/0 auto-configure stacked-vlan-ranges]
user@host# set ranges 3001-4000,any
```

**NOTE:** You can configure multiple dynamic profile associations (up to 32) with different VLAN range groups on each physical interface.

## Configuring VLAN Dynamic Profile Override

You can override dynamic profile assignment to individual VLANs that are already part of a previously defined VLAN range. This functionality provides a type of exception to an assigned VLAN range. It enables you to configure individual VLAN IDs to use a different dynamic profile from the one assigned to the VLAN range that includes the individual VLAN ID.

To configure dynamic profile override for a specific VLAN:

1. Access the interface on which you want to create a dynamic profile override.

```
user@host# edit interfaces ge-0/0/0
```

2. Access the interface automatic configuration hierarchy.

```
[edit interfaces ge-0/0/0]
user@host# edit auto-configure
```

3. Access either the single-tagged or dual-tagged (stacked) VLAN ranges that you want to modify.

```
[edit interfaces ge-0/0/0 auto-configure]  
user@host# edit vlan-ranges
```

or

```
[edit interfaces ge-0/0/0 auto-configure]  
user@host# edit stacked-vlan-ranges
```

4. Define the **override** statement along with the VLAN tag that you want to override and the dynamic profile that you want to use when overriding the specified VLAN tag.

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]  
user@host# set override tag 20 dynamic-profile NewProfile
```

or

```
[edit interfaces ge-0/0/0 auto-configure stacked-vlan-ranges]  
user@host# set override tag 20 dynamic-profile NewProfile
```

---

## Configuring Dynamic Authentication for VLAN Interfaces

You can use dynamic profiles, in conjunction with RADIUS, to dynamically create logical VLAN interfaces in the default logical system and in a specified routing instance. As DHCP clients in the same VLAN become active, corresponding interfaces are assigned to any specified routing instances. You can also dynamically create an underlying VLAN interface for incoming subscribers, associate interfaces created on this VLAN with the default logical system and a specified routing instance, and define RADIUS authentication values for the dynamically created interfaces.

Before you configure dynamic VLAN authentication, configure DHCP Local Server or DHCP Relay over which you want the dynamic VLAN interfaces to function.

For information about DHCP Local Server or DHCP Relay, see:

- [Extended DHCP Local Server Overview on page 186](#)
- [Extended DHCP Relay Agent Overview on page 258](#)

**NOTE:** You can also configure dynamically created VLAN interfaces over PPP or PPPoE interfaces. For information about how to configure PPP or PPPoE, see the Junos® OS Network Interfaces.

---

To configure dynamic authentication for dynamically created VLAN interfaces:

1. Configure an access profile that contains the appropriate accounting order, authentication order, and server access values.

For information about how to configure an access profile, RADIUS accounting, RADIUS statistics, and how to define RADIUS server access, see:

- [Configuring an Access Profile for Subscriber Management on page 137](#)
- [Specifying the Authentication and Accounting Methods for Subscriber Access on page 24](#)
- [Configuring Per-Subscriber Session Accounting on page 29](#)
- [Configuring Router or Switch Interaction with RADIUS Servers on page 23](#)

2. Configure a dynamic profile that uses the default logical system and creates specific routing instances to contain dynamically created VLAN interfaces.

See “Configuring a VLAN Dynamic Profile That Associates VLAN Interfaces with Separate Routing Instances” on page 678.

3. Define the VLAN physical interface for automatic configuration.

See the following topics:

- [Enabling VLAN Tagging](#)
- [Configuring Which VLAN Ethernet Packet Types Dynamic Profiles Can Accept on page 681](#)
- [Configuring VLAN Ranges for Use with Dynamic Profiles on page 684](#)
- [Configuring an Authentication Password for VLAN or Stacked VLAN Ranges on page 683](#)
- [Configuring VLAN Interface Username Information for AAA Authentication on page 689](#)

4. Associate an access profile to the VLAN interface.

See “Attaching Access Profiles” on page 137.

5. Associate a dynamic profile to the VLAN interface.

See “Configuring VLAN Interfaces to Use Dynamic Profiles” on page 680.

**Related  
Documentation**

- [Dynamic 802.1Q VLAN Overview on page 661](#)

---

## Configuring VLAN Interface Username Information for AAA Authentication

---

You can define interface information that is included in the username that is subsequently passed to the external AAA authentication service (for example, RADIUS) when creating dynamic VLANs or stacked VLANs. The AAA authentication service uses this information to authenticate the VLAN or stacked VLAN physical interface. After the interface is

authenticated, the AAA service can send the required routing instance values to the system for use in dynamically creating VLAN or stacked VLAN interfaces.

**NOTE:** The following example configures username information on VLANs. However, you can also configure dynamic authentication on stacked VLANs by configuring the same statements at the `[edit interfaces interface-name auto-configure stacked-vlan-ranges authentication]` hierarchy level.

To configure VLAN interface username information:

1. Access the interface over which you want to configure username information.

```
user@host# edit interfaces ge-0/0/0
```

2. Edit the **auto-configure** stanza.

```
[edit interfaces ge-0/0/0]
user@host# edit auto-configure
```

3. Edit the **vlan-ranges** stanza.

```
[edit interfaces ge-0/0/0 auto-configure]
user@host# edit vlan-ranges
```

4. Edit the **authentication** stanza.

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]
user@host# edit authentication
```

5. Edit the **username-include** stanza.

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges]
user@host# edit username-include
```

6. Specify the username statements that you want the AAA authentication service to use to authenticate the username.

```
[edit interfaces ge-0/0/0 auto-configure vlan-ranges authentication username-include]
user@host# set delimiter
```

**Related  
Documentation**

- [Configuring Dynamic Authentication for VLAN Interfaces on page 688](#)
- [Option 82 Suboptions in Authentication Usernames for Autosense VLANs on page 690](#)

---

## Option 82 Suboptions in Authentication Usernames for Autosense VLANs

You can specify the Option 82 suboptions that are concatenated with the username during the authentication process for autosense VLANs. The option 82 value used in creating the username is based on the option 82 value that is encoded in the incoming DHCP discover packet.

You can specify either, both, or neither of the Agent Circuit ID (suboption 1) and the Agent Remote ID (suboption 2). If you specify both, the Agent Circuit ID is supplied first, followed by a delimiter, and then the Agent Remote ID. If you specify that neither suboption is

supplied, the raw payload of Option 82 from the PDU is concatenated to the username. The use of Option 82 suboptions is supported for DHCPv4 discover packets only.

## Automatically Removing VLANs with No Subscribers

You can always clear or delete subscriber VLANs manually. However, you can also configure the interface to automatically remove dynamic subscriber VLANs when no client sessions (for example, DHCP or PPPoE) exist on the VLAN.

When configuring automatic removal of dynamic subscriber VLANs, keep the following in mind:

- You can configure automatic VLAN removal only on individual physical interfaces. You cannot configure the feature globally.
- Automatic VLAN removal is not supported for use on Layer 2 Wholesale interfaces.
- PPPoE subscriber interfaces require the use of a dynamic profiles when configured over dynamic VLANs. However, dynamic profiles are not required for use with DHCP subscriber interfaces that use underlying dynamic VLANs. Because the `remove-when-no-subscribers` functionality triggers when no dynamic client sessions exist on a dynamic VLAN, automatic removal of underlying dynamic VLANs is not supported when DHCP subscriber interfaces are not created using dynamic profiles.
- The `maintain-subscriber` statement and `remove-when-no-subscribers` statement are mutually exclusive. When the router is configured to maintain subscribers, you cannot also specify that dynamically configured VLAN interfaces are removed when no subscribers exist.
- If PPPoE subscriber session lockout is also configured, the router does not remove the unused subscriber VLAN until the lockout time has expired for each client undergoing lockout on the underlying interface.

To configure automatic removal of subscriber VLANs when no client sessions exist on the VLAN:

1. Access the interface for which you want to enable automatic removal of subscriber VLANs.

```
user@host# edit interfaces ge-1/1/1
```

2. Access the interface automatic configuration hierarchy.

```
[edit interfaces ge-1/1/1]
user@host# edit auto-configure
```

3. Enable subscriber VLAN removal with the `remove-when-no-subscribers` statement.

```
[edit interfaces ge1/1/1 auto-configure]
user@host# set remove-when-no-subscribers
```

## Configuring Dynamic VLANs Based on Agent Circuit Identifier Information

---

On MX Series routers with Modular Port Concentrators/Modular Interface Cards (MPCs/MICs) that face the access side of the network, you can configure dynamic VLAN subscriber interfaces based on agent circuit identifier (ACI) information, also known as *ACI-based dynamic VLANs*, for DHCP and PPPoE subscribers. To do so, you create an *ACI interface set*, which is a logical collection of subscriber interfaces that originate at the same household or on the same access-loop port, and then reference the ACI interface set in the dynamic profile for a PPPoE or IP demultiplexing (IP demux) logical subscriber interface.

Grouping subscriber interfaces into ACI interface sets to create ACI-based dynamic VLANs facilitates application of subscriber-based services, such as class of service (CoS) and interface-shared filters, to all of the subscriber interfaces from the same household.

Before you begin:

1. Configure the underlying physical interface for single-tag VLANs or stacked (dual-tag) VLANs.

See the following topics:

- [802.1Q VLANs Overview](#)
- [Configuring VLAN Dynamic Profiles on page 673](#)
- [Configuring VLAN Interfaces to Use Dynamic Profiles on page 680](#)

2. Create a dynamic profile that defines the logical subscriber interface.

See the following topics:

- [Configuring a Basic Dynamic Profile on page 633](#)
- [Configuring Dynamic PPPoE Subscriber Interfaces Using Dynamic Profiles on page 857](#)
- [Configuring Dynamic Subscriber Interfaces Using IP Demux Interfaces in Dynamic Profiles on page 729](#)

To configure a dynamic VLAN subscriber interface based on ACI information:

1. Create a dynamic profile that defines the dynamic ACI interface set.

See [“Defining Agent Circuit Identifier Interface Sets” on page 694](#).

2. (Optional) Include attributes for PPPoE, CoS, and interface-shared filters in the dynamic profile for the ACI interface set.

See [“Defining Agent Circuit Identifier Interface Sets” on page 694](#).

3. (Optional) In the dynamic profile for the ACI interface set, configure the router to use the Actual-Data-Rate-Downstream VSA [26-130] or Access-Loop-Encapsulation VSA [26-144] value in PPPoE control packets to adjust CoS shaping-rate and overhead-accounting attributes at a per-household level.

See [“Adjusting the CoS Shaping Rate and Overhead Accounting Parameters for Agent Circuit Identifier-Based Dynamic VLANs”](#) on page 701.

4. Dynamically or statically configure the underlying VLAN logical interface to enable dynamic subscriber interface creation based on ACI information.
  - For dynamic underlying VLAN interfaces, see [“Configuring Dynamic Underlying VLAN Interfaces to Use Agent Circuit Identifier Information”](#) on page 696.
  - For static underlying VLAN interfaces, see [“Configuring Static Underlying VLAN Interfaces to Use Agent Circuit Identifier Information”](#) on page 698.
5. Associate the dynamic ACI interface set with the dynamic PPPoE or dynamic IP demux logical subscriber interface.

See [“Configuring Dynamic VLAN Subscriber Interfaces Based on Agent Circuit Identifier Information”](#) on page 699.

6. (Optional) In the dynamic profile for the PPPoE (**pp0**) subscriber interface, configure the router to use the Actual-Data-Rate-Downstream VSA [26-130] or Access-Loop-Encapsulation VSA [26-144] value in PPPoE control packets to adjust CoS shaping-rate and overhead-accounting attributes at a per-subscriber level.

See [“Adjusting the CoS Shaping Rate and Overhead Accounting Parameters for Agent Circuit Identifier-Based Dynamic VLANs”](#) on page 701.

7. (Optional) Verify the ACI-based dynamic VLAN subscriber interface configuration.

See [“Verifying and Managing Agent Circuit Identifier-Based Dynamic VLAN Configuration”](#) on page 706.

8. (Optional) Clear the ACI interface set from the router when the interface set no longer has any active subscriber sessions.

See [“Clearing Agent Circuit Identifier Interface Sets”](#) on page 707.

## Defining Agent Circuit Identifier Interface Sets

To configure the router to create dynamic VLAN subscriber interfaces for DHCP and PPPoE subscribers based on agent circuit identifier (ACI) information, you must create a dynamic ACI interface set. An *ACI interface set* is a logical collection of subscriber interfaces that originate at the same household or on the same access-loop port.

Because DHCP and PPPoE traffic sent to the router from the same household carries the same ACI value in DHCP and PPPoE control packets, the router groups these subscriber interfaces into a single ACI interface set. Grouping subscriber interfaces into ACI interface sets facilitates application of attributes for PPPoE, class of service (CoS), and interface-shared filters to all of the subscriber interfaces from the same household.

To configure an ACI interface set in a dynamic profile:

1. Name the dynamic profile that defines the ACI interface set.

```
[edit]
user@host# edit dynamic-profiles profile-name
```

2. Specify that you want to configure the interfaces for the dynamic profile.

```
[edit dynamic-profiles profile-name]
user@host# edit interfaces
```

3. Configure the dynamic ACI interface set.

```
[edit dynamic-profiles profile-name interfaces]
user@host# edit interface-set $junos-interface-set-name
```

You must use the **\$junos-interface-set-name** predefined dynamic variable to represent the name of the ACI interface set. The **\$junos-interface-set-name** variable is dynamically replaced with the actual ACI interface set name generated by the router when the first DHCP or PPPoE subscriber from that household logs in.

4. Include the interfaces for the dynamic ACI interface set.

```
[edit dynamic-profiles profile-name interfaces interface-set
"$junos-interface-set-name"]
user@host# set interface $junos-interface-ifd-name
```

You must use the **\$junos-interface-ifd-name** predefined dynamic variable to represent the name of the ACI interface set. The **\$junos-interface-ifd-name** variable is dynamically replaced with the name of the interface on which the DHCP or PPPoE subscriber accesses the router.

**NOTE:** The unit *logical-unit-number* statement is not required in the dynamic profile at the [edit dynamic-profiles *profile-name* interfaces interface-set *interface-set-name* interface *interface-name*] hierarchy level when you configure an ACI interface set.

5. (Optional) For dynamic PPPoE subscriber interfaces, configure the maximum number of dynamic PPPoE sessions that the router can activate for the ACI interface set.

```
[edit dynamic-profiles profile-name interfaces interface-set
"$junos-interface-set-name"]
user@host# edit pppoe-underlying-options
[edit dynamic-profiles profile-name interfaces interface-set "$junos-interface-set-name"
pppoe-underlying-options]
user@host# set max-sessions number
```

Issuing the **max-sessions** statement in a dynamic profile for an ACI interface set limits the maximum number of dynamic PPPoE sessions at the ACI interface set level from the same household.

6. (Optional) Apply attributes for CoS and interface filters to all subscriber interfaces belonging to the ACI interface set.

The following example shows the minimum dynamic profile required to define an ACI interface set named `aci-vlan-set-profile`. The **interface-set** stanza uses predefined dynamic variables to represent the interface set (`$junos-interface-set-name`) and the underlying physical interface (`$junos-interface-ifd-name`).

```
[edit dynamic-profiles aci-vlan-set-profile]
interfaces {
  interface-set "$junos-interface-set-name" {
    interface "$junos-interface-ifd-name";
  }
}
```

The following example shows a more complex dynamic profile for an ACI interface set named `aci-vlan-set-profile-pppoe-cos`. In addition to the required **interface-set** stanza, this profile includes optional attributes for PPPoE (**max-sessions** statement) and CoS. The router applies these PPPoE and CoS attributes to all subscriber interfaces from the same household, which is represented by the ACI interface set.

```
[edit dynamic-profiles aci-vlan-set-profile-pppoe-cos]
variables {
  ds1q1q2DP uid;
  ef1_dp uid;
}
interfaces {
  interface-set "$junos-interface-set-name" {
    interface "$junos-interface-ifd-name";
    pppoe-underlying-options {
      max-sessions 3;
    }
  }
}
class-of-service {
  traffic-control-profiles {
    tcp2 {
      scheduler-map "$ds1q1q2DP";
      shaping-rate 50m;
      overhead-accounting bytes -20;
      guaranteed-rate 30m;
    }
  }
}
interfaces {
```

```
interface-set "$junos-interface-set-name" {
    output-traffic-control-profile tcp2;
}
scheduler-maps {
    "$dslqlq2DP" {
        forwarding-class ef scheduler "$efl_dp";
    }
}
schedulers {
    "$efl_dp" {
        transmit-rate percent 25;
        priority low;
    }
}
```

## Configuring Dynamic Underlying VLAN Interfaces to Use Agent Circuit Identifier Information

---

After you define the agent circuit identifier (ACI) interface set, you must configure the underlying VLAN interface to enable creation of dynamic VLAN subscriber interfaces based on ACI information. You can configure the underlying VLAN interface statically or dynamically.

This topic describes how to configure the underlying VLAN interface *dynamically*.

Before you begin:

- Create a dynamic profile that defines the underlying VLAN interface.

See the following topics:

- [Configuring a Basic Dynamic Profile on page 633](#)
- [Configuring VLAN Dynamic Profiles on page 673](#)

- [Configuring VLAN Interfaces to Use Dynamic Profiles on page 680](#)

To configure a dynamic underlying VLAN interface to use ACI information:

- In the dynamic profile for the underlying VLAN interface, associate the dynamic profile that defines the ACI interface set with the underlying VLAN interface.

```
[edit dynamic-profiles profile-name]
user@host# set interfaces interface-name unit logical-unit-number auto-configure
agent-circuit-identifier dynamic-profile aci-interface-set-profile-name
```

For example, the following statement in a dynamic profile named `aci-vlan-underlying-profile-demux` associates the dynamic underlying VLAN interface with dynamic profile `aci-vlan-set-profile2` that defines the ACI interface set. You must use the predefined dynamic variable `$junos-interface-ifd-name` to represent the interface name, and `$junos-interface-unit` to represent the logical unit number.

```
[edit dynamic-profiles aci-vlan-underlying-profile-demux]
user@host# set interfaces "$junos-interface-ifd-name" unit "$junos-interface-unit"
auto-configure agent-circuit-identifier dynamic-profile aci-vlan-set-profile2
```

The following example shows the dynamic configuration that uses this statement. This configuration enables the underlying dynamic IP demultiplexing (IP demux) VLAN interface to create dynamic subscriber interfaces based on ACI information by applying a single default ACI interface set dynamic profile (`aci-vlan-set-profile2`) to all households on the VLAN interface.

```
[edit dynamic-profiles aci-vlan-underlying-profile-demux]
interfaces {
  "$junos-interface-ifd-name" {
    unit "$junos-interface-unit" {
      auto-configure {
        agent-circuit-identifier {
          dynamic-profile aci-vlan-set-profile2;
        }
      }
      vlan-id "$junos-vlan-id";
      demux-options {
        underlying-interface "$junos-interface-ifd-name";
      }
      family inet {
        unnumbered-address lo0.0 preferred-source-address 100.20.0.2;
      }
    }
  }
}
```

#### Related Documentation

- [Agent Circuit Identifier-Based Dynamic VLANs Overview on page 662](#)
- [Agent Circuit Identifier-Based Dynamic VLANs Components Overview on page 664](#)
- [Configuring Dynamic VLANs Based on Agent Circuit Identifier Information on page 692](#)
- [Verifying and Managing Agent Circuit Identifier-Based Dynamic VLAN Configuration on page 706](#)

## Configuring Static Underlying VLAN Interfaces to Use Agent Circuit Identifier Information

---

After you define the agent circuit identifier (ACI) interface set, you must configure the underlying VLAN interface to enable creation of dynamic VLAN subscriber interfaces based on ACI information. You can configure the underlying VLAN interface statically or dynamically.

This topic describes how to configure the underlying VLAN interface *statically*.

To configure a static underlying VLAN interface to use ACI information:

- Associate the dynamic profile that defines the ACI interface set with the static underlying VLAN interface.

```
[edit]
user@host# set interfaces interface-name unit logical-unit-number auto-configure
agent-circuit-identifier dynamic-profile aci-interface-set-profile-name
```

For example, the following statement associates static Gigabit Ethernet VLAN interface ge-1/0/0.0 with the dynamic profile aci-vlan-set-profile that defines the ACI interface set.

```
[edit]
user@host# set interfaces ge-1/0/0 unit 0 auto-configure agent-circuit-identifier
dynamic-profile aci-vlan-set-profile
```

The following example shows the static configuration that uses this statement. This configuration enables the underlying VLAN interface ge-1/0/0.0 to create dynamic subscriber interfaces based on ACI information by applying a single default ACI interface set dynamic profile (aci-vlan-set-profile) to all households on the VLAN interface.

```
[edit]
interfaces {
  ge-1/0/0 {
    flexible-vlan-tagging;
    unit 0 {
      vlan-id 100;
      auto-configure {
        agent-circuit-identifier {
          dynamic-profile aci-vlan-set-profile;
        }
      }
    }
  }
}
```

### Related Documentation

- [Agent Circuit Identifier-Based Dynamic VLANs Overview on page 662](#)
- [Agent Circuit Identifier-Based Dynamic VLANs Components Overview on page 664](#)
- [Configuring Dynamic VLANs Based on Agent Circuit Identifier Information on page 692](#)
- [Verifying and Managing Agent Circuit Identifier-Based Dynamic VLAN Configuration on page 706](#)

## Configuring Dynamic VLAN Subscriber Interfaces Based on Agent Circuit Identifier Information

After you define the dynamic agent circuit identifier (ACI) interface set and enable creation of ACI-based dynamic VLAN subscriber interfaces on the underlying VLAN interface, you must complete the configuration by associating the ACI interface set with the PPPoE or IP demultiplexing (IP demux) subscriber interface in the dynamic profile for the subscriber interface.

Before you begin:

- Create a dynamic profile that defines the logical subscriber interface.

See the following topics:

- [Configuring a Basic Dynamic Profile on page 633](#)
- [Configuring Dynamic PPPoE Subscriber Interfaces Using Dynamic Profiles on page 857](#)
- [Configuring Dynamic Subscriber Interfaces Using IP Demux Interfaces in Dynamic Profiles on page 729](#)

To configure a dynamic VLAN subscriber interface based on ACI information:

- In the dynamic profile for the PPPoE or IP demux subscriber interface, associate the dynamic ACI interface set with the dynamic VLAN subscriber interface name (**pp0** or **demux0**) and logical unit number.

```
[edit dynamic-profiles profile-name]
user@host# set interfaces interface-set $junos-interface-set-name interface
interface-name unit $junos-interface-unit
```

For example, the following statement in a dynamic profile named `aci-vlan-pppoe-profile` associates the dynamic ACI interface set with the dynamic **pp0** (PPPoE) logical subscriber interface. You must use the predefined dynamic variable **\$junos-interface-set-name** to represent the name of the dynamic ACI interface set, and **\$junos-interface-unit** to represent the logical unit number of the subscriber interface.

```
[edit dynamic-profiles aci-vlan-pppoe-profile]
user@host# set interfaces interface-set $junos-interface-set-name interface pp0 unit
$junos-interface-unit
```

Similarly, the following statement in a dynamic profile named `aci-vlan-demux-profile` associates the dynamic ACI interface set (represented by **\$junos-interface-set-name**) with the **demux0** (IP demux) logical subscriber interface.

```
[edit dynamic-profiles aci-vlan-demux-profile]
user@host# set interfaces interface-set $junos-interface-set-name interface demux0
unit $junos-interface-unit
```

The following examples show the dynamic configurations that use each of these statements. The following sample configuration shows a dynamic profile named `aci-vlan-pppoe-profile` for an ACI-based dynamic PPPoE (**pp0**) subscriber interface for use by PPPoE subscribers.

```
[edit dynamic-profiles aci-vlan-pppoe-profile]
interfaces {
  interface-set "$junos-interface-set-name" {
    interface pp0 {
      unit "$junos-interface-unit";
    }
  }
  pp0 {
    unit "$junos-interface-unit" {
      ppp-options {
        chap;
        pap;
      }
      pppoe-options {
        underlying-interface "$junos-underlying-interface";
        server;
      }
      no-keepalives;
      family inet {
        unnumbered-address lo0.0;
      }
    }
  }
}
```

The following sample configuration shows a dynamic profile named `aci-vlan-demux-profile` for an ACI-based dynamic IP demux(**demux0**) subscriber interface for use by DHCP subscribers.

```
[edit dynamic-profiles aci-vlan-demux-profile]
interfaces {
  interface-set "$junos-interface-set-name" {
    interface demux0 {
      unit "$junos-interface-unit";
    }
  }
  demux0 {
    unit "$junos-interface-unit" {
      demux-options {
        underlying-interface "$junos-underlying-interface";
      }
      family inet {
        demux-source {
          $junos-subscriber-ip-address;
        }
        unnumbered-address lo0.0 preferred-source-address 100.20.200.202;
      }
    }
  }
}
```

## Adjusting the CoS Shaping Rate and Overhead Accounting Parameters for Agent Circuit Identifier-Based Dynamic VLANs

You can configure the router to use either or both of the Actual-Data-Rate-Downstream [26-130] or Access-Loop-Encapsulation [26-144] DSL Forum vendor-specific attribute (VSA) values in PPPoE control packets to adjust the CoS shaping-rate and overhead-accounting attributes, respectively, for dynamic agent circuit identifier (ACI) interface sets and their associated ACI-based dynamic VLAN subscriber interfaces.

Before you begin:

- To configure adjustment of the CoS shaping rate and overhead accounting attributes on a per-household basis, create a dynamic profile that defines the dynamic ACI interface set.

See [“Defining Agent Circuit Identifier Interface Sets” on page 694](#).

- To configure adjustment of the CoS shaping rate and overhead accounting attributes on a per-subscriber basis, create a dynamic profile that defines the ACI-based dynamic PPPoE (pp0) subscriber interface associated with the ACI interface set.

See [“Configuring Dynamic VLAN Subscriber Interfaces Based on Agent Circuit Identifier Information” on page 699](#).

To configure the router to use the Actual-Data-Rate-Downstream or Access-Loop-Encapsulation VSA values in PPPoE control packets to adjust the CoS shaping-rate and overhead-accounting attributes for dynamic ACI interface sets and associated ACI-based dynamic VLAN subscriber interfaces, do either or both of the following:

- In a dynamic profile for an ACI interface set or a dynamic profile for an ACI-based PPPoE subscriber interface, configure adjustment of the CoS shaping-rate attribute based on the value of the Actual-Data-Rate-Downstream VSA.

```
[edit dynamic-profiles profile-name class-of-service dynamic-class-of-service-options]
user@host# set vendor-specific-tags actual-data-rate-downstream
```

- In a dynamic profile for an ACI interface set or a dynamic profile for an ACI-based PPPoE subscriber interface, configure adjustment of the CoS overhead-accounting attribute based on the value of the Access-Loop-Encapsulation VSA.

```
[edit dynamic-profiles profile-name class-of-service dynamic-class-of-service-options]
user@host# set vendor-specific-tags access-loop-encapsulation
```

## Configuring Ethernet OAM Support for Service VLANs with Double-Tagged Customer VLANs

---

On MX Series routers with MPC/MIC interfaces, you can enable propagation of the Ethernet IEEE 802.1ag Operation, Administration, and Maintenance (OAM) state of a static single-tagged service VLAN (S-VLAN) to the dynamic or static double-tagged customer VLAN (C-VLAN) that has the same S-VLAN (outer) tag as the S-VLAN, and, by extension, to subscriber interfaces configured on the C-VLAN. The static S-VLAN logical interface must be configured on a Gigabit Ethernet, 10-Gigabit Ethernet, or aggregated Ethernet physical interface.

Before you begin:

- Make sure the static single-tagged S-VLAN logical interface is configured with the Ethernet 802.1ag OAM connectivity fault management (CFM) continuity check protocol.

See IEEE 802.1ag OAM Connectivity Fault Management Overview.

To enable propagation of the Ethernet OAM state of a static single-tagged S-VLAN to dynamic or static double-tagged C-VLAN logical interfaces:

- Configure a Gigabit Ethernet (ge), 10-Gigabit Ethernet (xe), or aggregated Ethernet (ae) physical interface to propagate the S-VLAN Ethernet OAM state to C-VLAN logical interfaces that have the same S-VLAN (outer) tag as the S-VLAN interface.

[edit]

```
user@host# set interfaces interface-name-fpc/pic/port oam-on-svlan
```

For example, the following statement enables propagation of the Ethernet OAM state of a static single-tagged S-VLAN on Gigabit Ethernet interface ge-1/0/5 to a dynamic or static double-tagged C-VLAN logical interface with the same S-VLAN (outer) tag as the S-VLAN interface.

[edit]

```
user@host# set interfaces ge-1/0/5 oam-on-svlan
```

Including the **oam-on-svlan** statement when you configure a Gigabit Ethernet, 10-Gigabit Ethernet, or aggregated Ethernet physical interface causes the router to bring down both of the following when the CFM continuity check protocol detects that the OAM state of the S-VLAN logical interface is down:

- All dynamic or static double-tagged C-VLANs on the S-VLAN interface that have the same S-VLAN (outer) tag as the S-VLAN interface.
- All DHCP, IP demultiplexing (IP demux), and PPPoE logical subscriber interfaces configured on the associated C-VLANs.

**Example: Gigabit Ethernet Interface with Static S-VLAN, Dynamic C-VLAN, and Dynamic PPPoE Subscriber Interfaces**

The following example shows a dynamic subscriber access configuration that uses the **oam-on-svlan** statement on a Gigabit Ethernet interface. This example configures Gigabit Ethernet physical interface ge-1/0/5 with a static single-tagged S-VLAN logical interface (ge-1/0/5.1) that runs the Ethernet 802.1ag OAM CFM continuity check protocol. A dynamic profile named double-vlans creates a dynamic double-tagged C-VLAN interface, and a dynamic profile named pppoe-profile creates dynamic PPPoE subscriber interfaces on the C-VLAN interface. The **oam-on-svlan** statement for ge-1/0/5 propagates the Ethernet OAM state of S-VLAN interface ge-1/0/5.1 to the C-VLAN interface and the dynamic PPPoE subscriber interfaces.

For clarity, the configuration is divided into five steps.

1. Configure a dynamic profile named double-vlans that defines a dynamic double-tagged C-VLAN logical interface.

```
[edit]
dynamic-profiles {
  double-vlans {
    interfaces {
      "$junos-interface-ifd-name" {
        unit "$junos-interface-unit" {
          vlan-tags outer "$junos-stacked-vlan-id" inner "$junos-vlan-id";
          encapsulation ppp-over-ether;
          pppoe-underlying-options {
            dynamic-profile pppoe-profile;
          }
        }
      }
    }
  }
}
```

2. Configure a dynamic profile named pppoe-profile that defines dynamic PPPoE subscriber interfaces on the C-VLAN.

```
[edit]
dynamic-profiles {
  pppoe-profile {
    interfaces {
      pp0 {
        unit "$junos-interface-unit" {
          pppoe-options {
            underlying-interface "$junos-underlying-interface";
            server;
          }
          family inet {
            unnumbered-address lo0.0;
          }
        }
      }
    }
  }
}
```

```

    }
  }
}

```

3. Configure Gigabit Ethernet physical interface ge-1/0/5.

```

[edit]
interfaces {
  ge-1/0/5 {
    description "connect to remote router";
    flexible-vlan-tagging;
    oam-on-svlan;
    unit 1 {
      vlan-id 1;
    }
    auto-configure {
      stacked-vlan-ranges {
        dynamic-profile double-vlans {
          accept any;
          ranges {
            any,any;
          }
        }
      }
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 100.1.1.1/32 {
        primary;
      }
    }
  }
}
}

```

The preceding example in Step 3 configures a static, single-tagged S-VLAN logical interface (ge-1/0/5.1) with VLAN ID 1, and references the double-vlans dynamic profile to create a dynamic double-tagged C-VLAN logical interface with S-VLAN (outer) tag **any** and C-VLAN (inner) tag **any**. The tag value **any** represents the entire range of VLAN IDs or S-VLAN IDs, including VLAN ID 1.

Because the C-VLAN outer tag (**any**) matches the S-VLAN tag VLAN ID 1, the **oam-on-svlan** statement in the configuration causes the router to propagate the Ethernet OAM state of S-VLAN ge-1/0/5.1 to the dynamic double-tagged C-VLAN logical interface (created by the double-vlans dynamic profile) and, by extension, to the dynamic PPPoE subscriber interfaces on the C-VLAN (created by the pppoe-profile dynamic profile).

4. Configure the Ethernet 802.1ag OAM CFM continuity check protocol on the static S-VLAN interface (ge-1/0/5.1).

```

[edit]

```

```

protocols {
  oam {
    ethernet {
      connectivity-fault-management {
        action-profile myDefault {
          default-actions {
            interface-down;
          }
        }
        maintenance-domain md1 {
          level 1;
          maintenance-association ma1 {
            continuity-check {
              interval 1s;
            }
            mep 100 {
              interface ge-1/0/5.1;
              direction down;
              remote-mep 101 {
                action-profile myDefault;
              }
            }
          }
        }
      }
    }
  }
}

```

If the CFM continuity check protocol detects that the Ethernet OAM state of S-VLAN interface ge-1/0/5.1 is down, the **interface-down** action in the myDefault action profile causes the router to bring down both of the following:

- The dynamic double-tagged C-VLAN logical interface that has the same S-VLAN (outer) tag as S-VLAN interface ge-1/0/5.1
- The dynamic PPPoE subscriber interfaces configured on the dynamic C-VLAN interface

5. Create a PPP access profile.

For brevity, this configuration is only partially shown. The missing portions of the configuration are replaced with ellipses (...).

```

[edit]
access {
  ...
  profile ppp-authenticator {
    ...
  }
}

```

## Verifying and Managing Agent Circuit Identifier-Based Dynamic VLAN Configuration

---

**Purpose** View information about dynamic agent circuit identifier (ACI) interface sets and ACI-based dynamic VLAN subscriber interfaces configured on the router.

- Action**
- To display the logical and physical interface associations for the classifier, rewrite rules, scheduler map objects, and CoS adjustment settings:  
`user@host> show class-of-service interface interface-name`
  - To display the CoS associations for the specified dynamic ACI interface set:  
`user@host> show class-of-service interface-set aci-interface-set-name`
  - To display information about the specified CoS traffic shaping and scheduling profile:  
`user@host> show class-of-service traffic-control-profile profile-name`
  - To display address bindings and ACI interface set information in the client table on the extended DHCP local server:  
`user@host> show dhcp server binding detail`
  - To display status information about a specified Gigabit Ethernet interface:  
`user@host> show interfaces ge-fpc/pic/port.logical-unit-number`
  - To display status information about a specified IP demultiplexing (IP demux) interface:  
`user@host> show interfaces demux0.logical-interface-number`
  - To display information about all dynamic ACI interface sets configured on the router:  
`user@host> show interfaces interface-set`
  - To display session-specific information about ACI-based dynamic PPPoE subscriber interfaces:  
`user@host> show pppoe interfaces pp0.logical-unit-number`
  - To display information about PPPoE underlying interfaces, including whether creation of ACI-based dynamic VLAN subscriber interfaces is enabled on the underlying interface:

```
user@host> show pppoe underlying-interfaces logical-interface-name detail
```

- To display information about active subscriber sessions associated with ACI interface sets:

```
user@host> show subscribers detail
```

- To display information about active subscriber sessions associated with a specified ACI interface set:

```
user@host> show subscribers aci-interface-set-name aci-interface-set-name detail
```

- To display information about active subscriber sessions that have an agent circuit identifier value containing a matching substring:

```
user@host> show subscribers agent-circuit-identifier agent-circuit-identifier-substring detail
```

## Clearing Agent Circuit Identifier Interface Sets

**Purpose** Clear a specified dynamic agent circuit identifier (ACI) interface set configured on the router.

**Action** • To clear a specified ACI interface set that has no active members:

```
user@host> clear auto-configuration interfaces interface-set interface-set-name
```

For example, the following command clears the ACI interface set named `aci-1003-ge-1/0/0.4001`:

```
user@host> clear auto-configuration interfaces interface-set aci-1003-ge-1/0/0.4001
Interface-set aci-1003-ge-1/0/0.4001 deleted
```

**Meaning** The router dynamically creates an ACI interface set, if configured, when the first DHCP or PPPoE subscriber from a particular household logs in. However, the router does not automatically delete the ACI interface set when the last subscriber from that household logs out. As a result, you must use the **clear auto-configuration interfaces interface-set** command to explicitly clear the ACI interface set when it no longer has any active subscriber interface members. If you attempt to clear an ACI interface that still has active member interfaces, the router displays an error message and rejects the command.

When you specify the name of the ACI interface set to be cleared, you must use the ACI interface set name internally generated by the router, and not the actual ACI string carried in DHCP and PPPoE control packets. The router uses the following format to name ACI interface sets, as shown in the ACI interface set named `aci-1003-ge-1/0/0.4001`:

***aci-nnnn-interface-name.logical-unit-number***

where:

- *nnnn* is a randomly generated 4-digit identifier (1003 in the example)
- *interface-name* is the name of the dynamic subscriber interface (ge-1/0/0 in the example)
- *logical-unit-number* is the logical unit number of the dynamic subscriber interface (4001 in the example)

To view the names of the ACI interface sets configured on the router, use the **show subscribers** command.

## Example: Configuring a VLAN Dynamic Profile for VLANs with a TPID of 0x8100

---

```
vlan-prof1 {
  interfaces {
    "$junos-interface-ifd-name" {
      unit "$junos-interface-unit" {
        vlan-id "$junos-vlan-id"; #Note the statement and variable use.
        family inet {
          unnumbered-address lo0.0 preferred-source-address 10.20.0.2;
        }
      }
    }
  }
}
```

## Example: Configuring a VLAN Dynamic Profile for VLANs with Any TPID Value and Enabling Demux Interfaces over the VLAN Interface

---

```
vlan-prof-any-tpid {
  interfaces {
    $junos-interface-ifd-name {
      unit $junos-interface-unit {
        demux-source inet; #Enables demux interface use over the VLAN interface.
        vlan-tags outer $junos-vlan-id; #Statement/variable combination enables the
          recognition of any VLAN interface TPID value.
        family inet {
```

```
        unnumbered-address lo0.0 preferred-source-address 10.20.0.2;
    }
}
}
}
```

---

### Example: Configuring a Stacked VLAN Dynamic Profile

---

```
svlan-prof1 {
  interfaces {
    $junos-interface-ifd-name {
      unit $junos-interface-unit {
        vlan-tags outer $junos-stacked-vlan-id inner $junos-vlan-id;
        family inet {
          unnumbered-address lo0.0 preferred-source-address 100.20.0.2;
        }
      }
    }
  }
}
```

---

### Example: Dynamic VLAN Interface Configuration

---

```
interfaces {
  ge-0/0/0 {
    vlan-tagging;
    auto-configure {
      vlan-ranges {
        dynamic-profile vlan-prof1 {
          accept inet;
          ranges {
            any;
          }
        }
      }
    }
  }
}
```

---

### Example: Dynamic Stacked VLAN Interface Configuration

---

```
interfaces {
  ge-0/0/0 {
    stacked-vlan-tagging;
    auto-configure {
      stacked-vlan-ranges {
        dynamic-profile svlan-prof {
          accept inet;
          ranges {
            1-1, any;
          }
        }
      }
    }
  }
}
```

```

    }
}

```

### Example: Dynamic Flexible VLAN Interface Configuration

```

interfaces {
  ge-0/0/0 {
    flexible-vlan-tagging;
    auto-configure {
      vlan-ranges {
        dynamic-profile vlan-prof1 {
          accept inet;
          ranges {
            any;
          }
        }
      }
    }
    stacked-vlan-ranges {
      dynamic-profile svlan-prof1 {
        accept inet;
        ranges {
          1-1, any;
        }
      }
    }
  }
}

```

### Example: Configuring a Flexible VLAN Interface for Use with a Nonstandard Ethertype

This example specifies an ethertype of 0x9100 instead of the standard 0x8100.

```

interfaces {
  ge-0/0/0 {
    flexible-vlan-tagging;
    gigether-options {
      ethernet-switch-profile {
        tag-protocol-id 0x9100;
      }
    }
    auto-configure {
      vlan-ranges {
        dynamic-profile vlan-prof {
          accept inet;
          ranges {
            any;
          }
        }
      }
    }
    stacked-vlan-ranges {
      dynamic-profile svlan-prof {
        accept inet;
        ranges {
          1-1, any;
        }
      }
    }
  }
}

```

```
}  
}  
}  
}  
}  
}
```

## Subscriber Interface Overview

---

In this release, you can identify subscribers statically or dynamically.

To identify subscribers statically, you can reference a static VLAN interface in a dynamic profile. To identify subscribers dynamically, you create variables for demux interfaces that are dynamically created by DHCP when subscribers log in.

## Statically Identifying Subscribers

Before you can configure static subscriber interfaces in a dynamic profile, you must first configure the logical interfaces on the router to which you expect clients to connect. After you have created the static interfaces, you can modify them by using dynamic profiles to apply configuration parameters.

You can also configure subscribers by creating sets of static IP demux interfaces that are not referenced in a dynamic profile.

When configuring the interfaces stanza within a dynamic profile, you use variables to specify the interface name and the logical unit value. When a DHCP subscriber sends a DHCP request to the interface, the dynamic profile replaces the **interface-name** and **unit** variables with the actual interface name and logical unit number of the interface that received the DHCP request. After this association is made, the router configures the interface with any CoS or protocol (that is, IGMP) configuration within the dynamic profile, or applies any input or output filter configuration that you have associated with that dynamic profile.

```
[edit dynamic-profiles]
interfaces interface-name {
  unit logical-unit-number {
    family family {
      address address;
```

```

filter {
    input filter-name;
    output filter-name;
}
unnumbered-address interface-name <preferred-source-address address>;
vlan-id;
}
vlan-tagging;
}

```

## Dynamically Identifying Subscribers

You can configure demux interfaces to represent a subscriber interface in a dynamic profile. When a subscriber logs in using a DHCP access method, the demux interface is dynamically created.

You specify variables for the unit number, the name of the underlying interface, and the IP address in the dynamic profile. These variables are replaced with the values that are supplied by DHCP when the subscriber logs in.

## Static Subscriber Interfaces and VLAN Overview

This topic describes the topology for configuring subscriber interfaces over static VLAN interfaces in the current release.

In a dynamic profile, you can configure VLAN subscriber interfaces over the following statically created logical interface types:

- GE—Gigabit Ethernet
- XE—10-Gigabit Ethernet
- AE—Aggregated Ethernet

We recommend that you configure each subscriber on a statically created VLAN.

[Figure 11 on page 716](#) shows an example of subscriber interfaces on an individual VLAN.

**Figure 11: VLAN Subscriber Interfaces**

You can further separate VLANs on subscriber interfaces by configuring a VLAN interface as the underlying interface for a set of IP demux interfaces.

- For more information about demux interfaces, see [Subscriber Interfaces and Demultiplexing Overview on page 717](#)

## Subscriber Interfaces and Demultiplexing Overview

You can create logical subscriber interfaces using static or dynamic demultiplexing interfaces. In addition, you can use either IP demultiplexing interfaces or VLAN demultiplexing interfaces when creating logical subscriber interfaces.

Demultiplexing (demux) interfaces are logical interfaces that share a common, underlying logical interface (in the case of IP demux) or underlying physical interface (in the case of VLAN demux). You can use these interfaces to identify specific subscribers or to separate individual circuits by IP address (IP demux) or VLAN ID (VLAN demux).

The subscriber interfaces can provide different levels of services for individual subscribers in an access network. For example, you can apply CoS parameters for each subscriber.

### Interface Sets of Static Demux Interfaces

You can group static demux interfaces to create individual subscriber interfaces using interface sets. Interface sets enable you to provide the same level of service for a group of subscribers; for example, all residential subscribers who receive the basic data service.

[Figure 12 on page 717](#) shows a subscriber interface configured using a set of IP demux interfaces with an underlying VLAN interface.

**Figure 12: IP Demux Subscriber Interface**

### Dynamic Demultiplexing Interfaces

You can configure demux interfaces to represent a dynamic subscriber interface in a dynamic profile.

Demux interfaces are dynamically created by a DHCP access method when the underlying interface for the demux interface is configured for the access method. The DHCP access model creates the demux interface with the subscriber's assigned IP address (for IP demux interfaces) or VLAN ID (for VLAN demux interfaces).

To configure an IP demux interface in the dynamic profile, you specify variables for the unit number, the name of the underlying interface, and the IP address. To configure a VLAN demux interface in the dynamic profile, you specify variables for the unit number,

the name of the underlying interface, and the VLAN ID. These variables are replaced with the values that are supplied by DHCP when the subscriber logs in.

## Guidelines for Configuring Demux Interfaces for Subscriber Access

When you configure static or dynamic demux interfaces for subscriber access, consider the following guidelines:

- You can only configure interface sets of static demux interfaces and dynamic demux interfaces on MX Series 3D Universal Edge Routers. Hierarchical and per-unit scheduling is supported for dynamically created demux interfaces on the EQ DPC.
- You can configure IPv4 and IPv6 addressing for static and dynamic demux interfaces.
- You can configure only one **demux0** interface per chassis.
- For IP demux interfaces, you can define logical demux interfaces on top of the **demux0** interface (for example, **demux0.1**, **demux0.2**, and so on).
- Demux interfaces currently support only Gigabit Ethernet, Fast Ethernet, 10-Gigabit Ethernet, and aggregated Ethernet underlying interfaces.
- You must associate IP demux interfaces with an underlying logical interface.
- You must associate VLAN demux interfaces with an underlying device (physical interface).
- You cannot use a dynamic demux interface to represent multiple subscribers in a dynamic profile attached to an interface. One dynamic demux interface represents one subscriber. Do not configure the **aggregate-clients** option when attaching a dynamic profile to a demux interface for DHCP.

---

## IP Demux Interfaces over Static or Dynamic VLAN Demux Interfaces

You can configure a router with IP demux interfaces over VLAN demux interfaces. Just as IP demux interfaces demultiplex their underlying VLAN demux interfaces based on IP

address, VLAN demux interfaces demultiplex their underlying aggregate Ethernet or Ethernet interfaces based on VLAN ID.

When configuring IP demux interfaces over VLAN demux interfaces, keep the following in mind:

- Only single and dual VLAN tag options are supported as VLAN selectors.
- Both inet and inet6 families are supported.
- All firewall and CoS features are supported.
- Both static and dynamic VLAN demux interface creation is supported, including autosense VLAN creation.
- Both DPCs and MPCs are supported.

---

## MAC Address Validation for Subscriber Interfaces Overview

MAC address validation enables the router to validate that received packets contain a trusted IP source and an Ethernet MAC source address.

Configuring MAC address validation can provide additional validation when subscribers access billable services. MAC address validation provides additional security by enabling the router to drop packets that do not match, such as packets with spoofed addresses.

When subscribers log in, they are automatically assigned IP addresses by DHCP. With MAC address validation enabled, the router compares the IP source and MAC source addresses against trusted addresses, and forwards or drops the packets according to the match and the validation mode.

## Supported Types of Subscriber Interfaces

MAC address validation is supported on statically or dynamically created Ethernet interfaces and demux interfaces on MX Series 3D Universal Edge Routers as follows:

- When the router is configured for a normal (non-enhanced) network services mode, MAC address validation is supported on both DPCs and MPCs. The router can be populated completely with one or the other type of line card, or have a mix of both types. Normal network services mode is the default.
- When the router is configured for Enhanced IP Network Services mode or Enhanced Ethernet Network Services mode, MAC address validation is supported only on MPCs. If the router has both DPCs and MPCs, or only DPCs, you cannot configure the chassis to be in enhanced mode.

MAC address validation is optimized for scaling when the router is in enhanced network services modes. Enhanced network services modes affect other features, such as multicast and firewall filters, so you must take that in to consideration when deciding whether to configure enhanced mode. For more information about the enhanced network service modes, see *Network Services Mode Overview* in the *Junos OS System Basics Configuration Guide*.

In normal network services mode, you can use the **show interfaces statistics interface-name** command to display a per-interface count of the packets that failed validation and were dropped. In enhanced network services mode, this command does not count the dropped packets; you must contact Juniper Networks Customer Support for assistance in collecting this data.

## Trusted Addresses

A trusted address tuple is a 32-bit IP address and a 48-bit MAC address. Prefixes and ranges are not supported.

The IP source address and the MAC source address used for validation must be from a trusted source.

All static ARP addresses configured through the CLI are trusted addresses; dynamic ARP addresses are not considered trusted addresses.

Addresses dynamically created through an extended DHCP local server or extended DHCP relay are also trusted addresses. When a DHCP server and client negotiate an IP address, the resulting IP address and MAC address tuple is trusted. Each DHCP subscriber can generate more than one address tuple.

Each MAC address can have more than one IP address, which can result in more than one valid tuple. Each IP address must map to one MAC address.

## Types of MAC Address Validation

You can configure either of two types or modes of MAC address validation, loose or strict. The behavior of the two modes varies depending on how well the incoming packets match the trusted address tuples. The modes differ only when the IP source address

alone does not match any trusted IP address. [Table 67 on page 721](#) compares the behavior of the two modes. Dropped packets are considered to be spoofed.

Table 67: Comparison of MAC Address Validation Modes

Incoming Packet Addresses Match Trusted Address Tuple	Loose Mode Action	Strict Mode Action
<ul style="list-style-type: none"><li>IP source address matches and</li><li>MAC source address matches</li></ul>	Forwards packet	Forwards packet
<ul style="list-style-type: none"><li>IP source address matches but</li><li>MAC source address does not match</li></ul>	Drops packet	Drops packet
<ul style="list-style-type: none"><li>IP source address does not match and</li><li>MAC source address either matches or does not match</li></ul>	Forwards packet	Drops packet

Configuring strict mode is a more conservative strategy because it requires both received source addresses to match trusted addresses.

When you configure MAC address validation for IP demux interfaces in a dynamic profile and specify either loose or strict validation, the resulting behavior is always loose validation. To enable strict behavior for a dynamic IP demux interface, you must configure strict validation for both the IP demux interface and the underlying interface.

## Configuring Static Subscriber Interfaces in Dynamic Profiles

---

In this release, you can use dynamic profiles to configure statically created logical interfaces. Dynamic profiles enable you to dynamically apply configured values (including CoS, IGMP, or filter configuration) to the static interfaces, making them easier to manage.

To configure static interfaces, you must first configure the interfaces on the router to which you expect subscribers to connect.

The subscriber access feature supports the following statically-created interface types in dynamic profiles:

- GE—Gigabit Ethernet
- XE—10-Gigabit Ethernet
- AE—Aggregated Ethernet

This topic contains the following sections:

- [Configuring a Subscriber Interface with a Static VLAN Interface on page 724](#)
- [Configuring Static Subscriber Interfaces Using IP Demux Interfaces on page 724](#)

- [Configuring Static Subscriber Interfaces Using VLAN Demux Interfaces on page 725](#)
- [Associating Dynamic Profiles with Statically Created Interfaces on page 726](#)

## Configuring a Subscriber Interface with a Static VLAN Interface

This topic describes how to configure a subscriber interface with a static VLAN interface.

After you configure the static VLAN interface, you can reference it in a dynamic profile.

To configure a subscriber interface over a VLAN:

1. Configure the static VLAN interface and enable VLAN tagging.

```
[edit interfaces]
ge-5/0/0 {
  vlan-tagging;
}
```

2. Configure the units and assign the VLAN IDs.

```
unit 1 {
  proxy-arp;
  vlan-id 1;
  family inet {
    unnumbered-address lo0.0 preferred-source-address 192.1.1.1;
  }
}
unit 2 {
  proxy-arp;
  vlan-id 2;
  family inet {
    unnumbered-address lo0.0 preferred-source-address 192.1.1.1;
  }
}
```

3. Associate the static subscriber interface in a dynamic profile.

See [“Associating Dynamic Profiles with Statically Created Interfaces” on page 726](#).

## Configuring Static Subscriber Interfaces Using IP Demux Interfaces

You can configure a subscriber interface using a statically created IP demux interface. This interface can be referenced in a dynamic profile.

To configure a static IP demux subscriber interface:

1. Configure the IP demux interface on a physical device represented by a logical unit number. The logical interface resides on a physical device.

See [Configuring an IP Demultiplexing Interface](#).

2. Configure the underlying interface on which the IP demux interface is running.

See [Configuring an IP Demux Underlying Interface](#).

3. Specify the underlying interface on which the IP demux interface is running.

See [Specifying the Demux Underlying Interface](#).

4. Specify how ingress IPv4 traffic is to be demultiplexed based on packet destination or source addresses.

See [Configuring IP Demux Prefixes](#).

5. Associate the static subscriber interface in a dynamic profile.

See [“Associating Dynamic Profiles with Statically Created Interfaces” on page 726](#).

**NOTE:** VLAN demux interfaces currently support the Internet Protocol version 4 (IPv4) suite (`family inet`) and the Internet Protocol version 6 (IPv6) suite (`family inet6`).

## Configuring Static Subscriber Interfaces Using VLAN Demux Interfaces

You can configure a subscriber interface using a statically created VLAN demux interface. This interface can be referenced in a dynamic profile.

To configure a static VLAN demux subscriber interface:

1. Configure the VLAN demux interface.

See [Configuring a VLAN Demultiplexing Interface](#).

2. Configure the underlying interface on which the VLAN demux interface is running.

See [Configuring a VLAN Demux Underlying Interface](#).

3. Specify the underlying interface on which the VLAN demux interface is running.

See [Specifying the Demux Underlying Interface](#).

4. Specify how ingress IP traffic is to be demultiplexed based on the VLAN ID.

See [Associating VLAN IDs to VLAN Demux Interfaces](#).

5. Associate the static subscriber interface in a dynamic profile.

See [“Associating Dynamic Profiles with Statically Created Interfaces” on page 726](#).

**NOTE:** VLAN demux interfaces currently support the Internet Protocol version 4 (IPv4) suite (`family inet`) and the Internet Protocol version 6 (IPv6) suite (`family inet6`).

VLAN demux subscriber interfaces over aggregated Ethernet physical interfaces are supported only for MX Series routers that have only MPCs installed. If the router has other cards in addition to MPCs, the CLI accepts the configuration but errors are reported when the subscriber interfaces are brought up.

## Associating Dynamic Profiles with Statically Created Interfaces

When configuring the interfaces stanza within a dynamic profile, you use variables to specify the interface name and the logical unit value. When a DHCP subscriber sends a DHCP request to the interface, the dynamic profile replaces the interface name variable and logical unit name variable with the actual interface name and logical unit number of the interface that received the DHCP request.

**NOTE:** Configuration of the interface name variable and logical interface name variable at the [edit dynamic-profiles *profile-name* interfaces] hierarchy level is required for a dynamic profile to function.

To configure the interface for a dynamic profile, specify the interface name variable and include the **unit** statement and associated logical interface name variable:

1. Access the profile.

```
[edit]
user@host# edit dynamic-profiles basic-profile
```

2. Specify the interface name variable.

```
[edit dynamic-profiles basic-profile]
user@host# set interfaces $junos-interface-ifd-name
```

3. Specify the logical interface name variable with the **unit** statement.

When referencing an existing interface, specify the **\$junos-underlying-interface-unit** variable used by the router to match the unit value of the receiving interface:

```
[edit dynamic-profiles basic-profile]
user@host# set unit $junos-underlying-interface-unit
```

When creating dynamic interfaces, specify the **\$junos-interface-unit** variable used by the router to generate a unit value for the interface:

```
[edit dynamic-profiles basic-profile]
user@host# set unit $junos-interface-unit
```

## Configuring a Subscriber Interface Using a Set of Static IP Demux Interfaces

You can create logical subscriber interfaces from IP demux interfaces. IP demultiplexing (demux) interfaces are logical interfaces that share a common, underlying logical interface. IP demux interfaces can be used to identify specific subscribers or to separate individual circuits.

You can group individual subscriber interfaces using interface sets to provide the same level of service for a group of subscribers; for example, all residential subscribers who receive the basic data service. Interface sets can be defined as a list of logical interfaces (unit 0, unit 1, and so on).

To configure a group of static IP demux interfaces:

1. Configure the interface set.

```
interfaces {
  interface-set demux-set {
    interface demux0 {
      unit 0;
      unit 1;
    }
  }
}
```

2. Define the units of the interface set.

```
demux0 {
  unit 0 {
    demux-options {
      underlying-interface ge-2/0/1.1;
    }
    family inet {
      demux-source {
        1.1.1.0/24;
      }
      address 1.1.1.1/24;
    }
  }
  unit 1 {
    demux-options {
      underlying-interface ge-2/0/1.1;
    }
    family inet {
      demux-source {
        1.1.2.0/24;
      }
      address 1.1.2.1/24;
    }
  }
}
```

    interface demux0 {
      unit 0;
      unit 1;
    }
  }
}
```

2. Define the units of the interface set.

```
demux0 {
  unit 0 {
    vlan-id 10;
    demux-options {
      underlying-interface ge-2/0/1;
    }
    family inet {
      address 1.1.1.1/24;
    }
  }
  unit 1 {
    vlan-id 20;
    demux-options {
      underlying-interface ge-2/0/1;
    }
    family inet {
      address 1.1.2.1/24;
    }
  }
}
```

## Configuring Dynamic Subscriber Interfaces Using IP Demux Interfaces in Dynamic Profiles

You can configure dynamic subscriber interfaces using IP demux interfaces.

To enable the dynamic demux interface to be created by DHCP, you configure the demux options in a dynamic profile. Dynamic profiles enable you to dynamically apply configured values (including CoS, IGMP, or filter configuration) to the dynamic interfaces, making them easier to manage.

Before you begin:

- Configure the dynamic profile.

See [“Configuring a Basic Dynamic Profile” on page 633](#).

To configure dynamic subscriber interfaces:

1. Specify that you want to configure the **demux0** interface in the dynamic profile.

```
user@host# edit dynamic-profiles business-profile interfaces demux0
```

2. Configure the unit for the **demux0** interface.

- a. Configure the variable for the unit number of the **demux0** interface.

The variable is dynamically replaced with the unit number that DHCP supplies when the subscriber logs in.

```
[edit dynamic-profiles business-profile interfaces demux0]
user@host# edit unit $junos-interface-unit
```

- b. Configure the variable for the underlying interface of the demux interfaces and specify the **\$junos-underlying-interface** variable.

The variable is dynamically replaced with the underlying interface that DHCP supplies when the subscriber logs in.

```
[edit dynamic-profiles business-profile interfaces demux0 unit
 "$junos-interface-unit"]
user@host# set demux-options underlying-interface $junos-underlying-interface
```

3. Configure the family for the demux interfaces.

- a. Specify that you want to configure the family.

For IPv4:

```
[edit dynamic-profiles business-profile interfaces demux0 unit
 "$junos-interface-unit"]
user@host# edit family inet
```

For IPv6:

```
[edit dynamic-profiles business-profile interfaces demux0 unit  
"$junos-interface-unit"]  
user@host# edit family inet6
```

- b. Configure the unnumbered address for the family.

```
[edit dynamic-profiles business-profile interfaces demux0 unit  
"$junos-interface-unit" family inet]  
user@host# set unnumbered-address lo0.0
```

- c. Configure the variable for the IP address of the demux interface.

The variable is dynamically replaced with the IP address that DHCP supplies when the subscriber logs in. For IPv4, use `$junos-subscriber-ip-address`. For IPv6, use `$junos-subscriber-ipv6-address`. For IPv6 multiple address support, use `$junos-subscriber-ipv6-multi-address`.

```
[edit dynamic-profiles business-profile interfaces demux0 unit  
"$junos-interface-unit" family inet]  
user@host# set demux-source $junos-subscriber-ip-address
```

```
2. Configure the unit for the **demux0** interface.
  - a. Configure the variable for the unit number of the **demux0** interface.

The variable is dynamically replaced with the unit number that DHCP supplies when the subscriber logs in.

```
[edit dynamic-profiles business-profile interfaces demux0]
user@host# edit unit $junos-interface-unit
```

- b. Configure the variable for the underlying interface of the demux interfaces by specifying the `$junos-interface-ifd-name` variable.

The variable is dynamically replaced with the underlying device name that DHCP supplies when the subscriber logs in.

```
[edit dynamic-profiles business-profile interfaces demux0 unit
"$junos-interface-unit"]
user@host# set demux-options underlying-interface $junos-interface-ifd-name
```

- c. Configure the variable for the VLAN ID.

```
[edit dynamic-profiles business-profile interfaces demux0 unit
"$junos-interface-unit"]
user@host# set vlan-id $junos-vlan-id
```

3. Configure the family for the demux interfaces.

- a. Specify that you want to configure the family.

For IPv4:

```
[edit dynamic-profiles business-profile interfaces demux0 unit
"$junos-interface-unit"]
user@host# edit family inet
```

For IPv6:

```
[edit dynamic-profiles business-profile interfaces demux0 unit
"$junos-interface-unit"]
user@host# edit family inet6
```

- b. Configure the unnumbered address for the family.

```
[edit dynamic-profiles business-profile interfaces demux0 unit
"$junos-interface-unit" family inet]
user@host# set unnumbered-address lo0.0
```

## Configuring MAC Address Validation for Subscriber Interfaces

This topic describes how to configure MAC address validation for subscriber interfaces in dynamic profiles on MX Series routers.

The subscriber interfaces can be statically created and associated with a dynamic profile (for example, VLAN interfaces) or dynamically created in the dynamic profile (such as demux interfaces).

By default, MAC address validation is disabled.

This topic contains the following sections:

- [Configuring MAC Address Validation for Static Subscriber Interfaces on page 732](#)
- [Configuring MAC Address Validation for Dynamic Subscriber Interfaces on page 733](#)

## Configuring MAC Address Validation for Static Subscriber Interfaces

This topic describes how to configure MAC address validation for static subscriber interfaces in dynamic profiles on MX Series routers.

Before you begin:

- Configure the dynamic profile.  
See [“Configuring a Basic Dynamic Profile” on page 633](#).
- (Optional) Configure an enhanced network services mode.  
See [Configuring Junos OS to Run a Specific Network Services Mode in MX Series Routers](#).

To configure MAC address validation on static subscriber interfaces:

1. Configure the static VLAN interface.

```
[edit interfaces]
user@host# set interface-name unit logical-unit-number family inet
```

2. Configure the type of MAC address validation for the interface.

- To configure loose validation:

```
[edit interfaces interface-name unit logical-unit-number family inet]
user@host# set mac-validate loose
```

- To configure strict validation:

```
[edit interfaces interface-name unit logical-unit-number family inet]
user@host# set mac-validate strict
```

For example, to configure loose validation on interface fe-0/0/0.0, configure the following:

```
[edit interfaces fe-0/0/0 unit 0 family inet]
user@host# set mac-validate loose
```

After you configure MAC address validation:

- Associate the static VLAN interface with the dynamic profile.

See “Associating Dynamic Profiles with Statically Created Interfaces” on page 726.

## Configuring MAC Address Validation for Dynamic Subscriber Interfaces

This topic describes how to configure MAC address validation for subscriber interfaces created on demux interfaces in dynamic profiles on MX Series routers.

When you configure MAC address validation for demux interfaces in a dynamic profile and specify either **loose** or **strict** validation, the resulting behavior is always loose validation. To enable strict behavior for a dynamic IP demux interface, besides configuring either **loose** or **strict** mode on the IP demux interface, you must also configure strict validation on the underlying interface.

Before you begin:

- Configure the dynamic profile.

See “Configuring a Basic Dynamic Profile” on page 633.

- Configure the dynamic IP demux interface.

See “Configuring Dynamic Subscriber Interfaces Using IP Demux Interfaces in Dynamic Profiles” on page 729.

- (Optional) Configure an enhanced network services mode.

See Configuring Junos OS to Run a Specific Network Services Mode in MX Series Routers.

To configure loose MAC address validation for a dynamic subscriber interface:

- Configure loose validation for the demux interface.

```
[edit dynamic-profiles profile-name interfaces demux0 unit “$junos-interface-unit”
  family inet]
user@host# set mac-validate loose
```

For loose validation, you do not need to configure MAC address validation on the underlying interface.

To configure strict MAC address validation for a dynamic subscriber interface:

1. Configure validation for the demux interface.

```
[edit dynamic-profiles profile-name interfaces demux0 unit “$junos-interface-unit”
  family inet]
user@host# set mac-validate validation-mode
```

**NOTE:** Remember, although you must configure validation on the IP demux interface, it does not matter which mode you specify because the behavior is always loose.

2. Configure strict validation for the underlying interface.

```
[edit interfaces interface-name unit logical-unit-number family inet]
user@host# set mac-validate strict
```

The underlying interface in this case is statically configured—for example, ge-1/0/0.1—and assigned to a DHCP configuration group that is associated with the dynamic profile. In a more complicated configuration, the underlying interface itself can be configured by a dynamic profile; in that case the validation is configured in the profile that creates the underlying interface.

  - [Example: Configuring Dynamic Subscriber Interfaces on IP Demux Interfaces on page 739](#)

## Verifying Configuration and Status of Dynamic Subscribers and Associated Sessions, Services, and Firewall Filters

**Purpose** Verify configuration and status of dynamic subscribers, sessions, services, and firewall filters.

You can display information about subscribers in different ways, depending on the options you use with the **show subscriber** command. You can use details from one set of output with another command to display more detailed information of interest.

- Action**
- To display basic information for all subscribers:

```
user@host> show subscribers
Interface IP Address/VLAN ID User Name LS:RI
demux0.1073741824 0x8100.1500 0x8100.2900 test1@test.com default:testnet
demux0.1073741825 0x8100.1500 0x8100.2901 test1@test.com default:testnet
demux0.1073741826 0x8100.1500 0x8100.2902 test1@test.com default:testnet
demux0.1073741827 0x8100.1500 0x8100.2903 test1@test.com default:testnet
demux0.1073741826 172.16.200.6 test1@test.com default:testnet
demux0.1073741827 172.16.200.7 test1@test.com default:testnet
demux0.1073741824 172.16.200.8 test1@test.com default:testnet
demux0.1073741825 172.16.200.9 test1@test.com default:testnet

demux0.1073741828 20.20.0.2 test1@test.com default:default
```

- To display more detailed information about a particular subscriber interface:

```
user@host> show subscribers interface demux0.1073741826 extensive
Type: VLAN
User Name: test1@test.com
Logical System: default
Routing Instance: testnet
Interface: demux0.1073741826
Interface type: Dynamic
Dynamic Profile Name: profile-vdemux-relay-23qos
MAC Address: 00:00:6e:56:01:04
State: Active
Radius Accounting ID: 12
Session ID: 12
Stacked VLAN Id: 0x8100.1500
VLAN Id: 0x8100.2902
Login Time: 2011-10-20 16:21:59 EST
```

```
Type: DHCP
User Name: test1@test.com
IP Address: 172.16.200.6
IP Netmask: 255.255.255.0
Logical System: default
Routing Instance: testnet
Interface: demux0.1073741826
Interface type: Static
MAC Address: 00:00:6e:56:01:04
State: Active
Radius Accounting ID: 21
Session ID: 21
Login Time: 2011-10-20 16:24:33 EST
Service Sessions: 2
```

```
Service Session ID: 25
Service Session Name: SUB-QOS
State: Active
```

```
Service Session ID: 26
Service Session Name: service-cb-content
State: Active
IPv4 Input Filter Name: content-cb-in-demux0.1073741826-in
IPv4 Output Filter Name: content-cb-out-demux0.1073741826-out
```

- To display traffic information for firewall filters.

```
user@host> show firewall
...
Filter: content-cb-in-demux0.1073741826-in
Counters:
Name      Bytes  Packets
__junos-dyn-service-counter  84336      1004

Filter: content-cb-out-demux0.1073741826-out
Counters:
Name      Bytes  Packets
__junos-dyn-service-counter      0         0
...
```

Instead of issuing successive commands to track the details for one subscriber interface, you can choose to display detailed information for all subscribers. However, the more subscribers you have, the more tedious it becomes to look through all the results for particular items of interest.

- To display detailed information for all subscribers:

```
user@host> show subscribers detail
user@host> show subscribers extensive
```

**Meaning** The output examples in this section show increasingly detailed information about dynamically created subscriber interfaces, including how many there are, what they are, and their characteristics; how many service sessions are active and what they are; whether firewall filters are attached to the sessions and what those filters are; and how much, if any, traffic is being filtered.

In the sample output shown here, the **show subscriber** command lists all the subscriber logical interfaces, including demux0.1073741826. You then display details about that interface and its associated subscribers with the **show subscribers interface demux0.1073741826 extensive** command. The Service Session Name fields for service sessions 25 and 26 in that output show two services are active on the interface, SUB-QOS and service-cb-content. The IPv4 Input Filter Name and the IPv4 Output Filter Name fields show that two filters have been applied to the service-cb-content session: content-cb-in-demux0.1073741826-in and content-cb-out-demux0.1073741826-out. You then use the **show firewalls** command to list the filters and see how much, if any, traffic is being filtered.

## Example: Configuring Dynamic Subscriber Interfaces on IP Demux Interfaces

This example shows how to configure dynamic subscriber interfaces on IP demux interfaces. DHCP dynamically creates the demux interface when a subscriber logs in.

To configure subscribers on dynamic IP demux interfaces:

1. Configure the static VLAN as the underlying interface.

```

interfaces {
    ge-0/3/0 {
        vlan-tagging;
        unit 0 {
            vlan-id 0;
            demux-source inet;
            family inet {
                unnumbered-address lo0.0;
            }
        }
    }
    lo0 {
        unit 0 {
            family inet {
                address 90.1.1.1/24;
            }
        }
    }
}

```

2. Configure the creation of demux interfaces in the dynamic profile.

```

dynamic-profiles {
    subscriber-profile {
        interfaces {
            demux0 {
                "$junos-interface-ifd-name" {
                    unit "$junos-interface-unit" {
                        demux-options {
                            underlying-interface "$junos-underlying-interface";
                        }
                    }
                }
            }
            family inet {
                demux-source {
                    $junos-subscriber-ip-address;
                }
            }
            filter {
                input ingressFilter;
                output egressFilter;
            }
        }
    }
}

```

```

    }
    mac-validate loose;
  }
}
}
}
}
}
}
}

```

3. Configure the access method to dynamically create the demux interface.

DHCP relay is the access method used in this example.

```

forwarding-options {
  dhcp-relay {
    traceoptions {
      flag all;
    }
    server-group {
      router {
        100.20.42.1;
      }
      dynamic-profile subscriber-profile;
      active-server-group erx;
      group one {
        interface ge-0/0/2.0 upto ge-0/0/2.4000;
        interface-client-limit 200
      }
    }
  }
}

```

4. Configure the interface for DHCP.

```

interfaces {
  traceoptions {
    flag all;
  }
  ge-0/0/2 {
    unit 0 {
      demux-source inet;
      family inet {
        unnumbered-address lo0.0;
      }
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 100.20.32.2/32;
      }
    }
  }
}

```

---

This example shows how to configure a static IPv4 VLAN demux interface with gigabit Ethernet as the underlying interface. DHCP Local Server configuration enables the

association of subscribers to the VLAN demux interface by listing the gigabit Ethernet interface in the DHCP local server configuration.

To configure dynamic subscribers on VLAN demux interfaces:

1. Enable VLAN tagging on the underlying interface that you plan to use for the VLAN demux interfaces.

```
interfaces {
  ge-5/0/0 {
    vlan-tagging;
  }
}
```

2. Define the loopback interface.

```
interfaces {
  lo0 {
    unit 0 {
      family inet {
        address 192.16.1.1/32;
      }
    }
  }
}
```

3. Define the demux interface.

```
interfaces {
  demux0 {
    unit 102 {
      proxy-arp;
      vlan-id 103;
      demux-options {
        underlying-interface ge-5/0/0;
      }
      family inet {
        unnumbered-address lo0.0 preferred-source-address 173.16.1.1;
      }
    }
  }
}
```

4. Configure a dynamic profile for subscriber access.

```
dynamic-profiles {
  user-profile {
    interfaces {
      "$junos-interface-ifd-name" {
        unit "$junos-underlying-interface-unit" {
          family inet;
        }
      }
    }
  }
}
```

5. Configure the access method used to dynamically create the subscriber interfaces.

The following stanza specifies the gigabit Ethernet interface (**ge-5/0/0.0**) for use with the dynamically created subscriber interfaces.

```
system {
  services {
    dhcp-local-server {
      group myDhcpGroup {
        authentication {
          password test;
          username-include {
            user-prefix igmp-user1;
          }
        }
        dynamic-profile user-profile;
        interface ge-5/0/0.0;
      }
    }
  }
}
```

Instead of using the gigabit Ethernet interface, you can alternatively specify the specific demux interface (**demux0.102**) as the device to use with the subscriber interfaces as follows:

```
system {
  services {
    dhcp-local-server {
      group myDhcpGroup {
        authentication {
          password test;
          username-include {
            user-prefix igmp-user1;
          }
        }
        dynamic-profile user-profile;
        interface demux0.102;
      }
    }
  }
}
```

## Example: Configuring IPv4 Dynamic VLAN Demux Interfaces over a Gigabit Ethernet Underlying Interface with DHCP Local Server

---

This example shows how to configure the dynamic creation of IPv4 VLAN demux interfaces with gigabit Ethernet as the underlying interface. DHCP Local Server configuration enables the association of subscribers to the VLAN demux interface by listing the aggregated Ethernet interface in the DHCP local server configuration.

To configure dynamic subscribers on dynamic VLAN demux interfaces:

1. Enable VLAN tagging and VLAN auto-configuration on the underlying gigabit Ethernet interface that you plan to use for dynamically created VLAN demux interfaces.

```

interfaces {
  ge-5/0/0 {
    hierarchical-scheduler;
    vlan-tagging;
    auto-configure {
      vlan-ranges {
        dynamic-profile auto-vlanDemux-profile {
          accept inet;
          ranges {
            103-103;
          }
        }
      }
    }
  }
}

```

2. Define the loopback interface.

```

interfaces {
  lo0 {
    unit 0 {
      family inet {
        address 192.16.1.1/32;
      }
    }
  }
}

```

3. Configure a dynamic profile for subscriber access.

```

dynamic-profiles {
  user-profile {
    interfaces {
      "$junos-interface-ifd-name" {
        unit "$junos-underlying-interface-unit" {
          family inet;
        }
      }
    }
  }
}

```

4. Configure a dynamic profile for VLAN demux interface creation.

```

dynamic-profiles {
  auto-vlanDemux-profile {
    interfaces {
      demux0 {
        unit "$junos-interface-unit" {
          vlan-id "$junos-vlan-id";
          demux-options {
            underlying-interface "$junos-interface-ifd-name";
          }
        }
      }
    }
  }
}

```

```

    }
    family inet {
        filter {
            input rate_limit;
            output rate_limit;
        }
        unnumbered-address lo0.0 preferred-source-address 192.16.1.1;
    }
}
}
}
}
}
}
}

```

5. Configure the access method used to dynamically create the subscriber interfaces. The following stanza specifies the gigabit Ethernet interface (**ge-5/0/0.0**) for use with the dynamically created subscriber interfaces.

```

system {
  services {
    dhcp-local-server {
      group myDhcpGroup {
        authentication {
          password test;
          username-include {
            user-prefix igmp-user1;
          }
        }
        dynamic-profile user-profile;
        interface ge-5/0/0.0;
      }
    }
  }
}

```

Instead of using the gigabit Ethernet interface, you can alternatively specify **demux0** as the device to use with the subscriber interfaces as follows:

**NOTE:** Because the demux interfaces and unit numbers are created dynamically, the unit number is not specified for the demux0 interface.

```

system {
  services {
    dhcp-local-server {
      group myDhcpGroup {
        authentication {
          password test;
          username-include {
            user-prefix igmp-user1;
          }
        }
        dynamic-profile user-profile;
        interface demux0;
      }
    }
  }
}

```

```

    }
  }
}

```

## Example: Dynamic IP Demux Subscriber Interfaces over Dynamic VLAN Demux Interfaces

This example describes how to configure dynamic IP demux interfaces over dynamic VLAN demux interfaces. You can also configure dynamic IP demux interfaces over static VLAN interfaces. For information on how to configure static VLAN interfaces, see the Junos® OS Ethernet Interfaces.

- [Requirements on page 753](#)
- [Overview on page 753](#)
- [Configuration on page 753](#)
- [Verification on page 758](#)

### Requirements

Before you begin, make sure to configure either DHCP Relay or DHCP Local Server. You can find information about configuring either of these components in the Junos OS Subscriber Management, Release 12.3.

### Overview

You can create a subscriber interface using an IP demux interface stacked on a static or dynamic VLAN demux interface. IP demux interfaces are used to uniquely identify subscribers in an access network based on their IP address

#### Preparing a Subscriber Access Interface

#### CLI Quick Configuration

To quickly configure the aggregated Ethernet interface over which subscribers access the router:

```

[edit]
set chassis aggregated-devices ethernet device-count 1
set interfaces ge-5/0/9 gigether-options 802.3ad ae0
set interfaces ge-5/1/9 gigether-options 802.3ad ae0

```

```
set interfaces ae0 flexible-vlan-tagging
set interfaces ae0 auto-configure vlan-ranges dynamic-profile Auto-VLAN-Demux accept
inet
set interfaces ae0 auto-configure vlan-ranges dynamic-profile Auto-VLAN-Demux ranges
ranges 500-1000
set interfaces ae0 aggregated-ether-options lacp active
set interfaces ae0 aggregated-ether-options lacp link-protection
```

**Step-by-Step  
Procedure**

You must configure an interface over which clients initially access the router. We recommend that you specify the same VLAN tagging for the interface that you expect from incoming clients. This example uses flexible VLAN tagging to simultaneously support transmission of 802.1Q VLAN single-tag and dual-tag frames on logical interfaces on the same Ethernet port.

If you want it to automatically create dynamic VLANs, the interface must include the VLAN range type (single or stacked) and contain any specific ranges you want the VLANs to use.

To configure an interface for subscriber access:

1. Configure the number of aggregated Ethernet interfaces on the router.  

```
[edit]
user@host# set chassis aggregated-devices ethernet device-count 1
```
2. Access the physical interface over which you want subscribers to initially access the router.  

```
[edit]
user@host# edit interfaces ge-5/0/9
```
3. Specify the aggregated Ethernet interface to which the physical interface belongs.  

```
[edit interfaces ge-5/0/9]
user@host# set gigether-options 802.3ad ae0
```
4. Repeat Step 2 and Step 3 for each interface you want to assign to the aggregated Ethernet bundle.  

```
[edit]
user@host# set interfaces ge-5/1/9 gigether-options 802.3ad ae0
```
5. Access the aggregated Ethernet interface.  

```
[edit]
user@host# edit interfaces ae0
```
6. Specify the VLAN tagging that you want the aggregated Ethernet interfaces to use.  

```
[edit interfaces ae0]
user@host# set vlan-tagging
```
7. Edit the **auto-configure** stanza to automatically configure VLANs.  

```
[edit interfaces ae0]
user@host# edit auto-configure
```
8. Edit the **vlan-ranges** stanza for single-tagged VLANs.  

```
[edit interfaces ae0 auto-configure]
```

```
user@host# edit vlan-ranges
```

9. Specify the dynamic VLAN profile that you want the interface to use for dynamically creating single-tagged VLANs.

```
[edit interfaces ae0 auto-configure vlan-ranges]
user@host# edit dynamic-profile Auto-VLAN-Demux
```

10. Specify what VLAN Ethernet packet type the VLAN profile accepts.

```
[edit interfaces ae0 auto-configure vlan-ranges dynamic-profile Auto-VLAN-Demux]
user@host# set accept inet
```

11. Specify the VLAN ranges that you want the dynamic profile to use. The following example specifies a lower VLAN ID limit of 500 and an upper VLAN ID limit of 1000.

```
[edit interfaces ae0 auto-configure vlan-ranges dynamic-profile Auto-VLAN-Demux]
user@host# set ranges 500-1000
```

12. (Optional) Activate the transmission of LACP packets on the aggregated Ethernet interfaces.

```
[edit interfaces ae0]
user@host# set aggregated-ether-options lacp active
```

13. Specify that the aggregated Ethernet interfaces use link protection.

```
[edit interfaces ae0]
user@host# set aggregated-ether-options lacp link-protection
```

### Preparing the Loopback Interface

#### CLI Quick Configuration

To quickly configure the required loopback interface for this example:

```
[edit]
set interfaces lo0.0 unit 0 family inet address 100.100.100.1/32
```

#### Step-by-Step Procedure

You must configure a loopback interface for use as the unnumbered address and preferred source address for dynamically created interfaces.

To configure the required loopback interface for this example:

1. Configure a loopback interface.

```
[edit]
user@host# edit interfaces lo0.0
```

2. Specify that the loopback interface accept inet packets.

```
[edit interfaces lo0 unit 0]
user@host# edit family inet
```

3. Specify the IP address for the loopback interface.

```
[edit interfaces lo0 unit 0 family inet]
user@host# set address 100.100.100.1/32
```

### Configuring a Dynamic Profile to Dynamically Create Single-Tagged VLANs

---

**CLI Quick Configuration** To quickly configure the dynamic profile used to dynamically create single-tagged VLANs in the example:

```
[edit]
set dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit $junos-interface-unit
  demux-source inet
set dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit $junos-interface-unit
  proxy-arp
set dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit $junos-interface-unit
  vlan-id $junos-vlan-id
set dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit $junos-interface-unit
  demux options underlying-interface $junos-interface-ifd-name
set dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit $junos-interface-unit
  family inet unnumbered-address lo0.0 preferred source-address 100.100.100.1
```

**Step-by-Step Procedure** For dynamic IP demux interfaces to reside on a dynamic VLAN demux interface, the VLAN interface must first exist.

To configure a dynamic profile that automatically creates VLAN interfaces:

1. Create a dynamic profile for automatically creating single-tagged VLAN interfaces.

```
[edit]
user@host# edit dynamic-profiles Auto-VLAN-Demux
```

2. Specify that the dynamic VLAN profile use the demux interface.

```
[edit dynamic-profiles "Auto-VLAN-Demux"]
user@host# edit interfaces demux0
```

3. Specify that the dynamic profile apply the demux interface unit value to the dynamic VLANs.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0]
user@host# edit unit $junos-interface-unit
```

4. (Optional) Specify that the demux source accepts only IPv4 (inet) packets.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
 "$junos-interface-unit"]
user@host# set demux-source inet
```

5. (Optional) Specify that each dynamically created interface respond to any ARP request, as long as an active route exists to the target address of the ARP request.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
 "$junos-interface-unit"]
user@host# set proxy-arp
```

6. Specify that VLAN IDs are dynamically created.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
 "$junos-interface-unit"]
user@host# set vlan-id $junos-vlan-id
```

7. Specify the logical underlying interface for the dynamic VLANs.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# set demux-options underlying-interface $junos-interface-ifd-name
```

8. Specify that the VLAN demux interface can accept inet family packets for IPoE/DHCP subscribers.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# edit family inet
```

9. Specify the loopback address as the unnumbered address and preferred source address for the inet family.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit" family inet]
user@host# set unnumbered-address lo0.0 preferred-source-address 100.100.100.1
```

### Configuring a Dynamic Profile to Dynamically Create IP Demux Interfaces

#### CLI Quick Configuration

To quickly configure the dynamic profile used to dynamically create IP demux interfaces in the example:

```
[edit]
set dynamic-profiles DHCP-IP-Demux interfaces demux0 unit $junos-interface-unit
proxy-arp
set dynamic-profiles DHCP-IP-Demux interfaces demux0 unit $junos-interface-unit
demux-options underlying-interface $junos-underlying-interface
set dynamic-profiles DHCP-IP-Demux interfaces demux0 unit $junos-interface-unit
family inet demux-source $junos-subscriber-ip-address
set dynamic-profiles DHCP-IP-Demux interfaces demux0 unit $junos-interface-unit
family inet unnumbered-address lo0.0 preferred-source-address 100.100.100.1
```

#### Step-by-Step Procedure

To configure a dynamic profile that automatically creates IP demux interfaces:

1. Create a dynamic profile for dynamically creating IP demux interfaces.

```
[edit]
user@host# edit dynamic-profiles DHCP-IP-Demux
```

2. Specify that the dynamic profile use the demux0 interface.

```
[edit dynamic-profiles DHCP-IP-Demux]
user@host# edit interfaces demux0
```

3. Specify that the dynamic profile apply the interface unit value to the dynamic IP demux interfaces.

```
[edit dynamic-profiles DHCP-IP-Demux interfaces demux0]
user@host# edit unit $junos-interface-unit
```

4. (Optional) Configure the router to respond to any ARP request, as long as the router has an active route to the target address of the ARP request.

```
[edit dynamic-profiles DHCP-IP-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# set proxy-arp
```

5. Specify the logical underlying interface for the dynamic IP demux interfaces.

```
[edit dynamic-profiles DHCP-IP-Demux interfaces demux0 unit
 "$junos-interface-unit"]
user@host# set demux-options underlying-interface $junos-underlying-interface
```

6. Specify the protocol family information for the dynamic IP demux interfaces.

```
[edit dynamic-profiles DHCP-IP-Demux interfaces demux0 unit
 "$junos-interface-unit"]
user@host# edit family inet
```

7. Specify the demux source address is obtained from the incoming subscriber IP address.

```
[edit dynamic-profiles DHCP-IP-Demux interfaces demux0 unit "$junos-interface-unit"
 family inet]
user@host# set demux-source $junos-subscriber-ip-address
```

8. Specify the loopback interface as the unnumbered address and the demux interface IP address as the preferred source address for the dynamic IP demux interfaces.

```
[edit dynamic-profiles DHCP-IP-Demux interfaces demux0 unit "$junos-interface-unit"
 family inet]
user@host# set unnumbered-address lo0.0 preferred-source-address 100.100.100.1
```

## Verification

- [Subscriber Verification on page 758](#)
- [Interface Verification on page 758](#)

---

### Subscriber Verification

**Purpose** View subscriber information on the router.

**Action**

- To display dynamic subscriber information:  
`user@host# show subscribers detail`

---

### Interface Verification

**Purpose** View interface-specific information on the router.

**Action**

- To display interface-specific output:  
`user@host# show interfaces interface-name`

## Example: Concurrent Configuration of Dynamic DHCP IP Demux and PPPoE Demux Interfaces over the Same VLAN Demux Interface

This example shows how to configure both dynamic DHCP IP demux and PPPoE demux interfaces over the same dynamic VLAN demux interface. The example provides an IPv4 configuration. However, you can also configure concurrent IP over Ethernet/DHCP and PPPoE interfaces over the same VLAN interface using IPv6 addressing.

**NOTE:** You can also configure dynamic IP over Ethernet/DHCP and PPPoE interfaces concurrently over the same static VLAN interface. For information on how to configure static VLAN interfaces, see the Junos® OS Ethernet Interfaces.

- [Requirements on page 759](#)
- [Overview on page 759](#)
- [Configuration on page 759](#)
- [Verification on page 768](#)

### Requirements

Before you begin, make sure to configure either DHCP Relay or DHCP Local Server. You can find information about configuring either of these components in the Junos OS Subscriber Management, Release 12.3.

### Overview

With the introduction of the **family pppoe** statement, PPPoE is no longer treated as an exclusive encapsulation configuration and you can configure VLAN interfaces with multiple protocol interface stacks. For example, you can configure IP over Ethernet/DHCP and PPPoE interfaces concurrently over a single VLAN interface.

#### Preparing a Subscriber Access Interface

##### CLI Quick Configuration

To quickly configure the aggregated Ethernet interface over which subscribers access the router:

```
[edit]
set chassis aggregated-devices ethernet device-count 1
```

```
set interfaces ge-5/0/9 gigether-options 802.3ad ae0
set interfaces ge-5/1/9 gigether-options 802.3ad ae0
set interfaces ae0 flexible-vlan-tagging
set interfaces ae0 auto-configure vlan-ranges dynamic-profile Auto-VLAN-Demux accept
any
set interfaces ae0 auto-configure vlan-ranges dynamic-profile Auto-VLAN-Demux ranges
ranges 1000-1500
set interfaces ae0 auto-configure stacked-vlan-ranges dynamic-profile
Auto-Stacked-VLAN-Demux accept any
set interfaces ae0 auto-configure stacked-vlan-ranges dynamic-profile
Auto-Stacked-VLAN-Demux ranges 1501-2000,any
set interfaces ae0 aggregated-ether-options lacp active
set interfaces ae0 aggregated-ether-options lacp link-protection
```

**Step-by-Step  
Procedure**

When configuring multiple protocol interface stacks concurrently over the same VLAN interface, you must configure physical interfaces over which DHCP or PPPoE clients initially access the router. We recommend that you specify the same VLAN tagging for the interface that you expect from incoming clients. This example uses flexible VLAN tagging to simultaneously support transmission of 802.1Q VLAN single-tag and dual-tag frames on logical interfaces on the same Ethernet port.

To automatically create dynamic VLANs, the interface must also include the VLAN range type (single or stacked), dynamic profile reference, and any specific ranges you want the VLANs to use.

To configure a physical interface for subscriber access:

1. Access the physical interface over which you want subscribers to initially access the router.  

```
[edit]
user@host# edit interfaces ge-5/0/9
```
2. Specify the aggregated Ethernet interface to which the physical interface belongs.  

```
[edit interfaces ge-5/0/9]
user@host# set gigether-options 802.3ad ae0
```
3. Repeat Step 1 and Step 2 for each interface you want to assign to the aggregated Ethernet bundle.  

```
[edit]
user@host# set interfaces ge-5/1/9 gigether-options 802.3ad ae0
```
4. Access the aggregated Ethernet interface.  

```
[edit]
user@host# edit interfaces ae0
```
5. Specify the VLAN tagging that you want the aggregated Ethernet interfaces to use.  

```
[edit interfaces ae0]
user@host# set flexible-vlan-tagging
```
6. Edit the **auto-configure** stanza to automatically configure VLANs.  

```
[edit interfaces ae0]
user@host# edit auto-configure
```

7. Edit the **vlan-ranges** stanza for single-tagged VLANs.  

```
[edit interfaces ae0 auto-configure]
user@host# edit vlan-ranges
```
8. Specify the dynamic VLAN profile that you want the interface to use for dynamically creating single-tagged VLANs.  

```
[edit interfaces ae0 auto-configure vlan-ranges]
user@host# edit dynamic-profile Auto-VLAN-Demux
```
9. Specify what VLAN Ethernet packet type the VLAN profile accepts.  

```
[edit interfaces ae0 auto-configure vlan-ranges dynamic-profile Auto-VLAN-Demux]
user@host# set accept any
```
10. Specify the VLAN ranges that you want the dynamic profile to use. The following example specifies a lower VLAN ID limit of 1000 and an upper VLAN ID limit of 1500.  

```
[edit interfaces ae0 auto-configure vlan-ranges dynamic-profile Auto-VLAN-Demux]
user@host# set ranges 1000-1500
```
11. Edit the **stacked-vlan-ranges** stanza for the dual-tagged VLANs.  

```
[edit interfaces ae0 auto-configure]
user@host# edit stacked-vlan-ranges
```
12. Specify the dynamic VLAN profile that you want the interface to use for dynamically creating dual-tagged VLANs.  

```
[edit interfaces ae0 auto-configure stacked-vlan-ranges]
user@host# edit dynamic-profile Auto-Stacked-VLAN-Demux
```
13. Specify what VLAN Ethernet packet type the stacked VLAN profile accepts.  

```
[edit interfaces ae0 auto-configure stacked-vlan-ranges dynamic-profile
Auto-Stacked-VLAN-Demux]
user@host# set accept any
```
14. Specify the outer and inner stacked VLAN ranges that you want the dynamic profile to use. The following example specifies an outer stacked VLAN ID range from 1501 through 2000 (to avoid overlapping VLAN IDs with single-tag VLANs) and an inner stacked VLAN ID range of any (enabling a range from 1 through 4094 for the inner stacked VLAN ID).  

```
[edit interfaces ge-5/0/9 auto-configure stacked-vlan-ranges dynamic-profile
Auto-Stacked-VLAN-Demux]
user@host# set ranges 1501-2000,any
```
15. (Optional) Activate the transmission of LACP packets on the aggregated Ethernet interfaces.  

```
[edit interfaces ae0]
user@host# set aggregated-ether-options lacp active
```
16. Specify that the aggregated Ethernet interfaces use link protection.  

```
[edit interfaces ae0]
user@host# set aggregated-ether-options link-protection
```

### Preparing the Loopback Interface

---

- CLI Quick Configuration** To quickly configure the required loopback interface for this example:
- ```
[edit]
set interfaces lo0.0 unit 0 family inet address 100.100.100.1/32
```
- Step-by-Step Procedure** You must configure a loopback interface for use as the unnumbered address and preferred source address for dynamically created interfaces.
- To configure the required loopback interface for this example:
1. Configure a loopback interface.  

```
[edit]
user@host# edit interfaces lo0.0
```
  2. Specify that the loopback interface accept inet packets.  

```
[edit interfaces lo0 unit 0]
user@host# edit family inet
```
  3. Specify the IP address for the loopback interface.  

```
[edit interfaces lo0 unit 0 family inet]
user@host# set address 100.100.100.1/32
```

### Configuring a Dynamic Profile to Create Dynamic Single-Tagged VLANs

---

- CLI Quick Configuration** To quickly configure the dynamic profile used to dynamically create single-tagged VLANs in the example:
- ```
[edit]
set dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit $junos-interface-unit
  demux-source inet
set dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit $junos-interface-unit
  proxy-arp
set dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit $junos-interface-unit
  vlan-id $junos-vlan-id
set dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit $junos-interface-unit
  demux options underlying-interface $junos-interface-ifd-name
set dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit $junos-interface-unit
  family inet unnumbered-address lo0.0 preferred source-address 100.100.100.1
set dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit $junos-interface-unit
  family pppoe duplicate-protection
set dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit $junos-interface-unit
  family pppoe dynamic-profile PPP-Base-PAP
```
- Step-by-Step Procedure** For both dynamic DHCP IP demux and dynamic PPPoE interfaces to reside concurrently on a single-tagged VLAN interface, the VLAN interface must first exist.
- To configure a dynamic profile that automatically creates VLAN interfaces:
1. Create a dynamic profile for automatically creating VLAN interfaces.  

```
[edit]
```

```
user@host# edit dynamic-profiles Auto-VLAN-Demux
```

2. Specify that the dynamic VLAN profile use the demux interface.

```
[edit dynamic-profiles "Auto-VLAN-Demux"]
user@host# edit interfaces demux0
```

3. Specify that the dynamic profile apply the demux interface unit value to the dynamic VLANs.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0]
user@host# edit unit $junos-interface-unit
```

4. Specify that the demux source accept IPv4 (inet) packets.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# set demux-source inet
```

5. (Optional) Specify that each dynamically created interface respond to any ARP request, as long as an active route exists to the target address of the ARP request.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# set proxy-arp
```

6. Specify that VLAN IDs are dynamically created.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# set vlan-id $junos-vlan-id
```

7. Specify the logical underlying interface for the dynamic VLANs.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# set demux-options underlying-interface $junos-interface-ifd-name
```

8. Specify that the VLAN demux interface can accept inet family packets for IP over Ethernet/DHCP subscribers.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# edit family inet
```

9. Specify the loopback address as the unnumbered address and preferred source address for the inet family.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit" family inet]
user@host# set unnumbered-address lo0.0 preferred-source-address 100.100.100.1
```

10. Specify that the VLAN demux interface can accept pppoe family packets for PPPoE subscribers.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# edit family pppoe
```

11. Prevent multiple PPPoE sessions from being created for the same PPPoE subscriber on the same VLAN interface.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
 "$junos-interface-unit" family pppoe]
user@host# set duplicate-protection
```

12. Apply the dynamic PPP interface profile to any dynamic PPP interfaces.

```
[edit dynamic-profiles Auto-VLAN-Demux interfaces demux0 unit
 "$junos-interface-unit" family pppoe]
user@host# set dynamic-profile PPP-Base-PAP
```

### Configuring a Dynamic Profile to Create Dynamic Dual-Tagged VLANs

**CLI Quick Configuration** To quickly configure the dynamic profile used to dynamically create stacked/dual-tagged VLANs in the example:

```
[edit]
set dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
 $junos-interface-unit demux-source inet
set dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
 $junos-interface-unit proxy-arp
set dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
 $junos-interface-unit vlan-tags outer $junos-stacked-vlan-id
set dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
 $junos-interface-unit vlan-tags inner $junos-vlan-id
set dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
 $junos-interface-unit demux options underlying-interface $junos-interface-ifd-name
set dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
 $junos-interface-unit family inet unnumbered-address lo0.0 preferred source-address
 100.100.100.1
set dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
 $junos-interface-unit family pppoe duplicate-protection
set dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
 $junos-interface-unit family pppoe dynamic-profile PPP-Base-PAP
```

**Step-by-Step Procedure** For both dynamic DHCP IP demux and dynamic PPPoE interfaces to reside concurrently on a VLAN interface, the VLAN interface must first exist.

To configure a dynamic profile that automatically creates stacked/dual-tagged VLAN interfaces:

1. Create a dynamic profile for automatically creating VLAN interfaces.

```
[edit]
user@host# edit dynamic-profiles Auto-Stacked-VLAN-Demux
```

2. Specify that the dynamic VLAN profile use the demux interface.

```
[edit dynamic-profiles "Auto-Stacked-VLAN-Demux"]
user@host# edit interfaces demux0
```

3. Specify that the dynamic profile apply the demux interface unit value to the dynamic VLANs.

```
[edit dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0]
user@host# edit unit $junos-interface-unit
```

4. Specify that the demux source accept IPv4 (inet) packets.

- ```
[edit dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# set demux-source inet
```
5. (Optional) Specify that each dynamically created interface respond to any ARP request, as long as an active route exists to the target address of the ARP request.

```
[edit dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# set proxy-arp
```
  6. Specify that the outer VLAN ID is dynamically created.

```
[edit dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# set vlan-id -tags outer $junos-stacked-vlan-id
```
  7. Specify that the inner VLAN ID is dynamically created.

```
[edit dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# set vlan-id -tags inner $junos-vlan-id
```
  8. Specify the logical underlying interface for the dynamic VLANs.

```
[edit dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# set demux-options underlying-interface $junos-interface-ifd-name
```
  9. Specify that the VLAN demux interface can accept inet family packets for IP over Ethernet/DHCP subscribers.

```
[edit dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# edit family inet
```
  10. Specify the loopback address as the unnumbered address and preferred source address for the inet family.

```
[edit dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit" family inet]
user@host# set unnumbered-address lo0.0 preferred-source-address 100.100.100.1
```
  11. Specify that the VLAN demux interface can accept pppoe family packets for PPPoE subscribers.

```
[edit dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# edit family pppoe
```
  12. Prevent the activation of another dynamic PPPoE logical interface on the same demux underlying interface.

```
[edit dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit" family pppoe]
user@host# set duplicate-protection
```
  13. Apply the dynamic PPP interface profile to any dynamic PPP interfaces.

```
[edit dynamic-profiles Auto-Stacked-VLAN-Demux interfaces demux0 unit
"$junos-interface-unit" family pppoe]
user@host# set dynamic-profile PPP-Base-PAP
```

### Configuring a Dynamic Profile to Create Dynamic IP Demux Interfaces

---

- CLI Quick Configuration** To quickly configure the dynamic profile used to dynamically create DHCP IP demux interfaces in the example:
- ```
[edit]
set dynamic-profiles DHCP-IP-Demux interfaces demux0 unit $junos-interface-unit
  proxy-arp
set dynamic-profiles DHCP-IP-Demux interfaces demux0 unit $junos-interface-unit
  demux-options underlying-interface $junos-underlying-interface
set dynamic-profiles DHCP-IP-Demux interfaces demux0 unit $junos-interface-unit
  family inet demux-source $junos-subscriber-ip-address
set dynamic-profiles DHCP-IP-Demux interfaces demux0 unit $junos-interface-unit
  family inet unnumbered-address lo0.0 preferred-source-address 100.100.100.1
```
- Step-by-Step Procedure** To configure a dynamic profile that automatically creates IP demux interfaces:
1. Create a dynamic profile for dynamically creating IP demux interfaces.  

```
[edit]
user@host# edit dynamic-profiles DHCP-IP-Demux
```
  2. Specify that the dynamic profile use the demux0 interface.  

```
[edit dynamic-profiles DHCP-IP-Demux]
user@host# edit interfaces demux0
```
  3. Specify that the dynamic profile apply the interface unit value to the dynamic PPPoE interfaces.  

```
[edit dynamic-profiles DHCP-IP-Demux interfaces demux0]
user@host# edit unit $junos-interface-unit
```
  4. (Optional) Configure the router to respond to any ARP request, as long as the router has an active route to the target address of the ARP request.  

```
[edit dynamic-profiles DHCP-IP-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# set proxy-arp
```
  5. Specify the logical underlying interface for the dynamic IP demux interfaces.  

```
[edit dynamic-profiles DHCP-IP-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# set demux-options underlying-interface $junos-underlying-interface
```
  6. Specify the protocol family information for the dynamic IP demux interfaces.  

```
[edit dynamic-profiles DHCP-IP-Demux interfaces demux0 unit
"$junos-interface-unit"]
user@host# edit family inet
```
  7. Specify the demux source address is obtained from the incoming subscriber IP address.  

```
[edit dynamic-profiles DHCP-IP-Demux interfaces demux0 unit "$junos-interface-unit"
family inet]
user@host# set demux-source $junos-subscriber-ip-address
```

8. Specify the loopback interface as the unnumbered address and the demux interface IP address as the preferred source address for the dynamic IP demux interfaces.

```
[edit dynamic-profiles DHCP-IP-Demux interfaces demux0 unit "$junos-interface-unit"
family inet]
user@host# set unnumbered-address lo0.0 preferred-source-address 100.100.100.1
```

### Configuring a Dynamic Profile to Create Dynamic PPPoE Interfaces

#### CLI Quick Configuration

To quickly configure the dynamic profile used to dynamically create PPPoE interfaces in the example:

```
[edit]
set dynamic-profiles PPP-Base-PAP interfaces pp0 unit $junos-interface-unit ppp-options
pap
set dynamic-profiles PPP-Base-PAP interfaces pp0 unit $junos-interface-unit
pppoe-options underlying-interface $junos-underlying-interface server
set dynamic-profiles PPP-Base-PAP interfaces pp0 unit $junos-interface-unit
no-keepalives
set dynamic-profiles PPP-Base-PAP interfaces pp0 unit $junos-interface-unit family inet
unnumbered-address lo0.0
```

#### Step-by-Step Procedure

1. Create a dynamic profile for automatically creating PPPoE interfaces.
 

```
[edit]
user@host# edit dynamic-profiles PPP-Base-PAP
```
2. Specify that the dynamic PPPoE profile use the pp0 interface.
 

```
[edit dynamic-profiles PPP-Base-PAP]
user@host# edit interfaces pp0
```
3. Specify that the dynamic profile apply the interface unit value to the dynamic PPPoE interfaces.
 

```
[edit dynamic-profiles PPP-Base-PAP interfaces pp0]
user@host# edit unit $junos-interface-unit
```
4. Specify that dynamically created PPPoE interfaces use PAP authentication.
 

```
[edit dynamic-profiles PPP-Base-PAP interfaces pp0 unit "$junos-interface-unit"]
user@host# set ppp-options pap
```
5. Specify the logical underlying interface for the dynamic PPPoE interfaces.
 

```
user@host# set ppp-options pap

[edit dynamic-profiles PPP-Base-PAP interfaces pp0 unit "$junos-interface-unit"]
user@host# set pppoe-options underlying-interface $junos-underlying-interface
```
6. Specify that the router act as a PPPoE server.
 

```
[edit dynamic-profiles PPP-Base-PAP interfaces pp0 unit "$junos-interface-unit"]
user@host# set pppoe-options server
```
7. (Optional) Disable the sending of keepalive messages on the dynamic PPPoE interfaces.
 

```
[edit dynamic-profiles PPP-Base-PAP interfaces pp0 unit "$junos-interface-unit"]
user@host# set no-keepalives
```

8. Specify the protocol family information for the dynamic PPPoE interfaces.  
`[edit dynamic-profiles PPP-Base-PAP interfaces pp0 unit "$junos-interface-unit"]  
user@host# edit family inet`
9. Specify the loopback interface as the unnumbered address for the dynamic PPPoE interfaces.  
`[edit dynamic-profiles PPP-Base-PAP interfaces pp0 unit "$junos-interface-unit"]  
user@host# set unnumbered-address lo0.0`

## Verification

- [Subscriber Verification on page 768](#)
- [Interface Verification on page 768](#)

---

### Subscriber Verification

**Purpose** View subscriber information on the router.

- Action**
- To display dynamic subscriber information:  
`user@host# show subscribers detail`

---

### Interface Verification

**Purpose** View interface-specific information on the router.

- Action**
- To display interface-specific output:  
`user@host# show interfaces interface-name`

## Example: Configuring CoS on Static LSQ MLPPP Bundle Interfaces

This example shows how to configure dynamic subscriber services on MLPPP bundle interfaces. The MLPPP bundles must be configured on link services intelligent queuing (IQ) (LSQ) interfaces. The MLPPP interfaces must be statically configured.

To configure dynamic subscriber services on static LSQ MLPPP bundle interfaces:

1. Configure class of service features for the LSQ interfaces.

```
[edit]
class-of-service
classifiers {
  inet-precedence inet_classifier {
    forwarding-class best-effort {
      loss-priority low code-points 000;
    }
    forwarding-class expedited-forwarding {
      loss-priority low code-points 011;
    }
    forwarding-class assured-forwarding {
      loss-priority low code-points 100;
    }
  }
}
fragmentation-maps {
  sample-fragmap {
    forwarding-class {
      best-effort {
        fragment-threshold 1000;
        multilink-class 1;
      }
      assured-forwarding {
        fragment-threshold 1000;
        multilink-class 2;
      }
      expedited-forwarding {
        multilink-class 3;
      }
    }
  }
}
forwarding-classes {
  queue 0 best-effort;
  queue 1 expedited-forwarding;
  queue 2 assured-forwarding;
}
# traffic classifiers are statically defined
network traffic interface{
  classifiers {
    inet-precedence inet_classifier;
  }
}
scheduler-maps {
  allthree {
    forwarding-class best-effort scheduler be-scheduler;
    forwarding-class expedited-forwarding scheduler hiprior-sched;
    forwarding-class assured-forwarding scheduler vpn-sched;
  }
}
schedulers {
  be-scheduler {
```

```
        transmit-rate percent 30;
        priority low;
    }
    hprior-scheduler {
        transmit-rate percent 40;
        priority strict-high;
    }
    vpn-sched {
        transmit-rate percent 30;
        medium-high;
    }
}
}
```

2. Configure the MLPPP bundle interfaces and the LSQ interfaces.

```
[edit interfaces]
t1-3/1/0:1:1 {
    keepalives interval 600;
    encapsulation ppp;
    unit 0 {
        ppp-options {
            lcp-restart-timer 5000;
        }
        family mlppp {
            bundle lsq-3/3/0.0;
        }
    }
}
t1-3/1/0:1:2 {
    keepalives interval 600;
    encapsulation ppp;
    unit 0 {
        ppp-options {
            lcp-restart-timer 5000;
        }
        family mlppp {
            bundle lsq-3/3/0.0;
        }
    }
}
lsq-3/3/0 {
    unit 0 {
        encapsulation multilink-ppp;
        multilink-max-classes 4;
        ppp-options {
            ncp-restart-timer 10000;
            dynamic-profile mlppp-profile;
        }
        family inet {
            address 192.168.1.1/32 {
                destination 192.168.25.45;
            }
        }
    }
}
```

3. Configure the dynamic profile that is applied to the MLPPP bundle interfaces.

```
[edit]
dynamic-profiles {
  mlppp-profile {
    interfaces {
      "$junos-interface-ifd-name" {
        unit junos-underlying-interface-unit {
          family inet {
            filter {
              input "$junos-input-filter";
              output "$junos-output-filter";
            }
          }
        }
      }
    }
  }
  class-of-service {
    interfaces {
      "$junos-interface-ifd-name" {
        unit junos-underlying-interface-unit {
          output-traffic-control-profile tcp1;
          fragmentation-map sample-fragmap;
        }
      }
    }
  }
  traffic-control-profiles {
    tcp1 {
      scheduler-map "junos-cos-scheduler-map";
      shaping-rate "$junos-cos-shaping-rate";
      guaranteed-rate "$junos-cos-guaranteed-rate";
      delay-buffer-rate "$junos-cos-delay-buffer-rate";
    }
  }
  scheduler-maps {
    data_smap {
      forwarding-class be scheduler data_sch;
    }
  }
  schedulers {
    be_sch {
      ...
    }
  }
}
}
```

## Static and Dynamic VLAN Subscriber Interfaces over Aggregated Ethernet Overview

You can configure a subscriber interface represented by a static virtual LAN (VLAN) stacked on a two-link aggregated Ethernet logical interface. You must configure the aggregated Ethernet logical interface on Enhanced Queuing Dense Port Concentrators (EQ DPCs) or MPC/MIC interfaces in MX Series 3D Universal Edge Routers.

A static or dynamic VLAN subscriber interface over aggregated Ethernet can also support one-to-one active/backup link redundancy, depending on how you configure the underlying aggregated Ethernet interface.

To configure a static or dynamic VLAN subscriber interface over aggregated Ethernet, make sure you understand the following concepts.

- [Guidelines for Configuring an Aggregated Ethernet Logical Interface to Support a Static or Dynamic VLAN Subscriber Interface on page 773](#)

## **Guidelines for Configuring an Aggregated Ethernet Logical Interface to Support a Static or Dynamic VLAN Subscriber Interface**

The following guidelines for configuring an aggregated Ethernet logical interface also apply to configuring a static or dynamic VLAN subscriber interface stacked on a two-link aggregated Ethernet logical interface:

- If you need to support one-to-one active/backup link redundancy, configure the aggregated Ethernet interface in link protection mode, which requires that the two underlying physical interfaces be designated as primary and backup links.

- In addition, if you need to support one-to-one active/backup link redundancy at the DPC or MPC level, configure the aggregated Ethernet interface on physical interfaces that reside on different EQ DPCs or MPCs.

**NOTE:** One-to-one active/backup DPC redundancy is also supported with firewall filters and policy filters for static non-VLAN interfaces configured on an aggregated Ethernet logical interfaces, provided LACP is not active.

## Static or Dynamic Demux Subscriber Interfaces over Aggregated Ethernet Overview

You can configure a subscriber interface using a static or dynamic demux interface stacked on an aggregated Ethernet logical interface. Subscriber interfaces on static or dynamic demux interfaces can be used to identify specific subscribers (authenticated users) in an access network or to separate individual circuits. A subscriber interface on a static or dynamic demux interface over aggregated Ethernet can support one-to-one active/backup link redundancy or traffic load balancing, depending on how you configure the underlying aggregated Ethernet interface.

To configure a static or dynamic demux subscriber interface over aggregated Ethernet, make sure you understand the following concepts:

- [Options for Aggregated Ethernet Logical Interfaces That Support Demux Subscriber Interfaces on page 774](#)
- [Hardware Requirements with Static or Dynamic Demux Subscriber Interfaces over Aggregated Ethernet on page 775](#)
- [Features Supported with Static or Dynamic Demux Subscriber Interfaces over Aggregated Ethernet on page 775](#)

### Options for Aggregated Ethernet Logical Interfaces That Support Demux Subscriber Interfaces

Traffic forwarding through a demux logical interface is dependent on the configuration of the underlying interface. Using an aggregated Ethernet interface as the underlying interface for a static or dynamic demux subscriber interface provides you with the following options:

- **1:1 Active/Backup Link Redundancy**—If you need to support one-to-one active/backup link redundancy, configure the aggregated Ethernet interface in link protection mode,

which requires that two underlying physical interfaces be designated as primary and backup links. In addition, if you need to support one-to-one active/backup link redundancy at the line card level, configure the aggregated Ethernet interface on physical interfaces that reside either on different EQ DPCs or on different MPCs. When using LACP link protection, you can configure only two member links to an aggregated Ethernet interface: one active and one standby.

- **Load Balancing**—You can configure load balancing instead of 1:1 active/backup link redundancy. The Junos OS implementation of the IEEE 802.3ad standard balances traffic across the member links within an aggregated Ethernet bundle based on the Layer 3 information carried in the packet.

By default, the system supports hash-based distribution in load balancing scenarios. In this model, traffic for a logical interface can be distributed over multiple links in the aggregated Ethernet interface. If distribution flows are not even, egress CoS scheduling can be inaccurate. In addition, scheduler resources are required on every link of the aggregated Ethernet interface.

Targeted distribution enables you to target the egress traffic for IP and VLAN demux subscribers on a single member link, using a single scheduler resource. The system distributes the subscriber interfaces equally among the member links.

## Hardware Requirements with Static or Dynamic Demux Subscriber Interfaces over Aggregated Ethernet

IP demux subscriber interfaces over aggregated Ethernet interfaces are supported on EQ DPCs on MX Series routers.

VLAN demux subscriber interfaces over aggregated Ethernet interfaces are supported on MX Series routers that only have MPCs installed. If the router has other line cards in addition to MPCs, the CLI accepts the configuration but errors are reported when the subscriber interfaces are brought up.

## Features Supported with Static or Dynamic Demux Subscriber Interfaces over Aggregated Ethernet

Table 68 on page 776 lists key subscriber access features supported with static or dynamic demux subscriber interfaces, organized by type of underlying interface:

- Aggregated Ethernet
- Non-aggregated Ethernet (Gigabit Ethernet, Fast Ethernet, or 10-Gigabit Ethernet)

There are no feature limitations specific to demultiplexing. Instead, demux interfaces over aggregated Ethernet are subject to the same scaling and configuration limitations inherent to aggregated Ethernet logical interfaces.

Table 68: Features Supported with Static or Dynamic Demux Subscriber Interfaces

Feature	Static or Dynamic Demux Subscriber Interface	
	Aggregated Ethernet Underlying Interface	Non-aggregated Underlying Logical Interface
Protocol family support	IPv4, IPv6, and PPPoE	IPv4, IPv6, and PPPoE
Per-subscriber firewall filtering and statistics	Supported	Supported
Hierarchical CoS	Supported	Supported
Per-subscriber CoS parameters within the <b>[edit dynamic-profiles <i>profile-name</i> class-of-service]</b> hierarchy	Supported	Supported
Per-subscriber IGMP configuration within the <b>[edit dynamic-profiles <i>profile-name</i> protocols]</b> hierarchy	Yes	Yes

**NOTE:** IP demux interfaces must use OIF mapping. See Example: Configuring Multicast with Subscriber VLANs in the Multicast Protocols Configuration Guide for additional information.

## Distribution of Demux Subscribers in an Aggregated Ethernet Interface

This topic describes the distribution options available for demux subscriber interfaces over aggregated Ethernet.

### Distribution Models

By default, the system supports hash-based distribution for all subscriber interface types in an aggregated Ethernet bundle configured without link protection. In this model, traffic for a logical interface can be distributed over multiple links in the bundle. This model is desirable when there are many flows through the logical interface and you need to load balance those flows.

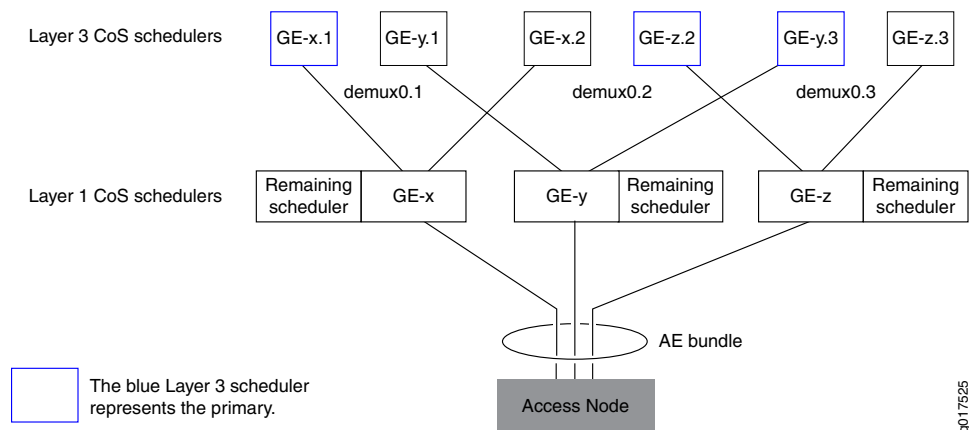

Note that if the distribution flows are not even, egress CoS scheduling can be inaccurate. In addition, scheduler resources are required on every link of the aggregated Ethernet interface. For example, if subscriber traffic is allocated 10 MB for a triple-play service over four links in a bundle, each of the links could receive 2.5 MB of traffic. High-density services such as video could be limited by the bandwidth on one of the links.

Targeted distribution enables you to target the egress traffic for an IP or VLAN demux subscriber on a single member link, using a single scheduler resource. To achieve load balancing over the member links, the system distributes the subscriber interfaces equally among the links. This enables the subscriber that is allocated 10 MB to be accurately scheduled as the traffic flows through.

### Sample Targeted Distribution Topology

Figure 13 on page 777 displays a sample targeted distribution of subscriber traffic across links in an aggregated Ethernet interface. A primary and backup link is allocated for each subscriber.

Figure 13: Targeted Subscriber Links

For example, if link **GE-x** went down, subscriber 1 can begin forwarding over the backup, which is link **GE-y**. When link **GE-y** comes back up, subscriber 1 switches back to its primary link, **GE-x**.

In the event that both **GE-x** and **GE-y** go down, subscriber 3 starts forwarding through its backup, **GE-z**. Subscriber 1 will have lost its primary and backup links, and will also begin forwarding out the **GE-z** link. A new level 3 scheduler is assigned for this subscriber on link **GE-z**. If there is a momentary lapse between the time that a new scheduler is allocated and forwarding switches to **GE-z**, the traffic will be forwarding through to the remaining scheduler. Subscriber 2 continues to forward through its primary link, **GE-z**.

### Redundancy and Redistribution Mechanisms

Two types of redundancy are available in the targeted distribution model: link redundancy and module redundancy.

By default, an aggregated Ethernet interface is enabled with link redundancy. Backup links for a subscriber are chosen based on the link with the least number of subscribers, which provides redundancy if a link fails.

The module redundancy option enables you to provide redundancy if a module or a link fails. Backup links for a subscriber are chosen on a different DPC or MPC from the primary link, based on the link with the least number of subscribers among the links on different modules. You can enable this for the aggregated Ethernet interface.

When links are removed, affected subscribers are redistributed among the active remaining backup links. When links are added to the system, no automatic redistribution occurs. New subscribers are assigned to the links with the fewest subscribers (which are typically the new links).

## Considerations and Best Practices

Keep the following guidelines in mind when configuring targeted distribution for demux subscribers:

- You can manage subscribers with both hash-based and targeted distribution models in the same network. For example, you can allocate subscribers with interface types such as PPPoE with hash-based distribution, and enable demux subscribers with targeted distribution.
- We recommend that you configure module redundancy to protect against module failures. When module redundancy is enabled, you can ensure an even distribution of subscribers if you allocate no more than 50 percent of the links on a single DPC or MPC.
- During normal network operations, the system maintains an even balance of subscribers among the links in a bundle, even as subscribers log in and out. However, if the distribution of a bundle becomes uneven (for example, when a link goes down and new subscribers are logging in), you can perform a manual rebalance of the bundle. In addition, you can configure periodic rebalancing of the bundle with a specific time interval.
- When you anticipate that a link will be down for an extended time, and you want to ensure that backup links are provisioned for all subscribers, we recommend that you remove the failed link from the bundle. This forces the affected subscribers to redistribute to other links.
- We recommend that you apply a remaining traffic-control profile to the logical interface to ensure that minimal scheduling parameters are applied to the remaining subscriber traffic. This provides scheduling for subscribers that do not have schedulers allocated because they have not been configured or they have been over-provisioned, or because of scheduler transitions on multiple link failures.
- If you perform a cold restart on the router when it is forwarding active subscribers, the subscriber interfaces with targeted distribution are assigned to the first links that become available when the system is initializing so forwarding can begin. To rebalance the system following a cold restart, perform a manual rebalance of the bundle. In addition, we recommend that you configure Graceful Routing Engine switchover (GRES) on the router to enable nonstop forwarding during switchover, and avoid performing cold restarts.

- To ensure appropriate and predictable targeted distribution, you must configure chassis network services to use **enhanced-ip** mode.
- Unless specifically separated, multicast traffic egresses in parallel with unicast traffic, sharing the CoS hierarchy and aggregated Ethernet flow distribution.

## Configuring a Static or Dynamic VLAN Subscriber Interface over Aggregated Ethernet

You can configure a subscriber link represented by a static virtual LAN (VLAN) stacked on an aggregated Ethernet logical interface.

You can configure subscriber management services such as firewall filters and CoS for this subscriber interface.

To configure a subscriber interface using a static VLAN interface over an aggregated Ethernet logical interface:

1. Configure the aggregated Ethernet interface.
  - a. Configure the number of aggregated Ethernet interfaces on the router.  
See [Configuring the Number of Aggregated Ethernet Interfaces on the Device](#).
  - b. Configure the aggregated Ethernet interface.  
See [Configuring an Aggregated Ethernet Interface](#).
  - c. (Optional) Configure LACP.  
See [Configuring Aggregated Ethernet LACP](#).
  - d. (Optional) Configure the minimum number of links.  
See [Configuring Aggregated Ethernet Minimum Links](#).
  - e. (Optional) Configure the link speed.  
See [Configuring Aggregated Ethernet Link Speed](#).
  - f. (Optional) Configure the aggregated Ethernet logical interface to support one-to-one active/backup link redundancy or traffic load balancing.  
See [Configuring Aggregated Ethernet Link Protection](#).

**NOTE:** Link protection is required if you want to configure hierarchical CoS on the aggregated Ethernet interface. For more information, see [“Configuring Hierarchical CoS for a Subscriber Interface of Aggregated Ethernet Links” on page 969](#).

2. Configure the static or dynamic VLAN interface.
  - For static VLAN interfaces, see [“Configuring a Subscriber Interface with a Static VLAN Interface” on page 724](#).
  - For dynamic VLAN interfaces, see [“Configuring VLAN Dynamic Profiles” on page 673](#) and [“Configuring VLAN Interfaces to Use Dynamic Profiles” on page 680](#).
3. Configure subscriber management services on the subscriber interface.

- For firewall filters, see [“Dynamically Attaching Statically Created Filters for Any Interface Type” on page 1114](#) or [“Dynamically Attaching Statically Created Filters for a Specific Interface Family Type” on page 1113](#).
- For hierarchical CoS, see [“Configuring Hierarchical CoS for a Subscriber Interface of Aggregated Ethernet Links” on page 969](#).

**Related Documentation**

## Configuring a Static or Dynamic IP Demux Subscriber Interface over Aggregated Ethernet

---

You can configure a subscriber interface using a static or dynamic IP demultiplexing (demux) logical interface stacked on an aggregated Ethernet logical interface. Optionally, you can configure the aggregated Ethernet logical interface to support one-to-one active/backup link redundancy or traffic load balancing.

1. Configure the aggregated Ethernet interface.
  - a. Configure the number of aggregated Ethernet interfaces on the router.  
See [Configuring the Number of Aggregated Ethernet Interfaces on the Device](#).
  - b. Configure the aggregated Ethernet interface.  
See [Configuring an Aggregated Ethernet Interface](#).
  - c. (Optional) Configure LACP.  
See [Configuring Aggregated Ethernet LACP](#).
  - d. (Optional) Configure the minimum number of links.  
See [Configuring Aggregated Ethernet Minimum Links](#).
  - e. (Optional) Configure the link speed.  
See [Configuring Aggregated Ethernet Link Speed](#).
  - f. (Optional) Configure the aggregated Ethernet logical interface to support one-to-one active/backup link redundancy or traffic load balancing.  
For general instructions, see [Configuring Aggregated Ethernet Link Protection](#).

**NOTE:** Link protection is required if you want to configure hierarchical CoS on the aggregated Ethernet interface. For more information, see [“Configuring Hierarchical CoS for a Subscriber Interface of Aggregated Ethernet Links” on page 969](#).

2. Configure the aggregated Ethernet logical interface as the underlying interface to support the static or dynamic IP demux subscriber interface.

The aggregated Ethernet interface needs to support demultiplexing of incoming traffic to the Ethernet links based on IPv4 destination or source addresses in the incoming packets. In addition, you must configure the IP address of each link.

See [Configuring an IP Demux Underlying Interface](#).

3. Configure the static or dynamic IP demux interface.
  - For static subscriber interfaces, see [“Configuring Static Subscriber Interfaces Using IP Demux Interfaces” on page 724](#).
  - For dynamic subscriber interfaces, see [“Configuring Dynamic Subscriber Interfaces Using IP Demux Interfaces in Dynamic Profiles” on page 729](#).

**NOTE:** IP demux interfaces currently support only the Internet Protocol version 4 (IPv4) suite (`family inet`).

4. (Optional) Configure subscriber management services on the subscriber interface.
  - For firewall filters, see [“Dynamically Attaching Statically Created Filters for Any Interface Type” on page 1114](#) or [“Dynamically Attaching Statically Created Filters for a Specific Interface Family Type” on page 1113](#).
  - For hierarchical CoS, see [“Configuring Hierarchical CoS for a Subscriber Interface of Aggregated Ethernet Links” on page 969](#).

**Related Documentation**

---

## Configuring a Static or Dynamic VLAN Demux Subscriber Interface over Aggregated Ethernet

---

You can configure a subscriber interface using a static or dynamic VLAN demultiplexing (demux) logical interface stacked on an aggregated Ethernet physical interface.

1. Configure the aggregated Ethernet interface.
  - a. Configure the number of aggregated Ethernet interfaces on the router.  
See [Configuring the Number of Aggregated Ethernet Interfaces on the Device](#).
  - b. Configure the aggregated Ethernet interface.  
See [Configuring an Aggregated Ethernet Interface](#).
  - c. (Optional) Configure LACP.  
See [Configuring Aggregated Ethernet LACP](#).
  - d. (Optional) Configure the minimum number of links.  
See [Configuring Aggregated Ethernet Minimum Links](#).
  - e. (Optional) Configure the link speed.  
See [Configuring Aggregated Ethernet Link Speed](#).
  - f. (Optional) Configure the aggregated Ethernet logical interface to support one-to-one active/backup link redundancy or traffic load balancing.  
For general instructions, see [Configuring Aggregated Ethernet Link Protection](#).

2. Configure the aggregated Ethernet physical interface as the underlying interface to support the static or dynamic VLAN demux subscriber interface.

The aggregated Ethernet interface needs to support demultiplexing of incoming traffic to the Ethernet links based on the VLAN ID in the incoming packets.

See [Configuring a VLAN Demux Underlying Interface](#).

3. Configure the static or dynamic VLAN demux interface.
  - For static subscriber interfaces, see [“Configuring Static Subscriber Interfaces Using VLAN Demux Interfaces” on page 725](#).
  - For dynamic subscriber interfaces, see [“Configuring Dynamic Subscriber Interfaces Using VLAN Demux Interfaces in Dynamic Profiles” on page 730](#).

**NOTE:** VLAN demux interfaces currently support the Internet Protocol version 4 (IPv4) suite (family inet) and the Internet Protocol version 6 (IPv6) suite (family inet6).

VLAN demux subscriber interfaces over aggregated Ethernet physical interfaces are supported only for MX Series routers that have only MPCs installed. If the router has other cards in addition to MPCs, the CLI accepts the configuration but errors are reported when the subscriber interfaces are brought up.

---

4. (Optional) Configure subscriber management services on the subscriber interface.

- For firewall filters, see [“Dynamically Attaching Statically Created Filters for Any Interface Type” on page 1114](#) or [“Dynamically Attaching Statically Created Filters for a Specific Interface Family Type” on page 1113](#).
- For hierarchical CoS, see [“Configuring Hierarchical CoS for a Subscriber Interface of Aggregated Ethernet Links” on page 969](#).

---

## Configuring the Distribution Type for Demux Subscribers on Aggregated Ethernet Interfaces

---

By default, the system supports hash-based distribution of subscriber traffic in aggregated Ethernet bundles. You can configure the system to target the egress traffic for a subscriber on a single member link, using a single scheduler resource. The system distributes the subscriber interfaces equally among the member links.

To configure targeted distribution:

1. Edit the chassis hierarchy level.

```
[edit]
user@host#edit chassis
```

2. Enable chassis network services for **enhanced-ip** mode.

```
[edit chassis]
user@host#set network-services enhanced-ip
```

3. Access the logical interface.

```
[edit]
user@host#edit interfaces demux0 unit logical-unit-number
```

4. Enable targeted distribution for the interface.

```
[edit interfaces demux0 unit logical-unit-number]
user@host#set targeted-distribution
```

- Related Documentation**

  - [Distribution of Demux Subscribers in an Aggregated Ethernet Interface on page 776](#)

## Configuring Link and Module Redundancy for Demux Subscribers in an Aggregated Ethernet Interface

---

By default, an aggregated Ethernet bundle with targeted distribution is enabled with link redundancy. Backup links for a subscriber are chosen based on the link with the fewest subscribers, which provides redundancy if a link fails.

We recommend that you configure the module redundancy option to provide redundancy if a module or a link fails. Backup links for a subscriber are chosen on a different DPC or MPC from the primary link, based on the link with the fewest subscribers among the links on different modules.

To configure module redundancy for an aggregated Ethernet bundle:

1. Access the aggregated Ethernet bundle for which you want to configure module redundancy.

```
edit
user@host# edit interfaces aex aggregated-ether-options
```

2. Enable module redundancy for the bundle.

```
[edit interfaces aex aggregated-ether-options]
user@host# logical-interface-fpc-redundancy
```

## Configuring Rebalancing of Demux Subscribers in an Aggregated Ethernet Interface

---

In a targeted distribution model, the system allocates demux subscriber interfaces equally among the member links in the aggregated Ethernet interface. When links are removed, affected subscribers are redistributed among the active remaining backup links. When links are added to the system, no automatic redistribution occurs. New subscribers are assigned to the links with the fewest subscribers (which are typically the new links).

During normal network operations, the system maintains an even balance of traffic among the links in a bundle, even as subscribers log in and out. However, if the distribution of a bundle becomes uneven (for example, when a link goes down for a period of time

and new subscribers are logging in), you can perform a manual rebalance of the bundle. In addition, you can configure periodic rebalancing of the bundle with a specific interval.

- [Configuring Periodic Rebalancing of Subscribers in an Aggregated Ethernet Interface on page 788](#)
- [Configuring Manual Rebalancing of Subscribers on an Aggregated Ethernet Interface on page 788](#)

## Configuring Periodic Rebalancing of Subscribers in an Aggregated Ethernet Interface

If subscribers are frequently logging in and logging out of your network, you can configure the system to periodically rebalance the links based on a specific time and interval.

To configure periodic rebalancing:

1. Access the aggregated Ethernet interface for which you want to configure periodic rebalancing.

```
edit
user@host# edit interfaces aenumber aggregated-ether-options
```

2. Configure the rebalancing parameters for the interface, including the time and the interval between rebalancing actions.

```
[edit interfaces aenumber aggregated-ether-options]
user@host# rebalance-periodic time hour:minute <interval hours>
```

## Configuring Manual Rebalancing of Subscribers on an Aggregated Ethernet Interface

To manually rebalance the subscribers among the links in an aggregated Ethernet bundle with targeted distribution:

- Issue the **request interface rebalance** command:

```
user@host# request interface rebalance interface <interface-name>
```

### Related Documentation

## Configuring the PPPoE Family for an Underlying Interface

You can configure the PPPoE family on an underlying interface as an alternative to configuring PPPoE encapsulation on that interface. You cannot configure both on the same interface. You can configure the same attributes for the PPPoE family as you can for an interface configured with **pppoe-underlying-options**.

Before you begin, configure the underlying interface. When you want to configure PPPoE on an aggregated Ethernet bundle, you must configure the PPPoE family over a VLAN demux interface as an intermediate underlying option. The VLAN demux interface can be static or dynamic.

The following topics describe how to configure basic static and dynamic interfaces:

- [Configuring a Subscriber Interface with a Static VLAN Interface on page 724](#)
- [Configuring Static Subscriber Interfaces Using VLAN Demux Interfaces on page 725](#)
- [Configuring Dynamic Subscriber Interfaces Using VLAN Demux Interfaces in Dynamic Profiles on page 730](#)

To configure the PPPoE family over an underlying interface:

1. Specify the PPPoE family.

```
[edit interfaces demux0 unit logical-unit-number]
user@host# set family pppoe
```

2. (Optional) Configure an alternative access concentrator name to be used instead of the system name in PPPoE control packets for the dynamic PPPoE subscriber interface.

```
[edit interfaces demux0 unit logical-unit-number family pppoe]
user@host# set access-concentrator name
```

3. (Optional) Configure duplicate protection to prevent the activation of another dynamic PPPoE logical interface on the same underlying interface when a dynamic PPPoE logical interface for a client with the same MAC address is already active on that interface.

```
[edit interfaces demux0 unit logical-unit-number family pppoe]
user@host# set duplicate-protection
```

4. (Optional) Attach a dynamic profile to determine the properties of the dynamic PPPoE logical interface when it is created.

```
[edit interfaces demux0 unit logical-unit-number family pppoe]
user@host# set dynamic-profile profile-name
```

5. (Optional) Configure the maximum number of concurrent PPPoE sessions that the router can activate on the underlying interface in either of the following ways:

- To configure the maximum number of concurrent PPPoE sessions on a per-interface basis, from 1 through the platform-specific default for your router, use the **max-sessions** statement:

```
[edit interfaces demux0 unit logical-unit-number family pppoe]
user@host# set max-sessions number
```

- To configure the maximum number of concurrent PPPoE sessions on a per-subscriber basis, use the value returned by RADIUS in the Max-Clients-Per-Interface Juniper Networks vendor-specific attribute (VSA) [26-143]. By default, the PPPoE maximum session value returned by RADIUS in the Max-Clients-Per-Interface VSA takes precedence over the PPPoE maximum session value configured with the **max-sessions** statement.

6. (Optional) Configure the router to ignore the value returned by RADIUS in the Max-Clients-Per-Interface VSA and restore the PPPoE maximum session value on the underlying interface to the value configured in the CLI with the **max-sessions** statement.

```
[edit interfaces demux0 unit logical-unit-number family pppoe]
user@host# set max-sessions-vsa-ignore
```

7. (Optional) Enable PPPoE subscriber session lockout on the PPPoE underlying interface in either of the following ways:

- To configure PPPoE subscriber session lockout with the default lockout period:

```
[edit interfaces interface-name unit logical-unit-number pppoe-underlying-options]
user@host# set short-cycle-protection
```

- To configure PPPoE subscriber session lockout with a nondefault lockout period:

```
[edit interfaces interface-name unit logical-unit-number pppoe-underlying-options]
user@host# set short-cycle-protection lockout-time-min minimum-seconds
lockout-time-max maximum-seconds
```

**BEST PRACTICE:** When you configure PPPoE subscriber session lockout, we recommend that you also enable duplicate protection to ensure that the MAC source address for each PPPoE session is unique on the underlying interface.

8. (Optional) Specify the service name table assigned to the underlying interface.

```
[edit interfaces demux0 unit logical-unit-number family pppoe]
user@host# set service-name-table table-name
```

## Example: Configuring a Static Subscriber Interface on a VLAN Interface over Aggregated Ethernet

---

This example shows how you can configure a subscriber interface using a static virtual LAN (VLAN) stacked on a two-link aggregated Ethernet logical interface. In this example, the underlying aggregated Ethernet logical interface is configured for one-to-one active/backup redundancy at the DPC level, and per-subscriber static hierarchical

class-of-service (CoS) is configured by applying CoS parameters at the aggregated Ethernet logical interface.

1. Define the number of aggregated Ethernet interfaces on the router.

In this example, only one aggregated Ethernet logical interface is configured on the router.

```
[edit]
chassis {
  aggregated-devices {
    ethernet {
      device-count 1;
    }
  }
}
```

2. Configure **ae0**, a two-link aggregated Ethernet logical interface to serve as the underlying interface for the static VLAN subscriber interface. In order to support hierarchical CoS, the physical ports must be on EQ DPCs in MX Series routers.

In this example, the LAG bundle is configured for one-to-one active/backup link redundancy. To support link redundancy at the DPC level, the LAG bundle attaches ports from two different EQ DPCs.

```
[edit]
interfaces {
  ge-5/0/3 {
    gigether-options {
      802.3ad {
        ae0;
        primary;
      }
    }
  }
  ge-5/1/2 {
    gigether-options {
      802.3ad {
        ae0;
        backup;
      }
    }
  }
}
```

3. Configure **ae0** to serve as the underlying interface for the static VLAN interface.

```
[edit]
interfaces {
  ae0 {
    hierarchical-scheduler;
    aggregated-ether-options {
      link-protection;
      minimum-links 1;
      link-speed 1g;
      lacp {
        active;
      }
    }
  }
}
```

```

    }
  }
}

```

4. Configure static traffic-shaping and scheduling parameters.

```

[edit]
class-of-service {
  forwarding-classes { # Associate queue numbers with class names
    queue 0 be;
    queue 1 e;
    queue 2 af;
    queue 3 nc;
  }
  schedulers { # Define output queue properties
    scheduler_be {
      transmit-rate percent 30;
      buffer-size percent 30;
    }
    scheduler_ef {
      transmit-rate percent 40;
      buffer-size percent 40;
    }
    scheduler_af {
      transmit-rate percent 25;
      buffer-size percent 25;
    }
    scheduler_nc {
      transmit-rate percent 5;
      buffer-size percent 5;
    }
  }
  scheduler-maps { # Associate queues with schedulers
    smap_2 {
      forwarding-class be scheduler_be;
      forwarding-class ef scheduler_ef;
      forwarding-class af scheduler_af;
      forwarding-class nc scheduler_nc;
    }
  }
}

```

5. Attach static CoS to the physical and logical interfaces of the aggregated Ethernet interface.

In this example, three traffic control profiles are defined, but only two profiles are applied to the static VLAN subscriber interface over aggregated Ethernet:

- The **tcp\_for\_ae\_device\_pir\_500m** profile defines a shaping rate, and it is applied to both of the underlying physical interfaces (**ge-5/0/3** and **ge-5/1/2**).
- The **tcp-for-ae\_smap\_video\_pir\_20m\_delay\_30m** profile defines a scheduler map, a shaping rate, and a delay buffer rate, and it is applied to one of the logical interfaces on the aggregated Ethernet bundle (**ae0.0**).

```

[edit]

```

```
class-of-service {
  traffic-control-profiles { # Configure traffic shaping and scheduling profiles
    tcp_for_ae_device_pir_500m {
      shaping-rate 20m;
    }
    tcp_for_ae_smap_video_pir_20m_delay_30m {
      scheduler-map smap_video;
      shaping-rate 20m;
      delay-buffer-rate 30m;
    }
    tcp_for_ae_smap_video_cir_50m_delay_75m {
      scheduler-map smap_video;
      guaranteed-rate 50m;
      delay-buffer-rate 75m;
    }
  }
  interfaces { # Apply two traffic-control profiles to the LAG
    ae0 { # Two underlying physical interfaces on separate EQ DPCs
      output-traffic-control-profile tcp-for-ae_device_pir_500m;
      unit 0 { # One of the two logical interfaces on 'ae0'
        output-traffic-control-profile tcp-for-ae_smap_video_pir_20m_delay_30m;
      }
    }
  }
}
```

## Example: Configuring a Static Subscriber Interface on an IP Demux Interface over Aggregated Ethernet

---

This example shows how you can configure a subscriber interface using a static IP demultiplexing (demux) interface stacked on a two-link aggregated Ethernet logical interface. In this example, the underlying aggregated Ethernet logical interface is configured for one-to-one active/backup redundancy at the DPC level.

1. Define the number of aggregated Ethernet interfaces on the router.

In this example, only one aggregated Ethernet logical interface is configured on the router:

```
[edit]
chassis {
  aggregated-devices {
    ethernet {
      device-count 1;
```

```

    }
  }
}

```

2. Configure **ae0**, a two-link aggregated Ethernet logical interface to serve as the underlying interface for the static IP demux subscriber interface.

In this example, the LAG bundle is configured for one-to-one active/backup link redundancy. To support link redundancy at the DPC level, the LAG bundle attaches ports from two different EQ DPCs.

```

[edit]
interfaces {
  ge-5/0/3 {
    gether-options {
      802.3ad {
        ae0;
        primary;
      }
    }
  }
  ge-5/1/2 {
    gether-options {
      802.3ad {
        ae0;
        backup;
      }
    }
  }
}

```

3. Configure the aggregated Ethernet logical interface with link protection enabled, and specify the logical demultiplexing source family type for both the active and backup links.

```

[edit]
interfaces {
  ae0 {
    aggregated-ether-options {
      link-protection;
      minimum-links 1;
      link-speed 1g;
    }
    unit 0 {
      demux-source inet {
        family inet {
          address 20.1.1.0/24;
        }
      }
    }
    unit 1 {
      demux-source inet {
        family inet {
          address 20.1.1.1/24;
        }
      }
    }
  }
}

```

4. Configure the IP demux interface over the aggregated Ethernet logical interface.

```
[edit]
interfaces {
  demux0 {
    unit 101 {
      demux-options {
        underlying-interface ae0.0;
      }
      family inet {
        demux-source 10.1.0.0/16;
        address 1.1.1.0/24;
      }
    }
    unit 101 {
      demux-options {
        underlying-interface ae0.1;
      }
      family inet {
        demux-source 10.1.0.1/16;
        address 1.1.1.1/24;
      }
    }
  }
}
```

## Example: Configuring a Static Subscriber Interface on a VLAN Interface over Aggregated Ethernet

---

This example shows how you can configure a subscriber interface using a static virtual LAN (VLAN) stacked on a two-link aggregated Ethernet logical interface. In this example, the underlying aggregated Ethernet logical interface is configured for one-to-one active/backup redundancy at the DPC level, and per-subscriber static hierarchical class-of-service (CoS) is configured by applying CoS parameters at the aggregated Ethernet logical interface.

1. Define the number of aggregated Ethernet interfaces on the router.

In this example, only one aggregated Ethernet logical interface is configured on the router.

```
[edit]
chassis {
  aggregated-devices {
    ethernet {
      device-count 1;
    }
  }
}
```

```

    }
  }
}

```

2. Configure **ae0**, a two-link aggregated Ethernet logical interface to serve as the underlying interface for the static VLAN subscriber interface. In order to support hierarchical CoS, the physical ports must be on EQ DPCs in MX Series routers.

In this example, the LAG bundle is configured for one-to-one active/backup link redundancy. To support link redundancy at the DPC level, the LAG bundle attaches ports from two different EQ DPCs.

```

[edit]
interfaces {
  ge-5/0/3 {
    gigether-options {
      802.3ad {
        ae0;
        primary;
      }
    }
  }
  ge-5/1/2 {
    gigether-options {
      802.3ad {
        ae0;
        backup;
      }
    }
  }
}

```

3. Configure **ae0** to serve as the underlying interface for the static VLAN interface.

```

[edit]
interfaces {
  ae0 {
    hierarchical-scheduler;
    aggregated-ether-options {
      link-protection;
      minimum-links 1;
      link-speed 1g;
      lacp {
        active;
      }
    }
  }
}

```

4. Configure static traffic-shaping and scheduling parameters.

```

[edit]
class-of-service {
  forwarding-classes { # Associate queue numbers with class names
    queue 0 be;
    queue 1 e;
    queue 2 af;
    queue 3 nc;
  }
}

```

```

}
schedulers { # Define output queue properties
  scheduler_be {
    transmit-rate percent 30;
    buffer-size percent 30;
  }
  scheduler_ef {
    transmit-rate percent 40;
    buffer-size percent 40;
  }
  scheduler_af {
    transmit-rate percent 25;
    buffer-size percent 25;
  }
  scheduler_nc {
    transmit-rate percent 5;
    buffer-size percent 5;
  }
}
scheduler-maps { # Associate queues with schedulers
  smap_2 {
    forwarding-class be scheduler_be;
    forwarding-class ef scheduler_ef;
    forwarding-class af scheduler_af;
    forwarding-class nc scheduler_nc;
  }
}
}

```

5. Attach static CoS to the physical and logical interfaces of the aggregated Ethernet interface.

In this example, three traffic control profiles are defined, but only two profiles are applied to the static VLAN subscriber interface over aggregated Ethernet:

- The **tcp\_for\_ae\_device\_pir\_500m** profile defines a shaping rate, and it is applied to both of the underlying physical interfaces (**ge-5/0/3** and **ge-5/1/2**).
- The **tcp-for-ae\_smap\_video\_pir\_20m\_delay\_30m** profile defines a scheduler map, a shaping rate, and a delay buffer rate, and it is applied to one of the logical interfaces on the aggregated Ethernet bundle (**ae0.0**).

```

[edit]
class-of-service {
  traffic-control-profiles { # Configure traffic shaping and scheduling profiles
    tcp_for_ae_device_pir_500m {
      shaping-rate 20m;
    }
    tcp_for_ae_smap_video_pir_20m_delay_30m {
      scheduler-map smap_video;
      shaping-rate 20m;
      delay-buffer-rate 30m;
    }
    tcp_for_ae_smap_video_cir_50m_delay_75m {
      scheduler-map smap_video;
      guaranteed-rate 50m;
    }
  }
}

```

```

        delay-buffer-rate 75m;
    }
}
interfaces { # Apply two traffic-control profiles to the LAG
    ae0 { # Two underlying physical interfaces on separate EQ DPCs
        output-traffic-control-profile tcp-for-ae_device_pir_500m;
        unit 0 { # One of the two logical interfaces on 'ae0'
            output-traffic-control-profile tcp-for-ae_smap_video_pir_20m_delay_30m;
        }
    }
}
}
}

```

## Example: Configuring IPv4 Static VLAN Demux Interfaces over an Aggregated Ethernet Underlying Interface with DHCP Local Server

This example shows how to configure a static IPv4 VLAN demux interface with aggregated Ethernet as the underlying interface. DHCP Local Server configuration enables the association of subscribers to the VLAN demux interface by listing the aggregated Ethernet interface in the DHCP local server configuration.

To configure dynamic subscribers on VLAN demux interfaces:

1. Enable hierarchical scheduling and VLAN tagging on the underlying interface that you plan to use for any VLAN demux interfaces.

```

interfaces {
    ae1 {
        hierarchical-scheduler;
        vlan-tagging;
        aggregated-ether-options {
            minimum-links 1;
            lacp {
                active;
                periodic slow;
                link-protection {
                    non-revertive;
                }
            }
        }
    }
}

```

2. Define the gigabit Ethernet interfaces that are part of the aggregated Ethernet interface.

```
interfaces {
  ge-5/0/0 {
    gigether-options {
      802.3ad ae1;
    }
  }
  ge-5/2/0 {
    gigether-options {
      802.3ad ae1;
    }
  }
}
```

3. Define the demux interface.

```
interfaces {
  demux0 {
    unit 102 {
      proxy-arp;
      vlan-id 103;
      demux-options {
        underlying-interface ae1;
      }
      family inet {
        unnumbered-address lo0.0 preferred-source-address 173.16.1.1;
      }
    }
  }
}
```

4. Define the loopback interface.

```
interfaces {
  lo0 {
    unit 0 {
      family inet {
        address 192.16.1.1/32;
      }
    }
  }
}
```

5. Configure a dynamic profile for initial subscriber access.

```
dynamic-profiles {
  user-profile {
    interfaces {
      "$junos-interface-ifd-name" {
        unit "$junos-underlying-interface-unit" {
          family inet;
        }
      }
    }
  }
  protocols {
    igmp {
      interface "$junos-interface-name" {
        version 3;
        immediate-leave;
      }
    }
  }
}
```

```

        promiscuous-mode;
    }
}
}
}

```

6. Configure the access method used to dynamically create the subscriber interfaces.

The following stanza specifies the aggregated Ethernet interface (**ae1.0**) for use with the dynamically created subscriber interfaces.

```

system {
  services {
    dhcp-local-server {
      group myDhcpGroup {
        authentication {
          password test;
          username-include {
            user-prefix igmp-user1;
          }
        }
        dynamic-profile user-profile;
        interface ae1.0;
      }
    }
  }
}

```

Instead of using the aggregated Ethernet interface, you can alternatively specify the specific demux interface (**demux0.102**) as the device to use with the subscriber interfaces as follows:

```

system {
  services {
    dhcp-local-server {
      group myDhcpGroup {
        authentication {
          password test;
          username-include {
            user-prefix igmp-user1;
          }
        }
        dynamic-profile user-profile;
        interface demux0.102;
      }
    }
  }
}

```

## Example: Separating Targeted Multicast Traffic for Demux Subscribers on Aggregated Ethernet Interfaces

This example shows how to separate targeted multicast traffic from targeted unicast traffic and send that multicast traffic to a different interface through the use of OIF maps.

- [Requirements on page 804](#)
- [Overview on page 804](#)
- [Configuration on page 804](#)
- [Verification on page 809](#)

### Requirements

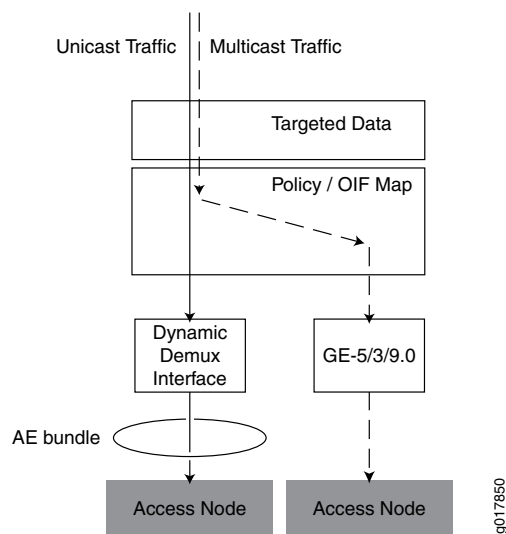

Before configuring this example, make sure to configure the distribution type for the interface. See “[Configuring the Distribution Type for Demux Subscribers on Aggregated Ethernet Interfaces](#)” on page 786 for instructions.

### Overview

In this example, targeted traffic distribution is already configured on the router. Dynamically created interfaces each carry their unicast traffic but all multicast traffic is sent to the GE-5/3/9.0 interface.

[Figure 14 on page 804](#) shows the sample network.

**Figure 14: Multicast Traffic Separation Using OIF Mapping**

### Configuration

- [Configure an OIF Map Policy on page 805](#)
- [Configure a DHCP VLAN Dynamic Profile on page 806](#)
- [Configure a VLAN Demux Dynamic Profile on page 807](#)

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set policy-options policy-statement OIF-v4-all term oif539 from route-filter 224.0.0.0/4
  orlonger
set policy-options policy-statement OIF-v4-all term oif539 then map-to-interface
  ge-5/3/9.0
set policy-options policy-statement OIF-v4-all term oif539 then accept
set dynamic-profiles dhcp-vlan-prof interfaces "$junos-interface-ifd-name" unit
  "$junos-underlying-interface-unit" family inet unnumbered-address lo0.0
set dynamic-profiles dhcp-vlan-prof interfaces "$junos-interface-ifd-name" unit
  "$junos-underlying-interface-unit" family inet unnumbered-address preferred-source-address 100.20.0.2
set dynamic-profiles demux-vlan-prof interfaces demux0 unit "$junos-interface-unit"
  vlan-id "$junos-vlan-id"
set dynamic-profiles demux-vlan-prof interfaces demux0 unit "$junos-interface-unit"
  demux-options underlying-interface "$junos-interface-ifd-name"
set dynamic-profiles demux-vlan-prof interfaces demux0 unit "$junos-interface-unit"
  targetted-distribution
set dynamic-profiles demux-vlan-prof interfaces demux0 unit "$junos-interface-unit"
  family inet unnumbered-address lo0.0
set dynamic-profiles demux-vlan-prof interfaces demux0 unit "$junos-interface-unit"
  family inet unnumbered-address preferred-source-address 100.20.0.2
set dynamic-profiles demux-vlan-prof protocols igmp interface "$junos-interface-name"
  version 2
set dynamic-profiles demux-vlan-prof protocols igmp interface "$junos-interface-name"
  promiscuous-mode
set dynamic-profiles demux-vlan-prof protocols igmp interface "$junos-interface-name"
  passive allow-receive
set dynamic-profiles demux-vlan-prof protocols igmp interface "$junos-interface-name"
  passive send-group-query
set dynamic-profiles demux-vlan-prof protocols igmp interface "$junos-interface-name"
  oif-map OIF-v4-all
```

### Configure an OIF Map Policy

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure the OIF map:

1. Access the router policy options:
 

```
[edit]
user@host#edit policy-options
```
2. Edit a policy statement.
 

```
[edit policy-options]
user@host edit policy-statement OIF-v4-all
```
3. Create a term for mapping incoming multicast traffic to a specific interface.
 

```
[edit policy-options OIF-v4-all]
```

```
user@host edit term oif539
```

4. Define the match condition for the term. In this case, the term matches any route prefix of 224/4 or longer (all multicast traffic).

```
[edit policy-options OIF-v4-all term oif539]  
user@host set from route-filter 224/4 orlonger
```

5. Define the action for the term. In this case, when a match occurs, the term accepts the traffic and maps it to interface GE-5/3/9.0.

```
[edit policy-options OIF-v4-all term oif539]  
user@host set then map-to-interface ge-5/3/9.0  
user@host set then accept
```

**Results** Confirm your configuration by issuing the **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]  
user@host# show policy-options  
policy-statement OIF-v4-all {  
  term oif539 {  
    from {  
      route-filter 224.0.0.0/4 orlonger;  
    }  
    then {  
      map-to-interface ge-5/3/9.0;  
      accept;  
    }  
  }  
}
```

---

### Configure a DHCP VLAN Dynamic Profile

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the CLI User Guide.

To configure a DHCP VLAN dynamic profile for client access:

1. Create a dynamic VLAN demux profile.

```
[edit]  
user@host#edit dynamic-profiles dhcp-vlan-prof
```

2. Edit the dynamic profile interface.

```
[edit dynamic-profiles dhcp-vlan-prof]  
user@host edit interfaces $junos-ifd-name
```

3. Edit the interface unit dynamic variable.

```
[edit dynamic-profiles demux-vlan-prof interfaces $junos-ifd-name]  
user@host edit unit $junos-underlying-interface-unit
```

4. Edit the interface family.

```
[edit dynamic-profiles demux-vlan-prof interfaces $junos-ifd-name unit
  $junos-underlying-interface-unit]
user@host edit family inet
```

5. Define the loopback address.

```
[edit dynamic-profiles demux-vlan-prof interfaces $junos-ifd-name unit
  $junos-underlying-interface-unit ]
user@host set unnumbered-address lo0.0 preferred-source-address 100.20.0.2
```

**Results** Confirm your configuration by issuing the **show dynamic-profiles** command. If the output for the dhcp-vlan-prof dynamic profile does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show dynamic-profiles
dhcp-vlan-prof {
  interfaces {
    "$junos-interface-ifd-name" {
      unit "$junos-underlying-interface-unit" {
        family inet {
          unnumbered-address lo0.0 preferred-source-address 100.20.0.2;
        }
      }
    }
  }
}
```

### Configure a VLAN Demux Dynamic Profile

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see Using the CLI Editor in Configuration Mode in the CLI User Guide.

To configure the OIF map:

1. Create a dynamic VLAN demux profile.

```
[edit]
user@host#edit dynamic-profiles demux-vlan-prof
```

2. Edit the dynamic profile demux0 interface.

```
[edit dynamic-profiles demux-vlan-prof]
user@host edit interfaces demux0
```

3. Edit the interface unit dynamic variable.

```
[edit dynamic-profiles demux-vlan-prof interfaces demux0]
user@host edit unit $junos-interface-unit
```

4. Specify the VLAN ID dynamic variable.

```
[edit dynamic-profiles demux-vlan-prof interfaces demux0 unit
  "$junos-interface-unit"]
```

- user@host set **vlan-id** \$junos-vlan-id
5. Access the demux options.  

```
[edit dynamic-profiles demux-vlan-prof interfaces demux0 unit  
"$junos-interface-unit"]  
user@host edit demux-options
```
  6. Define the demux underlying interface.  

```
[edit dynamic-profiles demux-vlan-prof interfaces demux0 unit  
"$junos-interface-unit" demux-options]  
user@host set underlying-interface $junos-interface-ifd-name
```
  7. Specify that dynamically created VLANs are using targeted distribution.  

```
[edit dynamic-profiles demux-vlan-prof interfaces demux0 unit  
"$junos-interface-unit"]  
user@host set targeted-distribution
```
  8. Edit the interface family.  

```
[edit dynamic-profiles demux-vlan-prof interfaces demux0 unit  
"$junos-interface-unit"]  
user@host edit family inet
```
  9. Define the loopback address.  

```
[edit dynamic-profiles demux-vlan-prof interfaces demux0 unit  
"$junos-interface-unit" family inet]  
user@host set unnumbered-address lo0.0 preferred-source-address 100.20.0.2
```
  10. Edit the dynamic profile IGMP protocol.  

```
[edit dynamic-profiles demux-vlan-prof]  
user@host edit protocols igmp
```
  11. Enable IGMP on dynamically created interfaces.  

```
[edit dynamic-profiles demux-vlan-prof protocols igmp]  
user@host edit interface $junos-interface-name
```
  12. Specify the IGMP version that you want dynamically created interfaces to use.  

```
[edit dynamic-profiles demux-vlan-prof protocols igmp interface  
$junos-interface-name]  
user@host set version 2
```
  13. Specify the OIF map that you want dynamically created IGMP interfaces to use.  

```
[edit dynamic-profiles demux-vlan-prof protocols igmp interface  
$junos-interface-name]  
user@host set oif-map OIF-v4-all
```
  14. Specify that IGMP selectively sends and receives control traffic such as IGMP reports, queries, and leaves.  

```
[edit dynamic-profiles demux-vlan-prof protocols igmp interface  
$junos-interface-name]  
user@host set passive allow-receive send-group-query
```

15. Specify that the interface accepts IGMP reports from hosts on any subnetwork.

```
[edit dynamic-profiles demux-vlan-prof protocols igmp interface
$junos-interface-name]
user@host set promiscuous-mode
```

**Results** Confirm your configuration by issuing the **show dynamic-profiles** commands. If the output for the dhcp-vlan-prof dynamic profile does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]
user@host# show dynamic-profiles
demux-vlan-prof {
  interfaces {
    demux0 {
      unit "$junos-interface-unit" {
        vlan-id "$junos-vlan-id";
        demux-options {
          underlying-interface "$junos-interface-ifd-name";
        }
        targetted-distribution;
        family inet {
          unnumbered-address lo0.0 preferred-source-address 100.20.0.2;
        }
      }
    }
  }
  protocols {
    igmp {
      interface "$junos-interface-name" {
        version 2;
        promiscuous-mode;
        passive allow-receive send-group-query;
        oif-map OIF-v4-all;
      }
    }
  }
}
```

## Verification

Confirm that the configuration is working properly.

- [Locate the Multicast Group Member on page 809](#)
- [Ensure the Targeting Aggregated Ethernet Interface for the Subscriber is Functional on page 810](#)
- [View the Packets for the Targeted Interface on page 811](#)

### Locate the Multicast Group Member

**Purpose** Locate the dynamic interface and ensure that it is associated with the appropriate IGMP group.

**Action** user@host>show igmp group

```
Interface: demux0.1073741824, Groups: 1
  Group: 225.0.0.1
    Source: 0.0.0.0
    Last reported by: 100.20.0.10
    Timeout: 52 Type: Dynamic
Interface: local, Groups: 2
  Group: 224.0.0.2
    Source: 0.0.0.0
    Last reported by: Local
    Timeout: 0 Type: Dynamic
  Group: 224.0.0.22
    Source: 0.0.0.0
    Last reported by: Local
    Timeout: 0 Type: Dynamic
```

**Meaning** The first **Interface** field shows the dynamically created demux interface, **demux0.1073741824**, and the **Group** field immediately below the first **Interface** field shows the group, **225.0.0.1**, to which the subscriber belongs.

#### Ensure the Targeting Aggregated Ethernet Interface for the Subscriber is Functional

---

**Purpose** Use the dynamic subscriber interface value to ensure that the targeting aggregated interface is functional.

**Action** user@host>show interfaces demux0.1073741824 extensive

```

Logical interface demux0.1073741824 (Index 810) (SNMP ifIndex 1613)
(Generation 170)
  Flags: SNMP-Traps 0x4000 VLAN-Tag [ 0x8100.1 ] Encapsulation: ENET2
  Demux:
    Underlying interface: ae0 (Index 708)
  Link:
    ge-1/0/0
    ge-5/3/7
  Targeting summary:
    ge-1/0/0, backup, Physical link is Up
    ge-5/3/7, primary, Physical link is Up
  Traffic statistics:
    Input bytes :           862
    Output bytes :          3160
    Input packets:           3
    Output packets:          30
  Local statistics:
    Input bytes :           862
    Output bytes :          3160
    Input packets:           3
    Output packets:          30
  Transit statistics:
    Input bytes :           0           0 bps
    Output bytes :           0           0 bps
    Input packets:           0           0 pps
    Output packets:          0           0 pps
  Protocol inet, MTU: 1500, Generation: 212, Route table: 0
    Flags: Sendbcast-pkt-to-re, Unnumbered
    Donor interface: lo0.0 (Index 802)
    Preferred source address: 100.20.0.2

```

**Meaning** The **Targeting summary** field shows that the primary interface, **ge-5/3/7**, is up.

### [View the Packets for the Targeted Interface](#)

**Purpose** Verify that packet traffic sent to targeted interface GE-5/3/9 consists only of multicast packets.

**Action** user@host>show interfaces ge-5/3/9 extensive

## Example: Configuring IPv4 Dynamic VLAN Demux Interfaces over an Aggregated Ethernet Underlying Interface with DHCP Local Server

This example shows how to configure the dynamic creation of IPv4 VLAN demux interfaces with aggregated Ethernet as the underlying interface. DHCP Local Server configuration enables the association of subscribers to the VLAN demux interface by listing the aggregated Ethernet interface in the DHCP local server configuration.

**NOTE:** VLAN demux subscriber interfaces over aggregated Ethernet physical interfaces are supported only for MX Series routers that have only MPCs installed. If the router has other cards in addition to MPCs, the CLI accepts the configuration but errors are reported when the subscriber interfaces are brought up.

To configure dynamic subscribers on dynamic VLAN demux interfaces:

1. Enable VLAN tagging and VLAN auto-configuration on the underlying aggregated Ethernet interface that you plan to use for dynamically created VLAN demux interfaces.

```
interfaces {
  ae1 {
    vlan-tagging;
    auto-configure {
      vlan-ranges {
        dynamic-profile auto-vlanDemux-profile {
          accept inet;
          ranges {
            any;
          }
        }
      }
    }
  }
  aggregated-ether-options {
    minimum-links 1;
    lacp {
      active;
      periodic slow;
      link-protection {
        non-revertive;
      }
    }
  }
}
```

2. Define the gigabit Ethernet interfaces that are part of the aggregated Ethernet interface.

```

interfaces {
  ge-5/0/0 {
    gigether-options {
      802.3ad ael;
    }
  }
  ge-5/2/0 {
    gigether-options {
      802.3ad ael;
    }
  }
}

```

3. Define the loopback interface.

```

interfaces {
  lo0 {
    unit 0 {
      family inet {
        address 192.16.1.1/32;
      }
    }
  }
}

```

4. Configure a dynamic profile for subscriber access.

```

dynamic-profiles {
  user-profile {
    interfaces {
      "$junos-interface-ifd-name" {
        unit "$junos-underlying-interface-unit" {
          family inet;
        }
      }
    }
  }
}

```

5. Configure a dynamic profile for VLAN demux interface creation.

```

dynamic-profiles {
  auto-vlanDemux-profile {
    interfaces {
      demux0 {
        unit "$junos-interface-unit" {
          vlan-id "$junos-vlan-id";
          demux-options {
            underlying-interface "$junos-interface-ifd-name";
          }
          family inet {
            filter {
              input rate_limit;
              output rate_limit;
            }
            unnumbered-address lo0.0 preferred-source-address 192.16.1.1;
          }
        }
      }
    }
  }
}

```

```

    }
  }
}

```

6. Configure the access method used to dynamically create the subscriber interfaces. The following stanza specifies the aggregated Ethernet interface (**ae1.0**) for use with the dynamically created subscriber interfaces.

```

system {
  services {
    dhcp-local-server {
      group myDhcpGroup {
        authentication {
          password test;
          username-include {
            user-prefix igmp-user1;
          }
        }
        dynamic-profile user-profile;
        interface ae1.0;
      }
    }
  }
}

```

Instead of using the aggregated Ethernet interface, you can alternatively specify **demux0** as the device to use with the subscriber interfaces as follows:

**NOTE:** Because the demux interfaces and unit values are created dynamically, the unit number is not specified for the demux0 interface.

```

system {
  services {
    dhcp-local-server {
      group myDhcpGroup {
        authentication {
          password test;
          username-include {
            user-prefix igmp-user1;
          }
        }
        dynamic-profile user-profile;
        interface demux0;
      }
    }
  }
}

```

## Example: Configuring IPv6 Dynamic VLAN Demux Interfaces over an Aggregated Ethernet Underlying Interface with DHCP Local Server

This example shows how to configure the dynamic creation of IPv6 VLAN demux interfaces with aggregated Ethernet as the underlying interface. DHCP Local Server configuration enables the association of subscribers to the VLAN demux interface by listing the aggregated Ethernet interface in the DHCP local server configuration.

**NOTE:** VLAN demux subscriber interfaces over aggregated Ethernet physical interfaces are supported only for MX Series routers that have only MPCs installed. If the router has other cards in addition to MPCs, the CLI accepts the configuration but errors are reported when the subscriber interfaces are brought up.

To configure dynamic subscribers on dynamic VLAN demux interfaces:

1. Enable VLAN tagging and VLAN auto-configuration on the underlying aggregated Ethernet interface that you plan to use for dynamically created VLAN demux interfaces.

```

interfaces {
  ae1 {
    vlan-tagging;
    auto-configure {
      vlan-ranges {
        dynamic-profile auto-vlanDemux-profile {
          accept inet6;
          ranges {
            any;
          }
        }
      }
    }
  }
  aggregated-ether-options {
    minimum-links 1;
    lacp {
      active;
      periodic slow;
      link-protection {
        non-revertive;
      }
    }
  }
}

```

2. Define the gigabit Ethernet interfaces that are part of the aggregated Ethernet interface.

```

interfaces {
  ge-5/0/0 {
    gigether-options {

```

```
        802.3ad ae1;
    }
}
ge-5/2/0 {
    gigether-options {
        802.3ad ae1;
    }
}
}
```

3. Define the loopback interface.

```
interfaces {
    lo0 {
        unit 0 {
            family inet6 {
                address 2009:174:1:1::1/128;
            }
        }
    }
}
```

4. Configure a dynamic profile for subscriber access.

```
dynamic-profiles {
    user-profile {
        interfaces {
            "$junos-interface-ifd-name" {
                unit "$junos-underlying-interface-unit" {
                    family inet6;
                }
            }
        }
    }
}
```

5. Configure a dynamic profile for VLAN demux interface creation.

```
dynamic-profiles {
    auto-vlanDemux-profile {
        interfaces {
            demux0 {
                unit "$junos-interface-unit" {
                    vlan-id "$junos-vlan-id";
                    demux-options {
                        underlying-interface "$junos-interface-ifd-name";
                    }
                    family inet6 {
                        filter {
                            input v6_rate_limit;
                            output v6_rate_limit;
                        }
                        unnumbered-address lo0.0 preferred-source-address 2009:174:1:1::1;
                    }
                }
            }
        }
    }
}
```

```
}

```

6. Configure the access method used to dynamically create the subscriber interfaces. The following stanza specifies the aggregated Ethernet interface (**ae1.0**) for use with the dynamically created subscriber interfaces.

```
system {
  services {
    dhcp-local-server {
      dhcpv6 {
        group myV6DhcpGroup {
          authentication {
            password test;
            username-include {
              user-prefix igmp-user1;
            }
          }
          dynamic-profile user-profile;
          interface ae1.0;
        }
      }
    }
  }
}
```

Instead of using the aggregated Ethernet interface, you can alternatively specify **demux0** as the device to use with the subscriber interfaces as follows:

**NOTE:** Because the demux interfaces and unit values are created dynamically, the unit number is not specified for the demux0 interface.

```
system {
  services {
    dhcp-local-server {
      dhcpv6 {
        group myV6DhcpGroup {
          authentication {
            password test;
            username-include {
              user-prefix igmp-user1;
            }
          }
          dynamic-profile user-profile;
          interface demux0;
        }
      }
    }
  }
}
```

## Example: Configuring IPv4 Dynamic Stacked VLAN Demux Interfaces over an Aggregated Ethernet Underlying Interface with DHCP Local Server

This example shows how to configure the dynamic creation of IPv4 stacked VLAN demux interfaces with aggregated Ethernet as the underlying interface. DHCP Local Server configuration enables the association of subscribers to the VLAN demux interface by listing the aggregated Ethernet interface in the DHCP local server configuration.

**NOTE:** VLAN demux subscriber interfaces over aggregated Ethernet physical interfaces are supported only for MX Series routers that have only MPCs installed. If the router has other cards in addition to MPCs, the CLI accepts the configuration but errors are reported when the subscriber interfaces are brought up.

To configure dynamic subscribers on dynamic VLAN demux interfaces:

1. Enable VLAN tagging and VLAN auto-configuration on the underlying aggregated Ethernet interface that you plan to use for dynamically created VLAN demux interfaces.

```

interfaces {
  ae1 {
    flexible-vlan-tagging;
    auto-configure {
      stacked-vlan-ranges {
        dynamic-profile auto-vlanDemux-profile {
          accept inet;
          ranges {
            any;
          }
        }
      }
    }
    aggregated-ether-options {
      minimum-links 1;
      lacp {
        active;
        periodic slow;
        link-protection {
          non-revertive;
        }
      }
    }
  }
}

```

2. Define the gigabit Ethernet interfaces that are part of the aggregated Ethernet interface.

```

interfaces {
  ge-5/0/0 {
    giger-options {
      802.3ad ae1;
    }
  }
}

```

```

    }
    ge-5/2/0 {
      gige-ether-options {
        802.3ad ael;
      }
    }
  }
}

```

3. Define the loopback interface.

```

interfaces {
  lo0 {
    unit 0 {
      family inet {
        address 192.16.1.1/32;
      }
    }
  }
}

```

4. Configure a dynamic profile for subscriber access.

```

dynamic-profiles {
  user-profile {
    interfaces {
      "$junos-interface-ifd-name" {
        unit "$junos-underlying-interface-unit" {
          family inet;
        }
      }
    }
  }
}

```

5. Configure a dynamic profile for VLAN demux interface creation.

```

dynamic-profiles {
  auto-vlanDemux-profile {
    interfaces {
      demux0 {
        unit "$junos-interface-unit" {
          vlan-tags outer "$junos-stacked-vlan-id" inner "$junos-vlan-id";
          demux-options {
            underlying-interface "$junos-interface-ifd-name";
          }
          family inet {
            filter {
              input rate_limit;
              output rate_limit;
            }
            unnumbered-address lo0.0 preferred-source-address 192.16.1.1;
          }
        }
      }
    }
  }
}

```

6. Configure the access method used to dynamically create the subscriber interfaces. The following stanza specifies the aggregated Ethernet interface (**ae1.0**) for use with the dynamically created subscriber interfaces.

```
system {
  services {
    dhcp-local-server {
      group myDhcpGroup {
        authentication {
          password test;
          username-include {
            user-prefix igmp-user1;
          }
        }
        dynamic-profile user-profile;
        interface ae1.0;
      }
    }
  }
}
```

Instead of using the aggregated Ethernet interface, you can alternatively specify **demux0** as the device to use with the subscriber interfaces as follows:

**NOTE:** Because the demux interfaces and unit values are created dynamically, the unit number is not specified for the demux0 interface.

```
system {
  services {
    dhcp-local-server {
      group myDhcpGroup {
        authentication {
          password test;
          username-include {
            user-prefix igmp-user1;
          }
        }
        dynamic-profile user-profile;
        interface demux0;
      }
    }
  }
}
```

## Example: Configuring a Static PPPoE Subscriber Interface on a Static Underlying VLAN Demux Interface over Aggregated Ethernet

This example shows how you can configure static PPPoE subscriber interfaces over aggregated Ethernet bundles to provide subscriber link redundancy.

- [Requirements on page 823](#)
- [Overview on page 823](#)
- [Configuration on page 823](#)
- [Verification on page 826](#)

### Requirements

PPPoE over VLAN demux interfaces over aggregated Ethernet requires the following hardware and software:

- MX Series 3D Universal Edge Routers
- MPCs
- Junos OS Release 11.2 or later

No special configuration beyond device initialization is required before you can configure this feature.

### Overview

Aggregated Ethernet bundles enable link redundancy between the router and networking devices connected by Ethernet links. This example describes how to configure link redundancy for static PPPoE subscribers over aggregated Ethernet interface with an intermediate static VLAN demux interface. Sample tasks include configuring a two-member aggregated Ethernet bundle on **ae0**, configuring a static VLAN demux interface, **demux0.100**, that underlies the PPPoE subscriber interface, **pp0.100**, and configuring the PPPoE subscriber interface including characteristics of the PPPoE family.

This example does not show all possible configuration choices.

### Configuration

#### CLI Quick Configuration

To quickly configure link redundancy for static PPPoE subscribers over a static VLAN demux interface over aggregated Ethernet, copy the following commands, paste them in a text file, remove any line breaks, and then copy and paste the commands into the CLI.

```
[edit]
set chassis aggregated-devices ethernet device-count 1
set interfaces ge-5/0/3 gigether-options 802.3ad ae0
set interfaces ge-5/0/3 gigether-options 802.3ad primary
set interfaces ge-5/1/2 gigether-options 802.3ad ae0
set interfaces ge-5/1/2 gigether-options 802.3ad backup
set interfaces ae0 flexible-vlan-tagging
set interfaces ae0 aggregated-ether-options link-protection
```

```
edit interfaces demux0 unit 100
set vlan-id 100
set demux-options underlying-interface ae0
set family pppoe access-concentrator pppoe-server-1
set family pppoe duplicate-protection
set family pppoe max-sessions 16000
top
edit interfaces pp0 unit 100
set pppoe-options underlying-interface demux0.100
set pppoe-options server
set family inet unnumbered-address lo0.0
top
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure link redundancy for static PPPoE subscribers over a static VLAN demux interface over aggregated Ethernet:

1. Define the number of aggregated Ethernet devices on the router.

```
[edit chassis]
user@host# set aggregated-devices ethernet device-count 1
```

2. Configure a two-link aggregated Ethernet logical interface to serve as the underlying interface for the static VLAN demux subscriber interface. In this example, the LAG bundle is configured for one-to-one active/backup link redundancy. To support link redundancy at the MPC level, the LAG bundle attaches to ports from two different MPCs.

```
[edit interfaces]
user@host# set ge-5/0/3 gigether-options 802.3ad ae0
user@host# set ge-5/0/3 gigether-options 802.3ad primary
user@host# set ge-5/1/2 gigether-options 802.3ad ae0
user@host# set ge-5/1/2 gigether-options 802.3ad backup
```

3. Enable link protection on the aggregated Ethernet logical interface and configure support for single and dual (stacked) VLAN tags.

```
[edit interfaces]
user@host# set ae0 aggregated-ether-options link-protection
user@host# set ae0 flexible-vlan-tagging
```

4. Configure the VLAN demux interface over the aggregated Ethernet logical interface.

```
[edit interfaces]
user@host# set demux0 unit 100 vlan-id 100
user@host# set demux0 unit 100 demux-options underlying-interface ae0
```

5. Configure the PPPoE family attributes on the VLAN demux interface.

```
[edit interfaces]
user@host# set demux0 unit 100 family pppoe access-concentrator pppoe-server-1
user@host# set demux0 unit 100 family pppoe duplicate-protection
user@host# set demux0 unit 100 family pppoe max-sessions 16000
```

6. Configure the VLAN demux interface as the underlying interface on which the PPPoE logical interface is created.

```
[edit interfaces]
user@host# set pp0 unit 100 pppoe-options underlying-interface demux0.100
user@host# set pp0 unit 100 pppoe-options server
user@host# set pp0 unit 100 family inet unnumbered-address lo0.0
```

**Results** From configuration mode, confirm the aggregated device configuration by entering the **show chassis** command. Confirm the interface configuration by entering the **show interfaces** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show chassis
aggregated-devices {
  ethernet {
    device-count 1;
  }
}

[edit]
user@host# show interfaces
ge-5/0/3 {
  gigether-options {
    802.3ad {
      ae0;
      primary;
    }
  }
}
ge-5/1/2 {
  gigether-options {
    802.3ad {
      ae0;
      backup;
    }
  }
}
ae0 {
  flexible-vlan-tagging;
  aggregated-ether-options {
    link-protection;
  }
}
demux0 {
  unit 100 {
    vlan-id 100;
    demux-options {
      underlying-interface ae0;
    }
  }
  family pppoe {
    access-concentrator pppoe-server-1;
    duplicate-protection;
    max-sessions 16000;
  }
}
```

```

    }
  }
}
pp0 {
  unit 100 {
    pppoe-options {
      underlying-interface demux0.100;
      server;
    }
    family inet {
      unnumbered-address lo0.0;
    }
  }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying the Aggregated Ethernet Interface Configuration on page 826](#)
- [Verifying the demux0 Interface Configuration on page 827](#)
- [Verifying the pp0 Interface Configuration on page 827](#)

### Verifying the Aggregated Ethernet Interface Configuration

**Purpose** Verify that the interface values match your configuration, the link is up, and traffic is flowing.

**Action** From operational mode, enter the **show interfaces redundancy** command.

```

user@host> show interfaces redundancy
Interface  State           Last change  Primary      Secondary    Current status
ae0        On primary                ge-5/0/3     ge-5/1/2     both up

```

From operational mode, enter the **show interfaces ae0** command.

```

user@host> show interfaces ae0
Physical interface: ae0, Enabled, Physical link is Up
  Interface index: 128, SNMP ifIndex: 606
  Link-level type: Ethernet, MTU: 1522, Speed: 1Gbps, BPDU Error: None,
  MAC-REWRITE Error: None, Loopback: Disabled, Source filtering: Disabled,
  Flow control: Disabled, Minimum links needed: 1, Minimum bandwidth needed: 0
  Device flags   : Present Running
  Interface flags: SNMP-Traps Internal: 0x4000
  Current address: 00:1f:12:b8:ef:c0, Hardware address: 00:1f:12:b8:ef:c0
  Last flapped   : 2011-03-11 13:24:18 PST (2d 03:34 ago)
  Input rate     : 1984 bps (2 pps)
  Output rate    : 0 bps (0 pps)

```

```

Logical interface ae0.32767 (Index 69) (SNMP ifIndex 709)
  Flags: SNMP-Traps 0x4004000 VLAN-Tag [ 0x0000.0 ] Encapsulation: ENET2
  Statistics          Packets      pps          Bytes          bps
  Bundle:
    Input :           371259         2        46036116        1984
    Output:              0         0             0             0

```

Protocol multiservice, MTU: Unlimited  
Flags: Is-Primary

**Meaning** The **show interfaces redundancy** output shows the redundant link configuration and that both link interfaces are up. The **show interfaces ae0** output shows that the aggregated Ethernet interface is up and that traffic is being received on the logical interface.

### Verifying the demux0 Interface Configuration

**Purpose** Verify that the VLAN demux interface displays the configured PPPoE family attributes and the member links in the aggregated Ethernet bundle.

**Action** From operational mode, enter the **show interfaces demux0** command.

```
user@host> show interfaces demux0.100
Logical interface demux0.100 (Index 76) (SNMP ifIndex 61160)
Flags: SNMP-Traps 0x4000 VLAN-Tag [ 0x8100.100 ]
Encapsulation: ENET2
Demux:
  Underlying interface: ae0 (Index 199)
Link:
  ge-5/0/3
  ge-5/1/2
Input packets : 2
Output packets: 18575
Protocol pppoe
  Dynamic Profile: none,
  Service Name Table: None,
  Max Sessions: 16000, Duplicate Protection: On,
  AC Name: pppoe-server-1
```

Alternatively, you can enter **show pppoe underlying-interfaces detail** to display the state and PPPoE family configuration for all configured underlying interfaces.

**Meaning** The output shows the name of the underlying interface, the member links of the aggregated bundle, and the PPPoE family configuration. The output shows packet counts when traffic is present on the logical interface.

### Verifying the pp0 Interface Configuration

**Purpose** Verify that the interface values match your configuration.

**Action** From operational mode, enter the **show interfaces pp0** command.

```
user@host> show interfaces pp0.100
Logical interface pp0.100 (Index 71) (SNMP ifIndex 710)
Flags: Point-To-Point SNMP-Traps 0x4000 Encapsulation: PPPoE
PPPoE:
  State: SessionUp, Session ID: 1,
  Session AC name: pppoe-server-1, Remote MAC address: 00:90:1a:00:18:34,
  Underlying interface: demux0.100 (Index 70)
Link:
  ge-5/0/3.32767
  ge-5/1/2.32767
Input packets : 18572
Output packets: 18572
```

```
Keepalive settings: Interval 10 seconds, Up-count 1, Down-count 3
Keepalive: Input: 0 (never), Output: 18566 (00:00:02 ago)
LCP state: Opened
NCP state: inet: Opened, inet6: Not-configured, iso: Not-configured, mpls:
Not-configured
CHAP state: Closed
PAP state: Success
  Protocol inet, MTU: 1500
    Flags: Sendbroadcast-pkt-to-re
    Addresses, Flags: Is-Primary
      Local: 45.63.24.1
```

**Meaning** This output shows information about the PPPoE logical interface created on the underlying VLAN demux interface. The output includes the PPPoE family and aggregated Ethernet redundant link information, and shows input and output traffic for the PPPoE interface.

## Example: Configuring a Dynamic PPPoE Subscriber Interface on a Static Underlying VLAN Demux Interface over Aggregated Ethernet

---

This example shows how you can configure dynamic PPPoE subscriber interfaces over aggregated Ethernet bundles to provide subscriber link redundancy.

- [Requirements on page 828](#)
- [Overview on page 829](#)
- [Configuration on page 829](#)
- [Verification on page 832](#)

### Requirements

PPPoE over VLAN demux interfaces over aggregated Ethernet requires the following hardware and software:

- MX Series 3D Universal Edge Routers
- MPCs
- Junos OS Release 11.2 or later

No special configuration beyond device initialization is required before you can configure this feature.

## Overview

Aggregated Ethernet bundles enable link redundancy between the router and networking devices connected by Ethernet links. This example describes how to configure link redundancy for dynamic PPPoE subscribers over aggregated Ethernet interface, **ae0**, with an intermediate static VLAN demux interface, **demux0.100**. Sample tasks include configuring a two-member aggregated Ethernet bundle, configuring a static VLAN demux interface that underlies the PPPoE subscriber interface, and configuring the dynamic profile that establishes the dynamic PPPoE subscriber interfaces.

The dynamic PPPoE profile (**pppoe-profile**) creates the PPPoE subscriber interface. It also configures the router to act as a PPPoE server and enables the local address to be derived from the specified address without assigning an explicit IP address to the interface. The **pppoe-profile** dynamic profile is assigned to the static, intermediate VLAN demux interface (**demux0.100**), which is configured with the PPPoE family (**family pppoe**) attributes. This dynamic profile includes the following predefined variables:

- **\$junos-interface-unit**—Represents the logical unit number of the dynamic PPPoE logical interface. This predefined variable is dynamically replaced with the unit number supplied by the router when the subscriber logs in.
- **\$junos-underlying-interface**—Represents the name of the underlying Ethernet interface. This predefined variable is dynamically replaced with the interface name supplied by the router when the subscriber logs in.

This example does not show all possible configuration choices.

## Configuration

### CLI Quick Configuration

To quickly configure link redundancy for dynamic PPPoE subscribers over a static VLAN demux interface over aggregated Ethernet, copy the following commands, paste them in a text file, remove any line breaks, and then copy and paste the commands into the CLI.

```
[edit]
set chassis aggregated-devices ethernet device-count 1
set interfaces ge-5/0/3 gigether-options 802.3ad ae0
set interfaces ge-5/0/3 gigether-options 802.3ad primary
set interfaces ge-5/1/2 gigether-options 802.3ad ae0
set interfaces ge-5/1/2 gigether-options 802.3ad backup
set interfaces ae0 flexible-vlan-tagging
set interfaces ae0 aggregated-ether-options link-protection
set interfaces demux0 unit 100 vlan-id 100
set interfaces demux0 unit 100 demux-options underlying-interface ae0
set interfaces demux0 unit 100 family pppoe access-concentrator pppoe-server-1
set interfaces demux0 unit 100 family pppoe duplicate-protection
set interfaces demux0 unit 100 family pppoe dynamic-profile pppoe-profile
edit dynamic-profiles pppoe-profile
edit interfaces pp0 unit $junos-interface-unit
set pppoe-options underlying-interface $junos-underlying-interface
set pppoe-options server
set family inet unnumbered-address lo0.0
top
```

**Step-by-Step  
Procedure**

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure link redundancy for dynamic PPPoE subscribers over a static VLAN demux interface over aggregated Ethernet:

1. Define the number of aggregated Ethernet devices on the router.

```
[edit chassis]
user@host# set aggregated-devices ethernet device-count 1
```

2. Configure a two-link aggregated Ethernet logical interface to serve as the underlying interface for the static VLAN demux subscriber interface. In this example, the LAG bundle is configured for one-to-one active/backup link redundancy. To support link redundancy at the MPC level, the LAG bundle attaches to ports from two different MPCs.

```
[edit interfaces]
user@host# set ge-5/0/3 gigether-options 802.3ad ae0
user@host# set ge-5/0/3 gigether-options 802.3ad primary
user@host# set ge-5/1/2 gigether-options 802.3ad ae0
user@host# set ge-5/1/2 gigether-options 802.3ad backup
```

3. Enable link protection on the aggregated Ethernet logical interface and configure support for single and dual (stacked) VLAN tags.

```
[edit interfaces]
user@host# set ae0 aggregated-ether-options link-protection
user@host# set ae0 flexible-vlan-tagging
```

4. Configure the VLAN demux interface over the aggregated Ethernet logical interface.

```
[edit interfaces]
user@host# set demux0 unit 100 vlan-id 100
user@host# set demux0 unit 100 demux-options underlying-interface ae0
```

5. Configure the PPPoE family attributes on the VLAN demux interface, including the dynamic profile.

```
[edit interfaces]
user@host# set demux0 unit 100 family pppoe access-concentrator pppoe-server-1
user@host# set demux0 unit 100 family pppoe duplicate-protection
user@host# set demux0 unit 100 family pppoe dynamic-profile pppoe-profile
```

6. Configure the dynamic profile that creates the PPPoE subscriber interfaces.

```
[edit dynamic-profiles pppoe-profile]
user@host# edit interfaces pp0 unit $junos-interface-unit
[edit dynamic-profiles pppoe-profile interfaces pp0 unit "$junos-interface-unit"]
user@host# set pppoe-options underlying-interface $junos-underlying-interface
user@host# set pppoe-options server
user@host# set family inet unnumbered-address lo0.0
```

**Results**

From configuration mode, confirm the aggregated device configuration by entering the **show chassis** command. Confirm the interface configuration by entering the **show interfaces** command. Confirm the dynamic profile configuration by entering the **show**

**dynamic-profiles** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show chassis
aggregated-devices {
  ethernet {
    device-count 1;
  }
}

[edit]
user@host# show interfaces
ge-5/0/3 {
  gigether-options {
    802.3ad {
      ae0;
      primary;
    }
  }
}
ge-5/1/2 {
  gigether-options {
    802.3ad {
      ae0;
      backup;
    }
  }
}
ae0 {
  flexible-vlan-tagging;
  aggregated-ether-options {
    link-protection;
  }
}
demux0 {
  unit 100 {
    vlan-id 100;
    demux-options {
      underlying-interface ae0;
    }
  }
  family pppoe {
    access-concentrator pppoe-server-1
    duplicate-protection;
    dynamic-profile pppoe-profile;
  }
}

[edit]
user@host# show dynamic-profiles
pppoe-profile {
  interfaces {
    pp0 {
      unit $junos-interface-unit {
        pppoe-options {
```

```

        underlying-interface $junos-underlying-interface;
        server;
    }
    family inet {
        unnumbered-address lo0.0;
    }
}
}
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform these tasks:

- [Verifying the Aggregated Ethernet Interface Configuration on page 832](#)
- [Verifying the demux0 Interface Configuration on page 833](#)

### Verifying the Aggregated Ethernet Interface Configuration

**Purpose** Verify that the interface values match your configuration, the link is up, and traffic is flowing.

**Action** From operational mode, enter the **show interfaces redundancy** command.

```

user@host> show interfaces redundancy
Interface  State           Last change  Primary      Secondary    Current status
ae0        On primary                ge-5/0/3     ge-5/1/2     both up

```

From operational mode, enter the **show interfaces ae0** command.

```

user@host> show interfaces ae0
Physical interface: ae0, Enabled, Physical link is Up
  Interface index: 128, SNMP ifIndex: 606
  Link-level type: Ethernet, MTU: 1522, Speed: 1Gbps, BPDU Error: None,
  MAC-REWRITE Error: None, Loopback: Disabled, Source filtering: Disabled,
  Flow control: Disabled, Minimum links needed: 1, Minimum bandwidth needed: 0
  Device flags   : Present Running
  Interface flags: SNMP-Traps Internal: 0x4000
  Current address: 00:1f:12:b8:ef:c0, Hardware address: 00:1f:12:b8:ef:c0
  Last flapped   : 2011-03-11 13:24:18 PST (2d 03:34 ago)
  Input rate     : 1984 bps (2 pps)
  Output rate    : 0 bps (0 pps)

```

```

Logical interface ae0.32767 (Index 69) (SNMP ifIndex 709)
  Flags: SNMP-Traps 0x4004000 VLAN-Tag [ 0x0000.0 ] Encapsulation: ENET2
  Statistics          Packets          pps          Bytes          bps
  Bundle:
    Input :           371259             2       46036116       1984
    Output:              0             0              0              0
  Protocol multiservice, MTU: Unlimited
  Flags: Is-Primary

```

**Meaning** The **show interfaces redundancy** output shows the redundant link configuration and that both link interfaces are up. The **show interfaces ae0** output shows that the aggregated Ethernet interface is up and that traffic is being received on the logical interface.

### Verifying the demux0 Interface Configuration

**Purpose** Verify that the VLAN demux interface displays the configured PPPoE family attributes and the member links in the aggregated Ethernet bundle.

**Action** From operational mode, enter the **show interfaces demux0** command.

```
user@host> show interfaces demux0.100
Logical interface demux0.100 (Index 76) (SNMP ifIndex 61160)
  Flags: SNMP-Traps 0x4000 VLAN-Tag [ 0x8100.100 ]
  Encapsulation: ENET2
  Demux:
    Underlying interface: ae0 (Index 199)
  Link:
    ge-5/0/3
    ge-5/1/2
  Input packets : 2
  Output packets: 18575
  Protocol pppoe
    Dynamic Profile: pppoe-profile,
    Service Name Table: None,
    Max Sessions: 16000, Duplicate Protection: On,
    AC Name: pppoe-server-1
```

Alternatively, you can enter **show pppoe underlying-interfaces detail** to display the state and PPPoE family configuration for all configured underlying interfaces. The output also provides information about PPPoE negotiation on a per-VLAN basis.

**Meaning** The output shows the name of the underlying interface, the member links of the aggregated bundle, and the PPPoE family configuration. The output shows packet counts when traffic is present on the logical interface.

### Requirements

PPPoE over VLAN demux interfaces over aggregated Ethernet requires the following hardware and software:

- MX Series 3D Universal Edge Routers
- MPCs
- Junos OS Release 11.2 or later

No special configuration beyond device initialization is required before you can configure this feature.

### Overview

Aggregated Ethernet bundles enable link redundancy between the router and networking devices connected by Ethernet links. This example describes how to configure link redundancy for dynamic PPPoE subscribers over aggregated Ethernet with an intermediate dynamic VLAN demux interface. Sample tasks include configuring a two-member aggregated Ethernet bundle, configuring dynamic profiles that establish the dynamic VLAN demux interface that underlies the PPPoE subscriber interface, and configuring the dynamic profile that establishes the dynamic PPPoE subscriber interfaces.

In this example, two different dynamic profiles are configured to instantiate either VLAN (**vlan-profile**) or S-VLAN (**svlan-profile**) demux interfaces. These profiles define PPPoE family options and include the dynamic PPPoE profile (**pppoe-profile**) that creates the PPPoE subscriber interface. Junos OS predefined variables are used in each profile to represent the interfaces and VLAN identifiers that are dynamically created. These dynamic profiles include the following predefined variables:

- **\$junos-interface-unit**—Represents the logical unit number of the dynamic VLAN demux interface. This predefined variable is dynamically replaced with the unit number supplied by the router when the subscriber logs in.
- **\$junos-interface-ifd-name**—Represents the underlying logical interface on which the PPPoE subscriber interface is created. This predefined variable is dynamically replaced with the name of the underlying interface supplied by the router when the subscriber logs in.

- **\$junos-vlan-id**—Represents the VLAN identifier. This predefined variable is dynamically replaced with a VLAN ID when the subscriber logs in. The VLAN ID is allocated within the VLAN range specified in the aggregated Ethernet configuration. In the case of the S-VLAN demux, **\$junos-vlan-id** represents the inner VLAN identifier.
- **\$junos-stacked-vlan-id**—Represents the outer VLAN identifier for the stacked VLAN. This predefined variable is dynamically replaced with a VLAN ID when the subscriber logs in. The VLAN ID is allocated within the VLAN range specified in the aggregated Ethernet configuration. This variable is not used for the VLAN demux configuration.

The dynamic PPPoE profile (**pppoe-profile**) creates the PPPoE subscriber interface. It also configures the router to act as a PPPoE server and enables the local address to be derived from the specified address without assigning an explicit IP address to the interface. The **pppoe-profile** dynamic profile is assigned to the dynamic, intermediate VLAN and S-VLAN demux interfaces. This dynamic profile includes the following predefined variables:

- **\$junos-interface-unit**—Represents the logical unit number of the dynamic PPPoE logical interface. This predefined variable is dynamically replaced with the unit number supplied by the router when the subscriber logs in.
- **\$junos-underlying-interface**—Represents the name of the underlying Ethernet interface. This predefined variable is dynamically replaced with the interface name supplied by the router when the subscriber logs in.

This example does not show all possible configuration choices.

## Configuration

### CLI Quick Configuration

To quickly configure link redundancy for dynamic PPPoE subscribers over a dynamic VLAN demux interface over aggregated Ethernet, copy the following commands, paste them in a text file, remove any line breaks, and then copy and paste the commands into the CLI.

```
[edit]
set chassis aggregated-devices ethernet device-count 1
set interfaces ge-5/0/3 gigether-options 802.3ad ae0
set interfaces ge-5/0/3 gigether-options 802.3ad primary
set interfaces ge-5/1/2 gigether-options 802.3ad ae0
set interfaces ge-5/1/2 gigether-options 802.3ad backup
edit interfaces ae0
set flexible-vlan-tagging
set aggregated-ether-options link-protection
edit auto-configure
set vlan-ranges dynamic-profile vlan-profile accept pppoe
set vlan-ranges dynamic-profile vlan-profile ranges 1-4094
set stacked-vlan-ranges dynamic-profile svlan-profile accept pppoe
set stacked-vlan-ranges dynamic-profile svlan-profile ranges 1-4094,1-4094
top
edit dynamic-profiles pppoe-profile
edit interfaces pp0 unit $junos-interface-unit
set pppoe-options underlying-interface $junos-underlying-interface
set pppoe-options server
set family inet unnumbered-address lo0.0
```

```
top
edit dynamic-profiles vlan-profile interfaces demux0
edit unit $junos-interface-unit
set vlan-id $junos-vlan-id
set demux-options underlying-interface $junos-interface-ifd-name
set family pppoe access-concentrator pppoe-server-1
set family pppoe duplicate-protection
set family pppoe dynamic-profile pppoe-profile
top
edit dynamic-profiles svlan-profile interfaces demux0
edit unit $junos-interface-unit
set vlan-tags outer $junos-stacked-vlan-id
set vlan-tags inner $junos-vlan-id
set demux-options underlying-interface $junos-interface-ifd-name
set family pppoe access-concentrator pppoe-server-1
set family pppoe duplicate-protection
set family pppoe dynamic-profile pppoe-profile
top
```

**Step-by-Step  
Procedure**

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode*.

To configure link redundancy for dynamic PPPoE subscribers over a dynamic VLAN demux interface over aggregated Ethernet:

1. Define the number of aggregated Ethernet devices on the router.

```
[edit chassis]
user@host# set aggregated-devices ethernet device-count 1
```

2. Configure a two-link aggregated Ethernet logical interface to serve as the underlying interface for the dynamic VLAN demux subscriber interface. In this example, the LAG bundle is configured for one-to-one active/backup link redundancy. To support link redundancy at the MPC level, the LAG bundle attaches to ports from two different MPCs.

```
[edit interfaces]
user@host# set ge-5/0/3 gigether-options 802.3ad ae0
user@host# set ge-5/0/3 gigether-options 802.3ad primary
user@host# set ge-5/1/2 gigether-options 802.3ad ae0
user@host# set ge-5/1/2 gigether-options 802.3ad backup
```

3. Enable link protection on the aggregated Ethernet logical interface and configure support for single and dual (stacked) VLAN tags.

```
[edit interfaces]
user@host# set ae0 aggregated-ether-options link-protection
user@host# set ae0 flexible-vlan-tagging
```

4. Configure the parameters for automatically configuring VLANs and S-VLANs, including the VLAN ranges and dynamic profiles.

```
[edit interfaces]
user@host# set ae0 auto-configure vlan-ranges dynamic-profile vlan-profile accept
pppoe
```

```

user@host# set ae0 auto-configure vlan-ranges dynamic-profile vlan-profile ranges
1-4094
user@host# set ae0 auto-configure stacked-vlan-ranges dynamic-profile
svlan-profile accept pppoe
user@host# set ae0 auto-configure stacked-vlan-ranges dynamic-profile
svlan-profile ranges 1-4094,1-4094

```

5. Configure the dynamic profile that creates the PPPoE subscriber interface.

```

[edit dynamic-profiles pppoe-profile]
user@host# edit interfaces pp0 unit $junos-interface-unit
[edit dynamic-profiles pppoe-profile interfaces pp0 unit "$junos-interface-unit"]
user@host# set pppoe-options underlying-interface $junos-underlying-interface
user@host# set pppoe-options server
user@host# set family inet unnumbered-address lo0.0

```

6. Configure the dynamic profile that creates VLAN demux underlying interfaces, including the PPPoE family attributes.

```

[edit dynamic-profiles vlan-profile]
user@host# edit interfaces demux0 unit $junos-interface-unit
[edit dynamic-profiles vlan-profile interfaces demux0 unit "$junos-interface-unit"]
user@host# set vlan-id $junos-vlan-id
user@host# set demux-options underlying-interface $junos-interface-ifd-name
user@host# set family pppoe access-concentrator pppoe-server-1
user@host# set family pppoe duplicate-protection
user@host# set family pppoe dynamic-profile pppoe-profile

```

7. Configure the dynamic profile that creates S-VLAN demux underlying interfaces, including the PPPoE family attributes.

```

[edit dynamic-profiles svlan-profile]
user@host# edit interfaces demux0 unit $junos-interface-unit
[edit dynamic-profiles svlan-profile interfaces demux0 unit "$junos-interface-unit"]
user@host# set vlan-tags outer $junos-stacked-vlan-id
user@host# set vlan-tags inner $junos-vlan-id
user@host# set demux-options underlying-interface $junos-interface-ifd-name
user@host# set family pppoe access-concentrator pppoe-server-1
user@host# set family pppoe duplicate-protection
user@host# set family pppoe dynamic-profile pppoe-profile

```

**Results** From configuration mode, confirm the aggregated device configuration by entering the **show chassis** command. Confirm the interface configuration by entering the **show interfaces** command. Confirm the dynamic profile configuration by entering the **show dynamic-profiles** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show chassis
aggregated-devices {
  ethernet {
    device-count 1;
  }
}

[edit]
user@host# show interfaces

```

```
ge-5/0/3 {
  gether-options {
    802.3ad {
      ae0;
      primary;
    }
  }
}
ge-5/1/2 {
  gether-options {
    802.3ad {
      ae0;
      backup;
    }
  }
}
ae0 {
  flexible-vlan-tagging;
  aggregated-ether-options {
    link-protection;
  }
  auto-configure {
    vlan-ranges {
      dynamic-profile {
        vlan-profile {
          accept pppoe;
          vlan-ranges 1-4094;
        }
      }
    }
    stacked-vlan-ranges {
      dynamic-profile {
        svlan-profile {
          accept pppoe;
          vlan-ranges 1-4094,1-4094;
        }
      }
    }
  }
}
[edit]
user@host# show dynamic-profiles
pppoe-profile {
  interfaces {
    pp0 {
      unit $junos-interface-unit {
        pppoe-options {
          underlying-interface $junos-underlying-interface;
          server;
        }
        family inet {
          unnumbered-address lo0.0;
        }
      }
    }
  }
}
```

```

    }
  }
  vlan-profile {
    interfaces {
      demux0 {
        unit "$junos-interface-unit" {
          vlan-id "$junos-vlan-id";
          demux-options {
            underlying-interface "$junos-interface-ifd-name";
          }
          family pppoe {
            access-concentrator pppoe-server-1;
            duplicate-protection;
            dynamic-profile pppoe-profile;
          }
        }
      }
    }
  }
}
svlan-profile {
  interfaces {
    demux0 {
      unit "$junos-interface-unit" {
        vlan-tags outer "$junos-stacked-vlan-id" inner "$junos-vlan-id";
        demux-options {
          underlying-interface "$junos-interface-ifd-name";
        }
        family pppoe {
          access-concentrator pppoe-server-1;
          duplicate-protection;
          dynamic-profile pppoe-profile;
        }
      }
    }
  }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

To confirm that the configuration is working properly, perform this task:

- [Verifying the Aggregated Ethernet Interface Configuration on page 839](#)

### Verifying the Aggregated Ethernet Interface Configuration

**Purpose** Verify that the interface values match your configuration, the link is up, and traffic is flowing.

**Action** From operational mode, enter the **show interfaces redundancy** command.

```

user@host> show interfaces redundancy
Interface  State           Last change   Primary    Secondary    Current status
ae0        On primary      ge-5/0/3      ge-5/0/3    ge-5/1/2    both up

```

From operational mode, enter the **show interfaces ae0** command.

```
user@host> show interfaces ae0
Physical interface: ae0, Enabled, Physical link is Up
  Interface index: 128, SNMP ifIndex: 606
  Link-level type: Ethernet, MTU: 1522, Speed: 1Gbps, BPDU Error: None,
  MAC-REWRITE Error: None, Loopback: Disabled, Source filtering: Disabled,
  Flow control: Disabled, Minimum links needed: 1, Minimum bandwidth needed: 0
  Device flags   : Present Running
  Interface flags: SNMP-Traps Internal: 0x4000
  Current address: 00:1f:12:b8:ef:c0, Hardware address: 00:1f:12:b8:ef:c0
  Last flapped   : 2011-03-11 13:24:18 PST (2d 03:34 ago)
  Input rate      : 1984 bps (2 pps)
  Output rate     : 0 bps (0 pps)

Logical interface ae0.32767 (Index 69) (SNMP ifIndex 709)
  Flags: SNMP-Traps 0x4004000 VLAN-Tag [ 0x0000.0 ] Encapsulation: ENET2
  Statistics          Packets          pps          Bytes          bps
  Bundle:
    Input  :          371259             2       46036116       1984
    Output :             0             0             0             0
  Protocol multiservice, MTU: Unlimited
  Flags: Is-Primary
```

**Meaning** The **show interfaces redundancy** output shows the redundant link configuration and that both link interfaces are up. The **show interfaces ae0** output shows that the aggregated Ethernet interface is up and that traffic is being received on the logical interface.

## Subscriber Interfaces and PPPoE Overview

---

You can configure the router to dynamically create Point-to-Point Protocol over Ethernet (PPPoE) logical interfaces on statically created underlying Ethernet interfaces. The router automatically and transparently creates the dynamic interface in response to the receipt of a PPPoE Active Discovery Request (PADR) control packet on the underlying interface. Because the router creates a dynamic PPPoE logical interface on demand when a subscriber logs in to the network, dynamic PPPoE logical interfaces are also referred to as *dynamic PPPoE subscriber interfaces*.

To enable the router to create a dynamic PPPoE logical interface on an underlying Ethernet interface, you define the attributes of the PPPoE logical interface in a dynamic profile, and then attach the dynamic profile to an Ethernet interface configured with PPPoE encapsulation. When the router receives a PADR control packet from a PPPoE client on an underlying interface with a PPPoE dynamic profile attached, the router uses the attributes defined in the profile to instantiate a dynamic PPPoE subscriber interface to handle the PPPoE session.

This overview covers the following topics:

- [Benefits of Using Dynamic PPPoE Subscriber Interfaces on page 842](#)
- [Supported Platforms for Dynamic PPPoE Subscriber Interfaces on page 843](#)
- [Sequence of Operations for PPPoE Subscriber Access on page 843](#)

## Benefits of Using Dynamic PPPoE Subscriber Interfaces

Configuring and using dynamic PPPoE subscriber interfaces offers the following benefits:

- On-demand dynamic interface creation

Configuring dynamic PPPoE subscriber interfaces provides the flexibility of dynamically creating the PPPoE subscriber interface only when needed; that is, when a subscriber logs in on the associated underlying Ethernet interface. By contrast, statically created interfaces allocate and consume system resources when the interface is created.

Configuring and using dynamically created interfaces helps you effectively and conveniently manage edge or access networks in which large numbers of subscribers are constantly logging in to and logging out from the network on a transient basis.

- Dynamic removal of PPPoE subscriber interfaces without manual intervention

When the PPPoE subscriber logs out or the PPPoE session is terminated, the router dynamically deletes the associated PPPoE subscriber interface without your intervention, thereby restoring any consumed resources to the router.

- Use of dynamic profiles to efficiently manage multiple subscriber interfaces

A *dynamic profile* is a set of characteristics that can be dynamically assigned to subscriber interfaces. By using a profile, you reduce the management of a large number of interfaces by applying a set of common characteristics to multiple interfaces. When you configure a dynamic profile for PPPoE, you use predefined dynamic variables in the profile to represent information that varies from subscriber to subscriber, such as the logical unit number and underlying interface name. These variables are dynamically replaced with the values supplied by the network when the subscriber logs in.

- Denial of service (DoS) protection

You can optionally configure the underlying Ethernet interface with certain PPPoE-specific attributes that can reduce the potential for DoS attacks. Duplicate protection, which is disabled by default, prevents activation of another dynamic PPPoE logical interface on the underlying interface when a PPPoE logical interface for the same client is already active on the underlying interface. You can also specify the maximum number of PPPoE sessions that the router can activate on the underlying interface. By enabling duplicate protection and restricting the maximum number of PPPoE sessions on the underlying interface, you can ensure that a single toxic PPPoE client cannot monopolize allocation of the PPPoE session.

- Support for dynamic PPPoE subscriber interface creation from PPPoE service name tables

You can assign a previously configured PPPoE dynamic profile to a named, **empty**, or **any** service entry in a PPPoE service name table, or to an agent circuit identifier/agent remote identifier (ACI/ARI) pair defined for these services. The router uses the attributes defined in the profile to instantiate a dynamic PPPoE subscriber interface based on the service name, ACI, and ARI information provided by the PPPoE client during PPPoE negotiation. To specify the routing instance in which to instantiate the dynamic PPPoE subscriber interface, you can assign a previously configured routing instance to a named, **empty**, or **any** service, or to an ACI/ARI pair defined for these services. The dynamic

profile and routing instance configured for the PPPoE service name table overrides the dynamic profile and routing instance assigned to the PPPoE underlying interface on which the dynamic subscriber interface is created.

## Supported Platforms for Dynamic PPPoE Subscriber Interfaces

Configuration of dynamic PPPoE subscriber interfaces over static underlying Ethernet interfaces is supported on the following routing platforms:

- Intelligent Queuing 2 (IQ2) PICs on M120 Multiservice Edge Router and M320 Multiservice Edge Router
- MPC/MIC interfaces on MX Series 3D Universal Edge Routers

## Sequence of Operations for PPPoE Subscriber Access

When a PPPoE subscriber logs in to the network, the PPPoE protocol defines the sequence of operations by which a connection is established and traffic flow is enabled on the dynamic PPPoE subscriber interface. Similarly, when the PPPoE subscriber logs out from the network, PPPoE defines the sequence that occurs to terminate the connection and remove the dynamic PPPoE subscriber interface from the router.

The router creates a dynamic PPPoE subscriber interface for each new PPPoE session, and removes the dynamic PPPoE subscriber interface when the session is terminated due to subscriber logout, PPP negotiation failure, or down status of the underlying Ethernet interface. Dynamic PPPoE subscriber interfaces are never reused for multiple PPPoE sessions.

### Sequence When a PPPoE Subscriber Logs In

In a PPPoE subscriber network, the router acts as a *remote access concentrator*, also known as a *PPPoE server*. For a PPPoE client to initiate a PPPoE session with a PPPoE server, it must first perform PPPoE Discovery to identify the Ethernet MAC address of the remote access concentrator that can service its request. Based on the network topology, there may be more than one remote access concentrator with which the client can communicate. The Discovery process enables a PPPoE client to find all remote access concentrators and then select one to connect to.

The following sequence occurs when a PPPoE subscriber logs in to the network. Steps 1 through 5 in this sequence are part of the PPPoE Discovery process.

1. The PPPoE client broadcasts a PPPoE Active Discovery Initiation (PADI) packet to all remote access concentrators in the network.
2. One or more remote access concentrators respond to the PADI packet by sending a PPPoE Active Discovery Offer (PADO) packet, indicating that they can service the client request. The PADO packet includes the name of the access concentrator from which it was sent.
3. The client sends a unicast PPPoE Active Discovery Request (PADR) packet to the access concentrator it selects.

4. On receipt of the PADR packet on the underlying interface associated with a PPPoE dynamic profile, the router uses the attributes configured in the dynamic profile to create the dynamic PPPoE logical interface.
5. The router sends a PPPoE Active Discovery Session (PADS) packet to confirm establishment of the PPPoE connection.
6. The PPP Link Control Protocol (LCP) negotiates the PPP link between the client and the PPPoE server.
7. The subscriber is authenticated using the PPP authentication protocol (CHAP or PAP) configured in the PPPoE dynamic profile.
8. The PPP Network Control Protocol (NCP) negotiates the IP routing protocol and network family.
9. The PPP server issues an IP access address for the client, and the router adds the client access route to its routing table.
10. The router instantiates the dynamic profile and applies the attributes configured in the profile to the dynamic PPPoE subscriber interface.
11. PPP NCP negotiation completes, enabling traffic flow between the PPPoE client and the PPPoE server.

---

#### Sequence When a PPPoE Subscriber Logs Out

The following sequence occurs when a PPPoE subscriber logs out of the network:

1. The client terminates the PPP connection and the router receives an LCP termination request.
2. The router removes the client access router from its routing table.
3. The router sends or receives a PPPoE Active Discovery Termination (PADT) packet to end the PPPoE connection.
4. The router deactivates the subscriber, gathers final statistics for the PPPoE session, and sends the RADIUS server an Acct-Stop accounting message.
5. The router de-instantiates the PPPoE dynamic profile and removes the PPPoE logical interface. The router does not reuse the PPPoE logical interface for future dynamic PPPoE sessions.

## Dynamic PPPoE Subscriber Interfaces over Static Underlying Interfaces Overview

Creating a dynamic PPPoE subscriber interface over a static underlying Ethernet interface consists of two basic steps:

1. Configure a dynamic profile to define the attributes of the PPPoE logical interface.
2. Attach the dynamic profile to a statically created underlying Ethernet interface configured with PPPoE encapsulation.

This overview describes the concepts you need to understand to configure a dynamic PPPoE subscriber interface, and covers the following topics:

- [PPPoE Dynamic Profile Configuration on page 845](#)
- [PPPoE Underlying Interface Configuration on page 846](#)
- [Address Assignment for Dynamic PPPoE Subscriber Interfaces on page 846](#)
- [Guidelines for Configuring Dynamic PPPoE Subscriber Interfaces on page 847](#)

### PPPoE Dynamic Profile Configuration

A *dynamic profile* is a template for configuring a dynamic interface. You use predefined dynamic variables in the PPPoE dynamic profile to represent information that varies from subscriber to subscriber, such as the logical unit number and underlying interface name. These variables are dynamically replaced with the values supplied by the network when the subscriber logs in. On receipt of traffic on an underlying Ethernet interface to which a dynamic profile is attached, the router creates the dynamic PPPoE logical interface, also referred to as a *dynamic PPPoE subscriber interface*, on the underlying interface and applies the properties configured in the dynamic profile.

To provide basic access for PPPoE subscribers, the dynamic profile must provide a minimal configuration for a **pp0** (PPPoE) logical interface that includes at least the following attributes:

- The logical unit number, represented by the **\$junos-interface-unit** predefined dynamic variable
- The name of the underlying Ethernet interface, represented by the **\$junos-underlying-interface** predefined dynamic variable
- Configuration of the router to act as a PPPoE server
- The PPP authentication protocol (PAP or CHAP)
- The unnumbered address for the **inet** (IPv4) or **inet6** (IPv6) protocol family

You can also optionally configure additional options for PPPoE subscriber access in the dynamic profile, including:

- The keepalive interval, or the option to disable sending keepalive messages
- The IPv4 or IPv6 address of the dynamic PPPoE logical interface

- The service sets and filters, input filters, and output filters to be applied to the dynamic PPPoE logical interface

## PPPoE Underlying Interface Configuration

After you configure a dynamic profile to define the attributes of a dynamic PPPoE subscriber interface, you must attach the dynamic profile to the underlying Ethernet interface on which you want the router to dynamically create the PPPoE logical interface. The underlying interface for a dynamic PPPoE logical interface must be statically created and configured with PPPoE (**ppp-over-ether**) encapsulation. When a PPPoE subscriber logs in on the underlying interface, the router dynamically creates the PPPoE logical interface and applies the attributes defined in the profile to the interface.

In addition to attaching the dynamic profile to the interface, you can also configure the underlying interface with one or more of the following optional PPPoE-specific attributes:

- Prevention of another dynamic PPPoE logical interface from being activated on the underlying interface when a PPPoE logical interface for a client with the same MAC address is already active on that interface
- Maximum number of dynamic PPPoE logical interfaces (sessions) that the router can activate on the underlying interface
- An alternative access concentrator name in the AC-NAME tag in a PPPoE control packet

## Address Assignment for Dynamic PPPoE Subscriber Interfaces

If the subscriber address for a dynamic PPPoE interface is not specified by means of the Framed-IP-Address (8) or Framed-Pool (88) RADIUS IETF attributes during authentication, the router allocates an IP address from the first IPv4 local address-assignment pool defined in the routing instance. For this reason, make sure that the local address assigned for the **inet** (IPv4) address family is in the same subnet as the addresses obtained from the first IPv4 local address-assignment pool.

The router allocates the IP address from the first IPv4 local address-assignment pool under either of the following conditions:

- RADIUS returns no address attributes.
- RADIUS authentication does not take place because only address allocation is requested.

If the first IPv4 local address-assignment pool has no available addresses, or if no IPv4 local address-assignment pools are configured, the router does not allocate an IP address to the dynamic PPPoE subscriber interface, and denies access to the associated subscriber. To avoid depletion of IP addresses, you can configure linked address-assignment pools on the first IPv4 local address-assignment pool to create one or more backup pools.

For more information, see [“Configuring Address-Assignment Pools” on page 156](#).

## Guidelines for Configuring Dynamic PPPoE Subscriber Interfaces

Observe the following guidelines when you configure dynamic PPPoE subscriber interfaces:

- You can configure dynamic PPPoE subscriber interfaces for the **inet** (IPv4) and **inet6** (IPv6) protocol families.
- When you configure the **pp0** (PPPoE) logical interface in a PPPoE dynamic profile, you must include the **pppoe-options** subhierarchy at the **[edit dynamic-profiles *profile-name* interfaces pp0 unit “\$junos-interface-unit”]** hierarchy level. At a minimum, the **pppoe-options** subhierarchy must include the name of the underlying Ethernet interface, represented by the **\$junos-underlying-interface** predefined dynamic variable, and the **server** statement, which configures the router to act as a PPPoE server. If you omit the **pppoe-options** subhierarchy from the configuration, the **commit** operation fails.
- When you configure CHAP or PAP authentication in a PPPoE dynamic profile, you cannot configure additional options for the **chap** or **pap** statements. This is because the router supports only unidirectional authentication for dynamic interfaces; that is, the router always functions as the authenticator.
- When you attach the PPPoE dynamic profile to an underlying Ethernet interface, ensure that both of the following conditions are met:
  - The PPPoE dynamic profile has already been configured on the router.
  - The underlying Ethernet interface has already been statically configured on the router with PPPoE (**ppp-over-ether**) encapsulation.
- You cannot attach a PPPoE dynamic profile to an underlying Ethernet interface that is already associated with static PPPoE logical interfaces. Conversely, you cannot associate static PPPoE logical interfaces with an underlying Ethernet interface that already has a PPPoE dynamic profile attached.

## PPPoE Maximum Session Limit Overview

---

The maximum session limit for PPPoE subscriber interfaces specifies the maximum number of concurrent static or dynamic PPPoE logical interfaces (sessions) that the router can activate on the PPPoE underlying interface, or the maximum number of active static or dynamic PPPoE sessions that the router can establish with a particular service entry in a PPPoE service name table.

You can configure the PPPoE maximum session limit in one of two ways:

- On a per-interface basis, by using the **max-sessions** CLI statement
- (Default) On a per-subscriber basis, by using the value returned by RADIUS in the Max-Clients-Per-Interface Juniper Networks vendor-specific attribute (VSA) [26-143]

This overview describes the concepts you need to understand to configure the PPPoE maximum session limit, and covers the following topics:

- [Per-Interface Configuration for PPPoE Maximum Session Limit Using the CLI on page 848](#)
- [Per-Subscriber Configuration for PPPoE Maximum Session Limit Using RADIUS on page 848](#)
- [Override of PPPoE Maximum Session Limit from RADIUS on page 849](#)

### Per-Interface Configuration for PPPoE Maximum Session Limit Using the CLI

To configure the PPPoE maximum session limit for a particular interface, you can use the **max-sessions** statement to specify either or both of the following, depending on the hierarchy level at which you include the statement:

- The maximum number of concurrent PPPoE sessions that the router can activate on the PPPoE underlying interface
- The maximum number of active PPPoE sessions using either static or dynamic PPPoE interfaces that the router can establish with a particular named service entry, **empty** service entry, or **any** service entry in a PPPoE service name table

You can configure the PPPoE maximum session value from 1 through the platform-specific default for your router. The default value is equal to the maximum number of PPPoE sessions supported on your routing platform. If the number of active PPPoE sessions exceeds the value configured with the **max-sessions** statement, the router prohibits creation of any new PPPoE sessions, and the PPPoE application on the router returns a PPPoE Active Discovery Session (PADS) packet with an error to the PPPoE client.

Changing the PPPoE maximum session value has no effect on dynamic PPPoE subscriber interfaces that are already active.

### Per-Subscriber Configuration for PPPoE Maximum Session Limit Using RADIUS

To configure the PPPoE maximum session limit for a particular subscriber, you can use the value returned by the RADIUS server in the Max-Clients-Per-Interface Juniper Networks VSA [26-143] during the subscriber authentication process. For PPPoE clients, the

Max-Clients-Per-Interface VSA returns the maximum number of sessions (PPPoE subinterfaces) per PPPoE major interface.

By default, the PPPoE maximum session value returned by RADIUS in the Max-Clients-Per-Interface VSA takes precedence over the PPPoE maximum session value configured with the **max-sessions** statement.

If you configure multiple subscribers on the same PPPoE underlying VLAN interface and RADIUS returns a different PPPoE maximum session value for each subscriber, the router uses the most recent PPPoE maximum session value returned by RADIUS to determine whether to override the current PPPoE maximum session value and create the new PPPoE session.

The following sequence describes how the router obtains the PPPoE maximum session value from RADIUS when a PPPoE subscriber logs in to initiate a session with the router. (In a PPPoE subscriber network, the router functions as a *remote access concentrator*, also known as a *PPPoE server*.)

1. The PPPoE client and the router participate in the PPPoE Discovery process to establish the PPPoE connection.
2. The PPP Link Control Protocol (LCP) negotiates the PPP link between the client and the router.
3. The PPP application sends the subscriber authentication request to the AAA application.
4. AAA sends the authentication request to an external RADIUS server.
5. The RADIUS server returns the PPPoE maximum session value for that subscriber to AAA in the Max-Clients-Per-Interface VSA as part of an Access-Accept message.

**NOTE:** The RADIUS server does not return the Max-Clients-Per-Interface VSA in Change of Authorization Request (CoA-Request) messages.

6. AAA passes the response from RADIUS to PPP.
7. PPP validates the subscriber parameters and, if authentication succeeds, passes the PPPoE maximum session value returned by RADIUS to the PPPoE application.
8. PPPoE uses the maximum session value returned by RADIUS to determine whether to override the current PPPoE maximum session value and create or tear down the new PPPoE session.

## Override of PPPoE Maximum Session Limit from RADIUS

By default, the PPPoE maximum session value returned by RADIUS in the Max-Clients-Per-Interface VSA [26-143] takes precedence over the PPPoE maximum session value configured with the **max-sessions** statement. To configure the router to ignore (clear) the PPPoE maximum session value returned by the RADIUS server in the Max-Clients-Per-Interface VSA, include the **max-sessions-vsa-ignore** statement at the same hierarchy levels that you can specify the **max-sessions** statement.

Including the **max-sessions-vsa-ignore** statement in your configuration restores the PPPoE maximum session value on the underlying interface to the value configured in the CLI with the **max-sessions** statement.

## Guidelines for Using PPPoE Maximum Session Limit from RADIUS

Consider the following guidelines when you use the PPPoE maximum session value returned by RADIUS in the Max-Clients-Per-Interface vendor-specific attribute (VSA) [26-143]:

- If the current number of sessions (including newly created sessions) is *less than* the new PPPoE maximum session value returned by RADIUS, the PPPoE application overrides the current value and enables interface creation to proceed.
- If the current number of sessions (including newly created sessions) is *equal to* the new PPPoE maximum session value returned by RADIUS, the PPPoE application overrides the current value and enables interface creation to proceed.
- If the current number of sessions (including newly created sessions) is *greater than* the new PPPoE maximum session value returned by RADIUS, the PPPoE application overrides the current value and brings down the new interface.

To illustrate these guidelines, [Table 69 on page 850](#) shows examples of how the router handles the PPPoE session when the current number of sessions is less than (first row), equal to (second row), and greater than (third row) the new PPPoE maximum session value returned by RADIUS when a new subscriber logs in.

**Table 69: Sample PPPoE Maximum Session Values During Subscriber Login**

New PPPoE Maximum Session Value from RADIUS	Current PPPoE Maximum Session Value	Existing Number of PPPoE Sessions	New PPPoE Maximum Session Value	New Number of PPPoE Sessions	Status of Session
10	5	4	10	5	PPPoE session up
5	5	4	5	5	PPPoE session up
3	5	4	3	4	PPPoE session down

## PPPoE Subscriber Session Lockout Overview

PPPoE subscriber session lockout, which is sometimes referred to as PPPoE encapsulation type lockout, configures the router to temporarily prevent (lock out) a failed or short-lived static or dynamic PPPoE subscriber session from reconnecting for a default or configurable period of time. This time period, known as the *lockout period*, is derived from a formula and increases exponentially based on the number of successive reconnection failures.

This overview describes the concepts you need to understand to configure PPPoE subscriber session lockout, and covers the following topics:

- [Benefits of Using PPPoE Subscriber Session Lockout on page 851](#)
- [Supported Platforms and Underlying Interfaces for PPPoE Subscriber Session Lockout on page 852](#)
- [How PPPoE Subscriber Session Lockout Works on page 852](#)
- [PPPoE Subscriber Session Lockout Period on page 853](#)
- [PPPoE Subscriber Session Lockout and Duplicate Protection on page 853](#)
- [PPPoE Subscriber Session Lockout and Automatic Removal of Dynamic Subscriber VLANs on page 854](#)

## Benefits of Using PPPoE Subscriber Session Lockout

Configuring and using PPPoE subscriber session lockout provides the following benefits:

- Reduces excessive loading on the router

By temporarily locking out failed or short-lived PPPoE sessions, PPPoE subscriber session lockout protects the router from excessive loading by:

- Reducing the resources required to receive and process PPPoE control packets to negotiate and terminate short-lived connections
- Reducing the resources required to allocate and deallocate services, such as class of service (CoS) and firewall filters, for failed or short-lived subscriber sessions

PPPoE subscriber session lockout increases router efficiency by temporarily deferring failed or short-lived subscriber sessions in favor of those sessions that can complete successfully.

- Reduces excessive loading on external authentication, authorization, and accounting (AAA) servers

PPPoE subscriber session lockout protects any external AAA servers, such as RADIUS or Diameter, from excessive loading:

- As a result of failed or short-lived PPPoE subscriber sessions that occur repeatedly for the same subscriber
- By reducing the resources required to authenticate and terminate these connections
- Enables lockout of a single failed or short-lived PPP session without disrupting other PPP sessions on the same PPPoE underlying interface

In some subscriber network configurations, the PPPoE underlying interface supports multiple upper-layer PPP sessions. Because PPPoE subscriber session lockout identifies each subscriber session by its unique media access control (MAC) source address on the underlying interface, the router is able to lock out only the offending PPP session while enabling other PPP sessions on the same underlying interface to successfully negotiate the connection.

## Supported Platforms and Underlying Interfaces for PPPoE Subscriber Session Lockout

You can configure PPPoE subscriber session lockout on the following platforms and underlying interface types:

- Supported platforms:
  - Intelligent Queuing 2 (IQ2) PICs on M120 Multiservice Edge Router and M320 Multiservice Edge Router
  - MPC/MIC interfaces on MX Series 3D Universal Edge Routers
- Supported PPPoE underlying interfaces:
  - Static VLAN logical interface
  - Static VLAN demultiplexing (demux) logical interface
  - Dynamic VLAN logical interface
  - Dynamic VLAN demux logical interface

## How PPPoE Subscriber Session Lockout Works

PPPoE subscriber session lockout is disabled on the router by default. When you enable PPPoE subscriber session lockout by issuing the **short-cycle-protection** statement, the router does the following:

1. Detects a short-lived subscriber session, also referred to as a *short-cycle event*.  
  
A short-lived subscriber session is detected, partially or completely created, and terminated by the router within 150 seconds. The router identifies each PPPoE subscriber session by its unique MAC source address on the PPPoE underlying interface.
2. Tracks the time between repeated short-cycle events to determine whether to increase the lockout time for a subsequent short-cycle event.

3. Applies a time penalty for each short-cycle event based on a default or configured lockout period and the number of consecutive short-cycle events that occur repeatedly for the same subscriber.

If you enable PPPoE subscriber session lockout but do not configure a lockout time range, the router uses the default lockout time range of 1 through 300 seconds (5 minutes).

4. Temporarily locks out the specified PPPoE subscriber by preventing connection to the router.

During lockout, the router drops negotiation packets for the PPPoE subscriber session until the lockout period expires. When the lockout period expires, the PPPoE subscriber session and its associated MAC source address resume normal negotiation of the connection.

Repeated creation of multiple short-lived (short-cycle) PPPoE subscriber sessions can cause excessive loading on the router. Conditions that can cause a short-lived subscriber session include:

- Authentication denials from external AAA servers, such as RADIUS, due to the absence of a corresponding entry in the RADIUS database or due to improper login attempts
- Configuration errors within a dynamic profile or RADIUS record
- Insufficient memory resources to create a dynamic PPPoE subscriber interface
- Protocol failure or error within the dynamic PPPoE subscriber interface
- Client logout shortly after a successful login; this action creates a complete dynamic PPPoE subscriber interface before the interface is torn down

## PPPoE Subscriber Session Lockout Period

The lockout period is the time during which the router temporarily prevents (locks out) a failed or short-lived PPPoE subscriber session identified by a unique MAC source address from reconnecting to the router. You can use the default lockout time range of 1 through 300 seconds (5 minutes), or you can override the default lockout period by configuring a nondefault lockout time in the range 1 through 86,400 seconds (24 hours).

## PPPoE Subscriber Session Lockout and Duplicate Protection

Duplicate protection, which is disabled on the router by default, prevents the activation of another PPPoE subscriber session on the same PPPoE underlying interface when a PPPoE subscriber session with the same media access control (MAC) address is already active on that interface. When you configure PPPoE subscriber session lockout, we recommend that you enable duplicate protection to ensure that the MAC source address for each active PPPoE session is unique on the underlying interface.

With PPPoE subscriber session lockout configured, the router identifies subscriber sessions by their unique MAC source address. If the router detects a short-lived (short-cycle) subscriber session, it applies the default or configured lockout period to that MAC source address to temporarily prevent reconnection. If the MAC source address is not unique on

the underlying interface, multiple PPPoE subscriber sessions with the same MAC source address might also be affected by the lockout.

## PPPoE Subscriber Session Lockout and Automatic Removal of Dynamic Subscriber VLANs

You can configure automatic removal of subscriber VLANs that have no PPPoE client sessions by issuing the **remove-when-no-subscribers** statement at the **[edit interfaces interface-name auto-configure]** hierarchy level. If PPPoE subscriber session lockout is also configured, the router does not remove the unused subscriber VLAN until the lockout time has expired for each PPPoE client undergoing lockout on the underlying interface.

---

## Understanding the Lockout Period for PPPoE Subscriber Session Lockout

When you configure PPPoE subscriber session lockout, the router applies a time penalty called the *lockout period* for each failed or short-lived subscriber session. During the lockout period, the router temporarily prevents (locks out) a failed or short-lived PPPoE subscriber session identified by a unique media access control (MAC) source address from reconnecting to the router.

This overview describes how the router determines and applies the PPPoE subscriber session lockout period, and covers the following topics:

- [Duration of PPPoE Subscriber Session Lockout Period on page 854](#)
- [How the Router Determines the PPPoE Subscriber Session Lockout Period on page 855](#)

### Duration of PPPoE Subscriber Session Lockout Period

The duration of the lockout period is based on a default or configured lockout time and the number of consecutive short-cycle (short-lived) events that occur repeatedly for the same subscriber. When you include the **short-cycle-protection** statement to configure PPPoE subscriber session lockout on a PPPoE underlying interface, you can use the default lockout time range of 1 through 300 seconds (5 minutes), or you can override the default lockout period by configuring a nondefault lockout time in the range 1 through 86,400 seconds (24 hours).

The lockout time penalty applied by the router for each short-cycle event differs depending on the event. For example, some short-cycle events represent normal subscriber behavior, such as a PPPoE subscriber logging in once per hour to check e-mail and logging out shortly thereafter. The router does not noticeably penalize a subscriber for these types of events.

By contrast, other short-cycle events are the result of repeated attempts to log in to the router for reasons such as an incorrectly typed password, customer premises equipment (CPE) that performs repeated auto-retries, or malicious attempts to access the Internet illegally. For these types of short-cycle events, the router applies a lockout time penalty that starts with a short time interval and increases exponentially. In these instances, the initial lockout time is short enough to avoid noticeably penalizing a subscriber who, for example, types a password incorrectly several times before entering the correct one.

For example, using the default lockout time range of 1 through 300 seconds, the increasing lockout period on the router is: 1 second, 2 seconds, 4 seconds, 8 seconds, 16 seconds, 32 seconds, 64 seconds, 128 seconds, 256 seconds, and finally, 300 seconds (5 minutes).

### How the Router Determines the PPPoE Subscriber Session Lockout Period

The router uses the following rules to determine the PPPoE subscriber session lockout period for short-lived PPPoE subscriber sessions:

- The lockout period is derived from the following formula:

$$(\text{minimum lockout time}) * (2^{n-1})$$

where  $n$  represents the number of consecutive short-cycle events for the same subscriber. The router identifies a PPPoE subscriber session by its MAC source address, which should be unique on the underlying PPPoE interface.

- The router increments the value of  $n$  when the time between short-cycle events is either within 15 minutes or the maximum lockout time, whichever is greater.
- When the time between short-cycle events is greater than either 15 minutes or the maximum lockout time, the value of  $n$  reverts to 1. This condition is referred to as a *lockout grace period*.
- The lockout period never exceeds the maximum configured lockout time.

For example, for a configured (nondefault) lockout time in the range 20 through 120 seconds, the increasing lockout period on the router is: 20 seconds, 40 seconds, 80 seconds, and finally, 120 seconds (2 minutes).

- A *short-cycle event* is detected, partially or completely created, and terminated by the router within 150 seconds. The router tracks the time between short-cycle events to determine whether to increase the lockout time for a subsequent short-cycle event for the same subscriber.

**NOTE:** When the calculated lockout time is equal to or exceeds the maximum lockout time, the router uses the maximum lockout time value until the time to the next short-cycle event exceeds the greater of 15 minutes or the maximum lockout time value. At that point, the lockout time reverts to the minimum lockout time value.

- The minimum lockout time value cannot exceed the maximum lockout time value.

When the minimum and maximum lockout time values are equal, the lockout time becomes fixed at that value.

## Configuring Dynamic PPPoE Subscriber Interfaces Using Dynamic Profiles

---

You can configure dynamic PPP-over-Ethernet (PPPoE) subscriber interfaces by using dynamic profiles. To enable the router to create a dynamic PPPoE subscriber interface on a PPPoE underlying interface, you define the attributes of the PPPoE logical interface in a dynamic profile, and then configure the underlying interface to use the dynamic profile.

To configure a dynamic PPPoE subscriber interface:

1. Configure a dynamic profile to define the attributes of the PPPoE logical interface.
  - To configure a basic dynamic profile for PPPoE subscriber access, see [“Configuring a Basic PPPoE Dynamic Profile” on page 858](#).
  - To configure a dynamic profile for PPPoE with additional options for subscriber access, see [“Configuring a PPPoE Dynamic Profile with Additional Options” on page 861](#).

2. Configure the underlying Ethernet interface to use the dynamic profile for PPPoE.

See [“Configuring an Underlying Interface for Dynamic PPPoE Subscriber Interfaces” on page 863](#).

3. (Optional) Assign a dynamic profile and routing instance to a service name or ACI/ARI pair in a PPPoE service name table to instantiate a dynamic PPPoE subscriber interface based on the information provided by the PPPoE client.

See [“Assigning a Dynamic Profile and Routing Instance to a Service Name or ACI/ARI Pair for Dynamic PPPoE Interface Creation”](#) on page 868.

4. (Optional) Verify the dynamic PPPoE configuration by displaying or clearing PPPoE session statistics, and displaying information about the underlying Ethernet interface and PPPoE logical interface.

See [“Verifying and Managing Dynamic PPPoE Configuration”](#) on page 872.

---

## Configuring a Basic PPPoE Dynamic Profile

---

You can configure a basic dynamic profile for PPPoE subscribers that access the network. The dynamic profile defines the attributes of the dynamic PPPoE logical interface, also referred to as a *dynamic PPPoE subscriber interface*.

To provide basic access for PPPoE subscribers, the dynamic profile must provide a minimal configuration for a **pp0** (PPPoE) logical interface that includes the following:

- The logical unit number, represented by the **\$junos-interface-unit** predefined dynamic variable
- The name of the underlying Ethernet interface, represented by the **\$junos-underlying-interface** predefined dynamic variable
- The **server** statement, which configures the router to act as a PPPoE server
- The PPP authentication protocol (PAP or CHAP)
- The unnumbered address for the **inet** (IPv4) or **inet6** (IPv6) protocol family

**NOTE:** The creation of dynamic PPPoE subscriber interfaces is supported for the **inet** and **inet6** protocol families.

---

To configure a basic PPPoE dynamic profile:

1. Name the dynamic profile.

[edit]

```
user@host# edit dynamic-profiles basic-pppoe-profile
```

2. Specify that you want to configure the **pp0** logical interface in the dynamic profile.

```
[edit dynamic-profiles basic-pppoe-profile]
```

```
user@host# edit interfaces pp0
```

3. Configure the predefined variable to represent the logical unit number for the **pp0** interface.

You must use the **\$junos-interface-unit** variable instead of the logical unit number for the **unit** statement. The **\$junos-interface-unit** variable is dynamically replaced with the actual unit number supplied by the network when the subscriber logs in.

```
[edit dynamic-profiles basic-pppoe-profile interfaces pp0]
```

```
user@host# edit unit $junos-interface-unit
```

4. Configure PPPoE-specific options for the **pp0** interface.

- a. Configure the predefined variable to represent the name of the underlying Ethernet interface on which the router creates the dynamic PPPoE logical interface.

You must use the **\$junos-underlying-interface** variable instead of the underlying interface name for the **underlying-interface** statement. The **\$junos-underlying-interface** variable is dynamically replaced with the actual name of the underlying interface supplied by the network when the subscriber logs in.

```
[edit dynamic-profiles basic-pppoe-profile interfaces pp0 unit
```

```
"$junos-interface-unit"]
```

```
user@host# set pppoe-options underlying-interface $junos-underlying-interface
```

- b. Configure the router to act as a PPPoE server, also known as a remote access concentrator.

```
[edit dynamic-profiles basic-pppoe-profile interfaces pp0 unit
```

```
"$junos-interface-unit"]
```

```
user@host# set pppoe-options server
```

5. Configure the PPP authentication protocol for the **pp0** interface.

For dynamic interfaces, the router supports only unidirectional authentication; that is, the router always functions as the authenticator. When you configure PPP authentication in a dynamic profile, the **chap** and **pap** statements do not support any additional configuration options.

- To configure CHAP authentication:

```
[edit dynamic-profiles basic-pppoe-profile interfaces pp0 unit "$junos-interface-unit"]
```

```
user@host# set ppp-options chap
```

- To configure PAP authentication:

```
[edit dynamic-profiles basic-pppoe-profile interfaces pp0 unit "$junos-interface-unit"]
```

```
user@host# set ppp-options pap
```

6. Configure the protocol family for the **pp0** interface.

- a. Specify that you want to configure the **inet** (IPv4) or **inet6** (IPv6) protocol family.

```
[edit dynamic-profiles basic-pppoe-profile interfaces pp0 unit
```

```
"$junos-interface-unit"]
```

```
user@host# edit family inet
```

- b. Configure the unnumbered address for the protocol family.

```
[edit dynamic-profiles basic-pppoe-profile interfaces pp0 unit "$junos-interface-unit"  
family inet]
```

```
user@host# set unnumbered-address lo0.0
```

## Configuring a PPPoE Dynamic Profile with Additional Options

You can configure a dynamic profile for PPPoE that has additional options for subscriber access. All of these optional statements, with the exception of the **keepalives** and **no-keepalives** statements, are configured at the **[edit dynamic-profiles *profile-name* interfaces pp0 unit "\$junos-interface-unit" family *family*]** hierarchy level. The **keepalives** and **no-keepalives** statements are configured at the **[edit dynamic-profiles *profile-name* interfaces pp0 unit "\$junos-interface-unit"]** hierarchy level.

The additional options for PPPoE subscriber access in a dynamic profile can include one or more of the following:

- The keepalive interval (**keepalives**), or the option to disable sending keepalive messages (**no-keepalives**)
- The IPv4 or IPv6 address of the dynamic PPPoE logical interface (**address**)
- Definition of the service sets and filters to be applied to the dynamic PPPoE logical interface, configured at the **[edit dynamic-profiles *profile-name* interfaces pp0 unit "\$junos-interface-unit" family *family* service]** hierarchy level
- Association of an input and output filter to the dynamic PPPoE logical interface, configured at the **[edit dynamic-profiles *profile-name* interfaces pp0 unit "\$junos-interface-unit" family *family* filter]** hierarchy level

**NOTE:** The creation of dynamic PPPoE subscriber interfaces is supported for the **inet** and **inet6** protocol families.

Before you begin:

- Configure a basic PPPoE dynamic profile.

See [“Configuring a Basic PPPoE Dynamic Profile” on page 858](#).

To configure a PPPoE dynamic profile with additional options for subscriber access:

1. Modify the keepalive interval, or configure the router to disable sending keepalive messages.
  - To modify the keepalive interval:
 

```
[edit dynamic-profiles business-pppoe-profile interfaces pp0 unit
"$junos-interface-unit"]
user@host# set keepalives interval 15
```
  - To disable sending keepalive messages:
 

```
[edit dynamic-profiles business-pppoe-profile interfaces pp0 unit
"$junos-interface-unit"]
user@host# set no-keepalives
```
2. Specify that you want to configure the **inet** (IPv4) or **inet6** (IPv6) protocol family.

```
[edit dynamic-profiles business-pppoe-profile interfaces pp0 unit  
"$junos-interface-unit"]  
user@host# edit family inet
```

3. Specify the IPv4 or IPv6 address of the dynamic PPPoE logical interface.

```
[edit dynamic-profiles business-pppoe-profile interfaces pp0 unit  
"$junos-interface-unit" family inet]  
user@host# set address 6.6.6.7/32
```

4. Specify the input and output service sets that you want to apply to the dynamic PPPoE logical interface.

```
[edit dynamic-profiles business-pppoe-profile interfaces pp0 unit  
"$junos-interface-unit" family inet]  
user@host# set service input service-set inputService_100  
user@host# set service input post-service-filter postService_20  
user@host# set service output service-set outputService_200
```

5. Specify the input and output filters that you want to apply to the dynamic PPPoE logical interface.

To control the order in which filters are processed, you can optionally specify a precedence value for the input filter, output filter, or both.

```
[edit dynamic-profiles business-pppoe-profile interfaces pp0 unit  
"$junos-interface-unit" family inet]  
user@host# set filter input pppoe-input-filter  
user@host# set filter output pppoe-output-filter precedence 50
```

## Configuring an Underlying Interface for Dynamic PPPoE Subscriber Interfaces

After you configure a dynamic profile to define the attributes of a dynamic PPPoE subscriber interface, you must attach the dynamic profile to a statically created underlying Ethernet interface configured with PPPoE (**ppp-over-ether**) encapsulation. You configure the underlying interface at the **[edit interfaces *interface-name* unit *logical-unit-number* pppoe-underlying-options]** hierarchy level.

In addition to attaching the dynamic profile to the interface by using the required **dynamic-profile** statement, you can also configure the underlying interface with one or more of the following optional PPPoE-specific attributes:

- Prevention of another dynamic PPPoE logical interface from being activated on the underlying interface when a PPPoE logical interface for a client with the same MAC address is already active on that interface (**duplicate-protection**)
- Maximum number of dynamic PPPoE logical interfaces (sessions) that the router can activate on the underlying interface on a per-interface basis (using the **max-sessions** statement) or on a per-subscriber basis (using the Max-Clients-Per-Interface Juniper Networks VSA [26-143])
- Lockout of failed or short-lived (also known as short-cycle) PPPoE subscriber sessions to prevent reconnection to the router for a default or configurable period of time (**short-cycle-protection**)
- An alternative access concentrator name in the AC-NAME tag in a PPPoE control packet (**access-concentrator**)

Before you begin:

1. Configure the static underlying Ethernet interface on which you want the router to dynamically create the PPPoE logical interface.

For information about configuring static Ethernet interfaces, see the Junos® OS Network Interfaces.

2. Configure a PPPoE dynamic profile in either of the following ways:

- To configure a basic PPPoE dynamic profile, see [“Configuring a Basic PPPoE Dynamic Profile” on page 858](#).
- To configure a PPPoE dynamic profile with additional options for subscriber access, see [“Configuring a PPPoE Dynamic Profile with Additional Options” on page 861](#).

To configure an underlying Ethernet interface for a dynamic PPPoE subscriber interface:

1. Specify the name and logical unit number of the static underlying Ethernet interface to which you want to attach the PPPoE dynamic profile.

```
[edit]
user@host# edit interfaces ge-1/0/1 unit 0
```

2. Configure PPPoE encapsulation on the underlying interface.

```
[edit interfaces ge-1/0/1 unit 0]
```

```
user@host# set encapsulation ppp-over-ether
```

3. Specify that you want to configure PPPoE-specific options on the underlying interface.

```
[edit interfaces ge-1/0/1 unit 0]
```

```
user@host# edit pppoe-underlying-options
```

4. Attach a previously configured PPPoE dynamic profile to the underlying interface.

The specified PPPoE dynamic profile must already be configured on the router. In addition, you cannot attach a PPPoE dynamic profile to an underlying Ethernet interface that is already associated with static PPPoE logical interfaces. Conversely, you cannot associate static PPPoE logical interfaces with an underlying Ethernet interface that already has a PPPoE dynamic profile attached.

```
[edit interfaces ge-1/0/1 unit 0 pppoe-underlying-options]
```

```
user@host# set dynamic-profile basic-pppoe-profile
```

5. (Optional) Enable duplicate protection to prevent activation of another dynamic PPPoE logical interface for the same client on the underlying interface.

```
[edit interfaces ge-1/0/1 unit 0 pppoe-underlying-options]
```

```
user@host# set duplicate-protection
```

6. (Optional) Configure the maximum number of concurrent PPPoE sessions that the router can activate on the underlying interface in either of the following ways:

- To configure the maximum number of concurrent PPPoE sessions on a per-interface basis, from 1 to the platform-specific default for your router, use the **max-sessions** statement:

```
[edit interfaces ge-1/0/1 unit 0 pppoe-underlying-options]
```

```
user@host# set max-sessions 20
```

- To configure the maximum number of concurrent PPPoE sessions on a per-subscriber basis, use the value returned by RADIUS in the Max-Clients-Per-Interface Juniper Networks vendor-specific attribute (VSA) [26-143]. By default, the PPPoE maximum session value returned by RADIUS in the Max-Clients-Per-Interface VSA takes precedence over the PPPoE maximum session value configured with the **max-sessions** statement.

7. (Optional) Configure the router to ignore the value returned by RADIUS in the Max-Clients-Per-Interface VSA and restore the PPPoE maximum session value on the underlying interface to the value configured in the CLI with the **max-sessions** statement.

```
[edit interfaces ge-1/0/1 unit 0 pppoe-underlying-options]
```

```
user@host# set max-sessions-vsa-ignore
```

8. (Optional) Enable PPPoE subscriber session lockout on the PPPoE underlying interface in either of the following ways:

- To configure PPPoE subscriber session lockout with the default lockout period:

```
[edit interfaces interface-name unit logical-unit-number pppoe-underlying-options]
```

```
user@host# set short-cycle-protection
```

- To configure PPPoE subscriber session lockout with a nondefault lockout period:

```
[edit interfaces interface-name unit logical-unit-number pppoe-underlying-options]
```

```
user@host# set short-cycle-protection lockout-time-min minimum-seconds
lockout-time-max maximum-seconds
```

**BEST PRACTICE:** When you configure PPPoE subscriber session lockout, we recommend that you also enable duplicate protection to ensure that the MAC source address for each PPPoE session is unique on the underlying interface.

9. (Optional) Specify the alternative name for the access concentrator, also known as the PPPoE server.

```
[edit interfaces ge-1/0/1 unit 0 pppoe-underlying-options]
user@host# set access-concentrator server-east
```

- For information about configuring static Ethernet underlying interfaces, see the Junos® OS Network Interfaces

## Limiting the Maximum Number of PPPoE Sessions on the Underlying Interface

You can limit the maximum number of concurrent static or dynamic PPPoE logical interfaces (sessions) that the router can activate on the PPPoE underlying interface, or the maximum number of active static or dynamic PPPoE sessions that the router can establish with a particular service entry in a PPPoE service name table.

You can configure the PPPoE maximum session limit in either of the following ways:

- On a per-interface basis, by using the **max-sessions** CLI statement.
- (Default) On a per-subscriber basis, by using the value returned by RADIUS in the Max-Clients-Per-Interface Juniper Networks vendor-specific attribute (VSA) [26-143]. By default, the PPPoE maximum session value returned by RADIUS in the Max-Clients-Per-Interface VSA takes precedence over the PPPoE maximum session value configured with the **max-sessions** statement.

Optionally, you can configure the router to ignore the PPPoE maximum session value returned by RADIUS in the Max-Clients-Per-Interface VSA by including the **max-sessions-vsa-ignore** statement in your configuration. Using the **max-sessions-vsa-ignore** statement restores the PPPoE maximum session value on the underlying interface to the value configured in the CLI with the **max-sessions** statement.

Before you begin:

- Configure the PPPoE underlying interface.

To configure the underlying interface for use with a PPPoE dynamic profile, see [“Configuring an Underlying Interface for Dynamic PPPoE Subscriber Interfaces” on page 863](#).

To configure the PPPoE family for an underlying interface, see [“Configuring the PPPoE Family for an Underlying Interface” on page 789](#).

To configure the PPPoE maximum session limit:

1. Specify that you want to configure PPPoE-specific options on the underlying interface:
  - For a PPPoE family in a dynamic profile for a VLAN demultiplexing (demux) logical interface:

```
[edit dynamic-profiles profile-name interfaces demux0 unit logical-unit-number]  
user@host# edit family pppoe
```
  - For a PPPoE family in a dynamic profile:

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number]  
user@host# edit family pppoe
```
  - For a PPPoE underlying interface in a dynamic profile:

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number]  
user@host# edit pppoe-underlying-options
```
  - For a PPPoE family on an underlying interface:

```
[edit interfaces interface-name unit logical-unit-number]
user@host# edit family pppoe
```

- For an underlying interface with PPPoE encapsulation:

```
[edit interfaces interface-name unit logical-unit-number]
user@host# edit pppoe-underlying-options
```

- For an underlying interface established with a particular service entry in a PPPoE service name table:

```
[edit protocols pppoe service-name-tables table-name]
user@host# edit service service-name
```

2. Configure the maximum number of concurrent PPPoE sessions that the router can activate on the underlying interface in either of the following ways:

- To configure the maximum number of concurrent PPPoE sessions on a per-interface basis, from 1 to the platform-specific default for your router, use the **max-sessions** statement:

```
[edit interfaces interface-name unit logical-unit-number pppoe-underlying-options]
user@host# set max-sessions number
```

- To configure the maximum number of concurrent PPPoE sessions on a per-subscriber basis, use the value returned by RADIUS in the Max-Clients-Per-Interface Juniper Networks vendor-specific attribute (VSA) [26-143]. By default, the PPPoE maximum session value returned by RADIUS in the Max-Clients-Per-Interface VSA takes precedence over the PPPoE maximum session value configured with the **max-sessions** statement.

3. (Optional) To restore the PPPoE maximum session value on the underlying interface to the value configured in the CLI with the **max-sessions** statement, configure the router to ignore the value returned by RADIUS in the Max-Clients-Per-Interface VSA.

```
[edit interfaces interface-name unit logical-unit-number pppoe-underlying-options]
user@host# set max-sessions-vsa-ignore
```

**NOTE:** You can issue the **max-sessions-vsa-ignore** statement at the same hierarchy levels as the **max-sessions** statement, with the exception of the **[edit protocols pppoe service-name-tables *table-name* service *service-name*]** hierarchy level.

## Assigning a Dynamic Profile and Routing Instance to a Service Name or ACI/ARI Pair for Dynamic PPPoE Interface Creation

---

You can create a dynamic PPPoE subscriber interface based on the service name, agent circuit identifier (ACI), and agent remote identifier (ARI) information provided by the PPPoE client during PPPoE negotiation. To do so, you assign a previously configured PPPoE dynamic profile to a named service, **empty** service, or **any** service entry in a PPPoE service name table, or to an ACI/ARI pair defined for these services.

Similarly, to specify the routing instance in which to instantiate the dynamic PPPoE subscriber interface, you can assign a previously configured routing instance to a named service, **empty** service, or **any** service in a PPPoE service name table, or to an ACI/ARI pair defined for these services.

Observe the following configuration guidelines when you assign a dynamic profile and routing instance to a PPPoE service name table to create a dynamic PPPoE subscriber interface:

- The dynamic profile and routing instance must already be configured on the router.
- The dynamic profile or routing instance assigned to the PPPoE service name table overrides the dynamic profile or routing instance assigned to the PPPoE underlying interface on which the dynamic subscriber interface is created.
- You cannot configure a dynamic profile or routing instance for an ACI/ARI pair already configured with a static interface (by using the **static-interface** statement). Conversely, you cannot configure a static interface for an ACI/ARI pair already configured with a dynamic profile or routing instance.

Before you begin:

1. Configure a PPPoE dynamic profile in either of the following ways:
  - To configure a basic PPPoE dynamic profile, see [“Configuring a Basic PPPoE Dynamic Profile” on page 858](#).
  - To configure a PPPoE dynamic profile with additional options for subscriber access, see [“Configuring a PPPoE Dynamic Profile with Additional Options” on page 861](#).
2. Configure the routing instance in which you want the router to instantiate the dynamic profile.

For information about configuring routing instances, see the Junos OS Routing Protocols Configuration Guide.

3. Create the PPPoE service name table on the router.

See [Creating a Service Name Table in the Junos® OS Network Interfaces](#).

To create a dynamic PPPoE subscriber interface based on the service name and, optionally, associated ACI/ARI pair configured in a PPPoE service name table, do one of the following:

- Assign a previously configured dynamic profile and routing instance to a named, **empty**, or **any** service.

```
[edit protocols pppoe service-name-tables table1]  
user@host# set service premium dynamic-profile premiumProfile routing-instance  
premiumRI
```

- Assign a previously configured dynamic profile and routing instance to the ACI/ARI pair defined for a named, **empty**, or **any** service.

```
[edit protocols pppoe service-name-tables table1]  
user@host# set service any agent-specifier aci west-ge-3/0/3 ari sunnyvale  
dynamic-profile standardProfile routing-instance standardRI
```

## Configuring Lockout of PPPoE Subscriber Sessions

---

You can configure the router to temporarily prevent (lock out) a failed or short-lived PPPoE subscriber session from reconnecting to the router for a default or configurable period of time. Configuring a lockout period on the PPPoE underlying interface for static or dynamic PPPoE subscriber sessions protects the router and any external authentication, authorization, and accounting (AAA) servers, such as RADIUS, from excessive loading as a result of failed or short-lived (also known as short-cycle) PPPoE subscriber sessions that occur repeatedly for the same subscriber.

You can configure the router to use the default PPPoE lockout period, 1 through 300 seconds (5 minutes). Alternatively, you can override the default lockout period by specifying a minimum lockout time and maximum lockout time, each of which can be from 1 through 86,400 seconds (24 hours).

Before you begin:

- Configure the PPPoE underlying interface.

To configure the underlying interface for use with a PPPoE dynamic profile, see [“Configuring an Underlying Interface for Dynamic PPPoE Subscriber Interfaces”](#) on page 863.

To configure the PPPoE family for an underlying interface, see [“Configuring the PPPoE Family for an Underlying Interface”](#) on page 789.

To configure temporary lockout of PPPoE subscriber sessions:

1. Specify that you want to configure PPPoE-specific options on the underlying interface:

- For a PPPoE family in a dynamic profile for a VLAN demultiplexing (demux) logical interface:

```
[edit dynamic-profiles profile-name interfaces demux0 unit logical-unit-number]  
user@host# edit family pppoe
```

- For a PPPoE family in a dynamic profile:

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number]  
user@host# edit family pppoe
```

- For a PPPoE underlying interface in a dynamic profile:

```
[edit dynamic-profiles profile-name interfaces interface-name unit logical-unit-number]  
user@host# edit pppoe-underlying-options
```

- For a PPPoE family on an underlying interface:

```
[edit interfaces interface-name unit logical-unit-number]  
user@host# edit family pppoe
```

- For an underlying interface with PPPoE encapsulation:

```
[edit interfaces interface-name unit logical-unit-number]  
user@host# edit pppoe-underlying-options
```

2. Enable duplicate protection to prevent negotiation of a dynamic or static PPPoE client session on the same underlying interface when a PPPoE client session with the same media access control (MAC) source address is already active on that interface.

```
[edit interfaces interface-name unit logical-unit-number pppoe-underlying-options]
user@host# set duplicate-protection
```

**BEST PRACTICE:** When you configure PPPoE subscriber session lockout, we recommend that you enable duplicate protection to ensure that the MAC source address for each PPPoE session is unique on the underlying interface.

3. Enable PPPoE subscriber session lockout on the PPPoE underlying interface in either of the following ways:

- To configure PPPoE subscriber session lockout with the default lockout period:

```
[edit interfaces interface-name unit logical-unit-number pppoe-underlying-options]
user@host# set short-cycle-protection
```

- To configure PPPoE subscriber session lockout with a nondefault lockout period:

```
[edit interfaces interface-name unit logical-unit-number pppoe-underlying-options]
user@host# set short-cycle-protection lockout-time-min minimum-seconds
lockout-time-max maximum-seconds
```

## Clearing Lockout of PPPoE Subscriber Sessions

**Purpose** Clear the lockout condition for the PPPoE subscriber session associated with a unique MAC source address.

**Action** • To clear the lockout condition for PPPoE subscriber sessions associated with all MAC source addresses on all underlying interfaces:

```
user@host> clear pppoe lockout
```

- To clear the lockout condition for the PPPoE subscriber session associated with the specified MAC source address:

```
user@host> clear pppoe lockout mac-address mac-address
```

- To clear the lockout condition for all PPPoE subscriber sessions on the specified underlying interface:

```
user@host> clear pppoe lockout underlying-interfaces underlying-interface-name
```

- To clear the lockout condition for the PPPoE subscriber session associated with the specified MAC source address on the specified underlying interface:

```
user@host> clear pppoe lockout mac-address mac-address underlying-interfaces  
underlying-interface-name
```

- To verify that the lockout condition has been cleared:

```
user@host> show pppoe lockout
```

**Related  
Documentation**

---

## Verifying and Managing Dynamic PPPoE Configuration

---

**Purpose** View or clear information about dynamic PPPoE logical interfaces, underlying interfaces for dynamic PPPoE logical interfaces, and PPPoE statistics.

- Action**
- To display information about the properties of all PPPoE underlying interfaces associated with a dynamic PPPoE profile:  

```
user@host> show pppoe underlying-interfaces
```
  - To display information about the PPPoE properties of a specified underlying interface associated with a dynamic PPPoE profile:  

```
user@host> show pppoe underlying-interfaces interface-name
```
  - To display session-specific information about PPPoE interfaces, including whether the interface was dynamically created or statically created:  

```
user@host> show pppoe interfaces
```
  - To display information for a specified PPPoE service name table, including the assigned dynamic profile and routing instance, if configured:  

```
user@ host> show pppoe service-name-tables table-name
```
  - To display information about all active PPPoE sessions on the router:  

```
user@host > show pppoe sessions
```
  - To display information for all active PPPoE sessions established for a specified service name:  

```
user@host > show pppoe sessions service service-name
```
  - To display information for all active PPPoE sessions established for a specified agent circuit identifier (ACI) or agent remote identifier (ARI) string:  

```
user@host > show pppoe sessions aci "west-ge-2/0/3"  
user@host > show pppoe sessions ari "sunnyvale"
```

- To display PPPoE control packet statistics for all PPPoE sessions:  
`user@host> show pppoe statistics`
- To display PPPoE control packet statistics for a specified PPPoE underlying interface:  
`user@host> show pppoe statistics interface-name`
- To clear (reset) PPPoE control packet statistics for all PPPoE sessions:  
`user@host> clear pppoe statistics`
- To clear (reset) PPPoE control packet statistics for a specified underlying Ethernet interface:  
`user@host> clear pppoe statistics underlying-interface-name`
- To display summary information about PPPoE subscriber sessions currently undergoing lockout or currently in a lockout grace period on all PPPoE underlying interfaces:  
`user@host> show pppoe lockout`
- To display summary information about PPPoE subscriber sessions currently undergoing lockout or currently in a lockout grace period on the specified PPPoE underlying interface:  
`user@host> show pppoe lockout underlying-interface-name`

# Dynamic PPPoE Subscriber Interfaces Examples

- [Example: Configuring a Dynamic PPPoE Subscriber Interface on a Static Gigabit Ethernet VLAN Interface on page 875](#)
- [Example: Configuring a PPPoE Service Name Table for Dynamic Subscriber Interface Creation on page 877](#)
- [Evaluation Order for Matching Client Information in PPPoE Service Name Tables on page 880](#)

## Example: Configuring a Dynamic PPPoE Subscriber Interface on a Static Gigabit Ethernet VLAN Interface

---

This example shows how to configure a dynamic PPPoE subscriber interface on a statically configured Gigabit Ethernet VLAN underlying interface. When a PPPoE subscriber logs in on the underlying interface, the router creates the dynamic PPPoE subscriber interface with the attributes specified in the dynamic profile.

In this example, the dynamic PPPoE profile, **pppoe-profile-east**, defines options for PPPoE subscribers accessing the network, and includes the predefined dynamic variables **\$junos-interface-unit**, which represents the logical unit number of the dynamic PPPoE logical interface, and **\$junos-underlying-interface**, which represents the name of the underlying Ethernet interface. The **pppoe-profile-east** dynamic profile is assigned to the underlying Ethernet VLAN interface **ge-2/0/3.1** that is configured with PPPoE (**ppp-over-ether**) encapsulation.

When the router dynamically creates the PPPoE subscriber interface on **ge-2/0/3.1** in response to a subscriber login, the values of **\$junos-interface-unit** and **\$junos-underlying-interface** are dynamically replaced with the actual logical unit number and interface name, respectively, that are supplied by the network when the PPPoE subscriber logs in.

To configure a dynamic PPPoE subscriber interface:

1. Configure a dynamic profile to define the attributes of the dynamic PPPoE subscriber interface.

```
[edit]  
dynamic-profiles {
```

```
pppoe-profile-east {
  interfaces {
    pp0 {
      unit "$junos-interface-unit" {
        ppp-options {
          chap;
        }
        pppoe-options {
          underlying-interface "$junos-underlying-interface";
          server;
        }
        keepalives interval 30;
        family inet {
          filter {
            input pppoe-input-filter-east;
            output pppoe-output-filter-east precedence 20;
          }
          service {
            input {
              service-set inputService-east;
              post-service-filter postService-east;
            }
            output {
              service-set outputService-east;
            }
          }
          address 6.6.6.1/32;
          unnumbered-address lo0.0;
        }
      }
    }
  }
}
```

2. Assign the dynamic PPPoE profile to the static underlying Ethernet interface, and define PPPoE-specific attributes for the underlying interface.

```
[edit]
interfaces {
  ge-2/0/3 {
    vlan-tagging;
    unit 1 {
      encapsulation ppp-over-ether;
      vlan-id 100;
      pppoe-underlying-options {
        access-concentrator server-east;
        duplicate-protection;
        dynamic-profile pppoe-profile-east;
        max-sessions 10;
      }
    }
  }
}
```

  - [Configuring an Underlying Interface for Dynamic PPPoE Subscriber Interfaces on page 863](#)

## Example: Configuring a PPPoE Service Name Table for Dynamic Subscriber Interface Creation

This example shows how to configure a PPPoE service name table to create a dynamic PPPoE subscriber interface based on the service name, agent circuit identifier (ACI), and agent remote identifier (ARI) information provided by PPPoE clients during PPPoE negotiation.

In this example, PPPoE service name table **TableDynamicPPPoE** includes an **any** service entry, **empty** service entry, and two named service entries: **Premium** and **Standard**. The PPPoE underlying interfaces configured for **TableDynamicPPPoE** are **ge-2/0/0.1** and **ge-2/0/0.2**. Only **ge-2/0/0.1** is configured for dynamic profile assignment and creation of dynamic PPPoE subscriber interfaces.

Following the configuration example, [Table 70 on page 879](#) explains how the router evaluates the entries in **TableDynamicPPPoE** to create a dynamic PPPoE subscriber interface in a specified routing instance for each of several sample clients.

To configure a PPPoE service name table to create dynamic PPPoE subscriber interfaces:

1. Configure the PPPoE service name table.

```
protocols {
  pppoe {
    service-name-tables TableDynamicPPPoE {
      service any {
        terminate;
        max-sessions 100;
        dynamic-profile AnyProfile;
        agent-specifier {
          aci "broadway-ge-1/0/1.0" ari "london" {
            terminate;
            dynamic-profile LondonProfile;
            routing-instance LondonRI;
          }
          aci "groton-ge-4/0/3.32" ari "paris" {
            delay 5;
            dynamic-profile ParisProfile;
            routing-instance ParisRI;
          }
        }
      }
      service empty {
        drop;
      }
    }
  }
}
```

```

    agent-specifier {
      aci "dunstable-ge-1/0/0.1" ari "kanata" {
        dynamic-profile BasicPppoeProfile;
        delay 10;
      }
    }
  }
  service Premium {
    terminate;
    dynamic-profile PremiumProfile;
  }
  service Standard {
    terminate;
    max-sessions 10;
    dynamic-profile StandardProfile;
    agent-specifier {
      aci "dunstable-ge-1/0/0.1" ari "kanata" {
        dynamic-profile BasicPppoeProfile;
        delay 10;
      }
    }
  }
}

```

2. Configure the PPPoE underlying interface for the service name table.

```

interfaces {
  ge-2/0/0 {
    vlan-tagging;
    unit 1 {
      vlan-id 1;
      pppoe-underlying-options {
        dynamic-profile BasicPppoeProfile;
        service-name-table TableDynamicPPPoE;
      }
    }
    unit 2 {
      vlan-id 2;
      pppoe-underlying-options {
        service-name-table TableDynamicPPPoE;
      }
    }
  }
}

```

[Table 70 on page 879](#) lists the service name, ACI value, and ARI value provided in several sample PPPoE client requests, and the name of the PPPoE underlying interface on which the router received each client request. The Results column describes the dynamic PPPoE subscriber interface created by the router based on *both* of the following:

- The values received from each PPPoE client during PPPoE negotiation
- The sequence in which the router evaluates the entries configured in the PPPoE service name table to find a match for the client's service name and ACI/ARI information, as

described in [“Evaluation Order for Matching Client Information in PPPoE Service Name Tables” on page 880](#)

**Table 70: Dynamic PPPoE Subscriber Interface Creation Based on PPPoE Client Request Values**

PPPoE Client	Service Name	ACI Value	ARI Value	Receiving Underlying Interface	Results
Client 1	Premium	broadway-ge-1/0/1.1	london	ge-2/0/0.1	Matches ACI/ARI pair configured for <b>any</b> service. Router creates dynamic PPPoE subscriber interface over <b>ge-2/0/0.1</b> using <b>LondonProfile</b> dynamic profile and <b>LondonRI</b> routing instance assigned to <b>any</b> service.
Client 2	Premium	dunstable-ge-1/0/1.0	toronto	ge-2/0/0.1	Matches base <b>Premium</b> service. Router creates dynamic PPPoE subscriber interface over <b>ge-2/0/0.1</b> using <b>PremiumProfile</b> dynamic profile and routing instance associated with <b>ge-2/0/0.1</b> underlying interface.
Client 3	empty	dunstable-ge-1/0/0.1	kanata	ge-2/0/0.1	Matches ACI/ARI pair configured for <b>empty</b> service and <b>Standard</b> service. Router creates dynamic PPPoE subscriber interface over <b>ge-2/0/0.1</b> after a delay of 10 seconds. Router uses <b>BasicPPPoEProfile</b> dynamic profile and routing instance associated with <b>ge-2/0/0.1</b> underlying interface.
Client 4	empty	slinger-ge-1/0/0.1	chicago	ge-2/0/0.2	Because receiving underlying interface <b>ge-2/0/0.2</b> is <i>not</i> associated with a dynamic profile, router does not create a dynamic PPPoE subscriber interface, and drops any PADI or PADR control packets received from this client.
Client 5	Standard	slinger-ge-1/0/0.1	chicago	ge-2/0/0.1	Matches base <b>Standard</b> service. Router creates dynamic PPPoE subscriber interface over <b>ge-2/0/0.1</b> using <b>StandardProfile</b> dynamic profile and routing instance associated with <b>ge-2/0/0.1</b> underlying interface.

## Evaluation Order for Matching Client Information in PPPoE Service Name Tables

When the router receives a service request from a PPPoE client, it evaluates the entries configured in the PPPoE service name table to find a match for the client's ACI/ARI information so it can take the appropriate action.

The order of evaluation is as follows:

1. The router evaluates the ACI/ARI information configured for the **any** service entry, and ignores the contents of the service name tag transmitted by the client.
2. If no match is found for the client information, the router evaluates the ACI/ARI information for the **empty** service entry and the named service entries. If an ACI/ARI pair is not configured for these service entries, the router evaluates the other attributes configured for the **empty** service and named services.
3. If there is still no match for the client information, the router evaluates the other attributes configured for the **any** service entry, and ignores both the ACI/ARI information for the **any** service and the contents of the service name tag transmitted by the client. If the **any** service is configured for the default action, **drop**, the router drops the PADR packet. If the **any** service is configured for a nondefault action (**terminate** or **delay**), the router evaluates the other attributes configured for the **any** service.

- [CoS Configuration Overview for MPLS Pseudowire Subscriber Interfaces on page 887](#)

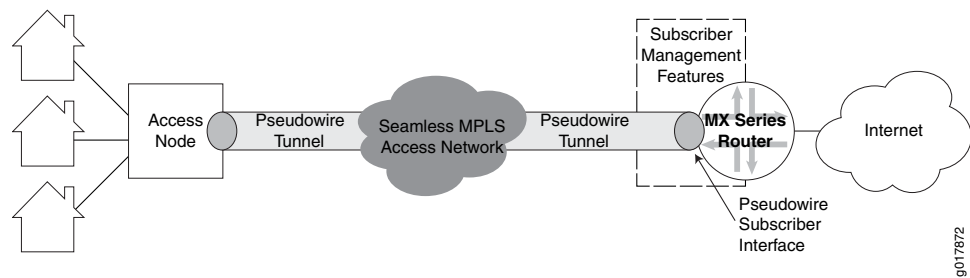

## Pseudowire Subscriber Logical Interfaces Overview

Subscriber management supports the creation of subscriber interfaces over point-to-point MPLS pseudowires. The pseudowire subscriber interface capability enables service providers to extend an MPLS domain from the access-aggregation network to the service edge, where subscriber management is performed. Service providers can take advantage of MPLS capabilities such as failover, rerouting, and uniform MPLS label provisioning, while using a single pseudowire to service a large number of DHCP and PPPoE subscribers in the service network.

The pseudowire is a tunnel that is either an MPLS-based Layer 2 VPN or Layer 2 circuit. The pseudowire tunnel transports Ethernet encapsulated traffic from an access node (for example, a DSLAM or other aggregation device) to the MX Series router that hosts the subscriber management services. The termination of the pseudowire tunnel on the MX Series router is similar to a physical Ethernet termination, and is the point at which subscriber management functions are performed. A service provider can configure multiple pseudowires on a per-DSLAM basis and then provision support for a large number of subscribers on a specific pseudowire. [Figure 15 on page 882](#) shows an MPLS network that provides subscriber management support.

At the access node end of the pseudowire, the subscriber traffic can be groomed into the pseudowire in a variety of ways, limited only by the number and types of interfaces that can be stacked on the pseudowire. You specify an anchor point, which identifies the logical tunnel interface that terminates the pseudowire tunnel at the access node.

Figure 15: MPLS Access Network with Subscriber Management Support

**NOTE:** Subscriber interfaces over MPLS pseudowires are supported on MX Series routers with MPCs.

Figure 16 on page 882 shows the protocol stack for a pseudowire subscriber logical interface. The pseudowire is a virtual device that is stacked above the logical tunnel interface (the IFD), and supports a circuit-oriented Layer 2 protocol (either Layer 2 VPN or Layer 2 circuit). The Layer 2 protocol provides the transport and service logical interfaces, and supports the protocol family (IPv4, IPv6, or PPPoE).

Figure 16: Pseudowire Subscriber Interface Protocol Stack

The pseudowire configuration is transparent to the subscriber management applications and has no impact on the packet payloads that are used for subscriber management.

Subscriber applications such as DHCP and PPPoE can be stacked over Layer 2 similar to the way in which they are stacked over a physical interface.

## Hierarchical CoS on MPLS Pseudowire Subscriber Interfaces Overview

Subscriber management supports the creation of subscriber interfaces over point-to-point MPLS pseudowires. The pseudowire subscriber interface capability enables service providers to extend an MPLS domain from the access-aggregation network to the service edge, where subscriber management is performed. The pseudowire is a tunnel that is either an MPLS-based Layer 2 VPN or Layer 2 circuit. The pseudowire tunnel transports Ethernet encapsulated traffic from an access node (for example, a DSLAM or other aggregation device) to the MX Series router that hosts the subscriber management services.

Junos OS supports two aspects of CoS for MPLS pseudowire subscriber interfaces. You can apply CoS rewrite rules and behavior aggregate (BA) classifiers to MPLS pseudowire subscriber interfaces. In addition, CoS performs egress hierarchical shaping towards the subscriber on MPLS pseudowire subscriber interfaces. CoS supports two hierarchical scheduling configurations for egress shaping on MPLS pseudowire subscriber interfaces:

- Two-level scheduling
- Three-level or implicit scheduling

**Related  
Documentation**

---

## CoS Two-Level Hierarchical Scheduling on MPLS Pseudowire Subscriber Interfaces

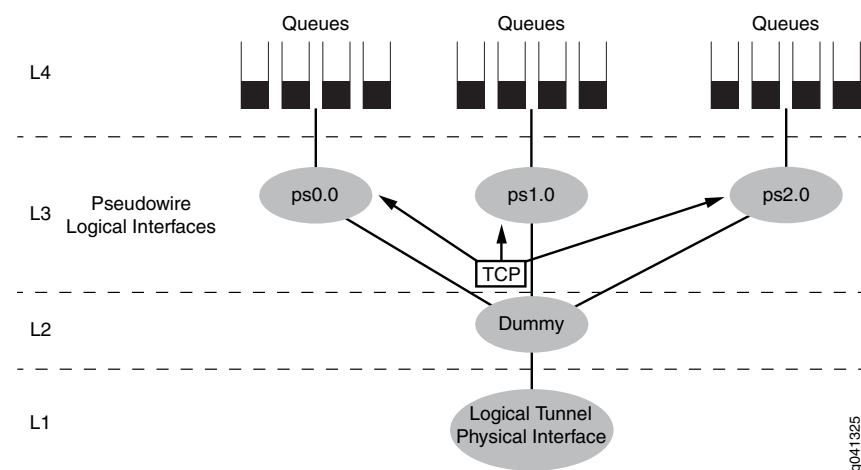

The MPLS pseudowire subscriber interface two-level scheduler configuration effectively uses only level 1 and level 3 for each pseudowire. The two-level scheduling hierarchy is as follows:

- Level 4—Forwarding class-based queues
- Level 3—Pseudowire transport interface
- Level 2—Common/shared level 2 node
- Level 1—Common/shared physical interface of the logical tunnel

You use the two-level scheduling when you have many pseudowires but you do not require shaping specific to the subscriber logical interface. For example, when your configuration is one subscriber per pseudowire interface.

Figure 17 on page 884 shows the scheduling hierarchy for the MPLS pseudowire subscriber interface two-level scheduler configuration. In two-level scheduling, the level 3 nodes are the pseudowire transport interfaces denoted as ps0.0, ps1.0, and ps2.0 (psN.0, where N= a number). At level 1 is the physical interface used for the logical tunnel anchor node. All of the pseudowire transport interfaces share a common level 2 node. You apply the traffic-control profile on the pseudowire transport interfaces at level 3.

**Figure 17: MPLS Pseudowire Subscriber Interface Two-Level Scheduler Configuration**

The two-level scheduler configuration has up to eight class of service queues over the level 3 scheduler node. For this configuration, include the **hierarchical-scheduler maximum-hierarchy-levels 2** option at the physical interface for the anchor logical tunnel.

**NOTE:** You cannot configure shaping policies on both the pseudowire logical interfaces and the subscriber logical interfaces over the same pseudowire. If a traffic-control profile is configured on a pseudowire logical interface, and CoS policies are configured on the subscriber logical interface over another pseudowire, all of the logical interfaces are at level 3 and act as peers.

## CoS Three-Level Hierarchical Scheduling on MPLS Pseudowire Subscriber Interfaces

CoS also supports three levels of hierarchical scheduling for MPLS pseudowire subscriber interfaces. Three-level scheduling hierarchies have up to eight classes of service. There are two variations of the three-level scheduling hierarchy depending on the location of the interface set. In both cases, the physical interface on which the logical tunnel resides is at level 1.

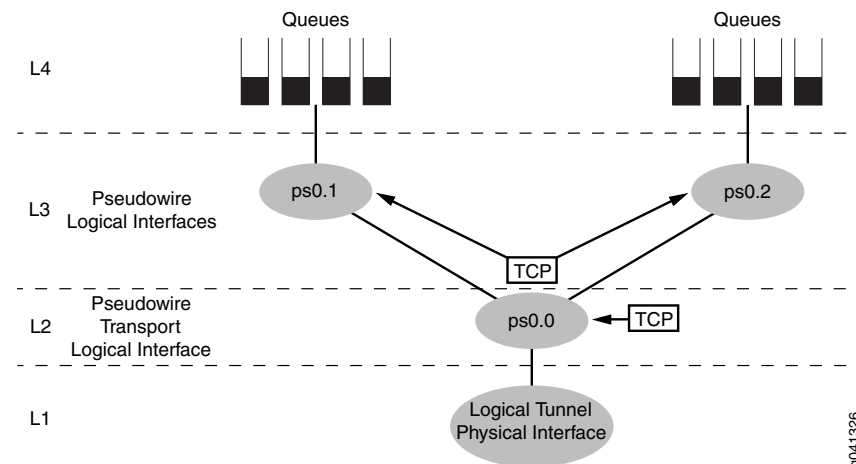

### Three-Level Scheduling Hierarchy Case 1: Pseudowire Logical Interfaces over a Transport Logical Interface

The first variation of the three-level scheduling hierarchy is the pseudowire logical interface over the pseudowire transport logical interface. This scheduling hierarchy is as follows:

- Level 4—Forwarding class-based queues
- Level 3—Pseudowire service interfaces
- Level 2—Pseudowire transport logical interface
- Level 1—Common/shared physical interface of the logical tunnel

[Figure 18 on page 885](#) shows this three-level scheduling hierarchy. At level 3 are the pseudowire service interfaces for the subscriber sessions, denoted as ps0.1 and ps0.2, at level 2 are the pseudowire transport logical interfaces, denoted as ps0.0, and at level 1 is the physical interface of the logical tunnel. You apply the traffic-control profiles at both the pseudowire transport logical interfaces (level 2) and the pseudowire service interfaces (level 3).

**Figure 18: Three-Level Scheduling Hierarchy Case 1: Pseudowire Service (Logical) Interfaces over a Transport Logical Interface**

### Three-Level Scheduling Hierarchy Case 2: Pseudowire Service Interfaces over a Pseudowire Service Interface Set

The second variation of the three-level hierarchical scheduling is the pseudowire service interfaces over the pseudowire service interface-set. This scheduling hierarchy is as follows:

- Level 4—Forwarding class-based queues
- Level 3—Pseudowire service interfaces
- Level 2—Interface set of the pseudowire service interfaces
- Level 1—Common/shared physical interface of the logical tunnel

Figure 19 on page 886 shows this three-level scheduling hierarchy. At level 3 are the pseudowire service (logical) interfaces, denoted as ps0.1 and ps0.2, at level 2 is the interface set for the pseudowire service interfaces, and at level 1 is the physical interface of the logical tunnel. You apply the traffic-control profile at the pseudowire service interfaces (level 3) and at the interface-set (level 2) for the pseudowire service interfaces. This case is most useful for subscriber edge customers.

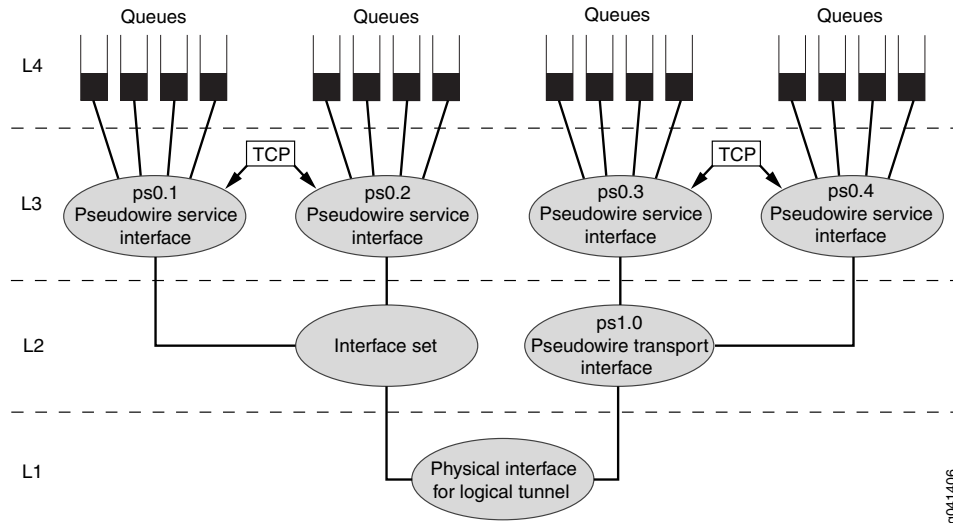

**Figure 19: Three-Level Scheduling Hierarchy Case 2: Pseudowire Service (Logical) Interfaces over a Pseudowire Service (Logical) Interface Set**

### Three-Level Scheduling Hierarchy Combined Deployment Scenario

Figure 20 on page 887 shows a deployment scenario that uses both Case 1 and Case 2 of the three-level hierarchical scheduling. At level 3 are the pseudowire service (logical) interfaces, denoted as ps0.1 through ps0.4. At level 2 is the interface set for pseudowire service interfaces ps0.1 and ps0.2 and the pseudowire transport logical interface ps1.0 for the pseudowire service (logical) interfaces ps0.3 and ps0.4. You apply the traffic-control profiles to the interfaces at both level 2 and 3, as well as interface set at level 2.

## CoS Configuration Overview for MPLS Pseudowire Subscriber Interfaces

CoS supports two-level and three-level hierarchies for MPLS pseudowire subscriber interfaces.

To configure two-level scheduling, include the **maximum-hierarchy-levels 2** option under the **[edit interfaces *interface-name* hierarchical-scheduler]** statement on the physical interface of the anchor logical tunnel.

To configure three-level scheduling, include the **implicit-hierarchy** option on the physical interface of the anchor logical tunnel. Refer to the following guidelines for this option:

- If an output traffic-control profile is configured on the pseudowire transport interface and on a pseudowire service interface, the two interfaces form a scheduling hierarchy. The pseudowire transport interface resides in a level 2 scheduler node and the pseudowire service interface resides in a level 3 scheduler node.

- If an output traffic-control profile is configured on the pseudowire services interface but not on a pseudowire transport interface, the pseudowire services interface resides in a level 3 scheduler node.
- If an output traffic-control profile is only configured on the pseudowire transport interface and not on the pseudowire services interface, the pseudowire transport interface resides in a level 3 scheduler node and all pseudowire traffic uses this node.

If the **implicit-hierarchy** option is not set under the physical interface of the anchor logical tunnel, logical interfaces behave normally with the hierarchical-scheduler mode configured with or without the **hierarchical-scheduler maximum-hierarchy-levels** option. In this case, when you apply a traffic-control profile to the pseudowire and service logical interfaces, they both reside in level 3 scheduler nodes and do not form a scheduling hierarchy, which might not be the desirable behavior. In business edge, where only the pseudowire logical interfaces need to be shaped, applying the traffic-control profile at just the transport logical interface may be sufficient.

When configuring the logical tunnel physical interface for the maximum hierarchy level, all pseudowire logical interfaces operating on the physical interface use the same hierarchy model. If you want to mix two-level and three-level scheduling hierarchies, you can group the pseudowires together by hierarchy levels and share the same logical tunnel anchor point. Alternately, you can choose to use three-level scheduling for all pseudowires over the anchor point.

To specify rewrite rules and classifiers on pseudowire interfaces, reference the pseudowire device under the **[edit class-of-service interfaces]** hierarchy and specify the rewrite rules and classifiers for the pseudowire interfaces.

To control all pseudowire traffic using the same logical tunnel interface, apply CoS policies at the physical interface for the anchor logical tunnel.

## Configuring a Pseudowire Subscriber Logical Interface

A pseudowire subscriber logical interface terminates an MPLS pseudowire tunnel from an access node to the MX Series router that hosts subscriber management, and enables you to perform subscriber management services at the interface.

To create a pseudowire subscriber logical interface, you configure the following characteristics:

1. Specify the number of pseudowire logical interfaces that the router can support.  
See [“Configuring the Maximum Number of Pseudowire Logical Interface Devices Supported on the Router” on page 891.](#)
2. Configure the pseudowire subscriber logical interface device.  
See [“Configuring a Pseudowire Subscriber Logical Interface Device” on page 891.](#)
3. Configure the transport logical interface.  
See [“Configuring the Transport Logical Interface for a Pseudowire Subscriber Logical Interface” on page 892.](#)
4. Configure the signaling for the pseudowire subscriber interface. You can use either Layer 2 circuit signaling or Layer 2 VPN signaling. The two signaling types are mutually exclusive for a given pseudowire.
  - To configure Layer 2 circuit signaling, see [“Configuring Layer 2 Circuit Signaling for Pseudowire Subscriber Logical Interfaces” on page 893.](#)
  - To configure Layer 2 VPN signaling, see [“Configuring Layer 2 VPN Signaling for Pseudowire Subscriber Logical Interfaces” on page 894.](#)
5. Configure the service logical interface.  
See [“Configuring the Service Logical Interface for a Pseudowire Subscriber Logical Interface” on page 895.](#)
6. Configure the underlying interface device.  
See [“Configuring an Underlying Interface for Dynamic PPPoE Subscriber Interfaces” on page 863.](#)
7. Configure CoS parameters and BA classification.  
See [“CoS Configuration Overview for MPLS Pseudowire Subscriber Interfaces” on page 887.](#)
8. (Optional) Associate a dynamic profile with the pseudowire subscriber logical interface.  
You can associate DHCP, PPPoE, and IP demux dynamic profiles with pseudowire subscriber logical interfaces. The support is similar to the typical Ethernet interface support.

**NOTE:** When using a PPPoE dynamic profile to create a pseudowire subscriber logical interface over a demux interface device, the dynamic profile must explicitly specify the correct pseudowire interface device over which the interface is created. The dynamic profile does not automatically create the interface over the demux0 interface device, as is the case with a VLAN demux interface.

---

For additional information about associating dynamic profiles to interfaces, see [“Dynamic Profile Attachment to DHCP Subscriber Interfaces Overview” on page 192](#) and [“Configuring VLAN Interfaces to Use Dynamic Profiles” on page 680](#).

9. (Optional) Configure interface set support for pseudowire subscriber logical interfaces.  
See [Configuring Interface Sets and Applying Interface Sets](#).
10. (Optional) Stack PPPoE logical interfaces over a pseudowire logical device.

**Related  
Documentation**

- [Pseudowire Subscriber Logical Interfaces Overview on page 881](#)

## Configuring the Maximum Number of Pseudowire Logical Interface Devices Supported on the Router

You must set the maximum number of pseudowire logical interface devices (pseudowire tunnels) that the router can use for subscriber logical interfaces. You can specify a maximum of 128 pseudowire logical interface devices for an MX Series router. Each pseudowire device supports a maximum of 4000 subscriber logical interfaces.

To configure the number of pseudowire logical interface devices that you want the router to support:

1. Specify that you want to configure the pseudowire service.  

```
[edit chassis]
user@host# edit pseudowire-service
```
2. Set the maximum number of pseudowire logical interface devices.  

```
[edit chassis pseudowire-service]
user@host# set device-count 25
```

**Related  
Documentation**

- [Pseudowire Subscriber Logical Interfaces Overview on page 881](#)
- [Configuring a Pseudowire Subscriber Logical Interface on page 889](#)

## Configuring a Pseudowire Subscriber Logical Interface Device

To configure a pseudowire logical interface device that the router uses for subscriber logical interfaces, you specify the logical tunnel that processes the pseudowire termination. You can also configure additional optional parameters for the interface device, such as VLAN tagging method, MTU, and gratuitous ARP support.

To configure the pseudowire subscriber interface device:

1. Specify that you want to configure the pseudowire subscriber logical interface device.  

```
user@host# edit interfaces ps0
```
2. Specify the logical tunnel interface that is the anchor point for the pseudowire logical interface device. The anchor point must be an **lt** device in the format **lt-fpc/pic/port**.

```
[edit interfaces ps0]
user@host# set anchor-point lt-1/0/10
```

3. (Optional) Specify the VLAN tagging method used for the pseudowire logical interface device. You can specify single tagging, dual (stacked) tagging, mixed (flexible) tagging, or no tagging.

```
[edit interfaces ps0]
user@host# set flexible-vlan-tagging
```

See Enabling VLAN Tagging for additional information about VLAN tagging.

4. (Optional) Specify the MTU for the pseudowire logical interface device. If you do not explicitly configure the MTU, the router uses the default value of 1500.

```
[edit interfaces ps0]
user@host# set mtu 2500
```

See Setting the Protocol MTU for additional information.

5. (Optional) Specify that the pseudowire logical interface device does not respond to gratuitous ARP requests.

```
[edit interfaces ps0]
user@host# set no-gratuitous-arp-request
```

See Configuring Gratuitous ARP for additional information.

6. Configure additional optional parameters for the pseudowire logical interface device, such as description, apply-groups, apply-groups-except, and traceoptions.

---

## Configuring the Transport Logical Interface for a Pseudowire Subscriber Logical Interface

---

This topic describes how to configure a pseudowire transport logical interface. A pseudowire device can have only one transport logical interface.

A pseudowire logical device and its related pseudowire logical interfaces are dependent on the state of the underlying logical transport interface device, which is either the Layer 2 VPN or Layer 2 circuit.

**NOTE:** We recommend that you use unit 0 to represent the transport logical interface for the pseudowire device. Non-zero unit numbers represent *service* logical interfaces used for pseudowire subscriber interfaces.

To configure a pseudowire transport logical interface:

1. Specify that you want to configure the pseudowire subscriber logical interface device.

```
[edit]
user@host# edit interfaces ps0
```

- Specify that you want to configure unit 0, which represents the transport logical interface.

```
[edit interfaces ps0]
user@host# edit unit 0
```

- Specify the **ethernet-ccc** encapsulation method for the transport logical interface.

```
[edit interfaces ps0 unit 0]
user@host# set encapsulation ethernet-ccc
```

**Related  
Documentation**

- [Pseudowire Subscriber Logical Interfaces Overview on page 881](#)
- [Configuring a Pseudowire Subscriber Logical Interface on page 889](#)

## Configuring Layer 2 Circuit Signaling for Pseudowire Subscriber Logical Interfaces

This topic describes the steps for configuring Layer 2 circuit signaling used for the pseudowire subscriber logical interface support. You can also use Layer 2 VPN signaling for pseudowire subscriber logical interfaces. The two methods are mutually exclusive; you can use only one method for a particular pseudowire.

To configure Layer 2 circuit signaling for pseudowire interfaces:

- Specify that you want to configure Layer 2 circuit parameters at the protocols hierarchy level.

```
[edit protocols]
user@host# edit l2circuit
```

- Specify the IP address of the neighbor, to identify the PE router used for the Layer 2 circuit.

```
[edit protocols l2circuit]
user@host# edit neighbor 192.168.102.15
```

- Specify the interface used by the Layer 2 circuit traffic.

```
[edit protocols l2circuit neighbor 192.168.102.15]
user@host# edit interface ps1.0
```

- Configure the virtual circuit ID that identifies the Layer 2 circuit for the pseudowire.

```
[edit protocols l2circuit neighbor 192.168.102.15 interface ps1.0]
user@host# set virtual-circuit-id 5
```

- (Optional) If multiple VLAN interfaces are carried over the pseudowire Layer 2 payload, configure the **no-vlan-id-validate** statement. This statement prevents VLAN validation in the signaling.

```
[edit protocols l2circuit neighbor 192.168.102.15 interface ps1.0]
user@host# set no-vlan-id-validate
```

For more information about Layer 2 circuits, see [Configuring Interfaces for Layer 2 Circuits](#).

## Configuring Layer 2 VPN Signaling for Pseudowire Subscriber Logical Interfaces

---

This topic describes the steps for configuring Layer 2 VPN signaling used for the pseudowire subscriber logical interface support. You can also use Layer 2 circuit signaling for pseudowire subscriber logical interfaces. The two methods are mutually exclusive; you can use only one method on a particular pseudowire.

To configure Layer 2 VPN signaling for pseudowire interfaces:

1. Specify the name of the routing instance you want to configure.

```
[edit]
user@host# edit routing-instances l2vpn0
```

2. Configure the Layer 2 VPN routing instance type.

```
[edit routing-instances l2vpn0]
user@host# set instance-type l2vpn
```

3. Associate the pseudowire logical interface for the Layer 2 VPN.

```
[edit routing-instances l2vpn0]
user@host# set interface ps1.0
```

4. Configure the unique identifier for the routes that belong to the Layer 2 VPN.

```
[edit routing-instances l2vpn0]
user@host# set route-distinguisher 111.1.1.1:100
```

5. Configure the VPN routing and forwarding (VRF) target of the routing instance.

```
[edit routing-instances l2vpn0]
user@host# set vrf-target target:10:100
```

6. Specify that you want to configure the Layer 2 VPN protocol for the routing instance.

```
[edit routing-instances l2vpn0]
user@host# edit protocols l2vpn
```

7. Configure the encapsulation type for the routing instance.

```
[edit routing-instances l2vpn0 protocols l2vpn]
user@host# set encapsulation-type ethernet
```

8. Specify the site name and site identifier for the Layer 2 VPN.

```
[edit routing-instances l2vpn0 protocols l2vpn]
user@host# set site PE1 site-identifier 1
```

9. Specify the interface that connects to the site, and the remote interface to which you want the specified interface to connect.

```
[edit routing-instances l2vpn0 protocols l2vpn]
user@host# set interface ps1.0 remote-site-id 2
```

10. Configure the tracing options for traffic that uses the Layer 2 VPN.

```
[edit routing-instances l2vpn0 protocols l2vpn]
user@host# set traceoptions file l2vpn flag all
```

## Configuring the Service Logical Interface for a Pseudowire Subscriber Logical Interface

This topic describes how to configure a pseudowire service logical interface. Service logical interfaces represent the attachment circuits for pseudowire logical interfaces.

As shown in [Figure 16 on page 882](#), a service logical interface may or may not be configured together with a higher subscriber logical interface, depending upon the business need. In a broadband edge configuration, the higher subscriber logical interface is the demarcation point for subscribers. However, in a business edge configuration, the service logical interface is the demarcation point for the business subscribers, and also serves as the subscriber logical interface, so there are no explicitly configured subscriber logical interfaces.

**NOTE:** Non-zero unit numbers represent *service* logical interfaces used for pseudowire subscriber interfaces. Use unit 0 to represent the *transport* logical interface for the pseudowire device.

To configure a pseudowire service logical interface:

1. Specify that you want to configure the pseudowire subscriber logical interface device.

```
[edit]
user@host# edit interfaces ps0
```

2. Configure the unit for the service logical interface. Use a non-zero unit number.

```
[edit interfaces ps0]
user@host# edit unit 1
```

3. Configure the VLAN tag IDs.

```
[edit interfaces ps0 unit 1]
user@host# set vlan-tags outer 1 inner 1
```

4. Configure the interface to respond to ARP requests when the device has an active route to the ARP request target address.

```
[edit interfaces ps0 unit 1]
user@host# set proxy-arp
```

5. Specify that you want to configure the protocol family information. Pseudowire service logical interfaces support IPv4 (inet), IPv6 (inet6), and PPPoE (pppoe) protocol families.

For example, to configure the IPv4 family:

- a. Specify that you want to configure IPv4.

```
[edit interfaces ps0 unit 1]
user@host# edit family inet
```

- b. Configure the parameters for the family.

```
[edit interfaces ps0 unit 1 family inet]
user@host# set filter input filter 1 output filter 4
user@host# set mac-validate loose
user@host# set input-hierarchical-policer policer-1
user@host# set unnumbered-address lo0.0 preferred-source-address 100.0.0.1
```

## Configuring CoS Two-Level Hierarchical Scheduling for MPLS Pseudowire Subscriber Interfaces

---

Before configuring CoS parameters for MPLS pseudowire subscriber interfaces, you must first complete these tasks:

1. Configure the pseudowire logical interfaces. See [“Configuring a Pseudowire Subscriber Logical Interface” on page 889](#).
2. Configure the pseudowire device count. See [“Configuring the Maximum Number of Pseudowire Logical Interface Devices Supported on the Router” on page 891](#).
3. Configure the pseudowire device including the logical tunnel anchor point. See [“Configuring a Pseudowire Subscriber Logical Interface Device” on page 891](#).
4. Configure the pseudowire transport logical interface. See [“Configuring the Transport Logical Interface for a Pseudowire Subscriber Logical Interface” on page 892](#).
5. Configure the pseudowire signaling (either Layer 2 circuit signaling or Layer 2 VPN signaling). See [“Configuring Layer 2 Circuit Signaling for Pseudowire Subscriber Logical Interfaces” on page 893](#) or [“Configuring Layer 2 VPN Signaling for Pseudowire Subscriber Logical Interfaces” on page 894](#).
6. Configure the pseudowire logical interfaces. See [“Configuring the Service Logical Interface for a Pseudowire Subscriber Logical Interface” on page 895](#).

To configure CoS policies on MPLS pseudowire subscriber interfaces using two-level scheduling:

1. Configure the hierarchical scheduler for the physical interface used for the logical tunnel (anchor point). For two-level scheduling the hierarchical scheduler must be set to **maximum-scheduler levels 2**.

```
[edit]
user@host#edit interfaces ps ps-anchor-device-name
user@host#set hierarchical-scheduler maximum-hierarchy-levels 2
```

2. Specify the traffic-control profile to use on the pseudowire logical interface.

```
[edit class-of-service]
user@host#edit interfaces ps ps-device-name
user@host#edit unit logical-unit-number
user@host#set output-traffic-control-profile profile-name
```

## 3. Configure the rewrite rule.

The available rewrite rule types for pseudowire interfaces are **dscp** and **inet-precedence**.

```
[edit class-of-service]
user@host#edit interfaces ps ps-device-name
user@host#edit unit logical-unit-number
user@host#edit rewrite-rules (dscp | inet-precedence) rewrite-name
user@host#edit forwarding-class class-name
user@host#set loss-priority class-name code-point (alias | bits)
```

## 4. Configure the classifier.

The available classifier types for pseudowire interfaces are **dscp** and **inet-precedence**.

```
[edit class-of-service]
user@host#edit interfaces ps ps-device-name
user@host#edit unit logical-unit-number
user@host#edit classifiers (dscp | inet-precedence) classifier-name
user@host#edit forwarding-class class-name
user@host#set loss-priority class-name code-points [aliases] [bit-patterns]
```

## 5. Apply the rewrite rule and classifier to the pseudowire interface.

For the *interface\_name* parameter, specify the pseudowire device name.

```
[edit class-of-service interfaces interface_name unit logical-unit-number]
user@host#set rewrite-rule (dscp | inet-precedence) (rewrite-name | default) protocol
protocol-types
user@host#set classifiers (dscp | inet-precedence) (classifier-name | default)
```

## Configuring CoS Three-Level Hierarchical Scheduling for MPLS Pseudowire Subscriber Interfaces (Logical Interfaces over a Transport Logical Interface)

Before configuring CoS three-level scheduling on pseudowire logical interfaces over a transport logical interface, you must first complete these tasks:

1. Configure the pseudowire logical interfaces. See [“Configuring a Pseudowire Subscriber Logical Interface” on page 889](#).
2. Configure the pseudowire device count. See [“Configuring the Maximum Number of Pseudowire Logical Interface Devices Supported on the Router” on page 891](#).

3. Configure the pseudowire device including the logical tunnel anchor point. See [“Configuring a Pseudowire Subscriber Logical Interface Device”](#) on page 891.
4. Configure the pseudowire transport logical interface. See [“Configuring the Transport Logical Interface for a Pseudowire Subscriber Logical Interface”](#) on page 892.
5. Configure the pseudowire signaling (either Layer 2 circuit signaling or Layer 2 VPN signaling). See [“Configuring Layer 2 Circuit Signaling for Pseudowire Subscriber Logical Interfaces”](#) on page 893 or [“Configuring Layer 2 VPN Signaling for Pseudowire Subscriber Logical Interfaces”](#) on page 894.
6. Configure the pseudowire logical interfaces. See [“Configuring the Service Logical Interface for a Pseudowire Subscriber Logical Interface”](#) on page 895.

Three-level scheduling on pseudowire logical interfaces over a transport logical interface requires you to apply the traffic-control profiles at both the pseudowire logical interface and the pseudowire transport logical interface. To configure CoS policies on three-level scheduling on pseudowire logical interfaces over a transport logical interface:

1. Configure the hierarchical scheduler for the physical interface used for the logical tunnel (anchor point). For three-level scheduling the hierarchical scheduler must be set to **implicit-hierarchy**.

```
[edit]
user@host#edit interfaces ps-anchor-device-name
user@host#set hierarchical-scheduler implicit-hierarchy
```

2. Specify the traffic-control profile to use on the pseudowire logical interface.

```
[edit class-of-service]
user@host#edit interfaces ps ps-device-name
user@host#edit unit logical-unit-number
user@host#set output-traffic-control-profile profile-name
```

3. Specify the traffic-control profile to use on the pseudowire transport logical interface.

```
[edit class-of-service]
user@host#edit interfaces ps ps-device-name
user@host#edit unit logical-unit-number
user@host#set output-traffic-control-profile profile-name
```

4. Configure the rewrite rule.

The available rewrite rule types for pseudowire interfaces are **dscp** and **inet-precedence**.

```
[edit class-of-service]
user@host#edit interfaces ps ps-device-name
user@host#edit unit logical-unit-number
user@host#edit rewrite-rules (dscp | inet-precedence) rewrite-name
user@host#edit forwarding-class class-name
user@host#set loss-priority class-name code-point (alias | bits)
```

5. Configure the classifier.

The available classifier types for pseudowire interfaces are **dscp** and **inet-precedence**.

```
[edit class-of-service]
user@host#edit interfaces ps ps-device-name
user@host#edit unit logical-unit-number
```

```

user@host#edit classifiers (dscp | inet-precedence) classifier-name
user@host#edit forwarding-class class-name
user@host#set loss-priority class-name code-points [aliases] [bit-patterns]

```

6. Apply the rewrite rule and classifier to the pseudowire interfaces.

For the *interface\_name* parameter, specify the pseudowire device name.

```

[edit class-of-service interfaces interface_name unit logical-unit-number]
user@host#set rewrite-rule (dscp | inet-precedence) (rewrite-name | default) protocol
protocol-types
user@host#set classifiers (dscp | inet-precedence) (classifier-name | default)

```

## Configuring CoS Three-Level Hierarchical Scheduling for MPLS Pseudowire Subscriber Interfaces (Logical Interfaces over a Pseudowire Interface Set)

Before configuring three-level scheduling on pseudowire logical interfaces over a pseudowire logical interface set, you must first complete the following tasks:

1. Configure the pseudowire logical interfaces. See [“Configuring a Pseudowire Subscriber Logical Interface” on page 889](#).
2. Configure the pseudowire device count. See [“Configuring the Maximum Number of Pseudowire Logical Interface Devices Supported on the Router” on page 891](#).
3. Configure the pseudowire device including the logical tunnel anchor point. See [“Configuring a Pseudowire Subscriber Logical Interface Device” on page 891](#).
4. Configure the pseudowire transport logical interface. See [“Configuring the Transport Logical Interface for a Pseudowire Subscriber Logical Interface” on page 892](#).
5. Configure the pseudowire signaling (either Layer 2 circuit signaling or Layer 2 VPN signaling). See [“Configuring Layer 2 Circuit Signaling for Pseudowire Subscriber Logical Interfaces” on page 893](#) or [“Configuring Layer 2 VPN Signaling for Pseudowire Subscriber Logical Interfaces” on page 894](#).
6. Configure the pseudowire logical interfaces. See [“Configuring the Service Logical Interface for a Pseudowire Subscriber Logical Interface” on page 895](#).

Three-level scheduling on pseudowire logical interfaces over a pseudowire logical interface set requires you to apply the traffic-control profiles at both the pseudowire logical interface and the pseudowire logical interface-set. To configure CoS policies on MPLS pseudowire subscriber interfaces using three-level implicit hierarchical scheduling:

1. Configure the hierarchical scheduler for the physical interface used for the logical tunnel (anchor point). For three-level scheduling the hierarchical scheduler must be set to **implicit-hierarchy**.

```
[edit]
user@host#edit interfaces ps-anchor-device-name
user@host#set hierarchical-scheduler implicit-hierarchy
```

2. Specify the traffic-control profile to use on the pseudowire logical interfaces.

```
[edit class-of-service]
user@host#edit interfaces ps ps-device-name
user@host#edit unit logical-unit-number
user@host#set output-traffic-control-profile profile-name
```

3. Define a pseudowire logical interface set and configure the traffic-control profile used for the interface set.

```
[edit class-of-service]
user@host#edit interfaces
user@host#edit interface-set interface-set-name
user@host#edit output-traffic-control-profile profile-name
```

4. Group the pseudowire logical interfaces in the pseudowire logical interface set.

```
[edit ]
user@host#edit interfaces
user@host#edit interface-set interface-set-name
user@host#edit interface ps ps-device-name
user@host#edit unit logical-unit-number
```

5. Configure the rewrite rule.

The available rewrite rule types for pseudowire interfaces are **dscp** and **inet-precedence**.

```
[edit class-of-service]
user@host#edit interfaces ps ps-device-name
user@host#edit unit logical-unit-number
user@host#edit rewrite-rules (dscp | inet-precedence) rewrite-name
user@host#edit forwarding-class class-name
user@host#set loss-priority class-name code-point (alias | bits)
```

6. Configure the classifier.

The available classifier types for pseudowire interfaces are **dscp** and **inet-precedence**.

```
[edit class-of-service]
user@host#edit interfaces ps ps-device-name
user@host#edit unit logical-unit-number
user@host#edit classifiers (dscp | inet-precedence) classifier-name
user@host#edit forwarding-class class-name
user@host#set loss-priority class-name code-points [aliases] [bit-patterns]
```

7. Apply the rewrite rule and classifier to the pseudowire interfaces.

For the *interface\_name* parameter, specify the ps device name.

```
[edit class-of-service interfaces interface_name unit logical-unit-number]  
user@host#set rewrite-rule (dscp | inet-precedence) (rewrite-name | default) protocol  
                  protocol-types  
user@host#set classifiers (dscp | inet-precedence) (classifier-name | default)
```

## CoS for Subscriber Access Overview

---

This topic describes class-of-service (CoS) functionality for dynamic subscriber access.

Junos CoS enables you to divide traffic into classes and offer various levels of throughput and packet loss when congestion occurs. This functionality allows packet loss to happen according to rules that you configure. The Junos CoS features provide a set of mechanisms that you can use to provide differentiated services when best-effort traffic delivery is insufficient.

In a subscriber access environment, service providers want to provide video, voice, and data services over the same network for subscribers. Subscriber traffic is delivered from the access network, through a router, through a switched Ethernet network, to an Ethernet digital subscriber line access multiplexer (DSLAM). The DSLAM forwards the subscriber's traffic to the residential gateway over a digital subscriber line (DSL). An MX Series router that is installed in a subscriber access network as an edge router can perform subscriber management functions that include subscriber identification and per-subscriber CoS.

In a subscriber access network, a subscriber is an authenticated user—a user that has logged in to the access network at a subscriber interface and then been verified by the configured authentication server and subsequently granted initial CoS services. Subscribers can be identified statically or dynamically. In this network, subscribers are mapped to VLANs, demux, or PPPoE interfaces.

You can configure the router to provide *hierarchical scheduling* or *per-unit scheduling* for subscribers:

- Hierarchical CoS enables you to apply traffic scheduling and queuing parameters (which can include a delay-buffer bandwidth) and packet transmission scheduling parameters (which can include buffer management parameters) to an individual subscriber interface rather than to all interfaces configured on the port. Hierarchical CoS enables you to dynamically modify queues when subscribers require services.

- Per-unit scheduling enables one set of output queues for each logical interface configured under the physical interface. In per-unit scheduling configurations, each Layer 3 scheduler node is allocated a dedicated set of queues.

Because the interface sets corresponding to VLANs using agent-circuit-identifier information are created dynamically, you can apply CoS attributes, such as shaping, at the household level. You must set and define the CoS policy for the agent-circuit-identifier virtual VLAN interface set using the dynamic profile for the agent-circuit-identifier interface set (not the subscriber profile). CoS on dynamic VLANs includes support for level 3 or level 2 scheduler nodes for a dynamic interface set. You can also configure a traffic control profile and a remaining traffic control profile for a dynamic interface set. CoS on dynamic VLANs enables you to configure a dynamic scheduler map for a traffic control profile that is used by a dynamic interface set. In this case, the dynamic scheduler map must use the unique ID format.

## Guidelines for Configuring Dynamic CoS for Subscriber Access

This topic describes the hardware requirements and guidelines for configuring dynamic CoS in a subscriber access environment.

### Hardware Requirements for Dynamic CoS

[Table 71 on page 907](#) lists the hardware requirements based on subscriber interface type for the hierarchical scheduling and per-unit scheduling dynamic CoS configurations.

Table 71: Hardware Required for Dynamic CoS Configurations

Dynamic CoS Configuration	Subscriber Interface Type	EQ DPCs on MX Series Routers	MPC/MIC Modules on MX Series Routers	IQ2 PICs on M120 and M320 Routers	IQ2E PICs on M120 and M320 Routers
Hierarchical CoS	Static and dynamic VLANs	Yes	Yes	No	No
	Static and dynamic VLANs over aggregated Ethernet	Yes	Yes	No	No
	Static or dynamic IP demux interfaces	Yes	Yes	No	No
	Static or dynamic IP demux interfaces over aggregated Ethernet	Yes	Yes	No	No
	Static or dynamic VLAN demux interfaces	No	Yes	No	No
	Static or dynamic VLAN demux interfaces over aggregated Ethernet	No	Yes	No	No
	Static PPPoE interfaces	No	Yes	Yes	Yes
	Dynamic PPPoE interfaces	No	Yes	No	Yes
	Static or dynamic PPPoE interfaces over aggregated Ethernet	No	Yes	No	No
	L2TP LAC tunnel over PPP	No	Yes	No	No
	L2TP LNS inline service over PPP	No	Yes	No	No

Table 71: Hardware Required for Dynamic CoS Configurations (*continued*)

Dynamic CoS Configuration	Subscriber Interface Type	EQ DPCs on MX Series Routers	MPC/MIC Modules on MX Series Routers	IQ2 PICs on M120 and M320 Routers	IQ2E PICs on M120 and M320 Routers
Per-unit scheduling	Static and dynamic VLANs	Yes	Yes	No	No
	Static and dynamic VLANs over aggregated Ethernet	No	No	No	No
	Static or dynamic IP demux interfaces	Yes	No	No	No
	Static or dynamic IP demux interfaces over aggregated Ethernet	No	No	No	No
	Static or dynamic VLAN demux interfaces	No	No	No	No
	Static or dynamic VLAN demux interfaces over aggregated Ethernet	No	No	No	No
	Static PPPoE interfaces	No	Yes	Yes	Yes
	Dynamic PPPoE interfaces	No	No	Yes	Yes
	Static or dynamic PPPoE interfaces over aggregated Ethernet	No	No	No	No
	L2TP LAC tunnel over PPP	No	No	No	No
	L2TP LNS inline service over PPP	No	No	No	No

## Configuration Guidelines for Dynamic Scheduling and Queuing

When configuring scheduling and queuing for subscriber access, consider the following guidelines:

- To improve CoS performance in IPv4, IPv6, and dual-stack networks that use a DHCP access model, we recommend that you use the **aggregate-clients replace** statement rather than the **aggregate-clients merge** statement.
- You can configure dynamic CoS with one of the following scheduling configurations:
  - For hierarchical scheduling configurations, you must enable hierarchical scheduling in the static CLI for the interface referenced in the dynamic profile. If not, the dynamic profile fails.
  - For per-unit scheduling configurations, you must enable per-unit scheduling in the static CLI for the interface referenced in the dynamic profile. If not, the dynamic profile fails and schedulers are not attached to the interface.
- You configure the traffic scheduling and shaping parameters in a traffic-control profile within the dynamic profile. You can configure the scheduler map and schedulers in a dynamic profile or in the **[edit class-of-service]** hierarchy. You must statically configure the remaining CoS parameters, such as hierarchical scheduling, classifiers, drop profiles, and forwarding classes, in the **[edit class-of-service]** hierarchy.
- You can configure only one traffic-control-profile under a dynamic profile.
- You must define the output-traffic-control-profile that binds the traffic-control profile to the interface within the same dynamic profile as the interface.
- We recommend that you provide different names for the schedulers defined in dynamic profiles that are used for access and services. For example, if there are two dynamic profiles, voice-profile and video-profile, provide unique names for the schedulers defined under those profiles.
- You must use a service dynamic profile with a different profile name for each RADIUS CoA request over the same logical interface.
- When you configure scheduler and scheduler map sharing in client profiles, schedulers and scheduler maps must use the unique ID format. If the client profile uses the unique ID format and you want to have either scheduler or scheduler map sharing for service activation, you must configure the service profile in unique ID format.

## Configuration Guidelines for Dynamic Classifiers and Rewrite Rules

When you configure classifiers and rewrite rules for subscriber access, consider the following guidelines:

- To apply classifiers and rewrite rules to a subscriber interface in a dynamic profile, you must configure the rewrite rule and classifier definitions in the static **[edit class-of-service]** hierarchy and reference them in the dynamic profile.

- If a static classifier or a rewrite rule definition that is referenced by a dynamic subscriber interface does not exist, the configuration is invalid and the subscriber cannot log in.
- If a network administrator changes the static classifiers and rewrite rules definitions that are referenced in a dynamic profile with an active subscriber interface logged in, the changes are applied to the active subscriber interface immediately.
- If a network administrator deletes a classifier or a rewrite rule definition that is referenced by an active dynamic subscriber interface, the system removes the classifier or rewrite rule binding from the interface. The classifier is replaced by the default classifier. If the network administrator adds the removed classifier or rewrite rule to the configuration while the dynamic interface is active, the addition does not take effect until the subscriber logs out and then logs in again.
- IP demux interfaces can only instantiate Layer 3 rules (both rewrite rules and classifiers).
  - An IP demux subscriber interface can implicitly inherit a classifier from the underlying interface. If an IP demux interface is created without a classifier and a Layer 2 classifier is attached to the underlying interface, the IP demux interface also inherits the Layer 2 classifier. The **show class-of-service interface *interface-name*** command does not display this attachment.

[Table 72 on page 910](#) lists the classification rule configuration for an IP demux subscriber interface with a VLAN underlying interface.

**Table 72: IP Demux Classification Rules**

VLAN Underlying Interface Classifier Configuration	IP Demux Interface Classifier Configuration	Resulting Classifier Configuration
Layer 2	—	VLAN Layer 2
Layer 2	Layer 3	Demux Layer 3
Layer 3	—	Default
Layer 3	Layer 3	Demux Layer 3

- An IP demux subscriber interface explicitly inherits Layer 2 rewrite rules from the underlying interface if a Layer 2 rewrite rule is present. The **show class-of-service interface *interface-name*** command displays the attachment.

[Table 73 on page 910](#) lists the rewrite rule configuration for an IP demux subscriber interface with a VLAN underlying interface.

**Table 73: IP Demux Rewrite Rules**

VLAN Underlying Interface Rewrite Rule Configuration	IP Demux Interface Rewrite Rule Configuration	Resulting Rewrite Rule Configuration
Layer 2	—	VLAN Layer 2

**Table 73: IP Demux Rewrite Rules (*continued*)**

VLAN Underlying Interface Rewrite Rule Configuration	IP Demux Interface Rewrite Rule Configuration	Resulting Rewrite Rule Configuration
Layer 2	Layer 3	VLAN Layer 2 and demux Layer 3
Layer 3	—	Default
Layer 3	Layer 3	Demux Layer 3

- An L2TP subscriber interface can implicitly inherit a classifier from the underlying interface.

[Table 74 on page 911](#) lists the classification rule configuration for an L2TP LAC subscriber interface with a VLAN underlying interface.

**Table 74: L2TP Classification Rules**

VLAN Underlying Interface Classifier Configuration	L2TP LAC Classifier Configuration	Resulting Classifier Configuration
Layer 2 or Fixed	Layer 2 or Fixed	VLAN Layer 2 or Fixed
Layer 2 or Fixed	Layer 3	Demux/PPPoE Layer 3
Layer 3	Layer 2 or Fixed	VLAN Layer 2 or Fixed
Layer 3	Layer 3	Demux/PPPoE Layer 3

- An L2TP LAC subscriber interface explicitly inherits Layer 2 rewrite rules from the underlying interface if a Layer 2 rewrite rule is present. [Table 75 on page 911](#) lists the rewrite rule configuration for an L2TP LAC subscriber interface with a VLAN underlying interface.

**Table 75: L2TP LAC Rewrite Rules**

VLAN Underlying Interface Rewrite Rule Configuration	L2TP Interface Rewrite Rule Configuration	Resulting Rewrite Rule Configuration
Layer 2	Layer 2	VLAN Layer 2
Layer 2	Layer 3	VLAN Layer 2 and demux/PPPoE Layer 3
Layer 3	Layer 2	VLAN Layer 2 and demux/PPPoE Layer 3
Layer 3	Layer 3	Demux/PPPoE Layer 3

## Configuring Static Hierarchical Scheduling and Queuing in a Dynamic Profile for Subscriber Access

---

You configure static scheduling and queuing in a dynamic profile for subscriber access.

To configure CoS in a dynamic profile for subscriber access using static scheduling and queuing parameters:

1. Configure the static CoS parameters in the **[edit class-of-service]** hierarchy.
  - a. Enable the hierarchical scheduler for the interface.  
See [Configuring Hierarchical Schedulers for CoS](#).
  - b. Configure the scheduler map and schedulers.  
When you configure static scheduling and queuing in a dynamic profile, you reference the scheduler map in the dynamic profile.  
See [Configuring Schedulers](#).
  - c. Configure the drop profiles.  
See [Configuring RED Drop Profiles](#).
  - d. Configure the forwarding classes.  
See [Configuring Forwarding Classes](#).
  - e. Configure the rewrite-rules and classifier definitions.  
See [Configuring Rewrite Rules and Defining Classifiers](#).

See the Junos OS Class of Service Configuration Guide for information about configuring the remaining CoS parameters.

2. Configure a static or dynamic subscriber interface that can be referenced in the dynamic profile.
  - For static VLAN interfaces, see [“Configuring Static Subscriber Interfaces in Dynamic Profiles” on page 723](#).
  - For dynamic VLAN interfaces, see [“Configuring a Static or Dynamic VLAN Subscriber Interface over Aggregated Ethernet” on page 782](#).
  - For dynamic IP demux interfaces, see [“Configuring Dynamic Subscriber Interfaces Using IP Demux Interfaces in Dynamic Profiles” on page 729](#) and [“Configuring a Static or Dynamic IP Demux Subscriber Interface over Aggregated Ethernet” on page 783](#).
  - For dynamic VLAN demux interfaces, see [“Configuring Dynamic Subscriber Interfaces Using VLAN Demux Interfaces in Dynamic Profiles” on page 730](#).
  - For dynamic PPPoE interfaces, see [“Configuring Dynamic PPPoE Subscriber Interfaces Using Dynamic Profiles” on page 857](#).
3. Configure CoS parameters in a dynamic profile.
  - a. Configure the dynamic profile.

See [“Configuring a Basic Dynamic Profile” on page 633](#).
  - b. Configure traffic shaping and scheduling parameters in the dynamic profile using a traffic-control profile.

Reference the scheduler map you configured in the static **[edit class-of-service]** hierarchy.

See [“Configuring Static Traffic Shaping and Scheduling Parameters in a Dynamic Profile” on page 919](#).
  - c. Apply CoS parameters to a subscriber interface by referencing an interface in the dynamic profile.

See [“Applying Traffic Shaping and Scheduling to a Subscriber Interface in a Dynamic Profile” on page 927](#).
4. To configure default values for subscribers on login, and enable subscribers to replace other CoS parameters when replacing services, configure variables in the dynamic profile.

See [“Configuring User-Defined CoS Variables in a Dynamic Service Profile” on page 946](#).

**Related Documentation**

- For hardware requirements and configuration guidelines, see [Guidelines for Configuring Dynamic CoS for Subscriber Access on page 906](#)

- [Example: Configuring Static Hierarchical Scheduling and Queuing for Subscriber Access on page 977](#)

## Configuring Dynamic Hierarchical Scheduling and Queuing in a Dynamic Profile for Subscriber Access

---

You can configure dynamic scheduling and queuing in dynamic profile for subscriber access.

To configure dynamic scheduling and queuing for subscriber access using dynamic scheduling and queuing parameters:

1. Configure the static CoS parameters in the **[edit class-of-service]** hierarchy.

- a. Enable the hierarchical scheduler for the interface.

See [Configuring Hierarchical Schedulers for CoS](#).

- b. Configure the drop profiles.

See [Configuring RED Drop Profiles](#).

- c. Configure the forwarding classes.

See [Configuring Forwarding Classes](#).

- d. Configure the rewrite-rules and classifier definitions.

See [Configuring Rewrite Rules and Defining Classifiers](#).

See the Junos OS Class of Service Configuration Guide for information about configuring the remaining CoS parameters.

2. Configure a static or dynamic subscriber interface that can be referenced in the dynamic profile.

- For static VLAN interfaces, see [“Configuring Static Subscriber Interfaces in Dynamic Profiles” on page 723](#).

- For dynamic VLAN interfaces, see [“Configuring a Static or Dynamic VLAN Subscriber Interface over Aggregated Ethernet” on page 782](#).

- For dynamic IP demux interfaces, see [“Configuring Dynamic Subscriber Interfaces Using IP Demux Interfaces in Dynamic Profiles” on page 729](#) and [“Configuring a Static or Dynamic IP Demux Subscriber Interface over Aggregated Ethernet” on page 783](#).

- For dynamic VLAN demux interfaces, see [“Configuring Dynamic Subscriber Interfaces Using VLAN Demux Interfaces in Dynamic Profiles” on page 730](#).

- For dynamic PPPoE interfaces, see [“Configuring Dynamic PPPoE Subscriber Interfaces Using Dynamic Profiles” on page 857](#).

3. Configure CoS parameters in a dynamic profile.

- a. Configure the dynamic profile.

See [“Configuring a Basic Dynamic Profile” on page 633](#).

- b. Configure traffic shaping and scheduling parameters in the dynamic profile using a traffic-control profile.

See [“Configuring Traffic Scheduling and Shaping for Subscriber Access” on page 919](#).

- c. Configure the schedulers and scheduler map in the dynamic profile.

You can configure the schedulers using dynamic variables or a combination of both static values and dynamic variables.

See [“Configuring Schedulers in a Dynamic Profile for Subscriber Access” on page 921](#).

- d. Apply CoS parameters to a subscriber interface by referencing an interface in the dynamic profile.
  - For traffic shaping and scheduling, see [“Applying Traffic Shaping and Scheduling to a Subscriber Interface in a Dynamic Profile” on page 927](#).
  - For rewrite-rules, see [“Applying a Rewrite Rule Definition to a Subscriber Interface in a Dynamic Profile” on page 928](#).
  - For classifiers, see [“Applying a Classifier to a Subscriber Interface in a Dynamic Profile” on page 929](#).

4. (Optional) Configure variables in access and service profiles to enable RADIUS to activate subscriber and upgrade services through CoA.

**NOTE:** Do not instantiate a CoA request using a service dynamic profile that is already in use on the same logical interface.

---

- a. Configure user-defined CoS variables in a dynamic profile.

See [“Configuring User-Defined CoS Variables in a Dynamic Service Profile” on page 946](#)

- b. (Optional) Enable multiple clients for the same subscriber (logical interface) to aggregate attributes by configuring the **aggregate-clients** option for the dynamic profile attached to a DHCP subscriber interface.

See [“Attaching Dynamic Profiles to DHCP Subscriber Interfaces” on page 220](#).

Because you have configured the scheduler map in the dynamic profile, queues are merged when subscribers change services. Other CoS parameters are replaced.

When multiple subscribers are enabled on a DHCP subscriber interface, and the dynamic profile referenced by DHCP does not have the **replace** keyword configured, the system does not replace the parameters. Instead, it combines the values of the parameters to their maximum scalar value.

#### Related Documentation

- For hardware requirements and configuration guidelines, see [Guidelines for Configuring Dynamic CoS for Subscriber Access on page 906](#)

- [Example: Configuring Dynamic Hierarchical Scheduling and Queuing for Subscriber Access on page 979](#)

## Configuring Per-Unit Scheduling in a Dynamic Profile for Subscriber Access

Per-unit scheduling enables one set of output queues for each logical interface configured under the physical interface. In per-unit scheduling configurations, each Layer 3 scheduler node is allocated a dedicated set of queues.

If you do not explicitly configure CoS parameters, a default traffic profile with queues is attached to the logical interface.

To configure per-unit scheduling and queuing for subscriber access:

1. Configure the static CoS parameters in the **[edit class-of-service]** hierarchy.

- a. Enable the per-unit scheduler for the physical interface.

```
[edit interfaces interface-name]  
user@host# set per-unit-scheduler
```

- b. Configure the drop profiles.

See [Configuring RED Drop Profiles](#).

- c. Configure the forwarding classes.

See [Configuring Forwarding Classes](#).

- d. Configure the rewrite-rules and classifier definitions.

See [Configuring Rewrite Rules and Defining Classifiers](#).

See the Junos OS Class of Service Configuration Guide for information about configuring the remaining CoS parameters.

2. Configure a static or dynamic subscriber interface that can be referenced in the dynamic profile.

- For static VLAN interfaces, see [“Configuring Static Subscriber Interfaces in Dynamic Profiles” on page 723](#).
- For dynamic IP demux interfaces, see [“Configuring Dynamic Subscriber Interfaces Using IP Demux Interfaces in Dynamic Profiles” on page 729](#).
- For dynamic PPPoE interfaces, see [“Configuring Dynamic PPPoE Subscriber Interfaces Using Dynamic Profiles” on page 857](#).

3. Configure CoS parameters in a dynamic profile.

- a. Configure the dynamic profile.

See [“Configuring a Basic Dynamic Profile” on page 633](#).

- b. Configure traffic shaping and scheduling parameters in the dynamic profile using a traffic-control profile.

See [“Configuring Traffic Scheduling and Shaping for Subscriber Access” on page 919](#).

- c. Configure the schedulers and scheduler map in the dynamic profile.

You can configure the schedulers using dynamic variables or a combination of both static values and dynamic variables.

See [“Configuring Schedulers in a Dynamic Profile for Subscriber Access” on page 921](#).

- d. Apply CoS parameters to a subscriber interface by referencing an interface in the dynamic profile.
  - For traffic shaping and scheduling, see [“Applying Traffic Shaping and Scheduling to a Subscriber Interface in a Dynamic Profile” on page 927](#).
  - For rewrite rules, see [“Applying a Rewrite Rule Definition to a Subscriber Interface in a Dynamic Profile” on page 928](#).
  - For classifiers, see [“Applying a Classifier to a Subscriber Interface in a Dynamic Profile” on page 929](#).
4. (Optional) Configure variables in access and service profiles to enable RADIUS to activate subscriber and upgrade services through CoA.

**NOTE:** Do not instantiate a CoA request using a service dynamic profile that is already in use on the same logical interface.

Because you have configured the scheduler map in the dynamic profile, queues are merged when subscribers change services. Other CoS parameters are replaced.

When multiple subscribers are enabled on a DHCP subscriber interface, and the dynamic profile referenced by DHCP does not have the **replace** keyword configured, the system does not replace the parameters. Instead, it combines the values of the parameters to their maximum scalar value.

- a. Configure CoS variables in a dynamic profile.

See [“Configuring User-Defined CoS Variables in a Dynamic Service Profile” on page 946](#)

- b. (Optional) Enable multiple clients for the same subscriber (logical interface) to aggregate attributes by configuring the **aggregate-clients** option for the dynamic profile attached to a DHCP subscriber interface.

See [“Attaching Dynamic Profiles to DHCP Subscriber Interfaces” on page 220](#).

## Configuring Traffic Scheduling and Shaping for Subscriber Access

---

You use traffic-control profiles to configure traffic shaping and scheduling properties. When you reference a traffic-control profile in a dynamic profile, you can provide hierarchical shaping and scheduling for a subscriber interface.

You can choose to configure static values or dynamic variables for the shaping parameters. The values for the dynamic variables are obtained from RADIUS when a subscriber logs in or when a subscriber changes services.

You cannot configure a traffic-control profile that contains a combination of static and dynamic parameters.

This topic includes the following tasks:

- [Configuring Static Traffic Shaping and Scheduling Parameters in a Dynamic Profile on page 919](#)
- [Configuring Dynamic Traffic Shaping and Scheduling Parameters in a Dynamic Profile on page 920](#)

## Configuring Static Traffic Shaping and Scheduling Parameters in a Dynamic Profile

To configure static traffic shaping and scheduling parameters in a traffic-control profile:

1. Create the traffic-control profile and assign a name.

```
[edit dynamic-profiles business-profile class-of-service]  
user@host# edit traffic-control-profiles profile-name
```

2. Do one of the following:

- Reference a static scheduler map in the dynamic profile. The scheduler map is statically configured in the `[edit class-of-service]` hierarchy.

```
[edit dynamic-profiles business-profile class-of-service traffic-control-profiles
  profile-name]
user@host# set scheduler-map map-name
```

- Reference a dynamic scheduler map in the dynamic profile. The scheduler map is dynamically configured in the `[edit dynamic-profiles profile-name class-of-service scheduler-maps]` hierarchy.

```
[edit dynamic-profiles business-profile class-of-service traffic-control-profiles
  profile-name]
user@host# set scheduler-map map-name
```

3. Configure the shaping rate to be used in the dynamic profile.

```
[edit dynamic-profiles business-profile class-of-service traffic-control-profiles
  profile-name]
user@host# set shaping-rate (rate <burst-size bytes>
```

4. Configure the guaranteed rate to be used in the dynamic profile.

```
[edit dynamic-profiles business-profile class-of-service traffic-control-profiles
  profile-name]
user@host# set guaranteed-rate (rate <burst-size bytes>
```

5. Configure the delay-buffer rate.

If you do not include this statement, the delay-buffer rate is based on the guaranteed rate if one is configured, or on the shaping rate if no guaranteed rate is configured.

```
[edit dynamic-profiles business-profile class-of-service traffic-control-profiles
  profile-name]
user@host# set delay-buffer-rate (percent percentage | rate)
```

## Configuring Dynamic Traffic Shaping and Scheduling Parameters in a Dynamic Profile

You can configure variables for the traffic shaping and scheduling parameters. The values for the parameters are dynamically obtained by RADIUS when a subscriber logs in or changes a service.

To configure dynamic traffic-control profiles in a dynamic profile:

1. Create the traffic-control profile.

```
[edit dynamic-profiles business-profile class-of-service]
user@host# edit traffic-control-profiles profile-name
```

2. Configure the scheduler map variable.

```
[edit dynamic-profiles business-profile class-of-service traffic-control-profiles
  profile-name]
user@host# set scheduler-map $junos-cos-scheduler-map
```

3. Configure the shaping rate variable.

```
[edit dynamic-profiles business-profile class-of-service traffic-control-profiles  
  profile-name]
```

```
user@host# set shaping-rate $junos-cos-shaping-rate <burst-size bytes>
```

4. Configure the guaranteed rate variable.

```
[edit dynamic-profiles business-profile class-of-service traffic-control-profiles  
  profile-name]
```

```
user@host# set guaranteed-rate $junos-cos-guaranteed-rate <burst-size [ bytes |  
  $junos-cos-guaranteed-rate-burst]>
```

5. Configure a variable for the delay-buffer rate.

If you do not include this statement, the delay-buffer rate is based on the guaranteed rate if one is configured, or the shaping rate if no guaranteed rate is configured.

```
[edit dynamic-profiles business-profile class-of-service traffic-control-profiles  
  profile-name]
```

```
user@host# set delay-buffer-rate $junos-cos-delay-buffer-rate
```

## Configuring Schedulers in a Dynamic Profile for Subscriber Access

You use schedulers to define the parameters of output queues. These properties include the amount of interface bandwidth assigned to the queue, the size of the memory buffer allocated for storing packets, the priority of the queue, and the tail drop profiles associated with the queue.

You can configure up to four schedulers in a dynamic profile.

Within a dynamic profile, you can choose to define schedulers with static values, dynamic variables, or a combination of static values and dynamic variables. The dynamic variables

enable RADIUS to provide the value for the scheduler parameter when the subscriber logs in.

- [Configuring Static Schedulers in a Dynamic Profile on page 922](#)
- [Configuring Dynamic Schedulers with Variables in a Dynamic Profile on page 923](#)
- [Configuring a Combination of Static and Dynamic Scheduler Parameters in a Scheduler Definition on page 924](#)

## Configuring Static Schedulers in a Dynamic Profile

This topic describes how to configure schedulers with static values in a dynamic profile for subscriber access.

To configure static scheduling and queuing in a dynamic profile:

1. Configure the scheduler and queuing parameters.

- a. Specify the scheduler for which you want to configure parameters.

```
[edit dynamic-profiles profile-name class-of-service]  
user@host# edit schedulers scheduler-name
```

- b. Configure the buffer size.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]  
user@host# set buffer-size remainder
```

- c. Configure the drop-profile map and drop profile.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]  
user@host# set drop-profile-map loss-priority any protocol any drop-profile d3
```

- d. Configure the priority.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]  
user@host# set priority low
```

- e. Configure the transmit rate.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]  
user@host# set transmit-rate percent 40
```

- f. Configure the excess rate.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]  
user@host# set excess-rate percent 90
```

- g. (Optional) Configure the priority value for the excess-rate.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]  
user@host# set excess-priority high
```

2. Associate the scheduler with a scheduler map.

- a. Configure the scheduler map name.

```
[edit dynamic-profiles profile-name class-of-service]  
user@host# set scheduler-maps data-smap
```

- b. Configure the forwarding class.

```
[edit dynamic-profiles profile-name class-of-service scheduler-maps map-name]
user@host# set forwarding-class be
```

- c. Configure the scheduler.

```
[edit dynamic-profiles profile-name class-of-service scheduler-maps map-name
forwarding-class forwarding-class-name]
user@host# set scheduler be_sch
```

## Configuring Dynamic Schedulers with Variables in a Dynamic Profile

You can configure variables for the dynamic scheduler parameters. These values are dynamically obtained by RADIUS when a subscriber logs in or changes a service using a RADIUS change of authorization (CoA) message.

To configure dynamic scheduling and queuing in a dynamic profile:

1. Configure the scheduler and queuing parameters.

- a. Specify the scheduler name using a variable.

```
[edit dynamic-profiles profile-name class-of-service]
user@host# edit schedulers $junos-cos-scheduler
```

- b. Configure the variable for the buffer size.

```
[edit dynamic-profiles profile-name class-of-service schedulers]
user@host# set buffer-size (percent $junos-cos-scheduler-bs | temporal
$junos-cos-scheduler-bs)
```

- c. Configure the variables for the drop-profile maps and the drop profile.

```
[edit dynamic-profiles profile-name class-of-service schedulers]
user@host# set drop-profile-map loss-priority low protocol any drop-profile
$junos-cos-scheduler-low
user@host# set drop-profile-map loss-priority medium-low protocol any
drop-profile $junos-cos-scheduler-medium-low
user@host# set drop-profile-map loss-priority medium-high protocol any
drop-profile $junos-cos-scheduler-medium-high
user@host# set drop-profile-map loss-priority high protocol any drop-profile
$junos-cos-scheduler-high
user@host# set drop-profile-map loss-priority any protocol any drop-profile
$junos-cos-scheduler-any
```

- d. Configure the variable for the priority.

```
[edit dynamic-profiles profile-name class-of-service schedulers]
user@host# set priority $junos-cos-scheduler-pri
```

- e. Configure the variable for the transmit rate.

```
[edit dynamic-profiles profile-name class-of-service schedulers]
user@host# set transmit-rate $junos-cos-scheduler-tx
```

- f. Configure the variable for the excess rate.

```
[edit dynamic-profiles profile-name class-of-service schedulers]
```

```
user@host# set excess-rate percent $junos-cos-scheduler-excess-rate
```

- g. Configure the variable for the priority of the excess-rate.

```
[edit dynamic-profiles profile-name class-of-service schedulers]  
user@host# set excess-priority $junos-cos-scheduler-excess-priority
```

2. Associate the scheduler with a scheduler map.

- a. Configure the scheduler map name.

```
[edit dynamic-profiles profile-name class-of-service]  
user@host# edit scheduler-maps scheduler-map-name
```

- b. Configure the forwarding class.

```
[edit dynamic-profiles profile-name class-of-service scheduler-maps  
  scheduler-map-name]  
user@host# set forwarding-class be
```

- c. Configure the scheduler.

```
[edit dynamic-profiles profile-name class-of-service scheduler-maps  
  scheduler-map-name]  
user@host# set scheduler $junos-cos-scheduler
```

## Configuring a Combination of Static and Dynamic Scheduler Parameters in a Scheduler Definition

Within a dynamic profile, you can choose to configure one dynamic scheduler definition, or combine static and dynamic scheduler parameters in many static scheduler definitions.

Combining static and dynamic scheduler parameters enables you to provide subscribers with unique rate configurations that the RADIUS definitions for predefined variables do not allow.

To configure a scheduler definition that contains static and dynamic scheduling and queuing parameters:

1. Configure the scheduler definition.
  - a. Specify the scheduler name.

**NOTE:** To configure a static scheduler that contains both static and dynamic parameters, you must specify a unique scheduler name, not the \$junos-cos-scheduler variable.

```
[edit dynamic-profiles profile-name class-of-service]  
user@host# edit schedulers scheduler-name
```

- b. Configure the buffer size.

Do either of the following:

- Configure a static value.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]
```

```
user@host# set buffer-size (percent percentage | remainder | temporal
microseconds)
```

- Configure a variable.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]
user@host# set buffer-size (percent $junos-cos-scheduler-bs | temporal
$junos-cos-scheduler-bs)
```

- c. Configure the drop-profile maps, the drop profile, and the priority.

Do either of the following:

- Configure static values.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]
user@host# set drop-profile-map loss-priority any protocol any drop-profile d3

[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]
user@host# set priority low
```

- Configure variables.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]
user@host# set drop-profile-map loss-priority low protocol any drop-profile
$junos-cos-scheduler-low
user@host# set drop-profile-map loss-priority medium-low protocol any
drop-profile $junos-cos-scheduler-medium-low
user@host# set drop-profile-map loss-priority medium-high protocol any
drop-profile $junos-cos-scheduler-medium-high
user@host# set drop-profile-map loss-priority high protocol any drop-profile
$junos-cos-scheduler-high
user@host# set drop-profile-map loss-priority any protocol any drop-profile
$junos-cos-scheduler-any
```

- d. Configure the priority.

Do either of the following:

- Configure a static value.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]
user@host# set excess-priority high
```

- Configure a variable.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]
user@host# set excess-priority $junos-cos-scheduler-excess-priority
```

- e. Configure the transmit rate.

Do either of the following:

- Configure a static value.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]
user@host# set transmit-rate
```

- Configure a variable.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]
user@host# set transmit-rate $junos-cos-scheduler-tx
```

- f. Configure the excess rate.

Do either of the following:

- Configure a static value.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]  
user@host# set excess-rate percent 250
```

- Configure a variable.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]  
user@host# set excess-rate percent $junos-cos-scheduler-excess-rate
```

- g. Configure the priority for the excess-rate.

Do either of the following:

- Configure a static value.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]  
user@host# set excess-priority high
```

- Configure a variable.

```
[edit dynamic-profiles profile-name class-of-service schedulers scheduler-name]  
user@host# set excess-priority percent $junos-cos-scheduler-excess-priority
```

2. Associate the scheduler with a scheduler map.

- a. Configure the scheduler map name.

```
[edit dynamic-profiles profile-name class-of-service]  
user@host# edit scheduler-maps scheduler-map-name
```

- b. Configure the forwarding class.

```
[edit dynamic-profiles profile-name class-of-service scheduler-maps  
  scheduler-map-name]  
user@host# set forwarding-class be
```

- c. Configure the scheduler.

```
[edit dynamic-profiles profile-name class-of-service scheduler-maps  
  scheduler-map-name]  
user@host# set scheduler $junos-cos-scheduler
```

**Related  
Documentation**

- For hardware requirements and configuration guidelines, see [Guidelines for Configuring Dynamic CoS for Subscriber Access on page 906](#)
- [Configuring Dynamic Hierarchical Scheduling and Queuing in a Dynamic Profile for Subscriber Access on page 915](#)

## Applying CoS Parameters to a Subscriber Interface in a Dynamic Profile

You provide CoS parameters to a subscriber by associating the CoS parameters with an interface in a dynamic profile.

Traffic and scheduling parameters can be configured in the dynamic profile and associated with a subscriber by attaching an output traffic control profile to the interface in the dynamic profile.

You configure rewrite rules and classifiers statically in the **[edit class-of-service]** hierarchy and reference them in the dynamic profile.

- [Applying Traffic Shaping and Scheduling to a Subscriber Interface in a Dynamic Profile on page 927](#)
- [Applying Minimal Shaping and Scheduling to Remaining Subscriber Traffic on page 928](#)
- [Applying a Rewrite Rule Definition to a Subscriber Interface in a Dynamic Profile on page 928](#)
- [Applying a Classifier to a Subscriber Interface in a Dynamic Profile on page 929](#)

## Applying Traffic Shaping and Scheduling to a Subscriber Interface in a Dynamic Profile

After you configure the traffic shaping and scheduling CoS parameters in a dynamic profile, you apply them to an interface. The output-traffic control profile enables you to provide traffic scheduling to the interface.

To apply CoS attributes to an interface in a dynamic profile:

1. Specify that you want to apply CoS attributes to an interface in the dynamic profile.

```
user@host# edit dynamic-profiles profile-name class-of-service
```

2. Configure the interface name and logical interface using a variable, and apply the output-traffic control profile to the interface.

```
[edit dynamic-profiles profile-name class-of-service interfaces]
user@host# set interfaces $junos-interface-ifd-name unit
$junos-underlying-interface-unit output-traffic-control-profile profile-name
```

You can use one of the following methods to specify the output-traffic control profile you want to use:

- Reference the **\$junos-cos-traffic-control-profile** predefined variable. At subscriber login, subscriber management takes one of the following actions, in the order listed:
  - a. If RADIUS is being used and it returns a value for the traffic-control profile, subscriber management uses the RADIUS value.
  - b. If RADIUS is not being used, subscriber management uses the default traffic-control profile (which is specified by the **predefined-variables-default** statement at the **[edit dynamic-profiles]** hierarchy).

For example:

```
user@host# set interfaces $junos-interface-ifd-name unit
$junos-underlying-interface-unit output-traffic-control-profile
$junos-cos-traffic-control-profile
```

- Explicitly reference the name of the traffic-control profile.

For example:

```
user@host# set interfaces $junos-interface-ifd-name unit
$junos-underlying-interface-unit output-traffic-control-profile tcp-sales-2
```

## Applying Minimal Shaping and Scheduling to Remaining Subscriber Traffic

It is beneficial to apply a remaining traffic-control profile to a logical interface to provide minimal CoS scheduling when you have not configured or over-provisioned Layer 3 schedulers. In the event that schedulers are not available, the remaining subscriber traffic receives the essential level of service.

To configure scheduling for remaining subscriber traffic:

1. Enable hierarchical scheduling for the interface.

```
[edit interfaces interface-name]
user@host# set hierarchical-scheduler
```

2. Apply the remaining traffic control profile to the port on which you enabled hierarchical scheduling.

```
[edit class-of-service interfaces interface-name]
user@host# set output-traffic-control-profile-remaining profile-name
```

## Applying a Rewrite Rule Definition to a Subscriber Interface in a Dynamic Profile

Rewrite rules define the marking for various CoS values, including DSCP, DSCP IPv6, IP precedence, and IEEE 802.1 CoS values. Rewrite rules have an associated forwarding class and code-point alias or bit set.

For dynamic CoS, you define the rewrite rules mapping for the CoS values statically, then reference the rewrite rule configuration in the dynamic profile for the subscriber interface.

To configure a rewrite rule in a dynamic profile:

1. Define the rewrite-rules mapping for the traffic that passes through all queues on the interface. The available rewrite-rules types for dynamic CoS are **dscp**, **dscpv6**, **ieee-802.1** and **inet-precedence**.

See Configuring Rewrite Rules.

2. Apply the rewrite-rules definition to the subscriber interface in the dynamic profile.

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name unit
logical-unit-number]
user@host# edit rewrite-rules
```

3. Configure the applicable rewrite rule markers in the dynamic profile.

- For DSCP:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name unit
  logical-unit-number rewrite-rules]
```

```
user@host# set dscp (rewrite-name | default)
```

- For DSCPv6:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name unit
  logical-unit-number rewrite-rules]
```

```
user@host# set dscp-ipv6 (rewrite-name | default)
```

- For IEEE 802.1:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name unit
  logical-unit-number rewrite-rules]
```

```
user@host# set ieee-802.1 (rewrite-name | default) vlan-tag (outer | outer-and-inner)
```

- For inet-precedence:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name unit
  logical-unit-number rewrite-rules]
```

```
user@host# set inet-precedence (rewrite-name | default)
```

## Applying a Classifier to a Subscriber Interface in a Dynamic Profile

You can apply the classification map to a subscriber interface in a dynamic profile.

For dynamic CoS, you define the classification map for the CoS values statically, then reference the classifier configuration in the dynamic profile for the subscriber interface.

To apply a classifier to an interface in a dynamic profile:

1. Define the classifier.

The available classifier types for dynamic CoS are **dscp**, **dscp-ipv6**, **ieee-802.1**, and **inet-precedence**.

See Defining Classifiers.

2. Apply the classifier definition to the subscriber interface in the dynamic profile.

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name unit
  logical-unit-number]
```

```
user@host# edit classifiers
```

3. Configure the applicable classifiers in the dynamic profile.

- For DSCP:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name unit
  logical-unit-number classifiers]
```

```
user@host# set dscp (classifier-name | default)
```

- For DSCPv6:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name unit
  logical-unit-number classifiers]
```

```
user@host# set dscp-ipv6 (classifier-name | default)
```

- For IEEE 802.1:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name unit
logical-unit-number classifiers]
```

```
user@host# set ieee-802.1 (classifier-name | default) vlan-tag (inner | outer)
```

- For inet-precedence:

```
[edit dynamic-profiles profile-name class-of-service interfaces interface-name unit
logical-unit-number classifiers]
```

```
user@host# set inet-precedence (classifier-name | default)
```

## Configuring Scheduler and Scheduler Map Sharing

The system generates unique identifiers (IDs) in dynamic profiles created for services. The generated unique IDs enable you to identify and configure separate parameter values with the same variable name. When applied to CoS, you can now configure scheduler and scheduler map sharing. In client-access profiles, schedulers and scheduler maps must use the unique ID format. If the client-access profile uses the unique ID format and you want to have either scheduler or scheduler map sharing for service activation, you must configure the service profile in unique ID format. Generating unique IDs based on schedulers and scheduler maps eliminates duplication and improves router performance and scalability. You can configure scheduler and scheduler map sharing by including the variables for CoS in the client access or service dynamic profile. All scheduler maps and schedulers must be in the unique ID format.

Before you configure variables for the client access or service dynamic profile:

- Create a basic dynamic profile.

See [“Configuring a Basic Dynamic Profile” on page 633](#).

To configure variables for the client access or service dynamic profile:

1. Configure the variables for the dynamic client access profile.

```
[edit dynamic-profiles client-profile variables]
```

```
user@host# set smap_data uid
```

```
user@host# set data_sched uid
```

2. Configure the CoS parameters for the variables in the scheduler profile.

```
[edit dynamic-profiles client-profile class-of-service]
```

```
user@host# edit schedulers “$data_sched”
```

```
user@host# set transmit-rate percent 10
```

```
user@host# set buffer-size remainder
```

```
user@host# set priority low
```

3. Configure the CoS parameters for the variables in the scheduler maps profile.

```
[edit dynamic-profiles client-profile class-of-service]
user@host# edit scheduler-maps "$smap_data"
user@host# edit forwarding-class be scheduler "$data_sched"
```

For example, you can configure scheduler maps and schedulers for a client access profile:

```
dynamic-profiles {
  cos-para {
    variables {
      data_smap uid;
      data_video_smap uid;
      voice_smap uid;
      data_sched uid;
      video_sched uid;
      voice_sched uid;
    }
    ...
  }
  class-of-service {
    traffic-control-profiles {
      tcp1 {
        scheduler-map "$junos-cos-scheduler-map";
        shaping-rate "$junos-cos-shaping-rate";
        guaranteed-rate 10m;
        delay-buffer-rate "$junos-cos-delay-buffer-rate";
      }
    }
    interfaces {
      "$junos-interface-ifd-name" {
        unit "$junos-underlying-interface-unit" {
          output-traffic-control-profile tcp1;
        }
      }
    }
    scheduler-maps {
      "$data_smap" {
        forwarding-class be scheduler "$data_sched";
      }
      "$data_video_smap" {
        forwarding-class be scheduler "$data_sched";
        forwarding-class af scheduler "$video_sched";
      }
      "$voice_smap" {
        forwarding-class ef scheduler "$voice_sched";
      }
    }
    schedulers {
      "$data_sched" {
        transmit-rate "$junos-cos-scheduler-tx";
        inactive: buffer-size percent "$junos-cos-scheduler-bs";
        priority "$junos-cos-scheduler-pri";
      }
      "$video_sched" {
        transmit-rate "$junos-cos-scheduler-tx";
        inactive: buffer-size percent "$junos-cos-scheduler-bs";
        priority "$junos-cos-scheduler-pri";
      }
    }
  }
}
```

```
        "$voice_sched" {  
            transmit-rate percent 10;  
            buffer-size remainder;;  
            priority low;  
        }  
    }  
}
```

## Applying CoS Attributes to VLANs Using Agent-Circuit-Identifiers

To apply CoS attributes, such as shaping, at the household level, you must set and define the CoS policy for the agent-circuit-identifier VLAN interface set using the dynamic profile for the agent-circuit-identifier interface set (not the subscriber profile). You can also configure a traffic control profile and a remaining traffic control profile for a dynamic interface set.

The following example is a CoS profile for an ACI set using a unique-ID based dynamic scheduler map:

Before you apply CoS attributes to VLANs:

- Create a basic dynamic profile.

See [“Configuring a Basic Dynamic Profile” on page 633](#).

Configure a CoS dynamic profile with a simple traffic control profile that is applied to the dynamic interface set that represents the ACI VLAN.

1. Configure CoS to support a dynamic interface set in the CoS profile:

```
[edit dynamic-profiles profile-name]  
user@host# edit interface "$junos-interface-name"
```

2. Configure the interfaces.

```
[edit dynamic-profiles profile-name interfaces]  
user@host# edit interface-set "$junos-interface-set-name"  
user@host# edit interface "$junos-interface-ifd-name"
```

3. Configure the CoS traffic control profile.

```
[edit class-of-service]  
user@host# edit traffic-control-profiles traffic-control-profile-name  
user@host# set shaping-rate rate  
user@host# set guaranteed-rate rate
```

4. Specify the interfaces.

```
[edit class-of-service interfaces]  
user@host# edit interface-set "$junos-interface-set-name"  
user@host# edit output-traffic-control-profile profile-name
```

The following example is a CoS profile for an ACI set using a unique ID-based dynamic scheduler map:

```
aci-set-profile {
  variables {
    ds1q0q2DP uid;
    ds1q1q2DP uid;
    be1_dp uid;
    ef1_dp uid;
    af1_dp uid;
    nc1_dp uid;
  }
  interfaces {
    interface-set "$junos-interface-set-name" {
      interface "$junos-interface-ifd-name";
    }
  }
  class-of-service {
    traffic-control-profiles {
      tcp2 {
        inactive: scheduler-map ss1q0q1DP;
        shaping-rate 50m;
        guaranteed-rate 30m;
        overhead-accounting bytes -20;
      }
      tcp3 {
        scheduler-map "$ds1q1q2DP";
        shaping-rate 30m;
        guaranteed-rate 10m;
        overhead-accounting bytes -20;
      }
    }
    interfaces {
      interface-set "$junos-interface-set-name" {
        output-traffic-control-profile tcp2;
        output-traffic-control-profile-remaining tcp3;
      }
    }
    scheduler-maps {
      "$ds1q0q2DP" {
        forwarding-class be scheduler "$be1_dp";
        forwarding-class af scheduler "$af1_dp";
        forwarding-class nc scheduler "$nc1_dp";
      }
      "$ds1q1q2DP" {
        forwarding-class ef scheduler "$ef1_dp";
        forwarding-class af scheduler "$af1_dp";
        forwarding-class nc scheduler "$nc1_dp";
      }
    }
    schedulers {
      "$be1_dp" {
        transmit-rate percent 25;
        priority low;
        drop-profile-map loss-priority low protocol any drop-profile d3;
        drop-profile-map loss-priority medium-low protocol any drop-profile d2;
      }
    }
  }
}
```

```
        drop-profile-map loss-priority medium-high protocol any drop-profile d1;
        drop-profile-map loss-priority high protocol any drop-profile d0;
    }
    "$efl_dp" {
        transmit-rate percent 25;
        priority low;
        drop-profile-map loss-priority low protocol any drop-profile d3;
        drop-profile-map loss-priority medium-low protocol any drop-profile d2;
        drop-profile-map loss-priority medium-high protocol any drop-profile d1;
        drop-profile-map loss-priority high protocol any drop-profile d0;
    }
    "$af1_dp" {
        transmit-rate percent 25;
        priority low;
        drop-profile-map loss-priority low protocol any drop-profile d3;
        drop-profile-map loss-priority medium-low protocol any drop-profile d2;
        drop-profile-map loss-priority medium-high protocol any drop-profile d1;
        drop-profile-map loss-priority high protocol any drop-profile d0;
    }
    "$nc1_dp" {
        transmit-rate percent 25;
        priority low;
        drop-profile-map loss-priority low protocol any drop-profile d3;
        drop-profile-map loss-priority medium-low protocol any drop-profile d2;
        drop-profile-map loss-priority medium-high protocol any drop-profile d1;
        drop-profile-map loss-priority high protocol any drop-profile d0;
    }
}
}
```

## Subscriber Interfaces That Provide Initial CoS Parameters Dynamically Obtained from RADIUS

---

You can configure interface-specific CoS parameters that the router obtains when subscribers log in at appropriately configured static or dynamic subscriber interfaces. This feature is supported only for interfaces on Enhanced Queuing Dense Port Concentrators (EQ DPCs) in MX Series 3D Universal Edge Routers.

To configure a dynamic profile to provide initial CoS Services, make sure you understand the following concepts:

- [Dynamic Configuration of Initial CoS in Access Profiles on page 935](#)
- [Predefined Variables for Dynamic Configuration of Initial Traffic Shaping on page 936](#)
- [Predefined Variables for Dynamic Configuration of Initial Scheduling and Queuing on page 937](#)

## Dynamic Configuration of Initial CoS in Access Profiles

When a router interface receives a join message from a DHCP subscriber, the Junos OS applies the values configured in the dynamic profile associated with that router interface. A dynamic profile that is activated through its association with a subscriber interface is known as an *access dynamic profile*. You can associate a dynamic profile with a subscriber interface on the router by including statements at the **[edit dynamic-profiles profile-name class-of-service interfaces]** hierarchy level.

The Junos OS supports predefined variables for obtaining a scheduler-map name and traffic-shaping parameters from the RADIUS authentication server and predefined variables for obtaining a scheduler name and scheduler parameters from the RADIUS authentication server. When a client authenticates over a router interface associated

with the access dynamic profile, the router replaces the predefined variables with interface-specific values obtained from the RADIUS server.

**NOTE:** To associate dynamically configured initial CoS features with a subscriber interface, reference *Junos OS predefined variables*—and not *user-defined variables*—in an access dynamic profile for that interface.

## Predefined Variables for Dynamic Configuration of Initial Traffic Shaping

You can configure an access dynamic profile that provides initial traffic-shaping parameters when a subscriber logs in. The Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the access dynamic profile is attached.

If you define the Juniper Networks authentication and authorization VSA for CoS traffic-shaping parameter values (attribute number 26–108) on the RADIUS authentication server, the RADIUS server includes the values in RADIUS Access-Accept messages it sends to the router when a subscriber successfully authenticates over the interface.

To provide an initial scheduler map name and traffic shaping parameters obtained from the RADIUS authentication server when a subscriber logs in, reference the Junos OS predefined variables for CoS listed in [Table 76 on page 936](#) in an access dynamic profile associated with the subscriber interface.

**Table 76: CoS Predefined Variables for Scheduler Map and Traffic Shaping**

Variable	Description
\$junos-cos-scheduler-map	<p>Scheduler-map name to be dynamically configured in a traffic-control profile in the access dynamic profile when a subscriber logs in.</p> <p><b>NOTE:</b> The scheduler map referenced by the <a href="#">scheduler-map</a> statement can be defined dynamically (at the <a href="#">[edit dynamic-profiles profile-name class-of-service scheduler-maps]</a> hierarchy level) or statically (at the <a href="#">[edit class-of-service scheduler-maps]</a> hierarchy level).</p>
\$junos-cos-shaping-rate	Shaping rate to be dynamically configured in a traffic-control profile in the access dynamic profile when a subscriber logs in. You can configure a RADIUS authentication server to include this information in the Accept-Accept message when a subscriber successfully authenticates over the static or dynamic subscriber interface to which the access dynamic profile is attached.
\$junos-cos-guaranteed-rate	Guaranteed rate to be dynamically configured in a traffic-control profile in the access dynamic profile when a subscriber logs in. You can configure a RADIUS authentication server to include this information in the Accept-Accept message when a subscriber successfully authenticates over the static or dynamic subscriber interface to which the access dynamic profile is attached.
\$junos-cos-delay-buffer-rate	Delay-buffer rate to be dynamically configured in a traffic-control profile in the access dynamic profile when a subscriber logs in. You can configure a RADIUS authentication server to include this information in the Accept-Accept message when a subscriber successfully authenticates over the static or dynamic subscriber interface to which the access dynamic profile is attached.

## Predefined Variables for Dynamic Configuration of Initial Scheduling and Queuing

You can configure an access dynamic profile that provides initial traffic-shaping parameters when a subscriber logs in. The Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the access dynamic profile is attached.

If you define the Juniper Networks authentication and authorization VSA for CoS scheduling and queuing parameter values (attribute number 26–146) on the RADIUS authentication server, the RADIUS server includes the values in RADIUS Access-Accept messages it sends to the router when a subscriber successfully authenticates over the interface.

To provide an initial scheduler name and scheduler and queuing parameters obtained from the RADIUS authentication server when a subscriber logs in, reference the Junos OS predefined variables listed in [Table 77 on page 937](#) in an access dynamic profile associated with the subscriber interface.

**Table 77: CoS Predefined Variables for Scheduling and Queuing**

Variable	Description
\$junos-cos-scheduler	Name of a scheduler to be dynamically configured in the access dynamic profile. You can configure a RADIUS authentication server to include this information in the Accept-Accept message when a subscriber successfully authenticates over the static or dynamic subscriber interface to which the access dynamic profile is attached.
\$junos-cos-scheduler-transmit-rate	Transmit rate to be dynamically configured for the scheduler in the access dynamic profile. You can configure a RADIUS authentication server to include this information in the Accept-Accept message when a subscriber successfully authenticates over the static or dynamic subscriber interface to which the access dynamic profile is attached.
\$junos-cos-scheduler-bs	Buffer size, as a percentage of total buffer, to be dynamically configured for the scheduler in the access dynamic profile. You can configure a RADIUS authentication server to include this information in the Accept-Accept message when a subscriber successfully authenticates over the static or dynamic subscriber interface to which the access dynamic profile is attached.
\$junos-cos-scheduler-pri	Packet-scheduling priority value to be dynamically configured for the scheduler in the access dynamic profile. You can configure a RADIUS authentication server to include this information in the Accept-Accept message when a subscriber successfully authenticates over the static or dynamic subscriber interface to which the access dynamic profile is attached.
\$junos-cos-scheduler-dropfile-low	<p>Name of the drop profile for RED for loss-priority level <b>low</b> to be dynamically configured for the scheduler in the access dynamic profile. You can configure a RADIUS authentication server to include this information in the Accept-Accept message when a subscriber successfully authenticates over the static or dynamic subscriber interface to which the access dynamic profile is attached.</p> <p><b>NOTE:</b> The drop profile must be configured statically (at the <a href="#">[edit class-of-service schedulers scheduler-name drop-profiles]</a> hierarchy level) for loss-priority <b>low</b>.</p>

Table 77: CoS Predefined Variables for Scheduling and Queuing (*continued*)

Variable	Description
\$junos-cos-scheduler-dropfile-medium-low	<p>Name of the drop profile for RED for loss-priority level <b>medium-low</b> to be dynamically configured for the scheduler in the access dynamic profile. The Junos OS obtains this information from the RADIUS server when a subscriber authenticates over the static or dynamic subscriber interface to which the access dynamic profile is attached.</p> <p><b>NOTE:</b> The drop profile must be configured statically (at the <b>[edit class-of-service schedulers scheduler-name drop-profiles]</b> hierarchy level).</p>
\$junos-cos-scheduler-dropfile-medium-high	<p>Name of the drop profile for RED for loss-priority level <b>medium-high</b> to be dynamically configured for the scheduler in the access dynamic profile. You can configure a RADIUS authentication server to include this information in the Accept-Accept message when a subscriber successfully authenticates over the static or dynamic subscriber interface to which the access dynamic profile is attached.</p> <p><b>NOTE:</b> The drop profile must be configured statically (at the <b>[edit class-of-service schedulers scheduler-name drop-profiles]</b> hierarchy level).</p>
\$junos-cos-scheduler-dropfile-high	<p>Name of the drop profile for RED for loss-priority level <b>high</b> to be dynamically configured for the scheduler in the access dynamic profile. You can configure a RADIUS authentication server to include this information in the Accept-Accept message when a subscriber successfully authenticates over the static or dynamic subscriber interface to which the access dynamic profile is attached.</p> <p><b>NOTE:</b> The drop profile must be configured statically (at the <b>[edit class-of-service schedulers scheduler-name drop-profiles]</b> hierarchy level).</p>
\$junos-cos-scheduler-dropfile-any	<p>Name of the drop profile for RED for loss-priority level <b>any</b> to be dynamically configured for the scheduler in the access dynamic profile. You can configure a RADIUS authentication server to include this information in the Accept-Accept message when a subscriber successfully authenticates over the static or dynamic subscriber interface to which the access dynamic profile is attached.</p> <p><b>NOTE:</b> The drop profile must be configured statically (at the <b>[edit class-of-service schedulers scheduler-name drop-profiles]</b> hierarchy level).</p>
