#### YEAR 2000 NOTICE

Juniper Networks hardware and software products are Year 2000 compliant. Junos OS has no known time-related limitations through the year 2038. However, the NTP application is known to have some difficulty in the year 2036.

#### END USER LICENSE AGREEMENT

The Juniper Networks product that is the subject of this technical documentation consists of (or is intended for use with) Juniper Networks software. Use of such software is subject to the terms and conditions of the End User License Agreement ("EULA") posted at <http://www.juniper.net/support/eula.html>. By downloading, installing or using such software, you agree to the terms and conditions of that EULA.

	Role of an Interior Gateway Protocol . . . . .	8
	Limitations of an Interior Gateway Protocol . . . . .	9
	Need for Spanning Link-State Distribution . . . . .	9
	Using BGP as a Solution . . . . .	10
	Overview . . . . .	10
	Implementation . . . . .	11
	Supported and Unsupported Features . . . . .	15
<b>Part 2</b>	<b>Configuring MPLS</b>	
<b>Chapter 2</b>	<b>MPLS Overview . . . . .</b>	<b>19</b>
	Introduction to MPLS . . . . .	20
	Supported MPLS Standards . . . . .	20
	Link-Layer Support in MPLS . . . . .	23
	MPLS and Traffic Engineering . . . . .	24

MPLS Label Overview .....	24
Special MPLS Labels .....	25
MPLS Label Allocation .....	26
Operations on MPLS Labels .....	27
Entropy Label Support in Mixed Mode Overview .....	28
Routers in an LSP .....	28
How a Packet Travels Along an LSP .....	28
Types of LSPs .....	29
Scope of LSPs .....	29
Constrained-Path LSP Computation .....	30
How CSPF Selects a Path .....	31
CSPF Path Selection Tie-Breaking .....	32
Computing CSPF Paths Offline .....	33
Path Computation for LSPs on an Overloaded Router .....	33
Computing Backup Paths for LSPs Using Fate Sharing .....	34
Using Labeled-Switched Paths to Augment SPF to Compute IGP Shortcuts . . .	34
Enabling IGP Shortcuts .....	36
LSPs Qualified in IGP Shortcut Computations .....	36
IGP Shortcut Applications .....	36
IGP Shortcuts and Routing Tables .....	37
IGP Shortcuts and VPNs .....	37
Advertising LSPs into IGP .....	38
IP and MPLS Packets on Aggregated Interfaces .....	39
MPLS Applications .....	39
BGP Destinations .....	40
IGP and BGP Destinations .....	41
Selecting a Forwarding LSP Next Hop .....	42
Example: Assigning Different Forwarding Next-Hop LSPs to Different Destination Prefixes .....	42
MPLS and Routing Tables .....	43
MPLS and Traffic Protection .....	45
Fast Reroute Overview .....	46
Detour Merging Process .....	48
Detour Computations .....	49
Fast Reroute Path Optimization .....	50
On-Demand Packet Loss and Delay Measurement for UHP LSPs Overview . . .	50
Importance of Measuring Packet Loss and Delay .....	50
Defining Packet Loss, Delay, and Throughput .....	51
Packet Loss and Delay Measurement Mechanisms .....	51
Packet Loss and Delay Metrics .....	52
Packet Loss and Delay Measurement Concepts .....	52
Packet Loss and Delay Measurement Functionality .....	55
Packet Loss and Delay Features .....	56

<b>Chapter 3</b>	<b>Configuring MPLS Routers</b>	<b>59</b>
	Configuring the Ingress Router for MPLS-Signaled LSPs	60
	Creating Named Paths	60
	Examples: Creating Named Paths	61
	Configuring Alternate Backup Paths Using Fate Sharing	62
	Configuring Fate Sharing	62
	Implications for CSPF	63
	Implications for CSPF When Fate Sharing with Bypass LSPs	64
	Example: Configuring Fate Sharing	64
	Example: Configuring an Explicit-Path LSP	64
	Example: Configuring a Constrained-Path LSP for Which Junos OS Makes All	
	Forwarding Decisions	65
	Example: Configuring a Constrained-Path LSP for Which Junos OS Makes Most	
	Forwarding Decisions and Considers Hop Constraints	66
	Example: Configuring a Constrained-Path LSP for Which Junos OS Makes Most	
	Forwarding Decisions and the Secondary Path Is Explicit	66
	Abstract Hops For MPLS LSPs Overview	67
	Understanding Abstract Hops	67
	Benefits of Using Abstract Hops	68
	Specifying a Sequence of Constraint Combinations	69
	Avoiding New Network Configuration on Transit Nodes	69
	Combining Centralized and Distributed Path Computation	
	Paradigms	69
	Junos Implementation of Abstract Hops	70
	Defining Abstract Hops	70
	Using Abstract Hops in Path Constraint	74
	Path Computation and Backtracking	77
	Sample Backtracking	77
	Improving Traffic Engineering Database Accuracy with RSVP PathErr	
	Messages	78
	PathErr Messages	79
	Identifying the Problem Link	80
	Configuring the Router to Improve Traffic Engineering Database	
	Accuracy	80
	Configuring MPLS-Signaled LSPs to Use GRE Tunnels	80
	Example: Configuring MPLS-Signaled LSPs to Use GRE Tunnels	81
	Example: Tunneling IPv6 Traffic over MPLS IPv4 Networks	82
	SRLG Overview	90
	Example: Configuring SRLG	92
	Example: Excluding SRLG Links Completely for the Secondary LSP	101
	Example: Configuring SRLG with Link Protection	106

Example: Configuring SRLG with Link Protection with the exclude-srlg Option . . . . .	127
Configuring the MPLS Transport Profile for OAM . . . . .	147
MPLS Transport Profile Overview . . . . .	147
Example: Configuring the MPLS Transport Profile for OAM . . . . .	147
Configuring MPLS Inter-AS Link-Node Protection with Labeled BGP . . . . .	160
Understanding MPLS Inter-AS Link Protection . . . . .	160
Example: Configuring MPLS Inter-AS Link-Node Protection . . . . .	162
Configuring Egress Protection Service Mirroring for BGP Signaled Layer 2 Services . . . . .	176
Example: Configuring MPLS Egress Protection Service Mirroring for BGP Signaled Layer 2 Services . . . . .	180
Example: Configuring Layer 3 VPN Egress Protection with PLR as Protector . . . . .	196
Example: Configuring Next-Hop-Based MPLS-Over-UDP Dynamic Tunnels . . . . .	222
Anti-spoofing Protection for Next-Hop-Based Dynamic Tunnels . . . . .	235
<b>Chapter 4 Configuring MPLS-Signaled LSPs . . . . .</b>	<b>239</b>
Configuring the Ingress and Egress Router Addresses for LSPs . . . . .	240
Configuring the Ingress Router Address for LSPs . . . . .	240
Configuring the Egress Router Address for LSPs . . . . .	240
Preventing the Addition of Egress Router Addresses to Routing Tables . . . . .	241
Configuring Primary and Secondary LSPs . . . . .	242
Configuring Primary and Secondary Paths for an LSP . . . . .	242
Configuring the Revert Timer for LSPs . . . . .	243
Specifying the Conditions for Path Selection . . . . .	244
Configuring a Text Description for LSPs . . . . .	245
Configuring the Entropy Label for LSPs . . . . .	246
Configuring Corouted Bidirectional LSPs . . . . .	248
Configuring Ultimate-Hop Popping for LSPs . . . . .	250
Configuring an LSP Across ASs . . . . .	253
Configuring Fast Reroute . . . . .	254
Configuring the Optimization Interval for Fast Reroute Paths . . . . .	256
Adding LSP-Related Routes to the inet.3 or inet6.3 Routing Table . . . . .	256
Configuring the Connection Between Ingress and Egress Routers . . . . .	257
Configuring LSP Metrics . . . . .	258
Configuring Dynamic LSP Metrics . . . . .	258
Configuring Static LSP Metrics . . . . .	259
Configuring CSPF Tie Breaking . . . . .	260
Configuring Load Balancing Based on MPLS Labels . . . . .	260
Disabling Normal TTL Decrementing . . . . .	264
Configuring MPLS Soft Preemption . . . . .	266
Disabling Constrained-Path LSP Computation . . . . .	267
Configuring Administrative Groups for LSPs . . . . .	268
Configuring Extended Administrative Groups for LSPs . . . . .	270
Configuring Preference Values for LSPs . . . . .	271
Disabling Path Route Recording by LSPs . . . . .	272
Configuring Class of Service for MPLS LSPs . . . . .	272
Class of Service for MPLS Overview . . . . .	272
Configuring the MPLS CoS Values . . . . .	273

Rewriting IEEE 802.1p Packet Headers with the MPLS CoS Value . . . . .	275
Achieving a Make-Before-Break, Hitless Switchover for LSPs . . . . .	275
Specifying the Amount of Time the Router Waits to Switch Over to New Paths . . . . .	277
Specifying the Amount of Time to Delay the Tear Down of Old Paths . . . . .	277
Achieving a Hitless, MBB Switchover Without Artificial Delays . . . . .	277
Configuring Adaptive LSPs . . . . .	278
Configuring Priority and Preemption for LSPs . . . . .	280
Optimizing Signaled LSPs . . . . .	280
Configuring the Smart Optimize Timer for LSPs . . . . .	284
Limiting the Number of Hops in LSPs . . . . .	285
Configuring the Bandwidth Value for LSPs . . . . .	285
Automatic Bandwidth Allocation for LSPs . . . . .	286
Configuring Automatic Bandwidth Allocation for LSPs . . . . .	286
Configuring Automatic Bandwidth Allocation on LSPs . . . . .	287
Configuring the Automatic Bandwidth Allocation Interval . . . . .	288
Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth . . . . .	289
Configuring the Automatic Bandwidth Adjustment Threshold . . . . .	289
Configuring a Limit on Bandwidth Overflow and Underflow Samples . . . . .	290
Configuring Passive Bandwidth Utilization Monitoring . . . . .	292
Requesting Automatic Bandwidth Allocation Adjustment . . . . .	292
Configuring Reporting of Automatic Bandwidth Allocation Statistics for LSPs . . . . .	293
Configuring Hot Standby of Secondary Paths for LSPs . . . . .	297
Damping Advertisement of LSP State Changes . . . . .	298
<b>Chapter 5</b>	
<b>Configuring Static and Explicit-Path LSPs . . . . .</b>	<b>299</b>
Configuring Static LSPs . . . . .	299
Configuring the Ingress Router for Static LSPs . . . . .	299
Example: Configuring the Ingress Router . . . . .	301
Configuring the Intermediate (Transit) and Egress Routers for Static LSPs . . . . .	302
Example: Configuring an Intermediate Router . . . . .	303
Example: Configuring an Egress Router . . . . .	304
Configuring a Bypass LSP for the Static LSP . . . . .	304
Configuring the Protection Revert Timer for Static LSPs . . . . .	305
Configuring Static Unicast Routes for Point-to-Multipoint LSPs . . . . .	305
Configuring Explicit-Path LSPs . . . . .	306

<b>Chapter 6</b>	<b>Configuring Point-to-Multipoint LSPs . . . . .</b>	<b>309</b>
	Point-to-Multipoint LSPs Overview . . . . .	309
	Configuring Primary and Branch LSPs for Point-to-Multipoint LSPs . . . . .	311
	Configuring the Primary Point-to-Multipoint LSP . . . . .	311
	Configuring a Branch LSP for Point-to-Multipoint LSPs . . . . .	311
	Configuring the Branch LSP as a Dynamic Path . . . . .	312
	Configuring the Branch LSP as a Static Path . . . . .	312
	Example: Configuring a Collection of Paths to Create an RSVP-Signaled Point-to-Multipoint LSP . . . . .	313
	Configuring Inter-Domain Point-to-Multipoint LSPs . . . . .	331
	Configuring Link Protection for Point-to-Multipoint LSPs . . . . .	332
	Configuring Graceful Restart for Point-to-Multipoint LSPs . . . . .	333
	Configuring a Multicast RPF Check Policy for Point-to-Multipoint LSPs . . . . .	334
	Example: Configuring Multicast RPF Check Policy for a Point-to-Multipoint LSP . . . . .	334
	Configuring Ingress PE Router Redundancy for Point-to-Multipoint LSPs . . . . .	335
	Enabling Point-to-Point LSPs to Monitor Egress PE Routers . . . . .	335
	Preserving Point-to-Multipoint LSP Functioning with Different Junos OS Releases . . . . .	336
<b>Chapter 7</b>	<b>Configuring DiffServ-Aware Traffic Engineering to Achieve Service Level Guarantees on an MPLS network . . . . .</b>	<b>337</b>
	DiffServ-Aware Traffic Engineering Introduction . . . . .	338
	DiffServ-Aware Traffic Engineering Standards . . . . .	338
	DiffServ-Aware Traffic Engineering Terminology . . . . .	338
	DiffServ-Aware Traffic Engineering Features . . . . .	339
	DiffServ-Aware Traffic Engineered LSPs . . . . .	340
	DiffServ-Aware Traffic Engineered LSPs Overview . . . . .	340
	DiffServ-Aware Traffic Engineered LSPs Operation . . . . .	341
	Multiclass LSPs . . . . .	341
	Multiclass LSP Overview . . . . .	342
	Establishing a Multiclass LSP on the Differentiated Services Domain . . . . .	342
	Configuring Routers for DiffServ-Aware Traffic Engineering . . . . .	343
	Configuring the Bandwidth Model . . . . .	344
	Configuring Traffic Engineering Classes . . . . .	345
	Requirements and Limitations for the Traffic Engineering Class Matrix . . . . .	346
	Configuring Class of Service for DiffServ-Aware Traffic Engineering . . . . .	346
	LSP Bandwidth Oversubscription Overview . . . . .	347
	LSP Size Oversubscription . . . . .	348
	LSP Link Size Oversubscription . . . . .	348
	Class Type Oversubscription and Local Oversubscription Multipliers . . . . .	348
	Class Type Bandwidth and the LOM . . . . .	349
	LOM Calculation for the MAM and Extended MAM Bandwidth Models . . . . .	349
	LOM Calculation for the Russian Dolls Bandwidth Model . . . . .	350
	Example: LOM Calculation . . . . .	350
	Configuring the Bandwidth Subscription Percentage for LSPs . . . . .	351
	Constraints on Configuring Bandwidth Subscription . . . . .	352

	Configuring LSPs for DiffServ-Aware Traffic Engineering . . . . .	353
	Configuring Class of Service for the Interfaces . . . . .	354
	Configuring IGP . . . . .	354
	Configuring Traffic-Engineered LSPs . . . . .	354
	Configuring Policing for LSPs . . . . .	355
	Configuring Fast Reroute for Traffic-Engineered LSPs . . . . .	355
	Configuring Multiclass LSPs . . . . .	356
	Configuring Class of Service for the Interfaces . . . . .	356
	Configuring the IGP . . . . .	357
	Configuring Class-Type Bandwidth Constraints for Multiclass LSPs . . . . .	357
	Configuring Policing for Multiclass LSPs . . . . .	358
	Configuring Fast Reroute for Multiclass LSPs . . . . .	358
<b>Chapter 8</b>	<b>Configuring Miscellaneous MPLS Properties . . . . .</b>	<b>361</b>
	Configuring the Maximum Number of MPLS Labels . . . . .	362
	Configuring MPLS to Pop the Label on the Ultimate-Hop Router . . . . .	363
	Advertising Explicit Null Labels to BGP Peers . . . . .	364
	Configuring Traffic Engineering for LSPs . . . . .	365
	Using LSPs for Both BGP and IGP Traffic Forwarding . . . . .	365
	Using LSPs for Forwarding in Virtual Private Networks . . . . .	366
	Using RSVP and LDP Routes for Forwarding but Not Route Selection . . . . .	366
	Advertising the LSP Metric in Summary LSAs . . . . .	367
	Enabling Interarea Traffic Engineering . . . . .	367
	Enabling Inter-AS Traffic Engineering for LSPs . . . . .	368
	Inter-AS Traffic Engineering Requirements . . . . .	369
	Inter-AS Traffic Engineering Limitations . . . . .	369
	Configuring OSPF Passive TE Mode . . . . .	370
	Configuring MPLS to Gather Statistics . . . . .	371
	Configuring System Log Messages and SNMP Traps for LSPs . . . . .	372
	Configuring MPLS Firewall Filters and Policers . . . . .	373
	Configuring MPLS Firewall Filters . . . . .	373
	Examples: Configuring MPLS Firewall Filters . . . . .	374
	Configuring Policers for LSPs . . . . .	375
	LSP Policer Limitations . . . . .	376
	Example: Configuring an LSP Policer . . . . .	377
	Configuring Automatic Policers . . . . .	377
	Configuring Automatic Policers for LSPs . . . . .	378
	Configuring Automatic Policers for DiffServ-Aware Traffic Engineering LSPs . . . . .	379
	Configuring Automatic Policers for Point-to-Multipoint LSPs . . . . .	379
	Disabling Automatic Policing on an LSP . . . . .	380
	Example: Configuring Automatic Policing for an LSP . . . . .	380
	Writing Different DSCP and EXP Values in MPLS-Tagged IP Packets . . . . .	381
	Configuring MPLS Rewrite Rules . . . . .	381
	Rewriting the EXP Bits of All Three Labels of an Outgoing Packet . . . . .	381
	Rewriting MPLS and IPv4 Packet Headers . . . . .	382

Configuring BFD for MPLS IPv4 LSPs .....	382
Configuring BFD for RSVP-Signaled LSPs .....	383
Configuring a Failure Action for the BFD Session on an RSVP LSP .....	384
BFD-Triggered Local Repair for Rapid Convergence .....	385
Understanding BFD-Triggered Local Protection .....	385
Purpose of BFD-Triggered Local Repair .....	386
Configuring BFD-Triggered Local Repair .....	387
Disabling BFD-Triggered Local Repair .....	387
Disabling BFD-Triggered Local Repair .....	387
Pinging LSPs .....	388
Pinging MPLS LSPs .....	388
Pinging Point-to-Multipoint LSPs .....	388
Pinging the Endpoint Address of MPLS LSPs .....	389
Pinging CCC LSPs .....	389
Pinging Layer 3 VPNs .....	389
Support for LSP Ping and Traceroute Commands Based on RFC 4379 .....	389
Tracing MPLS and LSP Packets and Operations .....	389
Configuring Link State Distribution Using BGP .....	390
Example: Configuring Link State Distribution Using BGP .....	393
Dynamic Bandwidth Management Using Container LSP Overview .....	410
Understanding RSVP Multipath Extensions .....	410
Junos OS RSVP Multipath Implementation .....	411
Current Traffic Engineering Challenges .....	411
Using Container LSP as a Solution .....	414
Accommodating the New Demand X .....	415
Creating New LSPs to Meet Demand X .....	415
Assigning Bandwidth to the New LSPs .....	415
Controlling the LSP Paths .....	415
Junos OS Container LSP Implementation .....	416
Container LSP Terminology .....	416
LSP Splitting .....	417
LSP Merging .....	419
Node and Link Protection .....	421
Naming Convention .....	421
Normalization .....	422
Constraint-Based Routing Path Computation .....	427
Sampling .....	428
Support for NSR, IPG-FA, and Static Routes .....	428
Configuration Statements Supported for Container LSPs .....	431
Impact of Configuring Container LSPs on Network Performance .....	435
Supported and Unsupported Features .....	436
Configuring Dynamic Bandwidth Management Using Container LSP .....	437
Example: Configuring Dynamic Bandwidth Management Using Container LSP .....	441
Configuring On-Demand Loss and Delay Measurement .....	466
Example: Configuring On-Demand Loss and Delay Measurement .....	467
Configuring Pro-Active Loss and Delay Measurements .....	476

	Example: Configuring Pro-active Loss and Delay Measurements for Bidirectional MPLS LSPs . . . . .	478
	MPLS Encapsulated Payload Load-balancing Overview . . . . .	485
	Configuring MPLS Encapsulated Payload for Load Balancing . . . . .	486
<b>Part 3</b>	<b>Configuring RSVP</b>	
<b>Chapter 9</b>	<b>RSVP Overview . . . . .</b>	<b>489</b>
	RSVP Overview . . . . .	489
	Supported RSVP Standards . . . . .	490
	Junos OS RSVP Protocol Implementation . . . . .	491
	RSVP Operation Overview . . . . .	492
	RSVP Authentication . . . . .	492
	RSVP and IGP Hello Packets and Timers . . . . .	492
	RSVP Message Types . . . . .	493
	Understanding RSVP Automatic Mesh . . . . .	493
	Path Messages . . . . .	495
	Resv Messages . . . . .	495
	PathTear Messages . . . . .	495
	ResvTear Messages . . . . .	495
	PathErr Messages . . . . .	496
	ResvErr Messages . . . . .	496
	ResvConfirm Messages . . . . .	496
	RSVP Reservation Styles . . . . .	496
	RSVP Refresh Reduction . . . . .	497
	MTU Signaling in RSVP . . . . .	498
	How the Correct MTU Is Signaled in RSVP . . . . .	499
	Determining an Outgoing MTU Value . . . . .	500
	MTU Signaling in RSVP Limitations . . . . .	500
<b>Chapter 10</b>	<b>Configuring RSVP . . . . .</b>	<b>501</b>
	Minimum RSVP Configuration . . . . .	501
	Configuring RSVP and MPLS . . . . .	502
	Example: Configuring RSVP and MPLS . . . . .	502
	Configuring RSVP Interfaces . . . . .	503
	Configuring RSVP Refresh Reduction . . . . .	503
	Determining the Refresh Reduction Capability of RSVP Neighbors . . . . .	505
	Configuring the RSVP Hello Interval . . . . .	505
	Configuring RSVP Authentication . . . . .	506
	Configuring the Bandwidth Subscription for Class Types . . . . .	506
	Configuring the RSVP Update Threshold on an Interface . . . . .	506
	Configuring RSVP for Unnumbered Interfaces . . . . .	507
	Configuring RSVP Node-ID Hellos . . . . .	508
	Example: Configuring RSVP Automatic Mesh . . . . .	509
	Configuring Hello Acknowledgments for Nonsession RSVP Neighbors . . . . .	512
	Switching LSPs Away from a Network Node . . . . .	513
	Configuring RSVP Setup Protection . . . . .	514
	Configuring Load Balancing Across RSVP LSPs . . . . .	514
	Configuring RSVP Automatic Mesh . . . . .	515
	Configuring Timers for RSVP Refresh Messages . . . . .	516

	Preempting RSVP Sessions . . . . .	517
	Configuring MTU Signaling in RSVP . . . . .	518
	Enabling MTU Signaling in RSVP . . . . .	518
	Enabling Packet Fragmentation . . . . .	519
	Configuring Ultimate-Hop Popping for LSPs . . . . .	519
	Configuring RSVP to Pop the Label on the Ultimate-Hop Router . . . . .	523
	Enabling Ultimate-Hop Popping on Point-to-Multipoint LSPs . . . . .	523
	Tracing RSVP Protocol Traffic . . . . .	524
	Examples: Tracing RSVP Protocol Traffic . . . . .	525
	show rsvp route-session-id . . . . .	528
<b>Chapter 11</b>	<b>Configuring RSVP Link Protection and Node Protection to Protect from Traffic Failures . . . . .</b>	<b>529</b>
	Link Protection . . . . .	529
	Multiple Bypass LSPs for Link Protection . . . . .	530
	Node Protection . . . . .	531
	Fast Reroute, Node Protection, and Link Protection . . . . .	532
	LSP Protection Overview . . . . .	532
	LSP Protection Types Comparison . . . . .	533
	One-to-One Backup Implementation . . . . .	533
	Facility Backup Implementation . . . . .	534
	Configuring Link Protection on Interfaces Used by LSPs . . . . .	536
	Configuring Bypass LSPs . . . . .	537
	Configuring the Next-Hop or Next-Next-Hop Node Address for Bypass LSPs . . . . .	538
	Configuring Administrative Groups for Bypass LSPs . . . . .	538
	Configuring the Bandwidth for Bypass LSPs . . . . .	538
	Configuring Class of Service for Bypass LSPs . . . . .	539
	Configuring the Hop Limit for Bypass LSPs . . . . .	539
	Configuring the Maximum Number of Bypass LSPs . . . . .	540
	Disabling CSPF for Bypass LSPs . . . . .	540
	Disabling Node Protection for Bypass LSPs . . . . .	541
	Configuring the Optimization Interval for Bypass LSPs . . . . .	541
	Configuring an Explicit Path for Bypass LSPs . . . . .	542
	Configuring the Amount of Bandwidth Subscribed for Bypass LSPs . . . . .	542
	Configuring Priority and Preemption for Bypass LSPs . . . . .	543
	Configuring Node Protection or Link Protection for LSPs . . . . .	543
	Configuring Inter-AS Node and Link Protection . . . . .	544
<b>Chapter 12</b>	<b>Configuring RSVP Graceful Restart for High Availability . . . . .</b>	<b>545</b>
	RSVP Graceful Restart . . . . .	545
	RSVP Graceful Restart Standard . . . . .	545
	RSVP Graceful Restart Terminology . . . . .	546
	RSVP Graceful Restart Operation . . . . .	546
	Processing the Restart Cap Object . . . . .	547
	Configuring RSVP Graceful Restart . . . . .	548
	Enabling Graceful Restart for All Routing Protocols . . . . .	548
	Disabling Graceful Restart for RSVP . . . . .	548
	Disabling RSVP Helper Mode . . . . .	549
	Configuring the Maximum Helper Recovery Time . . . . .	549

	Configuring the Maximum Helper Restart Time . . . . .	549
<b>Chapter 13</b>	<b>Configuring RSVP LSP Tunnels . . . . .</b>	<b>551</b>
	RSVP LSP Tunnels Overview . . . . .	551
	Example: RSVP LSP Tunnel Configuration . . . . .	553
	Verifying Your Work . . . . .	565
	Router 0 . . . . .	565
	Router 1 . . . . .	569
	Configuring Link Management Protocol Peers . . . . .	571
	Configuring Link Management Protocol Traffic Engineering Links . . . . .	571
	Configuring Peer Interfaces in OSPF and RSVP . . . . .	572
	Defining Label-Switched Paths for the FA-LSP . . . . .	572
	Establishing FA-LSP Path Information . . . . .	573
	Option: Tearing Down RSVP LSPs Gracefully . . . . .	573
<b>Part 4</b>	<b>Configuring LDP</b>	
<b>Chapter 14</b>	<b>LDP Overview . . . . .</b>	<b>577</b>
	LDP Introduction . . . . .	577
	Supported LDP Standards . . . . .	578
	Junos OS LDP Protocol Implementation . . . . .	578
	LDP Operation . . . . .	579
	LDP Message Types . . . . .	579
	Discovery Messages . . . . .	579
	Session Messages . . . . .	580
	Advertisement Messages . . . . .	580
	Notification Messages . . . . .	580
	Discovery Messages . . . . .	580
	Session Messages . . . . .	581
	Advertisement Messages . . . . .	581
	Notification Messages . . . . .	581
	Tunneling LDP LSPs in RSVP LSPs . . . . .	582
	Tunneling LDP LSPs in RSVP LSPs Overview . . . . .	582
	Label Operations . . . . .	583
	LDP Session Protection . . . . .	584
	LDP Native IPv6 Support Overview . . . . .	585
	Longest Match Support for LDP Overview . . . . .	585
<b>Chapter 15</b>	<b>Configuring LDP . . . . .</b>	<b>587</b>
	Minimum LDP Configuration . . . . .	588
	Enabling and Disabling LDP . . . . .	588
	Configuring the LDP Timer for Hello Messages . . . . .	589
	Configuring the LDP Timer for Link Hello Messages . . . . .	589
	Configuring the LDP Timer for Targeted Hello Messages . . . . .	589
	Configuring the Delay Before LDP Neighbors Are Considered Down . . . . .	589
	Configuring the LDP Hold Time for Link Hello Messages . . . . .	590
	Configuring the LDP Hold Time for Targeted Hello Messages . . . . .	591
	Enabling Strict Targeted Hello Messages for LDP . . . . .	591
	Configuring the Interval for LDP Keepalive Messages . . . . .	591

Configuring the LDP Keepalive Timeout . . . . .	592
Configuring Longest Match for LDP . . . . .	592
Example: Configuring Longest Match for LDP . . . . .	593
Configuring LDP Route Preferences . . . . .	609
LDP Graceful Restart . . . . .	609
Configuring LDP Graceful Restart . . . . .	610
Enabling Graceful Restart . . . . .	610
Disabling LDP Graceful Restart or Helper Mode . . . . .	611
Configuring Reconnect Time . . . . .	612
Configuring Recovery Time and Maximum Recovery Time . . . . .	612
Filtering Inbound LDP Label Bindings . . . . .	613
Examples: Filtering Inbound LDP Label Bindings . . . . .	614
Filtering Outbound LDP Label Bindings . . . . .	615
Examples: Filtering Outbound LDP Label Bindings . . . . .	616
Specifying the Transport Address Used by LDP . . . . .	617
Configuring the Prefixes Advertised into LDP from the Routing Table . . . . .	617
Example: Configuring the Prefixes Advertised into LDP . . . . .	618
Configuring FEC Deaggregation . . . . .	618
Configuring Policers for LDP FECs . . . . .	619
Configuring LDP IPv4 FEC Filtering . . . . .	620
Configuring BFD for LDP LSPs . . . . .	620
Configuring ECMP-Aware BFD for LDP LSPs . . . . .	623
Configuring a Failure Action for the BFD Session on an LDP LSP . . . . .	624
Configuring the Holddown Interval for the BFD Session . . . . .	625
Configuring OAM Ingress Policies for LDP . . . . .	625
Configuring LDP Link Protection . . . . .	625
Example: Configuring LDP Link Protection . . . . .	627
LDP Link Protection Overview . . . . .	627
Introduction to LDP . . . . .	627
Junos OS LDP Protocol Implementation . . . . .	628
Understanding Multipoint Extensions to LDP . . . . .	628
Using Multipoint Extensions to LDP on Targeted LDP Sessions . . . . .	628
Current Limitations of LDP Link Protection . . . . .	629
Using RSVP LSP as a Solution . . . . .	630
Understanding Multicast LDP Link Protection . . . . .	632
Different Modes for Providing LDP Link Protection . . . . .	633
Label Operation for LDP Link Protection . . . . .	635
Sample Multicast LDP Link Protection Configuration . . . . .	641
Make-Before-Break . . . . .	642
Caveats and Limitations . . . . .	644
Understanding Multicast-Only Fast Reroute . . . . .	644
PIM Functionality . . . . .	647
Multipoint LDP Functionality . . . . .	648
Packet Forwarding . . . . .	649
Limitations and Caveats . . . . .	650
Configuring Multicast-Only Fast Reroute . . . . .	651
Example: Configuring Multicast-Only Fast Reroute in a Multipoint LDP Domain . . . . .	654
Example: Configuring LDP Downstream on Demand . . . . .	670

Configuring LDP Native IPv6 Support . . . . .	675
Example: Configuring LDP Native IPv6 Support . . . . .	676
Example: Configuring Multipoint LDP In-Band Signaling for Point-to-Multipoint LSPs . . . . .	691
Understanding Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs . . . . .	692
How M-LDP Works . . . . .	693
Terminology . . . . .	697
Ingress Join Translation and Pseudo Interface Handling . . . . .	698
Ingress Splicing . . . . .	698
Reverse Path Forwarding . . . . .	698
LSP Root Detection . . . . .	698
Egress Join Translation and Pseudo Interface Handling . . . . .	699
Egress Splicing . . . . .	699
Supported Functionality . . . . .	699
Unsupported Functionality . . . . .	700
LDP Functionality . . . . .	700
Egress LER Functionality . . . . .	700
Transit LSR Functionality . . . . .	701
Ingress LER Functionality . . . . .	701
Example: Configuring Multipoint LDP In-Band Signaling for Point-to-Multipoint LSPs . . . . .	701
Configuring Miscellaneous LDP Properties . . . . .	722
Configuring LDP to Use the IGP Route Metric . . . . .	723
Preventing Addition of Ingress Routes to the inet.0 Routing Table . . . . .	723
Multiple-Instance LDP and Carrier-of-Carriers VPNs . . . . .	723
Configuring MPLS and LDP to Pop the Label on the Ultimate-Hop Router . . . . .	724
Enabling LDP over RSVP-Established LSPs . . . . .	724
Enabling LDP over RSVP-Established LSPs in Heterogeneous Networks . . . . .	724
Configuring the TCP MD5 Signature for LDP Sessions . . . . .	725
Configuring LDP Session Protection . . . . .	726
Disabling SNMP Traps for LDP . . . . .	727
Configuring LDP Synchronization with the IGP on LDP Links . . . . .	727
Configuring LDP Synchronization with the IGP on the Router . . . . .	728
Configuring the Label Withdrawal Timer . . . . .	728
Ignoring the LDP Subnet Check . . . . .	728
Configuring LDP LSP Traceroute . . . . .	729
Collecting LDP Statistics . . . . .	730
LDP Statistics Output . . . . .	730
Disabling LDP Statistics on the Penultimate-Hop Router . . . . .	731
LDP Statistics Limitations . . . . .	732
Tracing LDP Protocol Traffic . . . . .	732
Tracing LDP Protocol Traffic at the Protocol and Routing Instance Levels . . . . .	732
Tracing LDP Protocol Traffic Within FECs . . . . .	733
Examples: Tracing LDP Protocol Traffic . . . . .	734

<b>Part 5</b>	<b>Configuring Circuit Cross-Connect (CCC) and Translational Cross-Connect (TCC)</b>	
<b>Chapter 16</b>	<b>CCC and TCC Overview</b>	<b>739</b>
	CCC Overview	739
	Transmitting Nonstandard BPDUs	740
	TCC Overview	740
<b>Chapter 17</b>	<b>Configuring CCC and TCC</b>	<b>743</b>
	Configuring Layer 2 Switching Cross-Connects Using CCC	743
	Configuring the CCC Encapsulation for Layer 2 Switching	
	Cross-Connects	744
	Configuring ATM Encapsulation for Layer 2 Switching	
	Cross-Connects	744
	Configuring Ethernet Encapsulation for Layer 2 Switching	
	Cross-Connects	745
	Configuring Ethernet VLAN Encapsulation for Layer 2 Switching	
	Cross-Connects	745
	Configuring Aggregated Ethernet Encapsulation for Layer 2 Switching	
	Cross-Connects	746
	Configuring Frame Relay Encapsulation for Layer 2 Switching	
	Cross-Connects	747
	Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching	
	Cross-Connects	748
	Configuring the CCC Connection for Layer 2 Switching Cross-Connects	748
	Configuring MPLS for Layer 2 Switching Cross-Connects	748
	Example: Configuring a Layer 2 Switching Cross-Connect	749
	Configuring MPLS LSP Tunnel Cross-Connects Using CCC	751
	Configuring the CCC Encapsulation for LSP Tunnel Cross-Connects	752
	Configuring the CCC Connection for LSP Tunnel Cross-Connects	753
	Example: Configuring an LSP Tunnel Cross-Connect	754
	Configuring TCC	755
	Configuring the Encapsulation for Layer 2 Switching TCCs	755
	Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching	
	TCCs	756
	Configuring ATM Encapsulation for Layer 2 Switching TCCs	756
	Configuring Frame Relay Encapsulation for Layer 2 Switching TCCs	756
	Configuring Ethernet Encapsulation for Layer 2 Switching TCCs	757
	Configuring Ethernet Extended VLAN Encapsulation for Layer 2	
	Switching TCCs	757
	Configuring ARP for Ethernet and Ethernet Extended VLAN	
	Encapsulations	758
	Configuring the Connection for Layer 2 Switching TCCs	759
	Configuring MPLS for Layer 2 Switching TCCs	759
	CCC and TCC Graceful Restart	760
	Configuring CCC and TCC Graceful Restart	761
	Configuring CCC Switching for Point-to-Multipoint LSPs	761
	Configuring the Point-to-Multipoint LSP Switch on Ingress PE Routers	762
	Configuring Local Receivers on a Point-to-Multipoint CCC LSP Switch on	
	Ingress PE Routers	762

	Configuring the Point-to-Multipoint LSP Switch on Egress PE Routers . . .	763
<b>Part 6</b>	<b>Configuring GMPLS</b>	
<b>Chapter 18</b>	<b>GMPLS Overview . . . . .</b>	<b>767</b>
	Introduction to GMPLS . . . . .	767
	GMPLS Terms and Acronyms . . . . .	768
	Supported GMPLS Standards . . . . .	769
	GMPLS Operation . . . . .	770
	GMPLS and OSPF . . . . .	771
	GMPLS and CSPF . . . . .	771
	GMPLS Features . . . . .	772
<b>Chapter 19</b>	<b>Configuring GMPLS . . . . .</b>	<b>773</b>
	LMP Configuration Overview . . . . .	773
	Configuring LMP Traffic Engineering Links . . . . .	774
	Configuring the Local IP Address for Traffic Engineering Links . . . . .	775
	Configuring the Remote IP Address for Traffic Engineering Links . . . . .	775
	Configuring the Remote ID for Traffic Engineering Links . . . . .	776
	Configuring LMP Peers . . . . .	776
	Configuring the ID for LMP Peers . . . . .	777
	Configuring the Interface for Control Channels Between LMP Peers . . . . .	777
	Configuring the LMP Control Channel Interface for the Peer . . . . .	777
	Configuring the Remote IP Address for LMP Control Channels . . . . .	778
	Configuring Hello Message Intervals for LMP Control Channels . . . . .	779
	Controlling Message Exchange for LMP Control Channels . . . . .	780
	Preventing the Local Peer from Initiating LMP Negotiation . . . . .	780
	Associating Traffic Engineering Links with LMP Peers . . . . .	780
	Disabling the Traffic Engineering Link for LMP Peers . . . . .	781
	Configuring RSVP and OSPF for LMP Peer Interfaces . . . . .	781
	Configuring RSVP Signaling for LMP Peer Interfaces . . . . .	781
	Configuring OSPF Routing for LMP Peer Interfaces . . . . .	782
	Configuring the Hello Interval for LMP Peer Interfaces . . . . .	782
	Configuring MPLS Paths for GMPLS . . . . .	782
	Tracing LMP Traffic . . . . .	783
	Configuring MPLS LSPs for GMPLS . . . . .	784
	Configuring the Encoding Type . . . . .	784
	Configuring the GPID . . . . .	785
	Configuring the Signal Bandwidth Type . . . . .	785
	Configuring GMPLS Bidirectional LSPs . . . . .	785
	Allowing Nonpacket GMPLS LSPs to Establish Paths Through Routers	
	Running Junos OS . . . . .	786
	Gracefully Tearing Down GMPLS LSPs . . . . .	786
	Temporarily Deleting GMPLS LSPs . . . . .	786
	Permanently Deleting GMPLS LSPs . . . . .	787
	Configuring the Graceful Deletion Timeout Interval . . . . .	787
	GMPLS RSVP-TE VLAN LSP Signaling Overview . . . . .	788
	Understanding GMPLS RSVP-TE Signaling . . . . .	788
	Need for GMPLS RSVP-TE VLAN LSP Signaling . . . . .	788
	GMPLS RSVP-TE VLAN LSP Signaling Functionality . . . . .	790

	LSP Hierarchy with GMPLS RSVP-TE VLAN LSP . . . . .	791
	Path Specification for GMPLS RSVP-TE VLAN LSP . . . . .	791
	GMPLS RSVP-TE VLAN LSP Configuration . . . . .	791
	Associated Bidirectional Packet LSP . . . . .	792
	Make-Before-Break for Associated Bidirectional Packet and GMPLS RSVP-TE VLAN LSP . . . . .	793
	Supported and Unsupported Features . . . . .	794
	Example: Configuring GMPLS RSVP-TE VLAN LSP Signaling . . . . .	794
<b>Chapter 20</b>	<b>Using a Hierarchy of RSVP LSPs to Tunnel Multiple RSVP LSPs over a Single RSVP LSP . . . . .</b>	<b>819</b>
	Hierarchy of RSVP LSPs Overview . . . . .	819
	Hierarchy of RSVP LSPs Terminology . . . . .	819
	Hierarchy of RSVP LSPs Standard . . . . .	820

	Verify Router Connection . . . . .	959
	Verify Interfaces . . . . .	959
	Take Appropriate Action . . . . .	960
	Verify the LSP Again . . . . .	961

Verify the LSP . . . . .	962
Verify Router Connection . . . . .	964
Verify Interfaces . . . . .	964
Take Appropriate Action . . . . .	965
Verify the LSP Again . . . . .	966
Checklist for Checking the Data Link Layer . . . . .	967
Checking the Data Link Layer . . . . .	968
Verify the LSP . . . . .	969
Verify Interfaces . . . . .	970
Take Appropriate Action . . . . .	974
Verify the LSP Again . . . . .	975
Verify the LSP . . . . .	978
Verify Interfaces . . . . .	979
Take Appropriate Action . . . . .	982
Verify the LSP Again . . . . .	983
Checklist for Verifying the IP and IGP Layers . . . . .	986
Verifying the IP and IGP Layers . . . . .	988
Verifying the IP Layer . . . . .	990
Verify the LSP . . . . .	991
Verify IP Addressing . . . . .	992
Verify Neighbors or Adjacencies at the IP Layer . . . . .	993
Take Appropriate Action . . . . .	996
Verify the LSP Again . . . . .	997
Verify the LSP . . . . .	1000
Verify IP Addressing . . . . .	1001
Verify Neighbors or Adjacencies at the IP Layer . . . . .	1002
Take Appropriate Action . . . . .	1005
Verify the LSP Again . . . . .	1006
Verifying the OSPF Protocol . . . . .	1009
Verify the LSP . . . . .	1010
Verify OSPF Interfaces . . . . .	1012
Verify OSPF Neighbors . . . . .	1014
Verify the OSPF Protocol Configuration . . . . .	1014
Take Appropriate Action . . . . .	1015
Verify the LSP Again . . . . .	1017
Verify the LSP . . . . .	1020
Verify OSPF Interfaces . . . . .	1023
Verify OSPF Neighbors . . . . .	1024
Verify the LSP Again . . . . .	1025
Verify the LSP . . . . .	1027
Verify IS-IS Adjacencies and Interfaces . . . . .	1028
Verify the IS-IS Configuration . . . . .	1030
Verify the LSP Again . . . . .	1031
Checklist for Checking the RSVP Layer . . . . .	1033
Checking the RSVP Layer . . . . .	1034
Verify the LSP . . . . .	1036
Verify RSVP Sessions . . . . .	1038
Verify RSVP Neighbors . . . . .	1039
Verify RSVP Interfaces . . . . .	1040

Verify the RSVP Protocol Configuration . . . . .	1042
Take Appropriate Action . . . . .	1043
Verify the LSP Again . . . . .	1044
Verify the LSP . . . . .	1046
Verify RSVP Sessions . . . . .	1048
Verify RSVP Neighbors . . . . .	1049
Verify RSVP Interfaces . . . . .	1050
Verify the RSVP Protocol Configuration . . . . .	1052
Take Appropriate Action . . . . .	1052
Verify the LSP Again . . . . .	1053
Checklist for Determining LSP Status . . . . .	1056
Determining LSP Statistics . . . . .	1056
Checklist for Verifying LSP Use . . . . .	1058
Verifying LSP Use in Your Network . . . . .	1058
Verifying an LSP on the Ingress Router . . . . .	1059
Verifying an LSP on a Transit Router . . . . .	1060
Verifying an LSP on the Ingress Router . . . . .	1062
Verifying an LSP on a Transit Router . . . . .	1063
Verify That Load Balancing Is Working . . . . .	1064
Example: Load-Balanced MPLS Network . . . . .	1067
Router Configurations for the Load-Balanced MPLS Network . . . . .	1068
Traffic Flows Before Load Balancing . . . . .	1080
Verify the Operation of Uneven Bandwidth Load Balancing . . . . .	1082
Checklist for Collecting Crash Data . . . . .	1084
Understand Crash Data Collection . . . . .	1085
Collect Crash Data for a Routing Engine Kernel . . . . .	1086
Check the Routing Engine Core Files . . . . .	1086
List the Core Files . . . . .	1087
Compress the vmcore File . . . . .	1087
Log Software Version Information . . . . .	1088
Open a Case with JTAC . . . . .	1089
Check the Routing Engine Core Files . . . . .	1089
List the Core Files . . . . .	1089
Compress the vmcore File . . . . .	1090
Log Software Version Information . . . . .	1090
Open a Case with JTAC . . . . .	1091
Collect Crash Data for Routing Engine Daemons . . . . .	1091
Check for Daemon Core Files . . . . .	1091
List the Daemon Core Files . . . . .	1093
Compress the Daemon Core Files . . . . .	1093
Log Software Version Information . . . . .	1094
Open a Case with JTAC . . . . .	1095
Collect and Send Routing Engine Crash Data to JTAC . . . . .	1095
Check for Daemon Core Files . . . . .	1096
List the Daemon Core Files . . . . .	1097
Compress the Daemon Core Files . . . . .	1098

Collect Crash Data for the Packet Forwarding Engine Microkernel . . . . .	1098
Display the Crash Stack Traceback and Registration Information . . . . .	1099
Clear the NVRAM Contents . . . . .	1102
Check Packet Forwarding Engine Microkernel Core Files . . . . .	1103
List the Core Files Generated by the Crash . . . . .	1103
Compress the Core Files . . . . .	1104

## Documentation and Release Notes

---

To obtain the most current version of all Juniper Networks<sup>®</sup> technical documentation, see the product documentation page on the Juniper Networks website at <http://www.juniper.net/techpubs/>.

If the information in the latest release notes differs from the information in the documentation, follow the product Release Notes.

Juniper Networks Books publishes books by Juniper Networks engineers and subject matter experts. These books go beyond the technical documentation to explore the nuances of network architecture, deployment, and administration. The current list can be viewed at <http://www.juniper.net/books>.

## Supported Platforms

---

For the features described in this document, the following platforms are supported:

- [ACX Series](#)
- [T Series](#)
- [MX Series](#)
- [M Series](#)
- [PTX Series](#)

## Using the Examples in This Manual

---

If you want to use the examples in this manual, you can use the **load merge** or the **load merge relative** command. These commands cause the software to merge the incoming

configuration into the current candidate configuration. The example does not become active until you commit the candidate configuration.

If the example configuration contains the top level of the hierarchy (or multiple hierarchies), the example is a *full example*. In this case, use the **load merge** command.

If the example configuration does not start at the top level of the hierarchy, the example is a *snippet*. In this case, use the **load merge relative** command. These procedures are described in the following sections.

## Merging a Full Example

To merge a full example, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration example into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following configuration to a file and name the file **ex-script.conf**. Copy the **ex-script.conf** file to the **/var/tmp** directory on your routing platform.

```
system {
  scripts {
    commit {
      file ex-script.xsl;
    }
  }
}
interfaces {
  fxp0 {
    disable;
    unit 0 {
      family inet {
        address 10.0.0.1/24;
      }
    }
  }
}
```

2. Merge the contents of the file into your routing platform configuration by issuing the **load merge** configuration mode command:

```
[edit]
user@host# load merge /var/tmp/ex-script.conf
load complete
```

## Merging a Snippet

To merge a snippet, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration snippet into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following snippet to a file and name the file **ex-script-snippet.conf**. Copy the **ex-script-snippet.conf** file to the **/var/tmp** directory on your routing platform.

```
commit {
  file ex-script-snippet.xml; }
```

2. Move to the hierarchy level that is relevant for this snippet by issuing the following configuration mode command:

```
[edit]
user@host# edit system scripts
[edit system scripts]
```

3. Merge the contents of the file into your routing platform configuration by issuing the **load merge relative** configuration mode command:

```
[edit system scripts]
user@host# load merge relative /var/tmp/ex-script-snippet.conf
load complete
```

For more information about the **load** command, see [CLI Explorer](#).

## Documentation Conventions

[Table 1 on page xlvii](#) defines notice icons used in this guide.

**Table 1: Notice Icons**

Icon	Meaning	Description
	Informational note	Indicates important features or instructions.
	Caution	Indicates a situation that might result in loss of data or hardware damage.
	Warning	Alerts you to the risk of personal injury or death.
	Laser warning	Alerts you to the risk of personal injury from a laser.
	Tip	Indicates helpful information.
	Best practice	Alerts you to a recommended use or implementation.

[Table 2 on page xlviii](#) defines the text and syntax conventions used in this guide.

Table 2: Text and Syntax Conventions

Convention	Description	Examples
<b>Bold text like this</b>	Represents text that you type.	To enter configuration mode, type the <b>configure</b> command:  user@host> <b>configure</b>
Fixed-width text like this	Represents output that appears on the terminal screen.	user@host> <b>show chassis alarms</b>  No alarms currently active
<i>Italic text like this</i>	<ul style="list-style-type: none"> <li>Introduces or emphasizes important new terms.</li> <li>Identifies guide names.</li> <li>Identifies RFC and Internet draft titles.</li> </ul>	<ul style="list-style-type: none"> <li>A policy <i>term</i> is a named structure that defines match conditions and actions.</li> <li><i>Junos OS CLI User Guide</i></li> <li>RFC 1997, <i>BGP Communities Attribute</i></li> </ul>
<i>Italic text like this</i>	Represents variables (options for which you substitute a value) in commands or configuration statements.	Configure the machine's domain name:  [edit] root@# <b>set system domain-name</b> <i>domain-name</i>
Text like this	Represents names of configuration statements, commands, files, and directories; configuration hierarchy levels; or labels on routing platform components.	<ul style="list-style-type: none"> <li>To configure a stub area, include the <b>stub</b> statement at the [edit protocols ospf area area-id] hierarchy level.</li> <li>The console port is labeled <b>CONSOLE</b>.</li> </ul>
< > (angle brackets)	Encloses optional keywords or variables.	<b>stub &lt;default-metric metric&gt;;</b>
(pipe symbol)	Indicates a choice between the mutually exclusive keywords or variables on either side of the symbol. The set of choices is often enclosed in parentheses for clarity.	<b>broadcast   multicast</b>  <b>(string1   string2   string3)</b>
# (pound sign)	Indicates a comment specified on the same line as the configuration statement to which it applies.	<b>rsvp { # Required for dynamic MPLS only</b>
[ ] (square brackets)	Encloses a variable for which you can substitute one or more values.	<b>community name members [ community-ids ]</b>
Indentation and braces ( { } )	Identifies a level in the configuration hierarchy.	[edit] routing-options { static { route default { nexthop address; retain; } } }
;(semicolon)	Identifies a leaf statement at a configuration hierarchy level.	

---

## GUI Conventions

---

Table 2: Text and Syntax Conventions (*continued*)

Convention	Description	Examples
<b>Bold text like this</b>	Represents graphical user interface (GUI) items you click or select.	<ul style="list-style-type: none"> <li>In the Logical Interfaces box, select <b>All Interfaces</b>.</li> <li>To cancel the configuration, click <b>Cancel</b>.</li> </ul>
<b>&gt;</b> (bold right angle bracket)	Separates levels in a hierarchy of menu selections.	In the configuration editor hierarchy, select <b>Protocols&gt;Ospf</b> .

## Documentation Feedback

We encourage you to provide feedback, comments, and suggestions so that we can improve the documentation. You can provide feedback by using either of the following methods:

- Online feedback rating system—On any page of the Juniper Networks TechLibrary site at <http://www.juniper.net/techpubs/index.html>, simply click the stars to rate the content, and use the pop-up form to provide us with information about your experience. Alternately, you can use the online feedback form at <http://www.juniper.net/techpubs/feedback/>.
- E-mail—Send your comments to [techpubs-comments@juniper.net](mailto:techpubs-comments@juniper.net). Include the document or topic name, URL or page number, and software version (if applicable).

## Requesting Technical Support

Technical product support is available through the Juniper Networks Technical Assistance Center (JTAC). If you are a customer with an active J-Care or Partner Support Service support contract, or are covered under warranty, and need post-sales technical support, you can access our tools and resources online or open a case with JTAC.

- JTAC policies—For a complete understanding of our JTAC procedures and policies, review the *JTAC User Guide* located at <http://www.juniper.net/us/en/local/pdf/resource-guides/7100059-en.pdf>.
- Product warranties—For product warranty information, visit <http://www.juniper.net/support/warranty/>.
- JTAC hours of operation—The JTAC centers have resources available 24 hours a day, 7 days a week, 365 days a year.

## Self-Help Online Tools and Resources

For quick and easy problem resolution, Juniper Networks has designed an online self-service portal called the Customer Support Center (CSC) that provides you with the following features:

- Find CSC offerings: <http://www.juniper.net/customers/support/>
- Search for known bugs: <http://www2.juniper.net/kb/>
- Find product documentation: <http://www.juniper.net/techpubs/>
- Find solutions and answer questions using our Knowledge Base: <http://kb.juniper.net/>
- Download the latest versions of software and review release notes: <http://www.juniper.net/customers/csc/software/>
- Search technical bulletins for relevant hardware and software notifications: <http://kb.juniper.net/InfoCenter/>
- Join and participate in the Juniper Networks Community Forum: <http://www.juniper.net/company/communities/>
- Open a case online in the CSC Case Management tool: <http://www.juniper.net/cm/>

To verify service entitlement by product serial number, use our Serial Number Entitlement (SNE) Tool: <https://tools.juniper.net/SerialNumberEntitlementSearch/>

## Opening a Case with JTAC

You can open a case with JTAC on the Web or by telephone.

- Use the Case Management tool in the CSC at <http://www.juniper.net/cm/>.
- Call 1-888-314-JTAC (1-888-314-5822 toll-free in the USA, Canada, and Mexico).

For international or direct-dial options in countries without toll-free numbers, see <http://www.juniper.net/support/requesting-support.html>.

## Traffic Engineering Capabilities

---

The task of mapping traffic flows onto an existing physical topology is called *traffic engineering*. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the interior gateway protocol (IGP) and onto a potentially less congested physical path across a network.

Traffic engineering provides the capabilities to do the following:

- Route primary paths around known bottlenecks or points of congestion in the network.
- Provide precise control over how traffic is rerouted when the primary path is faced with single or multiple failures.
- Provide more efficient use of available aggregate bandwidth and long-haul fiber by ensuring that subsets of the network do not become overutilized while other subsets of the network along potential alternate paths are underutilized.
- Maximize operational efficiency.
- Enhance the traffic-oriented performance characteristics of the network by minimizing packet loss, minimizing prolonged periods of congestion, and maximizing throughput.
- Enhance statistically bound performance characteristics of the network (such as loss ratio, delay variation, and transfer delay) required to support a multiservices Internet.

## Components of Traffic Engineering

---

In the Junos<sup>®</sup> operating system (OS), traffic engineering is implemented with MPLS and RSVP. Traffic engineering is composed of four functional components:

- [Packet Forwarding Component on page 4](#)
- [Information Distribution Component on page 5](#)
- [Path Selection Component on page 6](#)
- [Signaling Component on page 7](#)

## Packet Forwarding Component

---

The packet forwarding component of the Junos traffic engineering architecture is MPLS, which is responsible for directing a flow of IP packets along a predetermined path across a network. This path is called a *label-switched path (LSP)*. LSPs are simplex; that is, the traffic flows in one direction from the head-end (ingress) router to a tail-end (egress) router. Duplex traffic requires two LSPs: one LSP to carry traffic in each direction. An LSP is created by the concatenation of one or more label-switched hops, allowing a packet to be forwarded from one router to another across the MPLS domain.

When an ingress router receives an IP packet, it adds an MPLS header to the packet and forwards it to the next router in the LSP. The labeled packet is forwarded along the LSP by each router until it reaches the tail end of the LSP, the egress router. At this point the MPLS header is removed, and the packet is forwarded based on Layer 3 information such as the IP destination address. The value of this scheme is that the physical path of the LSP is not limited to what the IGP would choose as the shortest path to reach the destination IP address.

This section discusses the following topics:

- [Packet Forwarding Based on Label Swapping on page 4](#)
- [How a Packet Traverses an MPLS Backbone on page 5](#)

### Related Documentation

- [Components of Traffic Engineering on page 4](#)

## Packet Forwarding Based on Label Swapping

---

The packet forwarding process at each router is based on the concept of label swapping. This concept is similar to what occurs at each Asynchronous Transfer Mode (ATM) switch in a permanent virtual circuit (PVC). Each MPLS packet carries a 4-byte encapsulation header that contains a 20-bit, fixed-length label field. When a packet containing a label arrives at a router, the router examines the label and copies it as an index to its MPLS forwarding table. Each entry in the forwarding table contains an interface-inbound label pair mapped to a set of forwarding information that is applied to all packets arriving on the specific interface with the same inbound label.

---

## How a Packet Traverses an MPLS Backbone

---

This section describes how an IP packet is processed as it traverses an MPLS backbone network.

At the entry edge of the MPLS backbone, the IP header is examined by the ingress router. Based on this analysis, the packet is classified, assigned a label, encapsulated in an MPLS header, and forwarded toward the next hop in the LSP. MPLS provides a high degree of flexibility in the way that an IP packet can be assigned to an LSP. For example, in the Junos traffic engineering implementation, all packets arriving at the ingress router that are destined to exit the MPLS domain at the same egress router are forwarded along the same LSP.

Once the packet begins to traverse the LSP, each router uses the label to make the forwarding decision. The MPLS forwarding decision is made independently of the original IP header: the incoming interface and label are used as lookup keys into the MPLS forwarding table. The old label is replaced with a new label, and the packet is forwarded to the next hop along the LSP. This process is repeated at each router in the LSP until the packet reaches the egress router.

When the packet arrives at the egress router, the label is removed and the packet exits the MPLS domain. The packet is then forwarded based on the destination IP address contained in the packet's original IP header according to the traditional shortest path calculated by the IP routing protocol.

---

## Information Distribution Component

---

Traffic engineering requires detailed knowledge about the network topology as well as dynamic information about network loading. To implement the information distribution component, simple extensions to the IGP are defined. Link attributes are included as part of each router's link-state advertisement. IS-IS extensions include the definition of new type length values (TLVs), whereas OSPF extensions are implemented with opaque link-state advertisements (LSAs). The standard flooding algorithm used by the link-state IGPs ensures that link attributes are distributed to all routers in the routing domain. Some of the traffic engineering extensions to be added to the IGP link-state advertisement include maximum link bandwidth, maximum reserved link bandwidth, current bandwidth reservation, and link coloring.

Each router maintains network link attributes and topology information in a specialized traffic engineering database. The traffic engineering database is used exclusively for calculating explicit paths for the placement of LSPs across the physical topology. A separate database is maintained so that the subsequent traffic engineering computation is independent of the IGP and the IGP's link-state database. Meanwhile, the IGP continues its operation without modification, performing the traditional shortest-path calculation based on information contained in the router's link-state database.

**Related Documentation**

- [Components of Traffic Engineering on page 4](#)

## Path Selection Component

---

After network link attributes and topology information are flooded by the IGP and placed in the traffic engineering database, each ingress router uses the traffic engineering database to calculate the paths for its own set of LSPs across the routing domain. The path for each LSP can be represented by either a strict or loose explicit route. An explicit route is a preconfigured sequence of routers that should be part of the physical path of the LSP. If the ingress router specifies all the routers in the LSP, the LSP is said to be identified by a strict explicit route. If the ingress router specifies only some of the routers in the LSP, the LSP is described as a loose explicit route. Support for strict and loose explicit routes allows the path selection process to be given broad latitude whenever possible, but to be constrained when necessary.

The ingress router determines the physical path for each LSP by applying a Constrained Shortest Path First (CSPF) algorithm to the information in the traffic engineering database. CSPF is a shortest-path-first algorithm that has been modified to take into account specific restrictions when the shortest path across the network is calculated. Input into the CSPF algorithm includes:

- Topology link-state information learned from the IGP and maintained in the traffic engineering database
- Attributes associated with the state of network resources (such as total link bandwidth, reserved link bandwidth, available link bandwidth, and link color) that are carried by IGP extensions and stored in the traffic engineering database
- Administrative attributes required to support traffic traversing the proposed LSP (such as bandwidth requirements, maximum hop count, and administrative policy requirements) that are obtained from user configuration

As CSPF considers each candidate node and link for a new LSP, it either accepts or rejects a specific path component based on resource availability or whether selecting the component violates user policy constraints. The output of the CSPF calculation is an explicit route consisting of a sequence of router addresses that provides the shortest path through the network that meets the constraints. This explicit route is then passed to the signaling component, which establishes the forwarding state in the routers along the LSP.

- [Components of Traffic Engineering on page 4](#)

## Offline Path Planning and Analysis

---

Despite the reduced management effort resulting from online path calculation, an offline planning and analysis tool is still required to optimize traffic engineering globally. Online calculation takes resource constraints into account and calculates one LSP at a time. The challenge with this approach is that it is not deterministic. The order in which LSPs are calculated plays a critical role in determining each LSP's physical path across the network. LSPs that are calculated early in the process have more resources available to them than LSPs calculated later in the process because previously calculated LSPs

consume network resources. If the order in which the LSPs are calculated is changed, the resulting set of physical paths for the LSPs also can change.

An offline planning and analysis tool simultaneously examines each link's resource constraints and the requirements of each LSP. Although the offline approach can take several hours to complete, it performs global calculations, compares the results of each calculation, and then selects the best solution for the network as a whole. The output of the offline calculation is a set of LSPs that optimizes utilization of network resources. After the offline calculation is completed, the LSPs can be established in any order because each is installed according to the rules for the globally optimized solution.

## Signaling Component

---

An LSP is not known to be workable until it is actually established by the signaling component. The signaling component, which is responsible for establishing LSP state and distributing labels, relies on a number of extensions to RSVP:

- The Explicit Route object allows an RSVP path message to traverse an explicit sequence of routers that is independent of conventional shortest-path IP routing. The explicit route can be either strict or loose.
- The Label Request object permits the RSVP path message to request that intermediate routers provide a label binding for the LSP that it is establishing.
- The Label object allows RSVP to support the distribution of labels without changing its existing mechanisms. Because the RSVP Resv message follows the reverse path of the RSVP path message, the Label object supports the distribution of labels from downstream nodes to upstream nodes.

## Flexible LSP Calculation and Configuration

---

Traffic engineering involves mapping traffic flow onto a physical topology. You can determine the paths online using constraint-based routing. Regardless of how the physical path is calculated, the forwarding state is installed across the network through RSVP.

The Junos OS supports the following ways to route and configure an LSP:

- You can calculate the full path for the LSP offline and individually configure each router in the LSP with the necessary static forwarding state. This is analogous to the way some Internet service providers (ISPs) configure their IP-over-ATM cores.
- You can calculate the full path for the LSP offline and statically configure the ingress router with the full path. The ingress router then uses RSVP as a dynamic signaling protocol to install a forwarding state in each router along the LSP.
- You can rely on constraint-based routing to perform dynamic online LSP calculation. You configure the constraints for each LSP; then the network itself determines the path that best meets those constraints. Specifically, the ingress router calculates the entire LSP based on the constraints and then initiates signaling across the network.

- You can calculate a partial path for an LSP offline and statically configure the ingress router with a subset of the routers in the path; then you can permit online calculation to determine the complete path.

For example, consider a topology that includes two east-west paths across the United States: one in the north through Chicago and one in the south through Dallas. If you want to establish an LSP between a router in New York and one in San Francisco, you can configure the partial path for the LSP to include a single loose-routed hop of a router in Dallas. The result is an LSP routed along the southern path. The ingress router uses CSPF to compute the complete path and RSVP to install the forwarding state along the LSP.

- You can configure the ingress router with no constraints whatsoever. In this case, normal IGP shortest-path routing is used to determine the path of the LSP. This configuration does not provide any value in terms of traffic engineering. However, it is easy and might be useful in situations when services such as virtual private networks (VPNs) are needed.

In all these cases, you can specify any number of LSPs as backups for the primary LSP, thus allowing you to combine more than one configuration approach. For example, you might explicitly compute the primary path offline, set the secondary path to be constraint-based, and have the tertiary path be unconstrained. If a circuit on which the primary LSP is routed fails, the ingress router notices the outage from error notifications received from a downstream router or by the expiration of RSVP soft-state information. Then the router dynamically forwards traffic to a hot-standby LSP or calls on RSVP to create a forwarding state for a new backup LSP.

## Link-State Distribution Using BGP Overview

- [Role of an Interior Gateway Protocol on page 8](#)
- [Limitations of an Interior Gateway Protocol on page 9](#)
- [Need for Spanning Link-State Distribution on page 9](#)
- [Using BGP as a Solution on page 10](#)
- [Supported and Unsupported Features on page 15](#)

### Role of an Interior Gateway Protocol

An interior gateway protocol (IGP) is a type of protocol used for exchanging routing information between devices within an autonomous system (AS). Based on the method of computing the best path to a destination, the IGPs are divided into two categories:

- Link-state protocols—Advertise information about the network topology (directly connected links and the state of those links) to all routers using multicast addresses and triggered routing updates until all the routers running the link-state protocol have identical information about the internetwork. The best path to a destination is calculated based on constraints such as maximum delay, minimum available bandwidth, and resource class affinity.

OSPF and IS-IS are examples of link-state protocols.

- Distance vector protocols—Advertise complete routing table information to directly connected neighbors using a broadcast address. The best path is calculated based on the number of hops to the destination network.

RIP is an example of a distance vector protocol.

As the name implies, the role of an IGP is to provide routing connectivity within or internal to a given routing domain. A routing domain is a set of routers under common administrative control that share a common routing protocol. An AS can consist of multiple routing domains, where IGP functions to advertise and learn network prefixes (routes) from neighboring routers to build a route table that ultimately contains entries for all sources advertising reachability for a given prefix. IGP executes a route selection algorithm to select the best path between the local router and each destination, and provides full connectivity among the routers making up a routing domain.

In addition to advertising internal network reachability, IGPs are often used to advertise routing information that is external to that IGP's routing domain through a process known as route redistribution. Route redistribution is the process of exchanging routing information among distinct routing protocols to tie multiple routing domains together when intra-AS connectivity is desired.

## Limitations of an Interior Gateway Protocol

While each individual IGP has its own advantages and limitations, the biggest limitations of IGP in general are performance and scalability.

IGPs are designed to handle the task of acquiring and distributing network topology information for traffic engineering purposes. While this model has served well, IGPs have inherent scaling limitations when it comes to distributing large databases. IGPs can autodetect neighbors, with which they acquire intra-area network topology information. However, the link-state database or a traffic engineering database has the scope of a single area or AS, thereby limiting applications, such as end-to-end traffic engineering, the benefit of having external visibility to make better decisions.

For label-switched networks, such as MPLS and Generalized MPLS (GMPLS), most existing traffic engineering solutions work in a single routing domain. These solutions do not work when a route from the ingress node to the egress node leaves the routing area or AS of the ingress node. In such cases, the path computation problem becomes complicated because of the unavailability of the complete routing information throughout the network. This is because service providers usually choose not to leak routing information beyond the routing area or AS for scalability constraints and confidentiality concerns.

## Need for Spanning Link-State Distribution

One of the limitations of IGP is its inability to span link-state distribution outside a single area or AS. However, spanning link-state information acquired by an IGP across multiple areas or ASs has the following needs:

- LSP path computation—This information is used to compute the path for MPLS LSPs across multiple routing domains, for example an inter-area TE LSP.

- External path computing entities—External path computing entities, such as Application Layer Traffic Optimization (ALTO) and Path Computation Elements (PCE), perform path computations based on the network topology and current state of connections within the network, including traffic engineering information. This information is typically distributed by IGPs within the network.

However, because the external path computing entities cannot extract this information from the IGPs, they perform network monitoring to optimize network services.

## Using BGP as a Solution

- [Overview on page 10](#)
- [Implementation on page 11](#)

### Overview

---

To meet the needs for spanning link-state distribution across multiple domains, an exterior gateway protocol (EGP) is required to collect link-state and traffic engineering information from an IGP area, share it with external component, and use it for computing paths for interdomain MPLS LSPs.

BGP is a standardized EGP designed to exchange routing and reachability information between autonomous systems (ASs). BGP is a proven protocol that has better scaling properties because it can distribute millions of entries (for example, VPN prefixes) in a scalable fashion. BGP is the only routing protocol in use today that is suited to carry all of the routes in the Internet. This is largely because BGP runs on top of TCP and can make use of TCP flow control. In contrast, the internal gateway protocols (IGPs) do not have flow control. When IGPs have too much route information, they begin to churn. When BGP has a neighboring speaker that is sending information too quickly, BGP can throttle down the neighbor by delaying TCP acknowledgments.

Another benefit of BGP is that it uses type, length, value (TLV) tuples and network layer reachability information (NLRI) that provide seemingly endless extensibility without the need for the underlying protocol to be altered.

The distribution of link-state information across domains is regulated using policies to protect the interests of the service provider. This requires a control over the topology distribution using policies. BGP with its implemented policy framework serves well in the interdomain route distribution. In Junos OS, BGP is completely policy driven. The operator must explicitly configure neighbors to peer with and explicitly accept routes into BGP. Furthermore, routing policy is used to filter and modify routing information. Thus, routing policies provide complete administrative control over the routing tables.

Although, within an AS, both IGP-TE and BGP-TE provide the same set of information, BGP-TE has better scaling characteristics that are inherited from the standard BGP protocol. This makes BGP-TE a more scalable choice for acquiring multi-area/multi-AS topology information.

By using BGP as a solution, the IGP-acquired information is used for distribution into BGP. The ISPs can selectively expose this information with other ISPs, service providers, and content distribution networks (CDNs) through normal BGP peering. This allows for

aggregation of the IGP-acquired information across multiple areas and ASs, such that an external path computing entity can access the information by passively listening to a route reflector.

### Implementation

In Junos OS, the IGPs install topology information into a database called the traffic engineering database. The traffic engineering database contains the aggregated topology information. The mechanism to distribute link-state information using BGP includes the process of advertising the traffic engineering database into BGP-TE (import), and installing entries from BGP-TE into the traffic engineering database (export).

**Figure 1: Junos OS Implementation of BGP Link-State Distribution**

- [Traffic Engineering Database Import on page 11](#)
- [Traffic Engineering Database Export on page 12](#)
- [Assigning Credibility Values on page 12](#)
- [BGP-TE NLRIs and TLVs on page 13](#)

#### ***Traffic Engineering Database Import***

To advertise the traffic engineering database into BGP-TE, the link and node entries in the traffic engineering database are converted in the form of routes. These converted

routes are then installed by the traffic engineering database on behalf of the corresponding IGP, into a user-visible routing table called **lsdist.0**, on conditions subject to route policies. The procedure of leaking entries from the traffic engineering database into **lsdist.0** is called traffic engineering database import as illustrated in [Figure 1 on page 11](#).

There are policies to govern the traffic engineering database import process. By default, no entries are leaked from the traffic engineering database into the **lsdist.0** table.

### ***Traffic Engineering Database Export***

BGP can be configured to export or advertise routes from the **lsdist.0** table, subject to policy. This is common for any kind of route origination in BGP. In order to advertise BGP-TE into the traffic engineering database, BGP needs to be configured with the BGP-TE address family, and an export policy that selects routes for redistribution into BGP.

BGP then propagates these routes like any other NLRI. BGP peers that have the BGP-TE family configured and negotiated receive BGP-TE NLRIs. BGP stores the received BGP-TE NLRIs in the form of routes in the **lsdist.0** table, which is the same table that stores locally originated BGP-TE routes. The BGP-installed routes in **lsdist.0** are then distributed to other peers like any other route. Thus, the standard route selection procedure applies to BGP-TE NLRIs received from multiple speakers.

To achieve interdomain TE, the routes in **lsdist.0** are leaked into the traffic engineering database through a policy. This process is called traffic engineering database export as illustrated in [Figure 1 on page 11](#).

There are policies to govern the traffic engineering database export process. By default, no entries are leaked from the **lsdist.0** table into the traffic engineering database.

**NOTE:** For SDN applications, such as PCE and ALTO, the BGP-TE advertised information cannot leak into the traffic engineering database of a router. In such cases, an external server that peers with the routers using BGP-TE is used to move topology information up into the sky/orchestration system that spans the network. These external servers can be deemed as BGP-TE consumers, where they receive BGP-TE routes, but do not advertise them.

---

### ***Assigning Credibility Values***

Once the entries are installed in the traffic engineering database, the BGP-TE learned information is made available for CSPF path computation. The traffic engineering database uses a protocol preference scheme that is based on credibility values. A protocol with a higher credibility value is preferred over a protocol with a lower credibility value. BGP-TE has the capability to advertise information learned from multiple protocols at the same time, and so in addition to the IGP-installed entries in the traffic engineering database, there can be BGP-TE installed entries that correspond to more than one protocol. The traffic engineering database export component creates a traffic engineering database protocol and credibility level for each protocol that BGP-TE supports. These credibility values are configurable in the CLI.

The credibility order for the BGP-TE protocols is as follows:

- Unknown—80
- OSPF—81
- ISIS Level 1—82
- ISIS Level 2—83
- Static—84
- Direct—85

### ***BGP-TE NLRIs and TLVs***

Like other BGP routes, BGP-TE NLRIs can also be distributed through a route reflector that speaks BGP-TE NLRI. Junos OS implements the route reflection support for the BGP-TE family.

The following is a list of supported NLRIs:

- Link NLRI
- Node NLRI
- IPv4 Prefix NLRI (receive and propagate)
- IPv6 Prefix NLRI (receive and propagate)

**NOTE:** Junos OS does not provide support for the route-distinguisher form of the above NLRIs.

The following is a list of supported fields in link and node NLRIs:

- Protocol-ID—NLRI originates with the following protocol values:
  - ISIS-L1
  - ISIS-L2
  - OSPF
- Identifier—This value is configurable. By default, the identifier value is set to 0.
- Local/Remote node descriptor—These include:
  - Autonomous system
  - BGP-LS Identifier—This value is configurable. By default, the BGP-LS identifier value is set to 0
  - Area-ID
  - IGP router-ID
- Link descriptors (Only for link NLRI)—This includes:

- Link Local/Remote Identifiers
- IPv4 interface address
- IPv4 neighbor address
- IPv6 neighbor/interface address—The IPv6 neighbor and interface addresses are not originated, but only stored and propagated when received.
- Multi-topology ID—This value is not originated, but stored and propagated when received.

The following is a list of supported LINK\_STATE attribute TLVs:

- Link attributes:
  - Administrative group
  - Max link bandwidth
  - Max reservable bandwidth
  - Unreserved bandwidth
  - TE default metric
  - SRLG
  - The following TLVs, which are not originated, but only stored and propagated when received:
    - Opaque link attributes
    - MPLS protocol mask
    - Metric
    - Link protection type
    - Link name attribute
- Node attributes:
  - IPv4 Router-ID
  - Node flag bits—Only the overload bit is set.
  - The following TLVs, which are not originated, but only stored and propagated when received:
    - Multi-topology
    - OSPF-specific node properties
    - Opaque node properties
    - Node name

- IS-IS area identifier
- IPv6 Router-ID
- Prefix attributes—These TLVs are stored and propagated like any other unknown TLVs.

## Supported and Unsupported Features

Junos OS supports the following features with link-state distribution using BGP:

- Advertisement of multiprotocol assured forwarding capability
- Transmission and reception of node and link-state BGP and BGP-TE NLRIs
- Nonstop active routing for BGP-TE NLRIs
- Policies

Junos OS does **not** support the following functionality for link-state distribution using BGP:

- Aggregated topologies, links, or nodes
- Route distinguisher support for BGP-TE NLRIs
- Multi-topology identifiers
- Multi-instance identifiers (excluding the default instance ID 0)
- Advertisement of the link and node area TLV
- Advertisement of MPLS signaling protocols
- Importing node and link information with overlapping address

## Introduction to MPLS

MPLS provides a mechanism for engineering network traffic patterns that is independent of routing tables. MPLS assigns short labels to network packets that describe how to forward them through the network. MPLS is independent of any routing protocol and can be used for unicast packets.

In the traditional Level 3 forwarding paradigm, as a packet travels from one router to the next, an independent forwarding decision is made at each hop. The IP network layer header is analyzed, and the next hop is chosen based on this analysis and on the information in the routing table. In an MPLS environment, the analysis of the packet header is performed just once, when a packet enters the MPLS cloud. The packet is then assigned to a stream, which is identified by a *label*, which is a short (20-bit), fixed-length value at the front of the packet. Labels are used as lookup indexes for the label forwarding table. For each label, this table stores forwarding information. You can associate additional information with a label—such as class-of-service (CoS) values—that can be used to prioritize packet forwarding.

---

## Supported MPLS Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for MPLS and traffic engineering.

- RFC 2858, *Multiprotocol Extensions for BGP-4*
- RFC 3031, *Multiprotocol Label Switching Architecture*
- RFC 3032, *MPLS Label Stack Encoding*
- RFC 3140, *Per Hop Behavior Identification Codes*
- RFC 3270, *Multi-Protocol Label Switching (MPLS) Support of Differentiated Services*

Only E-LSPs are supported.

- RFC 3443, *Time To Live (TTL) Processing in Multi-Protocol Label Switching (MPLS) Networks*
- RFC 3478, *Graceful Restart Mechanism for Label Distribution Protocol*
- RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*

Node protection in facility backup is not supported.

- RFC 4124, *Protocol Extensions for Support of Diffserv-aware MPLS Traffic Engineering*
- RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*
- RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*
- RFC 4385, *Pseudowire Emulation Edge-to-Edge (PWE3) Control Word for Use over an MPLS PSN.*

Supported on MX Series routers with the Channelized OC3/STM1 (Multi-Rate) Circuit Emulation MIC with SFP.

- RFC 4875, *Extensions to RSVP-TE for Point-to-Multipoint TE LSPs*
- RFC 4950, *ICMP Extensions for Multiprotocol Label Switching*
- RFC 5317, *Joint Working Team (JWT) Report on MPLS Architectural Considerations for a Transport Profile*
- RFC 5586, *MPLS Generic Associated Channel*
- RFC 5654, *Requirements of an MPLS Transport Profile*

The following capabilities are supported in the Junos OS implementation of MPLS Transport Profile (MPLS-TP):

- MPLS-TP OAM can send and receive packets with GAL and G-Ach, without IP encapsulation.
- Two unidirectional RSVP LSPs between a pair of routers can be associated with each other to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages. A single Bidirectional Forwarding Detection (BFD) session is established for the associated bidirectional LSP.
- RFC 5712, *MPLS Traffic Engineering Soft Preemption*
- RFC 5718, *An In-Band Data Communication Network For the MPLS Transport Profile*
- RFC 5860, *Requirements for Operations, Administration, and Maintenance (OAM) in MPLS Transport Networks*
- RFC 5884, *Bidirectional Forwarding Detection (BFD) for MPLS Label Switched Paths (LSPs)*
- RFC 5921, *A Framework for MPLS in Transport Networks*
- RFC 5950, *Network Management Framework for MPLS-based Transport Networks*
- RFC 5951, *Network Management Requirements for MPLS-based Transport Networks*
- RFC 5960, *MPLS Transport Profile Data Plane Architecture*

- RFC 6215, *MPLS Transport Profile User-to-Network and Network-to-Network Interfaces*
- RFC 6291, *Guidelines for the Use of the “OAM” Acronym in the IETF.*
- RFC 6370, *MPLS Transport Profile (MPLS-TP) Identifiers*
- RFC 6371, *Operations, Administration, and Maintenance Framework for MPLS-Based Transport Networks.*
- RFC 6372, *MPLS Transport Profile (MPLS-TP) Survivability Framework*
- RFC 6373, *MPLS-TP Control Plane Framework*
- RFC 6388, *Label Distribution Protocol Extensions for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*

Only Point-to-Multipoint LSPs are supported.

- RFC 6424, *Mechanism for Performing Label Switched Path Ping (LSP Ping) over MPLS Tunnels*
- RFC 6425, *Detecting Data-Plane Failures in Point-to-Multipoint MPLS - Extensions to LSP Ping*
- RFC 6426, *MPLS On-Demand Connectivity Verification and Route Tracing*
- RFC 6428, *Proactive Connectivity Verification, Continuity Check, and Remote Defect Indication for the MPLS Transport Profile*
- RFC 6510, *Resource Reservation Protocol (RSVP) Message Formats for Label Switched Path (LSP) Attributes Objects*
- Internet draft draft-ietf-mpls-rsvp-te-no-php-oob-mapping-01.txt, *Non PHP behavior and Out-of-Band Mapping for RSVP-TE LSPs*

The following RFCs and Internet drafts do not define standards, but provide information about MPLS, traffic engineering, and related technologies. The IETF classifies them variously as “Experimental,” “Historic,” or “Informational.”

- RFC 2547, *BGP/MPLS VPNs*
- RFC 2702, *Requirements for Traffic Engineering Over MPLS*
- RFC 2917, *A Core MPLS IP VPN Architecture*
- RFC 3063, *MPLS Loop Prevention Mechanism*
- RFC 3208, *PGM Reliable Transport Protocol Specification*

Only the network element is supported.

- RFC 3469, *Framework for Multi-Protocol Label Switching (MPLS)-based Recovery*
- RFC 3564, *Requirements for Support of Differentiated Services-aware MPLS Traffic Engineering*
- RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*
- RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*

- Internet draft draft-martini-l2circuit-encap-mpls-11.txt, *Encapsulation Methods for Transport of Layer 2 Frames Over IP and MPLS Networks*

Junos OS differs from the Internet draft in the following ways:

- A packet with a sequence number of 0 is treated as out of sequence.
- Any packet that does not have the next incremental sequence number is considered out of sequence.
- When out-of-sequence packets arrive, the expected sequence number for the neighbor is set to the sequence number in the Layer 2 circuit control word.
- Internet draft draft-martini-l2circuit-trans-mpls-19.txt, *Transport of Layer 2 Frames Over MPLS*
- Internet draft draft-raggarwa-mpls-p2mp-te-02.txt, *Establishing Point to Multipoint MPLS TE LSPs*

The features discussed in the indicated sections of the draft are not supported:

- Nonadjacent signaling for branch LSPs (section 7.1)
- Make-before-break and fast reroute (section 9)
- LSP hierarchy using point-to-point LSPs (section 10)

## Link-Layer Support in MPLS

MPLS supports the following link-layer protocols, which are all supported in the Junos OS MPLS implementation:

- Point-to-Point Protocol (PPP)—Protocol ID 0x0281, Network Control Protocol (NCP) protocol ID 0x8281.
- Ethernet/Cisco High-level Data Link Control (HDLC)—Ethernet type 0x8847.
- Asynchronous Transfer Mode (ATM)—Subnetwork attachment point encoded (SNAP-encoded) Ethernet type 0x8847. Support is included for both point-to-point mode or nonbroadcast multiaccess (NBMA) mode. Support is not included for encoding MPLS labels as part of ATM virtual path identifier/virtual circuit identifier (VPI/VCI).
- Frame Relay—SNAP-encoded, Ethernet type 0x8847. Support is not included for encoding MPLS labels as part of Frame Relay data-link connection identifier (DLCI).
- Generic routing encapsulation (GRE) tunnel—Ethernet type 0x8847.

## MPLS and Traffic Engineering

---

Traffic engineering allows you to control the path that data packets follow, bypassing the standard routing model, which uses routing tables. Traffic engineering moves flows from congested links to alternate links that would not be selected by the automatically computed destination-based shortest path. With traffic engineering, you can:

- Make more efficient use of expensive long-haul fibers.
- Control how traffic is rerouted in the face of single or multiple failures.
- Classify critical and regular traffic on a per-path basis.

The core of the traffic engineering design is based on building label-switched paths (LSPs) among routers. An LSP is connection-oriented, like a virtual circuit in Frame Relay or ATM. LSPs are not reliable: Packets entering an LSP do not have delivery guarantees, although preferential treatment is possible. LSPs also are similar to unidirectional tunnels in that packets entering a path are encapsulated in an envelope and switched across the entire path without being touched by intermediate nodes. LSPs provide fine-grained control over how packets are forwarded in a network. To provide reliability, an LSP can use a set of primary and secondary paths.

LSPs can be configured for BGP traffic only (traffic whose destination is outside of an autonomous system [AS]). In this case, traffic within the AS is not affected by the presence of LSPs. LSPs can also be configured for both BGP and interior gateway protocol (IGP) traffic; therefore, both intra-AS and inter-AS traffic is affected by the LSPs.

This section discusses the following topics:

- [Advertising LSPs into IGP on page 38](#)

## MPLS Label Overview

---

Packets traveling along an LSP are identified by a label—a 20-bit, unsigned integer in the range 0 through 1,048,575. For push labels on ingress routers, no labels in this range are

restricted. For incoming labels on the transit static LSP, the label value is restricted to 1,000,000 through 1,048,575.

On MX Series, PTX Series, and T Series routers, the value for entropy and flow labels is restricted to 16 through 1,048,575.

## Special MPLS Labels

Some of the reserved labels (in the 0 through 15 range) have well-defined meanings. For more complete details, see RFC 3032, *MPLS Label Stack Encoding*.

- 0, IPv4 Explicit Null label—This value is legal only when it is the sole label entry (no label stacking). It indicates that the label must be popped upon receipt. Forwarding continues based on the IP version 4 (IPv4) packet.
- 1, Router Alert label—When a packet is received with a top label value of 1, it is delivered to the local software module for processing.
- 2, IPv6 Explicit Null label—This value is legal only when it is the sole label entry (no label stacking). It indicates that the label must be popped on receipt. Forwarding continues based on the IP version 6 (IPv6) packet.
- 3, Implicit Null label—This label is used in the control protocol (LDP or RSVP) only to request label popping by the downstream router. It never actually appears in the encapsulation. Labels with a value of 3 should not be used in the data packet as real labels. No payload type (IPv4 or IPv6) is implied with this label.
- 4 through 6—Unassigned.
- 7, Entropy label indicator—This label is used when an Entropy label is in the label stack and precedes the Entropy label.
- 8 through 15—Unassigned.

Special labels are commonly used between the egress and penultimate routers of an LSP. If the LSP is configured to carry IPv4 packets only, the egress router might signal the penultimate router to use 0 as a final-hop label. If the LSP is configured to carry IPv6 packets only, the egress router might signal the penultimate router to use 2 as a final-hop label.

The egress router might simply signal the penultimate router to use 3 as the final label, which is a request to perform penultimate-hop label popping. The egress router will not process a labeled packet; rather, it receives the payload (IPv4, IPv6, or others) directly, reducing one MPLS lookup at egress.

For label-stacked packets, the egress router receives an MPLS label packet with its top label already popped by the penultimate router. The egress router cannot receive label-stacked packets that use label 0 or 2. It typically requests label 3 from the penultimate router.

## MPLS Label Allocation

In the Junos OS, label values are allocated per router or switch—the rest of this explanation uses router to cover both. The display output shows only the label (for example, **01024**). Labels for multicast packets are independent of those for unicast packets. Currently, the Junos OS does not support multicast labels.

Labels are assigned by downstream routers relative to the flow of packets. A router receiving labeled packets (the next-hop router) is responsible for assigning incoming labels. A received packet containing a label that is unrecognized (unassigned) is dropped. For unrecognized labels, the router does not attempt to unwrap the label to analyze the network layer header, nor does it generate an Internet Control Message Protocol (ICMP) destination unreachable message.

A packet can carry a number of labels, organized as a last-in, first-out stack. This is referred to as a *label stack*. At a particular router, the decision about how to forward a labeled packet is based exclusively on the label at the top of the stack.

Figure 2 on page 26 shows the encoding of a single label. The encoding appears after data link layer headers, but before any network layer header.

**Figure 2: Label Encoding**

Figure 3 on page 27 illustrates the purpose of the class-of-service bits (also known as the EXP or experimental bits). Bits 20 and 21 specify the queue number. Bit 22 is the packet loss priority (PLP) bit used to specify the random early detection (RED) drop profile. For more information about class of service and the class-of-service bits, see “Configuring Class of Service for MPLS LSPs” on page 272.

Figure 3: Class-of-Service Bits

Related Documentation

- [per-prefix-label on page 1492](#)

## Operations on MPLS Labels

The router supports the following label operations:

- **Push**—Add a new label to the top of the packet. For IPv4 packets, the new label is the first label. The time-to-live (TTL) and s bits are derived from the IP packet header. The MPLS class of service (CoS) is derived from the queue number. If the push operation is performed on an existing MPLS packet, you will have a packet with two or more labels. This is called label stacking. The top label must have its s bit set to 0, and might derive CoS and TTL from lower levels. The new top label in a label stack always initializes its TTL to 255, regardless of the TTL value of lower labels.
- **Pop**—Remove the label from the beginning of the packet. Once the label is removed, the TTL is copied from the label into the IP packet header, and the underlying IP packet is forwarded as a native IP packet. In the case of multiple labels in a packet (label stacking), removal of the top label yields another MPLS packet. The new top label might derive CoS and TTL from a previous top label. The popped TTL value from the previous top label is not written back to the new top label.
- **Swap**—Replace the label at the top of the label stack with a new label. The S and CoS bits are copied from the previous label, and the TTL value is copied and decremented (unless the **no-decrement-ttl** or **no-propagate-ttl** statement is configured). A transit router supports a label stack of any depth.
- **Multiple Push**—Add multiple labels (up to three) on top of existing packets. This operation is equivalent to pushing multiple times.
- **Swap and Push**—Replace the existing top of the label stack with a new label, and then push another new label on top.

## Entropy Label Support in Mixed Mode Overview

Starting with Junos OS Release 14.2, entropy label is supported in mixed mode chassis where the entropy label can be configured without enhanced-ip configuration. The entropy label helps transit routers load-balance MPLS traffic across ECMP paths or link aggregation groups. The entropy label introduces a load-balancing label to be used by routers to load balance traffic rather than relying on deep packet inspection, reducing the packet processing requirements in the forwarding plane at the expense of increased label stack depth. Junos OS supports the entropy label only for MX Series routers with MPCs or MICs and can be enabled with enhanced-ip mode. But, this leads to a packet drop if the core-facing interface has an entropy label configured on the MPC or MIC and the other end of this core-facing connection has a DPC line card. In order to avoid this, the entropy label is now supported in mixed mode where the entropy label can be configured without enhanced-ip configuration. This allows MX Series router DPCs to support a pop out entropy label. However, this does not support a flow label.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, entropy label is supported in mixed mode chassis where the entropy label can be configured without enhanced-ip configuration.

## Routers in an LSP

Each router in an LSP performs one of the following functions:

- Ingress router—The router at the beginning of an LSP. This router encapsulates IP packets with an MPLS Layer 2 frame and forwards it to the next router in the path. Each LSP can have only one ingress router.
- Egress router—The router at the end of an LSP. This router removes the MPLS encapsulation, thus transforming it from an MPLS packet to an IP packet, and forwards the packet to its final destination using information in the IP forwarding table. Each LSP can have only one egress router. The ingress and egress routers in an LSP cannot be the same router.
- Transit router—Any intermediate router in the LSP between the ingress and egress routers. A transit router forwards received MPLS packets to the next router in the MPLS path. An LSP can contain zero or more transit routers, up to a maximum of 253 transit routers in a single LSP.

A single router can be part of multiple LSPs. It can be the ingress or egress router for one or more LSPs, and it also can be a transit router in one or more LSPs. The functions that each router supports depend on your network design.

## How a Packet Travels Along an LSP

When an IP packet enters an LSP, the ingress router examines the packet and assigns it a label based on its destination, placing the label in the packet's header. The label

transforms the packet from one that is forwarded based on its IP routing information to one that is forwarded based on information associated with the label.

The packet is then forwarded to the next router in the LSP. This router and all subsequent routers in the LSP do not examine any of the IP routing information in the labeled packet. Rather, they use the label to look up information in their label forwarding table. They then replace the old label with a new label and forward the packet to the next router in the path.

When the packet reaches the egress router, the label is removed, and the packet again becomes a native IP packet and is again forwarded based on its IP routing information.

## Types of LSPs

---

There are three types of LSPs:

- Static LSPs—For static paths, you must manually assign labels on all routers involved (ingress, transit, and egress). No signaling protocol is needed. This procedure is similar to configuring static routes on individual routers. Like static routes, there is no error reporting, liveliness detection, or statistics reporting.
- LDP-signaled LSPs—See [“LDP Introduction” on page 577](#).
- RSVP-signaled LSPs—For signaled paths, RSVP is used to set up the path and dynamically assign labels. (RSVP signaling messages are used to set up signaled paths.) You configure only the ingress router. The transit and egress routers accept signaling information from the ingress router, and they set up and maintain the LSP cooperatively. Any errors encountered while establishing an LSP are reported to the ingress router for diagnostics. For signaled LSPs to work, a version of RSVP that supports tunnel extensions must be enabled on all routers.

There are two types of RSVP-signaled LSPs:

- Explicit-path LSPs—All intermediate hops of the LSP are manually configured. The intermediate hops can be strict, loose, or any combination of the two. Explicit path LSPs provide you with complete control over how the path is set up. They are similar to static LSPs but require much less configuration.
- Constrained-path LSPs—The intermediate hops of the LSP are automatically computed by the software. The computation takes into account information provided by the topology information from the IS-IS or OSPF link-state routing protocol, the current network resource utilization determined by RSVP, and the resource requirements and constraints of the LSP. For signaled constrained-path LSPs to work, either the IS-IS or OSPF protocol and the IS-IS or OSPF traffic engineering extensions must be enabled on all routers.

## Scope of LSPs

---

For constrained-path LSPs, the LSP computation is confined to one IGP domain, and cannot cross any AS boundary. This prevents an AS from extending its IGP into another AS.

Explicit-path LSPs, however, can cross as many AS boundaries as necessary. Because intermediate hops are manually specified, the LSP does not depend on the IGP topology or a local forwarding table.

## Constrained-Path LSP Computation

---

The Constrained Shortest Path First (CSPF) algorithm is an advanced form of the shortest-path-first (SPF) algorithm used in OSPF and IS-IS route computations. CSPF is used in computing paths for LSPs that are subject to multiple constraints. When computing paths for LSPs, CSPF considers not only the topology of the network, but also the attributes of the LSP and the links, and it attempts to minimize congestion by intelligently balancing the network load.

The constraints that CSPF considers include:

- LSP attributes
  - Administrative groups (that is, link color requirements)
  - Bandwidth requirements
  - Explicit route (strict or loose)
  - Hop limitations
  - Priority (setup and hold)
- Link attributes
  - Administrative groups (that is, link colors assigned to the link)
  - Reservable bandwidth of the links (static bandwidth minus the currently reserved bandwidth)

The data that CSPF considers comes from the following sources:

- Traffic engineering database—Provides CSPF with up-to-date topology information, the current reservable bandwidth of links, and the link colors. For the CSPF algorithm to perform its computations, a link-state IGP (such as OSPF or IS-IS) with special extensions is needed. For CSPF to be effective, the link-state IGP on all routers must support the special extensions. While building the topology database, the extended IGP must take into consideration the current LSPs and must flood the route information everywhere. Because changes in the reserved link bandwidth and link color cause database updates, an extended IGP tends to flood more frequently than a normal IGP. See [Figure 4 on page 31](#) for a diagram of the relationships between these components.
- Currently active LSPs—Includes all the LSPs that should originate from the router and their current operational status (up, down, or timeout).

Figure 4: CSPF Computation Process

This section discusses the following topics:

- [How CSPF Selects a Path on page 31](#)
- [CSPF Path Selection Tie-Breaking on page 32](#)
- [Computing CSPF Paths Offline on page 33](#)

## How CSPF Selects a Path

To select a path, CSPF follows certain rules. The rules are as follows:

1. Computes LSPs one at a time, beginning with the highest priority LSP (the one with the lowest setup priority value). Among LSPs of equal priority, CSPF services the LSPs in alphabetical order of the LSP names.
2. Prunes the traffic engineering database of all the links that are not full duplex and do not have sufficient reservable bandwidth.
3. If the LSP configuration includes the **include** statement, prunes all links that do not share any included colors.
4. If the LSP configuration includes the **exclude** statement, prunes all links that contain excluded colors. If the link does not have a color, it is accepted.
5. If several paths have equal cost, chooses the one whose last-hop address is the same as the LSP's destination.
6. If several equal cost paths remain, selects the one with the fewest number of hops.
7. If several equal-cost paths remain, applies the CSPF load-balancing rule configured on the LSP (least fill, most fill, or random).

CSPF finds the shortest path toward the LSP's egress router, taking into account explicit-path constraints. For example, if the path must pass through Router A, two separate SPF computations are performed, one from the ingress router to Router A, the other from Router A to the egress router. All CSPF rules are applied to both computations.

  - [CSPF Path Selection Tie-Breaking on page 32](#)

---

## CSPF Path Selection Tie-Breaking

If more than one path is still available after the CSPF rules ([“How CSPF Selects a Path” on page 31](#)) have been applied, a tie-breaking rule is applied to choose the path for the LSP. The rule used depends on the configuration. There are three tie-breaking rules:

- **Random**—One of the remaining paths is picked at random. This rule tends to place an equal number of LSPs on each link, regardless of the available bandwidth ratio. This is the default behavior.
- **Least fill**—The path with the largest minimum available bandwidth ratio is preferred. This rule tries to equalize the reservation on each link.
- **Most fill**—The path with the smallest minimum available bandwidth ratio is preferred. This rule tries to fill a link before moving on to alternative links.

The following definitions describe how a figure for minimum available bandwidth ratio is derived for the least fill and most fill rules:

- Reservable bandwidth = bandwidth of link x subscription factor of link
- Available bandwidth = reservable bandwidth – (sum of the bandwidths of the LSPs traversing the link)
- Available bandwidth ratio = available bandwidth/reservable bandwidth
- Minimum available bandwidth ratio (for a path) = the smallest available bandwidth ratio of the links in a path

**NOTE:** For the least fill or most fill behaviors to be used, the paths must have their bandwidth (specified using the `bandwidth` statement at the `[edit protocols mpls label-switched-path lsp-name]` hierarchy level) or minimum bandwidth (specified using the `minimum-bandwidth` statement at the `[edit protocols mpls label-switched-path lsp-name auto-bandwidth]` hierarchy level) configured to a value greater than 0. If the bandwidth or minimum bandwidth for the paths is either not configured or configured as 0, the minimum available bandwidth cannot be calculated and the random path selection behavior is used instead.

## Computing CSPF Paths Offline

---

The Junos OS provides online, real-time CSPF computation only; each router performs CSPF calculations independent of the other routers in the network. These calculations are based on currently available topology information—information that is usually recent, but not completely accurate. LSP placements are locally optimized, based on current network status.

To optimize links globally across the network, you can use an offline tool to perform the CSPF calculations and determine the paths for the LSPs. You can create such a tool yourself, or you can modify an existing network design tool to perform these calculations. You should run the tool periodically (daily or weekly) and download the results into the router. An offline tool should take the following into account when performing the optimized calculations:

- All the LSP's requirements
- All link attributes
- Complete network topology

---

## Path Computation for LSPs on an Overloaded Router

---

Setting the overload bit in a router running IS-IS causes it to appear overloaded and prevents it from being used for transit traffic. Any new MPLS LSPs, including RSVP-signaled or LDP-signaled LSPs, are re-routed away from an overloaded router. In the case of RSVP, this behavior applies to both Constrained Shortest Path First (CSPF) and non-CSPF LSPs. However, this behavior does not apply to new or existing bypass LSPs. Bypass LSPs are recalculated only when a different event triggers a path recalculation. For example, if you set the smart optimize timer with the `smart-optimize-timer` statement, the bypass LSP is rerouted away from the overloaded router only after the specified time elapses. Otherwise, the bypass LSP continues to transit the overloaded router.

You cannot establish any new transit LSPs through an overloaded router. However, you can configure ingress and egress LSPs through an overloaded router.

**NOTE:** When you set the overload bit on an IS-IS router, any new LSPs transiting through it are recomputed and re-routed away from it. However, existing CSPF LSPs remain active and are not torn down.

An example of when you might want to establish transit LSPs through an overloaded router is illustrated in [Figure 5 on page 34](#), which shows an aggregation router (Router A) dual-homed on two core routers (Router B and Router C). You want to include the aggregation router in the LSP mesh, but transit LSPs should not pass through it, because it is a less capable router with relatively low-bandwidth uplinks to the core. Certain failure and rerouting scenarios could make it impossible for the aggregation router

to establish some of its LSPs. Consequently, you run the router in a steady state with the overload bit set, but you are still able to establish ingress and egress LSPs through it.

## Computing Backup Paths for LSPs Using Fate Sharing

Fate sharing allows you to create a database of information that CSPF uses to compute one or more backup paths to use in case the primary path becomes unstable. The database describes the relationships between elements of the network, such as routers and links. You can specify one or more elements within a group.

Through fate sharing, you can configure backup paths that minimize the number of shared links and fiber paths with the primary paths as much as possible, to ensure that if a fiber is cut, the minimum amount of data is lost and a path still exists to the destination.

For a backup path to work optimally, it must not share links or physical fiber paths with the primary path, ensuring that a single point of failure will not affect the primary and backup paths simultaneously.

## Using Labeled-Switched Paths to Augment SPF to Compute IGP Shortcuts

Link-state protocols, such as OSPF and IS-IS, use the shortest-path-first (SPF) algorithm to compute the shortest-path tree to all nodes in the network. The results of such computations can be represented by the destination node, next-hop address, and output interface, where the output interface is a physical interface. Label-switched paths (LSPs) can be used to augment the SPF algorithm.

IGP typically performs two independent computations. The first is performed without considering any LSP. The result of the computation is stored in the inet.0 table. This step

is no different from traditional SPF computations and is always performed even if IGP shortcut is disabled.

The second computation is performed considering only LSPs as a logical interface. Each LSP's egress router is considered. The list of destinations whose shortest path traverses the egress router (established during the first computation) is placed in the inet.3 routing table. These destinations are given the egress router of the LSP as a next hop, enabling BGP on the local router to use these LSPs to access BGP next hops beyond the egress router. Normally, BGP can use only LSPs that terminate at the BGP next hop.

As an illustration, begin with a typical SPF tree (see [Figure 6 on page 35](#)).

**Figure 6: Typical SPF Tree, Sourced from Router A**

If an LSP connects Router A to Router D and if IGP shortcuts are enabled on Router A, you might have the SPF tree shown in [Figure 7 on page 35](#).

**Figure 7: Modified SPF Tree, Using LSP A–D as a Shortcut**

Note that Router D is now reachable through LSP A–D.

When computing the shortest path to reach Router D, Router A has two choices:

- Use IGP path A–B–D.
- Use LSP A–D.

Router A decides between the two choices by comparing the IGP metrics for path A–B–D with the LSP metrics for LSP A–D. If the IGP metric is lower, path A–B–D is chosen ([Figure 6 on page 35](#)). This path A–B–D is valid only when node D is not the tail-end of the LSP. If node D is the tail end of the LSP, even if the LSP metric is lower or both IGP and LSP metrics are equal, LSP A–D is used ([Figure 7 on page 35](#)).

Note that Router E is reachable through LSP A–D and Router F will take the IGP path.

## Enabling IGP Shortcuts

IGP shortcuts are supported for both IS-IS and OSPF. A link-state protocol is required for IGP shortcuts. Shortcuts are disabled by default. You can enable IGP shortcuts on a per-router basis; you do not need to enable shortcuts globally. A router's shortcut computation does not depend on another router performing similar computations, and shortcuts performed by other routers are irrelevant.

### Related Documentation

- [Example: Enabling OSPF Traffic Engineering Support](#)
- [Using Labeled-Switched Paths to Augment SPF to Compute IGP Shortcuts on page 34](#)

## LSPs Qualified in IGP Shortcut Computations

Not all LSPs are used in IGP shortcuts. Only those LSPs whose egress point (using the **to** statement) matches the router ID of the egress node are considered. Other LSPs, whose egress point matches the egress node interface address, are ignored in IGP shortcuts.

There are exceptions, however. If an LSP has an alias egress point (using the **install** statement) and it matches certain router IDs, it is included in the shortcut computation as well. If multiple equal metric LSPs destined to the same router ID exist, traffic can load-share among them.

## IGP Shortcut Applications

You can use shortcuts to engineer traffic traveling toward destination nodes that do not support MPLS LSPs. For example, in [“Modified SPF Tree, Using LSP A–D and LSP A–E as Shortcuts” on page 34](#), traffic traveling toward Router F enters LSP A–E. You can control traffic between Router A and Router F by manipulating LSP A–E; you do not need to explicitly set up an LSP between Router A and Router F.

In [Figure 8 on page 36](#), all traffic from Region 1 to Region 2 traverses LSP A–B if IGP shortcuts are enabled on the ingress router (Router A), permitting aggregation of interregional traffic into one LSP. To perform traffic engineering on the interregional traffic, you have to manipulate LSP A-B only, which avoids creating n2 LSPs from all routers in Region 1 to all routers in Region 2 and allows efficient resource controls on the backbone network.

Figure 8: IGP Shortcuts

Shortcuts allow you to deploy LSPs into a network in an incremental, hierarchical fashion. In [Figure 9 on page 37](#), each region can choose to implement traffic engineering LSPs

independently, without requiring cooperation from other regions. Each region can choose to deploy intraregion LSPs to fit the region's bandwidth needs, at the pace appropriate for the region.

**Figure 9: IGP Shortcuts in a Bigger Network**

When intraregion LSPs are in place, interregional traffic automatically traverses the intraregion LSPs as needed, eliminating the need for a full mesh of LSPs between edge routers. For example, traffic from Router A to Router D traverses LSPs A–B, B–C, and C–D.

## IGP Shortcuts and Routing Tables

IGP typically performs two independent computations. The first is performed without considering any LSP. The result of the computation is stored in the inet.0 table. This step is no different from traditional SPF computations and is always performed even if IGP shortcut is disabled.

The second computation is performed considering only LSPs as a logical interface. Each LSP's egress router is considered. The list of destinations whose shortest path traverses the egress router (established during the first computation) is placed in the inet.3 routing table. These destinations are given the egress router of the LSP as a next hop, enabling BGP on the local router to use these LSPs to access BGP next hops beyond the egress router. Normally, BGP can use only LSPs that terminate at the BGP next hop. Note that BGP is the only protocol that uses the inet.3 routing table. Other protocols will not route traffic through these LSPs.

If traffic engineering for IGP and BGP is enabled (see [“IGP and BGP Destinations” on page 41](#)), IGP moves all routes in inet.3 into inet.0, merging all routes while emptying the inet.3 table. The number of routes in inet.0 will be exactly the same as before. Route next-hops can traverse a physical interface, an LSP, or the combination of the two if the metrics are equal.

IGP shortcuts are enabled on a per-node basis. You do not need to coordinate with other nodes.

## IGP Shortcuts and VPNs

You can configure IGP shortcuts for either IS-IS or OSPF. IGP shortcuts allow the IGP to use an LSP as the next hop instead of the IGP route. IGP shortcuts can also be enabled for VPNs by also specifying the **bgp-igp-both-ribs** or **mpls-forwarding** options for the **traffic-engineering** statement at the **[edit protocols mpls]** hierarchy level. VPNs are dependant on routes stored in the inet.3 routing table. The **bgp-igp** option for the **traffic-engineering** statement moves all routes from the inet.3 routing table to the inet.0 routing table and is therefore incompatible with VPNs.

## Advertising LSPs into IGPs

You can configure your IGP to treat an LSP as a link. IGP shortcuts allow only the ingress router of an LSP to use the LSP in its SPF computation. However, other routers on the network do not know of the existence of that LSP, so they cannot use it. This can lead to suboptimal traffic engineering. In addition, only BGP can use an IGP shortcut to an LSP. When you advertise an LSP as a link into the IGP, all traffic can traverse it, and all routers know about it.

As an example, consider the network shown in [Figure 10 on page 38](#).

**Figure 10: SPF Computations with Advertised LSPs**

Assume that Router A is computing a path to Router D. The link between Router E and Router F has a metric of 20; all other links have a metric of 10. Here, the path chosen by Router A is A–B–C–D, which has a metric of 30, instead of A–E–F–D, which has a metric of 40.

If Router E has an LSP to Router D with a metric of 15, you want traffic from Router A to Router D to use the path A–E–D, which has a metric of 25, instead of the path A–B–C–D. However, because Router A does not know about the LSP between Router E and Router D, it cannot route traffic through this path.

For all routers on the network to know about the LSP between Router E and Router D, you need to advertise it. This advertisement announces the LSP as a unidirectional, point-to-point link in the link-state database, and all routers can compute paths using the LSP. The link-state database maintains information about the AS topology and contains information about the router's local state (for example, the router's usable interfaces and reachable neighbors). In [Figure 10 on page 38](#), Router A will see the link from Router E to Router D and route traffic along this lower-metric path.

Because an LSP is announced as a unidirectional link, you might need to configure a reverse LSP (one that starts at the egress router and ends at the ingress router) so that the SPF bidirectionality check succeeds. As a step in the SPF computation, IS-IS considers a link from Router E to Router D. Before IS-IS uses any link, it verifies that there is a link

from Router D to Router E (there is bidirectional connectivity between router E and D). Otherwise, the SPF computation will not use an announced LSP.

When an LSP is advertised to the IGP, the advertising router uses the LSP as the forwarding path for regular routes after installing them in the inet.0 routing table. All packets traversing the router could be forwarded through the LSP. Conversely, IGP shortcuts are used only to forward packets that are following BGP routes.

**NOTE:** Do not configure IGP shortcuts and advertise LSPs to the IGP at the same time.

## IP and MPLS Packets on Aggregated Interfaces

You can send IP and MPLS packets over aggregated interfaces. To the IP or MPLS session, there is a single LSP composed of the aggregated interfaces. Packets sent to an LSP that is part of an aggregated interface are redistributed over the aggregated member interfaces.

Sending IP and MPLS packets over aggregated interfaces has the following benefits:

- **Bandwidth aggregation**—You can increase the number of MPLS packet flows sent over each connection. In MPLS, a set of packets sharing the same label is considered a part of the same flow.
- **Link redundancy**—If a link or a line card failure affects an aggregate member link, the traffic flowing across that link is immediately forwarded across one of the remaining links.

The Junos OS supports aggregated SONET and Ethernet interfaces.

Note that the Junos implementation of IP and MPLS over aggregated interfaces (aggregated Ethernet devices only) complies with IEEE 802.3ad.

For information about how to configure aggregated Ethernet or aggregated SONET interfaces, see *Ethernet Interfaces Feature Guide for Routing Devices* and *Configuring Aggregated SONET/SDH Interfaces*.

## MPLS Applications

In the Junos OS implementation of MPLS, establishing an LSP installs on the ingress router a host route (a 32-bit mask) toward the egress router. The address of the host route is the destination address of the LSP. By default, the route has a preference value of 7, a value that is higher than all routes except direct interface and static routes. The 32-bit mask ensures that the route is more specific (that is, a longer match) than all other

subnet routes. The host routes can be used to traffic-engineer BGP destinations only, or both IGP and BGP destinations.

This section discusses the following topics:

- BGP Destinations on page 40
- IGP and BGP Destinations on page 41
- Selecting a Forwarding LSP Next Hop on page 42

## BGP Destinations

You can configure MPLS to control the paths that traffic takes to destinations outside an AS.

Both IBGP and EBGP take advantage of the LSP host routes without requiring extra configuration. BGP compares the BGP next-hop address with the LSP host route. If a match is found, the packets for the BGP route are label-switched over the LSP. If multiple BGP routes share the same next-hop address, all the BGP routes are mapped to the same LSP route, regardless of which BGP peer the routes are learned from. If the BGP next-hop address does not match an LSP host route, BGP routes continue to be forwarded based on the IGP routes within the routing domain. In general, when both an LSP route and an IGP route exist for the same BGP next-hop address, the one with the lowest preference is chosen.

Figure 11 on page 40 shows an MPLS topology that illustrates how MPLS and LSPs work. This topology consists of a single domain with four routers. The two routers at the edges of the domain, Router 1 and Router 4, are running EBGP to communicate with peers outside the domain and IBGP to communicate between themselves. For intradomain communication, all four routers are running an IGP. Finally, an LSP tunnel exists from Router 1 to Router 4.

Figure 11: MPLS Application Topology

When BGP on Router 1 receives prefixes from Router 4, it must determine how to reach a BGP next-hop address. Typically, when traffic engineering is not enabled, BGP uses IGP routes to determine how to reach next-hop addresses. (See the left side of [Figure 12 on page 41](#).) However, when traffic engineering is enabled, if the BGP next-hop matches the LSP tunnel endpoint (that is, the MPLS egress router), those prefixes enter the LSP tunnel. (To track these prefixes, look at the **Active Route** field in the **show mpls lsp** command output or at the output of the **show route label-switched-path path-name** command.) If the BGP next hop does not match an LSP tunnel endpoint, those prefixes are sent following the IGP's shortest path. (See [Figure 12 on page 41](#).)

**Figure 12: How BGP Determines How to Reach Next-Hop Addresses**

1445

## IGP and BGP Destinations

You can configure MPLS to control the paths that traffic takes to destinations within an AS.

When traffic engineering is for BGP destinations only, the MPLS host routes are installed in the inet.3 routing table (see [Figure 13 on page 44](#)), separate from the routes learned from other routing protocols. Not all inet.3 routes are downloaded into the forwarding table. Packets directly addressed to the egress router do not follow the LSP, which prevents routes learned from LSPs from overriding routes learned from IGP or other sources.

Traffic within a domain, including BGP control traffic between BGP peers, is not affected by LSPs. MPLS affects interdomain traffic only; that is, it affects only those BGP prefixes that are learned from an external domain. MPLS does not disrupt intradomain traffic, so IS-IS or OSPF routes remain undisturbed. If you issue a **ping** or **traceroute** command to any destination within the domain, the **ping** or **traceroute** packets follow the IGP path. However, if you issue a **ping** or **traceroute** command from Router 1 in [Figure 11 on page 40](#) (the LSP ingress router) to a destination outside of the domain, the packets use the LSP tunnel.

When traffic engineering for IGP and BGP destinations is enabled, the MPLS host routes are installed in the inet.0 table (see [Figure 14 on page 45](#)) and downloaded into the forwarding table. Any traffic destined to the egress router could enter the LSP. In effect, it moves all the routes in inet.3 into inet.0, causing the inet.3 table to be emptied.

RSVP packets automatically avoid all MPLS LSPs, including those established by RSVP or LDP. This prevents placing one RSVP session into another LSP, or in other words, nesting one LSP into another.

## Selecting a Forwarding LSP Next Hop

---

If more than one LSP tunnel to a BGP next hop exists, the prefixes learned from the BGP next hop are randomly divided among the LSP tunnels. To control which LSP BGP uses to forward data for a given prefix, use the **install-nexthop** statement in the export policy applied to the forwarding table.

- Related Documentation**

## MPLS and Routing Tables

The IGPs and BGP store their routing information in the inet.0 routing table, the main IP routing table. If the **traffic-engineering bgp** command is configured, thereby allowing only BGP to use MPLS paths for forwarding traffic, MPLS path information is stored in a separate routing table, inet.3. Only BGP accesses the inet.3 routing table. BGP uses both inet.0 and inet.3 to resolve next-hop addresses. If the **traffic-engineering bgp-igp** command is configured, thereby allowing the IGPs to use MPLS paths for forwarding traffic, MPLS path information is stored in the inet.0 routing table. ([Figure 13 on page 44](#) and [Figure 14 on page 45](#) illustrate the routing tables in the two traffic engineering configurations.)

Figure 13: Routing and Forwarding Tables, traffic-engineering bgp

The inet.3 routing table contains the host address of each LSP's egress router. This routing table is used on ingress routers to route packets to the destination egress router. BGP uses the inet.3 routing table on the ingress router to help in resolving next-hop addresses.

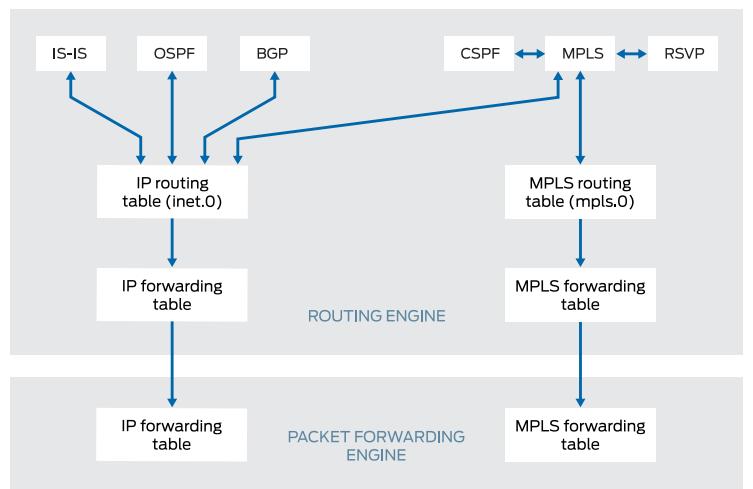

MPLS also maintains an MPLS path routing table (mpls.0), which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP.

Typically, the egress router in an LSP does not consult the mpls.0 routing table. (This router does not need to consult mpls.0 because the penultimate router in the LSP either changes the packet's label to a value of 0 or pops the label.) In either case, the egress router forwards it as an IPv4 packet, consulting the IP routing table, inet.0, to determine how to forward the packet.

When a transit or egress router receives an MPLS packet, information in the MPLS forwarding table is used to determine the next transit router in the LSP or to determine that this router is the egress router.

When BGP resolves a next-hop prefix, it examines both the inet.0 and inet.3 routing tables, seeking the next hop with the lowest preference. If it finds a next-hop entry with an equal preference in both routing tables, BGP prefers the entry in the inet.3 routing table.

Figure 14: Routing and Forwarding Tables, traffic-engineering bgp-igp

Generally, BGP selects next-hop entries in the inet.3 routing table because their preferences are always lower than OSPF and IS-IS next-hop preferences. When you configure LSPs, you can override the default preference for MPLS LSPs, which might alter the next-hop selection process.

When BGP selects a next-hop entry from the inet.3 routing table, it installs that LSP into the forwarding table in the Packet Forwarding Engine, which causes packets destined for that next hop to enter and travel along the LSP. If the LSP is removed or fails, the path is removed from the inet.3 routing table and from the forwarding table, and BGP reverts to using a next hop from the inet.0 routing table.

## MPLS and Traffic Protection

Typically, when an LSP fails, the router immediately upstream from the failure signals the outage to the ingress router. The ingress router calculates a new path to the egress router, establishes the new LSP, and then directs the traffic from the failed path to the new path. This rerouting process can be time-consuming and prone to failure. For example, the outage signals to the ingress router might get lost, or the new path might take too long to come up, resulting in significant packet drops. The Junos OS provides several complementary mechanisms for protecting against LSP failures:

- Standby secondary paths—You can configure primary and secondary paths. You configure secondary paths with the **standby** statement. To activate traffic protection, you need to configure these standby paths only on the ingress router. If the primary path fails, the ingress router immediately reroutes traffic from the failed path to the standby path, thereby eliminating the need to calculate a new route and signal a new path. For information about configuring standby LSPs, see [“Configuring Hot Standby of Secondary Paths for LSPs” on page 297](#).
- Fast reroute—You configure fast reroute on an LSP to minimize the effect of a failure in the LSP. Fast reroute enables a router upstream from the failure to route around the failure quickly to the router downstream of the failure. The upstream router then signals

the outage to the ingress router, thereby maintaining connectivity before a new LSP is established. For a detailed overview of fast reroute, see [“Fast Reroute Overview” on page 46](#). For information about configuring fast reroute, see [“Configuring Fast Reroute” on page 254](#).

- **Link protection**—You can configure link protection to help ensure that traffic traversing a specific interface from one router to another can continue to reach its destination in the event that this interface fails. When link protection is configured for an interface and configured for an LSP that traverses this interface, a bypass LSP is created that handles this traffic if the interface fails. The bypass LSP uses a different interface and path to reach the same destination. For information about configuring link protection, see [“Configuring Link Protection on Interfaces Used by LSPs” on page 536](#).

When standby secondary path, and fast reroute or link protection are configured on an LSP, full traffic protection is enabled. When a failure occurs in an LSP, the router upstream from the failure routes traffic around the failure and notifies the ingress router of the failure. This rerouting keeps the traffic flowing while waiting for the notification to be processed at the ingress router. After receiving the failure notification, the ingress router immediately reroutes the traffic from the patched primary path to the more optimal standby path.

Fast reroute and link protection provide a similar type of traffic protection. Both features provide a quick transfer service and employ a similar design. Fast reroute and link protection are both described in RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*. However, you need to configure only one or the other. Although you can configure both, there is little, if any, benefit in doing so.

## Fast Reroute Overview

Fast reroute provides redundancy for an LSP path. When you enable fast reroute, detours are precomputed and preestablished along the LSP. In case of a network failure on the current LSP path, traffic is quickly routed to one of the detours. [Figure 15 on page 47](#) illustrates an LSP from Router A to Router F, showing the established detours. Each detour is established by an upstream node to avoid the link toward the immediate downstream node and the immediate downstream node itself. Each detour might traverse through one or more label-switched routers (or switches) that are not shown in the figure.

Fast reroute protects traffic against any single point of failure between the ingress and egress routers (or switches). If there are multiple failures along an LSP, fast reroute itself might fail. Also, fast reroute does not protect against failure of the ingress or egress routers.

Figure 15: Detours Established for an LSP Using Fast Reroute

If a node detects that a downstream link has failed (using a link-layer-specific liveness detection mechanism) or that a downstream node has failed (for example, using the RSVP neighbor hello protocol), the node quickly switches the traffic to the detour and, at the same time, signals the ingress router about the link or node failure.

Figure 16 on page 47 illustrates the detour taken when the link between Router B and Router C fails.

Figure 16: Detour After the Link from Router B to Router C Fails

If the network topology is not rich enough (there are not enough routers with sufficient links to other routers), some of the detours might not succeed. For example, the detour from Router A to Router C in Figure 15 on page 47 cannot traverse link A-B and Router B. If such a path is not possible, the detour does not occur.

Note that after the node switches traffic to the detour, it might switch the traffic again to a newly calculated detour soon after. This is because the initial detour route might not be the best route. To make rerouting as fast as possible, the node switches traffic onto the initial detour without first verifying that the detour is valid. Once the switch is made, the node recomputes the detour. If the node determines that the initial detour is still valid, traffic continues to flow over this detour. If the node determines that the initial detour is no longer valid, it again switches the traffic to a newly computed detour.

**NOTE:** If you issue `show` commands after the node has switched traffic to the initial detour, the node might indicate that the traffic is still flowing over the original LSP. This situation is temporary and should correct itself quickly.

The time required for a fast-rerouting detour to take effect depends on two independent time intervals:

- Amount of time to detect that there is a link or node failure—This interval depends greatly on the link layer in use and the nature of the failure. For example, failure detection

on an SONET/SDH link typically is much faster than on a Gigabit Ethernet link, and both are much faster than detection of a router failure.

- Amount of time required to splice the traffic onto the detour—This operation is performed by the Packet Forwarding Engine, which requires little time to splice traffic onto the detour. The time needed can vary depending on the number of LSPs being switched to detours.

Fast reroute is a short-term patch to reduce packet loss. Because detour computation might not reserve adequate bandwidth, the detours might introduce congestion on the alternate links. The ingress router is the only router that is fully aware of LSP policy constraints and, therefore, is the only router able to come up with adequate long-term alternate paths.

Detours are created by use of RSVP and, like all RSVP sessions, they require extra state and overhead in the network. For this reason, each node establishes at most one detour for each LSP that has fast reroute enabled. Creating more than one detour for each LSP increases the overhead, but serves no practical purpose.

To reduce network overhead further, each detour attempts to merge back into the LSP as soon as possible after the failed node or link. If you can consider an LSP that travels through  $n$  router nodes, it is possible to create  $n - 1$  detours. For instance, in [Figure 17 on page 48](#), the detour tries to merge back into the LSP at Router D instead of at Router E or Router F. Merging back into the LSP makes the detour scalability problem more manageable. If topology limitations prevent the detour from quickly merging back into the LSP, detours merge with other detours automatically.

**Figure 17: Detours Merging into Other Detours**

## Detour Merging Process

This section describes the process used by a router to determine which LSP to select when the router receives path messages from different interfaces with identical Session and Sender Template objects. When this occurs, the router needs to merge the path states.

The router employs the following process to determine when and how to merge path states:

- When all the path messages do not include a fast reroute or a detour object, or when the router is the egress of the LSP, no merging is required. The messages are processed according to RSVP traffic engineering.
- Otherwise, the router *must* record the path state in addition to the incoming interface. If the path messages do not share the same outgoing interface and next-hop router, the router considers them to be independent LSPs and does not merge them.
- For all the path messages that share the same outgoing interface and next-hop router, the router uses the following process to select the final LSP:
  - If only one LSP originates from this node, select it as the final LSP.
  - If only one LSP contains a fast reroute object, select it as the final LSP.
  - If there are several LSPs and some of them have a detour object, eliminate those containing a detour object from the final LSP selection process.
  - If several final LSP candidates remain (that is, there are still both detour and protected LSPs), select the LSPs with fast reroute objects.
  - If none of the LSPs have fast reroute objects, select the ones without detour objects. If all the LSPs have detour objects, select them all.
  - Of the remaining LSP candidates, eliminate from consideration those that traverse nodes that other LSPs avoid.
  - If several candidate LSPs still remain, select the one with the shortest explicit route object (ERO) path length. If more than one LSP has the same path length, select one randomly.
- Once the final LSP has been identified, the router must transmit only the path messages that correspond to this LSP. All other LSPs are considered merged at this node.

## Detour Computations

Computing and setting up detours is done independently at each node. On a node, if an LSP has fast reroute enabled and if a downstream link or node can be identified, the router performs a Constrained Shortest Path First (CSPF) computation using the information in the local traffic engineering database. For this reason, detours rely on your IGP supporting traffic engineering extensions. Without the traffic engineering database, detours cannot be established.

CSPF initially attempts to find a path that skips the next downstream node. Attempting to find this path provides protection against downstream failures in either nodes or links. If a node-skipping path is not available, CSPF attempts to find a path on an alternate link to the next downstream node. Attempting to find an alternate link provides protection against downstream failures in links only. Detour computations might not succeed the first time. If a computation fails, the router recomputes detours approximately once every refresh interval until the computation succeeds. The RSVP metric for each detour is set to a value in the range from 10,000 through 19,999.

## Fast Reroute Path Optimization

---

A fast reroute protection path is nondeterministic. The actual protection path of a particular node depends on the history of the LSP and the network topology when the fast reroute path was computed. The lack of deterministic behavior can lead to operational difficulties and poorly optimized paths after multiple link flaps in a network. Even in a small network, after a few link flaps fast reroute paths can traverse an arbitrarily large number of nodes and can remain in that state indefinitely. This is inefficient and makes the network less predictable.

Fast reroute optimization addresses this deficiency. It provides a global path optimization timer, allowing you to optimize all LSPs that have fast reroute enabled and a detour path up and running. The timer value can be varied depending on the expected RE processing load.

The fast reroute optimization algorithm is based on the IGP metric only. As long as the new path's IGP metric is lower than the old path's, the CSPF result is accepted, even if the new path might be more congested (higher bandwidth utilization) or traverses more hops.

In conformance with RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*, when a new path is computed and accepted for fast reroute optimization, the existing detour is destroyed first and then the new detour is established. To prevent traffic loss, detours actively protecting traffic are not optimized.

## On-Demand Packet Loss and Delay Measurement for UHP LSPs Overview

---

This topic describes methods for measuring packet loss, delay, and throughput for point-to-point ultimate hop popping (UHP) label-switched paths (LSPs) in MPLS networks to enable monitoring of network performance.

- [Importance of Measuring Packet Loss and Delay on page 50](#)

### Importance of Measuring Packet Loss and Delay

The rise of bandwidth-consuming applications, such as IPTV and mobile video, coupled with the pressure to minimize the cost per bit and maximize the value per bit, is forcing carriers to transition their transport networks from circuit-based technologies to packet-based technologies. MPLS is a widely successful, connection-oriented packet transport technology that is ideally suited for packet-based transport networks.

With the emergence of new applications on data networks, it is becoming increasingly important for service providers to accurately predict the impact of new application rollouts. Understanding and modelling network performance in the network is especially relevant for deployment of new-world applications to ensure successful implementations. In packet networks, packet loss and delay are two of the most fundamental measures of performance. Their role is even more central when it comes to end-to-end measurements.

The traffic belonging to most of the end-to-end user applications is either loss sensitive (file transfer), delay sensitive (voice or video applications), or both (interactive computing applications). The service-level agreements (SLAs) of service providers depend on the ability to measure and monitor these network performance metrics, as the SLAs are directly or indirectly dependent on the loss and delay the customer traffic experiences in the service provider network.

To ensure compliance to the SLA, service providers need tools to measure and monitor the performance metrics for packet loss, one-way delay and two-way delay, and related metrics, such as delay variation and channel throughput. This measurement capability provides service providers with greater visibility into the performance characteristics of their networks, thereby facilitating planning, troubleshooting, and network performance evaluation.

## Defining Packet Loss, Delay, and Throughput

In packet networks, packet loss and delay are two of the most fundamental measures of performance.

- **Loss**—Packet loss is the failure of one or more transmitted packets to arrive at their destination. Packet loss refers to the packets of data that are dropped by the network to manage congestion.

Data applications are very tolerant to packet loss, as they are generally not time sensitive and can retransmit the packets that were dropped. However, in video conference environments and pure audio communications, such as VoIP, packet loss can create jitter.

- **Delay**—Packet delay (also called latency) is the amount of time it takes for a packet of data to get from one designated point to another, depending on the speed of the transmission medium, such as copper wire, optical fiber, or radio waves, and the delays in transmission by devices along the way, such as routers and modems.

A low latency indicates a high network efficiency.

- **Throughput**—Packet delay measures the amount of time between the start of an action and its completion, whereas throughput is the total number of such actions that occur in a given amount of time.

## Packet Loss and Delay Measurement Mechanisms

Packet delay and loss are two fundamental measures of network performance. Junos OS provides an on-demand mechanism to measure packet loss and delay over associated bidirectional MPLS ultimate hop popping (UHP) label-switched paths (LSPs).

The on-demand delay and packet loss measurement mechanism is initiated using the following CLI commands:

- **monitor mpls loss rsvp**—Performs an on-demand loss measurement for associated bidirectional UHP LSPs.
- **monitor mpls delay rsvp**—Performs an on-demand delay measurement for associated bidirectional UHP LSPs.
- **monitor mpls loss-delay rsvp**—Performs an on-demand combined loss and delay measurement for associated bidirectional UHP LSPs.

For initiating the delay and packet loss measuring mechanism, the desired parameters for measurement, such as the type of measurement and LSP name, need to be entered. On receiving the parameters, a summary of the performance monitoring data is displayed and the mechanism is terminated.

## Packet Loss and Delay Metrics

The following performance metrics are measured using the on-demand packet loss and delay mechanisms:

- Loss measurement (packet and octet)
- Throughput measurement (packet and octet)
- Two-way channel delay
- Round-trip delay
- Inter-packet delay variation (IPDV)

The **monitor mpls loss rsvp** command performs the loss and throughput measurement, and the **monitor mpls delay rsvp** command performs the two-way channel delay, round-trip delay, and IPDV measurements. The **monitor mpls loss-delay rsvp** command performs a combined loss and delay measurement and measures all of the above-mentioned performance metrics simultaneously.

## Packet Loss and Delay Measurement Concepts

The following concepts help to better understand the functionality of packet loss and delay:

- **Querier**—A querier is the ingress provider edge (PE) router, which originates the query message for loss or delay measurement.
- **Responder**—A responder is the egress PE router, which receives and responds to the query messages from a querier.
- **Associated bidirectional LSP**—An associated bidirectional LSP consists of two unidirectional LSPs that are tied together (or associated with each other) through configuration on both of the LSP end points.

The on-demand loss and delay measurement can be carried out only on associated bidirectional UHP LSPs.

- **Generic associated channel (G-Ach)**—The performance monitoring messages for the on-demand loss and delay measurement flow over the MPLS G-Ach. This type of channel supports only in-band responses, and does not provide support for out-of-band or no-response modes.
- **Measurement point (MP)**—MP is the location at which a condition is described for the measurement.

The MP for packet loss on the transmit side is between the switching fabric and the transmit interface. The counter value is stamped in the loss measurement message in the hardware before it is queued for transmission.

The MP for packet loss on the receive side is between the receive interface and the switching fabric. The MP is distributed on the receive side. Furthermore, when the transmit interface is an aggregate interface, the MP is distributed as well.

- **Query rate**—Query rate is the interval between two queries sent for loss and delay measurement.

Because the loss and delay measurement messages originate from the Routing Engine, a high query rate for multiple channels puts a heavy burden on the Routing Engine. The minimum query interval supported is 1 second.

The query rate should be high for 32-bit counters, because the counters might wrap quickly when data traffic rate is very high. The query rate can be low when 64-bit counters are in use at all the four measurement point locations involved in loss measurement. Junos OS supports only 64-bit counters.

- **Traffic class**—By default, loss measurement is supported for the whole channel. Junos OS also supports traffic class scoped packet loss measurement, where counters that maintain data traffic statistics per traffic class have to be created.

Per traffic class counters are not created by default. To configure traffic class scoped loss measurement, include the **traffic-class-statistics** statement at the **[edit protocols mpls statistics]** hierarchy level.

When **traffic-class-statistics** is configured, control packets flowing over the G-Ach are not counted in the transmit and receive counters.

**NOTE:** Enabling and disabling of traffic class statistics results in the resetting of all counters (aggregate counter and per-class counters) for the LSPs.

- **Loss measurement mode**—Junos OS supports the direct-mode of on-demand loss measurement, and does not provide support for the inferred-mode.

Direct loss measurement requires data traffic statistics to be maintained at the ingress and egress of two unidirectional LSPs of the associated bidirectional LSP. When an MX Series router is using only MPCs and MICs, counters to maintain data traffic statistics are created by default at the ingress of all types of LSPs and egress of UHP LSPs.

However, the direct-mode of loss measurement is not fully accurate due to the following reasons:

- Parallel forwarding nature of the hardware.
- Presence of equal cost multipath (ECMP) in the network, such as aggregated Ethernet interfaces, which can result in re-ordering of data packets relative to the loss measurement messages.
- Control packets that do not flow over G-Ach are not counted at the LSP ingress, but are counted at the LSP egress.
- Data traffic re-ordering relative to the loss measurement message when a Diffserv is implemented in the MPLS network and loss measurement scope is the complete channel and not traffic class scoped.

To overcome this limitation, perform traffic class scoped loss measurement when a Diffserv is implemented.

**NOTE:** Direct mode loss measurement is vulnerable to disruption when the ingress or egress interface associated with the LSP changes.

- **Loss measurement synchronization**—The synchronization conditions specified in section 2.9.8 of RFC 6374 do not hold true in the absolute sense. However, as the loss measurement counters are stamped in hardware, the errors introduced due to not satisfying the synchronization conditions are relatively small. These errors need to be quantified.

When the transmit or receive interface of the LSP is an aggregate interface, more errors are introduced as compared to when the interfaces are non-aggregate interfaces. In any case, the loss measurement counters are stamped in hardware, and the error needs to be quantified.

- **Delay measurement accuracy**—When the transmit and receive interfaces reside on different Packet Forwarding Engines, the clock must be synchronized on these Packet Forwarding Engines for two-way delay measurements. This condition holds true for the platform on which the on-demand delay measurement feature is implemented.

When there are aggregate interfaces or ECMP, the delay is measured for only one of the potential paths.

When a combined loss and delay message is used for delay calculation, the accuracy of delay is lower compared to when the delay measurement message is used in some cases, such as when the transmit or receive interface is an aggregate interface.

Delay measurement is always performed on a per-traffic-class basis, and the accuracy of the measurement needs to be quantified after testing.

- **Timestamp format**—Junos OS supports only the IEEE 1588 Precision Time Protocol (PTP) [IEEE1588] format for recording delay measurement messages. Network Time Format (NTP) is not supported.
- **Operations, administration, and maintenance (OAM)**—To indicate that all the OAM messages for MPLS LSPs flow over the MPLS G-Ach, and to enable the MPLS performance monitoring messages to be carried over the MPLS G-Ach, the **oam mpls-tp-mode** statement must be included at the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level.

## Packet Loss and Delay Measurement Functionality

Figure 18 on page 55 illustrates the basic methods used for the bidirectional measurement of packet loss and delay. A bidirectional channel exists between the two routers, Router A and Router B. The temporal reference points – T1, T2, T3, and T4 – are associated with a measurement operation that takes place at Router A. The operation consists of Router A sending a query message to Router B, and Router B sending back a response. Each reference point indicates the point of time at which either the query or the response message is transmitted or received over the channel.

Figure 18: Basic Bidirectional Measurement

In Figure 18 on page 55, Router A can arrange to measure the packet loss over the channel in the forward and reverse directions by sending loss measurement query messages to Router B. Each of the forward and reverse messages contain the count of packets transmitted prior to time T1 over the channel to Router B (A\_TxP).

When the message reaches Router B, two values are appended to the message and the message is reflected back to Router A. The two values are the count of packets received prior to time T2 over the channel from Router A (B\_RxP) and the count of packets transmitted prior to time T3 over the channel to Router A (B\_TxP).

When the response reaches Router A, a fourth value is appended to the message – the count of packets received prior to time T4 over the channel from Router B (A\_RxP).

These four counter values – (A\_TxP), (B\_RxP), (B\_TxP), and (A\_RxP) – enable Router A to compute the desired loss statistics. Because the transmit count at Router A and the receive count at Router B (and vice versa) might not be synchronized at the time of the first message, and to limit the effects of counter wrap, the loss is computed in the form of a delta between the messages.

The transmit loss (A\_TxLoss[n-1,n]) and receive loss (A\_RxLoss[n-1,n]) within the measurement interval marked by the messages LM[n-1] and LM[n] are computed by Router A as follows:

$$A\_TxLoss[n-1,n] = (A\_TxP[n] - A\_TxP[n-1]) - (B\_RxP[n] - B\_RxP[n-1])$$

$$A\_RxLoss[n-1,n] = (B\_TxP[n] - B\_TxP[n-1]) - (A\_RxP[n] - A\_RxP[n-1])$$

The arithmetic is modulo the counter size.

To measure at Router A the delay over the channel to Router B, a delay measurement query message is sent from Router A to Router B containing a timestamp recording the instant at which it is transmitted. In [Figure 18 on page 55](#), the timestamp is recorded in T1.

When the message reaches Router B, a timestamp is added, recording the instant at which it is received (T2). The message can now be reflected from Router B to Router A, with Router B adding its transmit timestamp (T3) and Router A adding its receive timestamp (T4).

These four timestamps – T1, T2, T3, and T4 – enable Router A to compute the one-way delay in each direction, as well as the two-way delay for the channel. The one-way delay computations require that the clocks of Routers A and B be synchronized.

At this point, Router A can compute the two-way channel delay and round-trip delay associated with the channel as follows:

$$\text{Two-way channel delay} = (T4 - T1) - (T3 - T2)$$

$$\text{Round-trip delay} = T4 - T1$$

## Packet Loss and Delay Features

### Supported Features of Packet Loss and Delay

Junos OS supports the following features with on-demand loss and delay measurement:

- Performance monitoring for associated bidirectional MPLS point-to-point UHP LSPs only
- Loss measurement
- Throughput measurement
- Two-way delay measurement (channel delay and round-trip delay)
- Inter-packet delay variation (IPDV)
- Direct-mode loss measurement
- Aggregated Ethernet and aggregated SONET interfaces
- Multichassis support
- 64-bit compatible

### Unsupported Features of Packet Loss and Delay

Junos OS does not support the following on-demand loss and delay measurement functionality:

- Loss and delay measurement for pseudowires (section 2.9.1 of RFC 6374)
- Unidirectional measurement (section 2.6 of RFC 6374)
- Dyadic measurement (section 2.7 of RFC 6374)
- Loss and delay measurement in loopback mode (section 2.8 of RFC 6374)
- Loss and delay measurement to an intermediate node from an LSP endpoint (section 2.9.5 of RFC 6374)
- External post-processing (section 2.9.7 of RFC 6374)
- Inferred-mode loss measurement (section 2.9.8 of RFC 6374)
- Pro-active mode
- Logical systems
- SNMP

## Configuring the Ingress Router for MPLS-Signaled LSPs

---

MPLS-signaled label-switched paths (LSPs) run from a specific ingress router to a specific egress router. For basic MPLS-signaled LSP function, you must configure the ingress router, but do not have to configure any other routers.

To configure signaled LSPs, perform the following tasks on the ingress router:

- [Creating Named Paths on page 60](#)
- [Configuring Alternate Backup Paths Using Fate Sharing on page 62](#)

### Creating Named Paths

To configure signaled LSPs, you must first create one or more named paths on the ingress router. For each path, you can specify some or all transit routers in the path, or you can leave it empty.

Each pathname can contain up to 32 characters and can include letters, digits, periods, and hyphens. The name must be unique within the ingress router. Once a named path is created, you can use the named path with the **primary** or **secondary** statement to configure LSPs at the **[edit protocols mpls label-switched-path *label-path-name*]** hierarchy level. You can specify the same named path on any number of LSPs.

To determine whether an LSP is associated with the primary or secondary path in an RSVP session, issue the **show rsvp session detail** command.

To create an empty path, create a named path by including the following form of the **path** statement. This form of the **path** statement is empty, which means that any path between the ingress and egress routers is accepted. In actuality, the path used tends to be the same path as is followed by destination-based, best-effort traffic.

```
path path-name;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

To create a path in which you specify some or all transit routers in the path, include the following form of the **path** statement, specifying one address for each transit router:

```
path path-name {  
  (address | hostname) <strict | loose>;  
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

In this form of the **path** statement, you specify one or more transit router addresses. Specifying the ingress or egress routers is optional. You can specify the address or

hostname of each transit router, although you do not need to list each transit router if its type is **loose**. Specify the addresses in order, starting with the ingress router (optional) or the first transit router, and continuing sequentially along the path up to the egress router (optional) or the router immediately before the egress router. You need to specify only one address per router hop. If you specify more than one address for the same router, only the first address is used; the additional addresses are ignored and truncated.

For each router address, you specify the type, which can be one of the following:

- **strict**—(Default) The route taken from the previous router to this router is a direct path and cannot include any other routers. If **address** is an interface address, this router also ensures that the incoming interface is the one specified. Ensuring that the incoming interface is the one specified is important when there are parallel links between the previous router and this router. It also ensures that routing can be enforced on a per-link basis.

For strict addresses, you must ensure that the router immediately preceding the router you are configuring has a direct connection to that router. The address can be a loopback interface address, in which case the incoming interface is not checked.

- **loose**—The route taken from the previous router to this router need not be a direct path, can include other routers, and can be received on any interface. The address can be any interface address or the address of the loopback interface.

### Examples: Creating Named Paths

Configure a path, **to-hastings**, to specify the complete strict path from the ingress to the egress routers through 14.1.1.1, 13.1.1.1, 12.1.1.1, and 11.1.1.1, in that order. There cannot be any intermediate routers except the ones specified. However, there can be intermediate routers between 11.1.1.1 and the egress router because the egress router is not specifically listed in the **path** statement. To prevent intermediate routers before egress, configure the egress router as the last router, with a **strict** type.

```
[edit protocols mpls]
path to-hastings {
  14.1.1.1 strict;
  13.1.1.1 strict;
  12.1.1.1 strict;
  11.1.1.1 strict;
}
```

Create a path, **alt-hastings**, to allow any number of intermediate routers between routers 14.1.1.1 and 11.1.1.1. In addition, intermediate routers are permitted between 11.1.1.1 and the egress router.

```
[edit protocols mpls]
path alt-hastings {
  14.1.1.1 strict;
  11.1.1.1 loose;
}
```

## Configuring Alternate Backup Paths Using Fate Sharing

You can create a database of information that Constrained Shortest Path First (CSPF) uses to compute one or more backup paths in case the primary path becomes unstable. The database describes the relationships between elements of the network, such as routers and links. Because these network elements share the same fate, this relationship is called fate sharing.

You can configure backup paths that minimize the number of shared links and fiber paths with the primary paths as much as possible to ensure that, if a fiber is cut, the minimum amount of data is lost and a path still exists to the destination.

For a backup path to work optimally, it must not share links or physical fiber paths with the primary path. This ensures that a single point of failure will not affect the primary and backup paths at the same time.

The following sections describe how to configure fate sharing and how it affects CSPF, and provides a fate sharing configuration example:

- [Configuring Fate Sharing on page 62](#)
- [Implications for CSPF on page 63](#)
- [Implications for CSPF When Fate Sharing with Bypass LSPs on page 64](#)
- [Example: Configuring Fate Sharing on page 64](#)

---

### Configuring Fate Sharing

To configure fate sharing, include the **fate-sharing** statement:

```
fate-sharing {  
  group group-name {  
    cost value;  
    from address <to address>;  
  }  
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Each fate-sharing group must have a name, which can be up to 32 characters long and can contain letters, digits, periods (.) and hyphens (-). You can define up to 512 groups.

Fate-sharing groups contain three types of objects:

- Point-to-point links—Identified by the IP addresses at each end of the link. Unnumbered point-to-point links are typically identified by borrowing IP addresses from other interfaces. Order is not important; **from 1.2.3.4 to 1.2.3.5** and **from 1.2.3.5 to 1.2.3.4** have the same meaning.
- Non-point-to-point links—Include links on a LAN interface (such as Gigabit Ethernet interfaces) or nonbroadcast multiaccess (NBMA) interfaces (such as Asynchronous Transfer Mode [ATM] or Frame Relay). You identify these links by their individual

interface address. For example, if the LAN interface **192.168.200.0/24** has four routers attached to it, each router link is individually identified:

```
from 192.168.200.1; # LAN interface of router 1
from 192.168.200.2; # LAN interface of router 2
from 192.168.200.3; # LAN interface of router 3
from 192.168.200.4; # LAN interface of router 4
```

You can list the addresses in any order.

- A router node—Identified by its configured router ID.

All objects in a group share certain similarities. For example, you can define a group for all fibers that share the same fiber conduit, all optical channels that share the same fiber, all links that connect to the same LAN switch, all equipment that shares the same power source, and so on. All objects are treated as /32 host addresses.

For a group to be meaningful, it should contain at least two objects. You can configure groups with zero or one object; these groups are ignored during processing.

An object can be in any number of groups, and a group can contain any number of objects. Each group has a configurable cost attributed to it, which represents the level of impact this group has on CSPF computations. The higher the cost, the less likely a backup path will share with the primary path any objects in the group. The cost is directly comparable to traffic engineering metrics. By default, the cost is 1. Changing the fate-sharing database does not affect established LSPs until the next reoptimization of CSPF. The fate-sharing database does influence fast-reroute computations.

### Implications for CSPF

When CSPF computes the primary paths of an LSP (or secondary paths when the primary path is not active), it ignores the fate-sharing information. You always want to find the best possible path (least IGP cost) for the primary path.

When CSPF computes a secondary path while the primary path (of the same LSP) is active, the following occurs:

1. CSPF identifies all fate-sharing groups that are associated with the primary path. CSPF does this by identifying all links and nodes that the primary path traverses and compiling group lists that contain at least one of the links or nodes. CSPF ignores the ingress and egress nodes in the search.
2. CSPF checks each link in the traffic engineering database against the compiled group list. If the link is a member of a group, the cost of the link is increased by the cost of the group. If a link is a member of multiple groups, all group costs are added together.
3. CSPF performs the check for every node in the traffic engineering database, except the ingress and egress node. Again, a node can belong to multiple groups, so costs are additive.
4. The router performs regular CSPF computation with the adjusted topology.

### Implications for CSPF When Fate Sharing with Bypass LSPs

---

When fate sharing is enabled with link protection or link-node protection, CSPF operates as follows when calculating the bypass LSP path:

- CSPF identifies the fate-sharing groups that are associated with the primary LSP path. CSPF does this by identifying the immediate downstream link and immediate downstream nodes that the bypass is trying to protect. CSPF compiles group lists that contain the immediate downstream link and immediate downstream nodes.
- CSPF checks each link (from ingress to the immediate downstream node) in the traffic engineering database against the compiled group list. If the link is a member of a group, the cost of the link is increased by the cost of the group.
- CSPF identifies the downstream link that is not in the fate-shared path.

This calculation prevents bypasses from using the same physical link as the primary LSP path when viable alternatives are available.

### Example: Configuring Fate Sharing

---

Configure fate-sharing groups **east** and **west**. Because **west** has no objects, it is ignored during processing.

```
[edit routing-options]
fate-sharing {
  group east {
    cost 20; # Optional, default value is 1
    from 1.2.3.4 to 1.2.3.5; # A point-to-point link
    from 192.168.200.1; # LAN interface
    from 192.168.200.2; # LAN interface
    from 192.168.200.3; # LAN interface
    from 192.168.200.4; # LAN interface
    from 10.168.1.220; # Router ID of a router node
    from 10.168.1.221; # Router ID of a router node
  }
  group west {
    .....
  }
}
```

### Example: Configuring an Explicit-Path LSP

---

On the ingress router, create an explicit-path LSP, and specify the transit routers between the ingress and egress routers. In this configuration, no constrained-path computation is performed. For the primary path, all intermediate hops are strictly specified so that its route cannot change. The secondary path must travel through router 14.1.1.1 first, then take whatever route is available to reach the destination. The remaining route taken by the secondary path is typically the shortest path computed by the IGP.

```
[edit]
interfaces {
  so-0/0/0 {
    unit 0 {
```

```

        family mpls;
    }
}
protocols {
    rsvp {
        interface so-0/0/0;
    }
    mpls {
        path to-hastings {
            14.1.1.1 strict;
            13.1.1.1 strict;
            12.1.1.1 strict;
            11.1.1.1 strict;
        }
        path alt-hastings {
            14.1.1.1 strict;
            11.1.1.1 loose; # Any IGP route is acceptable
        }
        label-switched-path hastings {
            to 11.1.1.1;
            hop-limit 32;
            bandwidth 10m; # Reserve 10 Mbps
            no-cspf; # do not perform constrained-path computation
            primary to-hastings;
            secondary alt-hastings;
        }
    }
    interface so-0/0/0;
}
}

```

### Example: Configuring a Constrained-Path LSP for Which Junos OS Makes All Forwarding Decisions

On the ingress router, create a constrained-path LSP in which the Junos OS makes all the forwarding decisions. When the LSP is successfully set up, a route toward 10.1.1.1/32 is installed in the inet.3 table so that all BGP routes with matching BGP next-hop addresses can be forwarded through the LSP.

```

[edit]
interfaces {
    so-0/0/0 {
        unit 0 {
            family mpls;
        }
    }
}
protocols {
    rsvp {
        interface so-0/0/0;
    }
    mpls {
        label-switched-path to-hastings {
            to 10.1.1.1;
        }
    }
}

```

```
        interface so-0/0/0;  
    }  
}
```

---

### Example: Configuring a Constrained-Path LSP for Which Junos OS Makes Most Forwarding Decisions and Considers Hop Constraints

---

On the ingress router, create a constrained-path LSP in which the Junos OS makes most of the forwarding decisions, taking into account the hop constraints listed in the **path** statements. The LSP is adaptive so that no bandwidth double-counting occurs on links shared by primary and secondary paths. To acquire the necessary link bandwidth, this LSP is allowed to preempt lower priority sessions. Finally, this path always keeps the secondary path in hot-standby state for quick failover.

```
[edit protocols]  
mpls {  
  path to-hastings {  
    14.1.1.1 loose;  
  }  
  path alt-hastings {  
    12.1.1.1 loose;  
    11.1.1.1 strict;  
  }  
  label-switched-path hastings {  
    to 11.1.1.1;  
    bandwidth 10m; # Reserve 10 Mbps  
    priority 0 0; # Preemptive, but not preemptable  
    adaptive; # Set adaptivity  
    primary to-hastings;  
    secondary alt-hastings {  
      standby;  
      bandwidth 1m; # Reserve only 1 Mbps for the secondary path  
    }  
  }  
  interface all;  
}
```

---

### Example: Configuring a Constrained-Path LSP for Which Junos OS Makes Most Forwarding Decisions and the Secondary Path Is Explicit

---

On the ingress router, create a constrained-path LSP in which the Junos OS makes most of the forwarding decisions for the primary path, subject to constraints of the path **to-hastings**, and in which the secondary path is an explicit path. The primary path must transit green or yellow links and must stay away from red links. The primary path is periodically recomputed and reoptimized. Finally, this path always keeps the secondary path in hot-standby state for quick failover.

When the LSP is up—either because the primary or secondary path is up, or because both paths are up—the prefix 16.0.0.0/8 is installed in the inet.3 table so that all BGP routes whose BGP next hop falls within that range can use the LSP. Also, the prefix 17/8 is installed in the inet.0 table so that BGP can resolve only its next hop through that prefix. The route also can be reached with the **traceroute** or **ping** command. These two routes are in addition to the 11.1.1.1/32 route.

```

[edit protocols]
mpls {
  admin-groups {
    green 1;
    yellow 2;
    red 3;
  }
  path to-hastings {
    14.1.1.1 loose;
  }
  path alt-hastings {
    14.1.1.1 strict;
    13.1.1.1 strict;
    12.1.1.1 strict;
    11.1.1.1 strict;
  }
  label-switched-path hastings {
    to 11.1.1.1;
    bandwidth 100m;
    install 16.0.0.0/8; # in inet.3; cannot use to traceroute or ping
    install 17.0.0.0/8 active; # installed in inet.0; can use to traceroute or ping
    primary to-hastings {
      admin-group { # further constraints for path computation
        include-all [ green yellow ];
        exclude red;
      }
      optimize-timer 3600; # reoptimize every hour
    }
    secondary alt-hastings {
      standby;
      no-cspf; # do not perform constrained-path computation
    }
  }
}
interface all;

```

## Abstract Hops For MPLS LSPs Overview

An abstract hop is a logical combination of the existing traffic engineering constraints, such as admin groups, extended admin groups, and Shared Risk Link Group (SRLG), along with the ordering property of real hops, resulting in a user-defined group or cluster of routers that can be used as constraint for setting up an MPLS LSP. Abstract hops overcome the limitations of existing path constraint specifications and provide several benefits to the traffic engineering capabilities of MPLS.

- [Understanding Abstract Hops on page 67](#)
- [Benefits of Using Abstract Hops on page 68](#)
- [Junos Implementation of Abstract Hops on page 70](#)

## Understanding Abstract Hops

The path constraint for setting up of an MPLS label-switched path (LSP) can either be specified as individual routers in the form of real hops, or as a set of routers by way of administrative group or color specification. When a path constraint uses real hops (strict

or loose), the LSP is set up along a specified sequence of routers (for example, R1, R2, ...Rn). When a path constraint uses administrative group or color specification, a group of routers that meet the specified criteria is used to set up the LSP (for example, Ga, Gb, ...Gn), and unlike real hop constraint, there is no sequence among the different groups of routers used in the constraint.

The drawback of real hop constraint is that in a failure scenario, if any of the router hops goes down or the bandwidth utilization of the attached interface gets saturated, the path goes down (or relies on local/end to end protection). Setting up an LSP with the real hop constraint would not be possible, and although other alternative routers may be available to recover or set up the LSP, the LSP remains down until the operator configures another router hop sequence as the path constraint to bring the path up again or to disengage the protection path.

The administrative group or color specification constraints overcome this limitation of real hop constraint to a certain extent. Here, when one of the routers in the group goes down or has its link capacity saturated, setting up of the LSP is not affected. This is because the next hop router to be used in the path constraint is not picked beforehand, and the LSP is set up along other routers that have the same administrative group or color. However, the drawback with router group constraint is that a sequence cannot be specified among the hop constraints.

Abstract hops overcome these drawbacks, by logically combining the existing traffic engineering constraints, such as admin groups, extended admin groups, and Shared Risk Link Group (SRLG) along with the ordering property of real hops, resulting in a capability to define sequenced set of routers as path constraint. As a result, when a sequence of abstract hops is used in a path constraint, ordering is achieved among the groups of routers that meet a logical combination of link or node attributes called constituent attributes.

A path can use a combination of real and abstract hops as constraints. When using abstract hops, instead of specifying a sequence of routers (R1, R2, ...Rn) as with real hops, a sequence set of router groups or abstract hops (G1, G2...Gn) is specified as path constraint. Each specified router group, Gi for example, consists of some user defined set of routers - R1, R2, Rj...Rn. When one of the routers in the group goes down, say Router Rj in group Gi, another router, say Router Rk, from the same group Gi is picked up by path computation to replace the router that went down (that is, Router Rj). This is because the path constraint is sequenced and has to go through a sequence of abstract hops, instead of a sequence of individual routers.

## Benefits of Using Abstract Hops

Abstract hops are user defined router groups. Similar to real hop constraints that use a sequence of individual routers, a sequence of abstract hops can be used for setting up a label-switched path (LSP). This provides resiliency to sequenced path constraints. The other benefits of using abstract hops include:

- [Specifying a Sequence of Constraint Combinations on page 69](#)
- [Avoiding New Network Configuration on Transit Nodes on page 69](#)
- [Combining Centralized and Distributed Path Computation Paradigms on page 69](#)

### Specifying a Sequence of Constraint Combinations

---

Currently, it is possible to specify a path that can go through links that satisfy multiple attributes. Such a path constraint is called a compound constraint combination; for example, a constraint (Ci) that includes low latency links of green color and also excludes SRLG north.

However, there is no support for specifying a path with a sequence of compound constraint combinations. For example, a sequenced constraint (C1, C2, Ci, ...Cn) that includes low latency green links, no latency blue links, and then low latency red links.

The need for such a sequenced compound constraint combination arises when there is a requirement to establish paths through a sequence of geographical regions with a different link affinity (attributes) requirement in each region. Abstract hops meet this requirement by allowing computing nodes to map each constraint combination (Ci, for example) with the user-defined group of routers, that is the abstract hops.

### Avoiding New Network Configuration on Transit Nodes

---

With current path constraint specification capabilities, it is possible to include or exclude links of certain attributes along an entire path; for example, excluding SRLG west from a path. However, there is no support to either conditionally exclude or include attributes, or to apply different exclude or include attributes in different parts of the path; for example, excluding SRLG west only when traversing red links.

As a workaround, a new admin group can be created to identify all such red links that do not have SRLG west, and configure all the relevant links appropriately with that admin group. The drawback of this approach is that configuration changes is required throughout the network to reflect the new admin-group membership.

Instead, by using abstract hops, the configuration changes can be contained on the ingress router only. At the ingress router, the constraint combination is mapped to the abstract hop, thereby meeting the above-mentioned requirement without making any new configuration on the transit nodes.

### Combining Centralized and Distributed Path Computation Paradigms

---

Traffic engineering of MPLS paths can be achieved by distributed computing or with a centralized controller for computing paths. A combination of both the computation types is called the hybrid computation paradigm. The key feature of the hybrid computation approach is the ability of the centralized controller [referred to as a Path Computation Element (PCE)] to loosely specify the path computation directives, per path, to the ingress router [referred to as a Path Computation Client (PCC)], and the ability of the ingress router to use it as input for path computation.

A sequence of abstract hops serves the purpose of acting as the guideline from the centralized controller. Abstract hops provide the flexibility to the controller to weave into the path constraint and attributes. This also enables the controller to build in the element of sequence in the constraint. The controller does not have to specify the very hops the path needs to take, leaving room for the ingress router to act within the limits of the guideline or directive.

[Table 3 on page 70](#) lists the key features of the hybrid computation paradigm and provides a comparison of this approach with the current path computation methods.

**Table 3: Hybrid Computation for Abstract Hops**

Features	Distributed Constrained Shortest Path First	Centralized Constrained Shortest Path First	Hybrid Constrained Shortest Path First
React to frequent changes in a large network	Yes		Yes
Sophisticated path computation with global view		Yes	Yes
Incorporation of business logic in path computation		Yes	Yes
Resilience (no single point of failure)	Yes		Yes
Predictability		Yes	Yes
React to network load in (close to) real-time	Yes		Yes
Field tested (versus early adoption)	Yes		Yes

## Junos Implementation of Abstract Hops

The order-aware abstract hops is introduced in Junos OS Release 17.1. The following sections describe the implementation of abstract hops in Junos OS:

- [Defining Abstract Hops on page 70](#)
- [Using Abstract Hops in Path Constraint on page 74](#)
- [Path Computation and Backtracking on page 77](#)
- [Sample Backtracking on page 77](#)

### Defining Abstract Hops

An abstract hop is a group of routers that users can define. The user can control which routers to include in the group by defining a logical combination of heterogeneous link attributes or constraints called constituent attributes. The routers whose emanating links satisfy the defined constituent attributes make it into the group of routers representing the abstract hop.

The mapping of constituent attributes with the abstract hop is local to the computing node or the ingress of the LSP being setup. As a result, abstract hops do not have associated interior gateway protocol updates or signaling protocol extensions, and implementing abstract hops in a network does not require new configuration on the transit nodes.

The logical combination of constituent attributes is enabled with the **constituent-list** configuration statement using the **constituent-any-list** and **constituent-all-list** properties. The constituent attributes in the constituent list (any or all) can be of the same or of different type.

- **constituent-any-list**—List of constituent attributes where any one of the defined constituent attributes should be met to satisfy the overall constituent list criteria.
- **constituent-all-list**—List of constituent attributes where all of the defined constituent attributes have to be met to satisfy the overall constituent list criteria.

Abstract hops definition allows one level of nesting, where the abstract hop can be defined as a list of one or more of such constituent lists. To do this, the abstract hop itself is used as a **OR-list** or **AND-list**, where each element is a **constituent-all-list** or a **constituent-any-list**. For example, ( ( A AND B ) OR ( C AND D ) ) and ( ( A OR B ) AND ( C AND D ) ).

- **OR-list**—At least one of the constituent-all-list or constituent-any-list in the abstract hop definition should be satisfied by a link or node to be part of the abstract hop.
- **AND-list**—All of the constituent-all-list or constituent-any-list in the abstract hop definition should be satisfied by the link or node to be part of the abstract hop.

#### **Sample Abstract Hop Definition**

Taking as an example, the definition of abstract hops hopA and hopB is as follows:

Abstract hops hopA and hopB should include all routers whose emanating links satisfy the logical combination of the following link attributes, respectively:

- **hopA**—((Admin group red && Srlg south) || (Admin group green || Srlg north)), where:
  - *Admin group red* and *Srlg south* belong to include-all constituent list (listA1, in this example).
  - *Admin group green* and *Srlg north* belong to include-any constituent list (listA2, in this example).
  - || is the OR operator.
- **hopB**—((Extended admin group g1 || Srlg south) && ! (Admin group blue && srlg-west)), where:
  - *Extended admin group g1* and *Srlg south* belong to the include-any constituent list (listB1, in this example).
  - *Admin group blue* and *srlg-west* belong to the exclude-all constituent list (listB2, in this example).
  - && ! is the AND operator.

The configuration for abstract hops hopA and hopB is as follows:

- **hopA configuration**  
[edit protocols mpls]

```
Constituent-list listA1 {
  Admin-group red;
  Srlg south;
}
Constituent-list listA2 {
  Admin-group green;
  Srlg north;
}
Abstract-hop hopA{
  Operator OR;
  Constituent-list listA1 include-all-list;
  Constituent-list listA2 include-any-list;
}
```

- **hopB configuration**

```
[edit protocols mpls]
Constituent-list listB1 {
  Extended Admin-group g1;
  Srlg south;
}
Constituent-list listB2 {
  Admin-group blue;
  Srlg west;
}
Abstract-hop hopB{
  Operator AND;
  Constituent-list listB1 include-any-list;
  Constituent-list listB2 exclude-all-list;
}
```

### Verifying abstract hop configuration

The **show mpls abstract hop membership <abstract hop name>** command is used to check members of an abstract hop. The command output provides the abstract hop to traffic engineering database node mapping.

```
user@host> show mpls abstract-hop-membership
```

```
Abstract hop: hop1
  Credibility: 0
Address: 128.102.165.105
Address: 128.102.166.237
Address: 128.102.168.0
Address: 128.102.173.123
```

```
Abstract hop: hop2

Abstract hop hopA is for low latency AND SRLG west, and abstract hop hopB is for excluding SRLG west. [Figure 19 on page 74](#) displays the ingress view of these abstract hops.

Figure 19: Ingress View of Abstract Hops

### Using Abstract Hops in Path Constraint

The user associates a unique identifier with each abstract hop definition. This identifier is used for referring to the abstract hop in the path constraint. A sequence of abstract hops can be specified as path constraint, similar to the usage of real IP hops. The path constraint could also be a sequence of abstract hops interleaved by real IP hops.

Using abstract hops or real hops in a path constraint requires more than one Constrained Shortest Path First pass to the destination, typically one pass per hop. When real hops are provided as path constraint, the constraint computation involves as many passes as the number of hops in the path constraint, where each pass ends on reaching a hop in the constraint list. The starting point for each pass is the destination of the previous pass, with the first pass using the ingress router as the start.

On the other hand, when path constraint uses strict or loose abstract hops, constraint computation comprises of passes where each pass is to process the subsequent abstract hop in the constraint list. In such a case, more than one node qualifies to be the destination for the pass. The set of nodes is called the viable router set for the pass.

An abstract hop traverses member nodes by using the following:

- Links that satisfy the logical combination of defined constituent attributes
- Any kind of links

The means of abstract hops traversing the member nodes is controlled by the use of the abstract hop qualifiers—strict, loose, and loose-link—in defining the path constraint. Taking for example, abstract hop A is processed differently with different qualifiers.

- **Strict**—After the last processed hop in the constraint list, the path traverses only links or nodes having membership of abstract hop A, before reaching a node with A's membership that is a feasible starting point for processing the next abstract hop.
- **Loose**—After the last processed hop in the constraint list, the path can traverse any real nodes that do not have abstract hop membership of A, before reaching a node with abstract hop membership A, that is a feasible starting point for processing the next abstract hop.

- **Loose-link**—After the last processed hop in the constraint list, the path can traverse any real nodes that do not have abstract hop membership of A, before reaching a node with abstract hop membership A, that is a feasible starting point for processing the next abstract hop. But the path should have traversed at least one link of abstract hop A membership in the course of the same.

In other words the abstract hop of type loose-link is said to be processed only if any of the viable routers is reached in constraint through a link of associated abstract hop membership.

### Sample Abstract Hops Specification

Table 4 on page 75 provides sample use case for using abstract hops in path constraints.

**Table 4: Using Abstract Hops in Path Constraints**

Purpose of Path Constraint	Abstract Hop Qualifier	Configuration	Viable Router Set	Affinity
Traverse nodes that are members of hopA taking only links that satisfy hopA.	Strict	<pre>[edit protocols mpls] Path path_hopA_s {   hopA abstract strict; }</pre>	All members of abstract hopA. That is, A1, A2...An.	hopA (Pick only links that satisfy abstract hopA).
Traverse nodes that are members of hopA but not necessarily links that satisfy hopA	Loose	<pre>[edit protocols mpls] Path path_hopA_l {   hopA abstract loose; }</pre>	All members of abstract hopA. That is, A1, A2...An.	None (Any kind of links).
Traverse nodes that are members of hopA by taking at least one link that satisfies hopA.	Loose-link  <b>NOTE:</b> The loose-link qualifier is viewed as loose followed by strict for the same abstract hop. In other words, hopA loose-link is the same as hopA loose and hopA strict.	<pre>[edit protocols mpls] Path path_hopA_ll {   hopA abstract loose-link; }</pre>	In this case, there are two constraint passes associated with hopA in the path constraint. The viable router set for both passes is:  All members of abstract hopA. That is, A1, A2...An.  <b>NOTE:</b> During path computation, a router is traversed only once.	In this case, there are two constraint passes associated with hopA in the path constraint. The affinity for the two passes is:  <ul style="list-style-type: none"> <li>• Pass 1—None (Any kind of links).</li> <li>• Pass 2—hopA (Pick only links that satisfy abstract hopA).</li> </ul>

Table 4: Using Abstract Hops in Path Constraints (*continued*)

Purpose of Path Constraint	Abstract Hop Qualifier	Configuration	Viable Router Set	Affinity
Traverse nodes that are members of hopA, taking only links that satisfy hopA, followed by nodes that are members of hopB taking only links that satisfy hopB.	Strict	<pre>[edit protocols mpls] Path path_hopA_hopB_s {   hopA abstract strict;   hopB abstract strict; }</pre>	<ul style="list-style-type: none"> <li>hopA—Intersection of member set of hopA and hopB.</li> <li><b>NOTE:</b> When an abstract hop is followed by a strict abstract hop, the intersection of the two member sets is considered as viable router set.</li> <li>hopB—All members of abstract hopB. That is, B1, B2...Bn.</li> </ul>	<ul style="list-style-type: none"> <li>hopA—hopA (Pick only links that satisfy abstract hopA).</li> <li>hopB—hopB (Pick only links that satisfy abstract hopB).</li> </ul>
Traverse nodes that are members of hopA taking only links that satisfy hopA, followed by nodes that are members of hopB taking any kind of links.	Strict and loose	<pre>[edit protocols mpls] Path path_hopA_s_hopB_l {   hopA abstract strict;   hopB abstract loose; }</pre>	<ul style="list-style-type: none"> <li>hopA—All members of abstract hopA. That is, A1, A2...An.</li> <li>hopB—All members of abstract hopB. That is, B1, B2...Bn.</li> </ul>	<ul style="list-style-type: none"> <li>hopA—hopA (Pick only links that satisfy abstract hopA).</li> <li>hopB—None (Pick any links).</li> </ul>
Traverse nodes that are members of hopA by taking any kinds of links, followed by nodes that are members of hopB taking any kind of links.	Loose	<pre>[edit protocols mpls] Path path_hopA_l_hopB_l {   hopA abstract loose;   hopB abstract loose; }</pre>	<ul style="list-style-type: none"> <li>hopA—All members of abstract hopA. That is, A1, A2...An.</li> <li>hopB—All members of abstract hopB. That is, B1, B2...Bn.</li> </ul>	None (pick any links).
Traverse nodes that are members of hopA by taking any kinds of links, followed by nodes that are members of hopB taking only links that satisfy hopB.	Loose and strict	<pre>[edit protocols mpls] Path path_hopA_l_hopB_s {   hopA abstract loose;   hopB abstract strict; }</pre>	<ul style="list-style-type: none"> <li>hopA—Intersection of the members of hopA and hopB. When an abstract hop is followed by a strict abstract hop, the intersection of the two member sets is considered as viable router set.</li> <li>hopB—All members of abstract hopB. That is, B1, B2...Bn.</li> </ul>	<ul style="list-style-type: none"> <li>hopA—None (pick any links).</li> <li>hopB—hopB (Pick only links that satisfy abstract hopB).</li> </ul>

Figure 20 on page 77 displays path constraints for abstract hops hopA, hopB, and hopC with loose, strict, and loose abstract hop qualifiers, respectively.

Figure 20: Sample Path Constraints for Abstract Hops

The Constrained Shortest Path First passes for the abstract hops are as follows:

- Pass 1 associated with hopA
  - Viable routers—Routers R1 and R2 (Intersection of hopA and hopB, as hopB is a strict abstract hop).
  - Affinity—None (as hopA is loose).
- Pass 2 associated with hopB
  - Viable routers—Routers R1, R2, R3, and R4
  - Affinity—Pick only hopB compliant links (as hopB is a strict abstract hop).
- Pass 3 associated with hopC
  - Viable routers—Routers R5, R6, R7, and the egress router.
  - Affinity—None (as hopC is a loose abstract hop).

### Path Computation and Backtracking

In each Constrained Shortest Path First pass, when the nearest router from viable router set is reached using links satisfying affinity figured for the pass, the abstract hop associated with the pass is said to be processed. The viable router thus reached serves as the start for the next constraint pass. If any constraint pass fails, and it is not the one with the ingress router as start, then the pass is backtracked to the previous pass and the process is repeated.

### Sample Backtracking

When a Constrained Shortest Path First pass  $p$  (other than the first one) fails, the exit router of the previous pass ( $p-1$ ) that served as start for the current pass  $p$  is disqualified in the viable router set of the previous pass ( $p-1$ ). Then the previous pass ( $p-1$ ) is re-executed to find the next best exit router or destination for the pass  $p-1$  from the viable router set.

The router thus determined serves as the new start router for the pass  $p$ . This procedure is repeated as long as there are failures and there are viable routers that are not explored.

The **show mpls lsp abstract-hop-computation name *lsp-name*** command provides the various constraint passes involved per LSP and the qualifying exit routers for each pass. The command output also gives the affinity per pass, and shows the current start router chosen for the pass. For each viable router, the state of backtracking is displayed, where it can either be valid or disqualified.

```

## Improving Traffic Engineering Database Accuracy with RSVP PathErr Messages

---

An essential element of RSVP-based traffic engineering is the traffic engineering database. The traffic engineering database contains a complete list of all network nodes and links participating in traffic engineering, and a set of attributes each of those links can hold. (For more information about the traffic engineering database, see [“Constrained-Path LSP Computation” on page 30](#).) One of the most important link attributes is bandwidth.

Bandwidth availability on links changes quickly as RSVP LSPs are established and terminated. It is likely that the traffic engineering database will develop inconsistencies relative to the real network. These inconsistencies cannot be fixed by increasing the rate of IGP updates.

Link availability can share the same inconsistency problem. A link that becomes unavailable can break all existing RSVP LSPs. However, its unavailability might not readily be known by the network.

When you configure the **rsvp-error-hold-time** statement, a source node (ingress of an RSVP LSP) learns from the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes. Information from the PathErr messages is incorporated into subsequent LSP computations, which can improve the accuracy and speed of LSP setup. Some PathErr messages are also used to update traffic engineering database bandwidth information, reducing inconsistencies between the traffic engineering database and the network.

You can control the frequency of IGP updates by using the **update-threshold** statement. See [“Configuring the RSVP Update Threshold on an Interface” on page 506](#).

This section discusses the following topics:

- [PathErr Messages on page 79](#)
- [Identifying the Problem Link on page 80](#)
- [Configuring the Router to Improve Traffic Engineering Database Accuracy on page 80](#)

## PathErr Messages

PathErr messages report a wide variety of problems by means of different code and subcode numbers. You can find a complete list of these PathErr messages in RFC 2205, *Resource Reservation Protocol (RSVP), Version 1, Functional Specification* and RFC 3209, *RSVP-TE: Extensions to RSVP for LSP Tunnels*.

When you configure the **rsvp-error-hold-time** statement, two categories of PathErr messages, which specifically represent link failures, are examined:

- Link bandwidth is low for this LSP: Requested bandwidth unavailable—code 1, subcode 2

This type of PathErr message represents a global problem that affects all LSPs transiting the link. They indicate that the actual link bandwidth is lower than that required by the LSP, and that it is likely that the bandwidth information in the traffic engineering database is an overestimate.

When this type of error is received, the available link bandwidth is reduced in the local traffic engineering database, affecting all future LSP computations.

- Link unavailable for this LSP:
  - Admission Control failure—code 1, any subcode except 2
  - Policy Control failures—code 2
  - Service Preempted—code 12
  - Routing problem—no route available toward destination—code 24, subcode 5

These types of PathErr messages are generally pertinent to the specified LSP. The failure of this LSP does not necessarily imply that other LSPs could also fail. These errors can indicate maximum transfer unit (MTU) problems, service preemption (either manually initiated by the operator or by another LSP with a higher priority), that a next-hop link is down, that a next-hop neighbor is down, or service rejection because of policy considerations. It is best to route this particular LSP away from the link.

## Identifying the Problem Link

Each PathErr message includes the sender's IP address. This information is propagated unchanged toward the ingress router. A lookup in the traffic engineering database can identify the node that originated the PathErr message.

Each PathErr message carries enough information to identify the RSVP session that triggered the message. If this is a transit router, it simply forwards the message. If this router is the ingress router (for this RSVP session), it has the complete list of all nodes and links the session should traverse. Coupled with the originating node information, the link can be uniquely identified.

## Configuring the Router to Improve Traffic Engineering Database Accuracy

To improve the accuracy of the traffic engineering database, configure the **rsvp-error-hold-time** statement. When this statement is configured, a source node (ingress of an RSVP LSP) learns from the failures of its LSP by monitoring PathErr messages transmitted from downstream nodes. Information from the PathErr messages is incorporated into subsequent LSP computations, which can improve the accuracy and speed of LSP setup. Some PathErr messages also are used to update traffic engineering database bandwidth information, reducing inconsistencies between the traffic engineering database and the network.

To configure how long MPLS should remember RSVP PathErr messages and consider them in CSPF computation, include the **rsvp-error-hold-time** statement:

```
rsvp-error-hold-time seconds;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

The time can be a value from 1 to 240 seconds. The default is 25 seconds. Configuring a value of 0 disables the monitoring of PathErr messages.

## Configuring MPLS-Signaled LSPs to Use GRE Tunnels

---

MPLS LSPs can use generic routing encapsulation (GRE) tunnels to cross routing areas, autonomous systems, and ISPs. Bridging MPLS LSPs over an intervening IP domain is possible without disrupting the outlying MPLS domain.

LSPs can reach any destination that the GRE tunnels can reach. MPLS applications can be deployed without requiring all transit nodes to support MPLS, or requiring all transit nodes to support the same label distribution protocols (LDP or RSVP). If you use CSPF, you must configure OSPF or IS-IS through the GRE tunnel. Traffic engineering is not supported over GRE tunnels; for example, you cannot reserve bandwidth or set priority or preemption.

**NOTE:** Use the `no-control word` statement to disable the control word when the topology uses GRE as the connection mechanism between provider edge routers and one of the provider edge routers is an M Series Multiservice Edge Router.

For more information about GRE tunnels, see the *Junos OS Services Interfaces Library for Routing Devices*.

## Example: Configuring MPLS-Signaled LSPs to Use GRE Tunnels

To configure MPLS over GRE tunnels:

1. Enable **family mpls** under the GRE interface configuration:

```
[edit interfaces]
interface gr-1/2/0 {
  unit 0 {
    tunnel {
      source 192.168.1.1;
      destination 192.168.1.2;
    }
    family inet {
      address 5.1.1.1/30;
    }
    family iso;
    family mpls;
  }
}
```

2. Enable RSVP and MPLS over the GRE tunnel:

```
[edit protocols]
rsvp {
  interface gr-1/2/0.0;
}
mpls {
  ...
  interface gr-1/2/0.0;
}
```

3. Configure LSPs to travel through the GRE tunnel endpoint address:

```
[edit protocols]
mpls {
  label-switched-path gre-tunnel {
    to 5.1.1.2;
    ...
  }
}
```

Standard LSP configuration options apply. If the routing table specifies that a particular route will traverse a GRE tunnel, the RSVP packets will traverse the tunnel as well.

## Example: Tunneling IPv6 Traffic over MPLS IPv4 Networks

---

This example shows how to configure the Junos OS to tunnel IPv6 over an MPLS-based IPv4 network. External BGP (EBGP) is used between the customer edge (CE) and provider edge (PE) devices. The remote CE devices have different AS numbers for loop detection.

- [Requirements on page 82](#)
- [Overview on page 82](#)
- [Configuration on page 85](#)
- [Verification on page 90](#)

### Requirements

No special configuration beyond device initialization is required before you configure this example.

### Overview

Detailed information about the Juniper Networks implementation of IPv6 over MPLS is described in the following Internet drafts:

- Internet draft draft-ietf-l3vpn-bgp-ipv6-07.txt, *BGP-MPLS IP VPN extension for IPv6 VPN* (expires January 2006)
- Internet draft draft-ooms-v6ops-bgp-tunnel-06.txt, *Connecting IPv6 Islands over IPv4 MPLS using IPv6 Provider Edge Routers* (expires July 2006)

These Internet drafts are available on the IETF website at <http://www.ietf.org/>.

This example shows you how to interconnect a two IPv6 networks over an IPv4-based network core, giving you the ability to provide IPv6 service without having to upgrade the routers in your core network. Multiprotocol Border Gateway Protocol (MP-BGP) is configured to exchange routes between the IPv6 networks, and data is tunneled between these IPv6 networks by means of IPv4-based MPLS.

In [Figure 21 on page 83](#), Routers PE1 and PE2 are dual-stack BGP routers, meaning they have both IPv4 and IPv6 stacks. The PE routers link the IPv6 networks through the customer edge (CE) routers to the IPv4 core network. The CE routers and the PE routers connect through a link layer that can carry IPv6 traffic. The PE routers use IPv6 on the CE router-facing interfaces and use IPv4 and MPLS on the core-facing interfaces. Note that one of the connected IPv6 networks could be the global IPv6 Internet.

Figure 21: IPv6 Networks Linked by MPLS IPv4 Tunnels

The two PE routers are linked through an MP-BGP session using IPv4 addresses. They use the session to exchange IPv6 routes with an IPv6 (value 2) address family indicator (AFI) and a subsequent AFI (SAFI) (value 4). Each PE router sets the next hop for the IPv6 routes advertised on this session to its own IPv4 address. Because MP-BGP requires the BGP next hop to correspond to the same address family as the network layer reachability information (NLRI), this IPv4 address needs to be embedded within an IPv6 format.

The PE routers can learn the IPv6 routes from the CE routers connected to them using routing protocols Routing Information Protocol next generation (RIPng) or MP-BGP, or through static configuration. Note that if BGP is used as the PE-router-to-CE-router protocol, the MP-BGP session between the PE router and CE router could occur over an IPv4 or IPv6 Transmission Control Protocol (TCP) session. Also, the BGP routes exchanged on that session would have SAFI unicast. You must configure an export policy to pass routes between IBGP and EBGP, and between BGP and any other protocol.

The PE routers have MPLS LSPs routed to each others' IPv4 addresses. IPv4 provides signaling for the LSPs by means of either LDP or RSVP. These LSPs are used to resolve the next-hop addresses of the IPv6 routes learned from MP-BGP. The next hops use IPv4-mapped IPv6 addresses, while the LSPs use IPv4 addresses.

The PE routers always advertise IPv6 routes to each other using a label value of 2, the explicit null label for IPv6 as defined in RFC 3032, *MPLS Label Stack Encoding*. As a consequence, each of the forwarding next hops for the IPv6 routes learned from remote PE routers normally push two labels. The inner label is 2 (this label could be different if the advertising PE router is not a Juniper Networks routing platform), and the outer label is the LSP label. If the LSP is a single-hop LSP, then only Label 2 is pushed.

It is also possible for the PE routers to exchange plain IPv6 routes using SAFI unicast. However, there is one major advantage in exchanging labeled IPv6 routes. The

penultimate-hop router for an MPLS LSP can pop the outer label and then send the packet with the inner label as an MPLS packet. Without the inner label, the penultimate-hop router would need to discover whether the packet is an IPv4 or IPv6 packet to set the protocol field in the Layer 2 header correctly.

When the PE1 router in [Figure 21 on page 83](#) receives an IPv6 packet from the CE1 router, it performs a lookup in the IPv6 forwarding table. If the destination matches a prefix learned from the CE2 router, then no labels need to be pushed and the packet is simply sent to the CE2 router. If the destination matches a prefix that was learned from the PE2 router, then the PE1 router pushes two labels onto the packet and sends it to the provider router. The inner label is 2 and the outer label is the LSP label for the PE2 router.

Each provider router in the service provider's network handles the packet as it would any MPLS packet, swapping labels as it passes from provider router to provider router. The penultimate-hop provider router for the LSP pops the outer label and sends the packet to the PE2 router. When the PE2 router receives the packet, it recognizes the IPv6 explicit null label on the packet (Label 2). It pops this label and treats it as an IPv6 packet, performing a lookup in the IPv6 forwarding table and forwarding the packet to the CE3 router.

This example includes the following settings:

- In addition to configuring the **family inet6** statement on all the CE router-facing interfaces, you must also configure the statement on all the core-facing interfaces running MPLS. Both configurations are necessary because the router must be able to process any IPv6 packets it receives on these interfaces. You should not see any regular IPv6 traffic arrive on these interfaces, but you will receive MPLS packets tagged with Label 2. Even though Label 2 MPLS packets are sent in IPv4, these packets are treated as native IPv6 packets.
- You enable IPv6 tunneling by including the **ipv6-tunneling** statement in the configuration for the PE routers. This statement allows IPv6 routes to be resolved over an MPLS network by converting all routes stored in the inet.3 routing table to IPv4-mapped IPv6 addresses and then copying them into the inet6.3 routing table. This routing table can be used to resolve next hops for both inet6 and inet6-vpn routes.

**NOTE:** BGP automatically runs its import policy even when copying routes from a primary routing table group to a secondary routing table group. If IPv4 labeled routes arrive from a BGP session (for example, when you have configured the **labeled-unicast** statement at the `[edit protocols bgp family inet]` hierarchy level on the PE router), the BGP neighbor's import policy also accepts IPv6 routes, since the neighbor's import policy is run while doing the copy operation to the inet6.3 routing table.

---

- When you configure MP-BGP to carry IPv6 traffic, the IPv4 MPLS label is removed at the destination PE router. The remaining IPv6 packet without a label can then be forwarded to the IPv6 network. To enable this, include the **explicit-null** statement in the BGP configuration.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

**Device PE1**

### Configuring Device PE1

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the interfaces.

```

[edit interfaces]
user@PE1# set fe-1/2/0 unit 2 family inet6 address ::10.1.1.2/126
user@PE1# set fe-1/2/0 unit 2 family mpls

user@PE1# set fe-1/2/1 unit 5 family inet address 10.1.1.5/30
user@PE1# set fe-1/2/1 unit 5 family inet6
user@PE1# set fe-1/2/1 unit 5 family mpls

user@PE1# set lo0 unit 2 family inet address 1.1.1.2/32

```

2. Configure MPLS on the interfaces.

```

[edit protocols mpls]
user@PE1# set ipv6-tunneling
user@PE1# set interface fe-1/2/0.2
user@PE1# set interface fe-1/2/1.5

```

3. Configure BGP.

```

[edit protocols bgp]
user@PE1# set group toCE1 type external
user@PE1# set group toCE1 local-address ::10.1.1.2
user@PE1# set group toCE1 family inet6 unicast
user@PE1# set group toCE1 export send-bgp6
user@PE1# set group toCE1 peer-as 1
user@PE1# set group toCE1 neighbor ::10.1.1.1

user@PE1# set group toPE2 type internal
user@PE1# set group toPE2 local-address 1.1.1.2
user@PE1# set group toPE2 family inet6 labeled-unicast explicit-null
user@PE1# set group toPE2 export next-hop-self
user@PE1# set group toPE2 export send-v6

```

- ```
user@PE1# set group toPE2 neighbor 1.1.1.4
```
4. Configure OSPF

```
[edit protocols ospf area 0.0.0.0]
user@PE1# set interface fe-1/2/1.5
user@PE1# set interface lo0.2 passive
```
  5. Configure a signaling protocol.

```
[edit protocols]
user@PE1# set ldp interface fe-1/2/1.5
```
  6. Configure the routing policies.

```
[edit policy-options]
user@PE1# set policy-statement next-hop-self then next-hop self

user@PE1# set policy-statement send-bgp6 from family inet6
user@PE1# set policy-statement send-bgp6 from protocol bgp
user@PE1# set policy-statement send-bgp6 then accept

user@PE1# set policy-statement send-v6 from family inet6
user@PE1# set policy-statement send-v6 from protocol bgp
user@PE1# set policy-statement send-v6 from protocol direct
user@PE1# set policy-statement send-v6 then accept
```
  7. Configure the router ID and the autonomous system (AS) number.

```
[edit routing-options]
user@PE1# set router-id 1.1.1.2
user@PE1# set autonomous-system 2
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show policy-options**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
fe-1/2/0 {
  unit 2 {
    family inet6 {
      address ::10.1.1.2/126;
    }
    family mpls;
  }
}
fe-1/2/1 {
  unit 5 {
    family inet {
      address 10.1.1.5/30;
    }
    family inet6;
    family mpls;
  }
}
lo0 {
```

```

    unit 2 {
        family inet {
            address 1.1.1.2/32;
        }
    }
}

user@R1# show policy-options
policy-statement next-hop-self {
    then {
        next-hop self;
    }
}
policy-statement send-bgp6 {
    from {
        family inet6;
        protocol bgp;
    }
    then accept;
}
policy-statement send-v6 {
    from {
        family inet6;
        protocol [ bgp direct ];
    }
    then accept;
}

user@R1# show protocols
mpls {
    ipv6-tunneling;
    interface fe-1/2/0.2;
    interface fe-1/2/1.5;
}
bgp {
    group toCE1 {
        type external;
        local-address ::10.1.1.2;
        family inet6 {
            unicast;
        }
        export send-bgp6;
        peer-as 1;
        neighbor ::10.1.1.1;
    }
    group toPE2 {
        type internal;
        local-address 1.1.1.2;
        family inet6 {
            labeled-unicast {
                explicit-null;
            }
        }
        export [ next-hop-self send-v6 ];
        neighbor 1.1.1.4;
    }
}

```

```
ospf {  
  area 0.0.0.0 {  
    interface fe-1/2/1.5;  
    interface lo0.2 {  
      passive;  
    }  
  }  
}  
ldp {  
  interface fe-1/2/1.5;  
}  
  
user@R1# show routing-options  
router-id 1.1.1.2;  
autonomous-system 2;
```

If you are done configuring the device, enter **commit** from configuration mode. Configure the other devices in the topology, as shown in [“CLI Quick Configuration” on page 85](#).

## Verification

Confirm that the configuration is working properly.

### Verifying That the CE Devices Have Connectivity

---

**Purpose** Make sure that the tunnel is operating.

**Action** From operational mode, enter the **ping** command.

```
user@CE1> ping ::10.1.1.14  
PING6(56=40+8+8 bytes) ::10.1.1.1 --> ::10.1.1.14  
16 bytes from ::10.1.1.14, icmp_seq=0 hlim=61 time=10.687 ms  
16 bytes from ::10.1.1.14, icmp_seq=1 hlim=61 time=9.239 ms  
16 bytes from ::10.1.1.14, icmp_seq=2 hlim=61 time=1.842 ms  
  
user@CE3> ping ::10.1.1.1  
PING6(56=40+8+8 bytes) ::10.1.1.14 --> ::10.1.1.1  
16 bytes from ::10.1.1.1, icmp_seq=0 hlim=61 time=1.484 ms  
16 bytes from ::10.1.1.1, icmp_seq=1 hlim=61 time=1.338 ms  
16 bytes from ::10.1.1.1, icmp_seq=2 hlim=61 time=1.351 ms
```

**Meaning** The IPv6 CE devices can communicate over the core IPv4 network.

## SRLG Overview

---

In MPLS traffic engineering, a Shared Risk Link Group (SRLG) is a set of links sharing a common resource, which affects all links in the set if the common resource fails. These

links share the same risk of failure and are therefore considered to belong to the same SRLG. For example, links sharing a common fiber are said to be in the same SRLG because a fault with the fiber might cause all links in the group to fail.

An SRLG is represented by a 32-bit number unique within an IGP (OSPFv2 and IS-IS) domain. A link might belong to multiple SRLGs. The SRLG of a path in a label-switched path (LSP) is the set of SRLGs for all the links in the path. When computing the secondary path for an LSP, it is preferable to find a path such that the secondary and primary paths do not have any links in common in case the SRLGs for the primary and secondary paths are disjoint. This ensures that a single point of failure on a particular link does not bring down both the primary and secondary paths in the LSP.

When the SRLG is configured, the device uses the Constrained Shortest Path First (CSPF) algorithm and tries to keep the links used for the primary and secondary paths mutually exclusive. If the primary path goes down, the CSPF algorithm computes the secondary path by trying to avoid links that share any SRLG with the primary path. In addition, when computing the path for a bypass LSP, CSPF tries to avoid links that share any SRLG with the protected links.

When the SRLG is not configured, CSPF only takes into account the costs of the links when computing the secondary path.

Any change in link SRLG information triggers the IGP to send LSP updates for the new link SRLG information. CSPF recomputes the paths during the next round of reoptimization.

Junos OS Release 11.4 and later supports SRLG based on the following RFCs:

- RFC 4203, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*.
- RFC 5307, *IS-IS Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*.

**NOTE:** Currently, the “Fate Sharing” feature continues to be supported with the SRLG feature.

## Example: Configuring SRLG

---

This example shows how to configure Shared Risk Link Groups (SRLGs) on a device.

- [Requirements on page 92](#)
- [Overview on page 92](#)
- [Configuration on page 93](#)
- [Verification on page 98](#)

### Requirements

This example uses the following hardware and software components:

- Seven routers that can be a combination of M Series, MX Series, or T Series routers
- Junos OS Release 11.4 or later running on all the devices

### Overview

Junos OS Release 11.4 and later support SRLG configuration in an IGP (OSPFv2 and IS-IS) domain. In this example, you configure SRLG and associate it with the MPLS interface on a device.

The device uses the SRLG cost parameter for the Constrained Shortest Path First (CSPF) algorithm and tries to keep the links used for the primary and secondary paths mutually exclusive by avoiding links that share any SRLG with the primary path.

To configure the SRLG, you first define the SRLG parameters at the **[edit routing-options srlg srlg-name]** hierarchy level and then associate the SRLG with an MPLS interface at the **[edit mpls interface interface-name]** hierarchy level.

The **srlg srlg-name** statement has the following options:

- **srlg-cost**—Include a cost for the SRLG ranging from 1 through 65535. The cost of the SRLG determines the level of impact this SRLG has on the CSPF algorithm for path computations. The higher the cost, the less likely it is for a secondary path to share the same SRLG as the primary path. By default, the **srlg-cost** is 1.
- **srlg-value**—Include a group ID for the SRLG ranging from 1 through 4294967295.

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The primary path includes SRLG **srlg-a**. For the standby secondary path, the link P2>PE2 belongs to SRLG **srlg-a**. The

effective link metric, with the added **srlg-cost** of 10, becomes 11. Therefore, the computed secondary path is PE1>P3>P4>P5>PE2 with a CSPF link metric of 4.

## Configuration

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

set protocols ospf area 0.0.0.0 interface ge-0/0/1.0
set protocols ospf area 0.0.0.0 interface ge-0/0/2.0
set protocols ospf area 0.0.0.0 interface ge-0/0/3.0
set protocols ospf area 0.0.0.0 interface lo0.0

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure the ingress router PE1:

1. Configure the device interfaces.

```
[edit interfaces]
```

```
user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
```

```
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
```

```
user@PE1# set srlg srlg-a srlg-value 101
user@PE1# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS and the LSPs.

```
[edit protocols mpls]
```

```
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
```

```
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, **show protocols mpls**, and **show protocols rsvp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
interfaces {
```

```

ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.12.1/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.13.1/24;
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.14.1/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.1/32;
    }
  }
}
}

```

```

user@PE1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
  interface lo0.0;
}

```

```

user@PE1# show protocols mpls
optimize-timer 120;
label-switched-path pe1-pe2 {
  to 10.255.0.7;
  primary via-p1;
  secondary path2 {
    standby;
  }
}
path via-p1 {
  10.255.0.2 strict;
}
path path2;
interface ge-0/0/1.0;
interface ge-0/0/2.0;

```

```
interface ge-0/0/3.0;

user@PE1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;

user@PE1# show routing-options
routing-options {
  srlg {
    srlg-a {
      srlg-value 101;
      srlg-cost 10;
    }
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

**NOTE:** Repeat this procedure for every Juniper Networks router in the IGP domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

---

## Verification

Confirm that the configuration is working properly.

- [Verifying SRLG Definitions on page 98](#)
- [Verify TE-Link SRLG on page 98](#)
- [Verify Standby Secondary Path on page 99](#)

---

### Verifying SRLG Definitions

**Purpose** Verify SRLG-to-value mappings and SRLG cost.

**Action** user@PE1> show mpls srlg

| SRLG   | Value | Cost |
|--------|-------|------|
| srlg-a | 101   | 10   |

---

### Verify TE-Link SRLG

**Purpose** Verify the traffic engineering link SRLG association.

**Action** user@PE1> show ted link detail

```

...
10.255.0.2->192.168.27.7-1, Local: 192.168.27.2, Remote: 0.0.0.0
  Local interface index: 0, Remote interface index: 0
  LocalPath: 1, Metric: 1, StaticBW: 1000Mbps, AvailBW: 1000Mbps
  Color: 0 <none>
  SRLGs: srlg-a
  localBW [0] 0bps [1] 0bps [2] 0bps [3] 0bps
  localBW [4] 0bps [5] 0bps [6] 0bps [7] 0bps

...
10.255.0.3->192.168.37.7-1, Local: 192.168.37.3, Remote: 0.0.0.0
  Local interface index: 0, Remote interface index: 0
  LocalPath: 0, Metric: 1, StaticBW: 1000Mbps, AvailBW: 1000Mbps
  Color: 0 <none>
  SRLGs: srlg-a
  localBW [0] 0bps [1] 0bps [2] 0bps [3] 0bps
  localBW [4] 0bps [5] 0bps [6] 0bps [7] 0bps

...

```

**Meaning** Links P1-PE2 and P2-PE2 are associated with SRLG **srlg-a**.

### Verify Standby Secondary Path

**Purpose** Check the SRLG link cost and its impact on the CSPF computation of the standby secondary path link.

**Action** user@PE1> show mpls lsp ingress extensive  
Ingress LSP: 1 sessions

```

```

**Meaning** Check the standby secondary path. The effective link cost for P2>PE2 is 11 (with the added **srlg-cost** of 10). CSPF computes the secondary path as PE1>P3>P4>P5>PE2 with a CSPF link metric of 4.

  - [srlg-cost on page 1515](#)
  - [srlg-value on page 1515](#)

## Example: Excluding SRLG Links Completely for the Secondary LSP

This example shows how to configure the **exclude-srlg** option to exclude Shared Risk Link Group (SRLG) links for the secondary label-switched path (LSP).

- [Requirements on page 101](#)
- [Overview on page 101](#)
- [Configuration on page 102](#)
- [Verification on page 105](#)

### Requirements

This example uses the following hardware and software components:

- M Series, MX Series, or T Series devices
- Junos OS Release 11.4 or later running on all the devices

### Overview

For critical links where it is imperative to keep the secondary and primary paths completely disjoint from any common SRLG, you can optionally configure the **exclude-srlg** statement at the **[edit protocols mpls]** or **[edit protocols mpls label-switched-path *path-name*]** hierarchy levels. For logical systems, you configure the **exclude-srlg** statement at the **edit logical-systems protocols mpls[edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name*]** hierarchy level.

If **exclude-srlg** is configured, the Constrained Shortest Path First (CSPF) algorithm excludes any link belonging to the set of SRLGs in the primary path. If **exclude-srlg** is not configured, and if a link belongs to the set of SRLGs in the primary path, CSPF adds the SRLG cost to the metric, but still accepts the link for computing the path.

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The primary path includes SRLG **srlg-a**. For the standby secondary path, the link P2>PE2 belongs to SRLG **srlg-a**. Because

**exclude-srlg** is configured, CSPF rejects link P2>PE2 as the link belongs to the SRLG **srlg-a**. Therefore, the computed standby secondary path is PE1>P3>P4>P5>PE2.

## Configuration

**CLI Quick Configuration** To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

Router PE1
set interfaces ge-0/0/1 unit 0 family inet address 192.168.12.1/24
set interfaces ge-0/0/1 unit 0 family mpls
set interfaces ge-0/0/2 unit 0 family inet address 192.168.13.1/24
set interfaces ge-0/0/2 unit 0 family mpls
set interfaces ge-0/0/3 unit 0 family inet address 192.168.14.1/24

set protocols mpls exclude-srlg
set protocols mpls label-switched-path pe1-pe2 to 10.255.0.7
set protocols mpls label-switched-path pe1-pe2 primary via-p1
set protocols mpls label-switched-path pe1-pe2 secondary path2 standby
set protocols mpls path via-p1 10.255.0.2 strict
set protocols mpls path path2
set protocols mpls interface ge-0/0/1.0
set protocols mpls interface ge-0/0/2.0
set protocols mpls interface ge-0/0/3.0
set protocols ospf traffic-engineering
  
```

```

set protocols ospf area 0.0.0.0 interface ge-0/0/1.0
set protocols ospf area 0.0.0.0 interface ge-0/0/2.0
set protocols ospf area 0.0.0.0 interface ge-0/0/3.0
set protocols ospf area 0.0.0.0 interface lo0.0

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

1. Configure the device interfaces.

```

[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32

```

2. Configure OSPF on the interfaces.

```

[edit protocols ospf]
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

```

[edit routing-options]
user@PE1# set routing-options srlg srlg-a srlg-value 101

```

4. Configure MPLS and the LSPs.

```

[edit protocols mpls]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set exclude-srlg
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2

```

5. Configure the **exclude-srlg** statement to forcibly keep the links for the secondary path completely disjoint from the primary LSP path.

```

user@PE1 set protocols mpls exclude-srlg

```

6. Enable RSVP on the interfaces.

```

[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, **show protocols mpls**, and **show protocols rsvp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
interfaces {
  ge-0/0/1 {
    unit 0 {
      family inet {
        address 192.168.12.1/24;
      }
      family mpls;
    }
  }
  ge-0/0/2 {
    unit 0 {
      family inet {
        address 192.168.13.1/24;
      }
      family mpls;
    }
  }
  ge-0/0/3 {
    unit 0 {
      family inet {
        address 192.168.14.1/24;
      }
      family mpls;
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.255.0.1/32;
      }
    }
  }
}

user@PE1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
  interface lo0.0;
}

user@PE1# show protocols mpls
optimize-timer 120;
label-switched-path pe1-pe2 {
  to 10.255.0.7;
  primary via-p1;
  secondary path2 {
    standby;
  }
}
```

```

    }
  }
  path via-p1 {
    10.255.0.2 strict;
  }
  path path2;
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;

  user@PE1# show protocols rsvp
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;

  user@PE1# show routing-options
  routing-options {
    srlg {
      srlg-a srlg-value 101;
    }
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

**NOTE:** Repeat this procedure for every Juniper Networks router in the IGP domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

## Verification

Confirm that the configuration is working properly.

### Verifying the Secondary Path Link for the LSP

**Purpose** Verify that the link for the secondary path is completely disjoint from the primary path.

**Action** user@PE1> show mpls lsp detail  
Ingress LSP: 1 sessions

```

10.255.0.7
  From: 10.255.0.1, State: Up, ActiveRoute: 0, LSPname: pe1-pe2

  Standby path2 State: Up
    Priorities: 7 0
    OptimizeTimer: 120
    SmartOptimizeTimer: 180
    Reoptimization in 106 second(s).
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 4)
192.168.14.4 S 192.168.45.5 S 192.168.56.6 S 192.168.67.7 S
  Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node 10=SoftPreempt
20=Node-ID):
    192.168.14.4 192.168.45.5 192.168.56.6 192.168.67.7
Total 1 displayed, Up 1, Down 0

Link P1->PE2: SRLG srlg-a
Link P2->PE2: SRLG srlg-a

Primary path: PE1-P1-PE2 (CSPF metric: 2)
Standby secondary: PE1-P3-P4-P5-PE2 (CSPF metric: 4)

```

**Meaning** Primary path includes SRLG **srlg-a**. For the standby secondary path, the link P2>PE2 belongs to SRLG **srlg-a**. CSPF rejects link P2>PE2 because the link belongs to the SRLG **srlg-a**.

- Related Documentation**
- [SRLG Overview on page 90](#)
  - [Example: Configuring SRLG on page 92](#)
  - [exclude-srlg on page 1429](#)

## Example: Configuring SRLG with Link Protection

This example shows how to configure SRLG with link protection without the **exclude-srlg** option.

- [Requirements on page 107](#)
- [Overview on page 107](#)

- [Configuration on page 107](#)
- [Verification on page 125](#)

## Requirements

This example uses the following hardware and software components:

- M Series, MX Series, or T Series devices
- Junos OS Release 11.4 or later running on all the devices

## Overview

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The link P1>PE2 (primary path) and the link P2>PE2 belong to SRLG srlg-a.

You configure link protection for the interface P1>PE2 by including the **link-protection** statement.

When SRLG srlg-a is configured on the link P1>PE2 and P2>PE2, the bypass takes the longer path P1>P4>P5>PE2, not selecting the link P2>PE2 because of the added SRLG cost for srlg-a.

## Configuration

### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

**Router PE1**

```
set interfaces ge-0/0/1 unit 0 family inet address 192.168.12.1/24
set interfaces ge-0/0/1 unit 0 family mpls
set interfaces ge-0/0/2 unit 0 family inet address 192.168.13.1/24
set interfaces ge-0/0/2 unit 0 family mpls
set interfaces ge-0/0/3 unit 0 family inet address 192.168.14.1/24
set interfaces ge-0/0/3 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 10.255.0.1/32
set routing-options srlg srlg-a srlg-value 101
set routing-options srlg srlg-a srlg-cost 10
set protocols rsvp interface ge-0/0/1.0

### Configuring Device PE1

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure the ingress router PE1:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
```

```
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE1# set srlg srlg-a srlg-value 101
user@PE1# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS and the LSPs and configure link protection for the **pe1-pe2** LSP.

```
[edit protocols mpls]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set protocols mpls label-switched-path pe1-pe2 link-protection
user@PE1# set label-switched-path pe1-pe2 primary via-p1
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, **show protocols mpls**, and **show protocols rsvp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.12.1/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.13.1/24;
    }
    family mpls;
  }
}
```

```
    }  
  }  
  ge-0/0/3 {  
    unit 0 {  
      family inet {  
        address 192.168.14.1/24;  
      }  
      family mpls;  
    }  
  }  
  lo0 {  
    unit 0 {  
      family inet {  
        address 10.255.0.1/32;  
      }  
    }  
  }  
}  
  
user@PE1# show protocols ospf  
traffic-engineering;  
area 0.0.0.0 {  
  interface ge-0/0/1.0;  
  interface ge-0/0/2.0;  
  interface ge-0/0/3.0;  
  interface lo0.0;  
}  
  
user@PE1# show protocols mpls  
optimize-timer 120;  
label-switched-path pe1-pe2 {  
  to 10.255.0.7;  
  link-protection;  
  primary via-p1;  
  secondary path2 {  
    standby;  
  }  
}  
path via-p1 {  
  10.255.0.2 strict;  
}  
path path2;  
interface ge-0/0/1.0;  
interface ge-0/0/2.0;  
interface ge-0/0/3.0;  
  
user@PE1# show protocols rsvp  
interface ge-0/0/1.0;  
interface ge-0/0/2.0;  
interface ge-0/0/3.0;  
  
user@PE1# show routing-options  
srlg {  
  srlg-a {  
    srlg-value 101;  
    srlg-cost 10;  
  }  
}
```

```
}
```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device P1

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure device P1:

1. Configure the device interfaces.

##### [edit interfaces]

```
user@P1# set ge-0/0/1 unit 0 family inet address 192.168.12.2/24
user@P1# set ge-0/0/1 unit 0 family mpls
user@P1# set ge-0/0/2 unit 0 family inet address 192.168.27.2/24
user@P1# set ge-0/0/2 unit 0 family mpls
user@P1# set ge-0/0/3 unit 0 family inet address 192.168.23.2/24
user@P1# set ge-0/0/3 unit 0 family mpls
user@P1# set ge-0/0/4 unit 0 family inet address 192.168.25.2/24
user@P1# set ge-0/0/4 unit 0 family mpls
user@P1# set lo0 unit 0 family inet address 10.255.0.2/32
```

2. Configure OSPF on the interfaces.

##### [edit protocols ospf]

```
user@P1# set traffic-engineering
user@P1# set area 0.0.0.0 interface ge-0/0/1.0
user@P1# set area 0.0.0.0 interface ge-0/0/2.0
user@P1# set area 0.0.0.0 interface ge-0/0/3.0
user@P1# set area 0.0.0.0 interface ge-0/0/4.0
user@P1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

##### [edit routing-options]

```
user@P1# set srlg srlg-a srlg-value 101
user@P1# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces and associate the SRLG **srlg-a** with interface **ge-0/0/2.0** for the P1>PE2 link.

##### [edit protocols mpls]

```
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 srlg srlg-a
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

5. Enable RSVP on the interfaces and configure **link-protection** for interface **ge-0/0/2.0**.

##### [edit protocols rsvp]

```
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 link-protection
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P1# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.12.2/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.27.2/24;
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.23.2/24;
    }
    family mpls;
  }
}
ge-0/0/4 {
  unit 0 {
    family inet {
      address 192.168.25.2/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.2/32;
    }
  }
}

user@P1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
  interface ge-0/0/4.0;
  interface lo0.0;
}
```

```

user@P1# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
  srlg srlg-a;
}
interface ge-0/0/3.0;
interface ge-0/0/4.0;

user@P1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
  link-protection;
}
interface ge-0/0/3.0;
interface ge-0/0/4.0;

user@P1# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device P2

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P2:

1. Configure the device interfaces.

```

[edit interfaces]
user@P2# set ge-0/0/1 unit 0 family inet address 192.168.13.3/24
user@P2# set ge-0/0/1 unit 0 family mpls
user@P2# set ge-0/0/2 unit 0 family inet address 192.168.37.3/24
user@P2# set ge-0/0/2 unit 0 family mpls
user@P2# set ge-0/0/3 unit 0 family inet address 192.168.23.3/24
user@P2# set ge-0/0/3 unit 0 family mpls
user@P2# set lo0 unit 0 family inet address 10.255.0.3/32

```

2. Configure OSPF on the interfaces.

```

[edit protocols ospf]
user@P2# set traffic-engineering
user@P2# set area 0.0.0.0 interface ge-0/0/1.0
user@P2# set area 0.0.0.0 interface ge-0/0/2.0
user@P2# set area 0.0.0.0 interface ge-0/0/3.0
user@P2# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

```

[edit routing-options]
user@P2# set srlg srlg-a srlg-value 101
user@P2# set srlg srlg-a srlg-cost 10

```

4. Configure MPLS on the interfaces and associate the SRLG **srlg-a** with interface **ge-0/0/2.0** for the P2>PE2 link.

```
[edit protocols mpls]
user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0 srlg srlg-a
user@P2# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0
user@P2# set interface ge-0/0/3.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P2# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.13.3/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.37.3/24;
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.23.3/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.3/32;
    }
  }
}
}
}

user@P2# show protocols ospf
traffic-engineering;
```

```

area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}

user@P2# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
    srlg srlg-a;
}
interface ge-0/0/3.0;
}

user@P2# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;

user@P2# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device P3

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P3:

1. Configure the device interfaces.

#### [edit interfaces]

```

user@P3# set ge-0/0/1 unit 0 family inet address 192.168.14.4/24
user@P3# set ge-0/0/1 unit 0 family mpls
user@P3# set ge-0/0/2 unit 0 family inet address 192.168.45.4/24
user@P3# set ge-0/0/2 unit 0 family mpls
user@P3# set lo0 unit 0 family inet address 10.255.0.4/32

```

2. Configure OSPF on the interfaces.

#### [edit protocols ospf]

```

user@P3# set traffic-engineering
user@P3# set area 0.0.0.0 interface ge-0/0/1.0
user@P3# set area 0.0.0.0 interface ge-0/0/2.0
user@P3# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

#### [edit routing-options]

```

user@P3# set srlg srlg-a srlg-value 101
user@P3# set srlg srlg-a srlg-cost 10

```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P3# set interface ge-0/0/1.0
user@P3# set interface ge-0/0/2.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P3# set interface ge-0/0/1.0
user@P3# set interface ge-0/0/2.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P3# show interfaces
interfaces {
  ge-0/0/1 {
    unit 0 {
      family inet {
        address 192.168.14.4/24;
      }
      family mpls;

### Configuring Device P4

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P4:

1. Configure the device interfaces.

```

[edit interfaces]
user@P4# set ge-0/0/1 unit 0 family inet address 192.168.45.5/24
user@P4# set ge-0/0/1 unit 0 family mpls
user@P4# set ge-0/0/2 unit 0 family inet address 192.168.56.5/24
user@P4# set ge-0/0/2 unit 0 family mpls
user@P4# set ge-0/0/3 unit 0 family inet address 192.168.25.5/24
user@P4# set ge-0/0/3 unit 0 family mpls
user@P4# set lo0 unit 0 family inet address 10.255.0.5/32

```

2. Configure OSPF on the interfaces.

```

[edit protocols ospf]
user@P4# set traffic-engineering
user@P4# set area 0.0.0.0 interface ge-0/0/1.0
user@P4# set area 0.0.0.0 interface ge-0/0/2.0
user@P4# set area 0.0.0.0 interface ge-0/0/3.0
user@P4# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

```

[edit routing-options]
user@P4# set srlg srlg-a srlg-value 101
user@P4# set srlg srlg-a srlg-cost 10

```

4. Configure MPLS on the interfaces.

```

[edit protocols mpls]
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0

```

5. Enable RSVP on the interfaces.

```

[edit protocols rsvp]
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P4# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.45.5/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.56.5/24;
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.25.5/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.5/32;
    }
  }
}

user@P4# show protocols ospf

    srlg-value 101;
    srlg-cost 10;
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device P5

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P5:

1. Configure the device interfaces.

```

[edit interfaces]
user@P5# set ge-0/0/1 unit 0 family inet address 192.168.56.6/24
user@P5# set ge-0/0/1 unit 0 family mpls
user@P5# set ge-0/0/2 unit 0 family inet address 192.168.67.6/24
user@P5# set ge-0/0/2 unit 0 family mpls
user@P5# set lo0 unit 0 family inet address 10.255.0.6/32

```

2. Configure OSPF on the interfaces.

```

[edit protocols ospf]
user@P5# set traffic-engineering
user@P5# set area 0.0.0.0 interface ge-0/0/1.0
user@P5# set area 0.0.0.0 interface ge-0/0/2.0
user@P5# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

```

[edit routing-options]
user@P5# set srlg srlg-a srlg-value 101
user@P5# set srlg srlg-a srlg-cost 10

```

4. Configure MPLS on the interfaces.

```

[edit protocols mpls]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0

```

5. Enable RSVP on the interfaces.

```

[edit protocols rsvp]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@P5# show interfaces

```

```
ge-0/0/1 {  
  unit 0 {  
    family inet {  
      address 192.168.56.6/24;  
    }  
    family mpls;  
  }  
}  
ge-0/0/2 {  
  unit 0 {  
    family inet {  
      address 192.168.67.6/24;  
    }  
    family mpls;  
  }  
}  
lo0 {  
  unit 0 {  
    family inet {  
      address 10.255.0.6/32;  
    }  
  }  
}
```

```
user@P5# show protocols ospf  
traffic-engineering;  
area 0.0.0.0 {  
  interface ge-0/0/1.0;  
  interface ge-0/0/2.0;

}
```

```
user@P5# show protocols mpls  
interface ge-0/0/1.0;  
interface ge-0/0/2.0;
```

```
user@P5# show protocols rsvp  
interface ge-0/0/1.0;  
interface ge-0/0/2.0;
```

```
user@P5# show routing-options  
srlg {  
  srlg-a {  
    srlg-value 101;  
    srlg-cost 10;  
  }  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Configuring Device PE2

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure PE2:

1. Configure the device interfaces.

```
[edit interfaces]
user@PE2# set ge-0/0/1 unit 0 family inet address 192.168.27.7/24
user@PE2# set ge-0/0/1 unit 0 family mpls
user@PE2# set ge-0/0/2 unit 0 family inet address 192.168.37.7/24
user@PE2# set ge-0/0/2 unit 0 family mpls
user@PE2# set ge-0/0/3 unit 0 family inet address 192.168.67.7/24
user@PE2# set ge-0/0/3 unit 0 family mpls
user@PE2# set lo0 unit 0 family inet address 10.255.0.7/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@PE2# set traffic-engineering
user@PE2# set area 0.0.0.0 interface ge-0/0/1.0
user@PE2# set area 0.0.0.0 interface ge-0/0/2.0
user@PE2# set area 0.0.0.0 interface ge-0/0/3.0
user@PE2# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@PE2# set srlg srlg-a srlg-value 101
user@PE2# set srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
interfaces {
  ge-0/0/1 {
    unit 0 {
      family inet {
        address 192.168.27.7/24;
```

```
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.37.7/24;
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.67.7/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.7/32;
    }
  }
}
}
```

```
user@PE2# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
  interface lo0.0;
}
```

```
user@PE2# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE2# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;
```

```
user@PE2# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

### Verifying the SRLG Cost Is Added to the TE Link

**Purpose** Verify that the SRLG cost is added to the TE link if it belongs to the SRLG of the protected link. Issue the **show ted link detail** and **show rsvp session extensive bypass** commands on device P1.

**Action** user@P1> show ted link detail

```
...
10.255.0.2->192.168.27.7-1, Local: 192.168.27.2, Remote: 0.0.0.0
  Local interface index: 0, Remote interface index: 0
  LocalPath: 0, Metric: 1, StaticBW: 1000Mbps, AvailBW: 1000Mbps
  Color: 0 <none>
  SRLGs: srlg-a

  Record route: <self> 192.168.25.5 192.168.56.6 192.168.67.7
Total 1 displayed, Up 1, Down 0
```

**Meaning** The shortest path for the bypass protecting the link P1->PE2 would have been P1->P2->PE2. Because the links P1>PE2 and P2>PE2 both belong to SRLG **srlg-a**, the SRLG cost of 10 for **srlg-a** is added to the metric for the link P2>PE2. This makes the metric for the link P2>PE2 too high to be selected for the shortest path. Therefore, the CSPF result for the computed path for the bypass becomes P1>P4>P5>PE2.

**Related Documentation**

- [Example: Configuring SRLG with Link Protection with the exclude-srlg Option on page 127](#)

## Example: Configuring SRLG with Link Protection with the `exclude-srlg` Option

---

This example shows how to configure SRLG with link protection with the **`exclude-srlg`** option.

- [Requirements on page 127](#)
- [Overview on page 127](#)
- [Configuration on page 128](#)
- [Verification on page 145](#)

### Requirements

This example uses the following hardware and software components:

- M Series, MX Series, or T Series devices
- Junos OS Release 11.4 or later running on all the devices

### Overview

In this example, PE1 is the ingress router and PE2 is the egress router. P1, P2, and P3, P4, and P5 are transit routers. OSPF is configured on all the routers as the interior gateway protocol (IGP). SRLG is configured on all seven routers. The link P1>PE2 (primary path) and the link P2>PE2 belong to SRLG **`srlg-a`**.

You configure link protection for the interface P1>PE2 by including the **`link-protection`** statement along with the **`exclude-srlg`** option. This makes the bypass LSP and the protected link completely disjoint in any SRLG.

When SRLG **srlg-a** is configured on the link P1>PE2 and P2>PE2, the link P2>PE2 is rejected for CSPF consideration due to the **exclude-srlg** configuration. Therefore, the computed path for the bypass becomes P1>P4>P5>PE2.

## Configuration

### CLI Quick Configuration

To quickly configure this section of the example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

#### Router PE1

```

### Configuring Device PE1

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure the ingress router PE1:

1. Configure the device interfaces.

**[edit interfaces]**

```

user@PE1# set ge-0/0/1 unit 0 family inet address 192.168.12.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set ge-0/0/2 unit 0 family inet address 192.168.13.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls
user@PE1# set ge-0/0/3 unit 0 family inet address 192.168.14.1/24
user@PE1# set ge-0/0/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32

```

2. Configure OSPF on the interfaces.

**[edit protocols ospf]**

```

user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set area 0.0.0.0 interface ge-0/0/2.0
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0
user@PE1# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

**[edit routing-options]**

```

user@PE1# set routing-options srlg srlg-a srlg-value 101
user@PE1# set routing-options srlg srlg-a srlg-cost 10

```

4. Configure MPLS and the LSPs and configure link protection for the **pe1-pe2** LSP.

**[edit protocols mpls]**

```

user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
user@PE1# set optimize-timer 120
user@PE1# set label-switched-path pe1-pe2 to 10.255.0.7
user@PE1# set protocols mpls label-switched-path pe1-pe2 link-protection
user@PE1# set label-switched-path pe1-pe2 primary via-pl

```

```
user@PE1# set label-switched-path pe1-pe2 secondary path2 standby
user@PE1# set path via-p1 10.255.0.2 strict
user@PE1# set path path2
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE1# set interface ge-0/0/1.0
user@PE1# set interface ge-0/0/2.0
user@PE1# set interface ge-0/0/3.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show routing-options**, **show protocols mpls**, and **show protocols rsvp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.12.1/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.13.1/24;
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.14.1/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.1/32;
    }
  }
}

user@PE1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
```

```

    interface lo0.0;
  }

user@PE1# show protocols mpls

label-switched-path pe1-pe2 {
  to 10.255.0.7;
  link-protection;
  primary via-p1;
  secondary path2 {
    standby;
  }
}
path via-p1 {
  10.255.0.2 strict;
}
path path2;
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;

user@PE1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;

user@PE1# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device P1

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure device P1:

1. Configure the device interfaces.

#### [edit interfaces]

```

user@P1# set ge-0/0/1 unit 0 family inet address 192.168.12.2/24
user@P1# set ge-0/0/1 unit 0 family mpls
user@P1# set ge-0/0/2 unit 0 family inet address 192.168.27.2/24
user@P1# set ge-0/0/2 unit 0 family mpls
user@P1# set ge-0/0/3 unit 0 family inet address 192.168.23.2/24
user@P1# set ge-0/0/3 unit 0 family mpls
user@P1# set ge-0/0/4 unit 0 family inet address 192.168.25.2/24
user@P1# set ge-0/0/4 unit 0 family mpls
user@P1# set lo0 unit 0 family inet address 10.255.0.2/32

```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P1# set traffic-engineering
user@P1# set area 0.0.0.0 interface ge-0/0/1.0
user@P1# set area 0.0.0.0 interface ge-0/0/2.0
user@P1# set area 0.0.0.0 interface ge-0/0/3.0
user@P1# set area 0.0.0.0 interface ge-0/0/4.0
user@P1# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P1# set routing-options srlg srlg-a srlg-value 101
user@P1# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces and associate the SRLG with interface **ge-0/0/2.0** for the P1>PE2 link.

```
[edit protocols mpls]
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 srlg srlg-a
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

5. Enable RSVP on the interfaces and include the **link-protection** statement with the **exclude-srlg** option for interface **ge-0/0/2.0**.

```
[edit protocols rsvp]
user@P1# set interface ge-0/0/1.0
user@P1# set interface ge-0/0/2.0 link-protection exclude-srlg
user@P1# set interface ge-0/0/3.0
user@P1# set interface ge-0/0/4.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P1# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.12.2/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.27.2/24;
    }
    family mpls;
  }
}
ge-0/0/3 {
  unit 0 {
    family inet {
```

```

        address 192.168.23.2/24;
    }
    family mpls;
}
}
ge-0/0/4 {
    unit 0 {
        family inet {
            address 192.168.25.2/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.0.2/32;
        }
    }
}
}

user@P1# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface ge-0/0/4.0;
    interface lo0.0;
}

user@P1# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
    srlg srlg-a;
}
interface ge-0/0/3.0;
interface ge-0/0/4.0;

user@P1# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
    link-protection {
        exclude-srlg;
    }
}
interface ge-0/0/3.0;
interface ge-0/0/4.0;
}

user@P1# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Configuring Device P2

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P2:

1. Configure the device interfaces.

```
[edit interfaces]
user@P2# set ge-0/0/1 unit 0 family inet address 192.168.13.3/24
user@P2# set ge-0/0/1 unit 0 family mpls
user@P2# set ge-0/0/2 unit 0 family inet address 192.168.37.3/24
user@P2# set ge-0/0/2 unit 0 family mpls
user@P2# set ge-0/0/3 unit 0 family inet address 192.168.23.3/24
user@P2# set ge-0/0/3 unit 0 family mpls
user@P2# set lo0 unit 0 family inet address 10.255.0.3/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P2# set traffic-engineering
user@P2# set area 0.0.0.0 interface ge-0/0/1.0
user@P2# set area 0.0.0.0 interface ge-0/0/2.0
user@P2# set area 0.0.0.0 interface ge-0/0/3.0
user@P2# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P2# set routing-options srlg srlg-a srlg-value 101
user@P2# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces and associate the SRLG with interface **ge-0/0/2.0** for the P2>PE2 link.

```
[edit protocols mpls]
user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0 srlg srlg-a
user@P2# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P2# set interface ge-0/0/1.0
user@P2# set interface ge-0/0/2.0
user@P2# set interface ge-0/0/3.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P2# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
```

```

        address 192.168.13.3/24;
    }
    family mpls;
}
}
ge-0/0/2 {
    unit 0 {
        family inet {
            address 192.168.37.3/24;
        }
        family mpls;
    }
}
ge-0/0/3 {
    unit 0 {
        family inet {
            address 192.168.23.3/24;
        }
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.0.3/32;
        }
    }
}
}
}

```

```

user@P2# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}

```

```

user@P2# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0 {
    srlg srlg-a;
}
interface ge-0/0/3.0;
}

```

```

user@P2# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;

```

```

user@P2# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}

```

```
}  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

---

### Configuring Device P3

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P3:

1. Configure the device interfaces.

```
[edit interfaces]
```

```
user@P3# set ge-0/0/1 unit 0 family inet address 192.168.14.4/24
```

```
user@P3# set ge-0/0/1 unit 0 family mpls
```

```
user@P3# set ge-0/0/2 unit 0 family inet address 192.168.45.4/24
```

```
user@P3# set ge-0/0/2 unit 0 family mpls
```

```
user@P3# set lo0 unit 0 family inet address 10.255.0.4/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
```

```
user@P3# set traffic-engineering
```

```
user@P3# set area 0.0.0.0 interface ge-0/0/1.0
```

```
user@P3# set area 0.0.0.0 interface ge-0/0/2.0
```

```
user@P3# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
```

```
user@P3# set routing-options srlg srlg-a srlg-value 101
```

```
user@P3# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
```

```
user@P3# set interface ge-0/0/1.0
```

```
user@P3# set interface ge-0/0/2.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
```

```
user@P3# set interface ge-0/0/1.0
```

```
user@P3# set interface ge-0/0/2.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P3# show interfaces  
interfaces {  
  ge-0/0/1 {  
    unit 0 {  
      family inet {  
        address 192.168.14.4/24;
```

```

    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.45.4/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.4/32;
    }
  }
}
}

user@P3# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface lo0.0;
}

user@P3# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;

user@P3# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;

user@P3# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device P4

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P4:

1. Configure the device interfaces.

**[edit interfaces]**

```
user@P4# set ge-0/0/1 unit 0 family inet address 192.168.45.5/24
```

```
user@P4# set ge-0/0/1 unit 0 family mpls
user@P4# set ge-0/0/2 unit 0 family inet address 192.168.56.5/24
user@P4# set ge-0/0/2 unit 0 family mpls
user@P4# set ge-0/0/3 unit 0 family inet address 192.168.25.5/24
user@P4# set ge-0/0/3 unit 0 family mpls
user@P4# set lo0 unit 0 family inet address 10.255.0.5/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P4# set traffic-engineering
user@P4# set area 0.0.0.0 interface ge-0/0/1.0
user@P4# set area 0.0.0.0 interface ge-0/0/2.0
user@P4# set area 0.0.0.0 interface ge-0/0/3.0
user@P4# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P4# set routing-options srlg srlg-a srlg-value 101
user@P4# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P4# set interface ge-0/0/1.0
user@P4# set interface ge-0/0/2.0
user@P4# set interface ge-0/0/3.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@P4# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 192.168.45.5/24;
    }
    family mpls;
  }
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 192.168.56.5/24;
    }
    family mpls;
  }
}
}
```

```

ge-0/0/3 {
  unit 0 {
    family inet {
      address 192.168.25.5/24;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.5/32;
    }
  }
}

user@P4# show protocols ospf
traffic-engineering;
area 0.0.0.0 {
  interface ge-0/0/1.0;
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
  interface lo0.0;
}

user@P4# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;

user@P4# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;

user@P4# show routing-options
srlg {
  srlg-a {
    srlg-value 101;
    srlg-cost 10;
  }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device P5

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure P5:

1. Configure the device interfaces.

#### [edit interfaces]

```

user@P5# set ge-0/0/1 unit 0 family inet address 192.168.56.6/24
user@P5# set ge-0/0/1 unit 0 family mpls
user@P5# set ge-0/0/2 unit 0 family inet address 192.168.67.6/24

```

```
user@P5# set ge-0/0/2 unit 0 family mpls
user@P5# set lo0 unit 0 family inet address 10.255.0.6/32
```

2. Configure OSPF on the interfaces.

```
[edit protocols ospf]
user@P5# set traffic-engineering
user@P5# set area 0.0.0.0 interface ge-0/0/1.0
user@P5# set area 0.0.0.0 interface ge-0/0/2.0
user@P5# set area 0.0.0.0 interface lo0.0
```

3. Configure the SRLG definitions.

```
[edit routing-options]
user@P5# set routing-options srlg srlg-a srlg-value 101
user@P5# set routing-options srlg srlg-a srlg-cost 10
```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@P5# set interface ge-0/0/1.0
user@P5# set interface ge-0/0/2.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device PE2

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see the *CLI User Guide*.

To configure PE2:

1. Configure the device interfaces.

#### [edit interfaces]

```

user@PE2# set ge-0/0/1 unit 0 family inet address 192.168.27.7/24
user@PE2# set ge-0/0/1 unit 0 family mpls
user@PE2# set ge-0/0/2 unit 0 family inet address 192.168.37.7/24
user@PE2# set ge-0/0/2 unit 0 family mpls
user@PE2# set ge-0/0/3 unit 0 family inet address 192.168.67.7/24
user@PE2# set ge-0/0/3 unit 0 family mpls
user@PE2# set lo0 unit 0 family inet address 10.255.0.7/32

```

2. Configure OSPF on the interfaces.

#### [edit protocols ospf]

```

user@PE2# set traffic-engineering
user@PE2# set area 0.0.0.0 interface ge-0/0/1.0
user@PE2# set area 0.0.0.0 interface ge-0/0/2.0
user@PE2# set area 0.0.0.0 interface ge-0/0/3.0
user@PE2# set area 0.0.0.0 interface lo0.0

```

3. Configure the SRLG definitions.

#### [edit routing-options]

```

user@PE2# set routing-options srlg srlg-a srlg-value 101
user@PE2# set routing-options srlg srlg-a srlg-cost 10

```

4. Configure MPLS on the interfaces.

```
[edit protocols mpls]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

5. Enable RSVP on the interfaces.

```
[edit protocols rsvp]
user@PE2# set interface ge-0/0/1.0
user@PE2# set interface ge-0/0/2.0
user@PE2# set interface ge-0/0/3.0
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols ospf**, **show protocols mpls**, **show protocols rsvp**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
interfaces {
  ge-0/0/1 {
    unit 0 {
      family inet {
        address 192.168.27.7/24;
      }
      family mpls;
    }
  }
  ge-0/0/2 {
    unit 0 {
      family inet {
        address 192.168.37.7/24;
      }
      family mpls;
    }
  }
  ge-0/0/3 {
    unit 0 {
      family inet {
        address 192.168.67.7/24;
      }
      family mpls;
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 10.255.0.7/32;
      }
    }
  }
}

user@PE2# show protocols ospf
traffic-engineering;
```

```

area 0.0.0.0 {
    interface ge-0/0/1.0;
    interface ge-0/0/2.0;
    interface ge-0/0/3.0;
    interface lo0.0;
}

user@PE2# show protocols mpls
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;

user@PE2# show protocols rsvp
interface ge-0/0/1.0;
interface ge-0/0/2.0;
interface ge-0/0/3.0;

user@PE2# show routing-options
srlg {
    srlg-a {
        srlg-value 101;
        srlg-cost 10;
    }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

### Verifying the SRLG Cost Is Added to the TE Link

**Purpose** Verify that the TE link is excluded if it belongs to the SRLG of the protected link when **link-protection** is configured with **exclude-srlg**. Issue the **show ted link detail** and **show rsvp session extensive bypass** commands on device P1.

**Action** user@P1> show ted link detail

```
...
10.255.0.2->192.168.27.7-1, Local: 192.168.27.2, Remote: 0.0.0.0

  Explct route: 192.168.25.5 192.168.56.6 192.168.67.7
  Record route: <self> 192.168.25.5 192.168.56.6 192.168.67.7
Total 1 displayed, Up 1, Down 0
```

**Meaning** The shortest path for the bypass protecting the link P1>PE2 would have been P1>P2>PE2. Because the links P1>PE2 and P2>PE2 both belong to SRLG **srlg-a**, the link P2>PE2 is rejected for CSPF consideration due to the **exclude-srlg** constraint. Therefore, the computed path for the bypass becomes P1>P4>P5>PE2.

## Configuring the MPLS Transport Profile for OAM

---

- [MPLS Transport Profile Overview on page 147](#)
- [Example: Configuring the MPLS Transport Profile for OAM on page 147](#)

### MPLS Transport Profile Overview

RFC 5654, *Requirements of an MPLS Transport Profile*, describes the requirements for the MPLS Transport Profile (MPLS-TP) that extends capabilities for Operation, Administration, and Maintenance (OAM) when MPLS is used for transport services and transport network operations. These capabilities help in troubleshooting and maintenance of a pseudowire or label-switched path (LSP).

MPLS-TP mechanisms for OAM contain two main components:

- Generic Associated Channel Label (GAL)—A special label that enables an exception mechanism that informs the egress label-switching router (LSR) that a packet it receives on an LSP belongs to an associated control channel or the control plane.
- Generic Associated Channel Header (G-Ach)—A special header field that identifies the type of payload contained in the MPLS label-switched paths (LSPs). G-Ach has the same format as a pseudowire associated control channel header.

For more information about MPLS-TP, see RFC 5654, *Requirements of an MPLS Transport Profile*. For specific information about GAL and G-Ach, see RFC 5586, *MPLS Generic Associated Channel*.

The following capabilities are supported in the Junos OS implementation of MPLS-TP:

- MPLS-TP OAM can send and receive packets with GAL and G-Ach, without IP encapsulation.
- Two unidirectional RSVP LSPs between a pair of routers can be associated with each other to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages. A single Bidirectional Forwarding Detection (BFD) session is established for the associated bidirectional LSP.

### Example: Configuring the MPLS Transport Profile for OAM

This example shows how to configure the MPLS Transport Profile (MPLS-TP) for sending and receiving of OAM GAL and G-Ach messages across a label-switched path (LSP).

- [Configuration on page 150](#)
- [Verification on page 157](#)

## Requirements

---

This example uses the following hardware and software components:

- Six devices that can be a combination of M Series, MX Series, and T Series routers
- Junos OS Release 12.1 or later running on the devices

## Overview

---

Junos OS Release 12.1 and later support MPLS Transport Profile (MPLS-TP) Operation, Administration, and Maintenance (OAM) capabilities. MPLS-TP introduces new capabilities for OAM when MPLS is used for transport services and transport network operations. This includes configuring Generic Associated Channel Label (GAL) and Generic Associated Channel Header (G-Ach) for OAM messages.

This example shows how to configure MPLS-TP OAM capability to send and receive GAL and G-Ach OAM messages without IP encapsulation. In addition, it also shows how to associate two unidirectional RSVP label-switched paths (LSPs) between a pair of routers to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages.

Junos OS Release 12.1 and later support the following MPLS-TP capabilities:

- MPLS-TP OAM capability and the infrastructure required for MPLS applications to send and receive packets with GAL and G-Ach, without IP encapsulation.
- LSP-ping and Bidirectional Forwarding Detection (BFD) applications to send and receive packets using GAL and G-Ach, without IP encapsulation on transport LSPs.
- The association of two unidirectional RSVP LSPs, between a pair of routers, with each other to create an associated bidirectional LSP for binding a path for the GAL and G-Ach OAM messages. The associated bidirectional LSP model is supported only for associating the primary paths. A single BFD session is established for the associated bidirectional LSP.

Junos OS Release 12.1 and later does not support the following MPLS-TP capabilities:

- Point-to-multipoint RSVP LSPs and BGP LSPs
- Loss Measurement and Delay Measurement

You can enable GAL and G-Ach OAM operation using the following configuration statements:

- **mpls-tp-mode**—Include this statement at the **[edit protocols mpls oam]** hierarchy level to enable GAL and G-Ach OAM operation, without IP encapsulation, on all LSPs in the MPLS network.

```
[edit protocols mpls oam]  
mpls-tp-mode;
```

Include this statement at the `[edit protocols mpls label-switched-path lsp-name oam]` hierarchy level to enable GAL and G-Ach OAM operation without IP encapsulation on a specific LSP in the network.

```
[edit protocols mpls label-switched-path lsp-name oam]
mpls-tp-mode;
```

**NOTE:** Starting with Junos OS Release 16.1, MPLS-TP supports two additional channel types for the default LSPING (0x0008) channel type under the `mpls-tp-mode` statement. These additional channel types provide on-demand connectivity verification (CV) with and without IP/UDP encapsulation.

- On-demand CV (0x0025)—This channel type is a new pseudowire channel type and is used for on-demand CV without IP/UDP encapsulation, where IP addressing is not available or non-IP encapsulation is preferred.
- IPv4 (0x0021)—This channel type uses the IP/UDP encapsulation and provides interoperability support with other vendor devices using IP addressing.

The GACH-TLV is used along with the default LSPING channel type. As per RFC 7026, GACH-TLV is deprecated for 0x0021 and 0x0025 channel types.

To configure a channel type for MPLS-TP, include the `lsping-channel-type channel-type` statement at the `[edit protocols mpls label-switched-path lsp-name oam mpls-tp-mode]` and `[edit protocols mpls oam mpls-tp-mode]` hierarchy levels.

- **associate-lsp *lsp-name* from *from-ip-address***—Include this statement at the `[edit protocols mpls label-switched-path lsp-name]` hierarchy level to configure associated bidirectional LSPs on the two ends of the LSP.

```
[edit protocols mpls label-switched-path lsp-name ]
associate-lsp lsp-name {
  from from-ip-address;
}
```

The **from *from-ip-address*** configuration for the LSP is optional. If omitted, it is derived from the **to** address of the ingress LSP configuration.

- **transit-lsp-association**—Include this statement at the `[edit protocols mpls]` hierarchy level to associate two LSPs at a transit router.

```
[edit protocols mpls]
transit-lsp-association transit-association-lsp-group-name {
  lsp-name-1 name-of-associated-lsp-1;
  from-1 address-of-associated-lsp-1;
  lsp-name-2 name-of-associated-lsp-2;
  from-2 address-of-associated-lsp-2;
}
```

The association of the LSPs in the transit nodes is useful for the return LSP path for TTL-expired LSP ping packets or traceroute.

In this example, R0 is the ingress router and R4 is the egress router. R1, R2, R3, and R5 are transit routers. The associated bidirectional LSP is established between the transit routers for sending and receiving the GAL and G-Ach OAM messages.

Figure 22 on page 150 shows the topology used in this example.

**Figure 22: MPLS-TP OAM Associated Bidirectional LSPs**

g040928

## Configuration

### CLI Quick Configuration

**NOTE:** This example shows the configuration on all devices and shows step-by-step procedures for configuring the ingress router, R0, and transit router R1. Repeat the step-by-step procedure described for the ingress router, R0, on the egress router, R4. Repeat the step-by-step procedure for the transit router, R1, on the other transit routers, R2, R3, and R5. Be sure to modify the appropriate interface names, addresses, and other parameters appropriately.

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

**Router R0**

### *Configuring Device R0*

**Step-by-Step Procedure** To configure the ingress router, R0:

1. Configure the interfaces.

**[edit interfaces]**

```

user@R0# set ge-4/1/1 unit 0 family inet address 10.10.11.1/30
user@R0# set ge-4/1/1 unit 0 family iso
user@R0# set ge-4/1/1 unit 0 family inet6
user@R0# set ge-4/1/1 unit 0 family mpls
user@R0# set ge-5/0/0 unit 0 family inet address 10.10.10.1/30
user@R0# set ge-5/0/0 unit 0 family iso
user@R0# set ge-5/0/0 unit 0 family inet6
user@R0# set ge-5/0/0 unit 0 family mpls

```

2. Configure MPLS on the interfaces.

**[edit protocols mpls]**

- ```
user@R0# set interface ge-5/0/0.0
user@R0# set interface ge-4/1/1.0
```
3. Configure an interior gateway protocol, such as OSPF.  

```
[edit protocols ospf]
user@R0# set traffic-engineering
user@R0# set area 0.0.0.0 interface ge-5/0/0.0
user@R0# set area 0.0.0.0 interface ge-4/1/1.0
user@R0# set area 0.0.0.0 interface lo0.0 passive
```
  4. Configure a signaling protocol, such as RSVP.  

```
[edit protocols rsvp]
user@R0# set interface ge-5/0/0.0
user@R0# set interface ge-4/1/1.0
```
  5. Configure the LSP.  

```
[edit protocols mpls]
user@R0# set label-switched-path r0-to-r4 to 10.255.8.86
```
  6. Enable GAL and G-Ach OAM operation without IP encapsulation on the LSPs.  

```
[edit protocols mpls]
user@R0# set label-switched-path r0-to-r4 oam mpls-tp-mode
```
  7. Configure associated bidirectional LSPs on the two ends of the LSP.  

```
[edit protocols mpls]
user@R0# set label-switched-path r0-to-r4 associate-lsp to-r0 from 10.255.8.86
```
  8. After you are done configuring the device, commit the configuration.  

```
[edit]
user@R0# commit
```

**Results** Confirm your configuration by issuing the **show interfaces** and **show protocols** commands.

```
user@R0# show interfaces

### Configuring Device R1

**Step-by-Step Procedure** To configure the transit router, R1:

1. Configure the interfaces.
 

```

[edit interfaces]
user@R1# set ge-0/0/5 unit 0 family inet address 10.10.10.2/30
user@R1# set ge-0/0/5 unit 0 family iso
user@R1# set ge-0/0/5 unit 0 family inet6
user@R1# set ge-0/0/5 unit 0 family mpls
user@R1# set ge-0/2/2 unit 0 family inet address 10.10.12.2/30
user@R1# set ge-0/2/2 unit 0 family iso
user@R1# set ge-0/2/2 unit 0 family inet6
user@R1# set ge-0/2/2 unit 0 family mpls
user@R1# set ge-2/0/2 unit 0 family inet address 10.10.11.2/30
user@R1# set ge-2/0/2 unit 0 family iso
user@R1# set ge-2/0/2 unit 0 family inet6
user@R1# set ge-2/0/2 unit 0 family mpls
user@R1# set ge-1/0/2 unit 0 family inet address 10.10.13.2/30
user@R1# set ge-1/0/2 unit 0 family iso
user@R1# set ge-1/0/2 unit 0 family inet6
user@R1# set ge-1/0/2 unit 0 family mpls

```
2. Configure MPLS on the interfaces.
 

```

[edit protocols mpls]
user@R1# set interface ge-0/0/5.0
user@R1# set interface ge-2/0/2.0
user@R1# set interface ge-1/0/2.0

```

```
user@R1# set interface ge-0/2/2.0
```

3. Configure an interior gateway protocol, such as OSPF.

```
[edit protocols ospf]
user@R1# set traffic-engineering
user@R1# set area 0.0.0.0 interface ge-0/0/5.0
user@R1# set area 0.0.0.0 interface ge-2/0/2.0
user@R1# set area 0.0.0.0 interface ge-1/0/2.0
user@R1# set area 0.0.0.0 interface ge-0/2/2.0 metric 100
user@R1# set area 0.0.0.0 interface lo0.0 passive
```

4. Configure a signaling protocol, such as RSVP.

```
[edit protocols rsvp]
user@R1# set interface ge-0/0/5.0
user@R1# set interface ge-2/0/2.0
user@R1# set interface ge-1/0/2.0
user@R1# set interface ge-0/2/2.0
```

5. Configure the association of the two LSPs on the transit router.

```
[edit protocols mpls]
user@R1# set transit-lsp-association trace1 lsp-name-1 r0-to-r4
user@R1# set transit-lsp-association trace1 from-1 10.255.8.207
user@R1# set transit-lsp-association trace1 lsp-name-2 r4-to-r0
user@R1# set transit-lsp-association trace1 from-2 10.255.8.86
```

6. If you are done configuring the device, commit the configuration.

```
[edit]
user@R1# commit
```

**Results** Confirm your configuration by issuing the **show interfaces** and **show protocols** commands.

```
user@R1# show interfaces

#### Release History Table

Release	Description
16.1	Starting with Junos OS Release 16.1, MPLS-TP supports two additional channel types for the default LSPING (0x0008) channel type under the <code>mpls-tp-mode</code> statement.

## Configuring MPLS Inter-AS Link-Node Protection with Labeled BGP

- [Understanding MPLS Inter-AS Link Protection on page 160](#)
- [Example: Configuring MPLS Inter-AS Link-Node Protection on page 162](#)

### Understanding MPLS Inter-AS Link Protection

Link protection is essential in an MPLS network to ensure traffic restoration in case of an interface failure. The ingress router chooses an alternate link through another interface to send traffic to its destination.

In [Figure 23 on page 161](#), autonomous system border routers (ASBRs) run external BGP (EBGP) to ASBRs in another autonomous system (AS) to exchange labels for /32 IPv4 routes. Inside the ASs, internal BGP (IBGP) propagates the routes to provider edge (PE) devices. If the link from Device ASBR3 to Device ASBR1 goes down, until Device ASBR3 reinstalls the new next hop, all traffic going toward AS 64510 from AS 64511 through the ASBR3-ASBR1 link is dropped. A fast traffic restoration can be achieved if Device ASBR3

preprograms a backup path either through Device ASBR4 or through a direct path to Device ASBR2 if one exists (not shown in the diagram). This assumes that Device ASBR3 learns a loop-free MPLS path for routes that need to be protected either through IBGP or EBGP.

This solution does not handle a failure on Device ASBR3 for traffic going toward AS 64511 from AS 64510 through the ASBR3-ASBR1 link. This solution is limited to downstream inter-AS link-node protection with labeled BGP. This solution does not support service restoration between provider (P) and ASBR routers when there is an ASBR failure. For example, this solution does not handle a failure on the P3-ASBR3 link.

This supported functionality is similar to BGP multipath, except only one next hop is used for active forwarding, and a second path is in protected mode.

**Figure 23: MPLS Inter-AS Link-Node Protection Conceptual Topology**

In an MPLS inter-AS environment, link protection can be enabled when **labeled-unicast** is used to send traffic between ASs. Hence, MPLS inter-AS link protection is configured on the link between two routers in different ASs.

To configure link protection on an interface, use the **protection** statement at the **[edit protocols bgp group group-name family inet labeled-unicast]** hierarchy level:

```
protocols {
  bgp {
    group test1 {
      type external;
      local-address 192.168.1.2;
      family inet {
```

```
labeled-unicast {  
    protection;  
}  
}  
}  
}
```

**NOTE:** MPLS inter-AS link protection is supported only with `labeled-unicast` and external peers in a master routing instance.

The link on which protection is configured is known as the protection path. A protection path is selected only after the best path selection and is not selected in the following cases:

- The best path is a non-BGP path.
- Multiple next hops are active, as in BGP multipath.

## Example: Configuring MPLS Inter-AS Link-Node Protection

This example shows how to configure tail-end protection in an inter-AS deployment with Layer 3 VPNs.

- [Requirements on page 162](#)
- [Overview on page 162](#)
- [Configuration on page 164](#)
- [Verification on page 173](#)

---

### Requirements

No special configuration beyond device initialization is required before configuring this example.

---

### Overview

In [Figure 24 on page 163](#), autonomous system border routers (ASBRs) run external BGP (EBGP) to ASBRs in another autonomous system (AS) to exchange labels for /32 IPv4 routes. Inside the ASs, internal BGP (IBGP) propagates the routes to provider edge (PE) devices.

If the link from Device ASBR3 to Device ASBR1 goes down, until ASBR3 reinstalls the new next hop, all traffic going toward AS 64510 from AS 64511 through the ASBR3-ASBR1 link is dropped.

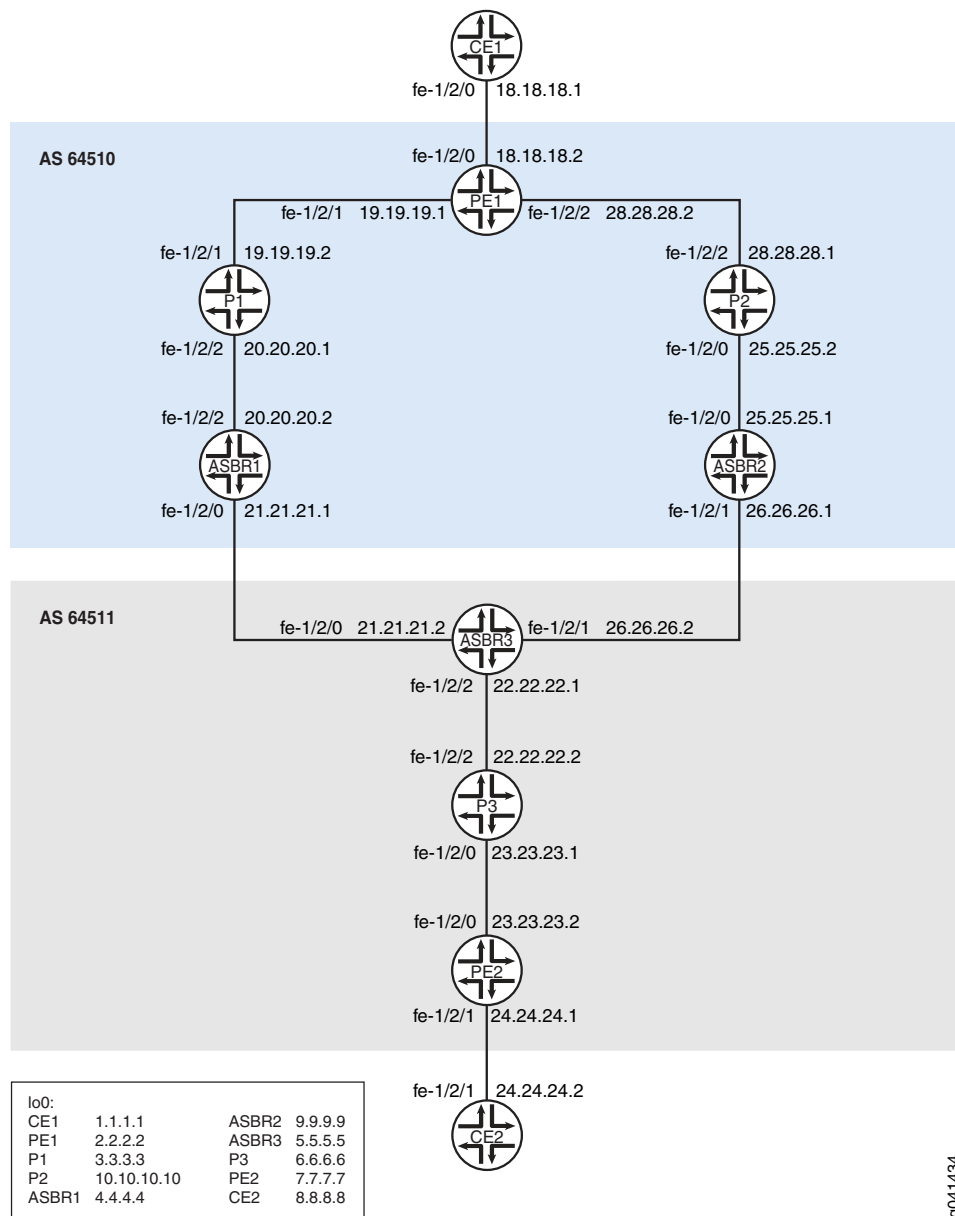

This example shows how to achieve fast traffic restoration by configuring Device ASBR3 to preprogram a backup path through Device ASBR2.

**NOTE:** This solution does not handle the Device P3 to Device ASBR3 failure. Nor does it handle a failure on Device ASBR3 for traffic going toward AS 64511 from AS 64510 through the ASBR3-ASBR1 link. This traffic is dropped.

Figure 24: MPLS Inter-AS Link-Node Protection Example Topology

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the EBGp scenario:

1. Configure the router interfaces.

```
[edit interfaces]
user@ASBR3# set fe-1/2/0 unit 0 description to-ASBR1
user@ASBR3# set fe-1/2/0 unit 0 family inet address 21.21.21.2/30
user@ASBR3# set fe-1/2/0 unit 0 family mpls

user@ASBR3# set fe-1/2/2 unit 0 description to-P3
user@ASBR3# set fe-1/2/2 unit 0 family inet address 22.22.22.1/30
user@ASBR3# set fe-1/2/2 unit 0 family mpls

user@ASBR3# set fe-1/2/1 unit 0 description to-ASBR2
user@ASBR3# set fe-1/2/1 unit 0 family inet address 26.26.26.2/30
user@ASBR3# set fe-1/2/1 unit 0 family mpls

user@ASBR3# set lo0 unit 0 family inet address 5.5.5.5/32
```

2. Configure an interior gateway protocol (IGP), such as OSPF or IS-IS.

```
[edit protocols ospf]
user@ASBR3# set traffic-engineering

[edit protocols ospf area 0.0.0.0]
user@ASBR3# set interface fe-1/2/2.0
user@ASBR3# set interface lo0.0 passive
user@ASBR3# set interface fe-1/2/1.0
```

3. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@ASBR3# set autonomous-system 64511
```

4. Configure the routing policy.

```
[edit policy-options policy-statement To-ASBR1]
user@ASBR3# set term 1 from route-filter 7.7.7.7/32 exact
user@ASBR3# set term 1 then accept
user@ASBR3# set term 2 then reject
```

```
[edit policy-options policy-statement To-ASBR2]
user@ASBR3# set term 1 from route-filter 7.7.7.7/32 exact
user@ASBR3# set term 1 then accept
user@ASBR3# set term 2 then reject
```

```
[edit policy-options policy-statement next-hop-self]
user@ASBR3# set then next-hop self
```

5. Configure the EBGp sessions.

```
[edit protocols bgp group To-ASBR1]
user@ASBR3# set type external
```

```

user@ASBR3# set family inet labeled-unicast protection
user@ASBR3# set family inet labeled-unicast per-prefix-label
user@ASBR3# set export To-ASBR1
user@ASBR3# set neighbor 21.21.21.1 peer-as 64510

```

```

[edit protocols bgp group To-ASBR2]
user@ASBR3# set type external
user@ASBR3# set family inet labeled-unicast protection
user@ASBR3# set family inet labeled-unicast per-prefix-label
user@ASBR3# set export To-ASBR2
user@ASBR3# set neighbor 26.26.26.1 peer-as 64510

```

6. Configure the IBGP sessions.

```

[edit protocols bgp group To-PE2]
user@ASBR3# set type internal
user@ASBR3# set local-address 5.5.5.5
user@ASBR3# set family inet unicast
user@ASBR3# set export next-hop-self
user@ASBR3# set neighbor 7.7.7.7 family inet labeled-unicast

```

7. Configure MPLS.

```

[edit protocols mpls]
user@ASBR3# set traffic-engineering bgp-igp-both-ribs
user@ASBR3# set label-switched-path To_PE2 to 7.7.7.7
user@ASBR3# set interface lo0.0
user@ASBR3# set interface fe-1/2/0.0
user@ASBR3# set interface fe-1/2/2.0
user@ASBR3# set interface fe-1/2/1.0

```

8. Configure a signaling protocol.

```

[edit protocols rsvp]
user@ASBR3# set interface fe-1/2/2.0
user@ASBR3# set interface lo0.0
user@ASBR3# set interface fe-1/2/0.0
user@ASBR3# set interface fe-1/2/1.0

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options**, commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@ASBR3# show interfaces
fe-1/2/0 {
  unit 0 {

Stale routes from peer are kept for: 300
Peer does not support Restarter functionality
NLRI that restart is negotiated for: inet-labeled-unicast
NLRI of received end-of-rib markers: inet-labeled-unicast
NLRI of all end-of-rib markers sent: inet-labeled-unicast
Peer supports 4 byte AS extension (peer-as 64510)
Peer does not support Addpath
Table inet.0 Bit: 10002
  RIB State: BGP restart is complete
  Send state: in sync
  Active prefixes:          1
  Received prefixes:        1
  Accepted prefixes:        1
  Suppressed due to damping: 0
  Advertised prefixes:      1
Last traffic (seconds): Received 21   Sent 9   Checked 42
Input messages: Total 170   Updates 2   Refreshes 0   Octets 3326
Output messages: Total 168   Updates 1   Refreshes 0   Octets 3307
Output Queue[0]: 0

```

**Meaning** The output shows that the **Protection** option is enabled for the EBGp peers, Device ASBR1 and Device ASBR2.

This is also shown with the **NLRI configured with protection: inet-labeled-unicast** screen output.

### *Checking the Routes*

**Purpose** Make sure that the backup path is installed in the routing table.

```

Action user@ASBR3> show route 2.2.2.2
inet.0: 12 destinations, 14 routes (12 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2.2.2.2/32          *[BGP/170] 01:36:25, MED 2, localpref 100
                   AS path: 64510 I, validation-state: unverified
                   > to 21.21.21.1 via fe-1/2/0.0, Push 299824
                   to 26.26.26.1 via fe-1/2/1.0, Push 299808
                   [BGP/170] 01:36:25, MED 2, localpref 100
                   AS path: 64510 I, validation-state: unverified
                   > to 26.26.26.1 via fe-1/2/1.0, Push 299808

```

**Meaning** The **show route** command displays active as well as backup paths to Device PE1.

## Configuring Egress Protection Service Mirroring for BGP Signaled Layer 2 Services

Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node. If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

Figure 1 shows a simplified topology of the use case that explains this feature.

**Figure 25: Egress Protection LSP Configured from Router PE1 to Router PE2**

CE1 is multihomed to PE1 and PE2. There are two paths connecting CE1 and CE2. The working path is CE2-PE3-P-PE1-CE1, via pseudowire PW21. The protecting path is CE2-PE3-P-PE2-CE1, via pseudowire PW22. Traffic is flowing through the working path under normal circumstances. When the end-to-end OAM between CE1 and CE2 detects failure on the working path, traffic will be switched from the working path to the protecting path. The end-to-end failure detection and recovery relies on control plane hence should be relatively slow. To achieve faster protection, local repair mechanisms similar to those used by MPLS fast reroute should be used. In Figure 1 above, if link or node failed in the core network (like link failure on P-PE1, P-PE3, or node failure on P), the MPLS fast reroute will happen on the transport LSPs between PE1 and PE3. The failure could be locally repaired within tens of milliseconds. However, if link or node failure happens at the edge (like link failure on PE3-CE2 or node failure on PE3), there is no local repair currently so we have to rely on the CE1-CE2 end-to-end protection to repair the failure.

- Device CE2—Traffic origin
- Router PE3—Ingress PE router
- Router PE1— (Primary) Egress PE router
- Router PE2—Protector PE router
- Device CE1—Traffic destination

When the link between CE1– PE1 goes down, PE1 will briefly redirect that traffic towards CE1, to PE2. PE2 forwards it to CE1 until ingress router PE3 recalculates to forward the traffic to PE2.

Initially the traffic direction was; CE2 – PE3 – P – PE1 – CE1.

When the link between CE1– PE1 goes down, the traffic will be; CE2 – PE3 – P – PE1 – PE2 – CE1. PE3 then recalculates the path; CE2 – PE3 – P – PE2 – CE1.

1. Configure RSVP on PE1, PE2, and PE3.

```
[edit protocols]
user@PE1# set interface all
user@PE2# set interface all
user@PE3# set interface all
```

2. Configure MPLS.

```
[edit protocols mpls]
user@PE1# set interface all
user@PE2# set interface all
user@PE3# set interface all
```

3. Set PE1 as **primary** and PE2 as **protector** nodes.

```
[edit protocols mpls]
user@PE1# set egress-protection context-identifier address primary
user@PE2# set egress-protection context-identifier address protector
```

4. Enable **egress-protection** on PE1 and PE2.

```
[edit protocols bgp]
user@PE1# set group ibgp family l2vpn egress-protection
user@PE2# set group ibgp family l2vpn egress-protection
```

5. Configure LDP and ISIS on PE1, PE2, and PE3.

```
[edit protocols ldp]
user@PE1# set interface all
user@PE2# set interface all
user@PE3# set interface all

[edit protocols isis]
user@PE1# set interface all point-to-point
user@PE2# set interface all point-to-point
user@PE3# set interface all point-to-point
```

6. Configure a load balancing policy at PE1, PE2, and PE3.

```
[edit]
user@PE1# set policy-options policy-statement lb then load-balance per-packet
user@PE2# set policy-options policy-statement lb then load-balance per-packet
user@PE3# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options at PE1, PE2, and PE3, to export routes based on the load balancing policy.

```
[edit]
user@PE1# set routing-options traceoptions file ro.log
user@PE1# set routing-options traceoptions flag normal
user@PE1# set routing-options traceoptions flag route
```

```
user@PE1# set routing-options autonomous-system 100
user@PE1# set routing-options forwarding-table export lb
```

```
[edit]
user@PE2# set routing-options traceoptions file ro.log
user@PE2# set routing-options traceoptions flag normal
user@PE2# set routing-options traceoptions flag route
user@PE2# set routing-options autonomous-system 100
user@PE2# set routing-options forwarding-table export lb
```

```
[edit]
user@PE3# set routing-options traceoptions file ro.log
user@PE3# set routing-options traceoptions flag normal
user@PE3# set routing-options traceoptions flag route
user@PE3# set routing-options autonomous-system 100
user@PE3# set routing-options forwarding-table export lb
```

8. Configure BGP at PE1 to advertise nrli from the routing instance with context-ID as next-hop.

```
[edit]
user@PE1# set routing-instances foo egress-protection context-identifier
context-identifier
```

9. Configure l2vpn at PE1, PE2, and PE3

At PE1:

```
[edit routing-instances]
foo {
  instance-type l2vpn;
  egress-protection {
    context-identifier {
      198.51.100.0;
    }
  }
  interface ge-2/0/2.0;
  route-distinguisher 10.255.183.58:1;
  vrf-target target:9000:1;
  protocols {
    l2vpn {
      encapsulation-type ethernet-vlan;
      site foo {
        site-identifier 1;
        multi-homing;
        site-preference primary;
        interface ge-2/0/2.0 {
          remote-site-id 2;
        }
      }
    }
  }
}
```

At PE2:

```
[edit routing-instances]
foo {
  instance-type l2vpn;
```

```
egress-protection {
  protector;
}
interface ge-2/0/2.0;
route-distinguisher 10.255.183.57:1;
vrf-target target:9000:1;
protocols {
  l2vpn {
    encapsulation-type ethernet-vlan;
    site foo {
      site-identifier 1;
      multi-homing;
      site-preference backup;
      interface ge-2/0/2.0 {
        remote-site-id 2;
      }
    }
  }
}
```

At PE3:

```
[edit routing-instances]
foo {
  instance-type l2vpn;
  interface ge-2/1/2.0;
  route-distinguisher 10.255.183.61:1;
  vrf-target target:9000:1;
  protocols {
    l2vpn {
      encapsulation-type ethernet-vlan;
      site foo {
        site-identifier 2;
        interface ge-2/1/2.0;
      }
    }
  }
}
```

Release History Table

Release	Description
14.2	Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node.

## Example: Configuring MPLS Egress Protection Service Mirroring for BGP Signaled Layer 2 Services

---

Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node. If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

This example shows how to configure link protection for BGP signaled Layer 2 services.

- [Requirements on page 180](#)
- [Overview on page 180](#)
- [Configuration on page 181](#)
- [Verification on page 194](#)

### Requirements

MX Series Routers running Junos OS Release 14.2 or later.

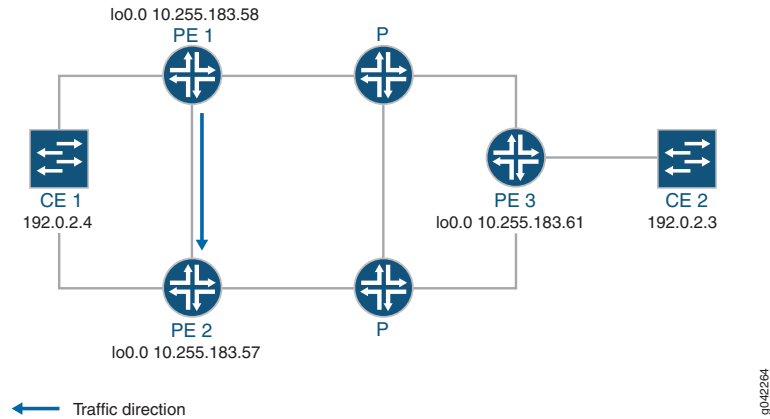

### Overview

If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

This example includes the following configuration concepts and statements that are unique to the configuration of an egress protection LSP:

- **context-identifier**—Specifies an IPv4 or IPv6 address used to define the pair of PE routers participating in the egress protection LSP. It is assigned to each ordered pair of primary PE and the protector to facilitate protection establishment. This address is globally unique, or unique in the address space of the network where the primary PE and the protector reside.
- **egress-protection**—Configures the protector information for the protected Layer 2 circuit and configures the protector Layer 2 circuit at the **[edit protocols mpls]** hierarchy level. Configures an LSP as an egress protection LSP at the **[edit protocols mpls]** hierarchy level.
- **protector**—Configures the creation of standby pseudowires on the backup PE for link or node protection for the instance.

Figure 26: Egress Protection LSP Configured from Router PE1 to Router PE2

In the event of a failure of the egress PE Router PE1, traffic is switched to the egress protection LSP configured between Router PE1 and Router PE2 (the protector PE router):

- Device CE2—Traffic origin
- Router PE3—Ingress PE router
- Router PE1— (Primary) Egress PE router
- Router PE2—Protector PE router
- Device CE1—Traffic destination

When the link between CE1– PE1 goes down, PE1 will briefly redirect that traffic toward CE1, to PE2. PE2 forwards it to CE1 until ingress router PE3 recalculates to forward the traffic to PE2.

Initially the traffic direction was: CE2 – PE3 – P – PE1 – CE1.

When the link between CE1– PE1 goes down, the traffic will be: CE2 – PE3 – P – PE1 – PE2 –CE1. PE3 then recalculates the path: CE2 – PE3 – P – PE2 – CE1.

This example shows how to configure routers PE1, PE2, and PE3.

## Configuration

- [Step-by-Step Procedure on page 184](#)
- [Results on page 188](#)

### CLI Quick Configuration

To quickly configure an egress protection LSP, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configurations, copy and then paste the commands into the CLI and enter **commit** from configuration mode.

PE1

```
set protocols rsvp interface all
```

```
set protocols rsvp interface fxp0.0 disable
set protocols mpls interface all
set protocols mpls interface fxp0.0 disable
set protocols mpls egress-protection context-identifier 198.51.100.3 primary
set protocols mpls egress-protection context-identifier 198.51.100.3 advertise-mode
  stub-alias
set protocols mpls egress-protection traceoptions file ep size 100m
set protocols mpls egress-protection traceoptions flag all
set protocols bgp traceoptions file bgp.log world-readable
set protocols bgp group ibgp type internal
set protocols bgp group ibgp local-address 10.255.183.58
set protocols bgp group ibgp family inet unicast
set protocols bgp group ibgp family l2vpn signaling egress-protection
set protocols bgp group ibgp neighbor 192.0.2.3
set protocols bgp group ibgp neighbor 192.0.2.4
set protocols isis traceoptions file isis-edge size 10m world-readable
set protocols isis traceoptions flag error
set protocols isis level 1 disable
set protocols isis level 2 wide-metrics-only
set protocols isis interface all point-to-point
set protocols isis interface all level 2 metric 10
set protocols isis interface fxp0.0 disable
set protocols ldp interface all
set protocols ldp interface fxp0.0 disable
set policy-options policy-statement lb then load-balance per-packet

set routing-instances foo protocols l2vpn site foo site-identifier 2
set routing-instances foo protocols l2vpn site foo interface ge-2/1/2.0 remote-site-id 1

```

### Step-by-Step Procedure

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure an egress protection LSP for router PE1:

1. Configure RSVP.

```

[edit protocols rsvp]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable

```

2. Configure MPLS to use the egress protection LSP to protect against a link failure to Device CE1.

```

[edit protocols mpls]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
user@PE1# set egress-protection context-identifier 198.51.100.3 primary
user@PE1# set egress-protection context-identifier 198.51.100.3 advertise-mode
  stub-alias
user@PE1# set egress-protection traceoptions file ep size 100m
user@PE1# set egress-protection traceoptions flag all

```

3. Configure BGP.

```

[edit protocols bgp]
user@PE1# set traceoptions file bgp.log world-readable
user@PE1# set group ibgp type internal
user@PE1# set group ibgp local-address 10.255.183.58
user@PE1# set group ibgp family inet unicast
user@PE1# set group ibgp family l2vpn signaling egress-protection
user@PE1# set group ibgp neighbor 192.0.2.3
user@PE1# set group ibgp neighbor 192.0.2.4

```

4. Configure IS-IS.

```

[edit protocols isis]
user@PE1# set traceoptions file isis-edge size 10m world-readable
user@PE1# set traceoptions flag error
user@PE1# set level 1 disable
user@PE1# set level 2 wide-metrics-only
user@PE1# set interface all point-to-point
user@PE1# set interface all level 2 metric 10
user@PE1# set interface fxp0.0 disable

```

5. Configure LDP.
 

```
[edit protocols ldp]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
```
6. Configure a load-balancing policy.
 

```
[edit]
user@PE1# set policy-options policy-statement lb then load-balance per-packet
```
7. Configure the routing options to export routes based on the load-balancing policy.
 

```
[edit routing-options]
user@PE1# set traceoptions file ro.log
user@PE1# set traceoptions flag all
user@PE1# set autonomous-system 100
user@PE1# set forwarding-table export lb
```
8. Configure BGP to advertise nrli from the routing instance with context-ID as next-hop.
 

```
[edit routing-instances]
user@PE1# set foo instance-type l2vpn
user@PE1# set foo egress-protection context-identifier 198.51.100.3
user@PE1# set foo interface ge-2/0/2.0
user@PE1# set foo route-distinguisher 10.255.183.58:1
user@PE1# set foo vrf-target target:9000:1
```
9. Configure l2vpn instance to use the egress LSP configured.
 

```
[edit routing-instances]
user@PE1# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE1# set foo protocols l2vpn site foo site-identifier 1
user@PE1# set foo protocols l2vpn site foo multi-homing
user@PE1# set foo protocols l2vpn site foo site-preference primary
user@PE1# set foo protocols l2vpn site foo interface ge-2/0/2.0 remote-site-id 2
```
10. If you are done configuring the device, enter **commit** from configuration mode.

#### Step-by-Step Procedure

To configure an egress protection LSP for Router PE2:

1. Configure RSVP.
 

```
[edit protocols rsvp]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
```
2. Configure MPLS and the LSP that acts as the egress protection LSP.
 

```
[edit protocols mpls]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
user@PE2# set egress-protection context-identifier 198.51.100.3 protector
user@PE2# set egress-protection context-identifier 198.51.100.3 advertise-mode stub-alias
user@PE2# set egress-protection traceoptions file ep size 100m
user@PE2# set egress-protection traceoptions flag all
```
3. Configure BGP.
 

```
[edit protocols bgp]
```

- ```
user@PE2# set traceoptions file bgp.log world-readable
user@PE2# set group ibgp type internal
user@PE2# set group ibgp local-address 10.255.183.57
user@PE2# set group ibgp family inet unicast
user@PE2# set group ibgp family l2vpn signaling
user@PE2# set group ibgp family l2vpn egress-protection
user@PE2# set group ibgp neighbor 192.0.2.3
user@PE2# set group ibgp neighbor 192.0.2.4
```
4. Configure IS-IS.

```
[edit protocols isis]
user@PE2# set traceoptions file isis-edge size 10m world-readable
user@PE2# set traceoptions flag error
user@PE2# set level 1 disable
user@PE2# set level 2 wide-metrics-only
user@PE2# set interface all point-to-point
user@PE2# set interface all level 2 metric 10
user@PE2# set interface fxp0.0 disable
```
  5. Configure LDP.

```
[edit protocols ldp]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
```
  6. Configure a load-balancing policy.

```
[edit]
user@PE2# set policy-options policy-statement lb then load-balance per-packet
```
  7. Configure the routing options to export routes based on the load-balancing policy.

```
[edit routing-options]
user@PE2# set traceoptions file ro.log
user@PE2# set traceoptions flag all
user@PE2# set autonomous-system 100
user@PE2# set forwarding-table export lb
```
  8. Configure BGP to advertise nrli from the routing instance with context-ID as next-hop.

```
[edit routing-instances]
user@PE2# set foo instance-type l2vpn
user@PE2# set foo egress-protection protector
user@PE2# set foo interface ge-2/0/2.0
user@PE2# set foo route-distinguisher 10.255.183.57:1
user@PE2# set foo vrf-target target:9000:1
```
  9. Configure l2vpn instance to use the egress LSP configured.

```
[edit routing-instances]
user@PE2# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE2# set foo protocols l2vpn site foo hot-standby
user@PE2# set foo protocols l2vpn site foo site-identifier 1
user@PE2# set foo protocols l2vpn site foo multi-homing
user@PE2# set foo protocols l2vpn site foo site-preference backup
user@PE2# set foo protocols l2vpn site foo interface ge-2/0/2.0 remote-site-id 2
```
  10. If you are done configuring the device, enter **commit** from configuration mode.

**Step-by-Step Procedure**

To configure an egress protection LSP for Router PE3:

1. Configure RSVP.
 

```
[edit protocols rsvp]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
```
2. Configure MPLS.
 

```
[edit protocols mpls]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
```
3. Configure BGP.
 

```
[edit protocols bgp]
user@PE3# set traceoptions file bgp.log world-readable
user@PE3# set group ibgp type internal
user@PE3# set group ibgp local-address 10.255.183.61
user@PE3# set group ibgp family inet unicast
user@PE3# set group ibgp family l2vpn signaling
user@PE3# set group ibgp neighbor 192.0.2.3
user@PE3# set group ibgp neighbor 192.0.2.4
```
4. Configure IS-IS.
 

```
[edit protocols isis]
user@PE3# set traceoptions file isis-edge size 10m world-readable
user@PE3# set traceoptions flag error
user@PE3# set level 1 disable
user@PE3# set level 2 wide-metrics-only
user@PE3# set protocols isis interface all point-to-point
[edit protocols isis]
user@PE3# set protocols isis interface all level 2 metric 10
[edit protocols isis]
user@PE3# set protocols isis interface fxp0.0 disable
```
5. Configure LDP.
 

```
[edit protocols ldp]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
```
6. Configure a load-balancing policy.
 

```
[edit]
user@PE3# set policy-options policy-statement lb then load-balance per-packet
```
7. Configure the routing options to export routes based on the load-balancing policy.
 

```
[edit routing-options]
user@PE3# set traceoptions file ro.log
user@PE3# set traceoptions flag normal
user@PE3# set traceoptions flag route
user@PE3# set autonomous-system 100
user@PE3# set forwarding-table export lb
```
8. Configure BGP to advertise nlri from the routing instance with context-ID as next-hop.
 

```
[edit]
```

```

user@PE3# set routing-instances foo instance-type l2vpn
user@PE3# set routing-instances foo interface ge-2/1/2.0
user@PE3# set routing-instances foo route-distinguisher 10.255.183.61:1
user@PE3# set routing-instances foo vrf-target target:9000:1

```

9. Configure l2vpn to specify the interface that connects to the site and the remote interface to which you want the specified interface to connect.

```

[edit routing-instances]
user@PE3# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE3# set foo protocols l2vpn site foo site-identifier 2
user@PE3# set foo protocols l2vpn site foo interface ge-2/1/2.0 remote-site-id 1

```

10. If you are done configuring the device, enter **commit** from configuration.

## Results

From configuration mode, confirm your configuration on Router PE1 by entering the **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

## Verification

Confirm that the configuration is working properly.

- [Verifying the L2VPN Configuration on page 194](#)
- [Verifying the Routing Instance Details on page 195](#)
- [Verifying the IS-IS Configuration on page 195](#)
- [Verifying the MPLS Configuration on page 196](#)

### Verifying the L2VPN Configuration

**Purpose** Verify that LSP is protected by the connection protection logic.

**Action** From operational mode, run the **show l2vpn connections extensive** command.

```
user@PE2> show l2vpn connections extensive
```

```

Layer-2 VPN connections:
Legend for connection status (St)
EI -- encapsulation invalid      NC -- interface encapsulation not CCC/TCC/VPLS
EM -- encapsulation mismatch    WE -- interface and instance encaps not same
VC-Dn -- Virtual circuit down  NP -- interface hardware not present
CM -- control-word mismatch     -> -- only outbound connection is up
CN -- circuit not provisioned   <- -- only inbound connection is up
OR -- out of range             Up -- operational
OL -- no outgoing label        Dn -- down
LD -- local site signaled down  CF -- call admission control failure
RD -- remote site signaled down SC -- local and remote site ID collision
LN -- local site not designated LM -- local site ID not minimum designated
RN -- remote site not designated RM -- remote site ID not minimum designated
XX -- unknown connection status IL -- no incoming label
MM -- MTU mismatch             MI -- Mesh-Group ID not available
BK -- Backup connection        ST -- Standby connection
PF -- Profile parse failure     PB -- Profile busy
RS -- remote site standby       SN -- Static Neighbor
LB -- Local site not best-site  RB -- Remote site not best-site
VM -- VLAN ID mismatch

Legend for interface status
Up -- operational
Dn -- down
Instance: foo
Local site: foo (1)
connection-site      Type  St  Time last up      # Up trans

```

```

2                                rmt  Up  Aug 3 00:08:14 2001          1
Local circuit: ge-2/0/2.0, Status: Up
Remote PE: 192.0.2.3
Incoming label: 32769, Outgoing label: 32768
Egress Protection: Yes
  Time      Event                      Interface/Lbl/PE
  Aug 3 00:08:14 2001 PE route up
  Aug 3 00:08:14 2001 Out lbl Update          32768
  Aug 3 00:08:14 2001 In lbl Update           32769
  Aug 3 00:08:14 2001 ckt0 up                  fe-0/0/0.0

```

**Meaning** The **Egress Protection: Yes** output shows that the given PVC is protected by connection protection logic.

### Verifying the Routing Instance Details

**Purpose** Verify the routing instance information and the context identifier configured on the primary, which is used as the next-hop address in case of node-link failure.

**Action** From operational mode, run the **show route foo detail** command.

```

user@PE2> show route foo detail

foo:
Router ID: 0.0.0.0
Type: l2vpn non-forwarding State: Active
Interfaces:
  lt-1/2/0.56
Route-distinguisher: 10.255.255.11:1
Vrf-import: [ __vrf-import-foo-internal__ ]
Vrf-export: [ __vrf-export-foo-internal__ ]
Vrf-import-target: [ target:100:200 ]
Vrf-export-target: [ target:100:200 ]
Fast-reroute-priority: low
Vrf-edge-protection-id: 198.51.100.3
Tables:
  foo.l2vpn.0          : 5 routes (3 active, 0 holddown, 0 hidden)
  foo.l2id.0           : 6 routes (2 active, 0 holddown, 0 hidden)

```

**Meaning** The context-id is set to **198.51.100.3** and the **Vrf-import: [ \_\_vrf-import-foo-internal\_\_ ]** in the output mentions the policy used for rewriting the next-hop address.

### Verifying the IS-IS Configuration

**Purpose** Verify the IS-IS context identifier information.

**Action** From operational mode, run the **show isis context-identifier detail** command.

```

user@PE2> show isis context-identifier detail

IS-IS context database:
Context      L  Owner      Role      Primary      Metric
198.51.100.3 2  MPLS      Protector pro17-b-lr-R1 0
Advertiser pro17-b, Router ID 10.255.107.49, Level 2, tlv protector
Advertiser pro17-b-lr-R1, Router ID 10.255.255.11, Metric 1, Level 2, tlv prefix

```

**Meaning** Router PE2 is the protector and the configured context identifier is in use for the MPLS protocol.

### Verifying the MPLS Configuration

**Purpose** Verify the context identifier details on the primary and protector PEs.

**Action** From operational mode, run the **show mpls context-identifier detail** command.

```

user@PE1> show mpls context-identifier detail

ID: 198.51.100.3
  Type: primary, Metric: 1, Mode: alias

Total 1, Primary 1, Protector 0

user@PE2> show mpls context-identifier detail

ID: 198.51.100.3
  Type: protector, Metric: 16777215, Mode: alias
  Context table: __198.51.100.3__.mpls.0, Label out: 299968

user@PE2> show mpls egress-protection detail

```

```

Instance          Type      Protection-Type
foo               local-l2vpn Protector
  Route Target 100:200

```

**Meaning** Context-id is **198.51.100.3**, advertise-mode is **alias**, the MPLS table created for egress protection is **\_\_198.51.100.3\_\_.mpls.0**, and the egress instance name is **foo**, which is of type **local-l2vpn**.

### Release History Table

| Release | Description                                                                                                                                        |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node. |

## Example: Configuring Layer 3 VPN Egress Protection with PLR as Protector

This example shows how to configure fast service restoration at the egress of a Layer 3 VPN when the customer is multihomed to the service provider.

Starting in Junos OS Release 15.1, the enhanced point of local repair (PLR) functionality addresses a special scenario of egress node protection, where the PLR and the protector are co-located as one router. In this case, there is no need to have a bypass LSP reroute

traffic during local repair. Instead, the PLR or the protector can send the traffic directly to the target CE (in Co-located protector model where the PLR or the protector is also the backup PE that is directly connected to the CE) or to the backup PE (in Centralized protector model where the backup PE is a separate router).

- [Requirements on page 197](#)
- [Overview on page 197](#)
- [Configuration on page 198](#)
- [Verification on page 214](#)

## Requirements

No special configuration beyond device initialization is required before configuring this example.

This example requires Junos OS Release 15.1 or later.

## Overview

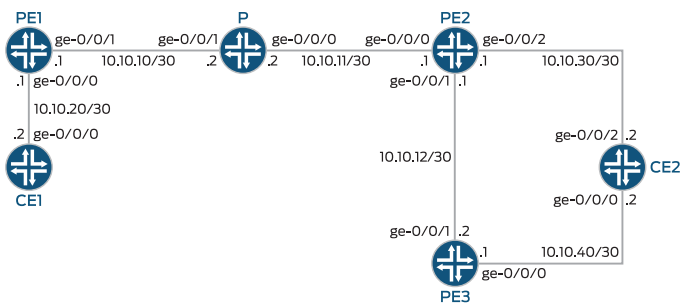

As a special scenario of egress node protection, if a router is both a Protector and a PLR, it installs backup next hops to protect the transport LSP. In particular, it does not need a bypass LSP for local repair.

In the Co-located protector model, the PLR or the Protector is directly connected to the CE via a backup AC, while in the Centralized protector model, the PLR or the protector has an MPLS tunnel to the backup PE. In either case, the PLR or the Protector will install a backup next hop with a label followed by a lookup in a **context label** table, i.e. **\_\_context\_\_.mpls.0**. When the egress node fails, the PLR or the Protector will switch traffic to this backup next hop in PFE. The outer label (the transport LSP label) of packets is popped, and the inner label (the layer 3 VPN label allocated by the egress node) is looked up in **\_\_context\_\_.mpls.0**, which results in forwarding the packets directly to the CE (in Collocated protector model) or the backup PE (in Centralized protector model).

## Topology

[Figure 27 on page 197](#) shows the sample network.

**Figure 27: Co-located PLR and protector in collocated protector model**

```

### Configuring Device CE1

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

1. Configure interfaces.
 

```

[edit interfaces]
user@CE1# set ge-0/0/0 unit 0 family inet address 10.10.20.2/30
user@CE1# set lo0 unit 0 family inet address 10.255.162.87/32

```

### Configuring Device PE1

- Step-by-Step Procedure**
1. Configure the interfaces.
 

```

[edit interfaces]
user@PE1# set ge-0/0/0 unit 0 family inet address 10.10.20.1/30
user@PE1# set ge-0/0/1 unit 0 family inet address 10.10.10.1/30
user@PE1# set ge-0/0/1 unit 0 family iso
user@PE1# set ge-0/0/1 unit 0 family inet6
user@PE1# set ge-0/0/1 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 127.0.0.1/32
user@PE1# set lo0 unit 0 family inet address 10.255.162.84/32 primary

```

- ```
user@PE1# set lo0 unit 0 family iso address
47.0005.80ff.f800.0000.0108.0001.0102.5516.2084.00
user@PE1# set lo0 unit 0 family inet6 address abcd::10:255:162:84/128 primary
```
2. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@PE1# set autonomous-system 65000
user@PE1# set forwarding-table export pplb
```
  3. Configure RSVP.

```
[edit protocols rsvp]
user@PE1# set interface all link-protection
user@PE1# set interface fxp0.0 disable
```
  4. Enable MPLS.

```
[edit protocols mpls]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
```
  5. Configure BGP.

```
[edit protocols bgp]
user@PE1# set group vpn type internal
user@PE1# set group vpn local-address 10.255.162.84
user@PE1# set group vpn family inet-vpn unicast
user@PE1# set group vpn neighbor 10.255.162.91
user@PE1# set group vpn neighbor 10.255.162.89
user@PE1# set vpn-apply-export
```
  6. Enable IS-IS.

```
[edit protocols isis]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
user@PE1# set interface lo0.0 passive
```
  7. (Optional) Configure OSPF

```
[edit protocols ospf]
user@PE1# set area 0.0.0.0 interface all
user@PE1# set area 0.0.0.0 interface fxp0.0 disable
user@PE1# set area 0.0.0.0 interface lo0.0 passive
user@PE1# set traffic-engineering
```
  8. Configure the routing instance.

```
[edit routing-instances]
user@PE1# set vpn instance-type vrf
user@PE1# set vpn interface ge-1/0/0.0
user@PE1# set vpn route-distinguisher 100:100
user@PE1# set vpn vrf-import vpn-imp
user@PE1# set vpn vrf-export vpn-exp
user@PE1# set vpn vrf-table-label
user@PE1# set vpn protocols bgp group vpn type external
user@PE1# set vpn protocols bgp group vpn family inet unicast
user@PE1# set vpn protocols bgp group vpn family inet6 unicast
user@PE1# set vpn protocols bgp group vpn peer-as 65001
user@PE1# set vpn protocols bgp group vpn as-override
```

```
user@PE1# set vpn protocols bgp group vpn neighbor 10.10.20.2
```

9. Configure the routing policy.

```
[edit]
user@PE1# set policy-options policy-statement vpn-exp term 1 from protocol direct
user@PE1# set policy-options policy-statement vpn-exp term 1 from route filter
10.10.20.0/24 exact
user@PE1# set policy-options policy-statement vpn-exp term 1 then community
add vpn
user@PE1# set policy-options policy-statement vpn-exp term 1 then accept
user@PE1# set policy-options policy-statement vpn-imp term 1 from community
vpn
user@PE1# set policy-options policy-statement vpn-imp term 1 then accept
user@PE1# set policy-options policy-statement vpn-imp term 2 then reject
user@PE1# set policy-options community vpn members target:1:1
```

### Configuring Device P

#### Step-by-Step Procedure

1. Configure the device interfaces.

```
[edit interfaces]
user@P# set ge-0/0/0 unit 0 family inet address 10.10.11.2/30
user@P# set ge-0/0/0 unit 0 family inet6
user@P# set ge-0/0/0 unit 0 family iso
user@P# set ge-0/0/0 unit 0 family mpls
user@P# set ge-0/0/1 unit 0 family inet address 10.10.10.2/30
user@P# set ge-0/0/1 unit 0 family inet6
user@P# set ge-0/0/1 unit 0 family iso
user@P# set ge-0/0/1 unit 0 family mpls
user@P# set lo0 unit 0 family inet address 127.0.0.1/32
user@P# set lo0 unit 0 family inet address 10.255.162.86/32 primary
user@P# set lo0 unit 0 family inet6 address abcd::10:255:162:86/128 primary
user@P# set lo0 unit 0 family iso address
47.0005.80ff.f800.0000.0108.0001.0102.5516.2086.00
```

2. Enable IS-IS.

```
[edit protocols isis]
user@P# set interface all
user@P# set interface fxp0.0 disable
```

3. Enable MPLS.

```
[edit protocols mpls ]
user@P# set interface all
user@P# set interface fxp0.0 disable
```

4. Configure RSVP.

```
[edit protocols rsvp]
user@P# set interface all link-protection
user@P# set interface fxp0.0 disable
```

5. (Optional) Configure OSPF.

```
[edit protocols ospf]
user@P# set area 0.0.0.0 interface all
user@P# set area 0.0.0.0 interface fxp0.0 disable
```

```

user@P# set area 0.0.0.0 interface lo0.0 passive
user@P# set traffic-engineering

```

## Configuring Device PE2

### Step-by-Step Procedure

1. Configure the interfaces.
 

```

[edit interfaces]
user@PE2# set ge-0/0/0 unit 0 family inet address 10.10.11.1/30
user@PE2# set ge-0/0/0 unit 0 family iso
user@PE2# set ge-0/0/0 unit 0 family inet6
user@PE2# set ge-0/0/0 unit 0 family mpls
user@PE2# set ge-0/0/1 unit 0 family inet address 10.10.12.1/30
user@PE2# set ge-0/0/1 unit 0 family iso
user@PE2# set ge-0/0/1 unit 0 family inet6
user@PE2# set ge-0/0/1 unit 0 family mpls
user@PE2# set ge-0/0/2 unit 0 family inet address 10.10.30.1/30
user@PE2# set lo0 unit 0 family inet address 127.0.0.1/32
user@PE2# set lo0 unit 0 family inet address 10.255.162.91/32 primary
user@PE2# set lo0 unit 0 family iso address
47.0005.80ff.f800.0000.0108.0001.0102.5516.2091.00
user@PE2# set lo0 unit 0 family inet6 address abcd::10:255:162:91/128 primary

```
2. Configure autonomous number(AS).
 

```

[edit routing-options]
user@PE2# set autonomous-system 65000
user@PE2# set forwarding-table export pplb

```
3. Configure RSVP.
 

```

[edit protocols rsvp]
user@PE2# set interface all link-protection
user@PE2# set interface fxp0.0 disable

```
4. Configure MPLS.
 

```

[edit protocols mpls]
user@PE2# set label-switched-path to_PE1 to 10.255.162.84
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
user@PE2# set egress-protection context-identifier 1.1.1.1 protector
user@PE2# set egress-protection context-identifier 1.1.1.1 advertise-mode stub-alias

```
5. Configure BGP.
 

```

[edit protocols bgp]
user@PE2# set group vpn family inet-vpn unicast egress-protection
user@PE2# set group vpn local-address 10.255.162.91
user@PE2# set group vpn neighbor 10.255.162.84
user@PE2# set group vpn neighbor 10.255.162.89
user@PE2# set group vpn type internal
user@PE2# set vpn-apply-export

```
6. Configure IS-IS.
 

```

[edit protocols isis]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable

```

```

user@PE2# set interface lo0.0 passive
user@PE2# set level 2 disable
user@PE2# set traceoptions file isis.log
user@PE2# set traceoptions flag all detail

```

7. (Optional) Configure OSPF.

```

[edit protocols ospf]
user@PE2# set area 0.0.0.0 interface all
user@PE2# set area 0.0.0.0 interface fxp0.0 disable
user@PE2# set area 0.0.0.0 interface lo0.0 passive
user@PE2# set traffic-engineering

```

8. Configure the routing policy.

```

[edit policy-options]
user@PE2# set community vpn members target:1:1
user@PE2# set policy-statement pplb term 1 then load-balance per-packet
user@PE2# set policy-statement vpn-exp term 1 from protocol bgp
user@PE2# set policy-statement vpn-exp term 1 then community add vpn
user@PE2# set policy-statement vpn-exp term 1 then accept
user@PE2# set policy-statement vpn-imp term 1 from community vpn
user@PE2# set policy-statement vpn-imp term 1 then accept
user@PE2# set policy-statement vpn-imp term 2 then reject

```

9. Configure the routing instance.

```

[edit routing-instances]
user@PE2# set vpn instance-type vrf
user@PE2# set vpn interface ge-3/2/4.0
user@PE2# set vpn route-distinguisher 100:100
user@PE2# set vpn vrf-import vpn-imp
user@PE2# set vpn vrf-export vpn-exp
user@PE2# set vpn vrf-table-label
user@PE2# set vpn protocols bgp group vpn type external
user@PE2# set vpn protocols bgp group vpn family inet unicast
user@PE2# set vpn protocols bgp group vpn family inet6 unicast
user@PE2# set vpn protocols bgp group vpn peer-as 65001
user@PE2# set vpn protocols bgp group vpn as-override
user@PE2# set vpn protocols bgp group vpn neighbor 10.10.30.2

```

### Configuring Device PE3

#### Step-by-Step Procedure

1. Configure the interfaces.

```

[edit interfaces]
user@PE3# set ge-0/0/0 unit 0 family inet address 10.10.40.1/30
user@PE3# set ge-0/0/1 unit 0 family inet address 10.10.12.2/30
user@PE3# set ge-0/0/1 unit 0 family iso
user@PE3# set ge-0/0/1 unit 0 family inet6
user@PE3# set ge-0/0/1 unit 0 family mpls
user@PE3# set lo0 unit 0 family inet address 127.0.0.1/32
user@PE3# set lo0 unit 0 family inet address 10.255.162.89/32 primary
user@PE3# set lo0 unit 0 family iso address
47.0005.80ff.f800.0000.0108.0001.0102.5516.2089.00
user@PE3# set lo0 unit 0 family inet6 address abcd::10:255:162:89/128 primary

```

2. Configure the autonomous number (AS).

- ```
[edit routing-options]
user@PE3# set autonomous-system 65000
user@PE3# set forwarding-table export pplb
```
3. Configure RSVP.

```
[edit protocols rsvp]
user@PE3# set interface all link-protection
user@PE3# set interface fxp0.0 disable
```
  4. Configure MPLS.

```
[edit protocols mpls]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
user@PE3# set egress-protection context-identifier 1.1.1.1 primary
user@PE3# set egress-protection context-identifier 1.1.1.1 advertise-mode stub-alias
user@PE3# set label-switched-path to_PE2 to 10.255.162.91
user@PE3# set label-switched-path to_PE1 to 10.255.162.84
```
  5. Configure BGP.

```
[edit protocols bgp]
user@PE3# set group vpn type internal
user@PE3# set group vpn local-address 10.255.162.89
user@PE3# set group vpn family inet-vpn unicast
user@PE3# set group vpn neighbor 10.255.162.84 local-preference 300
user@PE3# set group vpn neighbor 10.255.162.91
user@PE3# set vpn-apply-export
```
  6. Configure IS-IS.

```
[edit protocols isis]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
user@PE3# set interface lo0.0 passive
user@PE3# set level 2 disable
```
  7. (Optional) Configure OSPF.

```
[edit protocols ospf]
user@PE3# set area 0.0.0.0 interface all
user@PE3# set area 0.0.0.0 interface fxp0.0 disable
user@PE3# set area 0.0.0.0 interface lo0.0 passive
user@PE3# set traffic-engineering
```
  8. Configure the routing instance.

```
[edit routing-instances]
user@PE3# set vpn egress-protection context-identifier 1.1.1.1
user@PE3# set vpn instance-type vrf
user@PE3# set vpn interface ge-1/1/0.0
user@PE3# set vpn protocols bgp group vpn type external
user@PE3# set vpn protocols bgp group vpn family inet unicast
user@PE3# set vpn protocols bgp group vpn family inet6 unicast
user@PE3# set vpn protocols bgp group vpn peer-as 65001
user@PE3# set vpn protocols bgp group vpn as-override
user@PE3# set vpn protocols bgp group vpn neighbor 10.10.40.2
user@PE3# set vpn route-distinguisher 100:100
user@PE3# set vpn vrf-export vpn-exp
```

```

user@PE3# set vpn vrf-import vpn-imp
user@PE3# set vpn vrf-table-label

```

### Configuring Device CE2

#### Step-by-Step Procedure

1. Configure the interfaces.  

```

[edit interfaces]
user@CE2# set ge-0/0/0 unit 0 family inet address 10.10.40.2/30
user@CE2# set ge-0/0/2 unit 0 family inet address 10.10.30.2/30
user@CE2# set lo0 unit 0 family inet address 127.0.0.1/32
user@CE2# set lo0 unit 0 family inet address 10.255.162.88/32 primary
user@CE2# set lo0 unit 0 family iso address
47.0005.80ff.f800.0000.0108.0001.0102.5516.2088.00
user@CE2# set lo0 unit 0 family inet6 address abcd::10:255:162:88/128 primary

```

### Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

Device CE1 user@CE1# show interfaces

#### Release History Table

| Release | Description                                                                                                                                                                                                                                                                                              |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15.1    | Starting in Junos OS Release 15.1, the enhanced point of local repair (PLR) functionality addresses a special scenario of egress node protection, where the PLR and the protector are co-located as one router. In this case, there is no need to have a bypass LSP reroute traffic during local repair. |

## Example: Configuring Next-Hop-Based MPLS-Over-UDP Dynamic Tunnels

This example shows how to configure a dynamic MPLS-over-UDP tunnel that includes a tunnel composite next hop. With the MPLS-over-UDP tunnel configured, a device can scale up to 4,000 dynamic UDP tunnels. Because of this advantage, configuring the MPLS-over-UDP tunnels is beneficial for data center deployments that require mesh IP connectivity from one provider edge (PE) device to all other PE devices in the network.

- [Requirements on page 222](#)
- [Overview on page 223](#)
- [Configuration on page 225](#)
- [Verification on page 230](#)
- [Troubleshooting on page 234](#)

### Requirements

This example uses the following hardware and software components:

- Five routers that can be a combination of M Series Multiservice Edge Routers, MX Series 3D Universal Edge Routers, T Series Core Routers, and PTX Series Packet Transport Routers.
- Junos OS Release 16.2 or later running on the PE routers.

Before you begin:

1. Enable a tunnel services configuration on the Flexible PIC Concentrator.
2. Configure the device interfaces, including the loopback interface.
3. Configure the router ID and autonomous system number for the device.
4. Establish an internal BGP (IBGP) session with the remote PE device.
5. Establish OSPF peering among the devices.

## Overview

Starting with Junos OS Release 16.2, a dynamic UDP tunnel supports the creation of a tunnel composite next hop for every UDP tunnel configured. These next-hop-based dynamic UDP tunnels are referred to as MPLS-over-UDP tunnels. The tunnel composite next hop are enabled by default for the MPLS-over-UDP tunnels, and they include the dynamic tunnel's encapsulation data and a VPN label (when chained composite next hop is not enabled).

With this feature, a device can scale up to 4,000 UDP tunnels. This scaling advantage is beneficial for data center deployments that require mesh IP connectivity from one PE device to all other PE devices in the network.

**NOTE:** For the same tunnel destination, the next-hop-based dynamic tunnel encapsulation can either be GRE or UDP. Having both tunnel encapsulations for the same tunnel destination causes a commit error under the dynamic-tunnel configuration.

When configuring a next-hop-based dynamic MPLS-over-UDP tunnel, be aware of the following considerations:

- An IBGP session must be configured between the PE devices.
- A switchover between the next-hop-based dynamic tunnel encapsulations (UDP and GRE) is allowed,
- Having both GRE and UDP next-hop-based dynamic tunnel encapsulation types for the same tunnel destination leads to a commit failure.
- Graceful Routing Engine switchover (GRES) is supported with MPLS-over-UDP, and the MPLS-over-UDP tunnel type flags are unified ISSU and NSR compliant.
- MPLS-over-UDP tunnels are supported on virtual MX (vMX).
- MPLS-over-UDP tunnels support dynamic GRE tunnel creation based upon new IPv4-mapped-IPv6 next hops.
- MPLS-over-UDP tunnel are supported in interoperability with contrail, wherein the MPLS-over-UDP tunnels are created from the contrail vRouter to an MX gateway. To enable this, the following community is required to be advertised in the route from the MX Series router to the contrail vRouter:

```
[edit policy-options community]
  udp members 0x030c:64512:13;
```

At a given point in time, only one tunnel type is supported on the contrail vRouter—next-hop-based dynamic GRE tunnels, MPLS-over-UDP tunnels, or VXLAN.

- The following features are not supported with the next-hop-based dynamic MPLS-over-UDP tunnel configuration:
  - RSVP automatic mesh
  - Plain IPV6 GRE and UDP tunnel configuration
  - Logical systems

### Topology

Figure 28 on page 224 illustrates a Layer 3 VPN scenario over dynamic MPLS-over-UDP tunnels. The customer edge (CE) devices, CE1 and CE2, connect to provider edge (PE) devices, PE1 and PE2, respectively. The PE devices are connected to a provider device (Device P1), and an internal BGP (IBGP) session interconnects the two PE devices. Two dynamic next-hop-based MPL-over-UDP tunnels are configured between the PE devices.

**Figure 28: Dynamic MPLS-over-UDP Tunnels**

g040335

The MPLS-over-UDP tunnel is handled as follows:

1. After a MPLS-over-UDP tunnel is configured, a tunnel destination mask route with a tunnel composite next hop is created for the tunnel in the inet.3 routing table. This IP tunnel route is withdrawn only when the dynamic tunnel configuration is deleted.

The tunnel composite next-hop attributes include the following:

- When Layer 3 VPN composite next hop is disabled—Source and destination address, encapsulation string, and VPN label.
  - When Layer 3 VPN composite next hop and per-prefix VPN label allocation are enabled—Source address, destination address, and encapsulation string.
  - When Layer 3 VPN composite next hop is enabled and per-prefix VPN label allocation is disabled—Source address, destination address, and encapsulation string. The route in this case is added to the other virtual routing and forwarding instance table with a secondary route.
2. The PE devices are interconnected using an IBGP session. The IBGP route next hop to a remote BGP neighbor is the protocol next hop, which is resolved using the tunnel mask route with the tunnel next hop.
  3. After the protocol next hop is resolved over the tunnel composite next hop, indirect next hops with forwarding next hops are created.
  4. The tunnel composite next hop is used to forward the next hops of the indirect next hops.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

CE1  set interfaces ge-0/0/0 unit 0 family inet address 10.0.0.1/8
      set interfaces lo0 unit 0 family inet address 127.0.0.1/8

### Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Enable tunnel services configuration on the device.  

```

[edit chassis]
user@PE1# set fpc 0 pic 1 tunnel-services

```
2. Configure the device interfaces including the loopback interface of the device.  

```

[edit interfaces]
user@PE1# set ge-0/0/0 unit 0 family inet address 10.0.0.2/8

user@PE1# set ge-0/0/1 unit 0 family inet address 192.0.2.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls

user@PE1# set lo0 unit 0 family inet address 127.0.0.2/8

```
3. Configure a static route for routes from Device PE1 with Device P1 as the next-hop destination.  

```

[edit routing-options]
user@PE1# set static route 33.0.0.0/8 next-hop 192.0.2.2

```
4. Configure the router-ID and autonomous system number for Device PE1.  

```

[edit routing-options]
user@PE1# set router-id 127.0.0.2
user@PE1# set autonomous-system 100

```
5. Configure IBGP peering between the PE devices.  

```

[edit protocols]
user@PE1# set bgp group IBGP type internal
user@PE1# set bgp group IBGP local-address 127.0.0.2
user@PE1# set bgp group IBGP family inet-vpn unicast
user@PE1# set bgp group IBGP neighbor 127.0.0.4

```

6. Configure OSPF on all the interfaces of Device PE1, excluding the management interface.  

```
[edit protocols]
user@PE1# set ospf area 0.0.0.0 interface ge-0/0/1.0
user@PE1# set ospf area 0.0.0.0 interface lo0.0 passive
```
7. Enable next-hop-based dynamic GRE tunnel configuration on Device PE1.  

```
[edit routing-options]
user@PE1# set dynamic-tunnels gre next-hop-based-tunnel
```
8. Configure the MPLS-over-UDP tunnel parameters from Device PE1 to Device PE2.  

```
[edit routing-options]
user@PE1# set dynamic-tunnels udp-dyn-tunnel-to-pe2 source-address 127.0.0.2
user@PE1# set dynamic-tunnels udp-dyn-tunnel-to-pe2 udp
user@PE1# set dynamic-tunnels udp-dyn-tunnel-to-pe2 destination-networks
127.0.0.0/8
```
9. Configure a policy to enable load balancing on a per-packet basis.  

```
[edit policy-options]
user@PE1# set policy-statement pplb term 1 then load-balance per-packet
user@PE1# set policy-statement pplb term 1 then accept
```
10. Export the load-balancing policy to the forwarding table.  

```
[edit routing-options]
user@PE1# set forwarding-table export pplb
```
11. Configure a VRF routing instance on Device PE1 and other routing instance parameters.  

```
[edit routing-instances]
user@PE1# set MPLS-over-UDP-PE1 instance-type vrf
user@PE1# set MPLS-over-UDP-PE1 interface ge-0/0/0.0
user@PE1# set MPLS-over-UDP-PE1 route-distinguisher 127.0.0.2:1
user@PE1# set MPLS-over-UDP-PE1 vrf-target target:600:1
```
12. Enable BGP in the routing instance configuration for peering with Device CE1.  

```
[edit routing-instances]
user@PE1# set MPLS-over-UDP-PE1 protocols bgp group pe1-ce1 peer-as 200
user@PE1# set MPLS-over-UDP-PE1 protocols bgp group pe1-ce1 neighbor 10.0.0.1
as-override
```

---

## Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, **show policy-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/0 {
  unit 0 {

---

### Verifying the Connection Between PE Devices

**Purpose** Verify the BGP peering status between Device PE1 and Device PE2, and the BGP routes received from Device PE2.

**Action** From operational mode, run the **show bgp summary** and **show route receive-protocol bgp ip-address table bgp.l3vpn.0** commands.

```
user@PE1> show bgp summary
Groups: 2 Peers: 2 Down peers: 0
Table Tot Paths Act Paths Suppressed History Damp State Pending
bgp.l3vpn.0
                2          2          0          0          0          0
Peer          AS      InPkt    OutPkt    OutQ    Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
127.0.0.4      100      139      136       0       0      58:23 Establ

    bgp.l3vpn.0: 2/2/2/0
    MPLS-over-UDP-PE1.inet.0: 2/2/2/0
10.0.0.1        200      135      136       0       0      58:53
Establ
    MPLS-over-UDP-PE1.inet.0: 1/1/1/0

user@PE1> show route receive-protocol bgp 127.0.0.4 table bgp.l3vpn.0
bgp.l3vpn.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
Prefix          Nexthop          MED    Lclpref    AS path
127.0.0.4:1:127.0.0.5/8
*                127.0.0.4              100      200 I
127.0.0.4:1:200.1.1.0/24
*                127.0.0.4              100      I
```

- Meaning**
- In the first output, the BGP session state is **Establ**, which means that the session is up and the PE devices are peered.
  - In the second output, Device PE1 has learned two BGP routes from Device PE2.

#### Verify the Dynamic Tunnel Routes on Device PE1

**Purpose** Verify the routes in the inet.3 routing table and the dynamic tunnel database information on Device PE1.

**Action** From operational mode, run the **show route table inet.3**, **show dynamic-tunnels database terse**, **show dynamic-tunnels database**, and **show dynamic-tunnels database summary** commands.

```

user@PE1> show route table inet.3
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

127.0.0.0/8      *[Tunnel/300] 00:21:18
                  Tunnel
127.0.0.4/8      *[Tunnel/300] 00:21:18
                  Tunnel Composite

user@PE1> show dynamic-tunnels database terse
Table: inet.3

Destination-network: 127.0.0.0/8
Destination      Source      Next-hop      Type      Status
127.0.0.4/8      127.0.0.2   0xb395b10 nhid 613   udp      Up

user@PE1> show dynamic-tunnels database
Table: inet.3

Destination-network: 55.0.0.0/8

Destination-network: 55.66.0.0/16

Destination-network: 55.66.77.0/24
Tunnel to: 127.0.0.4/8
Reference count: 2
Next-hop type: UDP
Source address: 127.0.0.2 Tunnel Id: 2
Next hop: tunnel-composite, 0xb395b10, nhid 613
VPN Label: Push 299776 Reference count: 3
Traffic Statistics: Packets 0, Bytes 0
State: Up

user@PE1> show dynamic-tunnels database summary
Dynamic Tunnels, Total 1 displayed
GRE Tunnel:
Active Tunnel Mode, Next Hop Base
IFL Based, Total 0 displayed, Up 0, Down 0
Nexthop Based, Total 0 displayed, Up 0, Down 0
RSVP Tunnel:
Total 0 displayed
UDP Tunnel:
Total 1 displayed, Up 1, Down 0

```

**Meaning**

- In the first output, because Device PE1 is configured with the MPLS-over-UDP tunnel, a tunnel composite route is created for the inet.3 routing table route entry.
- In the remaining outputs, the MPLS-over-UDP tunnel is displayed with the tunnel encapsulation type, tunnel next hop parameters, and tunnel status.

### Verify the Dynamic Tunnel Routes on Device PE2

**Purpose** Verify the routes in the inet.3 routing table and the dynamic tunnel database information on Device PE2.

**Action** From operational mode, run the **show route table inet.3**, and the **show dynamic-tunnels database terse** commands.

```
user@PE2> show route table inet.3
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
127.0.0.0/8      *[Tunnel/300] 00:39:31
                  Tunnel
127.0.0.2/8      *[Tunnel/300] 00:24:53
                  Tunnel Composite
```

```
user@PE1> show dynamic-tunnels database terse
Table: inet.3
```

```
Destination-network: 127.0.0.0/8
Destination      Source      Next-hop      Type      Status
127.0.0.2/8      127.0.0.4    0xb395450 nhid 615    udp      Up
```

**Meaning** The outputs show the MPLS-over-UDP tunnel creation and the next-hop ID assigned as the next-hop interface, similar to Device PE1.

### Verifying That the Routes Have the Expected Indirect-Next-Hop Flag

**Purpose** Verify that Device PE1 and Device PE2 are configured to maintain the indirect next hop to forwarding next-hop binding on the Packet Forwarding Engine forwarding table.

**Action** From operational mode, run the **show krt indirect-next-hop** command on Device PE1 and Device PE2.

```
user@PE1> show krt indirect-next-hop
Indirect Nexthop:
Index: 1048574 Protocol next-hop address: 127.0.0.4
RIB Table: bgp.l3vpn.0

Policy Version: 1                      References: 2
Locks: 3                               0xb2ab740
Flags: 0x0
INH Session ID: 0x0
INH Version ID: 0
Ref RIB Table: unknown
  Tunnel type: UDP, Reference count: 3, nhid: 615
  Destination address: 127.0.0.2, Source address: 127.0.0.4
  Tunnel id: 1, VPN Label: Push 299776, TTL action: prop-ttl
  IGP FRR Interesting proto count : 2
  Chain IGP FRR Node Num          : 1
    IGP Resolver node(hex)        : 0xb3d3a28
    IGP Route handle(hex)         : 0xb1ae634    IGP rt_entry protocol
: Tunnel
  IGP Actual Route handle(hex) : 0x0          IGP Actual rt_entry protocol
: Any

```

**Meaning** The outputs show that a next-hop-based dynamic MPLS-over-UDP tunnel is created between the PE devices.

## Troubleshooting

To troubleshoot the next-hop-based dynamic tunnels, see:

- [Troubleshooting Commands on page 234](#)

### Troubleshooting Commands

**Problem** The next-hop-based dynamic MPLS-over-UDP tunnel configuration is not taking effect.

**Solution** To troubleshoot the next-hop-based MPLS-over-UDP tunnel configuration, use the following **traceroute** commands at the **[edit routing-options dynamic-tunnels]** statement hierarchy:

- **traceoptions file *file-name***
- **traceoptions file size *file-size***
- **traceoptions flag all**

For example:

```

[edit routing-options dynamic-tunnels]
traceoptions {
  file udp_dyn_pe1.wri size 4294967295;
  flag all;
}

```

## Anti-spoofing Protection for Next-Hop-Based Dynamic Tunnels

With increasing deployment of high-scale IP tunnels in data centers, there is a need to add security measures that allow users to limit malicious traffic from compromised virtual machines (VMs) into the data centers. One possible attack is the injecting of traffic into an arbitrary customer VPN from a compromised VM through the gateway router. In such cases, anti-spoofing checks on IP tunnels ensure that only legitimate sources are injecting traffic into the data centers from their designated IP tunnels.

Next-hop-based dynamic IP tunnels create a tunnel composite next hop for every dynamic tunnel created on the device. The tunnel composite next hop includes the dynamic tunnel's source and destination IP address, encapsulation data, and a VPN label (when chained composite next hop is not enabled). Configuring next-hop-based dynamic tunnels provides a scaling advantage over the number of dynamic tunnels that can be created on a device. It also benefits data center deployments that require mesh IP connectivity from one provider edge (PE) device to all other PE devices in the network. In addition to these benefits, Junos OS Release 17.1 and future releases provide anti-spoofing capabilities for the next-hop-based dynamic IP tunnels. With this addition, a security measure is implemented to prevent spurious virtual machines from accessing and consuming resources from a wrong VPN.

Anti-spoofing is implemented using reverse path forwarding checks in the Packet Forwarding Engine. The checks are placed in the downstream direction of the tunnels terminating at the gateway router. Currently, when the gateway router receives traffic from a tunnel, only the destination from the inner IP header is checked and the packet is forwarded accordingly. When anti-spoofing protection is enabled, the gateway router also does a source look-up of the inner IP header in the VPN, in addition to checking the tunnel destination. This ensures that the source is reachable on the same tunnel on which the packet was received. As a result, in addition to checking the tunnel destination, anti-spoofing protection ensures that the tunnel traffic is received from a legitimate source on the designated tunnels.

[Figure 29 on page 236](#) illustrates a sample topology with the requirements for anti-spoofing protection.

Figure 29: Anti-Spoofing Protection for Next-hop-based Dynamic Tunnels

In this example, the gateway router is Router G. Router G has two VPNs—Red and Blue. The two servers, Server A and Server B, can reach the Red and Blue VPNs on Router G through the next-hop-based dynamic tunnels T1 and T2, respectively. Several hosts and virtual machines, P, Q, R, S, T, connected to the servers can reach the VPNs through the gateway router, Router G. Router G has the virtual routing and forwarding tables for Red and Blue VPNs, each populated with the reachability information for the virtual machines in those VPNs.

For example, in VPN Red, Router G uses tunnel T1 to reach host P, tunnel T2 to reach hosts R and S, and load balancing is done between tunnels T1 and T2 to reach the multi-homed host Q. In VPN Blue, Router G uses tunnel T1 to reach hosts P and R, and tunnel T2 to reach hosts Q and T.

The benefits of the anti-spoofing reverse path forwarding checks are as follows:

- Reverse path forwarding check passes when:

- Packet comes from a legitimate source on its designated tunnel.

Host P in VPN Red sends a packet to host X using tunnel T1. Because Router G can reach host P through tunnel T1, it allows the packet to pass and forwards the packet to host X.

- Packet comes from a multi-homed source on its designated tunnels.

Host Q in VPN Red is multi-homed on servers A and B, and can reach Router G through tunnels T1 and T2. Host Q sends a packet to host Y using tunnel T1, and a packet to host X using tunnel T2. Because Router G can reach host Q through tunnels T1 and T2, it allows the packets to pass and forwards them to hosts Y and X, respectively.

In cases where per-next-hop label is configured, there is no VPN context in the data-path to do a source IP lookup for reverse path forwarding checks. To enable this, the MPLS

route lookup should provide the VPN ID, using which the Packet Forwarding Engine can lookup the inner source IP address.

Layer 3 VPNs do not have anti-spoofing protection enabled by default. To enable anti-spoofing for next-hop based dynamic tunnels, include the **ip-tunnel-rpf-check** statement at the **[edit routing-instances *routing-instance-name* routing-options forwarding-table]** hierarchy level. The reverse path forwarding check is applied to the virtual routing and forwarding routing instance only, and the default mode is set to **strict**, where the packet that comes from a source on a non-designated tunnel does not pass the check. The **ip-tunnel-rpf-check** mode can be set as **loose**, where the reverse path forwarding check fails when the packet comes from a non-existing source. An optional firewall filter can be configured under the **ip-tunnel-rpf-check** statement to count and log the packets that failed the reverse path forwarding check.

Sample anti-spoofing configuration:

```
[edit routing-instances routing-instance-name routing-options forwarding-table]
ip-tunnel-rpf-check {
    mode loose;
    fail-filter filter-name;
}
```

While configuring the anti-spoofing protection for next-hop based dynamic tunnels, take the following into consideration:

- Anti-spoofing protection can be enabled for IPv4 tunnels and IPv4 data traffic only. The anti-spoofing capabilities are not supported on IPv6 tunnels and IPv6 data traffic.
- Anti-spoofing for next-hop based dynamic tunnels can detect and prevent the case of a compromised virtual machine (inner source reverse path forwarding check) and not a compromised server, that is label-spoofing.
- The next-hop based IP tunnels can originate and terminate on inet.0 routing table.
- The **rpf fail-filter** is applicable to the inner IP packet. However, for virtual tunnels, the outer header (GRE) is stripped off by the time the packet reaches the virtual tunnel Packet forwarding Engine.
- Enabling anti-spoofing checks does not affect the scaling limit of the next-hop based dynamic tunnels on a device.
- The system resource utilization with anti-spoofing protection enabled for the virtual routing and forwarding routing instance is slightly higher than the utilization of next-hop based dynamic tunnels without the anti-spoofing protection enabled.
- Anti-spoofing protection requires additional source IP address checks, which might have an impact on the network performance.
- Graceful Routing Engine switchover (GRES) and in-service software upgrade are supported with the anti-spoofing protection.

## Configuring the Ingress and Egress Router Addresses for LSPs

---

The following sections describe how to specify the addresses of an LSP's ingress and egress routers:

- [Configuring the Ingress Router Address for LSPs on page 240](#)
- [Configuring the Egress Router Address for LSPs on page 240](#)
- [Preventing the Addition of Egress Router Addresses to Routing Tables on page 241](#)

### Configuring the Ingress Router Address for LSPs

The local router always is considered to be the ingress router, which is the beginning of the LSP. The software automatically determines the proper outgoing interface and IP address to use to reach the next router in an LSP.

By default, the router ID is chosen as the address of the ingress router. To override the automatic selection of the source address, specify a source address in the **from** statement:

```
from address;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls label-switched-path lsp-name]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name]`

The outgoing interface used by the LSP is not affected by the source address that you configure.

### Configuring the Egress Router Address for LSPs

When configuring an LSP, you must specify the address of the egress router by including the **to** statement:

```
to address;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls label-switched-path lsp-name]`
- `[edit protocols mpls static-label-switched-path lsp-name]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name]`
- `[edit logical-systems logical-system-name protocols mpls static-label-switched-path lsp-name]`

When you are setting up a signaled LSP, the **to** statement is the only required statement. All other statements are optional.

After the LSP is established, the address of the egress router is installed as a host route in the routing table. This route can then be used by BGP to forward traffic.

To have the software send BGP traffic over an LSP, the address of the egress router is the same as the address of the BGP next hop. You can specify the egress router's address as any one of the router's interface addresses or as the BGP router ID. If you specify a different address, even if the address is on the same router, BGP traffic is not sent over the LSP.

To determine the address of the BGP next hop, use the **show route detail** command. To determine the destination address of an LSP, use the **show mpls lsp** command. To determine whether a route has gone through an LSP, use the **show route** or **show route forwarding-table** command. In the output of these last two commands, the **label-switched-path** or **push** keyword included with the route indicates it has passed through an LSP. Also, use the **traceroute** command to trace the actual path to which the route leads. This is another indication whether a route has passed through an LSP.

You also can manipulate the address of the BGP next hop by defining a BGP import policy filter that sets the route's next-hop address.

## Preventing the Addition of Egress Router Addresses to Routing Tables

You must configure an address using the **to** statement for all LSPs. This address is always installed as a /32 prefix in the inet.3 or inet.0 routing tables. You can prevent the egress router address configured using the **to** statement from being added to the inet.3 and inet.0 routing tables by including the **no-install-to-address** statement.

Some reasons not to install the **to** statement address in the inet.3 and inet.0 routing tables include the following:

- Allow Constrained Shortest Path First (CSPF) RSVP LSPs to be mapped to traffic intended for secondary loopback addresses. If you configure an RSVP tunnel, including the **no-install-to-address** statement, and then configure an **install pfx/ <active>** policy later, you can do the following:
  - Verify that the LSP was set up correctly without impacting traffic.
  - Map traffic to the LSP in incremental steps.
  - Map traffic to the destination loopback address (the BGP next hop) by removing the **no-install-to-address** statement once troubleshooting is complete.
- Prevent CCC connections from losing IP traffic. When an LSP determines that it does not belong to a connection, it installs the address specified with the **to** statement in the inet.3 routing table. IP traffic is then forwarded to the CCC remote endpoint, which can cause some types of PICs to fail.

To prevent the egress router address configured using the **to** statement from being added to the inet.3 and inet.0 routing tables, include the **no-install-to-address** statement:

`no-install-to-address;`

You can include this statement at the following hierarchy levels:

- [edit protocols mpls `label-switched-path` *lsp-name*]
- [edit protocols mpls `static-label-switched-path` *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls `label-switched-path` *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls `static-label-switched-path` *lsp-name*]

---

## Configuring Primary and Secondary LSPs

By default, an LSP routes itself hop-by-hop toward the egress router. The LSP tends to follow the shortest path as dictated by the local routing table, usually taking the same path as destination-based, best-effort traffic. These paths are “soft” in nature because they automatically re-route themselves whenever a change occurs in a routing table or in the status of a node or link.

To configure the path so that it follows a particular route, create a named path using the **path** statement, as described in [“Creating Named Paths” on page 60](#). Then apply the named path by including the **primary** or **secondary** statement. A named path can be referenced by any number of LSPs.

To configure primary and secondary paths for an LSP, complete the steps in the following sections:

- [Configuring Primary and Secondary Paths for an LSP on page 242](#)
- [Configuring the Revert Timer for LSPs on page 243](#)
- [Specifying the Conditions for Path Selection on page 244](#)

### Configuring Primary and Secondary Paths for an LSP

The **primary** statement creates the primary path, which is the LSP's preferred path. The **secondary** statement creates an alternative path. If the primary path can no longer reach the egress router, the alternative path is used.

To configure primary and secondary paths, include the **primary** and **secondary** statements:

```
primary path-name {  
  ...  
}  
secondary path-name {  
  ...  
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols mpls `label-switched-path` *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls `label-switched-path` *lsp-name*]

When the software switches from the primary to a secondary path, it continuously attempts to revert to the primary path, switching back to it when it is again reachable, but no sooner than the retry time specified in the **retry-timer** statement. (For more information, see [“Configuring the Connection Between Ingress and Egress Routers” on page 257.](#))

You can configure zero or one primary path. If you do not configure a primary path, the first secondary path that is established is selected as the path.

You can configure zero or more secondary paths. All secondary paths are equal. The software does not attempt to switch among secondary paths. If the current secondary path is not available, the next one is tried in no particular order. To create a set of equal paths, specify secondary paths without specifying a primary path.

If you do not specify any named paths, or if the path that you specify is empty, the software makes all routing decisions necessary to reach the egress router.

## Configuring the Revert Timer for LSPs

For LSPs configured with both primary and secondary paths, it is possible to configure the revert timer. If a primary path goes down and traffic is switched to the secondary path, the revert timer specifies the amount of time (in seconds) that the LSP must wait before it can revert traffic back to a primary path. If during this time, the primary path experiences any connectivity problems or stability problems, the timer is restarted. You can configure the revert timer for both static and dynamic LSPs.

The Junos OS also makes a determination as to which path is the preferred path. The preferred path is the path that has not encountered any difficulty in the last revert timer period. If both the primary and secondary paths have encountered difficulty, neither path is considered preferred. However, if one of the paths is dynamic and the other static, the dynamic path is selected as the preferred path.

If you have configured BFD on the LSP, Junos OS waits until the BFD session comes up on the primary path before starting the revert timer counter.

The range of values you can configure for the revert timer is 0 through 65,535 seconds. The default value is 60 seconds.

If you configure a value of 0 seconds, the traffic on the LSP, once switched from the primary path to the secondary path, remains on the secondary path permanently (until the network operator intervenes or until the secondary path goes down).

You can configure the revert timer for all LSPs on the router at the **[edit protocols mpls]** hierarchy level or for a specific LSP at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level.

To configure the revert timer, include the **revert-timer** statement:

```
revert-timer seconds;
```

For a list of hierarchy levels at which you can include this statement, see the summary section for this statement.

## Specifying the Conditions for Path Selection

When you have configured both primary and secondary paths for an LSP, you may need to ensure that only a specific path is used.

The **select** statement is optional. If you do not include it, MPLS uses an automatic path selection algorithm.

The **manual** and **unconditional** options do the following:

- **manual**—The path is immediately selected for carrying traffic as long as it is up and stable. Traffic is sent to other working paths if the current path is down or degraded (receiving errors). This parameter overrides all other path attributes except the **select unconditional** statement.
- **unconditional**—The path is selected for carrying traffic unconditionally, regardless of whether the path is currently down or degraded (receiving errors). This parameter overrides all other path attributes.

Because the **unconditional** option switches to a path without regard to its current status, be aware of the following potential consequences of specifying it:

- If a path is not currently up when you enable the **unconditional** option, traffic can be disrupted. Ensure that the path is functional before specifying the **unconditional** option.
- Once a path is selected because it has the **unconditional** option enabled, all other paths for the LSP are gradually cleared, including the primary and standby paths. No path can act as a standby to an unconditional path, so signaling those paths serves no purpose.

For a specific path, the **manual** and **unconditional** options are mutually exclusive. You can include the **select** statement with the **manual** option in the configuration of only one of an LSP's paths, and the **select** statement with the **unconditional** option in the configuration of only one other of its paths.

Enabling or disabling the **manual** and **unconditional** options for the **select** statement while LSPs and their paths are up does not disrupt traffic.

To specify that a path be selected for carrying traffic if it is up and stable for at least the revert timer window, include the **select** statement with the **manual** option:

```
select manual;
```

To specify that a path should always be selected for carrying traffic, even if it is currently down or degraded, include the **select** statement with the **unconditional** option:

```
select unconditional;
```

You can include the **select** statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* (**primary** | **secondary**) *path-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* (**primary** | **secondary**) *path-name*]

## Configuring a Text Description for LSPs

You can provide a textual description for an LSP by enclosing any descriptive text that includes spaces within quotation marks (" "). The descriptive text you include is displayed in the detail output of the **show mpls lsp** or the **show mpls container-lsp** command.

Adding a text description for an LSP has no effect on the operation of the LSP. The LSP text description can be no more than 80 characters in length.

To provide a textual description for an LSP, include the **description** statement at any of the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit protocols mpls **container-label-switched-path** *lsp-name*]
- [edit protocols mpls **static-label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **static-label-switched-path** *lsp-name*]

Before you begin:

- Configure the device interfaces.
- Configure the device for network communication.
- Enable MPLS on the device interfaces.
- Configure an LSP in the MPLS domain.

To add a text description for an LSP:

1. Enter any text describing the LSP.

```
[edit protocols mpls lsp lsp-name]
user@host# set description text
```

For example:

```
[edit protocols mpls lsp LSP1]
user@host# set description "Connecting remote device"
```

2. Verify and commit the configuration.

For example:

```
[edit protocols mpls lsp]
user@host# set protocols mpls label-switched-path LSP1 to 1.1.1.1
user@host# set protocols mpls label-switched-path LSP1 description "Connecting
remote device"
user@host# set protocols mpls interface ge-1/0/8.0

[edit]
user@host# commit
commit complete
```

3. View the description of an LSP using the **show mpls lsp detail** or **show mpls container-lsp detail** command, depending on the type of LSP configured.

```
user@host> show mpls lsp detail
```

```
Ingress LSP: 1 sessions
```

```
1.1.1.1
```

```
From: 0.0.0.0, State: Up, ActiveRoute: 1, LSPname: LSP1

## Configuring the Entropy Label for LSPs

The insertion of entropy labels for an LSP enables transit routers to load-balance MPLS traffic across ECMP paths or Link Aggregation groups using just the MPLS label stack as a hash input without having to rely on deep packet inspection. Deep packet inspection requires more of the router's processing power and different routers have differing deep-packet inspection capabilities.

To configure the entropy label for an LSP, complete the following steps:

1. On the ingress router, include the **entropy-label** statement at the **[edit protocols mpls labeled-switched-path *labeled-switched-path-name*]** hierarchy level or at the **[edit protocols mpls static-labeled-switched-path *labeled-switched-path-name* ingress]** hierarchy level. The entropy label is added to the MPLS label stack and can be processed in the forwarding plane.

```
entropy-label;
```

**NOTE:** This is only applicable for RSVP and static LSPs.

2. On the ingress router, you can configure an ingress policy for LDP-signaled LSPs:

```
entropy-label {
  ingress-policy policy-name;
```

```
}
```

Configure the ingress policy at the **[edit policy-options]** hierarchy level:

```
policy-options {
  policy-statement policy-name {
    term term-name {
      from {
        prefix-list prefix-list-name;
      }
      then actions;
    }
  }
}
```

The following shows an example of an entropy label ingress policy.

```
policy-options {
  policy-statement entropy-policy {
    term no-insert-entropy-label {
      from {
        prefix-list no-entropy-label-fec;
      }
      then accept;
    }
  }
}
```

3. (Optional) By default, routers that support the pushing and popping of entropy labels are configured with the **load-balance-label-capability** statement at the **[edit forwarding-options]** hierarchy level to signal the labels on a per-LSP basis. If the peer router is not equipped to handle load-balancing labels, you can prevent the provider edge (PE) router from signaling the entropy label capability by configuring the **no-load-balance-label-capability** statement at the **[edit forwarding-options]** hierarchy level.

```
[edit forwarding-options]
user@PE no-load-balance-label-capability;
```

Transit routers require no configuration. The presence of the entropy label indicates to the transit router to load balance based solely on the MPLS label stack.

Penultimate hop routers pop the entropy label by default.

## Configuring Corouted Bidirectional LSPs

A corouted bidirectional packet LSP is a combination of two LSPs sharing the same path between a pair of ingress and egress nodes, as shown in [Figure 30 on page 248](#). It is established using the GMPLS extensions to RSVP-TE. This type of LSP can be used to carry any of the standard types of MPLS-based traffic, including Layer 2 VPNs, Layer 2 circuits, and Layer 3 VPNs. You can configure a single BFD session for the bidirectional LSP (you do not need to configure a BFD session for each LSP in each direction). You can also configure a single standby bidirectional LSP to provide a backup for the primary bidirectional LSP. Corouted bidirectional LSPs are supported for both penultimate hop popping (PHP) and ultimate hop popping (UHP).

High availability is available for bidirectional LSPs. You can enable graceful restart and nonstop active routing. Graceful restart and nonstop active routing are supported when the restarting router is the ingress, egress, or transit router for the bidirectional LSP.

Figure 30: Corouted Bidirectional LSP

To configure a corouted bidirectional LSP:

1. In configuration mode, configure the ingress router for the LSP and include the **corouted-bidirectional** statement to specify that the LSP be established as a corouted bidirectional LSP.

The path is computed using CSPF and initiated using RSVP signaling (just like a unidirectional RSVP signaled LSP). Both the path to the egress router and the reverse path from the egress router are created when this configuration is committed.

```
[edit protocols mpls]
user@PE1# set label-switched-path sample-lsp corouted-bidirectional
```

2. (Optional) For a reverse path, configure an LSP on the egress router and include the **corouted-bidirectional-passive** statement to associate the LSP with another LSP.

No path computation or signaling is used for this LSP since it relies on the path computation and signaling provided by the ingress LSP. You cannot configure both the **corouted-bidirectional** statement and the **corouted-bidirectional-passive** statement on the same LSP.

```
[edit protocols mpls]
user@PE1# set label-switched-path sample-lsp-reverse-path
corouted-bidirectional-passive
```

This statement also makes it easier to debug corouted bidirectional LSPs. If you configure the **corouted-bidirectional-passive** statement (again, on the egress router), you can issue **ping mpls lsp-end-point**, **ping mpls ldp**, **ping mpls rsvp**, **traceroute mpls**

`ldp`, and `traceroute mpls rsvp` commands to test the coreouted bidirectional LSP from the egress router.

3. Use the `show mpls lsp extensive` and the `show rsvp session extensive` commands to display information about the bidirectional LSP.

The following shows output for the `show rsvp session extensive` command when run on an ingress router with a bidirectional LSP configured:

```
user@PE1> show rsvp session extensive
Ingress RSVP: 2 sessions

## Configuring Ultimate-Hop Popping for LSPs

By default, RSVP-signaled LSPs use penultimate-hop popping (PHP). [Figure 31 on page 250](#) illustrates a penultimate-hop popping LSP between Router PE1 and Router PE2. Router CE1 forwards a packet to its next hop (Router PE1), which is also the LSP ingress. Router PE1 pushes label 1 on the packet and forwards the labeled packet to Router P1. Router P1 completes the standard MPLS label swapping operation, swapping label 1 for label 2, and forwards the packet to Router P2. Since Router P2 is the penultimate-hop router for the LSP to Router PE2, it first pops the label and then forwards the packet to Router PE2. When Router PE2 receives it, the packet can have a service label, an explicit-null label, or just be a plain IP or VPLS packet. Router PE2 forwards the unlabeled packet to Router CE2.

**Figure 31: Penultimate-Hop Popping for an LSP**

You can also configure ultimate-hop popping (UHP) (as shown in [Figure 32 on page 250](#)) for RSVP-signaled LSPs. Some network applications can require that packets arrive at the egress router (Router PE2) with a non-null outer label. For an ultimate-hop popping LSP, the penultimate router (Router P2 in [Figure 32 on page 250](#)) performs the standard MPLS label swapping operation (in this example, label 2 for label 3) before forwarding the packet to egress Router PE2. Router PE2 pops the outer label and performs a second lookup of the packet address to determine the end destination. It then forwards the packet to the appropriate destination (either Router CE2 or Router CE4).

**Figure 32: Ultimate-Hop Popping for an LSP**

The following network applications require that you configure UHP LSPs:

- MPLS-TP for performance monitoring and in-band OAM
- Edge protection virtual circuits

The following features do not support the UHP behavior:

- LDP-signaled LSPs
- Static LSPs
- Point-to-multipoint LSPs
- CCC
- **traceroute** command

For more information about UHP behavior, see Internet draft [draft-ietf-mpls-rsvp-te-no-php-oob-mapping-01.txt](#), *Non PHP behavior and Out-of-Band Mapping for RSVP-TE LSPs*.

For point-to-point RSVP-signaled LSPs, UHP behavior is signaled from the LSP ingress. Based on the ingress router configuration, RSVP can signal the UHP LSP with the non-PHP flag set. RSVP PATH messages carry the two flags in the LSP-ATTRIBUTES object. When the egress router receives the PATH message, it assigns a non-null label to the LSP. RSVP also creates and installs two routes in the mpls.0 routing table. S refers to the S bit of the MPLS label, which indicates whether or not the bottom of the label stack has been reached.

- Route S=0—Indicates that there are more labels in the stack. The next hop for this route points to the mpls.0 routing table, triggering a chained MPLS label lookup to discover the remaining MPLS labels in the stack.
- Route S=1—Indicates that there are no more labels. The next hop points to the inet.0 routing table if the platform supports chained and multi-family lookup. Alternatively, the label route can point to a VT interface to initiate IP forwarding.

If you enable UHP LSPs, MPLS applications such as Layer 3 VPNs, VPLS, Layer 2 VPNs, and Layer 2 circuits can use the UHP LSPs. The following explains how UHP LSPs affect the different types of MPLS applications:

- Layer 2 VPNs and Layer 2 circuits—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label (S=0) is the UHP label, and the inner label (S=1) is the VC label. A lookup based on the transport label results in a table handle for the mpls.0 routing table. There is an additional route in the mpls.0 routing table corresponding to the inner label. A lookup based on the inner label results in the CE router next hop.
- Layer 3 VPN—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label (S=0) is the UHP label, and the inner label is the VPN label (S=1). A lookup based on the transport label results in the table handle for the mpls.0 routing table. There are two cases in this scenario. By default, Layer 3 VPNs advertise the per-next hop label. A lookup based on the inner label results in the next hop toward

the CE router. However, if you have configured the **vrf-table-label** statement for the Layer 3 VPN routing instance, the inner LSI label points to the VRF routing table. An IP lookup is also completed for the VRF routing table.

**NOTE:** UHP for Layer 3 VPNs configured with the **vrf-table-label** statement is supported on MX 3D Universal Edge Routers only.

- **VPLS**—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label is the transport label (S=0) and the inner label is the VPLS label (S=1). A lookup based on the transport label results in the table handle for the mpls.0 routing table. A lookup based on the inner label in mpls.0 routing table results in the LSI tunnel interface of the VPLS routing instance if tunnel-services is not configured (or a VT interface not available). MX 3D Series routers support chained lookup and multi-family lookup.

**NOTE:** UHP for VPLS configured with the **no-tunnel-service** statement is supported on MX 3D Series routers only.

- **IPv4 over MPLS**—A packet arrives at the PE router (egress of the UHP LSP) with one label (S=1). A lookup based on this label returns a VT tunnel interface. Another IP lookup is completed on the VT interface to determine where to forward the packet. If the routing platform supports multi-family and chained lookups (for example, MX 3D routers and PTX Series Packet Transport Routers), lookup based on label route (S=1) points to the inet.0 routing table.
- **IPv6 over MPLS**—For IPv6 tunneling over MPLS, PE routers advertise IPv6 routes to each other with a label value of 2. This is the explicit null label for IPv6. As a result, the forwarding next hops for IPv6 routes that are learned from remote PE routers normally push two labels. The inner label is 2 (it could be different if the advertising PE router is from another vendor), and the router label is the LSP label. Packets arrive at the PE router (egress of the UHP LSP) with two labels. The outer label is the transport label (S=0), and the inner label is the IPv6 explicit-null label (label 2). Lookup based on the inner label in the mpls.0 routing table redirects back to the mpls.0 routing table. On MX 3D Series routers, the inner label (label 2) is stripped off and an IPv6 lookup is done using the inet6.0 routing table.
- **Enabling both PHP and UHP LSPs**—You can configure both PHP and UHP LSPs over the same network paths. You can separate PHP and UHP traffic by selecting forwarding LSP next hops using a regular expression with the **install-nexthop** statement. You can also separate traffic by simply naming the LSPs appropriately.

The following statements enable ultimate-hop popping for an LSP. You can enable this feature on a specific LSP or for all of the ingress LSPs configured on the router. Configure these statements on the router at the LSP ingress.

1. To enable ultimate-hop popping, include the **ultimate-hop-popping** statement:

```
ultimate-hop-popping;
```

Include this statement at the **[edit protocols mpls label-switched-path *label-switched-path-name*]** hierarchy level to enable ultimate-hop popping on a specific LSP. Include this statement at the **[edit protocols mpls]** hierarchy level to enable ultimate-hop popping on all of the ingress LSPs configured on the router. You can also configure the **ultimate-hop-popping** statement under the equivalent **[edit logical-routers]** hierarchy levels.

**NOTE:** When you enable ultimate-hop popping, RSVP attempts to resignal existing LSPs as ultimate-hop popping LSPs in a make-before-break fashion. If an egress router does not support ultimate-hop popping, the existing LSP is torn down (RSVP sends a PathTear message along an LSP's path, removing the path state and dependent reservation state and releasing the associated networking resources).

If you disable ultimate-hop popping, RSVP resignals existing LSPs as penultimate-hop popping LSPs in a make-before-break fashion.

2. If you want to enable both ultimate-hop-popping and chained next hops on MX 3D Series routers only, you also need to configure the **enhanced-ip** option for the **network-services** statement:

```
network-services enhanced-ip;
```

You configure this statement at the **[edit chassis]** hierarchy level. Once you have configured the **network-services** statement, you need to reboot the router to enable UHP behavior.

## Configuring an LSP Across ASs

You can configure an LSP to traverse multiple areas in a network by including the **inter-domain** statement as a part of the LSP configuration. This statement allows the router to search for routes in the IGP database. You need to configure this statement on routers that might be unable to locate a path using intra-domain CSPF (by looking in the traffic engineering database (TED)). When you configure inter-area LSPs, the **inter-domain** statement is required.

Before you begin:

- Configure the device interfaces with family MPLS.
- Configure the device router ID and autonomous system number.
- Enable MPLS and RSVP on the router and transit interfaces.

- Configure your IGP to support traffic engineering.
- Set up an LSP from the ingress to the egress router.

To configure an LSP across multiple ASs on the ingress label-switched router (LER):

1. Enable MPLS on all the interfaces (excluding the management interface).

```
[edit protocols]
user@LER# set mpls interface all
user@LER# set mpls interface fxp0.0 disable
```

2. Enable RSVP on all the interfaces (excluding the management interface).

```
[edit protocols]
user@LER# set rsvp interface all
user@LER# set rsvp interface fxp0.0 disable
```

3. Configure the inter-area LSP.

```
[edit protocols]
user@LER# set mpls label-switched-path inter-area-LSP-name to
    egress-LER-ip-address
user@LER# set mpls label-switched-path inter-area-LSP-name inter-domain
```

4. Verify and commit the configuration.

```
[edit protocols]
user@LER# set rsvp interface ge-0/0/0.0
user@LER# set rsvp interface lo0.0
user@LER# set rsvp interface fxp0.0 disable
user@LER# set mpls statistics traffic-class-statistics
user@LER# set mpls label-switched-path R1-R2 to 20.0.0.1
user@LER# set mpls label-switched-path R1-R2 inter-domain
user@LER# set mpls interface ge-0/0/0.0
user@LER# set mpls interface lo0.0
user@LER# set mpls interface fxp0.0 disable
user@LER# set ospf traffic-engineering
user@LER# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@LER# set ospf area 0.0.0.0 interface lo0.0
```

## Configuring Fast Reroute

Fast reroute provides a mechanism for automatically rerouting traffic on an LSP if a node or link in an LSP fails, thus reducing the loss of packets traveling over the LSP.

To configure fast reroute on an LSP, include the **fast-reroute** statement on the ingress router (or switch):

```
fast-reroute {
  (bandwidth bps | bandwidth-percent percentage);
  (exclude [ group-names ] | no-exclude );
  hop-limit number;
  (include-all [ group-names ] | no-include-all);
}
```

```
(include-any [ group-names ] | no-include-any);
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

You do not need to configure fast reroute on the LSP's transit and egress routers (or switches). Once fast reroute is enabled, the ingress router (or switch) signals all the downstream routers (or switches) that fast reroute is enabled on the LSP, and each downstream router does its best to set up detours for the LSP. If a downstream router does not support fast reroute, it ignores the request to set up detours and continues to support the LSP. A router that does not support fast reroute will cause some of the detours to fail, but otherwise has no impact on the LSP.

**NOTE:** To enable PFE fast reroute, configure a routing policy statement with the **load-balance per-packet** statement at the [edit policy-options policy-statement *policy-name* then] hierarchy level on each of the routers where traffic might be rerouted. See also “[Configuring Load Balancing Across RSVP LSPs](#)” on page 514.

By default, no bandwidth is reserved for the rerouted path. To allocate bandwidth for the rerouted path, include either the **bandwidth** statement or the **bandwidth-percent** statement. You can only include one of these statements at a time. If you do not include either the **bandwidth** statement or the **bandwidth-percent** statement, the default setting is to not reserve bandwidth for the detour path.

When you include the **bandwidth** statement, you can specify the specific amount of bandwidth (in bits per second [bps]) you want to reserve for the detour path. The bandwidth does not need to be identical to that allocated for the LSP.

When you specify a bandwidth percent using the **bandwidth-percent** statement, the detour path bandwidth is computed by multiplying the bandwidth percentage by the bandwidth configured for the main traffic-engineered LSP. For information about how to configure the bandwidth for a traffic-engineered LSP, see “[Configuring Traffic-Engineered LSPs](#)” on page 354.

Hop-limit constraints define how many more routers a detour is allowed to traverse compared with the LSP itself. By default, the hop limit is set to 6. For example, if an LSP traverses 4 routers, any detour for the LSP can be up to 10 (that is, 4 + 6) router hops, including the ingress and egress routers.

By default, a detour inherits the same administrative (coloring) group constraints as its parent LSP when CSPF is determining the alternate path. Administrative groups, also known as link coloring or resource class, are manually assigned attributes that describe the “color” of links, such that links with the same color conceptually belong to the same class. If you specify the **include-any** statement when configuring the parent LSP, all links traversed by the alternate session must have at least one color found in the list of groups.

If you specify the **include-all** statement when configuring the parent LSP, all links traversed by the alternate session must have all of the colors found in the list of groups. If you specify the **exclude** statement when configuring the parent LSP, none of the links must have a color found in the list of groups. For more information about administrative group constraints, see [“Configuring Administrative Groups for LSPs” on page 268](#).

## Configuring the Optimization Interval for Fast Reroute Paths

You can enable path optimization for fast reroute by configuring the fast reroute optimize timer. The optimize timer triggers a periodic optimization process that recomputes the fast reroute detour LSPs to use network resources more efficiently.

To enable fast reroute path optimization, specify the number of seconds using the `optimize-timer` option for the **fast-reroute** statement:

```
fast-reroute seconds;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols rsvp]`
- `[edit logical-systems logical-system-name protocols rsvp]`

---

## Adding LSP-Related Routes to the inet.3 or inet6.3 Routing Table

By default, a host route toward the egress router is installed in the `inet.3` or `inet6.3` routing table. (The host route address is the one you configure in the **to** statement.) Installing the host route allows BGP to perform next-hop resolution. It also prevents the host route from interfering with prefixes learned from dynamic routing protocols and stored in the `inet.0` or `inet6.0` routing table.

Unlike the routes in the `inet.0` or `inet6.0` table, routes in the `inet.3` or `inet6.3` table are not copied to the Packet Forwarding Engine, and hence they cause no changes in the system forwarding table directly. You cannot use the **ping** or **traceroute** command through these routes. The only use for `inet.3` or `inet6.3` is to permit BGP to perform next-hop resolution. To examine the `inet.3` or `inet6.3` table, use the **show route table inet.3** or **show route table inet6.3** command.

To inject additional routes into the `inet.3` or `inet6.3` routing table, include the **install** statement:

```
install {  
    destination-prefix <active>;  
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit protocols mpls **static-label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **static-label-switched-path** *lsp-name*]

The specified routes are installed as aliases into the routing table when the LSP is established. Installing additional routes allows BGP to resolve next hops within the specified prefix and to direct additional traffic for these next hops to a particular LSP.

Including the **active** option with the **install** statement installs the specified prefix into the inet.0 or inet6.0 routing table, which is the primary forwarding table. The result is a route that is installed in the forwarding table any time the LSP is established, which means you can ping or trace the route. Use this option with care, because this type of prefix is very similar to a static route.

You use alias routes for routers that have multiple addresses being used as BGP next hops, or for routers that are not MPLS capable. In either of these cases, the LSP can be configured to another MPLS capable system within the local domain, which then acts as a “border” router. The LSP then terminates on the border router and, from that router, Layer 3 forwarding takes the packet to the true next-hop router.

In the case of an interconnect, the domain's border router can act as the proxy router and can advertise the prefix for the interconnect if the border router is not setting the BGP next hop to itself.

In the case of a point of presence (POP) that has routers that do not support MPLS, one router (for example, a core router) that supports MPLS can act as a proxy for the entire POP and can inject a set of prefixes that cover the POP. Thus, all routers within the POP can advertise themselves as interior BGP (IBGP) next hops, and traffic can follow the LSP to reach the core router. This means that normal IGP routing would prevail within the POP.

You cannot use the **ping** or **traceroute** commands on routes in the inet.3 or inet6.3 routing table.

For BGP next-hop resolution, it makes no difference whether a route is in inet.0/inet6.0 or inet.3/inet6.3; the route with the best match (longest mask) is chosen. Among multiple best-match routes, the one with the highest preference value is chosen.

---

## Configuring the Connection Between Ingress and Egress Routers

The ingress router might make many attempts to connect and reconnect to the egress router using the primary path. You can control how often the ingress router tries to establish a connection using the primary path and how long it waits between retry attempts.

The retry timer configures how long the ingress router waits before trying to connect again to the egress router using the primary path. The default retry time is 30 seconds. The time can be from 1 through 600 seconds. To modify this value, include the **retry-timer** statement:

**retry-timer** *seconds*;

You can configure this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

By default, no limit is set to the number of times an ingress router attempts to establish or reestablish a connection to the egress router using the primary path. To limit the number of attempts, include the **retry-limit** statement:

**retry-limit** *number*;

You can configure this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

The limit can be a value up to 10,000. When the retry limit is exceeded, no more attempts are made to establish a path connection. At this point, intervention is required to restart the primary path.

If you set a retry limit, it is reset to 1 each time a successful primary path is created.

---

## Configuring LSP Metrics

The LSP metric is used to indicate the ease or difficulty of sending traffic over a particular LSP. Lower LSP metric values (lower cost) increase the likelihood of an LSP being used. Conversely, high LSP metric values (higher cost) decrease the likelihood of an LSP being used.

The LSP metric can be specified dynamically by the router or explicitly by the user as described in the following sections:

- [Configuring Dynamic LSP Metrics on page 258](#)
- [Configuring Static LSP Metrics on page 259](#)

### Configuring Dynamic LSP Metrics

If no specific metric is configured, an LSP attempts to track the IGP metric toward the same destination (the **to** address of the LSP). IGP includes OSPF, IS-IS, Routing Information Protocol (RIP), and static routes. BGP and other RSVP or LDP routes are excluded.

For example, if the OSPF metric toward a router is 20, all LSPs toward that router automatically inherit metric 20. If the OSPF toward a router later changes to a different

value, all LSP metrics change accordingly. If there are no IGP routes toward the router, the LSP raises its metric to 65,535.

Note that in this case, the LSP metric is completely determined by IGP; it bears no relationship to the actual path the LSP is currently traversing. If LSP reroutes (such as through reoptimization), its metric does not change, and thus it remains transparent to users. Dynamic metric is the default behavior; no configuration is required.

## Configuring Static LSP Metrics

You can manually assign a fixed metric value to an LSP. Once configured with the **metric** statement, the LSP metric is fixed and cannot change:

**metric** *number*;

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit protocols mpls **static-label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **static-label-switched-path** *lsp-name*]

The LSP metric has several uses:

- When there are parallel LSPs with the same egress router, the metrics are compared to determine which LSP has the lowest metric value (the lowest cost) and therefore the preferred path to the destination. If the metrics are the same, the traffic is shared.

Adjusting the metric values can force traffic to prefer some LSPs over others, regardless of the underlying IGP metric.

- When an IGP shortcut is enabled (see [“Using Labeled-Switched Paths to Augment SPF to Compute IGP Shortcuts” on page 34](#)), an IGP route might be installed in the routing table with an LSP as the next hop, if the LSP is on the shortest path to the destination. In this case, the LSP metric is added to the other IGP metrics to determine the total path metric. For example, if an LSP whose ingress router is X and egress router is Y is on the shortest path to destination Z, the LSP metric is added to the metric for the IGP route from Y to Z to determine the total cost of the path. If several LSPs are potential next hops, the total metrics of the paths are compared to determine which path is preferred (that is, has the lowest total metric). Or, IGP paths and LSPs leading to the same destination could be compared by means of the metric value to determine which path is preferred.

By adjusting the LSP metric, you can force traffic to prefer LSPs, prefer the IGP path, or share the load among them.

- If router X and Y are BGP peers and if there is an LSP between them, the LSP metric represents the total cost to reach Y from X. If for any reason the LSP reroutes, the underlying path cost might change significantly, but X’s cost to reach Y remains the same (the LSP metric), which allows X to report through a BGP multiple exit

discriminator (MED) a stable metric to downstream neighbors. As long as Y remains reachable through the LSP, no changes are visible to downstream BGP neighbors.

It is possible to configure IS-IS to ignore the configured LSP metric by including the **ignore-lsp-metrics** statement at the **[edit protocols isis traffic-engineering shortcuts]** hierarchy level. This statement removes the mutual dependency between IS-IS and MPLS for path computation. For more information, see the *Junos OS Routing Protocols Library*.

---

## Configuring CSPF Tie Breaking

When selecting a path for an LSP, CSPF uses a tie-breaking process if there are several equal-cost paths. For information about how CSPF selects a path, see [“How CSPF Selects a Path” on page 31](#).

You can configure one of the following statements (you can only configure one of these statements at a time) to alter the behavior of CSPF tie-breaking:

- By default, a random tie-breaking rule for CSPF is used to select a path from the set of equal-cost paths. However, you can also explicitly configure this behavior using the **random** statement:

**random;**

- To prefer the path with the least-utilized links, include the **least-fill** statement:

**least-fill;**

- To prefer the path with the most-utilized links, include the **most-fill** statement:

**most-fill;**

You can include each of these statements at the following hierarchy levels:

- **[edit protocols mpls label-switched-path *lsp-name*]**
- **[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]**

**Related Documentation**

## Configuring Load Balancing Based on MPLS Labels

Load balancing occurs on a per-packet basis for MPLS flows on supported platforms. Entropy, or random distribution, is essential for the uniform distribution of packets to their next hops. By default, when load balancing is used to help distribute traffic, Junos OS employs a hash algorithm to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes, the next-hop address is reselected by means of the hash algorithm. You can configure how the hash algorithm is used to load-balance traffic across a set of equal-cost label switched paths (LSPs).

To ensure entropy for VPLS & VPWS traffic, Junos OS can create a hash based on data from the IP header and as many as three MPLS labels (the so-called top labels).

In some cases, as the number of network feature that use labels grows (such as MPLS Fast Reroute, and RFC 3107, RSVP and VPN) data in the top three labels can become static and thus not a sufficient source for entropy. Load balancing can become skewed as a result, or the incidence of out-of-order packet delivery may rise. For these cases, labels from the bottom of the label stack can be used (see Table 1, below for qualifications). Top labels and bottom labels cannot be used at the same time.

**NOTE:** MPC cards do not support the regular hash key configuration. For the MPC-based hash key configuration to be effective, you need an **enhanced-hash-key** configuration.

Load balancing is used to evenly distribute traffic when the following conditions apply:

- There are multiple equal-cost next hops over different interfaces to the same destination.
- There is a single next hop over an aggregated interface.

An LSP tends to load-balance its placement by randomly selecting one of the equal-cost next hops and using it exclusively. The random selection is made independently at each transit router, which compares Interior Gateway Protocol (IGP) metrics alone. No consideration is given to bandwidth or congestion levels.

This feature applies to aggregated Ethernet and aggregated SONET/SDH interfaces as well as multiple equal-cost MPLS next hops. In addition, on the T Series, MX Series, M120, and M320 routers only, you can configure load balancing for IPv4 traffic over Layer 2 Ethernet pseudowires. You can also configure load balancing for Ethernet pseudowires based on IP information. The option to include IP information in the hash key provides support for Ethernet circuit cross-connect (CCC) connections.

To load-balance based on the MPLS label information, configure the **family mpls** statement:

```
[edit forwarding-options hash-key]
family mpls {
  all-labels;
  bottom-label-1;
  bottom-label-2;
  bottom-label-3;
  label-1;
  label-2;
  label-3;
  no-labels;
  no-label-1-exp;
  payload {
    ether-pseudowire;
    ip {
      disable;
      layer-3-only;
      port-data {
        destination-lsb;
        destination-msb;
      }
    }
  }
}
```

```

        source-lsb;
        source-msb;
    }
}
}

```

You can include this statement at the following hierarchy levels:

- **[edit forwarding-options hash-key]**

[Table 5 on page 262](#) provides detailed information about all of the possible MPLS LSP load-balancing options.

**Table 5: MPLS LSP Load Balancing Options**

| Statement             | Supported Platforms                                                | MPLS LSP Load Balancing Options                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>all-labels</b>     | PTX Series                                                         | Up to eight MPLS labels are included in the hash key to identify the uniqueness of a flow in the Packet Forwarding Engine. This value is set by default.                                                                                                                                                                                                                                                                                               |
| <b>bottom-label-1</b> | MX Series with DPC (I-Chip). Not supported on M10i, M7i, and M120. | Uses the bottom-most label for calculating the hash key, for example if the top labels do not provide sufficient variable for the required level of entropy.                                                                                                                                                                                                                                                                                           |
| <b>bottom-label-2</b> | MX Series with DPC (I-Chip). Not supported on M10i, M7i, and M120. | Uses the second label from the bottom for calculating the hash key, for example if the top labels do not provide sufficient variable for the required level of entropy.                                                                                                                                                                                                                                                                                |
| <b>bottom-label-3</b> | MX Series with DPC (I-Chip). Not supported on M10i, M7i, and M120. | Uses the third label from the bottom for calculating the hash key, for example if the top labels do not provide sufficient variable for the required level of entropy.                                                                                                                                                                                                                                                                                 |
| <b>label-1</b>        | M Series, MX Series, T Series                                      | Include the first label in the hash key. Use this option for single label packets.                                                                                                                                                                                                                                                                                                                                                                     |
| <b>label-2</b>        | M Series, MX Series, T Series                                      | Include the second label in the hash key. You must also configure the <b>label-1</b> option. The entire first label and the first 16 bits of the second label are used in the hash key.                                                                                                                                                                                                                                                                |
| <b>label-3</b>        | M Series, MX Series, T Series                                      | Include the third label in the hash key. You must also configure the <b>label-1</b> option and the <b>label-2</b> option.                                                                                                                                                                                                                                                                                                                              |
| <b>no-labels</b>      | All                                                                | Excludes MPLS labels from the hash key.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>no-label-1-exp</b> | M Series, MX Series, T Series                                      | Excludes the EXP bit of the top label from the hash key. You must also configure the <b>label-1</b> option.<br><br>For Layer 2 VPNs, the router could encounter a packet reordering problem. When a burst of traffic pushes the customer traffic bandwidth to exceed its limits, the traffic might be affected in mid flow. Packets might be reordered as a result. By excluding the EXP bit from the hash key, you can avoid this reordering problem. |

Table 5: MPLS LSP Load Balancing Options (*continued*)

| Statement                   | Supported Platforms             | MPLS LSP Load Balancing Options                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>payload</b>              | All                             | Allows you to configure which parts of the IP packet payload to include in the hash key. For the PTX Series Packet Transport Router, this value is set by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>disable</b>              | PTX Series                      | Exclude IP payload from the hash key.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <del>ether-pseudowire</del> | M120, M320, MX Series, T Series | Load-balance IPv4 traffic over Layer 2 Ethernet pseudowires.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>ip</b>                   | All                             | Include the IPv4 or IPv6 address in the hash key. You must also configure either <b>label-l</b> or <b>no-labels</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>layer-3-only</b>         | All                             | Include only the Layer 3 IP information in the hash key. Excludes all of the <b>port-data</b> bytes from the hash key.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>port-data</b>            | M Series, MX Series, T Series   | Include the source and destination port field information. By default, the most significant byte and least significant byte of the source and destination port fields are used in the hash key. To select specific bytes to use in the hash key, include one or more of the <b>source-msb</b> , <b>source-lsb</b> , <b>destination-msb</b> , and <b>destination-lsb</b> options at the <b>[edit forwarding-options hash-key family mpls payload ip port-data]</b> hierarchy level. To prevent all four bytes from being hashed, include the <b>layer-3-only</b> statement at the <b>[edit forwarding-options hash-key family mpls payload ip]</b> hierarchy level. |
| <del>destination-lsb</del>  | M Series, MX Series, T Series   | Include the least significant byte of the destination port in the hash key. Can be combined with any of the other <b>port-data</b> options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <del>destination-msb</del>  | M Series, MX Series, T Series   | Include the most significant byte of the destination port in the hash key. Can be combined with any of the other <b>port-data</b> options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>source-lsb</b>           | M Series, MX Series, T Series   | Include the least significant byte of the source port in the hash key. Can be combined with any of the other <b>port-data</b> options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>source-msb</b>           | M Series, MX Series, T Series   | Include the most significant byte of the source port in the hash key. Can be combined with any of the other <b>port-data</b> options.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

The following examples illustrate ways in which you can configure MPLS LSP load balancing:

- To include the IP address as well as the first label in the hash key:
  - For M Series, MX Series, and T Series routers, configure the **label-l** statement and the **ip** option for the **payload** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-l;
payload {
  ip;
}
```

- For PTX Series Packet Transport Routers, the **all-labels** and **ip payload** options are configured by default, so no configuration is necessary.
- (M320 and T Series routers only) To include the IP address as well as both the first and second labels in the hash key, configure the **label-1** and **label-2** options and the **ip** option for the **payload** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
label-2;
payload {
  ip;
}
```

**NOTE:** You can include this combination of statements on M320 and T Series routers only. If you include them on an M Series Multiservice Edge Router, only the first MPLS label and the IP payload are used in the hash key.

- For T Series routers, ensure proper load balancing by including the **label-1**, **label-2**, and **label-3** options at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
label-2;
label-3;
```

- (M Series, MX Series, and T Series routers only) For Layer 2 VPNs, the router could encounter a packet reordering problem. When a burst of traffic pushes the customer traffic bandwidth to exceed its limits, the traffic might be affected in mid flow. Packets might be reordered as a result. By excluding the EXP bit from the hash key, you can avoid this reordering problem. To exclude the EXP bit of the first label from the hash calculations, include the **no-label-1-exp** statement at the **[edit forwarding-options hash-key family mpls]** hierarchy level:

```
[edit forwarding-options hash-key family mpls]
label-1;
no-label-1-exp;
payload {
  ip;
}
```

## Disabling Normal TTL Decrementing

By default, the time-to-live (TTL) field value in the packet header is decremented by 1 for every hop the packet traverses in the LSP, thereby preventing loops. If the TTL field value reaches 0, packets are dropped, and an Internet Control Message Protocol (ICMP) error packet is sent to the originating router.

If the normal TTL decrement is disabled, the TTL field of IP packets entering LSPs are decremented by only 1 on transiting the LSP, making the LSP appear as a one-hop router to diagnostic tools, such as **traceroute**. Decrementing the TTL field by 1 is done by the ingress router, which pushes a label on IP packets with the TTL field in the label initialized to 255. The label's TTL field value is decremented by 1 for every hop the MPLS packet traverses in the LSP. On the penultimate hop of the LSP, the router pops the label but does not write the label's TTL field value to the IP packet's TTL field. Instead, when the IP packet reaches the egress router, the IP packet's TTL field value is decremented by 1.

When you use **traceroute** to diagnose problems with an LSP from outside that LSP, **traceroute** sees the ingress router, even though the egress router performs the TTL decrement. The behavior of **traceroute** is different if it is initiated from the ingress router of the LSP. In this case, the egress router would be the first router to respond to **traceroute**.

You can disable normal TTL decrementing in an LSP so that the TTL field value does not reach 0 before the packet reaches its destination, thus preventing the packet from being dropped. You can also disable normal TTL decrementing to make the MPLS cloud appear as a single hop, thereby hiding the network topology.

There are two ways to disable TTL decrementing:

- On the ingress of the LSP, if you include the **no-decrement-ttl** statement, the ingress router negotiates with all downstream routers using a proprietary RSVP object, to ensure all routers are in agreement. If negotiation succeeds, the whole LSP behaves as one hop to transit IP traffic.

**no-decrement-ttl;**

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

**NOTE:** The RSVP object is proprietary to the Junos OS and might not work with other software. This potential incompatibility applies only to RSVP-signaled LSPs. When you include the **no-decrement-ttl** statement, TTL hiding can be enforced on a per-LSP basis.

- On the ingress router, you can include the **no-propagate-ttl** statement. The **no-propagate-ttl** statement applies to all LSPs, regardless of whether they are RSVP-signaled or LDP-signaled. Once set, all future LSPs traversing through this router behave as a single hop to IP packets. LSPs established before you configure this statement are not affected.

**no-propagate-ttl;**

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

The operation of the **no-propagate-ttl** statement is interoperable with other vendors' equipment. However, you must ensure that all routers are configured identically.

To configure the TTL behavior for a single VRF routing instance, include the **no-vrf-propagate-ttl** or the **vrf-propagate-ttl** statement in the routing instance configuration at the `[edit routing-instances instance-name]` hierarchy level. The **no-vrf-propagate-ttl** or the **vrf-propagate-ttl** statement overrides the behavior configured globally for the router. If the router is operating in default mode with normal TTL decrementing, the **no-vrf-propagate-ttl** overrides the global behavior for the routing instance on which the **no-vrf-propagate-ttl** statement is configured.

## Configuring MPLS Soft Preemption

Soft preemption attempts to establish a new path for a preempted LSP before tearing down the original LSP. The default behavior is to tear down a preempted LSP first, signal a new path, and then reestablish the LSP over the new path. In the interval between when the path is taken down and the new LSP is established, any traffic attempting to use the LSP is lost. Soft preemption prevents this type of traffic loss. The trade-off is that during the time when an LSP is being soft preempted, two LSPs with their corresponding bandwidth requirements are used until the original path is torn down.

MPLS soft preemption is useful for network maintenance. For example, you can move all LSPs away from a particular interface, then take the interface down for maintenance without interrupting traffic. MPLS soft preemption is described in detail in RFC 5712, *MPLS Traffic Engineering Soft Preemption*.

Soft preemption is a property of the LSP and is disabled by default. You configure it at the ingress of an LSP by including the **soft-preemption** statement:

```
soft-preemption;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls label-switched-path lsp-name]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name]`

You can also configure a timer for soft preemption. The timer designates the length of time the router should wait before initiating a hard preemption of the LSP. At the end of the time specified, the LSP is torn down and resignaled. The soft-preemption cleanup timer has a default value of 30 seconds; the range of permissible values is 0 through 180 seconds. A value of 0 means that soft preemption is disabled. The soft-preemption cleanup timer is global for all LSPs.

Configure the timer by including the **cleanup-timer** statement:

```
cleanup-timer seconds;
```

You can include this statement at the following hierarchy levels:

- `[edit protocols rsvp preemption soft-preemption]`

- [edit logical-systems *logical-system-name* protocols rsvp **preemption soft-preemption**]

**NOTE:** Soft preemption cannot be configured on LSPs for which secondary paths or fast reroute has been configured. The configuration fails to commit. However, you can enable soft preemption in conjunction with node and link protection.

## Disabling Constrained-Path LSP Computation

If the IGP is a link-state protocol (such as IS-IS or OSPF) and supports extensions that allow the current bandwidth reservation on each router's link to be reported, constrained-path LSPs are computed by default.

The Junos implementations of IS-IS and OSPF include the extensions that support constrained-path LSP computation.

- IS-IS—These extensions are enabled by default. To disable this support, include the **disable** statement at the [edit protocols isis **traffic-engineering**] hierarchy level, as discussed in the *Junos OS Routing Protocols Library*.
- OSPF—These extensions are disabled by default. To enable this support, include the **traffic-engineering** statement in the configurations of all routers running OSPF, as described in the *Junos OS Routing Protocols Library*.

If IS-IS is enabled on a router or you enable OSPF traffic engineering extensions, MPLS performs the constrained-path LSP computation by default. For information about how constrained-path LSP computation works, see [“Constrained-Path LSP Computation” on page 30](#).

Constrained-path LSPs have a greater chance of being established quickly and successfully for the following reasons:

- The LSP computation takes into account the current bandwidth reservation.
- Constrained-path LSPs reroute themselves away from node failures and congestion.

When constrained-path LSP computation is enabled, you can configure the LSP so that it is periodically reoptimized, as described in [“Optimizing Signaled LSPs” on page 280](#).

When an LSP is being established or when an existing LSP fails, the constrained-path LSP computation is repeated periodically at the interval specified by the retry timer until the LSP is set up successfully. Once the LSP is set up, no recomputation is done. For more information about the retry timer, see [“Configuring the Connection Between Ingress and Egress Routers” on page 257](#).

By default, constrained-path LSP computation is enabled. You might want to disable constrained-path LSP computation when all nodes do not support the necessary traffic engineering extensions. To disable constrained-path LSP computation, include the **no-cspf** statement:

**no-cspf;**

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

If you disable constrained-path LSP computation on LSPs by configuring the **no-cspf** statement and then attempt to advertise other LSPs with lower metrics than the IGP from this router in either IS-IS or OSPF, new LSPs cannot be established.

---

## Configuring Administrative Groups for LSPs

---

Administrative groups, also known as link coloring or resource class, are manually assigned attributes that describe the “color” of links, such that links with the same color conceptually belong to the same class. You can use administrative groups to implement a variety of policy-based LSP setups.

Administrative groups are meaningful only when constrained-path LSP computation is enabled.

You can assign up to 32 names and values (in the range 0 through 31), which define a series of names and their corresponding values. The administrative names and values must be identical across all routers within a single domain.

**NOTE:** The administrative value is distinct from the priority. You configure the priority for an LSP using the **priority** statement. See “[Configuring Priority and Preemption for LSPs](#)” on page 280.

To configure administrative groups, follow these steps:

1. Define multiple levels of service quality by including the **admin-groups** statement:

```
admin-groups {  
    group-name group-value;  
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

The following configuration example illustrates how you might configure a set of administrative names and values for a domain:

```
[edit protocols mpls]  
admin-groups {  
    gold 1;  
    silver 2;  
    copper 3;  
    best-effort 4;  
}
```

2. Define the administrative groups to which an interface belongs. You can assign multiple groups to an interface. Include the **interface** statement:

```
interface interface-name {
  admin-group [ group-names ];
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

If you do not include the **admin-group** statement, an interface does not belong to any group.

IGPs use the group information to build link-state packets, which are then flooded throughout the network, providing information to all nodes in the network. At any router, the IGP topology, as well as administrative groups of all the links, is available.

Changing the interface's administrative group affects only new LSPs. Existing LSPs on the interface are not preempted or recomputed to keep the network stable. If LSPs need to be removed because of a group change, issue the **clear RSVP session** command.

3. Configure an administrative group constraint for each LSP or for each primary or secondary LSP path. Include the **label-switched-path** statement:

```
label-switched-path lsp-name {
  to address;
  ...
  admin-group {
    exclude [ group-names ];
    include-all [ group-names ];
    include-any [ group-names ];
  }
  primary path-name {
    admin-group {
      exclude [ group-names ];
      include-all [ group-names ];
      include-any [ group-names ];
    }
  }
  secondary path-name {
    admin-group {
      exclude [ group-names ];
      include-all [ group-names ];
      include-any [ group-names ];
    }
  }
}
```

You can include the **label-switched-path** statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

If you omit the **include-all**, **include-any**, or **exclude** statements, the path computation proceeds unchanged. The path computation is based on the constrained-path LSP computation. For information about how the constrained-path LSP computation is calculated, see [“How CSPF Selects a Path” on page 31](#).

**NOTE:** Changing the LSP's administrative group causes an immediate recomputation of the route; therefore, the LSP might be rerouted.

---

## Configuring Extended Administrative Groups for LSPs

---

In MPLS traffic engineering, a link can be configured with a set of administrative groups (also known as colors or resource classes). Administrative groups are carried in the interior gateway protocol (IGP) (OSPFv2 and IS-IS) as a 32-bit value assigned to each link. Juniper Networks routers normally interpret this 32-bit value as a bit mask with each bit representing a group, limiting each network to a total of 32 distinct administrative groups (value range 0 through 31).

You configure extended administrative groups, represented by a 32-bit value, expanding the number of administrative groups supported in the network beyond just 32. The original range of values available for administrative groups is still supported for backwards compatibility.

The extended administrative groups configuration accepts a set of interfaces with a corresponding set of extended administrative group names. It converts the names into a set of 32-bit values and propagates this information into the IGP. The extended administrative group values are global and must be identically configured on all the supported routers participating in the network. The domain-wide extended administrative groups database, learned from other routers through IGP flooding, is used by Constrained Shortest Path First (CSPF) for path computation.

The following procedure describes how to configure extended administrative groups:

1. Configure the `admin-groups-extended-range` statement:

```
admin-groups-extended-range {  
    maximum maximum-number;  
    minimum minimum-number;  
}
```

You can include this statement at the following hierarchy levels:

- `[edit routing-options]`
- `[edit logical-systems logical-system-name routing-options]`

The `admin-groups-extended-range` statement includes the `minimum` and `maximum` options. The range maximum must be greater than the range minimum.

2. Configure the `admin-groups-extended` statement:

```
admin-groups-extended group-name {  
    group-value group-identifier;  
}
```

You can include this statement at the following hierarchy levels:

- `[edit routing-options]`

- [edit logical-systems *logical-system-name* routing-options]

The **admin-groups-extended** statement enables you to configure a group name and group value for the administrative group. The group value must be within the range of values configured using the **admin-groups-extended-range** statement.

3. The extended administrative groups for an MPLS interface consist of the set of extended administrative group names assigned for the interface. The interface extended administrative group names must be configured for the global extended administrative groups.

To configure an extended administrative group for an MPLS interface, specify the administrative group name within the MPLS interface configuration using the **admin-groups-extended** statement:

```
admin-groups-extended group-name;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols mpls interface *interface-name*]

4. The LSP extended administrative groups define the set of include and exclude constraints for an LSP and for a path's primary and secondary paths. The extended administrative group names must be configured for the global extended administrative groups.

To configure extended administrative groups for an LSP, include the **admin-group-extended** statement at an LSP hierarchy level:

```
admin-group-extended {
  apply-groups group-value;
  apply-groups-except group-value;
  exclude group-value;
  include-all group-value;
  include-any group-value;
}
```

The **admin-group-extended** statement includes the following options: **apply-groups**, **apply-groups-except**, **exclude**, **include-all**, and **include-any**. Each option enables you to configure one or more extended administrative groups.

For the list of the hierarchy levels at which you can configure this statement, see the statement summary for this statement.

5. To display the currently configured extended administrative groups, issue the **show mpls admin-groups-extended** command.

## Configuring Preference Values for LSPs

As an option, you can configure multiple LSPs between the same pair of ingress and egress routers. This is useful for balancing the load among the LSPs because all LSPs,

by default, have the same preference level. To prefer one LSP over another, set different preference levels for individual LSPs. The LSP with the lowest preference value is used. The default preference for RSVP LSPs is 7 and for LDP LSPs is 9. These preference values are lower (more preferred) than all learned routes except direct interface routes.

To change the default preference value, include the **preference** statement:

```
preference preference;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

---

## Disabling Path Route Recording by LSPs

The Junos implementation of RSVP supports the Record Route object, which allows an LSP to actively record the routers through which it transits. You can use this information for troubleshooting and to prevent routing loops. By default, path route information is recorded. To disable recording, include the **no-record** statement:

```
no-record;
```

For a list of hierarchy levels at which you can include the **record** and **no-record** statements, see the statement summary section for the statement.

---

## Configuring Class of Service for MPLS LSPs

The following sections provide an overview of MPLS class of service (CoS) and describe how to configure the MPLS CoS value:

- [Class of Service for MPLS Overview on page 272](#)
- [Configuring the MPLS CoS Values on page 273](#)
- [Rewriting IEEE 802.1p Packet Headers with the MPLS CoS Value on page 275](#)

---

### Class of Service for MPLS Overview

When IP traffic enters an LSP tunnel, the ingress router marks all packets with a CoS value, which is used to place the traffic into a transmission priority queue. On the router, for SDH/SONET and T3 interfaces, each interface has four transmit queues. The CoS value is encoded as part of the MPLS header and remains in the packets until the MPLS header is removed when the packets exit from the egress router. The routers within the LSP utilize the CoS value set at the ingress router. The CoS value is encoded by means of the CoS bits (also known as the EXP or experimental bits). For more information, see [“MPLS Label Allocation” on page 26](#).

MPLS class of service works in conjunction with the router’s general CoS functionality. If you do not configure any CoS features, the default general CoS settings are used. For MPLS class of service, you might want to prioritize how the transmit queues are serviced by configuring weighted round-robin, and to configure congestion avoidance using random early detection (RED)..

## Configuring the MPLS CoS Values

When traffic enters an LSP tunnel, the CoS value in the MPLS header is set in one of three ways:

- The number of the output queue into which the packet was buffered and the packet loss priority (PLP) bit are written into the MPLS header and are used as the packet's CoS value. This behavior is the default, and no configuration is required. *Default MPLS EXP Classifier* explains the default MPLS CoS values, and summarizes how the CoS values are treated.
- You set a fixed CoS value on all packets entering the LSP tunnel. A fixed CoS value means that all packets entering the LSP receive the same class of service.
- You set an MPLS EXP rewrite rule to override the default behavior.

To set a fixed CoS value on all packets entering the LSP, include the **class-of-service** statement:

```
class-of-service cos-value;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit protocols mpls label-switched-path *path-name*]
- [edit protocols mpls label-switched-path *path-name* primary *path-name*]
- [edit protocols mpls label-switched-path *path-name* secondary *path-name*]
- [edit protocols rsvp interface *interface-name* link-protection]
- [edit protocols rsvp interface *interface-name* link-protection bypass *destination*]
- [edit logical-systems *logical-system-name* protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name* primary *path-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *path-name* secondary *path-name*]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection ]
- [edit logical-systems *logical-system-name* protocols rsvp interface *interface-name* link-protection bypass *destination*]

The CoS value set using the **class-of-service** statement at the [edit protocols mpls] hierarchy level supersedes the CoS value set at the [edit class-of-service] hierarchy level for an interface. Effectively, the CoS value configured for an LSP overrides the CoS value set for an interface.

The **class-of-service** statement at the **[edit protocols mpls label-switched-path]** hierarchy level assigns an initial EXP value for the MPLS shim header of packets in the LSP. This value is initialized at the ingress routing device only and overrides the rewrite configuration established for that forwarding class. However, the CoS processing (weighted round robin [WRR] and RED) of packets entering the ingress routing device is not changed by the **class-of-service** statement on an MPLS LSP. Classification is still based on the behavior aggregate (BA) classifier at the **[edit class-of-service]** hierarchy level or the multifield classifier at the **[edit firewall]** hierarchy level.

**BEST PRACTICE:** We recommend configuring all routing devices along the LSP to have the same input classifier for EXP, and, if a rewrite rule is configured, all routing devices should have the same rewrite configuration. Otherwise, traffic at the next LSR might be classified into a different forwarding class, resulting in a different EXP value being written to the EXP header.

The CoS value can be a decimal number from 0 through 7. This number corresponds to a 3-bit binary number. The high-order 2 bits of the CoS value select which transmit queue to use on the outbound interface card.

The low-order bit of the CoS value is treated as the PLP bit and is used to select the RED drop profile to use on the output queue. If the low-order bit is 0, the non-PLP drop profile is used, and if the low-order bit is 1, the PLP drop profile is used. It is generally expected that RED will more aggressively drop packets that have the PLP bit set. For more information about RED and drop profiles, see *Managing Congestion Using RED Drop Profiles and Packet Loss Priorities*.

**NOTE:** Configuring the PLP drop profile to drop packets more aggressively (for example, setting the CoS value from 6 to 7) decreases the likelihood of traffic getting through.

Table 6 on page 274 summarizes how MPLS CoS values correspond to the transmit queue and PLP bit. Note that in MPLS, the mapping between the CoS bit value and the output queue is hard-coded. You cannot configure the mapping for MPLS; you can configure it only for IPv4 traffic flows, as described in *Understanding How Forwarding Classes Assign Classes to Output Queues*.

**Table 6: MPLS CoS Values**

| MPLS CoS Value | Bits | Transmit Queue | PLP Bit |
|----------------|------|----------------|---------|
| 0              | 000  | 0              | Not set |
| 1              | 001  | 0              | Set     |
| 2              | 010  | 1              | Not set |

Table 6: MPLS CoS Values (*continued*)

| MPLS CoS Value | Bits | Transmit Queue | PLP Bit |
|----------------|------|----------------|---------|
| 3              | 011  | 1              | Set     |
| 4              | 100  | 2              | Not set |
| 5              | 101  | 2              | Set     |
| 6              | 110  | 3              | Not set |
| 7              | 111  | 3              | Set     |

Because the CoS value is part of the MPLS header, the value is associated with the packets only as they travel through the LSP tunnel. The value is not copied back to the IP header when the packets exit from the LSP tunnel.

To configure class of service (CoS) for Multiprotocol Label Switching (MPLS) packets in a label-switched path (LSP):

1. Specify the CoS value

If you do not specify a CoS value, the IP precedence bits from the packet's IP header are used as the packet's CoS value.

## Rewriting IEEE 802.1p Packet Headers with the MPLS CoS Value

For Ethernet interfaces installed on a T Series router or an M320 router with a peer connection to an M Series router or a T Series router, you can rewrite both MPLS CoS and IEEE 802.1p values to a configured value (the MPLS CoS values are also known as the EXP or experimental bits). Rewriting these values allows you to pass the configured value to the Layer 2 VLAN path. To rewrite both the MPLS CoS and IEEE 802.1p values, you must include the EXP and IEEE 802.1p rewrite rules in the class of service interface configuration. The EXP rewrite table is applied when you configure the IEEE 802.1p and EXP rewrite rules.

For information about how to configure the EXP and IEEE 802.1p rewrite rules, see *Rewriting Packet Headers to Ensure Forwarding Behavior*.

## Achieving a Make-Before-Break, Hitless Switchover for LSPs

Adaptive label-switched paths (LSPs) might need to establish a new LSP instance and transfer traffic from an old LSP instance onto the new LSP instance before tearing down the old one. This type of configuration is referred to as a *make before break* (MBB).

RSVP-TE is a protocol used to establish LSPs in MPLS networks. The Junos OS implementation of RSVP-TE to achieve a hitless (no traffic loss) MBB switchover has relied on configuring the timer values in the following configuration statements:

- **optimize-switchover-delay**—Amount of time to wait before switching to the new LSP instance.
- **optimize-hold-dead-delay**—Amount of time to wait after switchover and before deletion of the old LSP instance.

Both the **optimize-switchover-delay** and **optimize-hold-dead-delay** statements apply to all LSPs that use the make-before-break behavior for LSP setup and teardown, not just for LSPs for which the **optimize-timer** statement has also been configured. The following MPLS features cause LSPs to be set up and torn down using make-before-break behavior:

- Adaptive LSPs
- Automatic bandwidth allocation
- BFD for LSPs
- Graceful Routing Engine switchover
- Link and node protection
- Nonstop active routing
- Optimized LSPs
- Point-to-multipoint (P2MP) LSPs
- Soft preemption
- Standby secondary paths

Both the **optimize-switchover-delay** and **optimize-hold-dead-delay** statements when configured add an artificial delay to the MBB process. The value of the **optimize-switchover-delay** statement varies with the size of the Explicit Route Objects (EROs). An ERO is an extension to RSVP that allows an RSVP PATH message to traverse an explicit sequence of routers that is independent of conventional shortest-path IP routing. The value of the **optimize-switchover-delay** statement also depends on the CPU load on each of the routers on the path. Customers set the **optimize-switchover-delay** statement by trial and error.

The value of the **optimize-hold-dead-delay** statement depends on how fast the ingress router moves all application prefixes to point to the new LSP. This is determined by the Packet Forwarding Engine load, which can vary from platform to platform. Customers have to set the **optimize-hold-dead-delay** statement by trial and error.

However, as of Release 15.1, Junos OS is able to achieve a hitless MBB switchover without configuring the artificial delays that such timer values introduce.

This topic summarizes the three methods of achieving a MBB switchover from an old LSP to a new LSP using Junos OS:

- [Specifying the Amount of Time the Router Waits to Switch Over to New Paths on page 277](#)
- [Specifying the Amount of Time to Delay the Tear Down of Old Paths on page 277](#)
- [Achieving a Hitless, MBB Switchover Without Artificial Delays on page 277](#)

## Specifying the Amount of Time the Router Waits to Switch Over to New Paths

To specify the amount of time the router waits to switch over LSP instances to newly optimized paths, use the **optimize-switchover-delay** statement. You only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). The timer in this statement helps to ensure that the new optimized paths have been established before traffic is switched over from the old paths. This timer can only be enabled or disabled for all of the LSPs configured on the router.

To configure the amount of time the router waits to switch over LSP instances to newly optimized paths, specify the time in seconds by using the **optimize-switchover-delay** statement:

```
optimize-switchover-delay seconds;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

## Specifying the Amount of Time to Delay the Tear Down of Old Paths

To specify the amount of time to delay the tear down of old paths after the router has switched traffic to new optimized paths, use the **optimize-hold-dead-delay** statement. You only need to configure this statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). The timer in this statement helps to ensure that old paths are not torn down before all routes have been switched over to the new optimized paths. This timer can be enabled for specific LSPs or for all of the LSPs configured on the router.

To configure the amount of time in seconds to delay the tear down of old paths after the router has switched traffic to new optimized paths, use the **optimize-hold-dead-delay** statement:

```
optimize-hold-dead-delay seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Achieving a Hitless, MBB Switchover Without Artificial Delays

As of Junos OS Release 15.1, there is another way to relinquish the old LSP instances after MBB switchover without relying on the arbitrary time intervals set up by the

**optimize-switchover-delay** or **optimize-hold-dead-delay** statement. For example, if you use the **optimize-hold-dead-delay** statement, you configure a time you think it is safe to wait before tearing down the old LSP instance after MBB. However, some routes might still be in the process of shifting to the new instance. Tearing down the old LSP instance prematurely results in one of the transit nodes dropping the traffic for those routes that have not shifted to the new LSP instance.

To avoid traffic loss, instead of using the **optimize-switchover-delay** statement, you can use MPLS-OAM (lsp ping), which confirms that the LSP data plane is established end-to-end. Instead of using the **optimize-hold-dead-delay** statement, you can use a feedback mechanism from the rpd infrastructure that confirms that all prefixes referring to the old LSP have been switched over. The feedback mechanism is sourced from the Tag library and relies on the routing protocol process (rpd) infrastructure to determine when all the routes using the old LSP instance have fully shifted to the new LSP instance after MBB switchover.

The feedback mechanism is always in place, and it is optional. Configure the **optimize-adaptive-teardown** statement to have the feedback mechanism used during MBB switchover. This feature is not supported for RSVP point-to-multipoint (P2MP) LSP instances. Global configuration of the **optimize-adaptive-teardown** statement only affects the point-to-point LSPs that are configured in the system.

You only need to configure the **optimize-adaptive-teardown** statement on routers acting as the ingress for the affected LSPs (you do not need to configure this statement on transit or egress routers). This feedback mechanism ensures that old paths are not torn down before all routes have been switched over to the new optimized paths. The global configuration of this configuration statement affects only the point-to-point LSPs that are configured in the system.

```
optimize-adaptive-teardown {  
  p2p:  
}
```

You can include this statement at the **[edit protocols mpls]** hierarchy level.

---

## Configuring Adaptive LSPs

An LSP occasionally might need to reroute itself for these reasons:

- The continuous reoptimization process is configured with the **optimize-timer** statement.
- The current path has connectivity problems.

- The LSP is preempted by another LSP configured with the **priority** statement and is forced to reroute.
- The explicit-path information for an active LSP is modified, or the LSP's bandwidth is increased.

You can configure an LSP to be *adaptive* when it is attempting to reroute itself. When it is adaptive, the LSP holds onto existing resources until the new path is successfully established and traffic has been cut over to the new LSP. To retain its resources, an adaptive LSP does the following:

- Maintains existing paths and allocated bandwidths—This ensures that the existing path is not torn down prematurely and allows the current traffic to continue flowing while the new path is being set up.
- Avoids double-counting for links that share the new and old paths—Double-counting occurs when an intermediate router does not recognize that the new and old paths belong to the same LSP and counts them as two separate LSPs, requiring separate bandwidth allocations. If some links are close to saturation, double-counting might cause the setup of the new path to fail.

By default, adaptive behavior is disabled. You can include the **adaptive** statement in two different hierarchy levels.

If you specify the **adaptive** statement at the LSP hierarchy levels, the adaptive behavior is enabled on all primary/secondary paths of the LSP. This means both the primary and secondary paths share the same bandwidth on common links.

To configure adaptive behavior for all LSP paths, include the **adaptive** statement in the LSP configuration:

```
adaptive;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

If you specify the **adaptive** statement at the [edit protocols mpls **label-switched-path** *lsp-name* (**primary** | **secondary**) *path-name*] hierarchy level, adaptive behavior is enabled only on the path on which it is specified. Bandwidth double-counting occurs between different paths. However, if you also have the **adaptive** statement configured at the [edit protocols mpls **label-switched-path** *lsp-name*] hierarchy level, it overrides the adaptive behavior of each individual path.

To configure adaptive behavior for either the primary or secondary level, include the **adaptive** statement:

```
adaptive;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* (**primary** | **secondary**) *path-name*]

- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* (*primary* | *secondary*) *path-name*]

## Configuring Priority and Preemption for LSPs

---

When there is insufficient bandwidth to establish a more important LSP, you might want to tear down a less important existing LSP to free the bandwidth. You do this by preempting the existing LSP.

Whether an LSP can be preempted is determined by two properties associated with the LSP:

- Setup priority—Determines whether a new LSP that preempts an existing LSP can be established. For preemption to occur, the setup priority of the new LSP must be higher than that of the existing LSP. Also, the act of preempting the existing LSP must produce sufficient bandwidth to support the new LSP. That is, preemption occurs only if the new LSP can be set up successfully.
- Reservation priority—Determines the degree to which an LSP holds on to its session reservation after the LSP has been set up successfully. When the reservation priority is high, the existing LSP is less likely to give up its reservation, and hence it is unlikely that the LSP can be preempted.

You cannot configure an LSP with a high setup priority and a low reservation priority, because permanent preemption loops might result if two LSPs are allowed to preempt each other. You must configure the reservation priority to be higher than or equal to the setup priority.

The setup priority also defines the relative importance of LSPs on the same ingress router. When the software starts, when a new LSP is established, or during fault recovery, the setup priority determines the order in which LSPs are serviced. Higher-priority LSPs tend to be established first and hence enjoy more optimal path selection.

To configure the LSP's preemption properties, include the **priority** statement:

**priority** *setup-priority reservation-priority*;

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Both **setup-priority** and **reservation-priority** can be a value from 0 through 7. The value 0 corresponds to the highest priority, and the value 7 to the lowest. By default, an LSP has a setup priority of 7 (that is, it cannot preempt any other LSPs) and a reservation priority of 0 (that is, other LSPs cannot preempt it). These defaults are such that preemption does not happen. When you are configuring these values, the setup priority should always be less than or equal to the hold priority.

## Optimizing Signaled LSPs

---

Once an LSP has been established, topology or resources changes might, over time, make the path suboptimal. A new path might have become available that is less

congested, has a lower metric, and traverses fewer hops. You can configure the router to recompute paths periodically to determine whether a more optimal path has become available.

If reoptimization is enabled, an LSP can be rerouted through different paths by constrained-path recomputations. However, if reoptimization is disabled, the LSP has a fixed path and cannot take advantage of newly available network resources. The LSP is fixed until the next topology change breaks the LSP and forces a recomputation.

Reoptimization is not related to failover. A new path is always computed when topology failures occur that disrupt an established path.

Because of the potential system overhead involved, you need to carefully control the frequency of reoptimization. Network stability might suffer when reoptimization is enabled. By default, the **optimize-timer** statement is set to 0 (that is, it is disabled).

LSP optimization is meaningful only when constrained-path LSP computation is enabled, which is the default behavior. For more information about constrained-path LSP computation, see [“Disabling Constrained-Path LSP Computation” on page 267](#). Also, LSP optimization is only applicable to ingress LSPs, so it is only necessary to configure the **optimize-timer** statement on the ingress router. The transit and egress routers require no specific configuration to support LSP optimization (other than to have MPLS enabled).

To enable path reoptimization, include the **optimize-timer** statement:

**optimize-timer** *seconds*;

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Once you have configured the **optimize-timer** statement, the reoptimization timer continues its countdown to the configured value even if you delete the **optimize-timer** statement from the configuration. The next optimization uses the new value. You can force the Junos OS to use a new value immediately by deleting the old value, committing the configuration, configuring the new value for the **optimize-timer** statement, and then committing the configuration again.

After reoptimization is run, the result is accepted only if it meets the following criteria:

1. The new path is not higher in IGP metric. (The metric for the old path is updated during computation, so if a recent link metric changed somewhere along the old path, it is accounted for.)
2. If the new path has the same IGP metric, it is not more hops away.
3. The new path does not cause preemption. (This is to reduce the ripple effect of preemption causing more preemption.)
4. The new path does not worsen congestion overall.

The relative congestion of the new path is determined as follows:

- a. The percentage of available bandwidth on each link traversed by the new path is compared to that for the old path, starting from the most congested links.
- b. For each current (old) path, the software stores the four smallest values for bandwidth availability for the links traversed in ascending order.
- c. The software also stores the four smallest bandwidth availability values for the new path, corresponding to the links traversed in ascending order.
- d. If any of the four new available bandwidth values are smaller than any of the corresponding old bandwidth availability values, the new path has at least one link that is more congested than the link used by the old path. Because using the link would cause more congestion, traffic is not switched to this new path.
- e. If none of the four new available bandwidth values is smaller than the corresponding old bandwidth availability values, the new path is less congested than the old path.

When all the above conditions are met, then:

5. If the new path has a lower IGP metric, it is accepted.
6. If the new path has an equal IGP metric and lower hop count, it is accepted.
7. If you choose **least-fill** as a load balancing algorithm, LSPs are load balanced as follows:
  - a. The LSP is moved to a new path that is utilized at least 10% less than the current path. This might reduce congestion on the current path by only a small amount. For example, if an LSP with 1 MB of bandwidth is moved off a path carrying a minimum of 200 MB, congestion on the original path is reduced by less than 1%.
  - b. For **random** or **most-fill** algorithms, this rule does not apply.

The following example illustrates how the **least-fill** load balancing algorithm works.

**Figure 33: least-fill Load Balancing Algorithm Example**

As shown in [Figure 33 on page 282](#), there are two potential paths for an LSP to traverse from router A to router H, the odd links from L1 through L13 and the even links from L2 through L14. Currently, the router is using the even links as the active path for the LSP. Each link between the same two routers (for example, router A and router B) has the same bandwidth:

- L1, L2 = 10GE
- L3, L4 = 1GE
- L5, L6 = 1GE
- L7, L8 = 1GE
- L9, L10 = 1GE

- L11, L12 = 10GE
- L13, L14 = 10GE

The 1GE links are more likely to be congested. In this example, the odd 1GE links have the following available bandwidth:

- L3 = 41%
- L5 = 56%
- L7 = 66%
- L9 = 71%

The even 1GE links have the following available bandwidth:

- L4 = 37%
- L6 = 52%
- L8 = 61%
- L10 = 70%

Based on this information, the router would calculate the difference in available bandwidth between the odd links and the even links as follows:

- $L4 - L3 = 41\% - 37\% = 4\%$
- $L6 - L5 = 56\% - 52\% = 4\%$
- $L8 - L7 = 66\% - 61\% = 5\%$
- $L10 - L9 = 71\% - 70\% = 1\%$

The total additional bandwidth available over the odd links is 14% ( $4\% + 4\% + 5\% + 1\%$ ). Since 14% is greater than 10% (the least-fill algorithm minimum threshold), the LSP is moved to the new path over the odd links from the original path using the even links.

8. Otherwise, the new path is rejected.

You can disable the following reoptimization criteria (a subset of the criteria listed previously):

- If the new path has the same IGP metric, it is not more hops away.
- The new path does not cause preemption. (This is to reduce the ripple effect of preemption causing more preemption.)
- The new path does not worsen congestion overall.
- If the new path has an equal IGP metric and lower hop count, it is accepted.

To disable them, either issue the **clear mpls lsp optimize-aggressive** command or include the **optimize-aggressive** statement:

```
optimize-aggressive;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

Including the **optimize-aggressive** statement in the configuration causes the reoptimization procedure to be triggered more often. Paths are rerouted more frequently. It also limits the reoptimization algorithm to the IGP metric only.

## Configuring the Smart Optimize Timer for LSPs

---

Because of network and router resource constraints, it is typically inadvisable to configure a short interval for the optimize timer. However, under certain circumstances, it might be desirable to reoptimize a path sooner than would normally be provided by the optimize timer.

For example, an LSP is traversing a preferred path that subsequently fails. The LSP is then switched to a less desirable path to reach the same destination. Even if the original path is quickly restored, it could take an excessively long time for the LSP to use it again, because it has to wait for the optimize timer to reoptimize the network paths. For such situations, you might want to configure the smart optimize timer.

When you enable the smart optimize timer, an LSP is switched back to its original path so long as the original path has been restored within 3 minutes of going down. Also, if the original path goes down again within 60 minutes, the smart optimize timer is disabled, and path optimization behaves as it normally does when the optimize timer alone is enabled. This prevents the router from using a flapping link.

The smart optimize timer is dependant on other MPLS features to function properly. For the scenario described here in which an LSP is switched to an alternate path in the event of a failure on the original path, it is assumed that you have configured one or more of the MPLS traffic protection features, including fast reroute, link protection, and standby secondary paths. These features help to ensure that traffic can reach its destination in the event of a failure.

At the least, you must configure a standby secondary path for the smart optimize timer feature to work properly. Fast reroute and link protection are more temporary solutions to a network outage. A secondary path ensures that there is a stable alternate path in the event the primary path fails. If you have not configured any sort of traffic protection for an LSP, the smart optimize timer by itself does not ensure that traffic can reach its

destination. For more information about MPLS traffic protection, see [“MPLS and Traffic Protection” on page 45](#).

When a primary path fails and the smart optimize timer switches traffic to the secondary path, the router might continue to use the secondary path even after the primary path has been restored. If the ingress router completes a CSPF calculation, it might determine that the secondary path is the better path.

This might be undesirable if the primary path should be the active path and the secondary path should be used as a backup only. Also, if the secondary path is being used as the active path (even though the primary path has been reestablished) and the secondary path fails, the smart optimize timer feature will not automatically switch traffic back to the primary path. However, you can enable protection for the secondary path by configuring node and link protection or an additional standby secondary path, in which case, the smart optimize timer can be effective.

Specify the time in seconds for the smart optimize timer using the **smart-optimize-timer** statement:

```
smart-optimize-timer seconds;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

## Limiting the Number of Hops in LSPs

By default, each LSP can traverse a maximum of 255 hops, including the ingress and egress routers. To modify this value, include the **hop-limit** statement:

```
hop-limit number;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The number of hops can be from 2 through 255. (A path with two hops consists of the ingress and egress routers only.)

## Configuring the Bandwidth Value for LSPs

Each LSP has a bandwidth value. This value is included in the sender's Tspec field in RSVP path setup messages. You can specify a bandwidth value in bits per second. If you configure more bandwidth for an LSP, it should be able to carry a greater volume of traffic. The default bandwidth is 0 bits per second.

A nonzero bandwidth requires that transit and egress routers reserve capacity along the outbound links for the path. The RSVP reservation scheme is used to reserve this capacity.

Any failure in bandwidth reservation (such as failures at RSVP policy control or admission control) might cause the LSP setup to fail. If there is insufficient bandwidth on the interfaces for the transit or egress routers, the LSP is not established.

To specify a bandwidth value for a signaled LSP, include the **bandwidth** statement:

```
bandwidth bps;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

---

## Automatic Bandwidth Allocation for LSPs

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure an LSP with minimal bandwidth; this feature can dynamically adjust the LSP's bandwidth allocation based on current traffic patterns. The bandwidth adjustments do not interrupt traffic flow through the tunnel.

You set a sampling interval on an LSP configured with automatic bandwidth allocation. The average bandwidth is monitored during this interval. At the end of the interval, an attempt is made to signal a new path for the LSP with the bandwidth allocation set to the maximum average value for the preceding sampling interval. If the new path is successfully established and the original path is removed, the LSP is switched over to the new path. If a new path is not created, the LSP continues to use its current path until the end of the next sampling interval, when another attempt is made to establish a new path. Note that you can set minimum and maximum bandwidth values for the LSP.

During the automatic bandwidth allocation interval, the router might receive a steady increase in traffic (increasing bandwidth utilization) on an LSP, potentially causing congestion or packet loss. To prevent this, you can define a second trigger to prematurely expire the automatic bandwidth adjustment timer before the end of the current adjustment interval.

---

## Configuring Automatic Bandwidth Allocation for LSPs

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure an LSP with minimal bandwidth, and this feature can dynamically adjust the LSP's bandwidth allocation based on current traffic patterns. The bandwidth adjustments do not interrupt traffic flow through the tunnel.

At the end of the automatic bandwidth allocation time interval, the current maximum average bandwidth usage is compared with the allocated bandwidth for the LSP. If the LSP needs more bandwidth, an attempt is made to set up a new path where bandwidth is equal to the current maximum average usage. If the attempt is successful, the LSP's traffic is routed through the new path and the old path is removed. If the attempt fails, the LSP continues to use its current path.

If you have configured link and node protection for the LSP and traffic has been switched to the bypass LSP, the automatic bandwidth allocation feature continues to operate and

take bandwidth samples from the bypass LSP. For the first bandwidth adjustment cycle, the maximum average bandwidth usage taken from the original link and node-protected LSP is used to resignal the bypass LSP if more bandwidth is needed. (Link and node protection are not supported on QFX Series switches.)

If you have configured fast-reroute for the LSP, you might not be able to use this feature to adjust the bandwidth. Because the LSPs use a fixed filter (FF) reservation style, when a new path is signaled, the bandwidth might be double-counted. Double-counting can prevent a fast-reroute LSP from ever adjusting its bandwidth when automatic bandwidth allocation is enabled. (Fast reroute is not supported on QFX Series switches.)

To configure automatic bandwidth allocation, complete the steps in the following sections:

- [Configuring Automatic Bandwidth Allocation on LSPs on page 287](#)
- [Requesting Automatic Bandwidth Allocation Adjustment on page 292](#)

**NOTE:** On the QFX10000 switches, you can only configure automatic bandwidth allocation at the `edit protocols mpls` hierarchy level. Logical systems are not supported.

## Configuring Automatic Bandwidth Allocation on LSPs

To enable automatic bandwidth allocation on an LSP, include the **auto-bandwidth** statement:

```
auto-bandwidth (MPLS Tunnel) {
  adjust-interval seconds;
  adjust-threshold percent;
  adjust-threshold-overflow-limit number;
  adjust-threshold-underflow-limit number;
  maximum-bandwidth bps;
  minimum-bandwidth bps;
  minimum-bandwidth-adjust-interval
  minimum-bandwidth-adjust-threshold-change
  minimum-bandwidth-adjust-threshold-value
  monitor-bandwidth;
}
```

You can include this statement at the following hierarchy levels:

- `[edit protocols mpls label-switched-path lsp-name]`
- `[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name]`

If an LSP has an automatic bandwidth configuration, you can disable automatic bandwidth adjustments on a particular path (either primary or secondary) by configuring a static bandwidth value and by disabling the CSPF computation (using the **no-cspf** statement).

For example:

```
user@host> show protocols mpls
```

```

label-switched-path primary-path {
  to 192.168.0.1;
  ldp-tunneling;
  optimize-timer 3571;
  least-fill;
  link-protection;
  adaptive;
  auto-bandwidth {
    adjust-interval 7177;
    adjust-threshold 5;
    minimum-bandwidth 1m;
    maximum-bandwidth 2500000000;
    adjust-threshold-overflow-limit 2;
    resignal-minimum-bandwidth;
  }
  primary primary-path;
  secondary secondary-path {
    bandwidth 0;
    no-cspf;
    priority 0 0;
  }
}

```

The statements configured at the **[edit protocols mpls label-switched-path *label-switched-path-name* auto-bandwidth]** hierarchy level are optional and explained in the following sections:

- [Configuring the Automatic Bandwidth Allocation Interval on page 288](#)
- [Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth on page 289](#)
- [Configuring the Automatic Bandwidth Adjustment Threshold on page 289](#)
- [Configuring a Limit on Bandwidth Overflow and Underflow Samples on page 290](#)
- [Configuring Passive Bandwidth Utilization Monitoring on page 292](#)

### Configuring the Automatic Bandwidth Allocation Interval

At the end of the automatic bandwidth allocation interval, the automatic bandwidth computation and new path setup process is triggered.

**NOTE:** To prevent unnecessary resignaling of LSPs, it is best to configure an LSP adjustment interval that is at least three times longer than the MPLS automatic bandwidth statistics interval. For example, if you configure a value of 30 seconds for the MPLS automatic bandwidth statistics interval (**interval** statement at the **[edit protocols mpls statistics]** hierarchy level), you should configure a value of at least 90 seconds for the LSP adjustment interval (**adjust-interval** statement at the **[edit protocols mpls label-switched-path *label-switched-path-name* auto-bandwidth]** hierarchy level). See also [“Configuring Reporting of Automatic Bandwidth Allocation Statistics for LSPs” on page 293](#).

To specify the bandwidth reallocation interval in seconds for a specific LSP, include the **adjust-interval** statement:

```
adjust-interval seconds;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name* **auto-bandwidth** (MPLS Tunnel)]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* **auto-bandwidth** (MPLS Tunnel)]

### Configuring the Maximum and Minimum Bounds of the LSP's Bandwidth

You can maintain the LSP's bandwidth between minimum and maximum bounds by specifying values for the **minimum-bandwidth** and **maximum-bandwidth** statements.

To specify the minimum amount of bandwidth allocated for a specific LSP, include the **minimum-bandwidth** statement:

```
minimum-bandwidth bps;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth** (MPLS Tunnel)]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth** (MPLS Tunnel)]

To specify the maximum amount of bandwidth allocated for a specific LSP, include the **maximum-bandwidth** statement:

```
maximum-bandwidth bps;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth** (MPLS Tunnel)]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth** (MPLS Tunnel)]

### Configuring the Automatic Bandwidth Adjustment Threshold

Use the **adjust-threshold** statement to specify the sensitivity of the automatic bandwidth adjustment of an LSP to changes in bandwidth utilization. You can set the threshold for when to trigger automatic bandwidth adjustments. When configured, bandwidth demand for the current interval is determined and compared to the LSP's current bandwidth allocation. If the percentage difference in bandwidth is greater than or equal to the specified **adjust-threshold** percentage, the LSP's bandwidth is adjusted to the current bandwidth demand.

For example, assume that the current bandwidth allocation is 100 megabits per second (Mbps) and that the percentage configured for the **adjust-threshold** statement is 15 percent. If the bandwidth demand increases to 110 Mbps, the bandwidth allocation is not adjusted. However, if the bandwidth demand increases to 120 Mbps (20 percent over

the current allocation) or decreases to 80 Mbps (20 percent under the current allocation), the bandwidth allocation is increased to 120 Mbps or decreased to 80 Mbps, respectively.

To configure the threshold for automatic bandwidth adjustment, include the **adjust-threshold** statement:

```
adjust-threshold percent;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name* auto-bandwidth (MPLS Tunnel)]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* auto-bandwidth (MPLS Tunnel)]

---

### Configuring a Limit on Bandwidth Overflow and Underflow Samples

The automatic bandwidth adjustment timer is a periodic timer which is triggered every adjust interval to determine whether any bandwidth adjustments are required on the LSP's active path. This interval is typically configured as a long period of time, usually hours. If, at the end of adjust interval, the change in bandwidth is above a certain adjust threshold, the LSP is resigaled with the new bandwidth.

During the automatic bandwidth adjustment interval, the router might receive a steady increase in traffic (increasing bandwidth utilization) on an LSP, potentially causing congestion or packet loss. To prevent this, you can define a second trigger to prematurely expire the automatic bandwidth adjustment timer before the end of the current adjustment interval.

Every statistics interval, the router samples the average bandwidth utilization of an LSP and if this has exceeded the current maximum average bandwidth utilization, the maximum average bandwidth utilization is updated.

During each sample period, the following conditions are also checked:

- Is the current average bandwidth utilization above the active bandwidth of the path?
- Has the difference between the average bandwidth utilization and the active bandwidth exceeded the adjust threshold (bandwidth utilization has changed significantly)?

If these conditions are true, it is considered to be one bandwidth overflow sample. Using the **adjust-threshold-overflow-limit** statement, you can define a limit on the number of bandwidth overflow samples such that when the limit is reached, the current automatic bandwidth adjustment timer is expired and a bandwidth adjustment is triggered. Once this adjustment is complete, the normal automatic bandwidth adjustment timer is reset to expire after the periodic adjustment interval.

To specify a limit on the number of bandwidth overflow samples before triggering an automatic bandwidth allocation adjustment, configure the **adjust-threshold-overflow-limit** statement:

```
adjust-threshold-overflow-limit number;
```

Similarly, if the current average bandwidth utilization is below the active bandwidth of the path by the configured adjusted threshold (meaning that bandwidth utilization has gone down significantly), the sample is considered to be an underflow sample. The adjusted (new signaling) bandwidth after an adjustment due to underflow is the maximum average bandwidth among the underflow samples. You can specify a limit on the number of bandwidth underflow samples before triggering an automatic bandwidth allocation adjustment by configuring the **adjust-threshold-underflow-limit** statement:

**adjust-threshold-underflow-limit** *number*;

These statements can be configured at the following hierarchy levels:

- [edit protocols mpls label-switched-path *lsp-name* auto-bandwidth (MPLS Tunnel)]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* auto-bandwidth (MPLS Tunnel)]

You must configure the **adjust-threshold** and **minimum-bandwidth** statements whenever you configure the **adjust-threshold-underflow-limit** statement. You must configure the **adjust-threshold** and **maximum-bandwidth** statements whenever you configure the **adjust-threshold-overflow-limit** statement.

- You must configure a nonzero value for the **adjust-threshold** statement if you configure the **adjust-threshold-overflow-limit** or **adjust-threshold-underflow-limit** statement.
- Any bandwidth increase or decrease below the value configured for the **adjust-threshold** statement does not constitute an overflow or underflow condition.
- To prevent unlimited increases in LSP bandwidth (to limit overflow beyond a certain bandwidth), you must also configure the **maximum-bandwidth** statement when you configure the **adjust-threshold-overflow-limit** statement.

The following describes the other aspects of the **adjust-threshold-overflow-limit** statement:

- It only applies to bandwidth overflows. If the bandwidth is decreasing, the normal automatic bandwidth adjustment interval is used.
- It does not affect manually triggered automatic bandwidth adjustment.
- It applies to single-class DiffServ-TE LSPs.
- Because the **adjust-threshold-overflow-limit** statement can trigger a bandwidth adjustment, it cannot be enabled at the same time as the **monitor-bandwidth** statement (for information about that statement, see [“Configuring Passive Bandwidth Utilization Monitoring” on page 292](#)).
- You cannot configure automatic bandwidth adjustments to occur more often than every 300 seconds. The **adjust-threshold-overflow-limit** statement is subject to the same minimum value with regard to the minimum frequency of adjustment allowed. Overflow condition based adjustments can occur no sooner than 300 seconds from the start of the overflow condition. Therefore it is required that:

**sample interval x adjust-threshold-overflow-limit >= 300s**

These values are checked during the commit operation. An error is returned if the value is less than 300 seconds.

- If you change the value of the **adjust-threshold-overflow-limit** statement on a working router, you can expect the following behavior:
  - If you increase the current value of the **adjust-threshold-overflow-limit** statement, the old value is replaced with the new one.
  - If you decrease the current value of the **adjust-threshold-overflow-limit** statement and the current bandwidth overflow count is less than the new value, the old value is replaced with the new one.
  - If you decrease the current value of the **adjust-threshold-overflow-limit** statement and the current bandwidth overflow count is greater than the new value, the adjustment timer is immediately expired and a bandwidth adjustment is initiated.

### Configuring Passive Bandwidth Utilization Monitoring

---

Use the **monitor-bandwidth** statement to switch to a passive bandwidth utilization monitoring mode. In this mode, no automatic bandwidth adjustments are made, but the maximum average bandwidth utilization is continuously monitored and recorded.

To configure passive bandwidth utilization monitoring, include the **monitor-bandwidth** statement:

```
monitor-bandwidth;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth** (MPLS Tunnel)]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **auto-bandwidth** (MPLS Tunnel)]

If you have configured an LSP with primary and secondary paths, the automatic bandwidth allocation statistics are carried over to the secondary path if the primary path fails. For example, consider a primary path whose adjustment interval is half complete and whose maximum average bandwidth usage is currently calculated as 50 Mbps. If the primary path suddenly fails, the time remaining for the next adjustment and the maximum average bandwidth usage are carried over to the secondary path.

### Requesting Automatic Bandwidth Allocation Adjustment

For MPLS LSP automatic bandwidth allocation adjustment, the minimum value for the adjustment interval is 5 minutes (300 seconds). You might find it necessary to trigger a bandwidth allocation adjustment manually, for example in the following circumstances:

- When you are testing automatic bandwidth allocation in a network lab.
- When the LSP is configured for automatic bandwidth allocation in monitor mode (the **monitor-bandwidth** statement is included in the configuration as described in [“Configuring Passive Bandwidth Utilization Monitoring” on page 292](#)), and want to initiate an immediate bandwidth adjustment.

To use the **request mpls lsp adjust-autobandwidth** command, the following must be true:

- Automatic bandwidth allocation must be enabled on the LSP.
- The criteria required to trigger a bandwidth adjustment have been met (the difference between the adjust bandwidth and the current LSP path bandwidth is greater than the threshold limit).

A manually triggered bandwidth adjustment operates only on the active LSP path. Also, if you have enabled periodic automatic bandwidth adjustment, the periodic automatic bandwidth adjustment parameters (the adjustment interval and the maximum average bandwidth) are not reset after a manual adjustment.

For example, suppose the periodic adjust interval is 10 hours and there are currently 5 hours remaining before an automatic bandwidth adjustment is triggered. If you initiate a manual adjustment with the **request mpls lsp adjust-autobandwidth** command, the adjust timer is not reset and still has 5 hours remaining.

To manually trigger a bandwidth allocation adjustment, you need to use the **request mpls lsp adjust-autobandwidth** command. You can trigger the command for all affected LSPs on the router, or you can specify a particular LSP:

```
user@host> request mpls lsp adjust-autobandwidth
```

Once you execute this command, the automatic bandwidth adjustment validation process is triggered. If all the criteria for adjustment are met, the LSP's active path bandwidth is adjusted to the adjusted bandwidth value determined during the validation process.

## Configuring Reporting of Automatic Bandwidth Allocation Statistics for LSPs

Automatic bandwidth allocation allows an MPLS tunnel to automatically adjust its bandwidth allocation based on the volume of traffic flowing through the tunnel. You can configure the device to collect statistics related to automatic bandwidth allocation by completing the following steps:

1. To collect statistics related to automatic bandwidth allocation, configure the **auto-bandwidth** option for the **statistics** statement at the **[edit protocols mpls]** hierarchy level. These settings apply to all LSPs configured on the router on which you have also configured the **auto-bandwidth** statement at the **[edit protocols mpls label-switched-path label-switched-path-name]** hierarchy level.

```
statistics {
  auto-bandwidth (MPLS Statistics);
  file filename <files number> <size size> <world-readable | no-world-readable>;
  interval seconds;
  no-transit-statistics;
```

```
transit-statistics-polling;
}
```

- Specify the **filename** for the files used to store the MPLS trace operation output using the **file** option. All files are placed in the directory **/var/log**. We recommend that you place MPLS tracing output in the file **mpls-log**.
- Specify the maximum number of trace files using the **files number** option. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.
- Specify the interval for calculating the average bandwidth usage by configuring a time in seconds using the **interval** option. You can also set the adjustment interval on a specific LSP by configuring the **interval** option at the **[edit protocols mpls label-switch-path label-switched-path-name statistics]** hierarchy level.

**NOTE:** To prevent unnecessary resignaling of LSPs, it is best to configure an LSP adjustment interval that is at least three times longer than the MPLS automatic bandwidth statistics interval. For example, if you configure a value of 30 seconds for the MPLS automatic bandwidth statistics interval (interval statement at the **[edit protocols mpls statistics]** hierarchy level), you should configure a value of at least 90 seconds for the LSP adjustment interval (adjust-interval statement at the **[edit protocols mpls label-switched-path label-switched-path-name auto-bandwidth]** hierarchy level).

- To trace automatic bandwidth allocation, include the **autobw-state flag** for the MPLS **traceoptions** statement at the **[edit protocols mpls]** hierarchy level.

The following configuration enables the MPLS traceoptions for automatic bandwidth allocation. The trace records are stored in a file called **auto-band-trace** (the filename is user configurable):

```
[edit protocols mpls]
traceoptions {
  file auto-band-trace size 10k files 10 world-readable;
  flag autobw-state;
}
```

- Using the **show log** command, you can display the automatic bandwidth allocation statistics file generated when you configure the **auto-bandwidth (MPLS Statistics)** statement. The following shows sample log file output taken from an MPLS statistics file named **auto-band-stats** on a router configured with an LSP named **E-D**. The log file shows that LSP **E-D** is operating over its reserved bandwidth limit initially. Before **Oct 30 17:14:57**, the router triggered an automatic bandwidth adjustment (you might see two sessions for an LSP undergoing an automatic bandwidth adjustment). By **Oct 30 17:16:57**, the LSP has been reestablished at a higher bandwidth and is now shown using less than 100 percent of its **Reserved Bw** (reserved bandwidth).

```
user@host> show log auto-band-stats
```

```

7. Issue the `show mpls lsp autobandwidth` command to display current information about automatic bandwidth allocation. The following shows sample output from the `show mpls lsp autobandwidth` command taken at about the same time as the log file shown previously:

```

user@host> show mpls lsp autobandwidth
Lspname          Last      Requested   Reserved   Highwater   AdjustTime LastAdjust
BW              BW              BW          mark        Left (sec)
E-D              300bps        812.005bps  812bps      1.56801kbps 294 sec     Wed Oct 30 17:15:26 2013

```

8. Issue the `file show` command to display the MPLS trace file. You need to specify the file location and file name (the file is located in `/var/log/`). The following shows sample trace file output is taken from an MPLS trace file named `auto-band-trace.0.gz` on a router configured with an LSP named **E-D**. The trace file shows that LSP **E-D** is operating over its reserved bandwidth limit initially. At **Oct 30 17:15:26**, the router triggers an automatic bandwidth adjustment (you might see two sessions for an LSP undergoing an automatic bandwidth adjustment). By **Oct 30 17:15:57**, the LSP has been reestablished at a higher bandwidth and is now shown using less than 100 percent of its **Reserved Bw** (reserved bandwidth).

```

user@host> file show /var/log/auto-band-trace.0.gz

## Configuring Hot Standby of Secondary Paths for LSPs

By default, secondary paths are set up only as needed. To have the system maintain a secondary path in a hot-standby state indefinitely, include the **standby** statement:

**standby;**

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls label-switched-path *lsp-name* secondary]**
- **[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name* secondary]**

The hot-standby state is meaningful only on secondary paths. Maintaining a path in a hot-standby state enables swift cutover to the secondary path when downstream routers on the current active path indicate connectivity problems. Although it is possible to configure the **standby** statement at the **[edit protocols mpls label-switched-path *lsp-name* primary *path-name*]** hierarchy level, it has no effect on router behavior.

If you configure the **standby** statement at the following hierarchy levels, the hot-standby state is activated on all secondary paths configured beneath that hierarchy level:

- **[edit protocols mpls]**
- **[edit protocols mpls label-switched-path *lsp-name*]**
- **[edit logical-systems *logical-system-name* protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]**

The hot-standby state has two advantages:

- It eliminates the call-setup delay during network topology changes. Call setup can suffer from significant delays when network failures trigger large numbers of LSP reroutes at the same time.
- A cutover to the secondary path can be made before RSVP learns that an LSP is down. There can be significant delays between the time the first failure is detected by protocol machinery (which can be an interface down, a neighbor becoming unreachable, a route becoming unreachable, or a transient routing loop being detected) and the time an LSP actually fails (which requires a timeout of soft state information between adjacent RSVP routers). When topology failures occur, hot-standby secondary paths can usually achieve the smallest cutover delays with minimal disruptions to user traffic.

When the primary path is considered to be stable again, traffic is automatically switched from the standby secondary path back to the primary path. The switch is performed no faster than twice the retry-timer interval and only if the primary path exhibits stability throughout the entire switch interval.

The drawback of the hot-standby state is that more state information must be maintained by all the routers along the path, which requires overhead from each of the routers.

## Damping Advertisement of LSP State Changes

---

When an LSP changes from being up to being down, or from down to up, this transition takes effect immediately in the router software and hardware. However, when advertising LSPs into IS-IS and OSPF, you may want to damp LSP transitions, thereby not advertising the transition until a certain period of time has transpired (known as the hold time). In this case, if the LSP goes from up to down, the LSP is not advertised as being down until it has remained down for the hold-time period. Transitions from down to up are advertised into IS-IS and OSPF immediately. Note that LSP damping affects only the IS-IS and OSPF advertisements of the LSP; other routing software and hardware react immediately to LSP transitions.

To damp LSP transitions, include the **advertisement-hold-time** statement:

**advertisement-hold-time** *seconds*;

*seconds* can be a value from 0 through 65,535 seconds. The default is 5 seconds.

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

## CHAPTER 5

# Configuring Static and Explicit-Path LSPs

- [Configuring Static LSPs on page 299](#)
- [Configuring Explicit-Path LSPs on page 306](#)

## Configuring Static LSPs

---

To configure static LSPs, configure the ingress router and each router along the path up to and including the egress router.

To configure static MPLS, perform the following tasks:

- [Configuring the Ingress Router for Static LSPs on page 299](#)
- [Configuring the Intermediate \(Transit\) and Egress Routers for Static LSPs on page 302](#)
- [Configuring a Bypass LSP for the Static LSP on page 304](#)
- [Configuring the Protection Revert Timer for Static LSPs on page 305](#)
- [Configuring Static Unicast Routes for Point-to-Multipoint LSPs on page 305](#)

## Configuring the Ingress Router for Static LSPs

The ingress router checks the IP address in the incoming packet's destination address field and, if it finds a match in the routing table, applies the label associated with that address to the packets. The label has forwarding information associated with it, including the address of the next-hop router, and the route preference and CoS values.

To configure static LSPs on the ingress router, include the **ingress** statement:

```
ingress {  
  bandwidth bps;  
  class-of-service cos-value;  
  description string;  
  install {  
    destination-prefix <active>;  
  }  
  link-protection bypass-name name;  
  metric metric;  
  next-hop (address | interface-name | address/interface-name);  
  no-install-to-address;  
  node-protection bypass-name name next-next-label label;  
  policing {  
    filter filter-name;
```

```
        no-auto-policing;
    }
    preference preference;
    push out-label;
    to address;
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols mpls static-label-switched-path *static-lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls static-label-switched-path *static-lsp-name*]

When you configure a static LSP on the ingress router, the **next-hop**, **push**, and **to** statements are required; the other statements are optional.

The configuration for a static LSP on the ingress router requires you to configure the following parts:

- Criteria for analyzing an incoming packet:
  - The **install** statement creates an LSP that handles IPv4 packets. All static MPLS routes created using the **install** statement are installed in inet.3 routing table, and the creating protocol is identified as static. This process is no different from creating static IPv4 routes at the [edit routing-options static] hierarchy level.
  - In the **to** statement, you configure the IP destination address to check when incoming packets are analyzed. If the address matches, the specified outgoing label (**push out-label**) is assigned to the packet, and the packet enters an LSP. Manually assigned outgoing labels can have values from 0 through 1,048,575. Each prefix that you specify is installed as a static route in the routing table.
- The **next-hop** statement, which supplies the IP address of the next hop to the destination. You can specify this as the IP address of the next hop, the interface name (for point-to-point interfaces only), or as **address/interface-name** to specify an IP address on an operational interface. When the next hop is on a directly attached interface, the route is installed in the routing table. You cannot configure a LAN or nonbroadcast multiaccess (NBMA) interface as a next-hop interface.
- Properties to apply to the LSP (all are optional):
  - Bandwidth reserved for this LSP (**bandwidth bps**)
  - Link protection and node protection to apply to the LSP (**bypass bypass-name**, **link-protection bypass-name name**, **node-protection bypass-name next-next-label label**)
  - Metric value to apply to the LSP (**metric**)
  - Class-of-service value to apply to the LSP (**class-of-service**)
  - Preference value to apply to the LSP (**preference**)
  - Traffic policing to apply to the LSP (**policing**)

- Text description to apply to the LSP ([description](#))
- Install or no-install policy ([install](#) or [no-install-to-address](#))

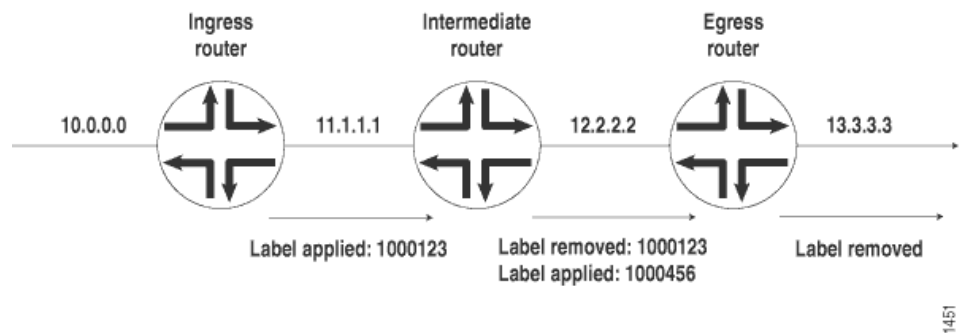

To determine whether a static ingress route is installed, use the command **show route table inet.3 protocol static**. Sample output follows. The **push** keyword denotes that a label is to be added in front of an IP packet.

```
10.0.0.0      *[Static/5] 00:01:48
> to 11.1.1.1 via so-0/0/0, push 1000123
```

### Example: Configuring the Ingress Router

Configure the ingress router for a static LSP that consists of three routers (see [Figure 34 on page 301](#)).

Figure 34: Static MPLS Configuration

For packets addressed to 10.0.0.0, assign label 1000123 and transmit them to the next-hop router at 11.1.1.1:

```
[edit]
interfaces {
  so-0/0/0 {
    unit 0 {
      family mpls;
    }
  }
}
protocols {
  mpls {
    static-label-switched-path path1 {
      ingress {
        next-hop 11.1.1.1;
        to 10.0.0.0;
        push 1000123;
      }
    }
  }
  interface so-0/0/0.0;
}
routing-options {
  static {
    route 10.0.0.0/8 {
```

```

        static-lsp-next-hop path];
    }
}

```

To determine whether the static ingress route is installed, use the following command:

```
user@host> show route table inet.0 protocol static
```

Sample output follows. The **push 1000123** keyword identifies the route.

```

10.0.0.0/8          *[Static/5] 00:01:48
> to 11.1.1.1 via so-0/0/0.0, push 1000123

```

## Configuring the Intermediate (Transit) and Egress Routers for Static LSPs

Intermediate (transit) and egress routers perform similar functions—they modify the label that has been applied to a packet. An intermediate router can change the label. An egress router removes the label (if the packet still contains a label) and continues forwarding the packet to its destination.

To configure static LSPs on intermediate and egress routers, include the **transit** statement:

```

static-label-switched-path lsp-name {
    transit incoming-label {
        bandwidth bps;
        description string;
        link-protection bypass-name name;
        next-hop (address | interface-name | address/interface-name);
        node-protection bypass-name name next-next-label label;
        pop;
        swap out-label;
    }
}

```

You can include these statements at the following hierarchy levels:

- [edit protocols mpls static-label-switched-path *static-lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls static-label-switched-path *static-lsp-name*]

For the **transit** statement configuration, the **next-hop** and **pop** | **swap** statements are required. The remaining statements are optional.

Each statement within the **transit** statement consists of the following parts:

- Packet label (specified in the **transit** statement)
- The **next-hop** statement, which supplies the IP address of the next hop to the destination. The address is specified as the IP address of the next hop, or the interface name (for point-to-point interfaces only), or **address** and **interface-name** to specify an IP address on an operational interface. When the specified next hop is on a directly attached interface, this route is installed in the routing table. You cannot configure a LAN or NBMA interface as a next-hop interface.

- Operation to perform on the labeled packet:
  - For egress routers, you generally just remove the packet's label altogether (**pop**) and continue forwarding the packet to the next hop. However, if the previous router removed the label, the egress router examines the packet's IP header and forwards the packet toward its IP destination.
  - For intermediate (transit) routers only, exchange the label for another label (**swap out-label**). Manually assigned incoming labels can have values from 1,000,000 through 1,048,575. Manually assigned outgoing labels can have values from 0 through 1,048,575.
- Label properties to apply to the packet (all are optional):
  - Bandwidth reserved for this route (**bandwidth bps**).
  - Link-protection and node-protection to apply to the LSP (**bypass bypass-name, link-protection bypass-name name, node-protection bypass-name next-next-label label**).
  - Text description to apply to the LSP (specified in the **description** statement).

The static routes are installed in the default MPLS routing table, `mpls.0`, and the creating protocol is identified as static. To verify that a static route is properly installed, use the command **show route table mpls.0 protocol static**. Sample output follows:

```
1000123      *[Static/5] 00:00:38
> to 12.2.2.2 via so-5/0/0.0, swap 1000456
```

You can configure a revert timer for a static LSP transiting an intermediate router. After traffic has been switched to a bypass static LSP, it is typically switched back to the primary static LSP when it comes back up. There is a configurable delay in the time (called the revert timer) between when the primary static LSP comes up and when traffic is reverted back to it from the bypass static LSP. This delay is needed because when the primary LSP comes back up, it is not certain whether all of the interfaces on the downstream node of the primary path have come up yet. You can display the revert timer value for an interface using the **show mpls interface detail** command. For more information, see [“Configuring the Revert Timer for LSPs” on page 243](#).

### Example: Configuring an Intermediate Router

For packets labeled **1000123** arriving on interface **so-0/0/0**, assign the label **1000456**, and transmit them to the next-hop router at **12.2.2.2**:

```
[edit]
interfaces {
  so-0/0/0 {
    unit 0 {
      family mpls;
    }
  }
}
protocols {
  mpls {
    static-label-switched-path path1 {
```

```
        transit 1000123 {
            next-hop 12.2.2.2;
            swap 1000456;
        }
    }
    interface so-0/0/0.0;
}
}
```

To determine whether the static intermediate route is installed, use the following command:

```
user@host> show route table mpls.0 protocol static
```

Sample output follows. The **swap 1000456** keyword identifies the route.

```
1000123          *[Static/5] 00:01:48
> to 12.2.2.2 via so-0/0/0, swap 1000456
```

---

### Example: Configuring an Egress Router

For packets labeled **1000456** arriving on interface **so-0/0/0**, remove the label and transmit the packets to the next-hop router at **13.3.3.3**:

```
[edit]
interfaces {
    so-0/0/0 {
        unit 0 {
            family mpls;
        }
    }
}
protocols {
    mpls {
        static-label-switched-path path1 {
            transit 1000456 {
                next-hop 13.3.3.3;
                pop;
            }
        }
        interface so-0/0/0.0;
    }
}
```

To determine whether the static egress route is installed, use the following command:

```
user@host> show route table mpls.0 protocol static
```

Sample output follows. The **pop** keyword identifies the egress route.

```
1000456          *[Static/5] 00:01:48
> to 13.3.3.3 via so-0/0/0, pop
```

### Configuring a Bypass LSP for the Static LSP

To enable a bypass LSP for the static LSP, configure the **bypass** statement:

```
bypass bypass-name {
    bandwidth bps;
```

```

description string;
next-hop (address | interface-name | address/interface-name);
push out-label;
to address;
}

```

## Configuring the Protection Revert Timer for Static LSPs

For static LSPs configured with a bypass static LSP, it is possible to configure the protection revert timer. If a static LSP goes down and traffic is switched to the bypass LSP, the protection revert timer specifies the amount of time (in seconds) that the LSP must wait before it can revert back to the original static LSP.

The range of values you can configure for the protection revert timer is 0 through 65,535 seconds. The default value is 5 seconds.

If you configure a value of 0 seconds, the traffic on the LSP, once switched from the original static LSP to the bypass static LSP, remains on the bypass LSP permanently (until the network operator intervenes or until the bypass LSP goes down).

You can configure the protection revert timer for all LSPs on the router at the **[edit protocols mpls]** hierarchy level or for a specific LSP at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level.

To configure the protection revert timer for static LSPs include the **protection-revert-time** statement:

```

protection-revert-time seconds;

```

For a list of hierarchy levels at which you can include this statement, see the summary section for this statement.

## Configuring Static Unicast Routes for Point-to-Multipoint LSPs

You can configure a static unicast IP route with a point-to-multipoint LSP as the next hop. For more information about point-to-multipoint LSPs, see [“Point-to-Multipoint LSPs Overview” on page 309](#), [“Configuring Primary and Branch LSPs for Point-to-Multipoint LSPs” on page 311](#), and [“Configuring CCC Switching for Point-to-Multipoint LSPs” on page 761](#).

To configure a static unicast route for a point-to-multipoint LSP, complete the following steps:

1. On the ingress PE router, configure a static IP unicast route with the point-to-multipoint LSP name as the next hop by including the **p2mp-lsp-next-hop** statement:

```

p2mp-lsp-next-hop point-to-multipoint-lsp-next-hop;

```

You can include this statement at the following hierarchy levels:

- **[edit routing-options static route *route-name*]**
- **[edit logical-systems *logical-system-name* routing-options static route *route-name*]**

2. On the egress PE router, configure a static IP unicast route with the same destination address configured in Step 1 (the address configured at the **[edit routing-options static route]** hierarchy level) by including the **next-hop** statement:

```
next-hop address;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-options static route route-name]**
- **[edit logical-systems logical-system-name routing-options static route route-name]**

**NOTE:** CCC and static routes cannot use the same point-to-multipoint LSP.

For more information on static routes, see the *Junos OS Routing Protocols Library*.

The following **show route** command output displays a unicast static route pointing to a point-to-multipoint LSP on the ingress PE router where the LSP has two branch next hops:

```
user@host> show route 5.5.5.5 detail
inet.0: 29 destinations, 30 routes (28 active, 0 holddown, 1 hidden)
5.5.5.5/32 (1 entry, 1 announced)
  *Static Preference: 5
    Next hop type: Flood
    Next hop: via so-0/3/2.0 weight 1
    Label operation: Push 100000
    Next hop: via tl-0/1/1.0 weight 1
    Label operation: Push 100064
    State: <Active Int Ext>
    Local AS: 10458
    Age: 2:41:15
    Task: RT
    Announcement bits (2): 0-KRT 3-BGP.0.0.0.0+179
    AS path: I
```

## Configuring Explicit-Path LSPs

If you disable constrained-path label-switched path (LSP) computation, as described in [“Disabling Constrained-Path LSP Computation” on page 267](#), you can configure LSPs manually or allow the LSPs to follow the IGP path.

When explicit-path LSPs are configured, the LSP is established along the path you specified. If the path is topologically not feasible, either because the network is partitioned or insufficient resources are available along some parts of the path, the LSP will fail. No alternative paths can be used. If the setup succeeds, the LSP stays on the defined path indefinitely.

To configure an explicit-path LSP, follow these steps:

1. Configure the path information in a named path, as described in [“Creating Named Paths” on page 60](#). To configure complete path information, specify every router hop between the ingress and egress routers, preferably using the **strict** attribute. To configure incomplete path information, specify only a subset of router hops, using the **loose** attribute in places where the path is incomplete.

For incomplete paths, the MPLS routers complete the path by querying the local routing table. This query is done on a hop-by-hop basis, and each router can figure out only enough information to reach the next explicit hop. It might be necessary to traverse a number of routers to reach the next (loose) explicit hop.

Configuring incomplete path information creates portions of the path that depend on the current routing table, and this portion of the path can reroute itself as the topology changes. Therefore, an explicit-path LSP that contains incomplete path information is not completely fixed. These types of LSPs have only a limited ability to repair themselves, and they tend to create loops or flaps depending on the contents of the local routing table.

2. To configure the LSP and point it to the named path, use either the **primary** or **secondary** statement, as described in [“Configuring Primary and Secondary LSPs” on page 242](#).
3. Disable constrained-path LSP computation by including the **no-cspf** statement either as part of the LSP or as part of a **primary** or **secondary** statement. For more information, see [“Disabling Constrained-Path LSP Computation” on page 267](#).
4. Configure any other LSP properties.

Using explicit-path LSPs has the following drawbacks:

- More configuration effort is required.
- Configured path information cannot take into account dynamic network bandwidth reservation, so the LSPs tend to fail when resources become depleted.
- When an explicit-path LSP fails, you might need to manually repair it.

Because of these limitations, we recommend that you use explicit-path LSPs only in controlled situations, such as to enforce an optimized LSP placement strategy resulting from computations with an offline simulation software package.

### Point-to-Multipoint LSPs Overview

---

A point-to-multipoint MPLS LSP is an LSP with a single source and multiple destinations. By taking advantage of the MPLS packet replication capability of the network, point-to-multipoint LSPs avoid unnecessary packet replication at the ingress router. Packet replication takes place only when packets are forwarded to two or more different destinations requiring different network paths.

This process is illustrated in [Figure 35 on page 310](#). Router PE1 is configured with a point-to-multipoint LSP to Routers PE2, PE3, and PE4. When Router PE1 sends a packet on the point-to-multipoint LSP to Routers P1 and P2, Router P1 replicates the packet and forwards it to Routers PE2 and PE3. Router P2 sends the packet to Router PE4.

This feature is described in detail in the Internet drafts [draft-raggarwa-mpls-p2mp-te-02.txt](#) (expired February 2004), *Establishing Point to Multipoint MPLS TE LSPs*, [draft-ietf-mpls-rsvp-te-p2mp-02.txt](#), *Extensions to Resource Reservation Protocol-Traffic Engineering (RSVP-TE) for Point-to-Multipoint TE Label-Switched Paths (LSPs)*, and RFC 6388, *Label Distribution Protocol Extensions for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths* (only point-to-multipoint LSPs are supported).

Figure 35: Point-to-Multipoint LSPs

The following are some of the properties of point-to-multipoint LSPs:

- A point-to-multipoint LSP enables you to use MPLS for point-to-multipoint data distribution. This functionality is similar to that provided by IP multicast.
- You can add and remove branch LSPs from a main point-to-multipoint LSP without disrupting traffic. The unaffected parts of the point-to-multipoint LSP continue to function normally.
- You can configure a node to be both a transit and an egress router for different branch LSPs of the same point-to-multipoint LSP.
- You can enable link protection on a point-to-multipoint LSP. Link protection can provide a bypass LSP for each of the branch LSPs that make up the point-to-multipoint LSP. If any of the primary paths fail, traffic can be quickly switched to the bypass.
- You can configure branch LSPs either statically, dynamically, or as a combination of static and dynamic LSPs.
- You can enable graceful Routing Engine switchover (GRES) and graceful restart for point-to-multipoint LSPs at ingress and egress routers. The point-to-multipoint LSPs must be configured using either static routes or circuit cross-connect (CCC). GRES and graceful restart allow the traffic to be forwarded at the Packet Forwarding Engine based on the old state while the control plane recovers. Feature parity for GRES and graceful restart for MPLS point-to-multipoint LSPs on the Junos Trio chipset is supported in Junos OS Releases 11.1R2, 11.2R2, and 11.4.

## Configuring Primary and Branch LSPs for Point-to-Multipoint LSPs

A point-to-multipoint MPLS label-switched path (LSP) is an RSVP LSP with multiple destinations. By taking advantage of the MPLS packet replication capability of the network, point-to-multipoint LSPs avoid unnecessary packet replication at the ingress router. For more information about point-to-multipoint LSPs, see [“Point-to-Multipoint LSPs Overview” on page 309](#).

To configure a point-to-multipoint LSP, you need to configure the primary LSP from the ingress router and the branch LSPs that carry traffic to the egress routers, as described in the following sections:

- [Configuring the Primary Point-to-Multipoint LSP on page 311](#)
- [Configuring a Branch LSP for Point-to-Multipoint LSPs on page 311](#)

### Configuring the Primary Point-to-Multipoint LSP

A point-to-multipoint LSP must have a configured primary point-to-multipoint LSP to carry traffic from the ingress router. The configuration of the primary point-to-multipoint LSP is similar to a signaled LSP. See [“Configuring the Ingress Router for MPLS-Signaled LSPs” on page 60](#) for more information. In addition to the conventional LSP configuration, you need to specify a path name for the primary point-to-multipoint LSP by including the **p2mp** statement:

```
p2mp p2mp-lsp-name;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls label-switched-path lsp-name]**
- **[edit logical-systems logical-system-name protocols mpls label-switched-path lsp-name]**

You can enable the optimization timer for point-to-multipoint LSPs. See [“Optimizing Signaled LSPs” on page 280](#) for more information.

### Configuring a Branch LSP for Point-to-Multipoint LSPs

The primary point-to-multipoint LSP sends traffic to two or more branch LSPs carrying traffic to each of the egress provider edge (PE) routers. In the configuration for each of these branch LSPs, the point-to-multipoint LSP path name you specify must be identical to the path name configured for the primary point-to-multipoint LSP. See [“Configuring the Primary Point-to-Multipoint LSP” on page 311](#) for more information.

To associate a branch LSP with the primary point-to-multipoint LSP, specify the point-to-multipoint LSP name by including the **p2mp** statement:

```
p2mp p2mp-lsp-name;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

**NOTE:** Any change in any of the branch LSPs of a point-to-multipoint LSP, either due to a user action or an automatic adjustment made by the router, causes the primary and branch LSPs to be resigaled. The new point-to-multipoint LSP is signaled first before the old path is taken down.

The following sections describe how you can configure the branch LSP as a dynamically signaled path using Constrained Shortest Path First (CSPF), as a static path, or as a combination of dynamic and static paths:

- [Configuring the Branch LSP as a Dynamic Path on page 312](#)
- [Configuring the Branch LSP as a Static Path on page 312](#)

---

### Configuring the Branch LSP as a Dynamic Path

By default, the branch LSP for a point-to-multipoint LSP is signaled dynamically using CSPF and requires no configuration.

When a point-to-multipoint LSP is changed, either by the addition or deletion of new destinations or by the recalculation of the path to existing destinations, certain nodes in the tree might receive data from more than one incoming interface. This can happen under the following conditions:

- Some of the branch LSPs to destinations are statically configured and might intersect with statically or dynamically calculated paths to other destinations.
- When a dynamically calculated path for a branch LSP results in a change of incoming interface for one of the nodes in the network, the older path is not immediately torn down after the new one has been signaled. This ensures that any data in transit relying on the older path can reach its destination. However, network traffic can potentially use either path to reach the destination.
- A faulty router at the ingress calculates the paths to two different branch destinations such that a different incoming interface is chosen for these branch LSPs on a router node common to these branch LSPs.

---

### Configuring the Branch LSP as a Static Path

You can configure the branch LSP for a point-to-multipoint LSP as a static path. See [“Configuring Static LSPs” on page 299](#) for more information.

## Example: Configuring a Collection of Paths to Create an RSVP-Signaled Point-to-Multipoint LSP

---

This example shows how to configure a collection of paths to create an RSVP-signaled point-to-multipoint label-switched path (LSP).

- [Requirements on page 313](#)
- [Overview on page 313](#)
- [Configuration on page 314](#)
- [Verification on page 330](#)

### Requirements

In this example, no special configuration beyond device initialization is required.

### Overview

In this example, multiple routing devices serve as the transit, branch, and leaf nodes of a single point-to-multipoint LSP. On the provider edge (PE), Device PE1 is the ingress node. The branches go from PE1 to PE2, PE1 to PE3, and PE1 to PE4. Static unicast routes on the ingress node (PE1) point to the egress nodes.

This example also demonstrates static routes with a next hop that is a point-to-multipoint LSP, using the `p2mp-lsp-next-hop` statement. This is useful when implementing filter-based forwarding.

**NOTE:** Another option is to use the `lsp-next-hop` statement to configure a regular point-to-point LSP to be the next hop. Though not shown in this example, you can optionally assign an independent preference and metric to the next hop.

---

### Topology Diagram

Figure 36 on page 314 shows the topology used in this example.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

#### Device PE1

```
set interfaces ge-2/0/2 unit 0 description PE1-to-CE1
set interfaces ge-2/0/2 unit 0 family inet address 10.0.244.10/30
set interfaces fe-2/0/10 unit 1 description PE1-to-P2
set interfaces fe-2/0/10 unit 1 family inet address 2.2.2.1/24
set interfaces fe-2/0/10 unit 1 family mpls
set interfaces fe-2/0/9 unit 8 description PE1-to-P3
set interfaces fe-2/0/9 unit 8 family inet address 6.6.6.1/24
set interfaces fe-2/0/9 unit 8 family mpls
set interfaces fe-2/0/8 unit 9 description PE1-to-P4
set interfaces fe-2/0/8 unit 9 family inet address 3.3.3.1/24

### Configuring the Ingress Label-Switched Router (LSR) (Device PE1)

#### Step-by-Step Procedure

To configure Device PE1:

1. Configure the interfaces, interface encapsulation, and protocol families.

```

[edit interfaces]
user@PE1# set ge-2/0/2 unit 0 description PE1-to-CE1
user@PE1# set ge-2/0/2 unit 0 family inet address 10.0.244.10/30
user@PE1# set fe-2/0/10 unit 1 description PE1-to-P2
user@PE1# set fe-2/0/10 unit 1 family inet address 2.2.2.1/24
user@PE1# set fe-2/0/10 unit 1 family mpls
user@PE1# set fe-2/0/9 unit 8 description PE1-to-P3
user@PE1# set fe-2/0/9 unit 8 family inet address 6.6.6.1/24
user@PE1# set fe-2/0/9 unit 8 family mpls
user@PE1# set fe-2/0/8 unit 9 description PE1-to-P4
user@PE1# set fe-2/0/8 unit 9 family inet address 3.3.3.1/24
user@PE1# set fe-2/0/8 unit 9 family mpls
user@PE1# set lo0 unit 1 family inet address 100.10.10.10/32

```

2. Enable RSVP, MPLS, and OSPF on the interfaces.

```
[edit protocols]
user@PE1# set rsvp interface fe-2/0/10.1
user@PE1# set rsvp interface fe-2/0/9.8
user@PE1# set rsvp interface fe-2/0/8.9
user@PE1# set rsvp interface lo0.1
user@PE1# set mpls interface fe-2/0/10.1
user@PE1# set mpls interface fe-2/0/9.8
user@PE1# set mpls interface fe-2/0/8.9
user@PE1# set mpls interface lo0.1
user@PE1# set ospf area 0.0.0.0 interface ge-2/0/2.0
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/10.1
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/9.8
user@PE1# set ospf area 0.0.0.0 interface fe-2/0/8.9
user@PE1# set ospf area 0.0.0.0 interface lo0.1
```

3. Configure the MPLS point-to-multipoint LSPs.

```
[edit protocols]
user@PE1# set mpls label-switched-path PE1-PE2 to 100.50.50.50
user@PE1# set mpls label-switched-path PE1-PE2 p2mp p2mp1
user@PE1# set mpls label-switched-path PE1-PE3 to 100.70.70.70
user@PE1# set mpls label-switched-path PE1-PE3 p2mp p2mp1
user@PE1# set mpls label-switched-path PE1-PE4 to 100.40.40.40
user@PE1# set mpls label-switched-path PE1-PE4 p2mp p2mp1
```

4. (Optional) Enable link protection on the LSPs.

Link protection helps to ensure that traffic sent over a specific interface to a neighboring router can continue to reach the router if that interface fails.

```
[edit protocols]
user@PE1# set mpls label-switched-path PE1-PE2 link-protection
user@PE1# set mpls label-switched-path PE1-PE3 link-protection
user@PE1# set mpls label-switched-path PE1-PE4 link-protection
```

5. Enable MPLS to perform traffic engineering for OSPF.

```
[edit protocols]
user@PE1# set mpls traffic-engineering bgp-igp
```

This causes the ingress routes to be installed in the inet.0 routing table. By default, MPLS performs traffic engineering for BGP only. You need to enable MPLS traffic engineering on the ingress LSR only.

6. Enable traffic engineering for OSPF.

```
[edit protocols]
user@PE1# set ospf traffic-engineering
```

This causes the shortest-path first (SPF) algorithm to take into account the LSPs configured under MPLS.

7. Configure the router ID.

```
[edit routing-options]
user@PE1# set router-id 100.10.10.10
```

8. Configure static IP unicast routes with the point-to-multipoint LSP name as the next hop for each route.

```
[edit routing-options]
user@PE1# set static route 5.5.5.0/24 p2mp-lsp-next-hop p2mp1
user@PE1# set static route 7.7.7.0/24 p2mp-lsp-next-hop p2mp1
user@PE1# set static route 4.4.4.0/24 p2mp-lsp-next-hop p2mp1
```

9. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE1# commit
```

### Configuring the Transit and Egress LSRs (Devices P2, P3, P4, PE2, PE3, and PE4)

#### Step-by-Step Procedure

To configure the transit and egress LSRs:

1. Configure the interfaces, interface encapsulation, and protocol families.

```
[edit]
user@P2# set interfaces fe-2/0/10 unit 2 description P2-to-PE1
user@P2# set interfaces fe-2/0/10 unit 2 family inet address 2.2.2.2/24
user@P2# set interfaces fe-2/0/10 unit 2 family mpls
user@P2# set interfaces fe-2/0/9 unit 10 description P2-to-PE2
user@P2# set interfaces fe-2/0/9 unit 10 family inet address 5.5.5.1/24
user@P2# set interfaces fe-2/0/9 unit 10 family mpls
user@P2# set interfaces lo0 unit 2 family inet address 100.20.20.20/32

user@PE2# set interfaces ge-2/0/3 unit 0 description PE2-to-CE2
user@PE2# set interfaces ge-2/0/3 unit 0 family inet address 10.0.224.10/30
user@PE2# set interfaces fe-2/0/10 unit 5 description PE2-to-P2
user@PE2# set interfaces fe-2/0/10 unit 5 family inet address 5.5.5.2/24
user@PE2# set interfaces fe-2/0/10 unit 5 family mpls
user@PE2# set interfaces lo0 unit 5 family inet address 100.50.50.50/32

user@P3# set interfaces fe-2/0/10 unit 6 description P3-to-PE1
user@P3# set interfaces fe-2/0/10 unit 6 family inet address 6.6.6.2/24
user@P3# set interfaces fe-2/0/10 unit 6 family mpls
user@P3# set interfaces fe-2/0/9 unit 11 description P3-to-PE3
user@P3# set interfaces fe-2/0/9 unit 11 family inet address 7.7.7.1/24
user@P3# set interfaces fe-2/0/9 unit 11 family mpls
user@P3# set interfaces lo0 unit 6 family inet address 100.60.60.60/32

user@PE3# set interfaces ge-2/0/1 unit 0 description PE3-to-CE3
user@PE3# set interfaces ge-2/0/1 unit 0 family inet address 10.0.134.10/30
user@PE3# set interfaces fe-2/0/10 unit 7 description PE3-to-P3
user@PE3# set interfaces fe-2/0/10 unit 7 family inet address 7.7.7.2/24
user@PE3# set interfaces fe-2/0/10 unit 7 family mpls
user@PE3# set interfaces lo0 unit 7 family inet address 100.70.70.70/32

user@P4# set interfaces fe-2/0/10 unit 3 description P4-to-PE1
user@P4# set interfaces fe-2/0/10 unit 3 family inet address 3.3.3.2/24
user@P4# set interfaces fe-2/0/10 unit 3 family mpls
user@P4# set interfaces fe-2/0/9 unit 12 description P4-to-PE4
user@P4# set interfaces fe-2/0/9 unit 12 family inet address 4.4.4.1/24
```

```
user@P4# set interfaces fe-2/0/9 unit 12 family mpls
user@P4# set interfaces lo0 unit 3 family inet address 100.30.30.30/32
```

```
user@PE4# set interfaces ge-2/0/0 unit 0 description PE4-to-CE4
user@PE4# set interfaces ge-2/0/0 unit 0 family inet address 10.0.104.9/30
user@PE4# set interfaces fe-2/0/10 unit 4 description PE4-to-P4
user@PE4# set interfaces fe-2/0/10 unit 4 family inet address 4.4.4.2/24
user@PE4# set interfaces fe-2/0/10 unit 4 family mpls
user@PE4# set interfaces lo0 unit 4 family inet address 100.40.40.40/32
```

2. Enable RSVP, MPLS, and OSPF on the interfaces.

```
[edit]
user@P2# set protocols rsvp interface fe-2/0/10.2
user@P2# set protocols rsvp interface fe-2/0/9.10
user@P2# set protocols rsvp interface lo0.2
user@P2# set protocols mpls interface fe-2/0/10.2
user@P2# set protocols mpls interface fe-2/0/9.10
user@P2# set protocols mpls interface lo0.2
user@P2# set protocols ospf area 0.0.0.0 interface fe-2/0/10.2

user@P4# set protocols mpls interface fe-2/0/10.3
user@P4# set protocols mpls interface fe-2/0/9.12
```

```

user@P4# set protocols mpls interface lo0.3
user@P4# set protocols ospf area 0.0.0.0 interface fe-2/0/10.3
user@P4# set protocols ospf area 0.0.0.0 interface fe-2/0/9.12
user@P4# set protocols ospf area 0.0.0.0 interface lo0.3

```

```

user@PE4# set protocols rsvp interface fe-2/0/10.4
user@PE4# set protocols rsvp interface lo0.4
user@PE4# set protocols mpls interface fe-2/0/10.4
user@PE4# set protocols mpls interface lo0.4
user@PE4# set protocols ospf area 0.0.0.0 interface ge-2/0/0.0
user@PE4# set protocols ospf area 0.0.0.0 interface fe-2/0/10.4
user@PE4# set protocols ospf area 0.0.0.0 interface lo0.4

```

3. Enable traffic engineering for OSPF.

```

[edit]
user@P2# set protocols ospf traffic-engineering

```

```

user@P3# set protocols ospf traffic-engineering

```

```

user@P4# set protocols ospf traffic-engineering

```

```

user@PE2# set protocols ospf traffic-engineering

```

```

user@PE3# set protocols ospf traffic-engineering

```

```

user@PE4# set protocols ospf traffic-engineering

```

This causes the shortest-path first (SPF) algorithm to take into account the LSPs configured under MPLS.

4. Configure the router IDs.

```

[edit]
user@P2# set routing-options router-id 100.20.20.20

```

```

user@P3# set routing-options router-id 100.60.60.60

```

```

user@P4# set routing-options router-id 100.30.30.30

```

```

user@PE2# set routing-options router-id 100.50.50.50

```

```

user@PE3# set routing-options router-id 100.70.70.70

```

```

user@PE4# set routing-options router-id 100.40.40.40

```

5. If you are done configuring the devices, commit the configuration.

```

[edit]
user@host# commit

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

### Configuring Device CE1

#### Step-by-Step Procedure

To configure Device CE1:

1. Configure an interface to Device PE1.

```
[edit interfaces]
user@CE1# set ge-1/3/2 unit 0 family inet address 10.0.244.9/30
user@CE1# set ge-1/3/2 unit 0 description CE1-to-PE1
```

2. Configure static routes from Device CE1 to the three other customer networks, with Device PE1 as the next hop.

```
[edit routing-options]
user@CE1# set static route 10.0.104.8/30 next-hop 10.0.244.10
user@CE1# set static route 10.0.134.8/30 next-hop 10.0.244.10
user@CE1# set static route 10.0.224.8/30 next-hop 10.0.244.10
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE1# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE1# show interfaces
ge-1/3/2 {
  unit 0 {
    family inet {
      address 10.0.244.9/30;
      description CE1-to-PE1;
    }
  }
}

user@CE1# show routing-options
static {
  route 10.0.104.8/30 next-hop 10.0.244.10;
  route 10.0.134.8/30 next-hop 10.0.244.10;
  route 10.0.224.8/30 next-hop 10.0.244.10;
}
```

### Configuring Device CE2

#### Step-by-Step Procedure

To configure Device CE2:

1. Configure an interface to Device PE2.

```
[edit interfaces]
user@CE2# set ge-1/3/3 unit 0 family inet address 10.0.224.9/30
user@CE2# set ge-1/3/3 unit 0 description CE2-to-PE2
```

2. Configure a static route from Device CE2 to CE1, with Device PE2 as the next hop.

```
[edit routing-options]
user@CE2# set static route 10.0.244.8/30 next-hop 10.0.224.10
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE2# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE2# show interfaces
ge-1/3/3 {
  unit 0 {
    family inet {
      address 10.0.224.9/30;
      description CE2-to-PE2;
    }
  }
}

user@CE2# show routing-options
static {
  route 10.0.244.8/30 next-hop 10.0.224.10;
}
```

---

### Configuring Device CE3

**Step-by-Step Procedure** To configure Device CE3:

1. Configure an interface to Device PE3.

```
[edit interfaces]
user@CE3# set ge-2/0/1 unit 0 family inet address 10.0.134.9/30
user@CE3# set ge-2/0/1 unit 0 description CE3-to-PE3
```

2. Configure a static route from Device CE3 to CE1, with Device PE3 as the next hop.

```
[edit routing-options]
user@CE3# set static route 10.0.244.8/30 next-hop 10.0.134.10
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE3# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE3# show interfaces
ge-2/0/1 {
  unit 0 {
```

```

        family inet {
            address 10.0.134.9/30;
            description CE3-to-PE3;
        }
    }
}

user@CE3# show routing-options
static {
    route 10.0.244.8/30 next-hop 10.0.134.10;
}

```

### Configuring Device CE4

#### Step-by-Step Procedure

To configure Device CE4:

1. Configure an interface to Device PE4.

```

[edit interfaces]
user@CE4# set ge-3/1/3 unit 0 family inet address 10.0.104.10/30
user@CE4# set ge-3/1/3 unit 0 description CE4-to-PE4

```

2. Configure a static route from Device CE4 to CE1, with Device PE4 as the next hop.

```

[edit routing-options]
user@CE4# set static route 10.0.244.8/30 next-hop 10.0.104.9

```

3. If you are done configuring the device, commit the configuration.

```

[edit]
user@CE4# commit

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@CE4# show interfaces
ge-3/1/3 {
    unit 0 {
        family inet {
            address 10.0.104.10/30;
            description CE4-to-PE4;
        }
    }
}

user@CE4# show routing-options
static {
    route 10.0.244.8/30 next-hop 10.0.104.9;
}

```

## Verification

Confirm that the configuration is working properly.

- [Verifying Connectivity on page 330](#)
- [Verifying the State of the Point-to-Multipoint LSP on page 330](#)
- [Checking the Forwarding Table on page 331](#)

---

### Verifying Connectivity

**Purpose** Make sure that the devices can ping each other.

**Action** Run the **ping** command from CE1 to the interface on CE2 connecting to PE2.

```
user@CE1> ping 10.0.224.9
PING 10.0.224.9 (10.0.224.9): 56 data bytes
64 bytes from 10.0.224.9: icmp_seq=0 ttl=61 time=1.387 ms
64 bytes from 10.0.224.9: icmp_seq=1 ttl=61 time=1.394 ms
64 bytes from 10.0.224.9: icmp_seq=2 ttl=61 time=1.506 ms
^C
--- 10.0.224.9 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.387/1.429/1.506/0.055 ms
```

Run the **ping** command from CE1 to the interface on CE3 connecting to PE3.

```
user@CE1> ping 10.0.134.9
PING 10.0.134.9 (10.0.134.9): 56 data bytes
64 bytes from 10.0.134.9: icmp_seq=0 ttl=61 time=1.068 ms
64 bytes from 10.0.134.9: icmp_seq=1 ttl=61 time=1.062 ms
64 bytes from 10.0.134.9: icmp_seq=2 ttl=61 time=1.053 ms
^C
--- 10.0.134.9 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.053/1.061/1.068/0.006 ms
```

Run the **ping** command from CE1 to the interface on CE4 connecting to PE4.

```
user@CE1> ping 10.0.104.10
PING 10.0.104.10 (10.0.104.10): 56 data bytes
64 bytes from 10.0.104.10: icmp_seq=0 ttl=61 time=1.079 ms
64 bytes from 10.0.104.10: icmp_seq=1 ttl=61 time=1.048 ms
64 bytes from 10.0.104.10: icmp_seq=2 ttl=61 time=1.070 ms
^C
--- 10.0.104.10 ping statistics ---
3 packets transmitted, 3 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.048/1.066/1.079/0.013 ms
```

---

### Verifying the State of the Point-to-Multipoint LSP

**Purpose** Make sure that the ingress, transit, and egress LSRs are in the Up state.

**Action** Run the `show mpls lsp p2mp` command on all of the LSRs. Only the ingress LSR is shown here.

```
user@PE1> show mpls lsp p2mp
Ingress LSP: 1 sessions
P2MP name: p2mp1, P2MP branch count: 3
To          From          State Rt P    ActivePath    LSPname
100.40.40.40 100.10.10.10 Up    0 *          PE1-PE4
100.70.70.70 100.10.10.10 Up    0 *          PE1-PE3
100.50.50.50 100.10.10.10 Up    0 *          PE1-PE2
Total 3 displayed, Up 3, Down 0
...
```

### Checking the Forwarding Table

**Purpose** Make sure that the routes are set up as expected by running the `show route forwarding-table` command. Only the routes to the remote customer networks are shown here.

**Action** user@PE1> show route forwarding-table

```
Routing table: default.inet
Internet:
Destination          Type RtRef Next hop          Type Index NhRef Netif
...
10.0.104.8/30         user    0 3.3.3.2          ucst  1006   6 fe-2/0/8.9
10.0.134.8/30         user    0 6.6.6.2          ucst  1010   6 fe-2/0/9.8
10.0.224.8/30         user    0 2.2.2.2          ucst  1008   6 fe-2/0/10.1
...
```

## Configuring Inter-Domain Point-to-Multipoint LSPs

An inter-domain P2MP LSP is a P2MP LSP that has one or more sub-LSPs (branches) that span multiple domains in a network. Examples of such domains include IGP areas and autonomous systems (ASs). A sub-LSP of an inter-domain P2MP LSP may be intra-area, inter-area, or inter-AS, depending on the location of the egress node (leaf) with respect to the ingress node (source).

On the ingress node, a name is assigned to the inter-domain P2MP LSP and shared by all constituent sub-LSPs. Each sub-LSP is configured separately, with its own egress node and optionally an explicit path. The location of the egress node of the sub-LSP with respect to the ingress node determines whether the sub-LSP is intra-area, inter-area, or inter-AS.

Inter-domain P2MP LSPs can be used to transport traffic in the following applications in a multi-area or multi-AS network:

- Layer 2 broadcast and multicast over MPLS
- Layer 3 BGP/MPLS VPN

- VPLS

On each domain boundary node (ABR or ASBR) along the path of the P2MP LSP, the **expand-loose-hop** statement must be configured at the **[edit protocols mpls]** hierarchy level so that CSPF can extend a loose-hop ERO (usually the first entry of the ERO list carried by RSVP Path message) towards the egress node or the next domain boundary node.

CSPF path computation for inter-domain P2MP LSPs:

- CSPF path computation is supported on each sub-LSP for inter-domain P2MP LSPs. A sub-LSP may be intra-area, inter-area, or inter-AS. CSPF treats an inter-area or inter-AS sub-LSP in the same manner as an inter-domain P2P LSP.
- On an ingress node or a domain boundary node (ABR or ASBR), CSPF can perform an Explicit Route Object (ERO) expansion per-RSVP query. The destination queried could be an egress node or a received loose-hop ERO. If the destination resides in a neighboring domain that the node is connected to, CSPF generates either a sequence of strict-hop EROs towards it or a sequence of strict-hop EROs towards another domain boundary node that can reach the destination.
- If RSVP fails to signal a path through a previously selected domain boundary node, RSVP attempts to signal a path through other available domain boundary nodes in a round-robin fashion.
- When a sub-LSP is added or removed to or from an inter-domain P2MP LSP, causing its path (branch) to be merged or pruned with or from the current P2MP tree, the paths being taken by the other sub-LSPs should not be affected, helping to prevent traffic disruption on those sub-LSPs.

Be aware of the following when deploying inter-domain P2MP LSPs in your network:

- Periodic path re-optimization is supported for inter-domain P2MP LSPs on ingress nodes. It can be turned on for an inter-domain P2MP LSP by configuring the **optimize-timer** statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level with the same interval for every sub-LSP.
- Only link protection bypass LSPs are supported for inter-domain P2MP LSPs. To enable it for an inter-domain P2MP LSP, link-protection must be configured for all sub-LSPs and on all of the RSVP interfaces that the P2MP LSP might travel through.
- Only OSPF areas are supported for inter-domain P2MP LSPs. IS-IS levels are not supported.

---

## Configuring Link Protection for Point-to-Multipoint LSPs

---

Link protection helps to ensure that traffic going over a specific interface to a neighboring router can continue to reach this router if that interface fails. When link protection is configured for an interface and a point-to-multipoint LSP that traverses this interface, a bypass LSP is created that handles this traffic if the interface fails. The bypass LSP uses a different interface and path to reach the same destination.

To extend link protection to all of the paths used by a point-to-multipoint LSP, link protection must be configured on each router that each branch LSP traverses. If you enable link protection on a point-to-multipoint LSP, you must enable link protection on all of the branch LSPs.

The Internet draft [draft-ietf-mpls-rsvp-te-p2mp-01.txt](#), *Extensions to RSVP-TE for Point to Multipoint TE LSPs*, describes link protection for point-to-multipoint LSPs.

To enable link protection on point-to-multipoint LSPs, complete the following steps:

1. Configure link protection on each branch LSP. To configure link protection, include the **link-protection** statement:

```
link-protection;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *branch-lsp-name*]
  - [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *branch-lsp-name*]
2. Configure link protection for each RSVP interface on each router that the branch LSP traverses. For information about how to configure link protection on RSVP interfaces, see [“Configuring Link Protection on Interfaces Used by LSPs” on page 536](#).

For more information on how to configure link protection, see [“Configuring Node Protection or Link Protection for LSPs” on page 543](#).

## Configuring Graceful Restart for Point-to-Multipoint LSPs

You can configure graceful restart on point-to-multipoint LSPs. Graceful restart allows a router undergoing a restart to inform its adjacent neighbors of its condition. The restarting router requests a grace period from the neighbor or peer, which can then cooperate with the restarting router. The restarting router can still forward MPLS traffic during the restart period; convergence in the network is not disrupted. The restart is not apparent to the rest of the network, and the restarting router is not removed from the network topology. RSVP graceful restart can be enabled on both transit routers and ingress routers.

To enable graceful restart on a router handling point-to-multipoint LSP traffic, include the **graceful-restart** statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- [edit routing-options]
- [edit logical-systems *logical-system-name* routing-options]

The graceful restart configuration for point-to-multipoint LSPs is identical to that of point-to-point LSPs. For more information on how to configure graceful restart, see [“Configuring RSVP Graceful Restart” on page 548](#).

## Configuring a Multicast RPF Check Policy for Point-to-Multipoint LSPs

You can control whether a reverse path forwarding (RPF) check is performed for a source and group entry before installing a route in the multicast forwarding cache. This makes it possible to use point-to-multipoint LSPs to distribute multicast traffic to PIM islands situated downstream from the egress routers of the point-to-multipoint LSPs.

By configuring the **rpf-check-policy** statement, you can disable RPF checks for a source and group pair. You would typically configure this statement on the egress routers of a point-to-multipoint LSP, because the interface receiving the multicast traffic on a point-to-multipoint LSP egress router might not always be the RPF interface.

You can also configure a routing policy to act upon a source and group pair. This policy behaves like an import policy, so if no policy term matches the input data, the default policy action is “acceptance.” An accept policy action enables RPF checks. A reject policy action (applied to all source and group pairs that are not accepted) disables RPF checks for the pair.

To configure a multicast RPF check policy for a point-to-multipoint LSP, specify the RPF check policy using the **rpf-check-policy** statement:

```
rpf-check-policy policy;
```

You can include this statement at the following hierarchy levels:

- [edit routing-options multicast]
- [edit logical-systems *logical-system-name* routing-options multicast]

You also must configure a policy for the multicast RPF check. You configure policies at the [edit policy-options] hierarchy level. For more information, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

**NOTE:** When you configure the **rpf-check-policy** statement, the Junos OS cannot perform RPF checks on incoming traffic and therefore cannot detect traffic arriving on the wrong interface. This might cause routing loops to form.

### Example: Configuring Multicast RPF Check Policy for a Point-to-Multipoint LSP

Configure a policy to ensure that an RPF check is not performed for sources with prefix **128.83/16** or longer that belong to groups having a prefix of **228/8** or longer:

```
[edit]
policy-options {
  policy-statement rpf-sg-policy {
    from {
      route-filter 228.0.0.0/8 orlonger;
      source-address-filter 128.83.0.0/16 orlonger;
    }
    then {
      reject;
    }
  }
}
```

```

    }
  }
}

```

## Configuring Ingress PE Router Redundancy for Point-to-Multipoint LSPs

You can configure one or more PE routers as part of a backup PE router group to enable ingress PE router redundancy. You accomplish this by configuring the IP addresses of the backup PE routers (at least one backup PE router is required) and the local IP address used by the local PE router.

You must also configure a full mesh of point-to-point LSPs between the primary and backup PE routers. You also need to configure BFD on these LSPs. See [“Configuring BFD for RSVP-Signaled LSPs” on page 383](#) and [“Configuring BFD for LDP LSPs” on page 620](#) for more information.

To configure ingress PE router redundancy for point-to-multipoint LSPs, include the **backup-pe-group** statement:

```

backup-pe-group pe-group-name {
  backups [addresses];
  local-address address;
}

```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections for these statements.

After you configure the ingress PE router redundancy backup group, you must also apply the group to a static route on the PE router. This ensures that the static route is active (installed in the forwarding table) when the local PE router is the designated forwarder for the backup PE group. You can only associate a backup PE router group with a static route that also has the **p2mp-lsp-next-hop** statement configured. For more information, see [“Configuring Static Unicast Routes for Point-to-Multipoint LSPs” on page 305](#).

## Enabling Point-to-Point LSPs to Monitor Egress PE Routers

Configuring an LSP with the **associate-backup-pe-groups** statement enables it to monitor the status of the PE router to which it is configured. You can configure multiple backup PE router groups using the same router's address. A failure of this LSP indicates to all of the backup PE router groups that the destination PE router is down. The **associate-backup-pe-groups** statement is not tied to a specific backup PE router group. It applies to all groups that are interested in the status of the LSP to that address.

To allow an LSP to monitor the status of the egress PE router, include the **associate-backup-pe-groups** statement:

```

associate-backup-pe-groups;

```

This statement can be configured at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

If you configure the **associate-backup-pe-groups** statement, you must configure BFD for the point-to-point LSP. For information about how to configure BFD for an LSP, see [“Configuring BFD for MPLS IPv4 LSPs” on page 382](#) and [“Configuring BFD for LDP LSPs” on page 620](#).

You also must configure a full mesh of point-to-point LSPs between the PE routers in the backup PE router group. A full mesh is required so that each PE router within the group can independently determine the status of the other PE routers, allowing each router to independently determine which PE router is currently the designated forwarder for the backup PE router group.

If you configure multiple LSPs with the **associate-backup-pe-groups** statement to the same destination PE router, the first LSP configured is used to monitor the forwarding state to that PE router. If you configure multiple LSPs to the same destination, make sure to configure similar parameters for the LSPs. With this configuration scenario, a failure notification might be triggered even though the remote PE router is still up.

## Preserving Point-to-Multipoint LSP Functioning with Different Junos OS Releases

In Junos OS Release 9.1 and earlier, Resv messages that include the S2L\_SUB\_LSP object are rejected by default. In Junos OS Release 9.2 and later, such messages are accepted by default. To ensure proper functioning of point-to-multipoint LSPs in a network that includes both devices running Junos OS Release 9.1 and earlier and devices running Junos 9.2 and later, you must include the **no-p2mp-sublsp** statement in the configuration of the devices running Junos 9.2 and later:

```
no-p2mp-sublsp;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

## DiffServ-Aware Traffic Engineering Introduction

---

Differentiated Services (DiffServ)-aware traffic engineering provides a way to guarantee a specified level of service over an MPLS network. The routers providing DiffServ-aware traffic engineering are part of a differentiated services network domain. All routers participating in a differentiated services domain must have DiffServ-aware traffic engineering enabled.

To help ensure that the specified service level is provided, it is necessary to ensure that no more than the amount of traffic specified is sent over the differentiated services domain. You can accomplish this goal by configuring a policer to police or rate-limit the volume of traffic transiting the differentiated service domain. For more information about how to configure policers for label-switched paths (LSPs), see “[Configuring Policers for LSPs](#)” on page 375.

This feature can help to improve the quality of Internet services such as voice over IP (VoIP). It also makes it possible to better emulate an Asynchronous Transfer Mode (ATM) circuit over an MPLS network.

## DiffServ-Aware Traffic Engineering Standards

---

The following RFCs provide information on DiffServ-aware traffic engineering and multiclass LSPs:

- RFC 3270, *Multi-Protocol Label Switching (MPLS) Support of Differentiated Services*
- RFC 3564, *Requirements for Support of Differentiated Services-aware MPLS Traffic Engineering*
- RFC 4124, *Protocol Extensions for Support of Differentiated-Service-Aware MPLS Traffic Engineering*
- RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diff-Serv-aware MPLS Traffic Engineering*
- RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diff-Serv-aware MPLS*

These RFCs are available on the IETF website at <http://www.ietf.org/>.

## DiffServ-Aware Traffic Engineering Terminology

---

### B

**Bandwidth model** The bandwidth model determines the values of the available bandwidth advertised by the interior gateway protocols (IGPs).

### C

**CAC** Call admission control (CAC) checks to ensure there is adequate bandwidth on the path before the LSP is established. If the bandwidth is insufficient, the LSP is not established and an error is reported.

|                                           |                                                                                                                                                                                                                                          |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Class type</b>                         | A collection of traffic flows that is treated equivalently in a differentiated services domain. A class type maps to a queue and is much like a class-of-service (CoS) forwarding class in concept. It is also known as a traffic class. |
| <b>D</b>                                  |                                                                                                                                                                                                                                          |
| <b>Differentiated Services</b>            | Differentiated Services make it possible to give different treatment to traffic based on the EXP bits in the MPLS header. Traffic must be marked appropriately and CoS must be configured.                                               |
| <b>Differentiated Services domain</b>     | The routers in a network that have Differentiated Services enabled.                                                                                                                                                                      |
| <b>DiffServ-aware traffic engineering</b> | A type of constraint-based routing. It can enforce different bandwidth constraints for different classes of traffic. It can also do CAC on each traffic engineering class when an LSP is established.                                    |
| <b>M</b>                                  |                                                                                                                                                                                                                                          |
| <b>MAM</b>                                | The maximum allocation bandwidth constraint model divides the available bandwidth between the different classes. Sharing of bandwidth between the class types is not allowed.                                                            |
| <b>Multiclass LSP</b>                     | A multiclass LSP functions like a standard LSP, but it also allows you to reserve bandwidth from multiple class types. The EXP bits of the MPLS header are used to distinguish between class types.                                      |
| <b>R</b>                                  |                                                                                                                                                                                                                                          |
| <b>RDM</b>                                | The Russian dolls bandwidth constraint model makes efficient use of bandwidth by allowing the class types to share bandwidth.                                                                                                            |
| <b>T</b>                                  |                                                                                                                                                                                                                                          |
| <b>Traffic engineering class</b>          | A paired class type and priority.                                                                                                                                                                                                        |
| <b>Traffic engineering class map</b>      | A map between the class types, priorities, and traffic engineering classes. The traffic engineering class mapping must be consistent across the Differentiated Services domain.                                                          |

---

## DiffServ-Aware Traffic Engineering Features

DiffServ-aware traffic engineering provides the following features:

- Traffic engineering at a per-class level rather than at an aggregate level
- Different bandwidth constraints for different class types (traffic classes)
- Different queuing behaviors per class, allowing the router to forward traffic based on the class type

In comparison, standard traffic engineering does not consider CoS, and it completes its work on an aggregate basis across all Differentiated Service classes.

DiffServ-aware traffic engineering provides the following advantages:

- Traffic engineering can be performed on a specific class type instead of at the aggregate level.
- Bandwidth constraints can be enforced on each specific class type.
- It forwards traffic based on the EXP bits.

This makes it possible to guarantee service and bandwidth across an MPLS network. With DiffServ-aware traffic engineering, among other services, you can provide ATM circuit emulation, VoIP, and a guaranteed bandwidth service.

The following describes how the IGP, Constrained Shortest Path First (CSPF), and RSVP participate in DiffServ-aware traffic engineering:

- The IGP can advertise the unreserved bandwidth for each traffic engineering class to the other members of the differentiated services domain. The traffic engineering database stores this information.
- A CSPF calculation is performed considering the bandwidth constraints for each class type. If all the constraints are met, the CSPF calculation is considered successful.
- When RSVP signals an LSP, it requests bandwidth for specified class types.

---

## DiffServ-Aware Traffic Engineered LSPs

A DiffServ-aware traffic engineered LSP is an LSP configured to reserve bandwidth for one of the supported class types and to carry traffic for that class type. The following sections discuss this type of LSPs:

- [DiffServ-Aware Traffic Engineered LSPs Overview on page 340](#)
- [DiffServ-Aware Traffic Engineered LSPs Operation on page 341](#)

---

## DiffServ-Aware Traffic Engineered LSPs Overview

A DiffServ-aware traffic engineered LSP is an LSP configured with a bandwidth reservation for a specific class type. This LSP can carry traffic for a single class type. On the packets, the class type is specified by the EXP bits (also known as the class-of-service bits) and the per-hop behavior (PHB) associated with the EXP bits. The mapping between the EXP bits and the PHB is static, rather than being signaled in RSVP.

The class type must be configured consistently across the Differentiated Services domain, meaning the class type configuration must be consistent from router to router in the network. You can unambiguously map a class type to a queue. On each node router, the class-of-service queue configuration for an interface translates to the available bandwidth for a particular class type on that link.

For more information about topics related to LSPs and DiffServ-aware traffic engineering, see the following:

- For forwarding classes and class of service, see the *Class of Service Feature Guide for Routing Devices*.
- For EXP bits, see [“MPLS Label Allocation” on page 26](#).
- For differentiated services, see RFC 3270, *Multi-Protocol Label Switching (MPLS) Support of Differentiated Services*.
- For information about how the IGPs and RSVP have been modified to support Differentiated Services-aware MPLS traffic engineering, see RFC 4124, *Protocol Extensions for Support of Differentiated-Service-Aware MPLS Traffic Engineering*.

## DiffServ-Aware Traffic Engineered LSPs Operation

---

When configuring a DiffServ-aware traffic engineered LSP, you specify the class type and the bandwidth associated with it. The following occurs when an LSP is established with bandwidth reservation from a specific class type:

1. The IGPs advertise how much unreserved bandwidth is available for the traffic engineering classes.
2. When calculating the path for an LSP, CSPF is used to ensure that the bandwidth constraints are met for the class type carried by the LSP at the specified priority level.  
  
CSPF also checks to ensure that the bandwidth model is configured consistently on each router participating in the LSP. If the bandwidth model is inconsistent, CSPF does not compute the path (except for LSPs from class type ct0).
3. Once a path is found, RSVP signals the LSP using the Classtype object in the path message. At each node in the path, the available bandwidth for the class types is adjusted as the path is set up.

An LSP that requires bandwidth from a particular class (except class type ct0) cannot be established through routers that do not understand the Classtype object. Preventing the use of routers that do not understand the Classtype object helps to ensure consistency throughout the Differentiated Services domain by preventing the LSP from using a router that cannot support Differentiated Services.

By default, LSPs are signaled with setup priority 7 and holding priority 0. An LSP configured with these values cannot preempt another LSP at setup time and cannot be preempted.

It is possible to have both LSPs configured for DiffServ-aware traffic engineering and regular LSPs configured at the same time on the same physical interfaces. For this type of heterogeneous environment, regular LSPs carry best-effort traffic by default. Traffic carried in the regular LSPs must have the correct EXP settings (either by remarking the EXP settings or by assuming that the traffic arrived with the correct EXP settings from the upstream router).

## Multiclass LSPs

---

Multiclass LSPs function like standard LSPs, but they also allow you to configure multiple class types with guaranteed bandwidth. The EXP bits of the MPLS header are used to distinguish between class types. Multiclass LSPs can be configured for a variety of

purposes. For example, you can configure a multiclass LSP to emulate the behavior of an ATM circuit. An ATM circuit can provide service-level guarantees to a class type. A multiclass LSP can provide a similar guaranteed level of service.

The following sections discuss multiclass LSPs:

- [Multiclass LSP Overview on page 342](#)
- [Establishing a Multiclass LSP on the Differentiated Services Domain on page 342](#)

---

## Multiclass LSP Overview

A multiclass LSP is an LSP that can carry several class types. One multiclass LSP can be used to support up to four class types. On the packets, the class type is specified by the EXP bits (also known as the class-of-service bits) and the per-hop behavior (PHB) associated with the EXP bits. The mapping between the EXP bits and the PHB is static, rather than being signaled in RSVP.

Once a multiclass LSP is configured, traffic from all of the class types can:

- Follow the same path
- Be rerouted along the same path
- Be taken down at the same time

Class types must be configured consistently across the Differentiated Services domain, meaning the class type configuration must be consistent from router to router in the network.

You can unambiguously map a class type to a queue. On each node router, the CoS queue configuration for an interface translates to the available bandwidth for a particular class type on that link.

The combination of a class type and a priority level forms a traffic engineering class. The IGP can advertise up to eight traffic engineering classes for each link.

For more information about the EXP bits, see [“MPLS Label Allocation” on page 26](#).

For more information about forwarding classes, see the *Class of Service Feature Guide for Routing Devices*.

---

## Establishing a Multiclass LSP on the Differentiated Services Domain

The following occurs when a multiclass LSP is established on the differentiated services domain:

1. The IGPs advertise how much unreserved bandwidth is available for the traffic engineering classes.
2. When calculating the path for a multiclass LSP, CSPF is used to ensure that the constraints are met for all the class types carried by the multiclass LSP (a set of constraints instead of a single constraint).

3. Once a path is found, RSVP signals the LSP using an RSVP object in the path message. At each node in the path, the available bandwidth for the class types is adjusted as the path is set up. The RSVP object is a hop-by-hop object. Multiclass LSPs cannot be established through routers that do not understand this object. Preventing routers that do not understand the RSVP object from carrying traffic helps to ensure consistency throughout the differentiated services domain by preventing the multiclass LSP from using a router that is incapable of supporting differentiated services.

By default, multiclass LSPs are signaled with setup priority 7 and holding priority 0. A multiclass LSP configured with these values cannot preempt another LSP at setup time and cannot be preempted.

It is possible to have both multiclass LSPs and regular LSPs configured at the same time on the same physical interfaces. For this type of heterogeneous environment, regular LSPs carry best-effort traffic by default. Traffic carried in the regular LSPs must have the correct EXP settings.

## Configuring Routers for DiffServ-Aware Traffic Engineering

To configure DiffServ-aware traffic engineering, include the **diffserv-te** statement:

```
diffserv-te {
  bandwidth-model {
    extended-mam;
    mam;
    rdm;
  }
  te-class-matrix {
    traffic-class {
      tenumber {
        priority priority;
        traffic-class ctnumber priority priority;
      }
    }
  }
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

You must include the **diffserv-te** statement in the configuration on all routers participating in the Differentiated Services domain. However, you are not required to configure the traffic engineering class matrix (by including the **te-class-matrix** statement at the [edit protocols mpls **diffserv-te**] or [edit logical-systems *logical-system-name* protocols mpls **diffserv-te**] hierarchy level).

**NOTE:** To prevent the possibility of an incorrect configuration when migrating to Diffserv-aware traffic engineering, a policy control failure error might be triggered if there is conflict between the old LSPs and the newly configured TE-class matrix.

An old node might request an LSP with setup and hold priorities in such a way that the combination of the ct0 class and the priority does not match with the configured TE-class matrix. All LSPs on the router that are configured prior to configuring diffserv-aware traffic engineering are designated as being from class ct0.

The error appears in the RSVP tracing logs as a **Session preempted** error. For the router where the error originates, the error could appear as follows:

```
Jun 17 16:35:59 RSVP error for session 10.255.245.6(port/tunnel ID 31133)
  Proto 0: (class ct0, priority 2) is not a valid TE-class Jun 17
16:35:59 RSVP originate PathErr 192.168.37.22->192.168.37.23 Session
preempted
```

For the router receiving the error, the error can appear as follows:

```
Jun 17 16:37:51 RSVP recv PathErr 192.168.37.22->192.168.37.23 Session
preempted LSP to-f(2/31133)
```

To configure DiffServ-aware traffic engineering, complete the procedures in the following sections:

- [Configuring the Bandwidth Model on page 344](#)
- [Configuring Traffic Engineering Classes on page 345](#)
- [Configuring Class of Service for DiffServ-Aware Traffic Engineering on page 346](#)

## Configuring the Bandwidth Model

You must configure a bandwidth model on all routers participating in the Differentiated Services domain. The bandwidth models available are MAM, extended MAM, and RDM:

- Maximum allocation bandwidth constraints model (MAM)—Defined in RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*.
- Extended MAM—A proprietary bandwidth model that behaves much like standard MAM. If you configure multiclass LSPs, you must configure the extended MAM bandwidth model.
- Russian-dolls bandwidth allocation model (RDM)—Makes efficient use of bandwidth by allowing the class types to share bandwidth. RDM is defined in RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*.

To configure a bandwidth model, include the **bandwidth-model** statement and specify one of the bandwidth model options:

```
bandwidth-model {
  extended-mam;
```

```

    mam;
    rdm;
}

```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls [diffserv-te](#)]
- [edit logical-systems *logical-system-name* protocols mpls [diffserv-te](#)]

**NOTE:** If you change the bandwidth model on an ingress router, all the LSPs enabled on the router are taken down and resigaled.

## Configuring Traffic Engineering Classes

Configuring traffic engineering classes is optional. [Table 7 on page 345](#) shows the default values for everything in the traffic engineering class matrix. The default mapping is expressed in terms of the default forwarding classes defined in the CoS configuration.

**Table 7: Default Values for the Traffic Engineering Class Matrix**

| Traffic Engineering Class | Class Type | Queue | Priority |
|---------------------------|------------|-------|----------|
| te0                       | ct0        | 0     | 7        |
| te1                       | ct1        | 1     | 7        |
| te2                       | ct2        | 2     | 7        |
| te3                       | ct3        | 3     | 7        |
| te4                       | ct0        | 0     | 0        |
| te5                       | ct1        | 1     | 0        |
| te6                       | ct2        | 2     | 0        |
| te7                       | ct3        | 3     | 0        |

If you want to override the default mappings, you can configure traffic engineering classes 0 through 7. For each traffic engineering class, you configure a class type (or queue) from 0 through 3. For each class type, you configure a priority from 0 through 7.

To configure traffic engineering classes explicitly, include the **te-class-matrix** statement:

```

te-class-matrix {
  tnumber {
    priority priority;
    traffic-class {
      ctnumber priority priority;
    }
  }
}

```

```

    }
  }

```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls [diffserv-te](#)]
- [edit logical-systems *logical-system-name* protocols mpls [diffserv-te](#)]

The following example shows how to configure traffic engineering class **te0** with class type **ct1** and a priority of 4:

```

[edit protocols mpls diffserv-te]
te-class-matrix {
  te0 traffic-class ct1 priority 4;
}

```

**NOTE:** If you explicitly configure a value for one of the traffic engineering classes, all the default values in the traffic engineering class matrix are dropped.

When you explicitly configure traffic engineering classes, you must also configure a bandwidth model; otherwise, the configuration commit operation fails.

### Requirements and Limitations for the Traffic Engineering Class Matrix

When you configure a traffic engineering class matrix, be aware of the following requirements and limitations:

- A mapping configuration is local and affects only the router on which it is configured. It does not affect other systems participating in the differentiated services domain. However, for a Differentiated Services domain to function properly, you need to configure the same traffic engineering class matrix on all the routers participating in the same domain.
- When explicitly configuring traffic engineering classes, you must configure the classes in sequence (**te0**, **te1**, **te2**, **te3**, and so on); otherwise, the configuration commit operation fails.

The first traffic engineering class you configure must be **te0**; otherwise, the configuration commit operation fails.

### Configuring Class of Service for DiffServ-Aware Traffic Engineering

To configure DiffServ-aware traffic engineering, you must also configure class of service. The following example illustrates a class-of-service configuration that would allocate 25 percent of the link bandwidth to each class:

```

class-of-service {
  interfaces {
    all {
      scheduler-map simple-map;
    }
  }
}

```

```

    }
  }
  scheduler-maps {
    simple-map {
      forwarding-class assured-forwarding scheduler simple_sched;
      forwarding-class best-effort scheduler simple_sched;
      forwarding-class network-control scheduler simple_sched;
      forwarding-class expedited-forwarding scheduler simple_sched;
    }
  }
  schedulers {
    simple_sched {
      transmit-rate percent 25;
      buffer-size percent 25;
    }
  }
}

```

For more information on how to configure class of service, see the *Class of Service Feature Guide for Routing Devices*.

## LSP Bandwidth Oversubscription Overview

LSPs are established with bandwidth reservations configured for the maximum amount of traffic you expect to traverse the LSP. Not all LSPs carry the maximum amount of traffic over their links at all times. For example, even if the bandwidth for link A has been completely reserved, actual bandwidth might still be available but not currently in use. This excess bandwidth can be used by allowing other LSPs to also use link A, oversubscribing the link. You can oversubscribe the bandwidth configured for individual class types or specify a single value for all of the class types using an interface.

You can use oversubscription to take advantage of the statistical nature of traffic patterns and to permit higher utilization of links.

The following examples describe how you might use bandwidth oversubscription and undersubscription:

- Use oversubscription on class types where peak periods of traffic do not coincide in time.
- Use oversubscription of class types carrying best-effort traffic. You take the risk of temporarily delaying or dropping traffic in exchange for making better utilization of network resources.
- Give different degrees of oversubscription or undersubscription of traffic for the different class types. For instance, you configure the subscription for classes of traffic as follows:
  - Best effort—**ct0 1000**
  - Voice—**ct3 1**

When you undersubscribe a class type for a multiclass LSP, the total demand of all RSVP sessions is always less than the actual capacity of the class type. You can use undersubscription to limit the utilization of a class type.

The bandwidth oversubscription calculation occurs on the local router only. Because no signaling or other interaction is required from other routers in the network, the feature can be enabled on individual routers without being enabled or available on other routers which might not support this feature. Neighboring routers do not need to know about the oversubscription calculation, they rely on the IGP.

The following sections describe the types of bandwidth oversubscription available in the Junos OS:

- [LSP Size Oversubscription on page 348](#)
- [LSP Link Size Oversubscription on page 348](#)
- [Class Type Oversubscription and Local Oversubscription Multipliers on page 348](#)

---

## LSP Size Oversubscription

For LSP size oversubscription, you simply configure less bandwidth than the peak rate expected for the LSP. You also might need to adjust the configuration for automatic policers. Automatic policers manage the traffic assigned to an LSP, ensuring that it does not exceed the configured bandwidth values. LSP size oversubscription requires that the LSP can exceed its configured bandwidth allocation.

Policing is still possible. However, the policer must be manually configured to account for the maximum bandwidth planned for the LSP, rather than for the configured value.

---

## LSP Link Size Oversubscription

You can increase the maximum reservable bandwidth on the link and use the inflated values for bandwidth accounting. Use the **subscription** statement to oversubscribe the link. The configured value is applied to all class type bandwidth allocations on the link. For more information about link size oversubscription, see [“Configuring the Bandwidth Subscription Percentage for LSPs” on page 351](#).

---

## Class Type Oversubscription and Local Oversubscription Multipliers

Local oversubscription multipliers (LOMs) allow different oversubscription values for different class types. LOMs are useful for networks where the oversubscription ratio needs to be configured differently on different links and where oversubscription values are required for different classes. You might use this feature to oversubscribe class types handling best-effort traffic, but use no oversubscription for class types handling voice traffic. An LOM is calculated locally on the router. No information related to an LOM is signaled to other routers in the network.

An LOM is configurable on each link and for each class type. The per-class type LOM allows you to increase or decrease the oversubscription ratio. The per-class-type LOM is factored into all local bandwidth accounting for admission control and IGP advertisement of unreserved bandwidths.

The LOM calculation is tied to the bandwidth model (MAM, extended MAM, and Russian dolls) used, because the effect of oversubscription across class types must be accounted for accurately.

**NOTE:** All LOM calculations are performed by the Junos OS and require no user intervention.

The formulas related to the oversubscription of class types are described in the following sections:

- [Class Type Bandwidth and the LOM on page 349](#)
- [LOM Calculation for the MAM and Extended MAM Bandwidth Models on page 349](#)
- [LOM Calculation for the Russian Dolls Bandwidth Model on page 350](#)
- [Example: LOM Calculation on page 350](#)

## Class Type Bandwidth and the LOM

The following formula expresses the relationship between the bandwidth of the class type and the LOM. The normalized bandwidth of the class type ( $N_B$ ) is equal to the reserved bandwidth of the class type ( $R_B$ ) divided by the LOM of the class type ( $L_C$ ):

$$N_B = R_B / L_C$$

When calculating available bandwidth, you need to subtract the normalized bandwidth from the relevant bandwidth constraint.

**NOTE:** When using an LOM, values advertised for the available bandwidth might be larger than the bandwidth constraint values. However, the values advertised in the maximum link bandwidth advertisement are not affected by local oversubscription.

## LOM Calculation for the MAM and Extended MAM Bandwidth Models

The following formulas show how the LOM is calculated for the MAM and extended MAM bandwidth models.

$$\text{Unreserved TE-Class}(i) = \text{LOM}_c \times [ \text{BC}_c - \text{SUM} ( \text{Normalized} ( \text{CT}_c, q ) ) ] \text{ for } q \leq p$$

Or

$$\text{Unreserved TE-Class}(i) = ( \text{LOM}_c \times \text{BC}_c ) - \text{SUM} ( \text{Reserved} ( \text{CT}_c, q ) ) \text{ for } q \leq p$$

where:

- LOM<sub>c</sub>—LOM for class type *c*.
- BC<sub>c</sub>—Bandwidth constraint for class type *c*.
- CT<sub>c</sub>—Class type *c*.
- TE-Class(*i*) ↔ (CT<sub>c</sub>, preemption *p*) in the configured TE-Class mapping.

## LOM Calculation for the Russian Dolls Bandwidth Model

The following formulas show how the LOM is calculated for the Russian dolls bandwidth model:

$$\text{Unreserved TE-Class (i)} = \text{LOM}_c \times \text{MIN} [$$

$$[ \text{BC}_c - \text{SUM} ( \text{Normalized} ( \text{CT}_b, q ) ) ] \text{ for } q \leq p \text{ and } c \leq b \leq 7,$$

$$\vdots$$

$$[ \text{BC}_0 - \text{SUM} ( \text{Normalized} ( \text{CT}_b, q ) ) ] \text{ for } q \leq p \text{ and } 0 \leq b \leq 7,$$

$$]$$

where:

- LOM<sub>c</sub>—LOM for class type *c*.
- BC<sub>c</sub>—Bandwidth constraint for class type *c*.
- TE-Class(*i*) ↔ (CT<sub>c</sub>, preemption *p*) in the configured TE-Class mapping.

Note that the impact of an LSP on the unreserved bandwidth of a class type does not depend only on the LOM for that class type—it also depends on the LOM for the class type of the LSP.

## Example: LOM Calculation

The following example illustrates how an LOM calculation is made for four classes of traffic: **ct0**, **ct1**, **ct2**, and **ct3**.

The class types have been assigned the following values:

```
ct0 = 40
ct1 = 30
ct2 = 20
ct3 = 10
```

These class type values yield the following bandwidth constraints:

```
BC0 = (ct3 + ct2 + ct1 + ct0) = 100
BC1 = (ct3 + ct2 + ct1) = 60
BC2 = (ct3 + ct2) = 30
BC3 = (ct3) = 10
```

LSPs from class type **ct0** can take up to 100 percent of bandwidth on the link. LSPs from class type **ct1** can take up to 60 percent of the bandwidth on the link, and so on.

If you assume for this example that the class types have the following LOM values:

LOM(ct0) = 8  
LOM(ct1) = 4  
LOM(ct2) = 2  
LOM(ct3) = 1

In the absence of any other reservation, LSPs from class type **ct0** can take up to 800 percent of the available bandwidth ( $8 \times 100 = 800$ ). In the absence of any other reservation, LSPs from class type **ct1** can take up to 240 percent of the available bandwidth ( $4 \times 60 = 240$ ), and so on.

The maximum amount of bandwidth that can be reserved is:

ct0 = LOM(ct0) x BC0 = 800  
ct1 = LOM(ct1) x BC1 = 240  
ct2 = LOM(ct2) x BC2 = 60  
ct3 = LOM(ct3) x BC3 = 10

For the undersubscribed class type **ct3**, the maximum reservable bandwidth is the same as the bandwidth constraint. For the overbooked class types, these values are not the values of the bandwidth constraint-taking into account the oversubscription for each class type separately. The oversubscription per class type in the sum is not taken into account because ultimately the entire bandwidth constraint can be filled with the bandwidth reservation of just one class type, so you have to account for that class type's bandwidth oversubscription only.

When calculating the available bandwidth for **CTc**, you need to express reservations from other classes as if they were from **CTc**. The reservation from class **ctx** is normalized with the LOM of **ctx**, but it is then multiplied by the LOM of **CTc**.

For the previous example, assume that **LSP1** has class type **ct3** configured with bandwidth of 10 and a priority of 0.

The values for the reservable bandwidth will be:

ct0 =  $8 \times (100 - 10) = 720$   
ct1 =  $4 \times \min((100-10), (60-10)) = 200$   
ct2 =  $2 \times \min((100-10), (60-10), (30-10)) = 40$   
ct3 =  $1 \times \min((100-10), (60-10), (30-10), (10-10)) = 0$

These numbers can be rationalized as follows: the normalized reservation is 10 percent. If this bandwidth came from class type **ct0**, it would be equivalent to an overbooked reservation of 80 percent. You can see that 720 percent ( $800 - 80 = 720$ ) of the bandwidth remains available for other LSPs.

---

## Configuring the Bandwidth Subscription Percentage for LSPs

---

By default, RSVP allows all of a class type's bandwidth (100 percent) to be used for RSVP reservations. When you oversubscribe a class type for a multiclass LSP, the aggregate demand of all RSVP sessions is allowed to exceed the actual capacity of the class type.

If you want to oversubscribe or undersubscribe all of the class types on an interface using the same percentage bandwidth, configure the percentage using the **subscription** statement:

**subscription percentage;**

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

To undersubscribe or oversubscribe the bandwidth for each class type, configure a percentage for each class type (**ct0**, **ct1**, **ct2**, and **ct3**) option for the **subscription** statement. When you oversubscribe a class type, an LOM is applied to calculate the actual bandwidth reserved. See “[Class Type Oversubscription and Local Oversubscription Multipliers](#)” on [page 348](#) for more information.

```
subscription {
  ct0 percentage;
  ct1 percentage;
  ct2 percentage;
  ct3 percentage;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

**percentage** is the percentage of class type bandwidth that RSVP allows to be used for reservations. It can be a value from 0 through 65,000 percent. If you specify a value greater than 100, you are oversubscribing the interface or class type.

The value you configure when you oversubscribe a class type is a percentage of the class type bandwidth that can actually be used. The default subscription value is 100 percent.

You can use the **subscription** statement to disable new RSVP sessions for one or more class types. If you configure a percentage of 0, no new sessions (including those with zero bandwidth requirements) are permitted for the class type.

Existing RSVP sessions are not affected by changing the subscription factor. To clear an existing session, issue the **clear rsvp session** command. For more information on the **clear rsvp session** command, see the [CLI Explorer](#).

## Constraints on Configuring Bandwidth Subscription

Be aware of the following issues when configuring bandwidth subscription:

- If you configure bandwidth constraints at the **[edit class-of-service interface *interface-name*]** hierarchy level, they override any bandwidth configuration you specify at the **[edit protocols rsvp interface *interface-name* bandwidth]** hierarchy level for Diffserv-TE. Also note that either of the CoS or RSVP bandwidth constraints can override the interface hardware bandwidth constraints.
- If you configure a bandwidth subscription value for a specific interface that differs from the value configured for all interfaces (by including different values for the **subscription** statement at the **[edit protocols rsvp interface *interface-name*]** and **[edit protocols rsvp interface all]** hierarchy levels), the interface-specific value is used for that interface.
- You can configure subscription for each class type only if you also configure a bandwidth model. If no bandwidth model is configured, the commit operation fails with the following error message:

```

user@host# commit check
[edit protocols rsvp interface all]
'subscription'
RSVP: Must have a diffserv-te bandwidth model configured when configuring
subscription per traffic class.
error: configuration check-out failed

```

- You cannot include the **subscription** statement both in the configuration for a specific class type and the configuration for the entire interface. The commit operation fails with the following error message:

```

user@host# commit check
[edit protocols rsvp interface all]
'subscription'
RSVP: Cannot configure both link subscription and per traffic class
subscription.
error: configuration check-out failed

```

## Configuring LSPs for DiffServ-Aware Traffic Engineering

You must configure the Differentiated Services domain (see [“Configuring Routers for DiffServ-Aware Traffic Engineering” on page 343](#)) before you can enable DiffServ-aware traffic engineering for LSPs. The Differentiated Services domain provides the underlying class types and corresponding traffic engineering classes that you reference in the LSP configuration. The traffic engineering classes must be configured consistently on each router participating in the Differentiated Services domain for the LSP to function properly.

**NOTE:** You must configure either MAM or RDM as the bandwidth model when you configure DiffServ-aware traffic engineering for LSPs. See [“Configuring the Bandwidth Model” on page 344](#).

The actual data transmitted over this Differentiated Services domain is carried by an LSP. Each LSP relies on the EXP bits of the MPLS packets to enable DiffServ-aware traffic engineering. Each LSP can carry traffic for a single class type.

All the routers participating in the LSP must be Juniper Networks routers running Junos OS Release 6.3 or later. The network can include routers from other vendors and Juniper Networks routers running earlier versions of the Junos OS. However, the DiffServ-aware traffic engineering LSP cannot traverse these routers.

**NOTE:** You cannot simultaneously configure multiclass LSPs and DiffServ-aware traffic engineering LSPs on the same router.

To enable DiffServ-aware traffic engineering for LSPs, you need to configure the following:

- [Configuring Class of Service for the Interfaces on page 354](#)
- [Configuring IGP on page 354](#)
- [Configuring Traffic-Engineered LSPs on page 354](#)

- [Configuring Policing for LSPs on page 355](#)
- [Configuring Fast Reroute for Traffic-Engineered LSPs on page 355](#)

## Configuring Class of Service for the Interfaces

The existing class-of-service (CoS) infrastructure ensures that traffic that is consistently marked receives the scheduling guarantees for its class. The classification, marking, and scheduling necessary to accomplish this are configured using the existing Junos OS CoS features.

**NOTE:** The Junos OS does not support CoS on ATM interfaces.

For information about how to configure CoS, see the *Class of Service Feature Guide for Routing Devices*.

## Configuring IGP

You can configure either IS-IS or OSPF as the IGP. The IS-IS and OSPF configurations for routers supporting LSPs are standard. For information about how to configure these protocols, see the *Junos OS Routing Protocols Library*.

## Configuring Traffic-Engineered LSPs

You configure an LSP by using the standard LSP configuration statements and procedures. To configure DiffServ-aware traffic engineering for the LSP, specify a class type bandwidth constraint by including the **bandwidth** statement:

```
label-switched-path lsp-name {  
  bandwidth {  
    ctnumber bps;  
  }  
}
```

For a list of hierarchy levels at which you can include the **bandwidth** statement, see the statement summary sections for this statement.

If you do not specify a bandwidth for a class type, **ct0** is automatically specified as the queue for the LSP. You can configure only one class type for each LSP, unlike multiclass LSPs.

The class type statements specify bandwidth (in bits per second) for the following classes:

- **ct0**—Bandwidth reserved for class 0
- **ct1**—Bandwidth reserved for class 1
- **ct2**—Bandwidth reserved for class 2
- **ct3**—Bandwidth reserved for class 3

You can configure setup and holding priorities for an LSP, but the following restrictions apply:

- The combination of class and priority must be one of the configured traffic engineering classes. The default setup priority is 7 and the default holding priority is 0.
- Configuring an invalid combination of class type and priority causes the commit operation to fail.
- Automatic bandwidth allocation is not supported. If you configure automatic bandwidth allocation, the commit operation fails.
- LSPs configured with the **bandwidth** statement but without specifying a class type use the default class type **ct0**.
- For migration issues, see Internet draft [draft-ietf-tewg-diff-te-07.txt](#).

## Configuring Policing for LSPs

Policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. You can configure multiple policers for each LSP.

For information about how to configure a policer for an LSP, see [“Configuring Policers for LSPs” on page 375](#).

## Configuring Fast Reroute for Traffic-Engineered LSPs

You can configure fast reroute for traffic engineered LSPs (LSPs carrying a single class of traffic). It is also possible to reserve bandwidth on the detour path for the class of traffic when fast reroute is enabled. The same class type number is used for both the traffic engineered LSP and its detour.

If you configure the router to reserve bandwidth for the detour path, a check is made to ensure that the link is capable of handling DiffServ-aware traffic engineering and for CoS capability before accepting it as a potential detour path. Unsupported links are not used.

You can configure the amount of bandwidth to reserve for detours using either the **bandwidth** statement or the **bandwidth-percent** statement. You can only configure one of these statements at a time. If you do not configure either the **bandwidth** statement or the **bandwidth-percent** statement, the default setting is to not reserve bandwidth for the detour path (the bandwidth guarantee will be lost if traffic is switched to the detour).

When you configure the **bandwidth** statement, you can specify the specific amount of bandwidth (in bits per second [bps]) you want to reserve for the detour path. For information, see [“Configuring Fast Reroute” on page 254](#).

The **bandwidth-percent** statement allows you to specify the bandwidth of the detour path as a percentage of the bandwidth configured for the protected path. For example, if you configure 100 millions bps of bandwidth for the protected path and configure 20 for the **bandwidth-percent** statement, the detour path will have 20 million bps of bandwidth reserved for its use.

To configure the percent of bandwidth used by the detour path based on the bandwidth of the protected path, include the **bandwidth-percent** statement:

```
bandwidth-percent percentage;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name* **fast-reroute**]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name* **fast-reroute**]

---

## Configuring Multiclass LSPs

A multiclass LSP is an LSP configured to reserve bandwidth for multiple class types and also carries the traffic for these class types. The differentiated service behavior is determined by the EXP bits.

You must configure the Differentiated Services domain (see “[Configuring Routers for DiffServ-Aware Traffic Engineering](#)” on page 343) before you can enable a multiclass LSP. The Differentiated Services domain provides the underlying class types and corresponding traffic engineering classes that you reference in a multiclass LSP configuration. The traffic engineering classes must be configured consistently on each router participating in the Differentiated Services domain for the multiclass LSP to function properly.

**NOTE:** You must configure extended MAM as the bandwidth model when you configure multiclass LSPs. See “[Configuring the Bandwidth Model](#)” on page 344.

All the routers participating in a multiclass LSP must be Juniper Networks routers running Junos OS Release 6.2 or later. The network can include routers from other vendors and Juniper Networks routers running earlier versions of the Junos OS. However, the multiclass LSP cannot traverse these routers.

To enable multiclass LSPs, you need to configure the following:

- [Configuring Class of Service for the Interfaces](#) on page 356
- [Configuring the IGP](#) on page 357
- [Configuring Class-Type Bandwidth Constraints for Multiclass LSPs](#) on page 357
- [Configuring Policing for Multiclass LSPs](#) on page 358
- [Configuring Fast Reroute for Multiclass LSPs](#) on page 358

## Configuring Class of Service for the Interfaces

The existing class-of-service infrastructure ensures that traffic that is consistently marked receives the scheduling guarantees for its class. The classification, marking, and scheduling necessary to consistently mark traffic are configured with the existing Junos OS CoS features.

**NOTE:** The Junos OS does not support ATM interfaces.

For information about how to configure CoS, see the *Class of Service Feature Guide for Routing Devices*.

## Configuring the IGP

You can configure either IS-IS or OSPF. The IS-IS and OSPF configurations for routers supporting multiclass LSPs are standard. For information about how to configure these protocols, see the *Junos OS Routing Protocols Library*.

## Configuring Class-Type Bandwidth Constraints for Multiclass LSPs

You configure a multiclass LSP by using the standard LSP configuration statements and procedures. To configure an LSP as a multiclass LSP, specify the class type bandwidth constraints by including the **bandwidth** statement:

```
bandwidth {
  ct0 bps;
  ct1 bps;
  ct2 bps;
  ct3 bps;
}
```

For a list of hierarchy levels at which you can include the **bandwidth** statement, see the statement summary sections for these statements.

The class type statements specify bandwidth (in bits per second) for the following classes:

- **ct0**—Bandwidth reserved for class 0
- **ct1**—Bandwidth reserved for class 1
- **ct2**—Bandwidth reserved for class 2
- **ct3**—Bandwidth reserved for class 3

For example, to configure 50 megabytes of bandwidth for class type 1 and 30 megabytes of bandwidth for class type 2, include the **bandwidth** statement as follows:

```
[edit protocols mpls]
label-switched-path traffic-class {
  bandwidth {
    ct1 50M;
    ct2 30M;
  }
}
```

You cannot configure a bandwidth for a class type and also configure a bandwidth at the **[edit protocols mpls label-switched-path *lsp-name* bandwidth]** hierarchy level. For example, the following configuration cannot be committed:

```
[edit protocols mpls]
label-switched-path traffic-class {
```

```
    bandwidth {  
      20M;  
      ct1 10M;  
    }  
  }
```

You can configure setup and holding priorities for a multiclass LSP, but the following restrictions apply:

- The setup and holding priorities apply to all classes for which bandwidth is requested.
- The combination of class and priority must be one of the configured traffic engineering classes. The default traffic engineering class configuration results in multiclass LSPs that cannot preempt and cannot be preempted. The default setup priority is 7 and the default holding priority is 0.
- Configuring an invalid combination of class type and priority causes the commit operation to fail.
- Automatic bandwidth allocation is not supported for multiclass LSPs. If you configure automatic bandwidth allocation, the commit operation fails.
- LSPs configured with the **bandwidth** statement but without specifying a class type use the default class type **ct0**.

## Configuring Policing for Multiclass LSPs

Policing allows you to control the amount of traffic forwarded through a particular multiclass LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. You can configure multiple policers for each multiclass LSP. You can also enable automatic policing for multiclass LSPs.

For information about how to configure a policer for a multiclass LSP, see [“Configuring Policers for LSPs” on page 375](#) and [“Configuring Automatic Policers” on page 377](#).

## Configuring Fast Reroute for Multiclass LSPs

You can enable fast reroute for multiclass LSPs. The bandwidth guarantees for the class types can be carried over to the detour path in case the primary path of the multiclass LSP fails. The same traffic class types configured for the primary multiclass LSP are also signaled for the detour LSP.

The bandwidth guarantee for the detour path is a percentage of the bandwidth configured for the class types of the primary path. For example, you configure a value of 50 percent for the detour path and the protected LSP carries traffic for class types CT0 through CT3. The detour path is signaled with the same class types (CT0 through CT3) but with 50 percent of the bandwidth configured for the protected LSP.

If you configure the router to reserve bandwidth for the detour path, a check is made to ensure that the link is capable of handling DiffServ-aware traffic engineering, that all of the traffic class types needed are available, and for CoS capability before accepting it as a potential detour path. Unsupported links are not used.

The bandwidth percentage for fast reroute is signaled from the ingress router to the egress router. All of the intermediate devices must complete their own CSPF computations and signaling.

When you configure the **bandwidth-percent** statement, the detour path bandwidth is computed by multiplying by the bandwidth configured for the primary multiclass LSP. For information about how to configure the bandwidth for the multiclass LSP, see [“Configuring Traffic-Engineered LSPs” on page 354](#).

To configure the percentage of bandwidth used by the detour path based on the bandwidth of the protected path, include the **bandwidth-percent** statement:

```
bandwidth-percent percentage;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name fast-reroute*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name fast-reroute*]

## Configuring the Maximum Number of MPLS Labels

For interfaces that you configure for MPLS applications, you can set the maximum number of labels upon which MPLS can operate.

By default, the maximum number of labels is three. You can change the maximum to four labels or five labels for applications that require four or five labels.

**NOTE:** When the maximum number of MPLS labels of an interface is modified, the MPLS interface is bounced. All LDP and RSVP sessions on that interface are restarted, resulting in all LSPs over that interface to flap.

For example, suppose you configure a two-tier carrier-of-carriers VPN service for customers who provide VPN service. A carrier-of-carrier VPN is a two-tiered relationship between a provider carrier (Tier 1 ISP) and a customer carrier (Tier 2 ISP). In a carrier-of-carrier VPN, the provider carrier provides a VPN backbone network for the customer carrier. The customer carrier in turn provides Layer 3 VPN service to its end customers. The customer carrier sends labeled traffic to the provider carrier to deliver it to the next hop on the other side of the provider carrier's network. This scenario requires a three-label stack: one label for the provider carrier VPN, another label for the customer carrier VPN, and a third label for the transport route.

If you add fast reroute service, the PE routers in the provider carrier's network must be configured to support a fourth label (the reroute label). If the customer carrier is using LDP as its signaling protocol and the provider carrier is using RSVP, the provider carrier must support LDP over RSVP tunnel service. This additional service requires an additional label, for a total of five labels.

To the customer carrier, the router it uses to connect to the provider carrier's VPN is a PE router. However, the provider carrier views this device as a CE router.

Table 8 on page 362 summarizes the label requirements.

**Table 8: Sample Scenarios for Using 3, 4, or 5 MPLS Labels**

| Number of Labels Required | Scenarios                                                                                                          |
|---------------------------|--------------------------------------------------------------------------------------------------------------------|
| 3                         | Carrier-of-carriers VPN or a VPN with two labels and fast reroute                                                  |
| 4                         | Combination of carrier-of-carriers and fast reroute                                                                |
| 5                         | Carrier-of-carriers with fast reroute and the customer carrier running LDP, with the provider carrier running RSVP |

The system reserves label space when you configure the maximum number of labels on the interface. When you configure features that require MPLS labels, the label push is automatic. You do not need to explicitly push the labels. The transport route can be a static, LDP-signaled, or RSVP-signaled LSP.

This feature is supported on the following routers:

- MX Series 3D Universal Edge Router
- M120 Multiservice Edge Router
- M320 Multiservice Edge Router with Enhanced III FPCs
- M7i Multiservice Edge Router and M10i Multiservice Edge Router with Enhanced Compact Forwarding Engine Board (CFEB-E)
- T640, T1600, TX Matrix, and TX Matrix Plus routers with Enhanced Scaling FPC1, Enhanced Scaling FP2, Enhanced Scaling FPC3, and Enhanced Scaling FPC4.

To configure and monitor the maximum number of labels:

1. Specify the maximum on the logical interface. Apply this configuration to the carrier's PE routers.

```
[edit interfaces ge-0/1/3 unit 0 family mpls]
user@switch# set maximum-labels 5
```

2. Verify the configuration.

```
[edit system]
user@switch# show interfaces ge-0/1/3.0
Logical interface ge-0/1/3.0 (Index 77) (SNMP ifIndex 507)
  Flags: SNMP-Traps Encapsulation: ENET2
  Input packets : 0
  Output packets: 0
  Protocol mpls, MTU: 1480, Maximum labels: 5
  Flags: Is-Primary
```

The command output includes the **Maximum labels: 5** field under the logical interface unit 0.

## Configuring MPLS to Pop the Label on the Ultimate-Hop Router

You can control the label value advertised on the egress router of a label-switched path (LSP). The default advertised label is label 3 (Implicit Null Label). If label 3 is advertised, the penultimate-hop router removes the label and sends the packet to the egress router. By enabling ultimate-hop popping, label 0 (IPv4 Explicit Null Label) is advertised. Ultimate-hop popping ensures that any packets traversing an MPLS network include a label.

**NOTE:** Juniper Networks routers queue packets based on the incoming label. Routers from other vendors might queue packets differently. Keep this in mind when working with networks containing routers from multiple vendors.

To configure MPLS to pop the label on the ultimate-hop router, include the **explicit-null** statement:

```
explicit-null;
```

You can configure this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

**Related  
Documentation**

- [MPLS Label Overview on page 24](#)
- [MPLS Label Allocation on page 26](#)

---

## Advertising Explicit Null Labels to BGP Peers

For the IPv4 (**inet**) family only, BGP peers in a routing group can send an explicit NULL label for a set of connected routes (direct and loopback routes) for the inet labeled-unicast and inet6 labeled-unicast NLRI. By default, peers advertise label 3 (implicit NULL). If the **explicit-null** statement is enabled, peers advertise label 0 (explicit NULL). The explicit NULL labels ensures that labels are always present on packets traversing an MPLS network. If the implicit NULL label is used, the penultimate hop router removes the label and sends the packet as a plain IP packet to the egress router. This might cause issues in queuing the packet properly on the penultimate hop router if the penultimate hop is another vendor's router. Some other vendors queue packets based on the CoS bits in the outgoing label rather than the incoming label.

To advertise an explicit null label, include the following statements in the configuration:

```
family inet {  
  labeled-unicast {  
    aggregate-label {  
      community community-name;  
    }  
    explicit-null {  
      connected-only;  
    }  
  }  
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The **connected-only** statement is required to advertise explicit null labels.

To verify that the explicit NULL label is being advertised for connected routes, use the **show route advertising-protocol bgp *neighbor-address*** command.

- [Configuring RSVP to Pop the Label on the Ultimate-Hop Router on page 523](#)

## Configuring Traffic Engineering for LSPs

When you configure an LSP, a host route (a 32-bit mask) is installed in the ingress router toward the egress router; the address of the host route is the destination address of the LSP. The **bgp** option for the **traffic engineering** statement at the **[edit protocols mpls]** hierarchy level is enabled by default (you can also explicitly configure the **bgp** option), allowing only BGP to use LSPs in its route calculations. The other **traffic-engineering** statement options allow you to alter this behavior in the master routing instance. This functionality is not available for specific routing instances. Also, you can enable only one of the **traffic-engineering** statement options (**bgp**, **bgp-igp**, **bgp-igp-both-ribs**, or **mpls-forwarding**) at a time.

**NOTE:** Enabling or disabling any of the **traffic-engineering** statement options causes all the MPLS routes to be removed and then reinserted into the routing tables.

You can configure OSPF and traffic engineering to advertise the LSP metric in summary link-state advertisements (LSAs) as described in the section [“Advertising the LSP Metric in Summary LSAs” on page 367](#).

The following sections describe how to configure traffic engineering for LSPs:

- [Using LSPs for Both BGP and IGP Traffic Forwarding on page 365](#)
- [Using LSPs for Forwarding in Virtual Private Networks on page 366](#)
- [Using RSVP and LDP Routes for Forwarding but Not Route Selection on page 366](#)
- [Advertising the LSP Metric in Summary LSAs on page 367](#)

### Using LSPs for Both BGP and IGP Traffic Forwarding

You can configure BGP and the IGPs to use LSPs for forwarding traffic destined for egress routers by including the **bgp-igp** option for the **traffic-engineering** statement. The **bgp-igp** option causes all inet.3 routes to be moved to the inet.0 routing table.

On the ingress router, include **bgp-igp** option for the **traffic-engineering** statement:

```
traffic-engineering bgp-igp;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

**NOTE:** The **bgp-igp** option for the **traffic-engineering** statement cannot be configured for VPN). VPNs require that routes be in the inet.3 routing table.

## Using LSPs for Forwarding in Virtual Private Networks

VPNs require that routes remain in the inet.3 routing table to function properly. For VPNs, configure the **bgp-igp-both-ribs** option of the **traffic-engineering** statement to cause BGP and the IGP to use LSPs for forwarding traffic destined for egress routers. The **bgp-igp-both-ribs** option installs the ingress routes in both the inet.0 routing table (for IPv4 unicast routes) and the inet.3 routing table (for MPLS path information).

On the ingress router, include the **traffic-engineering bgp-igp-both-ribs** statement:

```
traffic-engineering bgp-igp-both-ribs;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

When you use the **bgp-igp-both-ribs** statement, the routes from the inet.3 table get copied into the inet.0 table. The copied routes are LDP-signaled or RSVP-signaled, and are likely to have a lower preference than other routes in inet.0. Routes with a lower preference are more likely to be chosen as the active routes. This can be a problem because routing policies only act upon active routes. To prevent this problem, use the **mpls-forwarding** option instead.

## Using RSVP and LDP Routes for Forwarding but Not Route Selection

If you configure the **bgp-igp** or **bgp-igp-both-ribs** options for the **traffic-engineering** statement, high-priority LSPs can supersede IGP routes in the inet.0 routing table. IGP routes might no longer be redistributed since they are no longer the active routes.

If you configure the **mpls-forwarding** option for the **traffic-engineering** statement, LSPs are used for forwarding but are excluded from route selection. These routes are added to both the inet.0 and inet.3 routing tables. LSPs in the inet.0 routing table are given a low preference when the active route is selected. However, LSPs in the inet.3 routing table are given a normal preference and are therefore used for selecting forwarding next hops.

When you activate the **mpls-forwarding** option, routes whose state is **ForwardingOnly** are preferred for forwarding even if their preference is lower than that of the currently active route. To examine the state of a route, execute a **show route detail** command.

To use LSPs for forwarding but exclude them from route selection, include the **mpls-forwarding** option for the **traffic-engineering** statement:

```
traffic-engineering mpls-forwarding;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

When you configure the **mpls-forwarding** option, IGP shortcut routes are copied to the inet.0 routing table only.

Unlike the **bgp-igp-both-ribs** option, the **mpls-forwarding** option allows you to use the LDP-signaled and RSVP-signaled routes for forwarding, and keep the BGP and IGP routes active for routing purposes so that routing policies can act upon them.

For example, suppose a router is running BGP and it has a BGP route of 10.10.10.1/32 that it needs to send to another BGP speaker. If you use the **bgp-igp-both-ribs** option, and your router also has a label-switched-path (LSP) to 10.10.10.1, the MPLS route for 10.10.10.1 becomes active in the inet.0 routing table. This prevents your router from advertising the 10.10.10.1 route to the other BGP router. On the other hand, if you use the **mpls-forwarding** option instead of the **bgp-igp-both-ribs** option, the 10.10.10.1/32 BGP route is advertised to the other BGP speaker, and the LSP is still used to forward traffic to the 10.10.10.1 destination.

## Advertising the LSP Metric in Summary LSAs

You can configure MPLS and OSPF to treat an LSP as a link. This configuration allows other routers in the network to use this LSP. To accomplish this goal, you need to configure MPLS and OSPF traffic engineering to advertise the LSP metric in summary LSAs.

For MPLS, include the **traffic-engineering bgp-igp** and **label-switched-path** statements:

```
traffic-engineering bgp-igp;
label-switched-path lsp-name {
    to address;
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

For OSPF, include the **lsp-metric-into-summary** statement:

```
lsp-metric-into-summary;
```

You can include this statement at the following hierarchy levels:

- [edit protocols ospf traffic-engineering shortcuts]
- [edit logical-systems *logical-system-name* protocols ospf traffic-engineering shortcuts]

For more information about OSPF traffic engineering, see the *Junos OS Routing Protocols Library*.

## Enabling Interarea Traffic Engineering

The Junos OS can signal a contiguous traffic-engineered LSP across multiple OSPF areas. The LSP signaling must be done using either nesting or contiguous signaling, as described in RFC 4206, *Label-Switched Paths (LSP) Hierarchy with Generalized Multi-Protocol Label*

*Switching (GMPLS) Traffic Engineering (TE)*. However, contiguous signaling support is limited to just basic signaling. Reoptimization is not supported with contiguous signaling.

The following describes some of the interarea traffic engineering features:

- Interarea traffic engineering can be enabled when the loose-hop area border routers (ABRs) are configured on the ingress router using CSPF for the Explicit Route Object (ERO) calculation within an OSPF area. ERO expansion is completed on the ABRs.
- Interarea traffic engineering can be enabled when CSPF is enabled, but without ABRs specified in the LSP configuration on the ingress router (ABRs can be automatically designated).
- Differentiated Services (DiffServ) traffic engineering is supported as long as the class type mappings are uniform across multiple areas.

To enable interarea traffic engineering, include the **expand-loose-hop** statement in the configuration for each LSP transit router:

```
expand-loose-hop;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

---

## Enabling Inter-AS Traffic Engineering for LSPs

Generally, traffic engineering is possible for LSPs that meet the following conditions:

- Both ends of the LSP are in the same OSPF area or at the same IS-IS level.
- The two ends of the LSP are in different OSPF areas within the same autonomous system (AS). LSPs that end in different IS-IS levels are not supported.
- The two ends of an explicit-path LSP are in different OSPF ASs and the autonomous system border routers (ASBRs) are configured statically as the loose hops supported on the explicit-path LSP. For more information, see [“Configuring Explicit-Path LSPs” on page 306](#).

Without statically defined ASBRs on LSPs, traffic engineering is not possible between one routing domain, or AS, and another. However, when the ASs are under the control of single service provider, it is possible in some cases to have traffic engineered LSPs span the ASs and dynamically discover the OSPF ASBRs linking them (IS-IS is not supported with this feature).

Inter-AS traffic engineered LSPs are possible as long as certain network requirements are met, none of the limiting conditions apply, and OSPF passive mode is configured with EBGp. Details are provided in the following sections:

- [Inter-AS Traffic Engineering Requirements on page 369](#)
- [Inter-AS Traffic Engineering Limitations on page 369](#)
- [Configuring OSPF Passive TE Mode on page 370](#)

## Inter-AS Traffic Engineering Requirements

The proper establishment and functioning of inter-AS traffic engineered LSPs depend on the following network requirements, all of which must be met:

- All ASs are under control of a single service provider.
- OSPF is used as the routing protocol within each AS, and EBGp is used as the routing protocol between the ASs.
- ASBR information is available inside each AS.
- EBGp routing information is distributed by OSPF, and an IBGP full mesh is in place within each AS.
- Transit LSPs are *not* configured on the inter-AS links, but *are* configured between entry and exit point ASBRs on each AS.
- The EBGp link between ASBRs in different ASs is a direct link and must be configured as a passive traffic engineering link under OSPF. The remote link address itself, not the loopback or any other link address, is used as the remote node identifier for this passive link. For more information about OSPF passive traffic engineering mode configuration, see [“Configuring OSPF Passive TE Mode” on page 370](#).

In addition, the address used for the remote node of the OSPF passive traffic engineering link must be the same as the address used for the EBGp link. For more information about OSPF and BGP in general, see the *Junos OS Routing Protocols Library*.

## Inter-AS Traffic Engineering Limitations

Only LSP hierarchical, or nested, signaling is supported for inter-AS traffic engineered LSPs. Only point-to-point LSPs are supported (there is no point-to-multipoint support).

In addition, the following limitations apply. Any one of these conditions is sufficient to render inter-AS traffic engineered LSPs impossible, even if the above requirements are met.

- The use of multihop BGP is not supported.
- The use of policers or topologies that prevent BGP routes from being known inside the AS is not supported.
- Multiple ASBRs on a LAN between EBGp peers are not supported. Only one ASBR on a LAN between EBGp peers is supported (others ASBRs can exist on the LAN, but cannot be advertised).

- Route reflectors or policies that hide ASBR information or prevent ASBR information from being distributed inside the ASs are not supported.
- Bidirectional LSPs are not supported (LSPs are unidirectional from the traffic engineering perspective).
- Topologies with both inter-AS and intra-AS paths to the same destination are not supported.

In addition, several features that are routine with all LSPs are not supported with inter-AS traffic engineering:

- Admin group link colors are not supported.
- Secondary standby is not supported.
- Reoptimization is not supported.
- Crankback on transit routers is not supported.
- Diverse path calculation is not supported.
- Graceful restart is not supported.

These lists of limitations or unsupported features with inter-AS traffic engineered LSPs are not exhaustive.

## Configuring OSPF Passive TE Mode

Ordinarily, interior routing protocols such as OSPF are not run on links between ASs. However, for inter-AS traffic engineering to function properly, information about the inter-AS link, in particular, the address on the remote interface, must be made available inside the AS. This information is not normally included either in EBGp reachability messages or in OSPF routing advertisements.

To flood this link address information within the AS and make it available for traffic engineering calculations, you must configure OSPF passive mode for traffic engineering on each inter-AS interface. You must also supply the remote address for OSPF to distribute and include in the traffic engineering database.

To configure OSPF passive mode for traffic engineering on an inter-AS interface, include the **passive** statement for the link at the **[edit protocols ospf area *area-id* interface *interface-name*]** hierarchy level:

```
passive {
  traffic-engineering {
    remote-node-id ip-address; /* IP address at far end of inter-AS link */
  }
}
```

OSPF must be properly configured on the router. The following example configures the inter-AS link **so-1/1/0** to distribute traffic engineering information with OSPF within the AS. The remote IP address is **192.168.207.2**.

```
[edit protocols ospf area 0.0.0.0]
interface so-1/1/0 {
```

```

unit 0 {
  passive {
    traffic-engineering {
      remote-node-id 192.168.207.2;
    }
  }
}

```

## Configuring MPLS to Gather Statistics

You can configure MPLS so that it periodically gathers traffic statistics about all MPLS sessions, including transit sessions, by configuring the **statistics** statement. You must configure the **statistics** statement if you want to collect MPLS traffic statistics using SNMP polling of MPLS Management Information Bases (MIBs).

To enable or disable MPLS statistics collection, include the **statistics** statement:

```

statistics {
  auto-bandwidth (MPLS Statistics);
  file filename <files number> <size size> <world-readable | no-world-readable>;
  interval seconds;
  no-transit-statistics;
  transit-statistics-polling;
}

```

You can configure these statements at the following hierarchy levels:

- [edit protocols mpls]
- [edit logical-systems *logical-system-name* protocols mpls]

The default interval is 300 seconds.

If you configure the **file** option, the statistics are placed in a file, with one entry per LSP. During the specified interval, the following information is recorded in this file:

- The number of packets, number of bytes, packets per second, and bytes per second transmitted by each LSP. Feature parity for the display of packet and byte statistics for sub-LSPs of a point-to-multipoint LSP on the Junos Trio chipset is supported in Junos OS Releases 11.1R2, 11.2R2, and 11.4.
- The percent of bandwidth transmitted over a given LSP in relation to the bandwidth percentage configured for that LSP. If no bandwidth is configured for an LSP, 0 percent is recorded in the percentage column.

At the end of each periodic report, a summary shows the current time, total number of sessions, number of sessions read, number of sessions ignored, and read errors, if any. Ignored sessions are typically those not in the up state or those with a reserved (0 through 15) incoming label (typically the egress point of an LSP). The reason for a read error appears on the same line as the entry for the LSP on which the error occurred.

Gathering statistics is an unreliable process; occasional read errors might affect their accuracy. Sample output follows:

```
lsp6          0 pkt          0 Byte      0 pps      0 Bps      0
lsp5          0 pkt          0 Byte      0 pps      0 Bps      0
lsp6.1        34845 pkt      2926980 Byte 1049 pps   88179 Bps 132
lsp5.1        0 pkt          0 Byte      0 pps      0 Bps      0
lsp4          0 pkt          0 Byte      0 pps      0 Bps      0
Dec  7 17:28:38 Total 6 sessions: 5 success, 0 fail, 1 ignored
```

**Related Documentation**

- [Configuring Automatic Bandwidth Allocation for LSPs on page 286](#)

## Configuring System Log Messages and SNMP Traps for LSPs

Whenever an LSP makes a transition from up to down, or down to up, and whenever an LSP switches from one active path to another, the ingress router generates a system log message and sends an SNMP trap. The following shows a sample system log message:

```
RPD_MPLS_LSP_UP: MPLS LSP sheep1 up on primary(any) Route 192.168.1.1 192.168.1.2
192.168.1.3
RPD_MPLS_LSP_CHANGE: MPLS LSP sheep1 change on primary(any) Route 192.168.1.1
192.168.1.2 192.168.1.3
RPD_MPLS_LSP_DOWN: MPLS LSP sheep1 down on primary(any)
```

For information about the MPLS SNMP traps and the proprietary MPLS MIBs, see the *Network Management Administration Guide*.

System log messages for LSPs are generated by default. To disable the default logging of messages for LSPs, configure the **no-syslog** option under the **log-updown** statement:

```
log-updown {
  no-syslog;
}
```

To generate SNMP traps for LSPs, include the **trap** option to the **log-updown** statement:

```
log-updown {
  trap;
}
```

To generate SNMP traps whenever an LSP path goes down, include the **trap-path-down** option to the **log-updown** statement:

```
log-updown {
  trap-path-down;
}
```

To generate SNMP traps whenever an LSP path comes up, include the **trap-path-up** option to the **log-updown** statement:

```
log-updown {
  trap-path-up;
}
```

To disable the generation of system log messages, include the **no-syslog** option to the **log-updown** statement:

```
log-updown {
  no-syslog;
}
```

To disable the generation of SNMP traps, include the **no-trap** statement:

```
no-trap {
  mpls-lsp-traps;
  rfc3812-traps;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls log-updown]**
- **[edit logical-systems *logical-system-name* protocols mpls log-updown]**

For scalability reasons, only the ingress router generates SNMP traps. By default, MPLS issues traps for all configured LSPs. If you have many LSPs, the number of traps can become quite large. To disable the generation of SNMP traps, configure the **no-trap** statement.

The **no-trap** statement also includes the following options which allow you to block certain categories of MPLS SNMP traps:

- **mpls-lsp-traps**—Blocks the MPLS LSP traps defined in the **jnx-mpls.mib**, but allows the **rfc3812.mib** traps.
- **rfc-3812-traps**—Blocks the traps defined in the **rfc3812.mib**, but allows the MPLS LSP traps defined in the **jnx-mpls.mib**.

## Configuring MPLS Firewall Filters and Policers

You can configure an MPLS firewall filter to count packets based on the EXP bits for the top-level MPLS label in a packet. You can also configure policers for MPLS LSPs.

The following sections discuss MPLS firewall filters and policers:

- [Configuring MPLS Firewall Filters on page 373](#)
- [Examples: Configuring MPLS Firewall Filters on page 374](#)
- [Configuring Policers for LSPs on page 375](#)
- [Example: Configuring an LSP Policer on page 377](#)
- [Configuring Automatic Policers on page 377](#)
- [Writing Different DSCP and EXP Values in MPLS-Tagged IP Packets on page 381](#)

### Configuring MPLS Firewall Filters

You can configure an MPLS firewall filter to count packets based on the EXP bits for the top-level MPLS label in a packet. You can then apply this filter to a specific interface. You can also configure a policer for the MPLS filter to police (that is, rate-limit) the traffic on the interface to which the filter is attached. You cannot apply MPLS firewall filters to Ethernet (fxp0) or loopback (lo0) interfaces.

You can configure an MPLS firewall filter on the M Series Multiservice Edge Routers and the T Series Core Routers.

You can configure the following match criteria attributes for MPLS filters at the **[edit firewall family mpls filter *filter-name* term *term-name* from]** hierarchy level:

- **exp**
- **exp-exception**

These attributes can accept EXP bits in the range 0 through 7. You can configure the following choices:

- A single EXP bit—for example, **exp 3;**
- Several EXP bits—for example, **exp 0, 4;**
- A range of EXP bits—for example, **exp [0-5];**

If you do not specify a match criterion (that is, you do not configure the **from** statement and use only the **then** statement with the **count** action keyword), all the MPLS packets passing through the interface on which the filter is applied will be counted.

You also can configure any of the following action keywords at the **[edit firewall family mpls filter *filter-name* term *term-name* then]** hierarchy level:

- **count**
- **accept**
- **discard**
- **next**
- **policer**

For more information about how to configure firewall filters, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*. For more information about how to configure interfaces, see the *Junos OS Network Interfaces Library for Routing Devices* and the *Junos OS Services Interfaces Library for Routing Devices*.

## Examples: Configuring MPLS Firewall Filters

The following examples illustrate how you might configure an MPLS firewall filter and then apply the filter to an interface. This filter is configured to count MPLS packets with EXP bits set to either 0 or 4.

The following shows a configuration for an MPLS firewall filter:

```
[edit firewall]
family mpls {
  filter expf {
    term expt0 {
      from {
        exp 0,4;
      }
    }
  }
}
```

```

        then {
            count counter0;
            accept;
        }
    }
}

```

The following shows how to apply the MPLS firewall filter to an interface:

```

[edit interfaces]
so-0/0/0 {
    mtu 4474;
    encapsulation ppp;
    sonet-options {
        fcs 32;
    }
    unit 0 {
        point-to-point;
        family mpls {
            filter {
                input expf;
                output expf;
            }
        }
    }
}

```

The MPLS firewall filter is applied to the input and output of an interface (see the **input** and **output** statements in the preceding example).

## Configuring Policers for LSPs

MPLS LSP policing allows you to control the amount of traffic forwarded through a particular LSP. Policing helps to ensure that the amount of traffic forwarded through an LSP never exceeds the requested bandwidth allocation. LSP policing is supported on regular LSPs, LSPs configured with DiffServ-aware traffic engineering, and multiclass LSPs. You can configure multiple policers for each multiclass LSP. For regular LSPs, each LSP policer is applied to all of the traffic traversing the LSP. The policer's bandwidth limitations become effective as soon as the total sum of traffic traversing the LSP exceeds the configured limit.

You configure the multiclass LSP and DiffServ-aware traffic engineering LSP policers in a filter. The filter can be configured to distinguish between the different class types and apply the relevant policer to each class type. The policers distinguish between class types based on the EXP bits.

You configure LSP policers under the **family any** filter. The **family any** filter is used because the policer is applied to traffic entering the LSP. This traffic might be from different families: IPv6, MPLS, and so on. You do not need to know what sort of traffic is entering the LSP, as long as the match conditions apply to all types of traffic.

You can configure only those match conditions that apply across all types of traffic. The following are the supported match conditions for LSP policers:

- **forwarding-class**
- **packet-length**
- **interface**
- **interface-set**

To enable a policer on an LSP, first you need to configure a policing filter and then include it in the LSP configuration. For information about how to configure policers, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

To configure a policer for an LSP, specify a filter by including the **filter** option to the **policing** statement:

```
policing {  
    filter filter-name;  
}
```

You can include the **policing** statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit protocols mpls **static-label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **static-label-switched-path** *lsp-name*]

---

### LSP Policer Limitations

When configuring MPLS LSP policers, be aware of the following limitations:

- LSP policers are supported for packet LSPs only.
- LSP policers are supported for unicast next hops only. Multicast next hops are not supported.
- LSP policers are not supported on aggregated interfaces.
- The LSP policer runs before any output filters.
- Traffic sourced from the Routing Engine (for example, ping traffic) does not take the same forwarding path as transit traffic. This type of traffic cannot be policed.
- LSP policers work on all T Series routers and on M Series routers that have the Internet Processor II application-specific integrated circuit (ASIC).

**NOTE:** Starting with Junos OS Release 12.2R2, on T Series routers only, you can configure an LSP policer for a specific LSP to be shared across different protocol family types. To do so, you must configure the *logical-interface-policer* statement at the [edit firewall policer *policer-name*] hierarchy level.

---

## Example: Configuring an LSP Policer

The following example shows how you can configure a policing filter for an LSP:

```
[edit firewall]
policer police-ct1 {
  if-exceeding {
    bandwidth-limit 50m;
    burst-size-limit 1500;
  }
  then {
    discard;
  }
}
policer police-ct0 {
  if-exceeding {
    bandwidth-limit 200m;
    burst-size-limit 1500;
  }
  then {
    discard;
  }
}
family any {
  filter bar {
    term discard-ct0 {
      then {
        policer police-ct0;
        accept;
      }
    }
    term discard-ct1 {
      then {
        policer police-ct1;
        accept;
      }
    }
  }
}
```

## Configuring Automatic Policers

Automatic policing of LSPs allows you to provide strict service guarantees for network traffic. Such guarantees are especially useful in the context of Differentiated Services for traffic engineered LSPs, providing better emulation for ATM wires over an MPLS network. For more information about Differentiated Services for LSPs, see [“DiffServ-Aware Traffic Engineering Introduction” on page 338](#).

Differentiated Services for traffic engineered LSPs allow you to provide differential treatment to MPLS traffic based on the EXP bits. To ensure these traffic guarantees, it is insufficient to simply mark the traffic appropriately. If traffic follows a congested path, the requirements might not be met.

LSPs are guaranteed to be established along paths where enough resources are available to meet the requirements. However, even if the LSPs are established along such paths and are marked properly, these requirements cannot be guaranteed unless you ensure that no more traffic is sent to an LSP than there is bandwidth available.

It is possible to police LSP traffic by manually configuring an appropriate filter and applying it to the LSP in the configuration. However, for large deployments it is cumbersome to configure thousands of different filters. Configuration groups cannot solve this problem either, since different LSPs might have different bandwidth requirements, requiring different filters. To police traffic for numerous LSPs, it is best to configure automatic policers.

When you configure automatic policers for LSPs, a policer is applied to all of the LSPs configured on the router. However, you can disable automatic policing on specific LSPs.

**NOTE:** When you configure automatic policers for DiffServ-aware traffic engineering LSP, GRES is not supported.

**NOTE:** You cannot configure automatic policing for LSPs carrying CCC traffic.

The following sections describe how to configure automatic policers for LSPs:

- [Configuring Automatic Policers for LSPs on page 378](#)
- [Configuring Automatic Policers for DiffServ-Aware Traffic Engineering LSPs on page 379](#)
- [Configuring Automatic Policers for Point-to-Multipoint LSPs on page 379](#)
- [Disabling Automatic Policing on an LSP on page 380](#)
- [Example: Configuring Automatic Policing for an LSP on page 380](#)

---

### Configuring Automatic Policers for LSPs

---

To configure automatic policers for standard LSPs (neither DiffServ-aware traffic engineered LSPs nor multiclass LSPs), include the **auto-policing** statement with either the **class all *policer-action*** option or the **class ct0 *policer-action*** option:

```
auto-policing {  
    class all policer-action;  
    class ct0 policer-action;  
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

You can configure the following policer actions for automatic policers:

- **drop**—Drop all packets.

- **loss-priority-high**—Set the packet loss priority (PLP) to high.
- **loss-priority-low**—Set the PLP to low.

These policer actions are applicable to all types of LSPs. The default policer action is to do nothing.

Automatic policers for LSPs police traffic based on the amount of bandwidth configured for the LSPs. You configure the bandwidth for an LSP using the **bandwidth** statement at the **[edit protocols mpls label-switched-path *lsp-path-name*]** hierarchy level. If you have enabled automatic policers on a router, change the bandwidth configured for an LSP, and commit the revised configuration, the change does not take effect on the active LSPs. To force the LSPs to use the new bandwidth allocation, issue a **clear mpls lsp** command.

**NOTE:** You cannot configure automatic policers for LSPs that traverse aggregated interfaces or Multilink Point-to-Point Protocol (MLPPP) interfaces.

### Configuring Automatic Policers for DiffServ-Aware Traffic Engineering LSPs

To configure automatic policers for DiffServ-aware traffic engineering LSPs and for multiclass LSPs, include the **auto-policing** statement:

```
auto-policing {
  class all policer-action;
  class ctnumber policer-action;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

You include either the **class all *policer-action*** statement or a **class *ctnumber* *policer-action*** statement for each of one or more classes (you can configure a different policer action for each class). For a list of the actions that you can substitute for the ***policer-action*** variable, see “[Configuring Automatic Policers for LSPs](#)” on page 378. The default policer action is to do nothing.

**NOTE:** You cannot configure automatic policers for LSPs that traverse aggregated interfaces or MLPPP interfaces.

### Configuring Automatic Policers for Point-to-Multipoint LSPs

You can configure automatic policers for point-to-multipoint LSPs by including the **auto-policing** statement with either the **class all *policer-action*** option or the **class *ct0* *policer-action*** option. You only need to configure the **auto-policing** statement on the primary point-to-multipoint LSP (for more information on primary point-to-multipoint LSPs, see “[Configuring the Primary Point-to-Multipoint LSP](#)” on page 311). No additional

configuration is required on the subLSPs for the point-to-multipoint LSP.

Point-to-multipoint automatic policing is applied to all branches of the point-to-multipoint LSP. In addition, automatic policing is applied to any local VRF interfaces that have the same forwarding entry as a point-to-multipoint branch. Feature parity for automatic policers for MPLS point-to-multipoint LSPs on the Junos Trio chipset is supported in Junos OS Releases 11.1R2, 11.2R2, and 11.4.

The automatic policer configuration for point-to-multipoint LSPs is identical to the automatic policer configuration for standard LSPs. For more information, see [“Configuring Automatic Policers for LSPs” on page 378](#).

---

### Disabling Automatic Policing on an LSP

When you enable automatic policing, all of the LSPs on the router or logical system are affected. To disable automatic policing on a specific LSP on a router where you have enabled automatic policing, include the **policing** statement with the **no-auto-policing** option:

```
policing no-auto-policing;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls [label-switched-path](#) *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls [label-switched-path](#) *lsp-name*]

---

### Example: Configuring Automatic Policing for an LSP

Configure automatic policing for a multiclass LSP, specifying different actions for class types **ct0**, **ct1**, **ct2**, and **ct3**.

```
[edit protocols mpls]
diffserv-te {
  bandwidth-model extended-mam;
}
auto-policing {
  class ct1 loss-priority-low;
  class ct0 loss-priority-high;
  class ct2 drop;
  class ct3 loss-priority-low;
}
traffic-engineering bgp-igp;
label-switched-path sample-lsp {
  to 3.3.3.3;
  bandwidth {
    ct0 11;
    ct1 1;
    ct2 1;
    ct3 1;
  }
}
interface fxp0.0 {
  disable;
}
interface tl-0/5/3.0;
```

```
interface t1-0/5/4.0;
```

## Writing Different DSCP and EXP Values in MPLS-Tagged IP Packets

You can selectively set the DiffServ code point (DSCP) field of MPLS-tagged IPv4 and IPv6 packets to 0 without affecting output queue assignment, and continue to set the MPLS EXP field according to the configured rewrite table, which is based on forwarding classes. You can accomplish this by configuring a firewall filter for the MPLS-tagged packets.

For instructions on how to write different DSCP and EXP values in MPLS-tagged IP packets, see the *Class of Service Feature Guide for Routing Devices*. For instructions on how to configure firewall filters, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

**Related Documentation**

- [Firewall Filter Match Conditions for MPLS Traffic](#)

## Configuring MPLS Rewrite Rules

You can apply a number of different rewrite rules to MPLS packets.

For more information about how to configure statements at the **[edit class-of-service]** hierarchy level, see the *Class of Service Feature Guide for Routing Devices*.

The following sections describe how you can apply rewrite rules to MPLS packets:

- [Rewriting the EXP Bits of All Three Labels of an Outgoing Packet on page 381](#)
- [Rewriting MPLS and IPv4 Packet Headers on page 382](#)

### Rewriting the EXP Bits of All Three Labels of an Outgoing Packet

In interprovider, carrier-of-carrier, and complex traffic engineering scenarios, it is sometimes necessary to push three labels on the next hop.

By default, on M Series routers except the M320, the top MPLS EXP label of an outgoing packet is not rewritten when you configure swap-push-push and triple-push operations. You can rewrite the EXP bits of all three labels of an outgoing packet, thereby maintaining the class of service (CoS) of an incoming MPLS or non-MPLS packet.

To push three labels on incoming MPLS packets, include the **exp-swap-push-push default** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
exp-swap-push-push default;
```

To push three labels on incoming non-MPLS packets, include the **exp-push-push-push default** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules]
exp-push-push-push default;
```

For more information about how to configure statements at the **[edit class-of-service]** hierarchy level, see the *Class of Service Feature Guide for Routing Devices*.

## Rewriting MPLS and IPv4 Packet Headers

You can apply a rewrite rule to MPLS and IPv4 packet headers simultaneously. This allows you to initialize MPLS EXP and IP precedence bits at LSP ingress. You can configure different rewrite rules depending on whether the traffic is VPN or non-VPN.

To rewrite MPLS and IPv4 packet headers, include the **protocol** statement at the **[edit class-of-service interfaces *interface-name* unit *logical-unit-number* rewrite-rules exp *rewrite-rule-name*]** hierarchy level:

```
[edit class-of-service interfaces interface-name unit logical-unit-number rewrite-rules exp  
  rewrite-rule-name]  
  protocol types;
```

Use the **protocol** statement to specify the types of MPLS packets and packet headers to which to apply the rewrite rule. The MPLS packet can be a standard MPLS packet or an MPLS packet with an IPv4 payload. Specify the type of MPLS packet by using the following options:

- **mpls-any**—Applies the rewrite rule to MPLS packets and writes the code point value to MPLS headers.
- **mpls-inet-both**—Applies the rewrite rule to VPN MPLS packets with IPv4 payloads. Writes the code point value to the MPLS and IPv4 headers in T Series (except T4000 routers) and M320 routers. On M Series routers, except the M320, the **mpls-inet-both** option causes all ingress MPLS LSP packets with IPv4 payloads to be initialized with 000 code points for IP precedence and MPLS EXP values.
- **mpls-inet-both-non-vpn**—Applies the rewrite rule to any non-VPN MPLS packets with IPv4 payloads. Writes the code point value to the MPLS and IPv4 headers in T Series and M320 routers. On M Series routers, except the M320, the **mpls-inet-both-non-vpn** option causes all ingress MPLS LSP packets with IPv4 payloads to be initialized with 000 code points for IP precedence and MPLS EXP values.

For a detailed example on how to configure rewrite rules for MPLS and IPv4 packets and for more information about how to configure class of service, see the *Class of Service Feature Guide for Routing Devices*.

---

## Configuring BFD for MPLS IPv4 LSPs

You can configure Bidirectional Forwarding Detection (BFD) protocol on MPLS IPv4 LSPs as outlined in the Internet draft draft-ietf-bfd-mpls-02.txt, *BFD for MPLS LSPs*. BFD is used as a periodic Operation, Administration, and Maintenance (OAM) feature for LSPs to detect LSP data plane faults. You can configure BFD for LSPs that use either LDP or RSVP as the signaling protocol.

You can also use the LSP **ping** commands to detect LSP data plane faults. However, BFD has a couple of benefits: it requires less computer processing than LSP **ping** commands and can quickly detect faults in large numbers of LSPs (LSP **ping** commands must be issued for each LSP individually). On the other hand, BFD cannot be used to

verify the control plane against the data plane at the egress LSR, which is possible when an LSP **ping** echo request is associated with a forwarding equivalence class (FEC).

The BFD failure detection timers are adaptive and can be adjusted to be more or less aggressive. For example, the timers can adapt to a higher value if the adjacency fails, or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the **clear bfd adaptation** command to return BFD interval timers to their configured values. The **clear bfd adaptation** command is hitless, meaning that the command does not affect traffic flow on the routing device.

Starting from Junos OS Release 13.2R4, 13.3R2, and 14.1, you can set the time interval between LSP ping messages and the number of LSP ping responses, respectively, after which the Bidirectional Forwarding Detection (BFD) session is brought down. To so do, you configure the **lsp-ping-interval** statement and the **lsp-ping-multiplier** statement at the **[edit protocols mpls oam]** hierarchy level.

For configuration instructions for LDP-signaled LSPs, see [“Configuring BFD for LDP LSPs” on page 620](#). For configuration instructions for RSVP-signaled LSPs, see the following section.

## Configuring BFD for RSVP-Signaled LSPs

BFD for RSVP supports unicast IPv4 LSPs. When BFD is configured for an RSVP LSP on the ingress router, it is enabled on the primary path and on all standby secondary paths for that LSP. The source IP address for outgoing BFD packets from the egress side of an MPLS BFD session is based on the outgoing interface IP address. You can enable BFD for all LSPs on a router or for specific LSPs. If you configure BFD for a specific LSP, whatever values configured globally for BFD are overridden. The BFD sessions originate only at the ingress router and terminate at the egress router.

An error is logged whenever a BFD session for a path fails. The following example shows how BFD for RSVP LSP log messages might appear:

```
RPD_MPLS_PATH_BFD_UP: MPLS BFD session for path path1 up on LSP R0_to_R3
RPD_MPLS_PATH_BFD_DOWN: MPLS BFD session for path path1 down on LSP R0_to_R3
```

You can configure BFD for all of the RSVP LSPs on the router, a specific LSP, or the primary path of a specific LSP. To configure BFD for RSVP LSPs, include the **oam** and **bfd-liveness-detection** statements.

```
oam {
  bfd-liveness-detection {
    failure-action {
      make-before-break teardown-timeout seconds;
      teardown;
    }
    failure-action teardown;
    minimum-interval milliseconds;
    minimum-receive-interval milliseconds;
```

```

        minimum-transmit-interval milliseconds;
        multiplier detection-time-multiplier;
    }
    lsp-ping-interval time-interval;
    lsp-ping-multiplier multiplier;
}

```

You can configure this statement at the following hierarchy levels:

- [edit protocols mpls]
- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit protocols mpls **label-switched-path** *lsp-name* **primary** *path-name*]

The **bfd-liveness-detection** statement includes the following options:

- **minimum-interval**—Specifies the minimum transmit and receive interval.
- **minimum-receive-interval**—Specifies the minimum receive interval. The range is from 1 through 255,000 milliseconds.
- **minimum-transmit-interval**—Specifies the minimum transmit interval. The range is from 1 through 255,000 milliseconds.
- **lsp-ping-multiplier**—Specifies the detection time multiplier. The range is from 1 through 255.

**NOTE:** To avoid triggering false negatives, configure a BFD fault detection time that is longer than the fast reroute time.

You can also configure the **lsp-ping-interval** option to adjust the time interval between LSP pings. The LSP ping command for RSVP-signaled LSPs is **ping mpls rsvp**. For more information on the **ping mpls rsvp** command, see the [CLI Explorer](#).

## Configuring a Failure Action for the BFD Session on an RSVP LSP

When the BFD session for an RSVP LSP goes down, the LSP is torn down and resigaled. Traffic can be switched to a standby LSP, or you can simply tear down the LSP path. Any actions performed are logged.

When a BFD session for an RSVP LSP path goes down, you can configure the Junos OS to resignal the LSP path or to simply disable the LSP path. A standby LSP path could be configured to handle traffic while the primary LSP path is unavailable. The router can automatically recover from LSP failures that can be detected by BFD. By default, if a BFD session fails, the event is simply logged.

To enable the Junos OS to tear down an RSVP LSP path in the event of a BFD event, include the **failure-action** statement:

```

failure-action {
    make-before-break teardown-timeout seconds;
    teardown;
}

```

For a list of the hierarchy levels at which you can include this statement, see the statement summary section for this statement.

You can configure either the **teardown** or **make-before-break** options:

- **teardown**—Causes the LSP path to be taken down and resigaled immediately.
- **make-before-break**—Causes the Junos OS to attempt to signal a new LSP path before tearing down the old LSP path. You can also configure the **teardown-timeout** option to automatically tear down the LSP after the time period specified if the attempt to resignal the LSP fails within the **teardown-timeout** interval. If you specify a value of 0 for the **teardown-timeout** interval, the LSP is taken down and resigaled immediately (the same behavior as when you configure the **teardown** option).

To configure a failure action for all of the RSVP LSPs, include the **failure-action** statement at the **[edit protocols mpls oam bfd-liveness-detection]** hierarchy level. To configure a failure action for a specific RSVP LSP, include the **failure-action** statement at the **[edit protocols mpls label-switched-path *lsp-name* oam bfd-liveness-detection]** hierarchy level.

To configure a failure action for a specific primary path, include the **failure-action** statement at the **[edit protocols mpls label-switched path *lsp-name* primary *path-name* oam bfd-liveness-detection]** hierarchy level. To configure a failure action for a specific secondary LSP path, include the **failure-action** statement at the **[edit protocols mpls label-switched-path *lsp-name* secondary *path-name* oam bfd-liveness-detection]** hierarchy level.

Release History Table

| Release | Description                                                                                                                                                                                                                                            |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 13.2R4  | Starting from Junos OS Release 13.2R4, 13.3R2, and 14.1, you can set the time interval between LSP ping messages and the number of LSP ping responses, respectively, after which the Bidirectional Forwarding Detection (BFD) session is brought down. |

## BFD-Triggered Local Repair for Rapid Convergence

- [Understanding BFD-Triggered Local Protection on page 385](#)
- [Disabling BFD-Triggered Local Repair on page 387](#)

### Understanding BFD-Triggered Local Protection

The time it takes for a network to converge following a link or node failure can vary dramatically based on a number of factors, including network size, the protocols used, and network design. However, while each particular convergence event is different, the process of convergence is essentially consistent. The failure is detected, the failure is reported (flooded) in the network, an alternate path is found for traffic, and the forwarding plane is updated to pass traffic on a new path.

This overview discusses how Bidirectional Forwarding Detection (BFD)-triggered local repair contributes to a quicker restoration time for rapid convergence in an MPLS network.

- [Purpose of BFD-Triggered Local Repair on page 386](#)
- [Configuring BFD-Triggered Local Repair on page 387](#)

### Purpose of BFD-Triggered Local Repair

In Junos OS, general MPLS traffic protection for RSVP-signaled label-switched path (LSP) failures is provided by several complementary mechanisms. These protection mechanisms include local protection (fast reroute, link protection, and node-link protection) and path protection (primary and secondary paths). Local protection in conjunction with path protection can provide minimum packet loss for an LSP, and control the way the LSP is rerouted after a failure. Traditionally, both types of protection rely on fast detection of connectivity failure at the physical level. However, for transmission media without fast physical level detection, Junos OS supports BFD and MPLS ping for fast failure detection.

With links between routers, when a route goes down, the routing protocol process recalculates the next best path. When MPLS fast reroute (FRR) is enabled, ifl messages are flooded to all Flexible PIC Concentrators (FPCs). The edge FPC enables the bypass MPLS LSP tunnel. Lastly, all routes are repaired and sent through the bypass MPLS LSP tunnel. The amount of time it takes to repair all routes is proportional to the number of routes.

This repair scenario becomes more difficult when a switch lies between two links. See [Figure 37 on page 386](#).

**Figure 37: Topology with BFD-Triggered Local Repair**

When a link goes down at the remote end, the failure is not detected at the local end until the interior gateway protocol (IGP) goes down. To wait for the routing protocol process to recalculate the next best path takes too much time.

With BFD-triggered local repair enabled, the Packet Forwarding Engine completes the repair first, using the bypass MPLS LSP tunnel (that is preconfigured and installed), then informs the routing protocol process to recalculate a new route. By doing this, when the primary MPLS LSP tunnel goes down, the FPC can intermittently and immediately divert traffic to the FPC with the bypass MPLS LSP tunnel.

Using local repair in this way achieves a faster restoration time of less than 50 ms.

### Configuring BFD-Triggered Local Repair

BFD-triggered local repair is not configurable, but is part of the default configuration.

BFD-triggered local repair works within the legacy Junos OS features MPLS-FRR, BFD for IGP, and loop-free alternates (LFAs).

### Disabling BFD-Triggered Local Repair

By default, BFD-triggered local repair is enabled for all routing interfaces. If desired, you can disable BFD-triggered local repair at the **[edit routing-options]** hierarchy level.

#### Disabling BFD-Triggered Local Repair

To explicitly disable BFD-triggered local repair:

1. Include the **no-bfd-triggered-local-repair** statement at the **[edit routing-options]** hierarchy level:

```
user@host# set no-bfd-triggered-local-repair
```

2. (Optional) Verify your configuration settings before committing them by using the **show routing-options** command.

```
user@host# run show routing-options
```

Confirm your configuration by issuing the **show routing-options** command.

```
user@host# show routing-options
...
no-bfd-triggered-local-repair;
}
```

**NOTE:** When you disable this feature, you must also restart routing by including the **graceful-restart** statement for the IGP. For example, for OSPF, this is accomplished by including the **graceful-restart** statement at the **[edit protocols ospf]** hierarchy level.

## Pinging LSPs

---

The following sections describe how to use the **ping mpls** command to confirm LSP functioning.

- [Pinging MPLS LSPs on page 388](#)
- [Pinging Point-to-Multipoint LSPs on page 388](#)
- [Pinging the Endpoint Address of MPLS LSPs on page 389](#)
- [Pinging CCC LSPs on page 389](#)
- [Pinging Layer 3 VPNs on page 389](#)
- [Support for LSP Ping and Traceroute Commands Based on RFC 4379 on page 389](#)

### Pinging MPLS LSPs

You can ping a specific LSP. Echo requests are sent over the LSP as MPLS packets. The payload is a User Datagram Protocol (UDP) packet forwarded to an address in the 127/8 range (127.0.0.1 by default, this address is configurable) and port 3503. The label and interface information for building and sending this information as an MPLS packet is the same as for standard LSP traffic.

When the echo request arrives at the egress node, the receiver checks the contents of the packet and sends a reply containing the correct return value, by using UDP. The router sending the echo request waits to receive an echo reply after a timeout of 2 seconds (you cannot configure this value).

You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the remote router to be able to ping an LSP terminating there. You must configure MPLS even if you intend to ping only LDP forwarding equivalence classes (FECs).

To ping an MPLS LSP use the **ping mpls <count count> <ldp <fec>> <rsvp <exp forwarding-class> <lsp-name>>** command. To ping a secondary MPLS LSP, use the **ping mpls <count count> <rsvp <lsp-name>> standby path-name** command. For a detailed description of this command, see the [CLI Explorer](#).

**NOTE:** The **ping mpls** command is not supported within routing instances.

---

### Pinging Point-to-Multipoint LSPs

To ping a point-to-multipoint LSP, use the **ping mpls rsvp lsp-name multipoint** or **ping mpls rsvp egress address** commands. The **ping mpls rsvp lsp-name multipoint** command returns a list of all of the egress router identifiers and the current status of the point-to-multipoint LSP egress routers. The **ping mpls rsvp lsp-name multipoint egress address** command returns the current status of the specified egress router.

## Pinging the Endpoint Address of MPLS LSPs

To determine whether an LSP between two provider edge (PE) routers is up and running, you can ping the endpoint address of the LSP. To ping an MPLS LSP endpoint, use the **ping mpls lsp-end-point address** command. This command tells you what type of LSP (RSVP or LDP) terminates at the address specified and whether that LSP is up or down.

For a detailed description of this command, see the [CLI Explorer](#).

## Pinging CCC LSPs

You can ping a specific CCC LSP. The CCC LSP ping command is identical to the one used for MPLS LSPs. The command you use is **ping mpls <count count> <rsvp <lsp-name>>**. You can also ping a secondary standby CCC LSP by using the **ping mpls <count count> <rsvp <lsp-name>> standby path-name** command.

For a detailed description of this command, see the [CLI Explorer](#).

## Pinging Layer 3 VPNs

You can use a similar command, **ping mpls l3vpn vpn-name prefix prefix <count count>**, to ping a Layer 3 VPN. For more information about this command, see the *Junos OS VPNs Library for Routing Devices* and the [CLI Explorer](#).

## Support for LSP Ping and Traceroute Commands Based on RFC 4379

The Junos OS supports LSP **ping** and **traceroute** commands based on RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*.

LSP **ping** and **traceroute** commands based on RFC 4379 attempt to trace the path taken by an LSP by relying on MPLS TTL expiration. An LSP can take multiple paths from ingress to egress. This occurs in particular with Equal Cost Multipath (ECMP). The LSP **traceroute** command can trace all possible paths to an LSP node.

## Tracing MPLS and LSP Packets and Operations

To trace MPLS and LSP packets and operations, include the **traceoptions** statement:

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

You can specify the following MPLS-specific flags in the MPLS **traceoptions** statement:

- **all**—Trace all operations.
- **connection**—Trace all circuit cross-connect (CCC) activity.
- **connection-detail**—Trace detailed CCC activity.

- **cspf**—Trace CSPF computations.
- **cspf-link**—Trace links visited during CSPF computations.
- **cspf-node**—Trace nodes visited during CSPF computations.
- **error**—Trace MPLS error conditions.
- **graceful-restart**—Trace MPLS graceful restart events.
- **lsping**—Trace LSP ping packets and return codes.
- **nsr-synchronization**—Trace nonstop routing (NSR) synchronization events.
- **nsr-synchronization-detail**—Trace NSR synchronization events in detail.
- **state**—Trace all LSP state transitions.
- **static**—Trace static label-switched path.

When you configure trace options to track an MPLS LSP using the **cspf** option, the CSPF log displays information about the MPLS LSP using the term “generalized MPLS” (GMPLS). For example, a message in the CSPF log might state that the “link passes GMPLS constraints”. Generalized MPLS (GMPLS) is a superset of MPLS, so this message is normal and does not affect proper MPLS LSP operation.

For general information about tracing and global tracing options, see the *Junos OS Routing Protocols Library*.

---

## Configuring Link State Distribution Using BGP

---

You can enable distribution of topology information across multiple areas and autonomous systems (ASs) by extending the BGP protocol to carry link-state information, which was initially acquired using IGP. The IGP protocols have scaling limitations when it comes to distributing large databases. BGP is not only a more scalable vehicle for carrying multi-area and multi-AS topology information, but also provides the policy controls that can be useful for multi-AS topology distribution. The BGP link-state topology information is used for computing paths for MPLS LSPs spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

Before you begin:

1. Configure the device interfaces.
2. Configure the router ID and autonomous system number for the device.
3. Configure the following protocols:
  - RSVP
  - MPLS
  - IS-IS
  - OSPF

To enable link-state distribution using BGP:

1. Configure an internal BGP group, and assign the local address and neighbor address for the group.

```
[edit protocols]
user@R1# set bgp group internal-group-name type internal
user@R1# set bgp group internal-group-name local-address ip-address
user@R1# set bgp group internal-group-name neighbor ip-address
```

2. Include the BGP-TE signaling network layer reachability information (NLRI) to the internal BGP group.

```
[edit protocols]
user@R1# set bgp group internal-group-name family traffic-engineering unicast
```

3. Enable export of policy on the device.

```
[edit protocols]
user@R1# set bgp group internal-group-name export second-policy-name
```

4. Configure an external BGP group, and assign the local address and neighbor autonomous system to the group.

```
[edit protocols]
user@R1# set bgp group external-group-name type external
user@R1# set bgp group external-group-name neighbor ip-address local-address ip-address
user@R1# set bgp group external-group-name neighbor ip-address peer-as as-number
```

5. Include the BGP-TE signaling NLRI to the external BGP group.

```
[edit protocols]
user@R1# set bgp group external-group-name family traffic-engineering unicast
```

6. In configuration mode, go to the following hierarchy level:

```
[edit]
user@R1# edit policy-options
```

7. Configure policies to accept traffic from the BGP-TE NLRI.

```
[edit policy-options]
user@R1# set policy-statement policy-name from family traffic-engineering
user@R1# set policy-statement policy-name then accept
```

```
user@R1# set policy-statement bgp-import-policy term 1 from family traffic-engineering
user@R1# set policy-statement bgp-import-policy term 1 then next-hop self
user@R1# set policy-statement bgp-import-policy term 1 then accept
```

8. On the remote connecting device, configure policy to accept the OSPF and IS-IS traffic.

```
[edit policy-options]
user@R2# set policy-statement bgp-export-policy term 1 from protocol isis
user@R2# set policy-statement bgp-export-policy term 1 from protocol ospf
user@R2# set policy-statement bgp-export-policy term 1 then accept
user@R2# set policy-statement bgp-export-policy term 2 then reject
```

9. Verify and commit the configuration.

For example:

**R1**

```
[edit protocols]
user@R1# set rsvp interface all
user@R1# set rsvp interface fxp0.0 disable
user@R1# set mpls interface all
user@R1# set mpls interface fxp0.0 disable
user@R1# set bgp group ibgp type internal
user@R1# set bgp group ibgp local-address 10.255.105.141
user@R1# set bgp group ibgp family traffic-engineering unicast
user@R1# set bgp group ibgp export nlri2bgp
user@R1# set bgp group ibgp neighbor 10.255.105.137
user@R1# set bgp group ebgp type external
user@R1# set bgp group ebgp family traffic-engineering unicast
user@R1# set bgp group ebgp neighbor 8.42.1.104 local-address 8.42.1.102
user@R1# set bgp group ebgp neighbor 8.42.1.104 peer-as 65534
user@R1# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5502.4211
user@R1# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.104
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering
remote-node-id 8.42.1.104
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering
remote-node-router-id 10.255.105.139

[edit policy-options]
user@R1# set policy-statement accept-all from family traffic-engineering
user@R1# set policy-statement accept-all then accept
user@R1# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R1# set policy-statement nlri2bgp term 1 then next-hop self
user@R1# set policy-statement nlri2bgp term 1 then accept

[edit]
user@R1# commit
commit complete
```

**R2**

```
[edit policy-options]
user@R2# set policy-statement accept-all from family traffic-engineering
user@R2# set policy-statement accept-all then accept
user@R2# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R2# set policy-statement nlri2bgp term 1 then next-hop self
user@R2# set policy-statement nlri2bgp term 1 then accept
user@R2# set policy-statement ted2nlri term 1 from protocol isis
user@R2# set policy-statement ted2nlri term 1 from protocol ospf
user@R2# set policy-statement ted2nlri term 1 then accept
user@R2# set policy-statement ted2nlri term 2 then reject

[edit]
user@R2# commit
commit complete
```

## Example: Configuring Link State Distribution Using BGP

---

This example shows how to configure BGP to carry link-state information across multiple domains, which is used for computing paths for MPLS LSPs spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

- [Requirements on page 393](#)
- [Overview on page 393](#)
- [Configuration on page 394](#)
- [Verification on page 404](#)

### Requirements

This example uses the following hardware and software components:

- Four routers that can be a combination of M Series, MX Series, or T Series routers
- Junos OS Release 14.2 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
  - RSVP
  - MPLS
  - BGP
  - IS-IS
  - OSPF

### Overview

Starting with Junos OS Release 14.2, a new mechanism to distribute topology information across multiple areas and autonomous systems (ASs) is introduced by extending the BGP protocol to carry link-state information, which was initially acquired using IGP. The IGP protocols have scaling limitations when it comes to distributing large databases. BGP is not only a more scalable vehicle for carrying multi-area and multi-AS topology information, but also provides the policy controls that can be useful for multi-AS topology distribution. The BGP link-state topology information is used for computing paths for MPLS label-switched paths (LSPs) spanning multiple domains, such as inter-area TE LSP, and providing a scalable and policy-controlled means for external path computing entities, such as ALTO and PCE, to acquire network topology.

## Topology

Figure 38: Link-State Distribution Using BGP

In Figure 38 on page 394, Routers R0 and R1 and Routers R2 and R3 belong to different autonomous systems. Routers R0 and R1 run OSPF, and Routers R2 and R3 run IS-IS.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

R0
set interfaces ge-0/0/0 unit 0 family inet address 8.31.1.101/24

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router R1:

1. Configure the Router R1 interfaces.

```
[edit interfaces]
user@R1# set ge-0/0/0 unit 0 family inet address 8.31.1.103/24
user@R1# set ge-0/0/0 unit 0 family iso
user@R1# set ge-0/0/0 unit 0 family mpls
```

```
user@R1# set ge-0/0/1 unit 0 family inet address 8.42.1.102/24
user@R1# set ge-0/0/1 unit 0 family iso
user@R1# set ge-0/0/1 unit 0 family mpls
```

```
user@R1# set lo0 unit 0 family inet address 10.255.105.141/32
```

2. Configure the router ID and autonomous system of Router R1.

```
[edit routing-options]
user@R1# set router-id 10.255.105.141
user@R1# set autonomous-system 65533
```

3. Enable RSVP on all the interfaces of Router R1 (excluding the management interface).

```
[edit protocols]
user@R1# set rsvp interface all
user@R1# set rsvp interface fxp0.0 disable
```

4. Enable MPLS on all the interfaces of Router R1 (excluding the management interface).

```
[edit protocols]
user@R1# set mpls interface all
user@R1# set mpls interface fxp0.0 disable
```

5. Configure the BGP group for Router R1 to peer with Router R0, and assign the local address and neighbor address.

```
[edit protocols]
user@R1# set bgp group ibgp type internal
user@R1# set bgp group ibgp local-address 10.255.105.141
user@R1# set bgp group ibgp neighbor 10.255.105.137
```

6. Include the BGP-TE signaling network layer reachability information (NLRI) to the ibgp BGP group.

```
[edit protocols]
user@R1# set bgp group ibgp family traffic-engineering unicast
```

7. Enable export of policy nlri2bgp on Router R1.

```
[edit protocols]
user@R1# set bgp group ibgp export nlri2bgp
```

8. Configure the BGP group for Router R1 to peer with Router R2, and assign the local address and neighbor autonomous system to the ebgp BGP group.

```
[edit protocols]
user@R1# set bgp group ebgp type external
user@R1# set bgp group ebgp neighbor 8.42.1.104 local-address 8.42.1.102
user@R1# set bgp group ebgp neighbor 8.42.1.104 peer-as 65534
```

9. Include the BGP-TE signaling NLRI to the ebgp BGP group.

```
[edit protocols]
```

```
user@R1# set bgp group ebgp family traffic-engineering unicast
```

10. Enable passive traffic-engineering on the inter-AS link.

```
[edit protocols]
```

```
user@R1# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5502.4211
```

```
user@R1# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.104
```

11. Enable OSPF on the interface connecting Router R1 to Router R0 and on the loopback interface of Router R1, and enable traffic engineering capabilities.

```
[edit protocols]
```

```
user@R1# set ospf traffic-engineering
```

```
user@R1# set ospf area 0.0.0.0 interface lo0.0
```

```
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
```

12. Enable passive traffic-engineering on the inter-AS link.

```
[edit protocols]
```

```
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering  
remote-node-id 8.42.1.104
```

```
user@R1# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering  
remote-node-router-id 10.255.105.139
```

13. Configure policies to accept traffic from BGP-TE NLRI.

```
[edit policy-options]
```

```
user@R1# set policy-statement accept-all from family traffic-engineering
```

```
user@R1# set policy-statement accept-all then accept
```

```
user@R1# set policy-statement nlri2bgp term 1 from family traffic-engineering
```

```
user@R1# set policy-statement nlri2bgp term 1 then next-hop self
```

```
user@R1# set policy-statement nlri2bgp term 1 then accept
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 8.31.1.103/24;
    }
    family iso;

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router R2:

1. Configure the Router R2 interfaces.

```

[edit interfaces]
user@R2# set ge-0/0/0 unit 0 family inet address 8.64.1.104/24
user@R2# set ge-0/0/0 unit 0 family iso
user@R2# set ge-0/0/0 unit 0 family mpls

```

```

user@R2# set ge-0/0/1 unit 0 family inet address 8.42.1.104/24
user@R2# set ge-0/0/1 unit 0 family iso
user@R2# set ge-0/0/1 unit 0 family mpls

```

```

user@R2# set lo0 unit 0 family inet address 10.255.105.139/32
user@R2# set lo0 unit 0 family iso

```

2. Configure the router ID and autonomous system of Router R2.

```

[edit routing-options]
user@R2# set router-id 10.255.105.139
user@R2# set autonomous-system 65534

```

3. Enable RSVP on all the interfaces of Router R2 (excluding the management interface).

- ```
[edit routing-options]
user@R2# set rsvp interface all
user@R2# set rsvp interface fxp0.0 disable
```
4. Enable MPLS on all the interfaces of Router R2 (excluding the management interface).
 

```
[edit routing-options]
user@R2# set mpls interface all
user@R2# set mpls interface fxp0.0 disable
```
  5. Enable import of traffic engineering database parameters using the ted2nlri policy.
 

```
[edit protocols]
user@R2# set mpls traffic-engineering database import policy ted2nlri
```
  6. Configure the BGP group for Router R2 to peer with Router R1.
 

```
[edit protocols]
user@R2# set bgp group ebgp type external
```
  7. Include the BGP-TE signaling NLRI to the ebgp BGP group.
 

```
[edit protocols]
user@R2# set bgp group ebgp family traffic-engineering unicast
```
  8. Assign the local address and neighbor autonomous system to the ebgp BGP group.
 

```
[edit protocols]
user@R2# set bgp group ebgp peer-as 65533
user@R2# set bgp group ebgp neighbor 8.42.1.102
```
  9. Enable export of policy nlri2bgp on Router R2.
 

```
[edit protocols]
user@R2# set bgp group ebgp export nlri2bgp
```
  10. Enable IS-IS on the interface connecting Router R2 with Router R3 and the loopback interface of Router R2.
 

```
[edit protocols]
user@R2# set isis level 1 disable
user@R2# set isis interface ge-0/0/0.0
user@R2# set isis interface lo0.0
```
  11. Enable only IS-IS advertising on the interface connecting Router R2 with Router R1.
 

```
[edit protocols]
user@R2# set isis interface ge-0/0/1.0 passive remote-node-iso 0102.5501.8181
user@R2# set isis interface ge-0/0/1.0 passive remote-node-id 8.42.1.102
```
  12. Configure traffic engineering capability on Router R2.
 

```
[edit protocols]
user@R2# set ospf traffic-engineering
```
  13. Enable only OSPF advertisements on the interface connecting Router R2 with Router R1.
 

```
[edit protocols]
user@R2# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering
remote-node-id 8.42.1.102
```

```
user@R2# set ospf area 0.0.0.0 interface ge-0/0/1.0 passive traffic-engineering
remote-node-router-id 10.255.105.141
```

14. Configure policies to accept traffic from the BGP-TE NLRI.

```
[edit policy-options]
user@R2# set policy-statement accept-all from family traffic-engineering
user@R2# set policy-statement accept-all then accept
user@R2# set policy-statement nlri2bgp term 1 from family traffic-engineering
user@R2# set policy-statement nlri2bgp term 1 then next-hop self
user@R2# set policy-statement nlri2bgp term 1 then accept
user@R2# set policy-statement ted2nlri term 1 from protocol isis
user@R2# set policy-statement ted2nlri term 1 from protocol ospf
user@R2# set policy-statement ted2nlri term 1 then accept
user@R2# set policy-statement ted2nlri term 2 then reject
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R2# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 8.64.1.104/24;
    }

        }
    }
}
```

## Verification

Verify that the configuration is working properly.

- [Verifying the BGP Summary Status on page 404](#)
- [Verifying the MPLS LSP Status on page 405](#)
- [Verifying the Lsdist.0 Routing Table Entries on page 405](#)
- [Verifying the Traffic Engineering Database Entries on page 408](#)

### Verifying the BGP Summary Status

---

**Purpose** Verify that BGP is up and running on Routers R0 and R1.

**Action** From operational mode, run the **show bgp summary** command.

```
user@R0> show bgp summary
Groups: 1 Peers: 1 Down peers: 0
Table Tot Paths Act Paths Suppressed History Damp State Pending
lsdist.0
10 10 0 0 0 0
Peer AS InPkt OutPkt OutQ Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
10.255.105.141 65533 20 14 0 79 5:18
Establish
lsdist.0: 10/10/10/0
```

From operational mode, run the **show bgp summary** command.

```
user@R1> show bgp summary
Groups: 2 Peers: 2 Down peers: 0
Table Tot Paths Act Paths Suppressed History Damp State Pending
lsdist.0
10 10 0 0 0 0
Peer AS InPkt OutPkt OutQ Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
8.42.1.104 65534 24 17 0 70 6:43
Establish
lsdist.0: 10/10/10/0
10.255.105.137 65533 15 23 0 79 6:19
Establish
lsdist.0: 0/0/0/0
```

**Meaning** Router R0 is peered with Router R1.

### Verifying the MPLS LSP Status

**Purpose** Verify the status of the MPLS LSP on Router R0.

**Action** From operational mode, run the **show mpls lsp** command.

```
user@R0> show mpls lsp
Ingress LSP: 1 sessions
To From State Rt P ActivePath LSPname
10.255.105.135 10.255.105.137 Up 0 * to-R3-inter-as
Total 1 displayed, Up 1, Down 0

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

**Meaning** The MPLS LSP from Router R0 to Router R3 is established.

### Verifying the lsdist.0 Routing Table Entries

**Purpose** Verify the lsdist.0 routing table entries on Routers R0, R1, and R2.

**Action** From operational mode, run the **show route table lsdist.0** command.

```

user@R0> show route table lsdist.0
lsdist.0: 10 destinations, 10 routes (10 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

## Dynamic Bandwidth Management Using Container LSP Overview

---

RSVP LSPs with the autobandwidth feature are increasingly deployed in networks to meet traffic engineering needs. However, the current traffic engineering solutions for point-to-point LSPs are inefficient in terms of network bandwidth utilization, mainly because the ingress routers originating the RSVP LSPs either try to fit the LSPs along a particular path without creating parallel LSPs, or do not interact with the other routers in the network and probe for additional available bandwidth.

This feature provides an ingress router with the capability of acquiring as much network bandwidth as possible by creating parallel LSPs dynamically.

### Understanding RSVP Multipath Extensions

The RSVP multipath extensions proposed in the IETF [KOMPELLA-MLSP] allow the setup of traffic engineered multipath label-switched paths (container LSPs). The container LSPs, in addition to conforming to traffic engineering constraints, use multiple independent paths from a source to a destination, thereby facilitating load balancing of traffic. The multipath extensions require changes to the RSVP-TE protocol and allow for merging of labels at the downstream nodes (similar to LDP), which also helps in preserving forwarding resources.

The multipath extensions to RSVP provide the following benefits:

- Ease of configuration. Typically, multiple RSVP LSPs are configured for either load balancing or bin packing. With a container LSP, there is a single entity to provision, manage, and monitor LSPs. Changes in topology are handled easily and autonomously by the ingress LSP, by adding, changing, or removing member LSPs to rebalance traffic, while maintaining the same traffic engineering constraints.
- RSVP equal-cost multipath (ECMP) inherits the standard benefits of ECMP by absorbing traffic surges.
- Multipath traffic engineering allows for better and complete usage of network resources.
- Knowing the relationship among LSPs helps in computing diverse paths with constraint-based routing. It allows adjustment of member LSPs while other member LSPs continue to carry traffic.

- The intermediate routers have an opportunity to merge the labels of member LSPs. This reduces the number of labels that need to get added to the forwarding plane and in turn reduces the convergence time.

If the number of independent ECMP paths is huge, label merging overcomes the platform limitations on maximum (ECMP) next hops. With point-to-point RSVP LSPs that require link or node protection, the next hops are doubled as each LSP is programmed with both primary and backup next hops. RSVP multipath (or ECMP) obviates the need for backup next hops.

- When there is a link failure, the router upstream to the link failure can distribute traffic from the failed link to the remaining ECMP branches, obviating the need for bypass LSPs. The bypass LSP approach not only requires more state when signaling backup LSPs, but also suffers from scaling issues that result in merge-point timing out a protected path state block (PSB) before point of local repair (PLR) gets a chance to signal the backup LSP.

## Junos OS RSVP Multipath Implementation

In order to deploy RSVP multipath (ECMP) in a network, all the nodes through which ECMP LSPs pass must understand RSVP ECMP protocol extensions. This can be a challenge, especially in a multivendor networks.

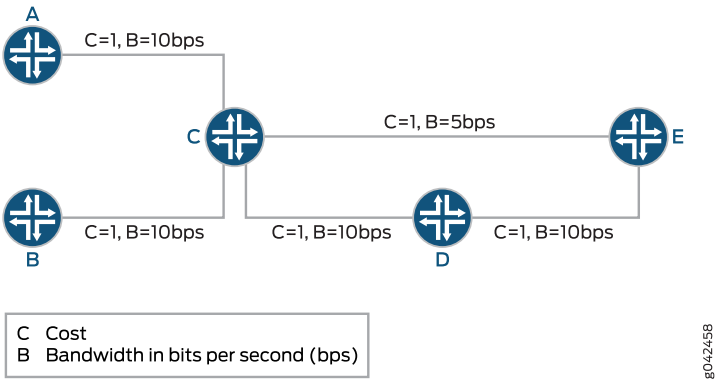

Junos OS implements the RSVP multipath extensions without the need for protocol extensions. A single container LSP, which has the characteristics of ECMP and RSVP TE, is provisioned. A container LSP consists of several member LSPs and is set up between the ingress and egress routing device. Each member LSP takes a different path to the same destination. The ingress routing device is configured with all the required parameters to compute the RSVP ECMP LSP. The parameters configured to compute a set of RSVP point-to-point LSPs can be used by the ingress routing device to compute the container LSP as well.

## Current Traffic Engineering Challenges

The main challenge for traffic engineering is to cope with the dynamics of both topology and traffic demands. Mechanisms are needed that can handle traffic load dynamics in scenarios with sudden changes in traffic demand and dynamically distribute traffic to benefit from available resources.

[Figure 39 on page 412](#) illustrates a sample network topology with all the LSPs having the same hold and setup priorities, and admission control restricted on the ingress router. All the links are annotated with a tuple (cost and capacity).

Figure 39: Sample Topology

Some of the traffic engineering problems seen in [Figure 39 on page 412](#) are listed here:

• **Bin Packing**

This problem arises because of a particular order in which LSPs are signaled. The ingress routers might not be able to signal some LSPs with required demands although bandwidth is available in the network, leading to under-utilization of link capacity.

For example, the following LSPs arrive in the sequence mentioned in [Table 9 on page 412](#).

Table 9: LSP Sequence Order for Bin Packing

Time	Source	Destination	Demand	ERO
1	A	E	5	A-C-D-E
2	B	E	10	No ERO

The LSP originating at Router B is not routable as constraint-based routing fails to find a feasible path. However, if Router B is signaled first, both the LSPs are routable. Bin packing happens because of lack of visibility of individual per-LSP, per-device bandwidth demands at the ingress routing device.

Bin packing can also happen when there is no requirement for ordering of LSPs. For example, if there is an LSP with demand X and there are two different paths to the destination from the ingress router with available bandwidths Y1 and Y2, such that Y1 is less than X, Y2 is less than X, and Y1 plus Y2 is greater than or equal to X.

In this case, even though there are enough network resources in terms of available bandwidth to satisfy the aggregate LSP demand X, the LSP might not be signaled or re-optimized with the new demand. In [Figure 39 on page 412](#), with container LSP support, the ingress B creates two LSPs each of size 5 when demand 10 is posed. One LSP is routed along B-C-E and another one along B-C-D-E.

• **Deadlock**

Considering [Figure 39 on page 412](#), the LSPs follow the sequence mentioned in [Table 10 on page 413](#).

Table 10: LSP Sequence Order for Deadlock

Time	Source	Destination	Demand	ERO	Event
1	A	E	2	A-C-D-E	Constraint-based routing with RSVP signaling
2	B	E	2	B-C-D-E	Constraint-based routing with RSVP signaling
3	A	E	2 to 20	A-C-D-E	Constraint-based routing fails, no RSVP signaling

At time 3, the demand on LSP from A to E increases from 2 to 20. If autobandwidth is configured, the change does not get detected until the adjustment timer expires. In the absence of admission control at A, the increased traffic demand might cause traffic to drop on other LSPs that share common links with the mis-behaving LSP.

This happens due to the following reasons:

- Lack of global state at all the ingress routers
- Signaling of mis-behaving demands
- Tearing down of mis-behaving demands

With container LSP configured, ingress A has more chances of splitting the load (even incrementally if not fully) across multiple LSPs. So, LSP from A is less likely to see prolonged traffic loss.

#### • Latency Inflation

Latency inflation is caused by the autobandwidth and other LSPs parameters. Some of the other factors that contribute to latency inflation include:

- LSP priority

LSPs choose longer paths because shorter paths between data centers located in the same city can be congested. The bandwidth on the shorter paths can get exhausted by equal or higher priority LSPs. Due to periodic LSP optimization by autobandwidth, LSP can get rerouted to a higher delay path. When many LSPs undergo less than optimal path selection, they can potentially form a chain of dependencies. Modifying the LSP priorities dynamically is a workaround to the issue; however, dynamically adjusting LSP priorities to find shorter paths is a challenging task.

- All or Nothing policy

When the demand on an LSP increases and at least one of the links along the shorter path is close to its reservation limit, LSP optimization can force the LSP to move to a longer latency path. LSP has to traverse a long path even though the short path is capable of carrying most of the traffic.

- Minimum and maximum bandwidth

Minimum and maximum bandwidth specify the boundaries for LSP sizes. If minimum bandwidth is small, an LSP is more prone to autobandwidth adjustment because a

small change in bandwidth is enough to cross the threshold limits. LSPs might reroute although bandwidth is available. On the other hand, if the minimum bandwidth is large, network bandwidth might be wasted. If the maximum bandwidth value is small, a large number of LSPs might be needed at the ingress router to accommodate the application demand. If the maximum bandwidth is large, the LSPs can grow larger in size. Such LSPs can suffer because of an all or nothing policy.

- Autobandwidth adjustment threshold

Bandwidth threshold dictates if LSPs need to be re-optimized and resized. If the value is small, LSPs are frequently re-optimized and rerouted. That might cause CPU spike because applications or protocols, such as BGP resolving over the LSPs, might keep the Routing Engine busy doing next-hop resolution. A large value might make an LSP immobile. With container LSP configured, an LSP is less likely to get subjected to one or no policy. An ingress router originates multiple LSPs, although not all LSPs potentially traverse high latency paths.

- Predictability

Service providers often want predictable behavior in terms of how LSPs get signaled and routed. Currently, without any global coordination, it is difficult to set up the same set of LSPs in a predictable way. Consider the two different orderings in [Table 11 on page 414](#) and [Table 12 on page 414](#). The ERO that an LSP uses depends on its signaling time.

**Table 11: LSP Sequence Order for Predictability**

Time	Source	Destination	Demand	ERO
1	A	E	5	A-C-D-E
2	B	E	5	B-C-E

**Table 12: LSP Sequence Order for Predictability**

Time	Source	Destination	Demand	ERO
1	B	E	5	B-C-E
2	A	E	5	A-C-D-E

Container LSP does not directly help LSPs find predictable EROs. If LSPs are getting rerouted because of an all or no policy without container LSP configured, such LSPs might see less churn if container LSPs are configured, because smaller LSPs have better chances of finding a shorter or same path.

## Using Container LSP as a Solution

A container LSP can be used as a solution to the challenges faced by the current traffic engineering features. Considering [Figure 39 on page 412](#), when the demand X on a container

LSP increases with the network capacity (max-flow) being more than the demand, the following approaches come into effect with a container LSP:

- [Accommodating the New Demand X on page 415](#)
- [Creating New LSPs to Meet Demand X on page 415](#)
- [Assigning Bandwidth to the New LSPs on page 415](#)
- [Controlling the LSP Paths on page 415](#)

---

### Accommodating the New Demand X

In the current implementation, autobandwidth attempts to re-signal an LSP with the new demand X and follows the all or nothing policy as mentioned earlier.

The container LSP approach computes several small (smaller than demand X) bandwidth LSPs such that the aggregate bandwidth is not less than X, and the ingress router performs this adjustment periodically. One of the triggers to create new LSPs or to delete old LSPs can be changed in aggregate bandwidth. The ingress router then load-balances the incoming traffic across the newly created LSPs.

---

### Creating New LSPs to Meet Demand X

Although the number of new LSPs created can be a maximum of the allowed configurable limit, there is not much benefit from these LSPs once the number of LSPs exceeds the number of possible diverse paths or equal-cost multipaths (ECMPs). The benefit of creating the smaller LSPs is seen when an ingress router uses the newly created LSPs for load-balancing traffic. This, however, depends on the network topology and state.

Creating multiple parallel LSPs by all the ingress routers in the network can lead to scaling issues at the transit routers. Thus, the number of new LSPs to be created depends on the size of the individual LSPs and the given aggregate demand, X in this case.

---

### Assigning Bandwidth to the New LSPs

In general, there can be a number of heuristics to allocate bandwidths to the newly created LSPs. An ingress router can solve an optimization problem in which it can maximize a given utility function. The output of an optimization problem is assigning optimal bandwidth values. However, to solve an optimization problem, the number of newly created LSPs has to be fixed. Therefore, it is complex to optimize the number and size of each LSP. Thus, to simplify the problem, the same amount of bandwidth is assumed for all the newly created LSPs, and then the number of required LSPs is computed.

---

### Controlling the LSP Paths

The flexibility to control the LSP paths is expressed in terms of the configuration for point-to-point LSPs and container LSPs. Controlling the LSP paths using the configuration parameters can be applied under two different aspects:

- **Topology**—There are no topology constraints with this feature. Each member LSP is treated like a point-to-point LSP and is re-optimized individually. An ingress router does not try to compute equal IGP cost paths for all its LSPs, but instead it computes paths for all the LSPs using current traffic engineering database information. While computing a path, constraint-based routing adheres to any constraints specified

through the configuration, although there is no change in the constraint-based routing method for path computation.

- **When to create a new LSP**—When to create a new LSP can be explicitly specified. By default, an ingress router periodically computes the aggregate traffic rate by adding up the traffic rate of all the individual LSPs. Looking at the aggregate bandwidth and configuration, the ingress router recomputes the number of LSPs and the bandwidths of the LSPs. The new LSPs are then signaled or the existing LSPs are re-signaled with the updated bandwidth. Instead of looking at the instantaneous aggregate rate, the ingress routers can compute an average (of aggregates) over some duration by removing outlier samples (of aggregates). Managing the LSPs that remain outstanding and active by considering aggregate bandwidth is more scalable than creating the new LSPs based on the usage of a particular LSP. The intervals and thresholds can be configured to track the aggregate traffic and trigger adjustment. These dynamic LSPs co-exist and interoperate with per-LSP autobandwidth configuration.

## Junos OS Container LSP Implementation

A container LSP is an ECMP TE LSP that acts like a container LSP consisting of one or more member LSPs. A point-to-point TE LSP is equivalent to a container LSP with a single member LSP. Member LSPs are added to the container LSP through a process called splitting, and removed from the container LSP through a process called merging.

- [Container LSP Terminology on page 416](#)
- [LSP Splitting on page 417](#)
- [LSP Merging on page 419](#)
- [Node and Link Protection on page 421](#)
- [Naming Convention on page 421](#)
- [Normalization on page 422](#)
- [Constraint-Based Routing Path Computation on page 427](#)
- [Sampling on page 428](#)
- [Support for NSR, IPG-FA, and Static Routes on page 428](#)

---

### Container LSP Terminology

The following terms are defined in the context of a container LSP:

- **Normalization**—An event occurring periodically when an action is taken to adjust the member LSPs, either to adjust their bandwidths, their number, or both. A normalization process is associated with a sampling process and periodically estimates aggregate utilization of a container LSP.
- **Nominal LSP**—The instance of a container LSP that is always present.
- **Supplementary LSP**—The instances or sub-LSPs of a container LSP, which are dynamically created or removed.

Autobandwidth is run over each of the member LSPs, and each LSP is resized according to the traffic it carries and the autobandwidth configuration parameters. The aggregate

demand on a container LSP is tracked by adding up the bandwidth across all the member LSPs.

- **Minimum signaling-bandwidth**—The minimum bandwidth with which a member LSP is signaled at the time of normalization or initialization. This could be different from the minimum-bandwidth defined under autobandwidth.
- **Maximum signaling-bandwidth** —The maximum bandwidth with which a member LSP is signaled at the time of normalization or initialization. This could be different from the maximum-bandwidth defined under autobandwidth.
- **Merging-bandwidth** —Specifies the lower bandwidth threshold on the aggregate bandwidth usage, such that if the aggregate usage falls below this value, the ingress router merges the member LSPs at the time of normalization.
- **Splitting-bandwidth** —Specifies the upper bandwidth threshold on the aggregate bandwidth usage, such that if the aggregate usage exceeds this value, the ingress router splits the member LSPs at the time of normalization.
- **Aggregate minimum-bandwidth** —Sum of merging-bandwidth of the current active member LSPs. This minimum bandwidth is different from the autobandwidth minimum-bandwidth.
- **Aggregate maximum-bandwidth**—Sum of the splitting-bandwidth of the current active member LSPs. This maximum bandwidth is different from the autobandwidth maximum-bandwidth.

---

### LSP Splitting

- [Operational Overview on page 417](#)
- [Operational Constraints on page 418](#)
- [Supported Criteria on page 418](#)
- [Splitting Triggers on page 419](#)

#### **Operational Overview**

The LSP splitting mechanism enables an ingress router to create new member LSPs or to re-signal existing LSPs with different bandwidths within a container LSP when a demand X is placed on the container LSP. With LSP splitting enabled, an ingress router periodically creates a number of LSPs (by signaling new ones or re-signaling existing ones) to accommodate a new aggregate demand X. In the current implementation, an ingress router tries to find an LSP path satisfying a demand X and other constraints. If no path is found, either the LSP is not signaled or it remains up, but with the old reserved bandwidth.

Between two normalization events (splitting or merging), individual LSPs might get re-sigaled with different bandwidths due to the autobandwidth adjustments. If a container LSP is not configured with autobandwidth, then the member LSPs are signaled with the static bandwidth value, if configured. There is no dynamic splitting in this case, as there is no dynamic estimation of aggregate bandwidth. The splitting adjustments with a specific bandwidth value can be manually triggered.

**NOTE:**

Be aware of the following considerations for LSP splitting:

- After LSP splitting, the ingress router continues to inject one forwarding adjacency. Forwarding adjacencies are not supported in IGP for this feature.
- Between two normalization events, two LSPs might have different bandwidths subjected to autobandwidth constraints.
- After LSPs are split (or merged), make-before-break uses the fixed filter (FF) style sharing unless the adaptive option is configured. However, two different LSPs do not do the shared explicit (SE) style sharing for this feature.
- When LSPs are re-signaled with modified bandwidths, some of the LSPs might not get signaled successfully, leading to failover options.

---

**Operational Constraints**

LSP splitting has the following operational constraints:

- LSP bandwidth—Although there are a number of ways to allocate bandwidth values to the LSPs, the Junos OS implementation supports only an equal-bandwidth allocation policy when normalization is done, wherein all the member LSPs are signaled or re-signaled with equal bandwidth.
- Number of LSPs—If an ingress router is configured to have a minimum number of LSPs, it maintains the minimum number of LSPs even if the demand can be satisfied with less than the minimum number of LSPs. In case the ingress router is unable to do constraint-based routing for computations on the sufficient number of LSPs or signal sufficient number of LSPs, the ingress router resorts to a number of fallback options.

By default, an incremental approach is supported as a fallback option (unless configured differently), where an ingress router makes attempts to bring up the sufficient number of LSPs, such that the new aggregate bandwidth exceeds the old aggregate bandwidth (and is as close to the desired demand as possible). The ingress router then load-balances traffic using the LSPs. The LSPs that could not be brought up are removed by the ingress router.

**Supported Criteria**

When a container LSP signals a member LSP, the member LSP gets signaled with minimum-signaling-bandwidth. Since each member LSP is configured with autobandwidth, between two normalization events, each LSP can undergo autobandwidth adjustment multiple times. As the traffic demand increases, the ingress router creates additional supplementary LSPs. All member LSPs are used for ECMP, so they should roughly have the same reserved bandwidth after normalization.

For example, if there are K LSPs signaled after normalization, each LSP is signaled with equal bandwidth B. The total aggregate bandwidth reserved is B.K, where B satisfies the following condition:

- Minimum signaling-bandwidth is less than or equal to B, which in turn is less than or equal to the maximum signaling-bandwidth

(minimum-signaling-bandwidth  $\leq$  B  $\leq$  maximum-signaling-bandwidth)

Until the next normalization event, each member LSP undergoes several autobandwidth adjustments. After any autobandwidth adjustment, if there are N LSPs with reserved bandwidths  $b_i$ , where  $i=1,2,\dots, N$ , each  $b_i$  should satisfy the following condition:

- Minimum bandwidth is less than or equal to  $b_i$ , which in turn is less than or equal to the maximum bandwidth

(minimum-bandwidth  $\leq b_i \leq$  maximum-bandwidth)

Both the above-mentioned conditions are applicable for per member LSP (nominal and supplementary), and essentially have the reserved bandwidth to exist within a range.

### ***Splitting Triggers***

Every time the normalization timer expires, the ingress router decides if LSP splitting is required. The ingress router works with the aggregate bandwidth instead of the individual LSP bandwidths. The following two variables are defined for aggregate bandwidth:

- **Current-Aggr-Bw**—Sum of reserved bandwidths of all current member LSPs.
- **New-Aggr-Bw**—Sum of traffic rates on all current member LSPs based on sampling.

Taking for example, if there are N member LSPs in the network at the time of normalization, the two approaches to trigger LSP splitting are as follows:

- **Absolute trigger**—LSP splitting is performed when **New-Aggr-Bw** is greater than **Aggregate-maximum-bandwidth**.

(**New-Aggr-Bw** > **Aggregate-maximum-bandwidth**)

- **Relative trigger**—The **Current-Aggr-Bw** is compared with **New-Aggr-Bw** at the ingress routing device. LSP splitting is performed when the difference in the bandwidth amount is off by a threshold.

( $[1-a] \times \text{Current-Aggr-Bw} < \text{New-Aggr-Bw} < [1+a] \times \text{Current-Aggr-Bw}$ , where  $0 \leq a \leq 1$ )

When **New-Aggr-Bw** is greater than or equal to  $[1+a]$  multiplied by **Current-Aggr-Bw**, the ingress routing device does not perform normalization, but instead LSP splitting is done. However, when both LSP splitting and LSP merging are configured on the ingress router, LSP splitting is triggered on the ingress router when one of the two conditions is satisfied.

### ***LSP Merging***

- [Operational Overview on page 420](#)
- [Operational Constraints on page 420](#)
- [Merging Triggers on page 420](#)

### **Operational Overview**

Junos OS supports two kinds of LSPs – CLI-configured LSPs and dynamically created LSPs. The CLI-configured LSPs are created manually and remain in the system until the configuration is modified. The dynamic LSPs are created dynamically by next generation MVPN, BGP virtual private LAN service (VPLS), or LDP, based on a template configuration, and are removed from the system when not used by any application for a certain duration. LSP merging follows a similar approach as dynamic LSPs.

LSP merging enables an ingress routing device to dynamically eliminate some member LSPs of the container LSP so less state information is maintained in the network. If an ingress router provisions several member LSPs between the ingress and egress routers, and there is an overall reduction in aggregate bandwidth (resulting in some LSPs being under-utilized), the ingress router distributes the new traffic load among fewer LSPs.

Although there are a number of ways to merge the member LSPs, Junos OS supports only overall-merge when normalization is being performed. An ingress router considers the aggregate demand and the minimum (or maximum) number of LSPs and revises the number of LSPs that should be active at an ingress routing device. As a result, the following can take place periodically as the normalization timer fires:

- Re-signaling some of the existing LSPs with updated bandwidth
- Creating new LSPs
- Removing some of the existing LSPs

### **Operational Constraints**

If a container LSP is not configured with autobandwidth, then the member LSPs are signaled with the static bandwidth value, if configured. LSP merging does not happen because there is no dynamic estimation of aggregate bandwidth. However, a manual trigger for splitting and adjusting with a specific bandwidth value can be configured.

#### **NOTE:**

- Nominal LSPs are never deleted as part of LSP merging.
  - Before deleting an LSP, the LSP is made inactive, so that traffic shifts to other LSPs before removing the LSP. This is because RSVP sends PathTear before deleting routes and next hops from the Packet Forwarding Engine.
  - When member LSPs are re-signaled with modified bandwidth, it might happen that some LSPs do not get signaled successfully.
- 

### **Merging Triggers**

Every time the normalization timer expires, the ingress router decides if LSP merging is required. The ingress router works with the aggregate bandwidth instead of the individual LSP bandwidths. The following two variables are defined for aggregate bandwidth:

- **Current-Aggr-Bw**—Sum of reserved bandwidths of all current member LSPs.

- **New-Aggr-Bw**—Sum of traffic rates on all current member LSPs based on sampling.

For example, if there are N member LSPs in the network at the time of normalization, the two approaches to trigger LSP merging are as follows:

- Absolute trigger—LSP merging is performed when **New-Aggr-Bw** is less than **Aggregate-minimum-bandwidth**.

$$(\text{New-Aggr-Bw} < \text{Aggregate-maximum-bandwidth})$$

- Relative trigger—The **Current-Aggr-Bw** is compared with **New-Aggr-Bw** at the ingress routing device. LSP merging is performed when the difference in the bandwidth amount is off by a threshold.

$$([1-a] \times \text{Current-Aggr-Bw} < \text{New-Aggr-Bw} < [1+a] \times \text{Current-Aggr-Bw}, \text{ where } 0 \leq a \leq 1)$$

When the **New-Aggr-Bw** value is less than or equal to  $[1+a]$  multiplied by the **Current-Aggr-Bw** value, the ingress routing device does not perform normalization, but instead LSP merging is done. However, when both LSP splitting and LSP merging are configured on the ingress router, LSP splitting is triggered on the ingress router when one of the two conditions is satisfied.

### Node and Link Protection

Junos OS supports the following mechanisms for node and link protection:

- Fast-reroute
- Link protection
- Node-link protection

Only one of the above-mentioned modes of protection can be configured on an ingress routing device at any given time. All member LSPs (nominal and supplementary) use the same mode of protection that is configured.

### Naming Convention

While configuring a container LSP, a name is assigned to the LSP. The name of a nominal and a supplementary LSP is formed by adding the configured-name suffix and an auto-generated suffix to the name of the container LSP. The name of the container LSP is unique and is checked for accuracy during the configuration parsing. The container LSP name should uniquely identify parameters, such as the ingress and egress router names.

**NOTE:** A container LSP member LSP and a point-to-point LSP on an ingress routing device cannot have the same LSP name.

The container LSPs follow a number-based LSP naming convention. For example, if the nominal LSP's configured name is **bob** and the number of member LSPs is N, the member LSPs are named **bob-*<configured-suffix>-1***, **bob-*<configured-suffix>-2***, ..., and **bob-*<configured-suffix>-N***.

After a normalization event, the number of member LSPs can change. For example, if the number of member LSPs increases from six to eight, then the ingress routing device keeps the first six LSPs named **bob-*<configured-suffix>-1***, **bob-*<configured-suffix>-2***, ..., and **bob-*<configured-suffix>-6***. The two additional LSPs are named **bob-7** and **bob-8**. The original LSPs might need to be re-optimized if their signaled bandwidth changes.

Similarly, if the number of member LSPs reduces from eight to six, the ingress routing device re-signals the member LSPs in such a way that the remaining active LSPs in the system are named **bob-*<configured-suffix>-1***, **bob-*<configured-suffix>-2***, ..., and **bob-*<configured-suffix>-6***.

In the process of creating new LSPs, an RSVP LSP named **bob-*<configured-suffix>-7*** can be configured.

---

### Normalization

- [Operational Overview on page 422](#)
- [Operational Constraints on page 422](#)
- [Inter-Operation with Autobandwidth on page 423](#)

#### **Operational Overview**

Normalization is an event that happens periodically. When it happens, a decision is made on the number of member LSPs that should remain active and their respective bandwidths in a container LSP. More specifically, the decision is made on whether new supplementary LSPs are to be created, or any existing LSPs are required to be re-signaled or deleted during the normalization event.

Between two normalization events, a member LSP can undergo several autobandwidth adjustments. A normalization timer, similar to re-optimization timer, is configured. The normalization timer interval should be no less than the adjustment interval or optimization timer.

**NOTE:** Normalization is not triggered based on network events, such as topology changes.

---

#### **Operational Constraints**

Normalization has the following operational constraints:

- Normalization happens only when none of the member LSPs are undergoing re-optimization or make-before-break. Normalization starts when all the member LSPs complete their ongoing make-before-break. If normalization is pending, new optimization should not be attempted until the normalization is complete.
- After normalization, an ingress routing device first computes a set of bandwidth-feasible paths using constraint-based routing computations. If enough constraint-based routing computed paths are not brought up with an aggregate bandwidth value that exceeds the desired bandwidth, several failover actions are taken.

- After a set of bandwidth-feasible paths are available, the ingress routing device signals those paths while keeping the original set of paths up with the old bandwidth values. The make-before-break is done with shared explicit (SE) sharing style, and when some of the LSPs do not get successfully re-signaled, a bounded number of retries is attempted for a specified duration. Only when all the LSPs are successfully signaled does the ingress router switch from the old instance of the container LSP to the newer instance. If all LSPs could not be successfully signaled, the ingress router keeps those instances of members that are up with higher bandwidth values.

For example, if the bandwidth of an old instance of a member LSP (LSP-1) is 1G, the LSP is split into LSP-1 with bandwidth 2G and LSP-2 with bandwidth 2G. If the signaling of LSP-1 with bandwidth 2G fails, the ingress router keeps LSP-1 with bandwidth 1G and LSP-2 with bandwidth 2G.

When there is a signaling failure, the ingress routing device stays in the error state, where some LSPs have updated bandwidth values only if the aggregate bandwidth has increased. The ingress router makes an attempt to bring up those LSPs that could not be successfully signaled, resulting in minimum traffic loss.

- If an LSP goes down between two normalization events, it can increase the load on other LSPs that are up. In order to prevent overuse of other LSPs, premature normalization can be configured in case of LSP failure. LSPs can go down because of pre-emption or lack of node or link protection. It might not be necessary to bring up the LSPs that are down because the normalization process re-runs the constraint-based routing path computations.

### ***Inter-Operation with Autobandwidth***

Taking as an example, there is one nominal LSP named LSP-1 configured with the following parameters:

- Splitting-bandwidth and maximum-signaling-bandwidth of 1G
- Merging-bandwidth and minimum-signaling-bandwidth of 0.8G
- Autobandwidth

Normalization is performed differently in the following scenarios:

- [Changes in Per-LSP Autobandwidth Adjustments on page 423](#)
- [Changes in Traffic Growth on page 425](#)
- [Computed Range and Configured Feasible Ranges on page 425](#)

### ***Changes in Per-LSP Autobandwidth Adjustments***

[Table 13 on page 424](#) illustrates how normalization splits and merges member LSPs as autobandwidth adjustments change per-LSP bandwidth with unconditional normalization.

Table 13: Normalization with Per-LSP Autobandwidth Adjustment Changes

Normalization Time	Current State	Events	Adjusted State
T0	No state.	Initialization	LSP-1 is signaled with bandwidth of 0.8G
T1	LSP-1 usage increases to 1.5G	<ul style="list-style-type: none"> <li>Multiple autobandwidth adjustments since T0 is possible.</li> <li>The ingress router decides to split LSP-1 into two LSPs, and creates LSP-2.</li> </ul>	LSP-1 = 0.8G LSP-2 = 0.8G
T2	LSP-1 usage increase to 2G LSP-2 usage increases to 0.9G (within limits)	<ul style="list-style-type: none"> <li>Aggregate bandwidth is 2.9G, which exceeds aggregate splitting maximum of 2G.</li> <li>The ingress router decides to split LSP-1 into three LSPs, and creates LSP-3.</li> </ul>	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G
T3	LSP-3 usage increases to 1.5G	<ul style="list-style-type: none"> <li>Aggregate bandwidth is 3.5G with a maximum aggregate splitting of 3G.</li> <li>The ingress router decides to split LSP-1 into four LSPs, and creates LSP-4.</li> </ul>	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G LSP-4 = 1G
T4	LSP-2 usage drops to 0.5G	<ul style="list-style-type: none"> <li>Aggregate bandwidth is 3G.</li> <li>The ingress router decides to merge LSP-1 and removes LSP-4.</li> </ul>	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G

Because autobandwidth is configured on a per-LSP basis, every time there is an autobandwidth adjustment, the ingress router re-signals each LSP with **Max Avg Bw**.

Another approach to handling the changes in per-LSP autobandwidth adjustments is to not allow individual LSPs to run autobandwidth on the ingress router, but to run autobandwidth in passive (monitor) mode. This way, sampling is done at every statistics interval for member LSPs only, and normalization is performed for the container LSP alone instead of acting on individual LSPs adjustment timer expiry.

As a result, the number of re-signaling attempts and bandwidth fluctuations for a given member LSP is reduced. Only the computed bandwidth-values per-member LSP is used by the ingress router to find an aggregate bandwidth to be used during normalization. Configuring autobandwidth adjustment followed by normalization (adjustments and normalization intervals are comparable) can lead to considerable overhead because of re-signaling.

Taking the same example, and applying the second approach, LSP-1 goes from 0.8G to 1.5G and then back to 0.8G. If the normalization timer is of the same order as the adjustment interval, the ingress router leaves LSP-1 alone with its original 0.8G and only signals LSP-2 with 0.8G. This helps achieve the final result of normalization, thus avoiding the extra signaling attempt on LSP-1 with 1.5G at adjustment timer expiry.

Because member LSPs always use equal bandwidth, any adjustment done on member LSPs is undone. The member LSPs are re-signaled with reduced bandwidth when compared to the reserved capacity in adjustment trigger with normalization trigger. Therefore, avoiding adjustment trigger for member LSPs might be useful assuming that normalization and adjustment intervals are of the same order.

**NOTE:** We recommend that the normalization timer be higher than the autobandwidth adjustment interval and regular optimization duration, as the traffic trends are observed at a longer time scale and normalization is performed one-to-three times per day. An LSP can undergo optimization for the following reasons:

- Normal optimization
- Autobandwidth adjustment
- Normalization

#### *Changes in Traffic Growth*

Table 14 on page 425 illustrates how normalization is performed when traffic grows in large factor.

**Table 14: Normalization with Traffic Growth**

Normalization Time	Current State	Events	Adjusted State
T0	No state		LSP-1 is signaled with bandwidth of 0.8G
T1	LSP-1 usage increase to 3G	<ul style="list-style-type: none"> <li>• Aggregate usage exceeds maximum splitting bandwidth</li> <li>• The ingress router decides to split LSP-1, and creates two more supplementary LSPs</li> </ul>	LSP-1 = 1G LSP-2 = 1G LSP-3 = 1G

Having fewer LSPs is preferred over signaling four LSPs each with 0.8G bandwidth, unless there is a constraint on the minimum number of LSPs.

#### ***Computed Range and Configured Feasible Ranges***

When an ingress router is configured with the minimum and maximum number of LSPs, and per LSP splitting-bandwidth and merging-bandwidth values, the bandwidth thresholds are used for splitting and merging. For this, the number of LSPs (N) should satisfy the following constraints:

$$\text{minimum-member-lsps} \leq N \leq \text{maximum-member-lsps}$$

At the time of normalization, based on the aggregate demand X:

$$\lceil X/\text{splitting-bandwidth} \rceil \leq N \leq \lfloor X/\text{merging-bandwidth} \rfloor$$

The above-mentioned constraints provide two ranges for N to work from. If the two ranges for N are overlapping, N will be selected from the overlapping interval (lowest possible N) to keep the number of LSPs small in the network.

Otherwise, if maximum-member-lsps is less than  $\lceil X/\text{splitting-bandwidth} \rceil$ , the ingress router keeps (at maximum) the maximum-member-lsps in the system, and the bandwidth of each LSP is  $\lceil X/\text{maximum-member-lsps} \rceil$  or the maximum-signaling-bandwidth, whichever is less. It is possible that some LSPs might not get signaled successfully.

Similarly, if minimum-member-lsps is greater than  $\lceil X/\text{merging-bandwidth} \rceil$ , the ingress router keeps (at minimum) the minimum-member-lsps in the system, and the bandwidth of each LSP is  $\lceil X/\text{minimum-member-lsps} \rceil$  or the minimum-signaling-bandwidth, whichever is less.

Taking as an example, normalization is performed as following in these cases:

- Case 1
  - minimum-member-lsps = 2
  - maximum-member-lsps = 10
  - aggregate demand = 10G
  - merging-bandwidth = 1G
  - splitting-bandwidth = 2.5G

In this case, the ingress routing device signals four member LSPs each with a bandwidth of 2G.

- Case 2
  - minimum-member-lsps = 5
  - maximum-member-lsps = 10
  - aggregate demand = 10G
  - merging-bandwidth = 2.5G
  - splitting-bandwidth = 10G

In this case, the ingress routing device signals five member LSPs each with a bandwidth of 2G. Here, the static configuration on the number of member LSPs takes precedence.

- Case 3
  - minimum-signaling-bandwidth = 5G
  - maximum-signaling-bandwidth = 40G
  - merging-bandwidth = 10G
  - splitting-bandwidth = 50G

When a container LSP comes up, the nominal LSP is signaled with minimum-signaling-bandwidth. At the time of normalization, the

new-aggregate-bandwidth is 100G. To find N and the bandwidth of each LSP, N should satisfy the following constraint:

$$100/50 \leq N \leq 100/10, \text{ which gives } 2 \leq N \leq 10$$

Therefore, N is equal to:

- N = 2, bandwidth =  $\min \{100/2G, 40G\} = 40G$

This option does not satisfy the new aggregate of 100G.

- N = 3, bandwidth =  $\min \{100/3G, 40G\} = 33.3G$

This option makes the aggregate bandwidth equal to 100G.

In this case, the ingress routing device signals three LSPs each with a bandwidth of 33.3G.

**NOTE:** The ingress router does not signal an LSP smaller than the minimum-signaling-bandwidth.

### Constraint-Based Routing Path Computation

Although there are no changes in the general constraint-based routing path computation, with a container LSP, there is a separate module that oversees the normalization process, schedules constraint-based routing events, and schedules switchover from an old instance to a new instance, when appropriate. An ingress routing device has to handle the constraint-based routing path computation periodically. When normalization occurs, an ingress router has to compute constraint-based routing paths, if the number of LSPs or the bandwidth of the LSPs needs to be changed.

For example, there are K LSPs at the ingress router with bandwidth values X-1, X-2, ..., and X-K. The current aggregate bandwidth value is Y, which is the sum of X-1 plus X-2 plus X-K. If there is a new demand of W, the ingress router first computes how many LSPs are required. If the ingress router only needs N LSPs (LSP-1, LSP-2, ..., and LSP-N) each with bandwidth value B, the task of the constraint-based routing module is to provide a set of bandwidth-feasible LSPs that can accommodate the new aggregate demand which is not less than Y.

The ingress router then tries to see if the constraint-based routing paths can be computed successfully for all N LSPs. If the paths for all the LSPs are found successfully, the constraint-based routing module returns the set to the normalization module.

It is possible that the constraint-based routing computation is not successful for some LSPs. In this case, the ingress routing device takes the following action:

- If the configuration allows for incremental-normalization, implying if the ingress router has enough LSPs whose aggregate exceeds Y, the constraint-based routing module returns that set of paths.
- Whether increment-normalization is configured or not, if constraint-based routing paths could not be computed for a sufficient number of LSPs, the ingress router has to repeat the process of finding a new set of LSPs. Initially, the ingress router starts

with the lowest value of N from the feasible region. Every time, the ingress router has to revise the number, it linearly increases it by 1. As a result, per LSP bandwidth becomes less and therefore, there is a greater chance of successful signaling. The process is repeated for all feasible values of N (or some bounded number of times or duration as configured).

The ingress router signals the LSPs after successful computations of the constraint-based routing path computation. It might happen that when the LSPs are signaled, signaling of many LSPs fail. In addition to the constraint-based routing path computations to be successful, the RSVP signaling should also succeed, such that the new aggregate is not less than the old aggregate bandwidth.

---

### Sampling

Sampling is important for normalization to function. With sampling configured, an ingress routing device is able to make a statistical estimate of the aggregate traffic demands. Every time the sampling timer fires, the ingress routing device can consider traffic rates on different LSPs and compute an aggregate bandwidth sample. This sampling timer is different from the statistics sampling done periodically by RSVP on all LSPs. The aggregate bandwidth is a sample to be used at the time of normalization. An ingress routing device can save past samples to compute an average (or some other statistical measure) and use it the next time normalization happens.

To remove any outlier samples, a sampling token is configured. In other words, from all the aggregate samples collected during the configured time, the bottom and top outliers are ignored before computing a statistical measure from the remaining samples.

The following two methods of computing an aggregate bandwidth value are supported:

- **Average**—All the aggregate bandwidth samples are considered by the ingress routing device, and then all the outlier samples are removed. The average bandwidth value is computed from the remaining samples to be used during normalization.
- **Max**—All the aggregate bandwidth samples are considered by the ingress routing device, and then all the outlier samples are removed. The maximum bandwidth value is picked from the remaining samples to be used during normalization.

The time duration, the number of past aggregate samples to store, the percentile value to determine, and the ignore outliers are user-configurable parameters.

---

### Support for NSR, IPG-FA, and Static Routes

Starting with Junos OS Release 15.1, container label-switched paths (LSPs) provide support for nonstop active routing (NSR), IGP forwarding adjacency (FA), and static routes to address the requirements of wider business cases.

- [NSR Support on page 429](#)
- [IPG-FA Support on page 430](#)
- [Static Route Support on page 431](#)

### NSR Support

A container LSP has the characteristics of ECMP and RSVP traffic engineering. Because a container LSP consists of several member LSPs between an ingress and an egress router, with each member LSP taking a different path to the same destination, the ingress router is configured with all the parameters necessary to compute an RSVP ECMP LSP. These parameters along with the forwarding state information have to be synchronized between the master and backup Routing Engines to enable the support for nonstop active routing (NSR) for container LSPs. While some of the forwarding state information on the backup Routing Engine is locally built based on the configuration, most of it is built based on periodic updates from the master Routing Engine. The container LSPs are created dynamically using the replicated states on the backup Routing Engine.

By default, normalization occurs once in every 6 hours and during this time, a number of autobandwidth adjustments happen over each member LSP. A member LSP is resized according to the traffic it carries and the configured autobandwidth configuration parameters. The aggregate demand on a container LSP is tracked by summing up the bandwidth across all the member LSPs.

For RSVP point-to-point LSPs, a Routing Engine switchover can be under any one of the following:

- **Steady state**

In the steady state, the LSP state is up and forwards traffic; however, no other event, such as the make-before-break (MBB), occurs on the LSP. At this stage, the RPD runs on both the Routing Engines, and the switchover event toggles between the master and backup Routing Engine. The backup Routing Engine has the LSP information replicated already. After the switchover, the new master uses the information of the replicated structure to construct the container LSP and en-queues the path (ERO) of LSP in the retrace mode. RSVP signals and checks if the path mentioned in the ERO is reachable. If the RSVP checks fail, then the LSP is restarted. If the RSVP checks succeed, the LSP state remains up.

- **Action leading to make-before-break (MBB)**

A container LSP can be optimized with updated bandwidth, and this change is done in a MBB fashion. During an MBB process, there are two path instances for a given LSP, and the LSP switches from one instance to another. For every Routing Engine switchover, the path is checked to find out where in the MBB process the path is. If the path is in the middle of the MBB process, with the main instance being down and the re-optimized path being up, then MBB can switch over to the new instance. The **show mpls lsp extensive** command output, in this case, is as follows:

```
13 Dec 3 01:33:38.941 Make-before-break: Switched to new instance
12 Dec 3 01:33:37.943 Record Route: 10.1.1.1
11 Dec 3 01:33:37.942 Up
10 Dec 3 01:33:37.942 Automatic Autobw adjustment succeeded: BW changes
from 100 bps to 281669 bps
9 Dec 3 01:33:37.932 Originate make-before-break call
8 Dec 3 01:33:37.931 CSPF: computation result accepted 10.1.1.1
7 Dec 3 01:28:44.228 CSPF: ERO retrace was successful 10.1.1.1
6 Dec 3 01:19:39.931 10.1.1.2 Down: mbb/reopt
5 Dec 3 01:18:29.286 Up: mbb/reopt
```

```

4 Dec 3 01:14:47.119 10.1.1.2 Down: mbb/reopt
3 Dec 3 01:13:29.285 Up: mbb/reopt
2 Dec 3 01:10:59.755 Selected as active path: selected by master RE

```

A similar behavior is retained for member LSPs during bandwidth optimization.

A Routing Engine switchover under the steady state (when normalization is not in progress), keeps the container LSPs up and running without any traffic loss. Events, such as an MBB due to autobandwidth adjustments, link status being down, or double failure, in the steady state are similar to a normal RSVP point-to-point LSP.

If the container LSP is in the process of normalization, and the normalization event is triggered either manually or periodically, it goes through the computation and execution phase. In either of the cases, zero percent traffic loss is not guaranteed.

- Normalization in the computation phase

During the computation phase, the master Routing Engine calculates the targeted member LSP count and bandwidth with which each member LSP should be re-signaled. The backup Routing Engine has limited information about the container LSP, such as the LSP name, LSP ID, current bandwidth of its member LSP, member LSP count, and the normalization retry count. If the switchover happens during the computation phase, then the backup Routing Engine is not aware of the targeted member LSP count and the bandwidth to be signaled. Since traffic statistics are not copied to the backup Routing Engine, it cannot compute the targeted member count and bandwidth. In this case, the new master Routing Engine uses the old data stored in the targeted member LSP count and the targeted bandwidth to signal the LSPs.

- Normalization in the execution phase

During the execution phase, RSVP of the master Routing Engine tries to signal the LSPs with the newly calculated bandwidth. If the switchover occurs during the signaling of LSPs with greater bandwidth or during LSP splitting or merging, then the new master Routing Engine uses the information of the targeted member count and bandwidth value to be signaled with, to bring up the LSPs.

### ***IPG-FA Support***

A forwarding adjacency (FA) is a traffic engineering label-switched path (LSP) that is configured between two nodes and used by an interior gateway protocol (IGP) to forward traffic. By default, an IGP does not consider MPLS traffic-engineering tunnels between sites, for traffic forwarding. Forwarding adjacency treats a traffic engineering LSP tunnel as a link in an IGP topology, thus allowing the nodes in the network also to forward the IP traffic to reach the destination over this FA LSP. A forwarding adjacency can be created between routing devices regardless of their location in the network.

To advertise a container LSP as an IGP-FA, the LSP name needs to be configured either under IS-IS or OSPF. For example:

```

IS-IS [edit]
protocols {
  isis {
    label-switched-path container-lsp-name;
  }
}

```

```

OSPF    [edit]
        protocols {
          ospf {
            area 0.0.0.0 {
              label-switched-path container-lsp-name;
            }
          }
        }

```

**NOTE:** The IGP-FA is applied to both container LSPs and regular point-to-point LSPs. If a container LSP and a point-to-point LSP share the same name, the point-to-point LSP is given preference for FA.

### Static Route Support

Static routes often include only one or very few paths to a destination and generally do not change. These routes are used for stitching services when policies and other protocols are not configured.

To advertise a container LSP as a static route, the LSP name needs to be configured under the static route configuration. For example:

```

Static Route  [edit]
              routing-options {
                static {
                  route destination {
                    lsp-next-hop container-lsp-name;
                  }
                }
              }

```

**NOTE:** The static route support is applied to both container LSPs and regular point-to-point LSPs. If a container LSP and a point-to-point LSP share the same name, the point-to-point LSP is given preference for static routing.

## Configuration Statements Supported for Container LSPs

Table 15 on page 432 lists the MPLS LSP configuration statements that apply to RSVP LSP and a container LSP (nominal and supplementary).

The configuration support is defined using the following terms:

- Yes—The configuration statement is supported for this type of LSP.
- No—The configuration statement is not supported for this type of LSP.
- N/A—The configuration statement is not applicable for this type of LSP.

Table 15: Applicability of RSVP LSPs Configuration to a Container LSP

Configuration Statement	RSVP LSP (Ingress)	Member LSP (Ingress)
adaptive (Default: non-adaptive)	Yes	Yes
admin-down	Yes	Yes
admin-group	Yes	Yes

### Impact of Configuring Container LSPs on Network Performance

A container LSP is a container LSP that allows multiple member LSPs to co-exist and be managed as a bundle. The member LSPs are similar to independent point-to-point RSVP LSPs. As a result, resource consumption is similar to the sum of resources consumed by each point-to-point RSVP LSP. However, provisioning a container LSP is more efficient, as under-utilized member LSPs are dynamically removed, thus saving memory and CPU resources.

The container LSP features are dependent on the presence of a functional base MPLS RSVP implementation. As a result, a container LSP does not introduce any security considerations beyond the existing considerations for the base MPLS RSVP functionality. The categories of possible attacks and countermeasures are as follows:

- Interaction with processes and router configuration

No new communication mechanisms with external hosts are required for a container LSP. Data arrives at the RSVP module through local software processes and router configuration, other than RSVP neighbor adjacency. Junos OS provides security controls on access to the router and router configuration.

- Communication with external RSVP neighbors

RSVP signaled MPLS LSPs depend on the services of RSVP and IGP to communicate RSVP messages among neighboring routers across the network. Because the RSVP sessions involve communication outside of the local router, they are subject to many forms of attack, such as spoofing of peers, injection of falsified RSVP messages and route updates, and attacks on the underlying TCP/UDP transport for sessions. Junos OS provides countermeasures for such attack vectors.

- Resource limits and denial of service

Junos OS provides several mechanisms through policers and filters to protect against denial-of-service attacks based on injecting higher than the expected traffic demands. At the MPLS LSP level, Junos OS allows operators to configure limits on the LSP

bandwidth and the number of LSPs. However, like point-to-point RSVP LSPs, container LSPs do not enforce limits on the volume of traffic forwarded over these LSPs.

## Supported and Unsupported Features

Junos OS supports the following container LSP features:

- Equal-bandwidth-based LSP splitting mechanism
- Aggregate-bandwidth-based LSP splitting and merging in a make-before-break way
- LSP-number-based naming mechanism for dynamically created member LSPs
- Periodic sampling mechanisms to estimate aggregate bandwidth
- Interoperability with auto-bandwidth feature
- ECMP using the dynamically created LSPs
- LDP-tunneling on the dynamically created LSP
- Configuring container LSP using IGP shortcuts
- Aggregated Ethernet links
- Logical systems

Junos OS does **not** support the following container LSP functionality:

- Node and link disjoint paths for different LSPs between an ingress and an egress routing device
- Bandwidth allocation policy different from equal bandwidth policy at the normalization event
- Constraint-based routing path computation to find equal IGP cost paths for different LSPs
- RSVP objects, such as **MLSP\_TUNNEL Sender Template**, and **MLSP\_TUNNEL Filter Specification** defined in [KOMPELLA-MLSP]
- Change in topology as a trigger for LSP splitting and merging
- Change in topology and link failure as a trigger for normalization, unless member LSPs go down
- Egress protection on container LSP
- Container LSP as a backup LSP for IGP interface
- Container LSP configured as IGP interface as forwarding address
- Container LSP as provider tunnel for multicast VPNs
- Dynamic LSPs for normalization
- CCC using container LSP
- Secondary paths for container LSP
- Bidirectional container LSP

- Policing
- Static routes using container LSPs as next hops on a best-effort basis
- External path computing entity, such as PCE
- Graceful Routing Engine switchover
- Nonstop active routing
- Unified ISSU
- Multichassis
- IPv6

## Configuring Dynamic Bandwidth Management Using Container LSP

---

You can configure a container LSP to enable load balancing across multiple point-to-point LSPs dynamically. A container LSP includes one or more member LSPs between the same ingress and egress routing devices. The member LSPs are similar to independent point-to-point LSPs, and each member LSP takes a different path to the same destination and can be routed along a different IGP cost path.

A container LSP provides support for dynamic bandwidth management by enabling the ingress router to dynamically add and remove member LSPs through a process called LSP splitting and LSP merging, respectively, based on configuration and aggregate traffic. Besides addition and deletion, member LSPs can also be re-optimized with different bandwidth values in a make-before-break way.

Before you begin:

1. Configure the device interfaces.
2. Configure the device router ID and autonomous system number.
3. Configure the following protocols:
  - RSVP
  - BGP
    - Configure a BGP group to peer device with remote provider edge (PE) device.
  - OSPF
    - Enable traffic engineering capabilities.
4. Configure a VRF routing instance.

To configure the PE device:

1. Enable MPLS on all the interfaces (excluding the management interface).

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```

2. Configure the MPLS statistics parameters.

```
[edit protocols]
user@PE1# set mpls statistics file file-name
user@PE1# set mpls statistics file size size
user@PE1# set mpls statistics interval seconds
user@PE1# set mpls statistics auto-bandwidth
```

3. Configure the label-switched path (LSP) template parameters.

```
[edit protocols]
user@PE1# set mpls label-switched-path template-name template
user@PE1# set mpls label-switched-path template-name optimize-timer seconds
user@PE1# set mpls label-switched-path template-name link-protection
user@PE1# set mpls label-switched-path template-name adaptive
user@PE1# set mpls label-switched-path template-name auto-bandwidth
    adjust-interval seconds
user@PE1# set mpls label-switched-path template-name auto-bandwidth
    adjust-threshold seconds
user@PE1# set mpls label-switched-path template-name auto-bandwidth
    minimum-bandwidth mbps
user@PE1# set mpls label-switched-path template-name auto-bandwidth
    maximum-bandwidth mbps
```

4. Configure a container LSP between the two PE routers, and assign the LSP template.

```
[edit protocols]
user@PE1# set mpls container-label-switched-path container-lsp-name to
    remote-PE-ip-address
user@PE1# set mpls container-label-switched-path container-lsp-name
    label-switched-path-template template-name
```

5. Configure the container LSP parameters.

```
[edit protocols]
user@PE1# set mpls container-label-switched-path container-lsp-name
    splitting-merging maximum-member-lsps number
user@PE1# set mpls container-label-switched-path container-lsp-name
    splitting-merging minimum-member-lsps number
user@PE1# set mpls container-label-switched-path container-lsp-name
    splitting-merging splitting-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name
    splitting-merging merging-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name
    splitting-merging maximum-signaling-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name
    splitting-merging minimum-signaling-bandwidth mbps
user@PE1# set mpls container-label-switched-path container-lsp-name
    splitting-merging normalization normalize-interval seconds
user@PE1# set mpls container-label-switched-path container-lsp-name
    splitting-merging normalization failover-normalization
```

```

user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging normalization normalization-retry-duration seconds
user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging normalization normalization-retry-limits number
user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging sampling cut-off-threshold number
user@PE1# set mpls container-label-switched-path container-lsp-name
splitting-merging sampling use-percentile number

```

6. Configure the policy statement to load-balance traffic.

```

[edit policy-options]
user@PE1# set policy-statement first-policy-name term 1 from protocol direct
user@PE1# set policy-statement first-policy-name term 1 then accept
user@PE1# set policy-statement second-policy-name then load-balance per-packet

```

**NOTE:** The policy to load-balance traffic should be assigned to the forwarding table configuration under the [edit routing-options] hierarchy level.

```

user@PE1# set forwarding-table export pplb

```

7. Verify and commit the configuration.

For example:

```

[edit protocols]
user@PE1# set rsvp preemption aggressive
user@PE1# set rsvp interface all aggregate
user@PE1# set rsvp interface fxp0.0 disable
user@PE1# set rsvp interface ge-0/0/1.0
user@PE1# set rsvp interface ge-0/0/2.0
user@PE1# set mpls statistics file auto-bw
user@PE1# set mpls statistics file size 10m
user@PE1# set mpls statistics interval 10
user@PE1# set mpls statistics auto-bandwidth
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 template
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 optimize-timer 30
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 link-protection
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 adaptive
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
adjust-interval 300
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
adjust-threshold 5
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
minimum-bandwidth 10m
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth
maximum-bandwidth 10m
user@PE1# set mpls label-switched-path PE1-PE2-template-1 template
user@PE1# set mpls label-switched-path PE1-PE2-template-1 auto-bandwidth
adjust-interval 8000
user@PE1# set mpls label-switched-path PE1-PE2-template-1 auto-bandwidth
minimum-bandwidth 5m
user@PE1# set mpls label-switched-path PE1-PE2-template-1 auto-bandwidth
maximum-bandwidth 10m

```

```
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100

## Example: Configuring Dynamic Bandwidth Management Using Container LSP

---

This example shows how to enable dynamic bandwidth management by configuring container label-switched paths (LSPs) that enable load balancing across multiple point-to-point member LSPs.

- [Requirements on page 441](#)
- [Overview on page 441](#)
- [Configuration on page 442](#)
- [Verification on page 450](#)

### Requirements

This example uses the following hardware and software components:

- Five routers that can be a combination of M Series, MX Series, or T Series routers, out of which two routers are provider edge (PE) routers and three routers are provider (P) routers
- Junos OS Release 14.2 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
  - RSVP
  - MPLS
  - BGP
  - OSPF

### Overview

Starting with Junos OS Release 14.2, a new type of LSP, called a container LSP, is introduced to enable load balancing across multiple point-to-point LSPs. A container LSP includes one or more member LSPs between the same ingress and egress routing devices. The member LSPs are similar to independent point-to-point LSPs, and each member LSP takes a different path to the same destination and can be routed along a different IGP cost path.

A container LSP provides support for dynamic bandwidth management by enabling the ingress router to dynamically add and remove member LSPs through a process called LSP splitting and LSP merging, respectively, based on configuration and aggregate traffic. Besides addition and deletion, member LSPs can also be re-optimized with different bandwidth values in a make-before-break way.

## Topology

Figure 40 on page 442 is a sample topology configured with container LSPs.

Figure 40: Dynamic Bandwidth Management Using Container LSP

In this example, Routers PE1 and PE2 are the PE routers connected to hosts Host1 and Host2, respectively. The core routers, Routers P1, and P2, and P3 connect to the PE routers.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

PE1 set interfaces ge-0/0/0 unit 0 family inet address 1.1.1/24
    set interfaces ge-0/0/1 unit 0 family inet address 10.10.10.1/24

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router PE1:

1. Configure the Router PE1 interfaces.

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 0 family inet address 1.1.1.1/24

user@PE1# set ge-0/0/1 unit 0 family inet address 10.10.10.1/24
user@PE1# set ge-0/0/1 unit 0 family mpls

user@PE1# set ge-0/0/2 unit 0 family inet address 40.40.40.1/24
user@PE1# set ge-0/0/2 unit 0 family mpls

user@PE1# set lo0 unit 0 family inet address 10.255.102.166/32
user@PE1# set lo0 unit 0 family mpls
```

2. Configure the router ID and autonomous system number for Router PE1.

```
[edit routing-options]
user@PE1# set router-id 10.255.102.166
```

- ```
user@PE1# set autonomous-system 1234
```
3. Enable the policy to load-balance traffic.  

```
[edit routing-options]  
user@PE1# set forwarding-table export pplb
```
  4. Enable RSVP on all Router PE1 interfaces (excluding the management interface).  

```
[edit protocols]  
user@PE1# set rsvp preemption aggressive  
user@PE1# set rsvp interface all aggregate  
user@PE1# set rsvp interface fxp0.0 disable  
user@PE1# set rsvp interface ge-0/0/1.0  
user@PE1# set rsvp interface ge-0/0/2.0
```
  5. Enable MPLS on all the interfaces of Router PE1 (excluding the management interface).  

```
[edit protocols]  
user@PE1# set mpls interface all  
user@PE1# set mpls interface fxp0.0 disable
```
  6. Configure the MPLS statistics parameters.  

```
[edit protocols]  
user@PE1# set mpls statistics file auto-bw  
user@PE1# set mpls statistics file size 10m  
user@PE1# set mpls statistics interval 10  
user@PE1# set mpls statistics auto-bandwidth
```
  7. Configure the label-switched path (LSP) template parameters.  

```
[edit protocols]  
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 template  
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 optimize-timer 30  
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 link-protection  
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 adaptive  
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth  
adjust-interval 300  
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth  
adjust-threshold 5  
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth  
minimum-bandwidth 10m  
user@PE1# set mpls label-switched-path PE1-to-PE2-template1 auto-bandwidth  
maximum-bandwidth 10m
```
  8. Configure a container LSP between Router PE1 and Router PE2, and assign the PE1-to-PE2-template1 LSP template.  

```
[edit protocols]  
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100 to  
10.255.102.128  
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100  
label-switched-path-template PE1-to-PE2-template1
```
  9. Configure the container LSP parameters.  

```
[edit protocols]  
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100  
splitting-merging maximum-member-lsps 20
```

```

user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging minimum-member-lsps 2
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging splitting-bandwidth 40m
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging merging-bandwidth 6m
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging maximum-signaling-bandwidth 10m
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging minimum-signaling-bandwidth 10m
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging normalization normalize-interval 400
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging normalization failover-normalization
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging normalization normalization-retry-duration 20
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging normalization normalization-retry-limits 3
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging sampling cut-off-threshold 1
user@PE1# set mpls container-label-switched-path PE1-PE2-container-100
splitting-merging sampling use-percentile 90

```

10. Configure the BGP group, and assign the local and neighbor IP addresses.

```

[edit protocols]
user@PE1# set bgp group to-PE2 type internal
user@PE1# set bgp group to-PE2 local-address 10.255.102.166
user@PE1# set bgp group to-PE2 neighbor 10.255.102.128
user@PE1# set bgp group to-PE2 family inet-vpn unicast
user@PE1# set bgp group to-PE2 export direct

```

11. Enable OSPF on all the interfaces of Router PE1 (excluding the management interface) along with traffic engineering capabilities.

```

[edit protocols]
user@PE1# set ospf traffic-engineering
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PE1# set ospf area 0.0.0.0 interface ge-0/0/2.0 metric 100

```

12. Configure the policy statement to load-balance traffic.

```

[edit policy-options]
user@PE1# set policy-statement direct term 1 from protocol direct
user@PE1# set policy-statement direct term 1 then accept
user@PE1# set policy-statement pplb then load-balance per-packet

```

13. Configure a routing instance on Router PE1, and assign the routing instance interface.

```

[edit routing-instances]
user@PE1# set vpn1 instance-type vrf
user@PE1# set vpn1 interface ge-0/0/0.0

```

14. Configure the route distinguisher, vrf target, and vrf-table label values for the VRF routing instance.

```

[edit routing-instances]
user@PE1# set vpn1 route-distinguisher 10.255.102.166:1

```

```
user@PE1# set vpn1 vrf-target target:1:1
user@PE1# set vpn1 vrf-table-label
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces

```

**Meaning** The container LSP is established between Routers PE1 and PE2.

### Verifying the Container LSP Status with Increased Bandwidth (Before Normalization)

**Purpose** Verify the status of the container LSP with increased bandwidth before normalization happens.

**Action** From operational mode, run the **show mpls container-lsp extensive** command.

```

user@PE1> show mpls container-lsp extensive
Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 2
Normalization
  Min LSPs: 2, Max LSPs: 20

Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

```

**Meaning** At the expiry of the normalization timer, the container LSP is split into five member LSPs, each with 10 Mbps (minimum and maximum signaling bandwidth). As a result, the

aggregate bandwidth is 50 Mbps.

### Verifying the Container LSP Splitting Process

**Purpose** Verify the container LSP splitting process after normalization happens.

**Action** From operational mode, run the **show route 2.2.2** command.

```
user@PE1> show route 2.2.2
vpn1.inet.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2.2.2.0/24          *[BGP/170] 00:12:14, localpref 100, from 10.255.102.128
                    AS path: I, validation-state: unverified
>to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-1
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-2
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-3
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-4
to 10.10.10.2 via ge-0/0/1.0, label-switched-path PE1-PE2-container100-5
```

**Meaning** After LSP splitting, Router PE1 has injected the forwarding adjacency.

### Verifying the Container LSP Statistics

**Purpose** Verify the container LSP statistics after normalization happens.

**Action** From operational mode, run the **show mpls container-lsp statistics** command.

```
user@PE1> show mpls container-lsp statistics
Ingress LSP: 1 sessions
Container LSP name                                State      Member LSP count
PE1-PE2-container-100                             Up          5
To          From          State      Packets      Bytes  LSPname
10.255.102.128 10.255.102.166 Up    15166271    2062612856
PE1-PE2-container-100-1
10.255.102.128 10.255.102.166 Up    12289912    1671428032
PE1-PE2-container-100-2
10.255.102.128 10.255.102.166 Up    13866911    1885899896
PE1-PE2-container-100-3
10.255.102.128 10.255.102.166 Up    12558707    1707984152
PE1-PE2-container-100-4
10.255.102.128 10.255.102.166 Up    11512151    1565652536
PE1-PE2-container-100-5
```

**Meaning** Traffic is load-balanced across the newly created member LSPs.

### Verifying the Container LSP Status with Decreased Bandwidth (Before Normalization)

**Purpose** Verify the status of the container LSP with decreased bandwidth before normalization happens.

**Action** From operational mode, run the **show mpls container-lsp detail** command.

```
user@PE1> show mpls container-lsp detail
Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 5
Normalization
  Min LSPs: 2, Max LSPs: 20
  Aggregate bandwidth: 50Mbps, Sampled Aggregate bandwidth: 2.0215Mbps
  NormalizeTimer: 400 secs, NormalizeThreshold: 10%
  Max Signaling BW: 10Mbps, Min Signaling BW: 10Mbps, Splitting BW: 40Mbps, Merging
  BW: 6Mbps
  Mode: incremental-normalization, failover-normalization
  Sampling: Outlier cut-off 1, Percentile 90 of Aggregate
  Normalization in 384 second(s)
---Output truncated---
```

**Meaning** Because normalization has not happened, the member LSP count remains at 5.

### Verifying the Container LSP Status with Decreased Bandwidth (After Normalization)

**Purpose** Verify the status of the container LSP with decreased bandwidth after normalization happens.

**Action** From operational mode, run the **show mpls container-lsp detail** command.

```
user@PE1> show mpls container-lsp detail
Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 2
Normalization
  Min LSPs: 2, Max LSPs: 20
  Aggregate bandwidth: 20Mbps, Sampled Aggregate bandwidth: 0bps
  NormalizeTimer: 400 secs, NormalizeThreshold: 10%
  Max Signaling BW: 10Mbps, Min Signaling BW: 10Mbps, Splitting BW: 40Mbps, Merging
  BW: 6Mbps
  Mode: incremental-normalization, failover-normalization
  Sampling: Outlier cut-off 1, Percentile 90 of Aggregate
  Normalization in 397 second(s)
  22 Jun  5 22:30:37.094 Clear history and statistics: on container
  (PE1-PE2-container-100)
  21 Jun  5 22:30:37.094 Delete member LSPs: PE1-PE2-container-100-3 through
  PE1-PE2-container-100-5
  20 Jun  5 22:30:37.090 Normalize: container (PE1-PE2-container-100) into 2
  members - each with bandwidth 10000000 bps
  19 Jun  5 22:30:37.090 Normalize: normalization with aggregate bandwidth 2037595
  bps
  18 Jun  5 22:30:37.090 Normalize: normalization with 2037595 bps
---Output truncated---
```

**Meaning** At the expiry of the normalization timer, the container LSP merging takes place because there is an overall reduction in bandwidth. The member LSPs are merged, and the member LSP count is 2 after normalization.

### Verifying the Container LSP Merging Process

---

**Purpose** Verify the container LSP splitting process after normalization happens.

**Action** From operational mode, run the **show route 2.2.2** command.

```
user@PE1> show route 2.2.2
vpn1.inet.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2.2.2.0/24          *[BGP/170] 01:09:45, localpref 100, from 10.255.102.128
                   AS path: I, validation-state: unverified
                   > to 10.10.10.2 via ge-0/0/1.0, label-switched-path
PE1-PE2-container-100-1
                   to 10.10.10.2 via ge-0/0/1.0, label-switched-path
PE1-PE2-container-100-2
```

**Meaning** After LSP merging, Router PE1 has deleted the merged member LSPs.

### Verifying Failover Normalization

---

**Purpose** Verify load redistribution when traffic is sent at 35 Mbps and the link between Routers P1 and P2 is disabled. Arrival of PathErr on link failure triggers immediate normalization.

To enable failover normalization, include the **failover-normalization** configuration statement at the **[edit protocols mpls container-label-switched-path container-lsp-name splitting-merging normalization]** hierarchy level.

**Action** From operational mode, run the **show mpls container-lsp** command.

```
user@PE1> show mpls container-lsp
Ingress LSP: 1 sessions
Container LSP name
PE1-PE2-container-100
To From State Rt P State Member LSP count
Up ActivePath 2
10.255.102.128 10.255.102.166 Up 0 *
PE1-PE2-container-100-1
10.255.102.128 10.255.102.166 Up 0 *
PE1-PE2-container-100-2
Total 2 displayed, Up 2, Down 0
```

After the ge-0/0/2 link between Routers P1 and P2 goes down, normalization is immediately triggered.

From operational mode, run the **show mpls container-lsp detail** command.

```
user@PE1> show mpls container-lsp detail
Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 4
Normalization
Min LSPs: 2, Max LSPs: 20
Aggregate bandwidth: 40Mbps, Sampled Aggregate bandwidth: 34.5538Mbps
NormalizeTimer: 3000 secs, NormalizeThreshold: 10%
Max Signaling BW: 10Mbps, Min Signaling BW: 10Mbps, Splitting BW: 40Mbps, Merging
BW: 6Mbps
Mode: incremental-normalization, failover-normalization
Sampling: Outlier cut-off 1, Percentile 90 of Aggregate
Normalization in 2970 second(s)
11 Jun 5 19:28:27.564 Normalization complete: container (PE1-PE2-container-100)

----Output truncated----
```

**Meaning** Arrival of PathErr message on link failure triggers immediate normalization.

### Verifying Incremental Normalization

**Purpose** Verify incremental normalization when enough bandwidth is not available.

On Router PE1, the RSVP interfaces static bandwidth is restricted to 22 Mbps each.

**Action** From operational mode, run the **show rsvp interface** command.

```
user@PE1> show rsvp interface
RSVP interface: 4 active
```

| Interface  | State | Active resv | Subscription | Static BW | Available BW | Reserved BW | Highwater mark |
|------------|-------|-------------|--------------|-----------|--------------|-------------|----------------|
| ge-0/0/2.0 | Up    | 0           | 100%         | 22Mbps    | 22Mbps       | 0bps        | 21.4031Mbps    |
| ge-0/0/1.0 | Up    | 2           | 100%         | 22Mbps    | 12Mbps       | 10Mbps      | 21.7011Mbps    |

Before normalization happens:

From operational mode, run the **show mpls container-lsp** command.

```
user@PE1> show mpls container-lsp
Ingress LSP: 1 sessions
Container LSP name
PE1-PE2-container-100
To From State Rt P State Up Member LSP count
ActivePath LSPname
10.255.102.128 10.255.102.166 Up 0 * PE1-PE2-container-100-1
PE1-PE2-container-100-1
10.255.102.128 10.255.102.166 Up 0 * PE1-PE2-container-100-2
PE1-PE2-container-100-2
```

After normalization happens:

From operational mode, run the **show mpls container-lsp** command.

```
user@PE1> show mpls container-lsp
Ingress LSP: 1 sessions
Container LSP name
PE1-PE2-container-100
To From State Rt P State Up Member LSP count
ActivePath LSPname
10.255.102.128 10.255.102.166 Up 0 * PE1-PE2-container-100-1
10.255.102.128 10.255.102.166 Up 0 * PE1-PE2-container-100-2
10.255.102.128 10.255.102.166 Up 0 * PE1-PE2-container-100-3
10.255.102.128 10.255.102.166 Up 0 * PE1-PE2-container-100-4
10.255.102.128 10.255.102.166 Up 0 * PE1-PE2-container-100-5
10.255.102.128 10.255.102.166 Up 0 * PE1-PE2-container-100-6
10.255.102.128 0.0.0.0 Dn 0 - PE1-PE2-container-100-7
Total 7 displayed, Up 6, Down 1
```

From operational mode, run the **show mpls container-lsp detail** command.

```
user@PE1> show mpls container-lsp detail
Ingress LSP: 1 sessions
Container LSP name: PE1-PE2-container-100, State: Up, Member count: 7
Normalization
Min LSPs: 2, Max LSPs: 10
Aggregate bandwidth: 40.8326Mbps, Sampled Aggregate bandwidth: 50.129Mbps
NormalizeTimer: 9000 secs, NormalizeThreshold: 10%
Max Signaling BW: 10Mbps, Min Signaling BW: 5Mbps, Splitting BW: 40Mbps, Merging BW: 5Mbps
Mode: incremental-normalization, failover-normalization
Sampling: Outlier cut-off 1, Percentile 90 of Aggregate
Normalization in 8072 second(s)
10 Jun 5 18:40:17.812 Normalization complete: container (PE1-PE2-container-100) with 7 members, retry-limit reached
9 Jun 5 18:40:08.028 Normalize: container (PE1-PE2-container-100) for target member count 7, member bandwidth 6805439 bps
8 Jun 5 18:39:58.301 Normalize: container (PE1-PE2-container-100) for target
```

```
member count 6, member bandwidth 7939679 bps
7 Jun 5 18:39:48.470 Clear history and statistics: on container
(PE1-PE2-container-100)
6 Jun 5 18:39:48.470 Normalize: container (PE1-PE2-container-100) into 5
members - each with bandwidth 9527615 bps
5 Jun 5 18:39:48.469 Normalize: normalization with aggregate bandwidth 47638076
bps
4 Jun 5 18:39:48.469 Normalize: normalization with 47638076 bps
3 Jun 5 18:39:09.471 Normalization complete: container (PE1-PE2-container-100)
with 2 members
2 Jun 5 18:38:59.822 Normalize: container (PE1-PE2-container-100) create 2
LSPs, min bw 5000000bps, member count 0
1 Jun 5 18:38:59.822 Normalize: normalization with aggregate bandwidth 0 bps
```

**Meaning** After normalization, the aggregate bandwidth after three retries is 40.8326 Mbps.

## Configuring On-Demand Loss and Delay Measurement

---

You can configure an on-demand loss and delay measurement for point-to-point ultimate hop popping (UHP) label-switched paths (LSPs) in MPLS networks to monitor network performance. The **monitor mpls loss rsvp**, **monitor mpls delay rsvp**, and **monitor mpls loss-delay rsvp** CLI commands provide an on-demand summary of performance metrics for direct mode packet loss, two-way packet delay, and related metrics, such as inter-packet delay variation and channel throughput measurement.

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

Before you begin:

1. Configure the device interfaces.
2. Configure the device router ID.
3. Configure the following protocols:
  - RSVP
  - OSPFEnable traffic engineering capabilities.
- MPLS

To configure the PE device:

1. Enable the chassis with tunnel services and enhanced IP network services configuration.

```
[edit chassis]
user@R1# set fpc fpc-slot pic pic-slot tunnel-services bandwidth bandwidth
user@R1# set network-services enhanced-ip
```
2. Configure an associated bidirectional LSP to the remote router.

```
[edit protocols]
user@R1# set mpls label-switched-path lsp-name to remote-router-ip-address
user@R1# set mpls label-switched-path lsp-name oam mpls-tp-mode
user@R1# set mpls label-switched-path lsp-name ultimate-hop-popping
user@R1# set mpls label-switched-path lsp-name associate-lsp lsp-name
```

3. Create traffic classes for maintaining data traffic statistics per traffic class.

This enables traffic class scoped loss measurement.

```
[edit protocols]
user@R1# set mpls statistics traffic-class-statistics
```

## Example: Configuring On-Demand Loss and Delay Measurement

This example shows how to enable on-demand loss and delay measurement for point-to-point ultimate hop popping (UHP) label-switched paths (LSPs) in MPLS networks to monitor network performance.

- [Requirements on page 467](#)
- [Overview on page 468](#)
- [Configuration on page 468](#)
- [Verification on page 472](#)

### Requirements

This example uses the following hardware and software components:

- Two MX Series 3D Universal Edge routers that contain MPC/MICs only
- Junos OS Release 14.2 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
  - RSVP
  - MPLS
  - OSPF

## Overview

Starting with Junos OS Release 14.2, an on-demand tool to monitor and measure packet loss, packet delay, or both for associated bidirectional MPLS ultimate hop popping (UHP) point-to-point label-switched paths (LSPs) is introduced. The tool can be enabled using the following CLI commands – **monitor mpls loss rsvp**, **monitor mpls delay rsvp**, and **monitor mpls loss-delay rsvp**.

These commands provide an on-demand summary of performance metrics for direct mode packet loss, two-way packet delay, and related metrics, such as inter-packet delay variation and channel throughput measurement.

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

## Topology

Figure 41 on page 468 illustrates the on-demand loss and delay measurement using a simple two-router topology.

**Figure 41: Configuring On-Demand Loss and Delay Measurement**

In this example, an associated bidirectional LSP is configured between Routers R1 and R2, for which the performance metrics is measured.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

R1 set chassis fpc 0 pic 3 tunnel-services bandwidth 1g
   set chassis network-services enhanced-ip
   set interfaces ge-0/0/0 unit 0 family inet address 1.1.1.1/30
   set interfaces ge-0/0/0 unit 0 family mpls
   set interfaces lo0 unit 0 family inet address 10.0.0.1/32
   set interfaces lo0 unit 0 family mpls
   set routing-options router-id 10.0.0.1
   set protocols rsvp interface ge-0/0/0.0
   set protocols rsvp interface lo0.0
   set protocols rsvp interface fxp0.0 disable
   set protocols mpls statistics traffic-class-statistics
   set protocols mpls label-switched-path R1-R2 to 20.0.0.1
   set protocols mpls label-switched-path R1-R2 oam mpls-tp-mode
   set protocols mpls label-switched-path R1-R2 ultimate-hop-popping
   set protocols mpls label-switched-path R1-R2 associate-lsp R2-R1
   set protocols mpls interface ge-0/0/0.0
   set protocols mpls interface lo0.0
   set protocols mpls interface fxp0.0 disable
  
```

```

set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-0/0/0.0
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface fxp0.0 disable

```

```

R2  set chassis fpc 0 pic 3 tunnel-services bandwidth 1g
    set chassis network-services enhanced-ip
    set interfaces ge-0/0/0 unit 0 family inet address 1.1.1.2/30
    set interfaces ge-0/0/0 unit 0 family mpls
    set interfaces lo0 unit 0 family inet address 20.0.0.1/32
    set interfaces lo0 unit 0 family mpls
    set routing-options router-id 20.0.0.1
    set protocols rsvp interface ge-0/0/0.0
    set protocols rsvp interface lo0.0
    set protocols rsvp interface fxp0.0 disable
    set protocols mpls statistics traffic-class-statistics
    set protocols mpls label-switched-path R2-R1 to 10.0.0.1
    set protocols mpls label-switched-path R2-R1 oam mpls-tp-mode
    set protocols mpls label-switched-path R2-R1 ultimate-hop-popping
    set protocols mpls label-switched-path R2-R1 associate-lsp R1-R2
    set protocols mpls interface ge-0/0/0.0
    set protocols mpls interface lo0.0
    set protocols mpls interface fxp0.0 disable
    set protocols ospf traffic-engineering
    set protocols ospf area 0.0.0.0 interface ge-0/0/0.0
    set protocols ospf area 0.0.0.0 interface lo0.0
    set protocols ospf area 0.0.0.0 interface fxp0.0 disable

```

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router R1:

1. Enable the chassis with tunnel services and enhanced IP network services configuration.  

```

[edit chassis]
user@R1# set fpc 0 pic 3 tunnel-services bandwidth 1g
user@R1# set network-services enhanced-ip

```
2. Configure the interfaces for Router R1.  

```

[edit interfaces]
user@R1# set ge-0/0/0 unit 0 family inet address 1.1.1.1/30
user@R1# set ge-0/0/0 unit 0 family mpls

user@R1# set lo0 unit 0 family inet address 10.0.0.1/32
user@R1# set lo0 unit 0 family mpls

```
3. Configure the router ID for Router R1.  

```

[edit routing-options]
user@R1# set router-id 10.0.0.1

```
4. Enable RSVP on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set rsvp interface ge-0/0/0.0
user@R1# set rsvp interface lo0.0
user@R1# set rsvp interface fxp0.0 disable
```

5. Enable MPLS on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set mpls interface ge-0/0/0.0
user@R1# set mpls interface lo0.0
user@R1# set mpls interface fxp0.0 disable
```

6. Configure an associated bidirectional LSP to Router R2.

```
[edit protocols]
user@R1# set mpls label-switched-path R1-R2 to 20.0.0.1
user@R1# set mpls label-switched-path R1-R2 oam mpls-tp-mode
user@R1# set mpls label-switched-path R1-R2 ultimate-hop-popping
user@R1# set mpls label-switched-path R1-R2 associate-lsp R2-R1
```

7. Create traffic classes for maintaining data traffic statistics per traffic class.

This enables traffic class scoped loss measurement.

```
[edit protocols]
user@R1# set mpls statistics traffic-class-statistics
```

8. Configure OSPF with traffic engineering capabilities, and enable OSPF on all the interfaces of Router R1, excluding the management interface.

```
[edit protocols]
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf interface fxp0.0 disable
```

---

## Results

From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show chassis
fpc 0 {
  pic 3 {
    tunnel-services {
      bandwidth 1g;
    }
  }
}
network-services enhanced-ip;

user@R1# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 1.1.1.1/30;
    }
  }
}
```

```

    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.0.0.1/32;
    }
    family mpls;
  }
}

user@R1# show routing-options
router-id 10.0.0.1;

user@R1# show protocols
rsvp {
  interface ge-0/0/0.0;
  interface lo0.0;
  interface fxp0.0 {
    disable;
  }
}
mpls {
  statistics {
    traffic-class-statistics;
  }
  label-switched-path R1-R2 {
    to 20.0.0.1;
    oam mpls-tp-mode;
    ultimate-hop-popping;
    associate-lsp R2-R1;
  }
  interface ge-0/0/0.0;
  interface lo0.0;
  interface fxp0.0 {
    disable;
  }
}
ospf {
  traffic-engineering;
  area 0.0.0.0 {
    interface ge-0/0/0.0;
    interface lo0.0;
    interface fxp0.0 {
      disable;
    }
  }
}
}

```

## Verification

Confirm that the configuration is working properly.

- [Verifying the LSP Status on page 472](#)
- [Verifying Packet Loss Measurement on page 472](#)
- [Verifying Packet Delay Measurement on page 474](#)
- [Verifying Packet Loss-Delay Measurement on page 474](#)

---

### Verifying the LSP Status

**Purpose** Verify that the associated bidirectional LSP between Routers R1 and R2 is up.

**Action** From operational mode, run the **show mpls lsp** command.

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To          From          State Rt P    ActivePath      LSPname
20.0.0.1    10.0.0.1                Up    0 *              R1-R2 Assoc-Bidir
Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions
To          From          State Rt Style Labelin Labelout LSPname
10.0.0.1    20.0.0.1      Up    0  1 FF  299776      - R2-R1 Assoc-Bidir
Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

**Meaning** The associated bidirectional LSP R1-R2 is up and active.

---

### Verifying Packet Loss Measurement

**Purpose** Verify the on-demand loss measurement result.

**Action** From operational mode, run the **monitor mpls loss rsvp R1-R2 count 2 detail** command.

```

user@R1> monitor mpls loss rsvp R1-R2 count 2 detail
(0)
Response code                : Success

## Configuring Pro-Active Loss and Delay Measurements

You can configure pro-active loss and delay measurements for point-to-point ultimate-hop popping label-switched paths (LSPs) in MPLS networks to monitor network performance. The **show performance-monitoring mpls lsp** CLI command provides a summary of performance metrics for direct mode packet loss, two-way packet delay, and related metrics, such as inter-packet delay variation and channel throughput measurement.

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

This feature provides the following performance metrics:

- Inter-packet delay variation (IPDV)
- Loss measurement
- Round-trip delay (RTT)
- Throughput measurement
- Two-way channel delay

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
  - MPLS
  - OSPF
  - RSVP

To configure pro-active loss and delay measurements on the PE device:

1. Configure an associated bidirectional LSP to Router R2.

```
[edit protocols]
user@host# set mpls label-switched-path lsp-name to remote-router-ip-address
user@host# set mpls label-switched-path lsp-name install
destination-prefix/prefix-length active
user@host# set mpls label-switched-path lsp-name oam mpls-tp-mode
user@host# set mpls label-switched-path lsp-name ultimate-hop-popping
user@host# set mpls label-switched-path lsp-name associate-lsp remote-lsp-name
```

2. Create traffic classes for maintaining data traffic statistics per traffic class.

This enables traffic class scoped loss and delay measurements.

```
[edit protocols]
user@host# set mpls statistics traffic-class-statistics
```

3. Configure performance monitoring at the querier side.

```
[edit protocols]
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
querier delay traffic-class tc-value query-interval milliseconds
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
querier loss traffic-class tc-value query-interval milliseconds
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
querier loss-delay traffic-class tc-value query-interval milliseconds
```

4. Configure performance monitoring at the responder side.

```
[edit protocols]
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
responder delay min-query-interval milliseconds
user@host# set mpls label-switched-path lsp-name oam performance-monitoring
responder loss min-query-interval milliseconds
```

## Example: Configuring Pro-active Loss and Delay Measurements for Bidirectional MPLS LSPs

---

This example shows how to configure pro-active loss and delay measurements for point-to-point ultimate-hop popping label-switched paths (LSPs) in MPLS networks to monitor network performance.

- [Requirements on page 478](#)
- [Overview on page 478](#)
- [Configuration on page 479](#)
- [Verification on page 483](#)

### Requirements

This example uses the following hardware and software components:

- Two MX Series 3D Universal Edge routers that contain MPC/MICs only
- Junos OS Release 15.1 or later running on all the routers

Before you begin:

1. Configure the device interfaces.
2. Configure the autonomous system numbers and router IDs for the devices.
3. Configure the following protocols:
  - a. MPLS
  - b. OSPF
  - c. RSVP

### Overview

Starting with Junos OS Release 15.1, a pro-active tool to monitor and measure packet loss, packet delay, or both for associated bidirectional MPLS ultimate-hop popping point-to-point label-switched paths (LSPs) is introduced.

This feature provides the following performance metrics:

- Inter-packet delay variation (IPDV)
- Loss measurement
- Round-trip delay (RTT)
- Throughput measurement
- Two-way channel delay

This functionality provides real-time visibility into network performance, thereby facilitating network performance planning, troubleshooting, and evaluation.

## Topology

Figure 41 on page 468 illustrates the pro-active loss and delay measurements using a simple two-router topology.

Figure 42: Configuring Pro-Active Loss and Delay Measurements

In this example, an associated bidirectional LSP is configured between Routers R1 and R2, for which the performance metrics are measured.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
R1  set chassis network-services enhanced-ip
    set interfaces ge-0/0/0 unit 0 family inet address 1.1.1.1/30
    set interfaces ge-0/0/0 unit 0 family mpls
    set interfaces lo0 unit 0 family inet address 10.0.0.1/32
    set interfaces lo0 unit 0 family mpls
    set protocols mpls interface ge-0/0/0.0
    set protocols mpls interface lo0.0
    set protocols mpls interface fxp0.0 disable
    set protocols mpls label-switched-path R1-R2 associate-lsp R2-R1
    set protocols mpls label-switched-path R1-R2 install 20.10.30.0/24 active
    set protocols mpls label-switched-path R1-R2 oam mpls-tp-mode
    set protocols mpls label-switched-path R1-R2 oam performance-monitoring querier delay
      traffic-class tc-0 query-interval 1000
    set protocols mpls label-switched-path R1-R2 oam performance-monitoring querier loss
      traffic-class none query-interval 1000
    set protocols mpls label-switched-path R1-R2 oam performance-monitoring querier
      loss-delay traffic-class tc-0 query-interval 1000
    set protocols mpls label-switched-path R1-R2 oam performance-monitoring responder
      delay min-query-interval 1000
    set protocols mpls label-switched-path R1-R2 oam performance-monitoring responder
      loss min-query-interval 1000
    set protocols mpls label-switched-path R1-R2 to 20.0.0.1
    set protocols mpls label-switched-path R1-R2 ultimate-hop-popping
    set protocols mpls statistics traffic-class-statistics
    set protocols ospf area 0.0.0.0 interface ge-0/0/0.0
    set protocols ospf area 0.0.0.0 interface lo0.0
    set protocols ospf area 0.0.0.0 interface fxp0.0 disable
    set protocols ospf traffic-engineering
    set protocols rsvp interface ge-0/0/0.0
    set protocols rsvp interface lo0.0
    set protocols rsvp interface fxp0.0 disable
    set routing-options router-id 10.0.0.1

R2  set chassis network-services enhanced-ip
```

```
set interfaces ge-0/0/0 unit 0 family inet address 1.1.1.2/30
set interfaces ge-0/0/0 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 20.0.0.1/32
set interfaces lo0 unit 0 family mpls
set protocols mpls interface ge-0/0/0.0
set protocols mpls interface lo0.0
set protocols mpls interface fxp0.0 disable
set protocols mpls label-switched-path R2-R1 associate-lsp R1-R2
set protocols mpls label-switched-path R2-R1 install 10.10.20.0/24 active
set protocols mpls label-switched-path R2-R1 oam mpls-tp-mode
set protocols mpls label-switched-path R2-R1 oam performance-monitoring responder
    delay min-query-interval 1000
set protocols mpls label-switched-path R2-R1 oam performance-monitoring responder
    loss min-query-interval 1000
set protocols mpls label-switched-path R2-R1 oam performance-monitoring querier delay
    traffic-class tc-0 query-interval 1000
set protocols mpls label-switched-path R2-R1 oam performance-monitoring querier loss
    traffic-class none query-interval 1000
set protocols mpls label-switched-path R2-R1 oam performance-monitoring querier
    loss-delay traffic-class tc-0 query-interval 1000
set protocols mpls label-switched-path R2-R1 to 10.0.0.1
set protocols mpls label-switched-path R2-R1 ultimate-hop-popping
set protocols mpls statistics traffic-class-statistics

set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface fxp0.0 disable
set protocols ospf traffic-engineering
set protocols rsvp interface ge-0/0/0.0
set protocols rsvp interface lo0.0
set protocols rsvp interface fxp0.0 disable
set routing-options router-id 20.0.0.1
```

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router R1:

1. Enable the enhanced IP network services configuration.  

```
[edit chassis]
user@R1# set network-services enhanced-ip
```
2. Configure the interfaces for Router R1.  

```
[edit interfaces]
user@R1# set ge-0/0/0 unit 0 family inet address 1.1.1.1/30
user@R1# set ge-0/0/0 unit 0 family mpls

user@R1# set lo0 unit 0 family inet address 10.0.0.1/32
user@R1# set lo0 unit 0 family mpls
```
3. Configure the router ID for Router R1.  

```
[edit routing-options]
user@R1# set router-id 10.0.0.1
```

4. Enable RSVP on all the interfaces of Router R1, excluding the management interface.
 

```
[edit protocols]
user@R1# set rsvp interface ge-0/0/0.0
user@R1# set rsvp interface lo0.0
user@R1# set rsvp interface fxp0.0 disable
```
5. Enable MPLS on all the interfaces of Router R1, excluding the management interface.
 

```
[edit protocols]
user@R1# set mpls interface ge-0/0/0.0
user@R1# set mpls interface lo0.0
user@R1# set mpls interface fxp0.0 disable
```
6. Configure an associated bidirectional LSP to Router R2.
 

```
[edit protocols]
user@R1# set mpls label-switched-path R1-R2 to 20.0.0.1
user@R1# set mpls label-switched-path R1-R2 install 20.10.30.0/24 active
user@R1# set mpls label-switched-path R1-R2 oam mpls-tp-mode
user@R1# set mpls label-switched-path R1-R2 ultimate-hop-popping
user@R1# set mpls label-switched-path R1-R2 associate-lsp R2-R1
```
7. Create traffic classes for maintaining data traffic statistics per traffic class.
 

This enables traffic class scoped loss and delay measurement.

```
[edit protocols]
user@R1# set mpls statistics traffic-class-statistics
```
8. Configure performance monitoring at the querier side.
 

```
[edit protocols]
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring querier
  delay traffic-class tc-0 query-interval 1000
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring querier
  loss traffic-class none query-interval 1000
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring querier
  loss-delay traffic-class tc-0 query-interval 1000
```
9. Configure performance monitoring at the responder side.
 

```
[edit protocols]
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring
  responder delay min-query-interval 1000
user@R1# set mpls label-switched-path R1-R2 oam performance-monitoring
  responder loss min-query-interval 1000
```
10. Configure OSPF with traffic engineering capabilities, and enable OSPF on all the interfaces of Router R1, excluding the management interface.
 

```
[edit protocols]
user@R1# set ospf traffic-engineering
user@R1# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@R1# set ospf area 0.0.0.0 interface lo0.0
user@R1# set ospf interface fxp0.0 disable
```

## Results

---

From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show chassis
network-services enhanced-ip;

user@R1# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 1.1.1.1/30;
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.0.0.1/32;
    }
    family mpls;
  }
}

user@R1# show routing-options
router-id 10.0.0.1;

user@R1# show protocols
rsvp {
  interface ge-0/0/0.0;
  interface lo0.0;
  interface fxp0.0 {
    disable;
  }
}
mpls {
  label-switched-path R1-R2 {
    to 20.0.0.1;
    install 20.10.30.0/24 active;
    oam {
      mpls-tp-mode;
      performance-monitoring {
        querier {
          loss {
            traffic-class none {
              query-interval 1000;
            }
          }
        }
        delay {
          traffic-class tc-0 {
            query-interval 1000;
          }
        }
      }
    }
  }
}
```

```

    }
    loss-delay {
        traffic-class none {
            query-interval 1000;
        }
    }
}
responder {
    loss {
        min-query-interval 1000;
    }
    delay {
        min-query-interval 1000;
    }
}
}
ultimate-hop-popping;
associate-lsp R2-R1;
}
}
ospf {
    traffic-engineering;
    area 0.0.0.0 {
        interface ge-0/0/0.0;
        interface lo0.0;
        interface fxp0.0 {
            disable;
        }
    }
}
}

```

## Verification

### Verifying Loss and Delay Measurement

**Purpose** Verify the loss and delay measurement.

**Action** From operational mode, run the **show performance-monitoring mpls lsp** command.

```
user@R1> show performance-monitoring mpls lsp
Session Total: 3 Up: 3 Down: 0
LSP name:R1-R2, PM State:Up

## MPLS Encapsulated Payload Load-balancing Overview

Routers can load-balance on a per-packet basis in MPLS. Load balancing can be performed on the information in both the IP header and on up to three MPLS labels, providing a more uniform distribution of MPLS traffic to next hops.

Load balancing is used to evenly distribute traffic when the following conditions apply:

- There are multiple equal-cost next hops over different interfaces to the same destination.
- There is a single next hop over an aggregated interface.

By default, when load balancing is used to help distribute traffic, a hash algorithm is used to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes in any way, the next-hop address is reselected by means of the hash algorithm.

In case of multiple transport layer networks such as Ethernet over MPLS or Ethernet pseudowire, the hash algorithm needs to look beyond the outer header of the payload and into the inner headers to generate an even distribution. To determine the inner encapsulation, the PFE relies on the presence of certain codes or numbers at fixed payload offsets; for example the presence of payload type 0X800 or the presence of protocol number 4 for an IPv4 packet. In Junos OS, you can configure **zero-control-word** option to indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload. On seeing this control word, which is four bytes having a numerical value of all zeros, the hash generator assumes the start of an Ethernet frame at the end of the control word in an MPLS ether-pseudowire packet.

**NOTE:** For DPC I-chip-based cards, configure the **zero-control-word** option at the **[edit forwarding-options hash-key family mpls ether-pseudowire]** hierarchy level; and for MPC cards, configure the **zero-control-word** option at the **[edit forwarding-options enhanced-hash-key family mpls ether-pseudowire]** hierarchy level.

## Configuring MPLS Encapsulated Payload for Load Balancing

---

By default, when load balancing is used to help distribute traffic, a hash algorithm is used to select a next-hop address to install into the forwarding table. Whenever the set of next hops for a destination changes in any way, the next-hop address is reselected by means of the hash algorithm. Configure the **zero-control-word** option to indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload. On seeing this control word, four bytes having a numerical value of all zeros, the hash generator assumes the start of the Ethernet frame at the end of the control word in an MPLS ether-pseudowire packet.

Before you begin to configure MPLS encapsulated payload for load balancing, configure routing and signaling protocols.

To configure MPLS encapsulated payload for load balancing:

1. Configure the **zero-control-word** option to indicate the start of an Ethernet frame in an MPLS ether-pseudowire payload.
  - For DPC I-chip-based cards, configure the **zero-control-word** option at the **[edit forwarding-options hash-key family mpls ether-pseudowire]** hierarchy level.  

```
[edit forwarding-options hash-key family mpls ether-pseudowire]  
user@host# set zero-control-word
```
  - For MPC cards, configure the **zero-control-word** option at the **[edit forwarding-options enhanced-hash-key family mpls ether-pseudowire]** hierarchy level.  

```
[edit forwarding-options hanced-hash-key family mpls ether-pseudowire]  
user@host# set zero-control-word
```

## RSVP Overview

---

RSVP is a resource reservation setup protocol that is used by both network hosts and routers. Hosts use RSVP to request a specific class of service (CoS) from the network for particular application flows. Routers use RSVP to deliver CoS requests to all routers along the data path. RSVP also can maintain and refresh states for a requested CoS application flow.

RSVP treats an application flow as a simplex connection. That is, the CoS request travels only in one direction—from the sender to the receiver. RSVP is a transport layer protocol that uses IP as its network layer. However, RSVP does not transport application flows. Rather, it is more of an Internet control protocol, similar to the Internet Control Message Protocol (ICMP) and Internet Group Management Protocol (IGMP). RSVP runs as a separate software process in the Junos OS and is not in the packet forwarding path.

RSVP is not a routing protocol, but rather is designed to operate with current and future unicast and multicast routing protocols. The routing protocols are responsible for choosing the routes to use to forward packets, and RSVP consults local routing tables to obtain routes. RSVP only ensures the CoS of packets traveling along a data path.

The receiver in an application flow requests the preferred CoS from the sender. To do this, the receiver issues an RSVP CoS request on behalf of the local application. The request propagates to all routers in reverse direction of the data paths toward the sender. In this process, RSVP requests might be merged, resulting in a protocol that scales well when there are a large number of receivers.

Because the number of receivers in an application flow is likely to change and the flow of delivery paths might change during the life of an application flow, RSVP takes a soft-state approach in its design, creating and removing the protocol states in routers and hosts incrementally over time. RSVP sends periodic refresh messages to maintain its state and to recover from occasional lost messages. In the absence of refresh messages, RSVP states automatically time out and are deleted.

---

## Supported RSVP Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for RSVP.

- RFC 2205, *Resource ReSerVation Protocol (RSVP)—Version 1 Functional Specification*
- RFC 2210, *The Use of RSVP with IETF Integrated Services*
- RFC 2211, *Specification of the Controlled-Load Network Element Service*
- RFC 2212, *Specification of Guaranteed Quality of Service*
- RFC 2215, *General Characterization Parameters for Integrated Service Network Elements*
- RFC 2745, *RSVP Diagnostic Messages*
- RFC 2747, *RSVP Cryptographic Authentication* (updated by RFC 3097)
- RFC 2961, *RSVP Refresh Overhead Reduction Extensions*
- RFC 3097, *RSVP Cryptographic Authentication—Updated Message Type Value*
- RFC 3209, *RSVP-TE: Extensions to RSVP for LSP Tunnels*

The Null Service Object for maximum transmission unit (MTU) signaling in RSVP is not supported.

- RFC 3473, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Resource ReserVation Protocol-Traffic Engineering (RSVP-TE) Extensions*

Only Section 9, “Fault Handling,” is supported.

- RFC 3477, *Signalling Unnumbered Links in Resource ReSerVation Protocol - Traffic Engineering (RSVP-TE)*
- RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*
- RFC 4203, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*  
(OSPF extensions can carry traffic engineering information over unnumbered links.)
- RFC 4558, *Node-ID Based Resource Reservation Protocol (RSVP) Hello: A Clarification Statement*
- RFC 4561, *Definition of a Record Route Object (RRO) Node-Id Sub-Object*  
The RRO node ID subobject is for use in inter-AS link and node protection configurations.
- RFC 4875, *Extensions to RSVP-TE for Point-to-Multipoint TE LSPs*

The following RFCs do not define standards, but provide information about RSVP and related technologies. The IETF classifies them variously as “Experimental” or “Informational.”

- RFC 2209, *Resource ReSerVation Protocol (RSVP)—Version 1 Message Processing Rules*
- RFC 2216, *Network Element Service Specification Template*
- RFC 4125, *Maximum Allocation Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*
- RFC 4127, *Russian Dolls Bandwidth Constraints Model for Diffserv-aware MPLS Traffic Engineering*

## Junos OS RSVP Protocol Implementation

The Junos implementation of RSVP supports RSVP version 1. The software includes support for all mandatory objects and RSVP message types, and supports message integrity and node authentications through the Integrity object.

The primary purpose of the Junos RSVP software is to support dynamic signaling within MPLS label-switched paths (LSPs). Supporting resource reservations over the Internet is only a secondary purpose of the Junos OS implementation. Since supporting resource reservations is secondary, the Junos RSVP software does not support the following features:

- IP multicasting sessions.

- Traffic control. The software cannot make resource reservations for real-time video or audio sessions.

With regard to the protocol mechanism, packet processing, and RSVP objects supported, the Junos OS implementation of the software is interoperable with other RSVP implementations.

## RSVP Operation Overview

---

RSVP creates independent sessions to handle each data flow. A session is identified by a combination of the destination address, an optional destination port, and a protocol. Within a session, there can be one or more senders. Each sender is identified by a combination of its source address and source port. An out-of-band mechanism, such as a session announcement protocol or human communication, is used to communicate the session identifier to all senders and receivers.

A typical RSVP session involves the following sequence of events:

1. A potential sender starts sending RSVP path messages to the session address.
2. A receiver, wanting to join the session, registers itself if necessary. For example, a receiver in a multicast application would register itself with IGMP.
3. The receiver receives the path messages.
4. The receiver sends appropriate Resv messages toward the sender. These messages carry a flow descriptor, which is used by routers along the path to make reservations in their link-layer media.
5. The sender receives the Resv message and then starts sending application data.

This sequence of events is not necessarily strictly synchronized. For example, receivers can register themselves before receiving path messages from the sender, and application data can flow before the sender receives Resv messages. Application data that is delivered before the actual reservation contained in the Resv message typically is treated as best-effort, non-real-time traffic with no CoS guarantee.

## RSVP Authentication

---

The Junos OS supports both the RSVP authentication style described in RFC 2747 (allowing for multivendor compatibility) and the RSVP authentication style described in Internet draft draft-ietf-rsvp-md5-03.txt. The Junos OS uses the authentication style described in Internet draft draft-ietf-rsvp-md5-08.txt by default. If the router receives an RFC 2747-style RSVP authentication from a neighbor, it switches to this style of authentication for that neighbor. The RSVP authentication style for each neighboring router is determined separately.

## RSVP and IGP Hello Packets and Timers

---

RSVP monitors the status of the interior gateway protocol (IGP) (IS-IS or OSPF) neighbors and relies on the IGP protocols to detect when a node fails. If an IGP protocol declares a neighbor down (because hello packets are no longer being received), RSVP also brings

down that neighbor. However, the IGP protocols and RSVP still act independently when bringing a neighbor up.

In the Junos OS, RSVP typically relies on IGP hello packet detection to check for node failures. RSVP sessions are kept up even if RSVP hello packets are no longer being received, so long as the router continues to receive IGP hello packets. RSVP sessions are maintained until either the router stops receiving IGP hello packets or the RSVP Path and Resv messages time out. Configuring a short time for the IS-IS or OSPF hello timers allows these protocols to detect node failures quickly.

RSVP hellos can be relied on when the IGP does not recognize a particular neighbor (for example, if IGP is not enabled on the interface) or if the IGP is RIP (not IS-IS or OSPF). Also, the equipment of other vendors might be configured to monitor RSVP sessions based on RSVP hello packets. This equipment might also take an RSVP session down due to a loss of RSVP hello packets.

We do not recommend configuring a short RSVP hello timer. If quick discovery of a failed neighbor is needed, configure short IGP (OSPF or IS-IS) hello timers.

OSPF and IS-IS have infrastructure to manage rapid hello message sending and receiving reliably, even if the routing protocols or some other process are straining the processing capability of the router. Under the same circumstances, RSVP hellos might time out prematurely even though the neighbor is functioning normally.

---

## RSVP Message Types

RSVP uses the following types of messages to establish and remove paths for data flows, establish and remove reservation information, confirm the establishment of reservations, and report errors:

- [Path Messages on page 495](#)
- [Resv Messages on page 495](#)
- [PathTear Messages on page 495](#)
- [ResvTear Messages on page 495](#)
- [PathErr Messages on page 496](#)
- [ResvErr Messages on page 496](#)
- [ResvConfirm Messages on page 496](#)

---

## Understanding RSVP Automatic Mesh

When adding sites to BGP and MPLS VPNs that use RSVP signaling, more configuration is needed to add provider edge (PE) routers than is needed to add customer edge (CE) devices. RSVP automatic mesh helps to reduce this configuration burden.

Service providers often use BGP and MPLS VPNs to efficiently scale the network while delivering revenue-generating services. In these environments, BGP is used to distribute the VPN routing information across the service provider's network, while MPLS is used

to forward that VPN traffic from one VPN site to another. BGP and MPLS VPNs are based on a peer model. To add a new CE device (site) to an existing VPN, you need to configure the CE router at the new site and the PE router connected to the CE router. You do not have to modify the configuration of all of the other PE routers participating in the VPN. The other PE routers automatically learn about the routes associated with the new site, a process called automatic discovery (AD).

The requirements are a bit different if you need to add a new PE router to the network. A BGP and MPLS VPN requires that the BGP session be fully meshed and that there also be a full mesh of PE router-to-PE router MPLS label-switched paths (LSPs) between all of the PE routers in the network. When you add a new PE router to the network, all of the existing PE routers must be reconfigured to peer with the new PE router. Much of the configuration effort can be reduced if you configure BGP route reflectors (mitigating the full mesh requirement for BGP) and if you configure (LDP) as the signaling protocol for MPLS.

However, if you need to add a new PE router to a network configured with a full mesh of RSVP-signaled LSPs, you must reconfigure each of the PE routers to have a peer relationship with the new PE router. You can configure RSVP automatic mesh to address this particular operational scenario. When you enable RSVP automatic mesh, RSVP LSPs are dynamically created between a new PE router and the existing PE routers, eliminating the need to reconfigure all of the PE routers manually. For dynamic LSP creation to function properly, BGP must be configured to exchange routes between all of the participating PE routers. If two BGP peers do not exchange routes, it is not possible to configure a dynamic LSP between them. The local router's inet.0 routing table must include a labeled route to each potential IBGP next-hop (future potential PE routers or LSP destinations).

RSVP includes numerous capabilities that are not available in LDP, including fast reroute, end-point control, and link management. RSVP automatic mesh helps to reduce the operation and maintenance requirements for RSVP, making it possible to deploy RSVP in larger and more complicated networks.

Every PE router can reach every other PE router in the network because this information is distributed by the IGP. A PE router can set up a point-to-point RSVP LSP to any other PE router in the network as long as it knows that such an LSP is required. To build a full mesh of LSPs between the PE routers requires that each PE router know which of the other PE routers make up the full mesh.

**NOTE:** In Junos OS, RSVP automatic mesh is configured using the `rsvp-te` configuration statement at the `[edit routing-options dynamic-tunnels dynamic-tunnel-name]` hierarchy level. The `rsvp-te` configuration statement is also available for use in routing instances as a provider-tunnel option. When implemented as a provider-tunnel option, `rsvp-te` is used to configure the RSVP point-to-multipoint LSPs for multiprotocol BGP multicast VPNs, not to configure RSVP automatic mesh.

## Path Messages

Each sender host transmits path messages downstream along the routes provided by the unicast and multicast routing protocols. Path messages follow the exact paths of application data, creating path states in the routers along the way, thus enabling routers to learn the previous-hop and next-hop node for the session. Path messages are sent periodically to refresh path states.

The refresh interval is controlled by a variable called the *refresh-time*, which is the periodical refresh timer expressed in seconds. A path state times out if a router does not receive a specified number of consecutive path messages. This number is specified by a variable called *keep-multiplier*. Path states are kept for  $(\text{keep-multiplier} + 0.5) \times 1.5 \times \text{refresh-time}$  seconds.

## Resv Messages

Each receiver host sends reservation request (Resv) messages upstream toward senders and sender applications. Resv messages must follow exactly the reverse path of path messages. Resv messages create and maintain a reservation state in each router along the way.

Resv messages are sent periodically to refresh reservation states. The refresh interval is controlled by the same refresh time variable, and reservation states are kept for  $(\text{keep-multiplier} + 0.5) \times 1.5 \times \text{refresh-time}$  seconds.

## PathTear Messages

PathTear messages remove (tear down) path states as well as dependent reservation states in any routers along a path. PathTear messages follow the same path as path messages. A PathTear typically is initiated by a sender application or by a router when its path state times out.

PathTear messages are not required, but they enhance network performance because they release network resources quickly. If PathTear messages are lost or not generated, path states eventually time out when they are not refreshed, and the resources associated with the path are released.

## ResvTear Messages

ResvTear messages remove reservation states along a path. These messages travel upstream toward senders of the session. In a sense, ResvTear messages are the reverse of Resv messages. ResvTear messages typically are initiated by a receiver application or by a router when its reservation state times out.

ResvTear messages are not required, but they enhance network performance because they release network resources quickly. If ResvTear messages are lost or not generated, reservation states eventually time out when they are not refreshed, and the resources associated with the reservation are released.

## PathErr Messages

---

When path errors occur (usually because of parameter problems in a path message), the router sends a unicast PathErr message to the sender that issued the path message. PathErr messages are advisory; these messages do not alter any path state along the way.

## ResvErr Messages

---

When a reservation request fails, a ResvErr error message is delivered to all the receivers involved. ResvErr messages are advisory; these messages do not alter any reservation state along the way.

## ResvConfirm Messages

---

Receivers can request confirmation of a reservation request, and this confirmation is sent with a ResvConfirm message. Because of the complex RSVP flow-merging rules, a confirmation message does not necessarily provide end-to-end confirmation of the entire path. Therefore, ResvConfirm messages are an indication, not a guarantee, of potential success.

Juniper Networks routers never request confirmation using the ResvConfirm message; however, a Juniper Networks router can send a ResvConfirm message if it receives a request from another vendor's equipment.

## RSVP Reservation Styles

---

A reservation request includes options for specifying the reservation style. The reservation styles define how reservations for different senders within the same session are treated and how senders are selected.

Two options specify how reservations for different senders within the same session are treated:

- Distinct reservation—Each receiver establishes its own reservation with each upstream sender.
- Shared reservation—All receivers make a single reservation that is shared among many senders.

Two options specify how senders are selected:

- Explicit sender—List all selected senders.
- Wildcard sender—Select all senders, which then participate in the session.

The following reservation styles, formed by a combination of these four options, currently are defined:

- **Fixed filter (FF)**—This reservation style consists of distinct reservations among explicit senders. Examples of applications that use fixed-filter-style reservations are video applications and unicast applications, which both require flows that have a separate reservation for each sender. The fixed filter reservation style is enabled on RSVP LSPs by default.
- **Wildcard filter (WF)**—This reservation style consists of shared reservations among wildcard senders. This type of reservation reserves bandwidth for any and all senders, and propagates upstream toward all senders, automatically extending to new senders as they appear. A sample application for wildcard filter reservations is an audio application in which each sender transmits a distinct data stream. Typically, only a few senders are transmitting at any one time. Such a flow does not require a separate reservation for each sender; a single reservation is sufficient.
- **Shared explicit (SE)**—This reservation style consists of shared reservations among explicit senders. This type of reservation reserves bandwidth for a limited group of senders. A sample application is an audio application similar to that described for wildcard filter reservations.

## RSVP Refresh Reduction

RSVP relies on soft-state to maintain the path and reservation states on each router. If the corresponding refresh messages are not sent periodically, the states eventually time out and reservations are deleted. RSVP also sends its control messages as IP datagrams with no reliability guarantee. It relies on periodic refresh messages to handle the occasional loss of Path or Resv messages.

The RSVP refresh reduction extensions, based on RFC 2961, addresses the following problems that result from relying on periodic refresh messages to handle message loss:

- **Scalability**—The scaling problem arises from the periodic transmission and processing overhead of refresh messages, which increases as the number of RSVP sessions increases.
- **Reliability and latency**—The reliability and latency problem stems from the loss of nonrefresh RSVP messages or one-time RSVP messages such as PathTear or PathErr. The time to recover from such a loss is usually tied to refresh interval and the keepalive timer.

The RSVP refresh reduction capability is advertised by enabling the refresh reduction (RR) capable bit in the RSVP common header. This bit is only significant between RSVP neighbors.

RSVP refresh reduction includes the following features:

- RSVP message bundling using the bundle message
- RSVP Message ID to reduce message processing overhead

- Reliable delivery of RSVP messages using Message ID, Message Ack, and Message Nack
- Summary refresh to reduce the amount of information transmitted every refresh interval

The RSVP refresh reduction specification (RFC 2961) allows you to enable some or all of the above capabilities on a router. It also describes various procedures that a router can use to detect the refresh reduction capabilities of its neighbor.

The Junos OS supports all of the refresh reduction extensions, some of which can be selectively enabled or disabled. The Junos OS supports Message ID and therefore can perform reliable message delivery only for Path and Resv messages.

For information about how to configure RSVP refresh reduction, see [“Configuring RSVP Refresh Reduction” on page 503](#).

---

## MTU Signaling in RSVP

The maximum transmission unit (MTU) is the largest size packet or frame, in bytes, that can be sent in a network. An MTU that is too large might cause retransmissions. Too small an MTU might cause the router to send and handle relatively more header overhead and acknowledgments. There are default values for MTUs associated with various protocols. You can also explicitly configure an MTU on an interface.

When an LSP is created across a set of links with different MTU sizes, the ingress router does not know what the smallest MTU is on the LSP path. By default, the MTU for an LSP is 1,500 bytes.

If this MTU is larger than the MTU of one of the intermediate links, traffic might be dropped, because MPLS packets cannot be fragmented. Also, the ingress router is not aware of this type of traffic loss, because the control plane for the LSP would still function normally.

To prevent this type of packet loss in MPLS LSPs, you can configure MTU signaling in RSVP. This feature is described in RFC 3209. Juniper Networks supports the Integrated Services object for MTU signaling in RSVP. The Integrated Services object is described in RFCs 2210 and 2215. MTU signaling in RSVP is disabled by default.

To avoid packet loss due to MTU mismatches, the ingress router needs to do the following:

- Signal the MTU on the RSVP LSP—To prevent packet loss from an MTU mismatch, the ingress router needs to know what the smallest MTU value is along the path taken by the LSP. Once this MTU value is obtained, the ingress router can assign it to the LSP.
- Fragment packets—Using the assigned MTU value, packets that exceed the size of the MTU can be fragmented into smaller packets on the ingress router before they are encapsulated in MPLS and sent over the RSVP-signaled LSP.

Once both MTU signaling and packet fragmentation have been enabled on an ingress router, any route resolving to an RSVP LSP on this router uses the signaled MTU value. For information about how to configure this feature, see [“Configuring MTU Signaling in RSVP” on page 518](#).

The following sections describe how MTU signaling in RSVP works:

- [How the Correct MTU Is Signaled in RSVP on page 499](#)
- [Determining an Outgoing MTU Value on page 500](#)
- [MTU Signaling in RSVP Limitations on page 500](#)

## How the Correct MTU Is Signaled in RSVP

How the correct MTU is signaled in RSVP varies depending on whether the network devices (for example, routers) explicitly support MTU signaling in RSVP or not.

If the network devices support MTU signaling in RSVP, the following occur when you enable MTU signaling:

- The MTU is signaled from the ingress router to the egress router by means of the Adspec object. Before forwarding this object, the ingress router enters the MTU value associated with the interface over which the path message is sent. At each hop in the path, the MTU value in the Adspec object is updated to the minimum of the received value and the value of the outgoing interface.
- The ingress router uses the traffic specification (Tspec) object to specify the parameters for the traffic it is going to send. The MTU value signaled for the Tspec object at the ingress router is the maximum MTU value (9192 bytes for M Series and T Series routers, 9500 bytes for PTX Series Packet Transport Routers). This value does not change en route to the egress router.
- When the Adspec object arrives at the egress router, the MTU value is correct for the path (meaning it is the smallest MTU value discovered). The egress router compares the MTU value in the Adspec object to the MTU value in the Tspec object. It signals the smaller MTU using the Flowspec object in the Resv message.
- When the Resv object arrives at the ingress router, the MTU value in this object is used as the MTU for the next hops that use the LSP.

In a network where there are devices that do not support MTU signaling in RSVP, you might have the following behaviors:

- If the egress router does not support MTU signaling in RSVP, the MTU is set to 1,500 bytes by default.
- A Juniper Networks transit router that does not support MTU signaling in RSVP sets an MTU value of 1,500 bytes in the Adspec object by default.

## Determining an Outgoing MTU Value

---

The outgoing MTU value is the smaller of the values received in the Adspec object compared to the MTU value of the outgoing interface. The MTU value of the outgoing interface is determined as follows:

- If you configure an MTU value under the **[family mpls]** hierarchy level, this value is signaled.
- If you do not configure an MTU, the **inet** MTU is signaled.

## MTU Signaling in RSVP Limitations

---

The following are limitations to MTU signaling in RSVP:

- Changes in the MTU value might cause a temporary loss of traffic in the following situations:
  - For link protection and node protection, the MTU of the bypass is only signaled at the time the bypass becomes active. During the time it takes for the new path MTU to be propagated, packet loss might occur because of an MTU mismatch.
  - For fast reroute, the MTU of the path is updated only after the detour becomes active, causing a delay in an update to the MTU at the ingress router. Until the MTU is updated, packet loss might occur if there is an MTU mismatch.

In both cases, only packets that are larger than the detour or bypass MTU are lost.

- When an MTU is updated, it triggers a change in the next hop. Any change in the next hop causes the route statistics to be lost.
- The minimum MTU supported for MTU signaling in RSVP is 1,488 bytes. This value prevents a false or incorrectly configured value from being used.
- For single-hop LSPs, the MTU value displayed by the **show** commands is the RSVP-signaled value. However, this MPLS value is ignored and the correct IP value is used.

### Minimum RSVP Configuration

---

To enable RSVP on a single interface, include the **rsvp** statement and specify the interface using the **interface** statement. This is the minimum RSVP configuration. All other RSVP configuration statements are optional.

```
rsvp {  
  interface interface-name;  
}
```

You can include these statements at the following hierarchy levels:

- **[edit protocols]**
- **[edit logical-systems *logical-system-name* protocols]**

To enable RSVP on all interfaces, substitute **all** for the *interface-name* variable.

If you have configured interface properties on a group of interfaces and want to disable RSVP on one of the interfaces, include the **disable** statement:

```
interface interface-name {  
  disable;  
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp interface interface-name ]
- [edit logical-systems logical-system-name protocols rsvp interface interface-name ]

---

## Configuring RSVP and MPLS

The primary purpose of the Junos RSVP software is to support dynamic signaling within label-switched paths (LSPs). When you enable both MPLS and RSVP on a router, MPLS becomes a client of RSVP. No additional configuration is required to bind MPLS and RSVP.

You can configure MPLS to set up signaled paths by using the **label-switched-path** statement at the [edit protocols mpls] hierarchy level. Each LSP translates into a request for RSVP to initiate an RSVP session. This request is passed through the internal interface between label switching and RSVP. After examining the request information, checking RSVP states, and checking the local routing tables, RSVP initiates one session for each LSP. The session is sourced from the local router and is destined for the target of the LSP.

When an RSVP session is successfully created, the LSP is set up along the paths created by the RSVP session. If the RSVP session is unsuccessful, RSVP notifies MPLS of its status. It is up to MPLS to initiate backup paths or continue retrying the initial path.

To pass label-switching signaling information, RSVP supports four additional objects: Label Request object, Label object, Explicit Route object, and Record Route object. For an LSP to be set up successfully, all routers along the path must support MPLS, RSVP, and the four objects. Of the four objects, the Record Route object is not mandatory.

To configure MPLS and make it a client of RSVP, do the following:

- Enable MPLS on all routers that will participate in the label switching (this is, on all routers that might be part of a label-switching path).
- Enable RSVP on all routers and on all router interfaces that form the LSP.
- Configure the routers at the beginning of the LSP.

### Example: Configuring RSVP and MPLS

The following shows a sample configuration for a router at the beginning of an LSP:

```
[edit]  
protocols {
```

```

mpls {
  label-switched-path sf-to-london {
    to 192.168.1.4;
  }
}
rsvp {
  interface so-0/0/0;
}
}

```

The following shows a sample configuration for all the other routers that form the LSP:

```

[edit]
protocols {
  mpls {
    interface so-0/0/0;
  }
  rsvp {
    interface so-0/0/0;
  }
}

```

## Configuring RSVP Interfaces

The following sections describe how to configure RSVP interfaces:

- [Configuring RSVP Refresh Reduction on page 503](#)
- [Configuring the RSVP Hello Interval on page 505](#)
- [Configuring RSVP Authentication on page 506](#)
- [Configuring the Bandwidth Subscription for Class Types on page 506](#)
- [Configuring the RSVP Update Threshold on an Interface on page 506](#)
- [Configuring RSVP for Unnumbered Interfaces on page 507](#)

## Configuring RSVP Refresh Reduction

You can configure RSVP refresh reduction on each interface by including the following statements in the interface configuration:

- **aggregate** and **reliable**—Enable all RSVP refresh reduction features: RSVP message bundling, RSVP message ID, reliable message delivery, and summary refresh.

In order to have refresh reduction and reliable delivery, you must include the **aggregate** and **reliable** statements.

- **no-aggregate**—Disable RSVP message bundling and summary refresh.
- **no-reliable**—Disable RSVP message ID, reliable message delivery, and summary refresh.

For more information on RSVP refresh reduction, see [“RSVP Refresh Reduction” on page 497](#).

If the **no-reliable** statement is configured on the router (reliable message delivery is disabled), the router accepts RSVP messages that include the Message ID object but

ignores the Message ID object and continues performing standard message processing. No error is generated in this case, and RSVP operates normally.

However, not all combinations between two neighbors with different refresh reduction capabilities function correctly. For example, a router is configured with either the **aggregate** statement and **no-reliable** statement or with the **reliable** and **no-aggregate** statements. If an RSVP neighbor sends a Summary Refresh object to this router, no error is generated, but the Summary Refresh object cannot be processed. Consequently, RSVP states can time out on this router if the neighbor is relying only on Summary Refresh to refresh those RSVP states.

We recommend, unless there are specific requirements, that you configure RSVP refresh reduction in a similar manner on each RSVP neighbor.

To enable all RSVP refresh reduction features on an interface, include the **aggregate** statement:

```
aggregate;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name*]

To disable RSVP message bundling and summary refresh, include the **no-aggregate** statement:

```
no-aggregate;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name*]

To enable RSVP message ID and reliable message delivery on an interface, include the **reliable** statement:

```
reliable;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name*]

To disable RSVP message ID, reliable message delivery, and summary refresh, include the **no-reliable** statement:

```
no-reliable;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name*]

### Determining the Refresh Reduction Capability of RSVP Neighbors

To determine the RSVP refresh reduction capability of an RSVP neighbor, you need the following information:

- The RR bit advertised by the neighbor
- The local configuration of RSVP refresh reduction
- The actual RSVP messages received from the neighbor

To obtain this information, you can issue a **show rsvp neighbor detail** command. Sample output follows:

```
user@host> show rsvp neighbor detail
RSVP neighbor: 6 learned
  Address: 192.168.224.178 via: fxp1.0 status: Up
    Last changed time: 10:06, Idle: 5 sec, Up cnt: 1, Down cnt: 0
    Message received: 36
    Hello: sent 69, received: 69, interval: 9 sec
    Remote instance: 0x60b8feba, Local instance: 0x74bc7a8d
    Refresh reduction: not operational

  Address: 192.168.224.186 via: fxp2.0 status: Down
    Last changed time: 10:17, Idle: 40 sec, Up cnt: 0, Down cnt: 0
    Message received: 6
    Hello: sent 20, received: 0, interval: 9 sec
    Remote instance: 0x0, Local instance: 0x2ae1b339
    Refresh reduction: incomplete
    Remote end: disabled, Ack-extension: enabled

  Address: 192.168.224.188 via: fxp2.0 status: Up
    Last changed time: 4:15, Idle: 0 sec, Up cnt: 1, Down cnt: 0
    Message received: 55
    Hello: sent 47, received: 31, interval: 9 sec
    Remote instance: 0x6436a35b, Local instance: 0x663849f0
    Refresh reduction: operational
    Remote end: enabled, Ack-extension: enabled
```

For more information on the **show rsvp neighbor detail** command.

### Configuring the RSVP Hello Interval

RSVP monitors the status of the interior gateway protocol (IGP) (IS-IS or OSPF) neighbors and relies on the IGP protocols to detect when a node fails. If an IGP protocol declares a neighbor down (because hello packets are no longer being received), RSVP also brings down that neighbor. However, the IGP protocols and RSVP still act independently when bringing a neighbor up.

For Juniper Networks routers, configuring a shorter or longer RSVP hello interval has no impact on whether or not an RSVP session is brought down. RSVP sessions are kept up even if RSVP hello packets are no longer being received. RSVP sessions are maintained until either the router stops receiving IGP hello packets or the RSVP Path and Resv messages time out.

However, the RSVP hello interval might impact when another vendor's equipment brings down an RSVP session. For example, a neighboring non-Juniper Networks router might be configured to monitor RSVP hello packets.

To modify how often RSVP sends hello packets, include the **hello-interval** statement:

```
hello-interval seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

## Configuring RSVP Authentication

All RSVP protocol exchanges can be authenticated to guarantee that only trusted neighbors participate in setting up reservations. By default, RSVP authentication is disabled.

RSVP authentication uses a Hashed Message Authentication Code (HMAC)-MD5 message-based digest. This scheme produces a message digest based on a secret authentication key and the message contents. (The message contents also include a sequence number.) The computed digest is transmitted with RSVP messages. Once you have configured authentication, all received and transmitted RSVP messages with all neighbors are authenticated on this interface.

MD5 authentication provides protection against forgery and message modification. It also can prevent replay attacks. However, it does not provide confidentiality, because all messages are sent in clear text.

By default, authentication is disabled. To enable authentication, configure a key on each interface by including the **authentication-key** statement:

```
authentication-key key;
```

You can include this statement at the following hierarchy levels:

- [edit protocols **rsvp** **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols **rsvp** **interface** *interface-name*]

## Configuring the Bandwidth Subscription for Class Types

By default, RSVP allows 100 percent of the bandwidth for a class type to be used for RSVP reservations. When you oversubscribe a class type for a multiclass LSP, the aggregate demand of all RSVP sessions is allowed to exceed the actual capacity of the class type.

For detailed instructions on how to configure the bandwidth subscription for class types, see [“Configuring the Bandwidth Subscription Percentage for LSPs” on page 351](#).

## Configuring the RSVP Update Threshold on an Interface

The interior gateway protocols (IGPs) maintain the traffic engineering database, but the current available bandwidth on the traffic engineering database links originates from RSVP. When a link's bandwidth changes, RSVP informs the IGPs, which can then update the traffic engineering database and forward the new bandwidth information to all

network nodes. The network nodes then know how much bandwidth is available on the traffic engineering database link (local or remote), and CSPF can correctly compute the paths.

However, IGP updates can consume excessive system resources. Depending on the number of nodes in a network, it might not be desirable to perform an IGP update for small changes in bandwidth. By configuring the **update-threshold** statement at the **[edit protocols rsvp]** hierarchy level, you can adjust the threshold at which a change in the reserved bandwidth triggers an IGP update.

You can configure a value of from 1 percent through 20 percent (the default is 10 percent) for when to trigger an IGP update. If the change in the reserved bandwidth is greater than or equal to the configured threshold percentage of the static bandwidth on that interface, then an IGP update occurs. For example, if you have configured the **update-threshold** statement to be 15 percent and the router discovers that the reserved bandwidth on a link has changed by 10 percent of the link bandwidth, RSVP does not trigger an IGP update. However, if the reserved bandwidth on a link changes by 20 percent of the link bandwidth, RSVP triggers an IGP update.

To adjust the threshold at which a change in the reserved bandwidth triggers an IGP update, include the **update-threshold** statement:

```
update-threshold percentage;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp interface interface-name]**
- **[edit logical-systems logical-system-name protocols rsvp interface interface-name]**

Because of the update threshold, it is possible for Constrained Shortest Path First (CSPF) to compute a path using outdated traffic engineering database bandwidth information on a link. If RSVP attempts to establish an LSP over that path, it might find that there is insufficient bandwidth on that link. When this happens, RSVP triggers an IGP traffic engineering database update, flooding the updated bandwidth information on the network. CSPF can then recompute the path by using the updated bandwidth information, and attempt to find a different path, avoiding the congested link. Note that this functionality is the default and does not need any additional configuration.

You can configure the **rsvp-error-hold-time** statement at the **[edit protocols mpls]** hierarchy level or the **[edit logical-systems logical-system-name protocols mpls]** hierarchy level to improve the accuracy of the traffic engineering database (including the accuracy of bandwidth estimates for LSPs) using information provided by PathErr messages. See [“Improving Traffic Engineering Database Accuracy with RSVP PathErr Messages” on page 78](#).

## Configuring RSVP for Unnumbered Interfaces

The Junos OS supports RSVP traffic engineering over unnumbered interfaces. Traffic engineering information about unnumbered links is carried in the IGP traffic engineering extensions for OSPF and IS-IS as described in RFC 4203, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*, and RFC 4205, *Intermediate System to Intermediate System (IS-IS) Extensions in Support of Generalized Multi-Protocol Label*

*Switching (GMPLS)*. Unnumbered links can also be specified in the MPLS traffic engineering signaling as described in RFC 3477, *Signalling Unnumbered Links in Resource ReSerVation Protocol - Traffic Engineering (RSVP-TE)*. This feature allows you avoid having to configure IP addresses for each interface participating in the RSVP-signaled network.

To configure RSVP for unnumbered interfaces, you must configure the router with a router ID using the **router-id** statement specified at the **[edit routing-options]** hierarchy level. The router ID must be available for routing (you can typically use the loopback address). The RSVP control messages for the unnumbered links are sent using the router ID address (rather than a randomly selected address).

To configure link protection and fast reroute on a router with unnumbered interfaces enabled, you must configure at least two addresses. We recommend that you configure a secondary interface on the loopback in addition to configuring the router ID.

---

## Configuring RSVP Node-ID Hellos

You can configure node-ID based RSVP hellos to ensure that Juniper Networks routers can interoperate with the equipment of other vendors. By default, Junos OS uses interface-based RSVP hellos. Node-ID based RSVP hellos are specified in RFC 4558, *Node-ID Based Resource Reservation Protocol (RSVP) Hello: A Clarification Statement*. RSVP node-ID hellos are useful if you have configured BFD to detect problems over RSVP interfaces, allowing you to disable interface hellos for these interfaces. You can also use node-ID hellos for graceful restart procedures.

Node-ID hellos can be enabled globally for all RSVP neighbors. By default, node-ID hello support is disabled. If you have not enabled RSVP node IDs on the router, the Junos OS does not accept any node-ID hello packets.

To enable RSVP node-ID hellos globally on the router, include the **node-hello** statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-systems-name* protocols rsvp]**

You can also explicitly disable RSVP interface hellos globally. This type of configuration might be necessary in networks where the Juniper Networks router has numerous RSVP connections with equipment from other vendors. However, if you disable RSVP interface hellos globally, you can also configure a hello interval on an RSVP interface using the **hello-interval** statement. This configuration disables RSVP interface hellos globally, but enables RSVP interface hellos on the specified interface (the RSVP interface you configure the **hello-interval** statement on). This configuration might be necessary in a heterogeneous network in which some devices support RSVP node-ID hellos and other devices support RSVP interface hellos.

To disable RSVP interface hellos globally on the router, include the **no-interface-hello** statement at the following hierarchy levels:

- **[edit protocols rsvp]**

- [\[edit logical-systems \*logical-systems-name\* protocols rsvp\]](#)

- Related Documentation
- [no-interface-hello on page 1568](#)
  - [node-hello on page 1565](#)

## Example: Configuring RSVP Automatic Mesh

Service providers often use BGP and MPLS VPNs to efficiently scale the network while delivering revenue-generating services. In these environments, BGP is used to distribute the VPN routing information across the service provider's network, while MPLS is used to forward that VPN traffic from one VPN site to another.

When adding a new PE router that will participate in BGP and MPLS VPNs, all of the previously existing PE routers must be configured to peer with the new PE router for both BGP and MPLS. As each new PE router is added to the service provider's network, the configuration burden soon becomes too much to handle.

The configuration requirements for BGP peering can be reduced with the use of route reflectors. In RSVP signaled MPLS networks, RSVP automatic mesh can minimize the configuration burden for the MPLS portion of the network. Configuring **rsvp-te** on all PE routers allows RSVP to automatically create the needed LSPs when a new PE router is added.

- [Requirements on page 509](#)
- [Overview on page 509](#)
- [Configuration on page 510](#)
- [Verification on page 511](#)

### Requirements

This example uses the following hardware and software components:

- A router running Junos OS Release 10.1 or later.
- A BGP and MPLS VPN using RSVP as the MPLS label-switched path (LSP) signaling protocol.

### Overview

This example shows how to configure RSVP automatic mesh on a PE router using the **rsvp-te** configuration statement. In order for RSVP automatic mesh to function properly, all of the PE routers in the full mesh configuration must have the **rsvp-te** statement configured. This ensures that any new PE routers that are added later will also benefit from the automatic mesh feature, provided that they too are configured with the **rsvp-te** statement.

Given this requirement, this example only shows the configuration on the newly added PE router. It is assumed that RSVP automatic mesh has already been configured on the existing PE routers.

## Topology

In [Figure 43 on page 510](#), there are three existing PE routers, PE1, PE2, and PE3, in the topology. PE4 has been added, and RSVP automatic mesh will be configured. The cloud represents the service provider network, and the network address, 192.0.2.0/24, is shown in the center of the figure.

Figure 43: Service Provider Network with PE Routers

## Configuration

Configuring RSVP automatic mesh involves performing these tasks:

- Enabling the **rsvp-te** configuration statement at the **[edit routing-options dynamic-tunnels *dynamic-tunnel-name*]** hierarchy level.
- Configuring the required **destination-networks** element.

This configuration element specifies the IPv4 prefix range for the destination network. Only tunnels within the specified prefix range can be created.

- Configuring the required **label-switched-path-template** element.

This configuration element takes either **default-template** or the name of a preconfigured LSP template as an argument. The **default-template** is a system-defined template that requires no user configuration.

- [Configuring RSVP Automatic Mesh on page 511](#)
- [Results on page 511](#)

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
PE4 Router    set routing-options dynamic-tunnels dt-1 rsvp-te rsvp-te-1 label-switched-path-template
               default-template
               set routing-options dynamic-tunnels dt-1 rsvp-te rsvp-te-1 destination-networks
               192.0.2.0/24
```

### Configuring RSVP Automatic Mesh

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To enable RSVP automatic mesh:

1. Configure **rsvp-te** at the **[edit routing-options dynamic-tunnels]** hierarchy level.

```
[edit routing-options dynamic-tunnels]
user@PE4# set dt-1 rsvp-te rsvp-te-1 label-switched-path-template
default-template
```

2. Configure **destination-networks** at the **[edit routing-options dynamic-tunnels]** hierarchy level.

```
[edit routing-options dynamic-tunnels]
user@PE4# set dt-1 rsvp-te rsvp-te-1 destination-networks 192.0.2.0/24
```

### Results

Issue the **show** command from the **[edit routing-options dynamic-tunnels]** hierarchy level to see the results of your configuration:

```
[edit routing-options dynamic-tunnels]
user@PE4#show
dt-1 {
  rsvp-te rsvp-te-1 {
    label-switched-path-template {
      default-template;
    }
    destination-networks {
      192.0.2.0/24;
    }
  }
}
```

### Verification

- [Verifying the Existence of RSVP Automatic Mesh Tunnels on Router PE4 on page 511](#)
- [Verifying the Existence of MPLS LSPs on Router PE4 on page 512](#)

### Verifying the Existence of RSVP Automatic Mesh Tunnels on Router PE4

**Purpose** To verify the operation of the newly configured PE4 router, issue the **show dynamic-tunnels database** command from operational mode. This command will show the destination network to which dynamic tunnels can be created.

**Action** user@PE4> show dynamic-tunnels database  
Table: inet.3  
Destination-network: 192.0.2.0/24

### Verifying the Existence of MPLS LSPs on Router PE4

---

|                              |                                                                                                                                                                                                                                                                                                                                                                                                         |

### Configuring Hello Acknowledgments for Nonsession RSVP Neighbors

---

The **hello-acknowledgements** statement controls the hello acknowledgment behavior between RSVP neighbors regardless of whether or not they are in the same session.

Hello messages received from RSVP neighbors that are not part of a common RSVP session are discarded. If you configure the **hello-acknowledgements** statement at the **[edit protocols rsvp]** hierarchy level, hello messages from nonsession neighbors are acknowledged with a hello acknowledgment message. When hellos are received from nonsession neighbors, an RSVP neighbor relationship is created and periodic hello messages can now be received from the nonsession neighbor. The **hello-acknowledgements** statement is disabled by default. Configuring this statement allows RSVP-capable routers to be discovered using hello packets and verifies that the interface is able to receive RSVP packets before sending any MPLS LSP setup messages.

Once you enable hello acknowledgments for nonsession RSVP neighbors, the router continues to acknowledge hello messages from any nonsession RSVP neighbors unless the interface itself goes down or you change the configuration. Interface-based neighbors are not automatically aged out.

**hello-acknowledgements;**

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

## Switching LSPs Away from a Network Node

You can configure the router to switch active LSPs away from a network node using a bypass LSP enabled for an interface. This feature might be used to maintain active networks when a device needs to be replaced without interrupting traffic transiting the network. The LSPs can be either static or dynamic.

1. You first need to configure either link or node protection for the traffic that needs to pass around the network device you intend to disable. To function properly, the bypass LSP must use a different logical interface than the protected LSP.
2. To prepare the router to begin switching traffic away from a network node, configure the **always-mark-connection-protection-tlv** statement:

```
always-mark-connection-protection-tlv;
```

The router then marks all OAM traffic transiting this interface in preparation for switching the traffic to an alternate path based on the OAM functionality.

You can configure this statement at the following hierarchy levels:

- **[edit protocols mpls interface *interface-name*]**
  - **[edit logical-systems *logical-system-name* protocols mpls interface *interface-name*]**
3. You then need to configure the **switch-away-lsps** statement to switch the traffic from the protected LSP to the bypass LSP, effectively bypassing the default downstream network device. The actual link itself is not brought down by this configuration.

To configure the router to switch traffic away from a network node, configure the **switch-away-lsps** statement:

```
switch-away-lsps;
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols mpls interface *interface-name*]**
- **[edit logical-systems *logical-system-name* protocols mpls interface *interface-name*]**

Note the following limitations related to switching active LSPs away from a network node:

- The switch-away feature is supported on MX Series routers only.
- The switch-away feature is not supported for switching traffic from primary point-to-multipoint LSPs to bypass point-to-multipoint LSPs. If you configure the **switch-away-lsps** statement for a point-to-multipoint LSP, traffic is not switched to the bypass point-to-multipoint LSP.
- If you configure the switch-away feature on an interface along the path of a dynamic LSP, new dynamic LSPs cannot be established over that path. The switch-away feature prevents the make-before-break behavior of RSVP-signaled LSPs. The make-before-break behavior normally causes the router to first attempt to re-signal a dynamic LSP before tearing down the original.

**Related  
Documentation**

- [Configuring Node Protection or Link Protection for LSPs on page 543](#)

---

## Configuring RSVP Setup Protection

---

You can configure the facility-backup fast reroute mechanism to provide setup protection for LSPs which are in the process of being signaled. Both point-to-point LSPs and point-to-multipoint LSPs are supported. This feature is applicable in the following scenario:

1. A failed link or node is present on the strict explicit path of an LSP before the LSP is signaled.
2. There is also a bypass LSP protecting the link or node.
3. RSVP signals the LSP through the bypass LSP. The LSP appears as if it was originally set up along its primary path and then failed over to the bypass LSP because of the link or node failure.
4. When the link or node has recovered, the LSP can be automatically reverted to the primary path.

You should configure the **setup-protection** statement at the **[edit protocols rsvp]** on each of the routers along the LSP path on which you want to enable LSP setup protection. You should also configure IGP traffic engineering on all of the routers on the LSP path. You can issue a **show rsvp session** command to determine whether or not the LSP has setup protection enabled on a router acting as a point of local repair (PLR) or a merge point.

To enable RSVP setup protection, include the **setup-protection** statement

```
setup-protection;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

---

## Configuring Load Balancing Across RSVP LSPs

---

By default, when you have configured several RSVP LSPs to the same egress router, the LSP with the lowest metric is selected and carries all traffic. If all of the LSPs have the same metric, one of the LSPs is selected at random and all traffic is forwarded over it.

Alternatively, you can load-balance traffic across all of the LSPs by enabling per-packet load balancing.

To enable per-packet load balancing on an ingress LSP, configure the **policy-statement** statement as follows:

```
[edit policy-options]
policy-statement policy-name {
  then {
```

```

        load-balance per-packet;
    }
    accept;
}

```

You then need to apply this statement as an export policy to the forwarding table.

Once per-packet load balancing is applied, traffic is distributed equally between the LSPs (by default).

You need to configure per-packet load balancing if you want to enable PFE fast reroute. To enable PFE fast reroute, include the **policy-statement** statement for per-packet load balancing shown in this section in the configuration of each of the routers where a reroute might take place. See also [“Configuring Fast Reroute” on page 254](#).

You can also load-balance the traffic between the LSPs in proportion to the amount of bandwidth configured for each LSP. This capability can better distribute traffic in networks with asymmetric bandwidth capabilities across external links, since the configured bandwidth of an LSP typically reflects the traffic capacity of that LSP.

To configure RSVP LSP load balancing, include the **load-balance** statement with the **bandwidth** option:

```

load-balance {
    bandwidth;
}

```

You can configure this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

Keep the following information in mind when you use the **load-balance** statement:

- If you configure the **load-balance** statement, the behavior of currently running LSPs is not altered. To force currently running LSPs to use the new behavior, you can issue a **clear mpls lsp** command.
- The **load-balance** statement only applies to ingress LSPs that have per-packet load balancing enabled.
- For Differentiated Services–aware traffic engineered LSPs, the bandwidth of an LSP is calculated by summing the bandwidth of all of the class types.

## Configuring RSVP Automatic Mesh

You can configure RSVP to establish point-to-point label-switched paths (LSPs) automatically for any new PE router added to a full mesh of LSPs. To enable this feature, you must configure the **rsvp-te** statement on all of the PE routers in the full mesh.

**NOTE:** You cannot configure RSVP automatic mesh in conjunction with CCC. CCC cannot use the dynamically generated LSPs.

To configure RSVP automatic mesh, include the **rsvp-te** statement:

```
rsvp-te {  
  destination-networks network-prefix;  
  label-switched-path-template (Multicast) {  
    default-template;  
    template-name;  
  }  
}
```

You can configure these statements at the following hierarchy levels:

- [edit routing-options dynamic-tunnels *tunnel-name*]
- [edit logical-systems *logical-system-name* routing-options dynamic-tunnels *tunnel-name*]

You must also configure the following statements to enable RSVP automatic mesh:

- **destination-networks**—Specify the IP version 4 (IPv4) prefix range for the destination network. Dynamic tunnels within the specified IPv4 prefix range can be initiated.
- **label-switched-path-template (Multicast)**—You can configure either the default template explicitly using the **default-template** option, or you can configure an LSP template of your own using the **template-name** option. The LSP template acts as a model configuration for the dynamically generated LSPs.

**Related  
Documentation**

- *Flooding Unknown Traffic Using Point-to-Multipoint LSPs in VPLS*
- [Example: Configuring RSVP Automatic Mesh on page 509](#)

---

## Configuring Timers for RSVP Refresh Messages

RSVP uses two related timing parameters:

- **refresh-time**—The refresh time controls the interval between the generation of successive refresh messages. The default value for the refresh time is 45 seconds. This number is derived from the **refresh-time** statement's default value of 30, multiplied by a fixed value of 1.5. This computation differs from RFC 2205, which states that the refresh time should be multiplied by a random value in the range from 0.5 through 1.5.

Refresh messages include path and Resv messages. Refresh messages are sent periodically so that reservation states in neighboring nodes do not time out. Each path and Resv message carries the refresh timer value, and the receiving node extracts this value from the messages.

- **keep-multiplier**—The keep multiplier is a small, locally configured integer from 1 through 255. The default value is 3. It indicates the number of messages that can be lost before a particular state is declared stale and must be deleted. The keep multiplier directly affects the lifetime of an RSVP state.

To determine the lifetime of a reservation state, use the following formula:

$$lifetime = (keep-multiplier + 0.5) \times (1.5 \times refresh-time)$$

In the worst case, (*keep-multiplier* – 1) successive refresh messages must be lost before a reservation state is deleted.

We do not recommend configuring a short RSVP hello timer. If quick discovery of a failed neighbor is needed, configure short IGP (OSPF or IS-IS) hello timers.

By default, the refresh timer value is 30 seconds. To modify this value, include the **refresh-time** statement:

```
refresh-time seconds;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp]
- [edit logical-systems *logical-system-name* protocols rsvp]

The default value of the keep multiplier is 3. To modify this value, include the **keep-multiplier** statement:

```
keep-multiplier number;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp]
- [edit logical-systems *logical-system-name* protocols rsvp]

---

## Preempting RSVP Sessions

Whenever bandwidth is insufficient to handle all RSVP sessions, you can control the preemption of RSVP sessions. By default, an RSVP session is preempted only by a new higher-priority session.

To always preempt a session when the bandwidth is insufficient, include the **preemption** statement with the **aggressive** option:

```
preemption aggressive;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp]
- [edit logical-systems *logical-system-name* protocols rsvp]

To disable RSVP session preemption, include the **preemption** statement with the **disabled** option:

```
preemption disabled;
```

To return to the default (that is, preempt a session only for a new higher-priority session), include the **preemption** statement with the **normal** option:

```
preemption normal;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp]

- [\[edit logical-systems \*logical-system-name\* protocols rsvp\]](#)

## Configuring MTU Signaling in RSVP

---

To configure maximum transmission unit (MTU) signaling in RSVP, you need to configure MPLS to allow IP packets to be fragmented before they are encapsulated in MPLS. You also need to configure MTU signaling in RSVP. For troubleshooting purposes, you can configure MTU signaling alone without enabling packet fragmentation.

To configure MTU signaling in RSVP, include the **path-mtu** statement:

```
path-mtu {  
  allow-fragmentation;  
  rsvp {  
    mtu-signaling;  
  }  
}
```

You can include this statement at the following hierarchy levels:

- [\[edit protocols mpls\]](#)
- [\[edit logical-systems \*logical-system-name\* protocols mpls\]](#)

The following sections describe how to enable packet fragmentation and MTU signaling in RSVP:

- [Enabling MTU Signaling in RSVP on page 518](#)
- [Enabling Packet Fragmentation on page 519](#)

## Enabling MTU Signaling in RSVP

To enable MTU signaling in RSVP, include the **rsvp mtu-signaling** statement:

```
rsvp mtu-signaling;
```

You can include this statement at the following hierarchy levels:

- [\[edit protocols mpls path-mtu\]](#)
- [\[edit logical-systems \*logical-system-name\* protocols mpls path-mtu\]](#)

Once you have committed the configuration, changes in the MTU signaling behavior for RSVP take effect the next time the path is refreshed.

You can configure the **mtu-signaling** statement by itself at the [\[edit protocols mpls path-mtu rsvp\]](#) hierarchy level. This can be useful for troubleshooting. If you configure just the **mtu-signaling** statement, you can use the **show rsvp session detail** command to determine what the smallest MTU is on an LSP. The **show rsvp session detail** command displays the MTU value received and sent in the Adspec object.

## Enabling Packet Fragmentation

To allow IP packets to be fragmented before they are encapsulated in MPLS, include the **allow-fragmentation** statement:

```
allow-fragmentation;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls path-mtu]
- [edit logical-systems *logical-system-name* protocols mpls path-mtu]

**NOTE:** Do not configure the **allow-fragmentation** statement alone. Always configure it in conjunction with the **mtu-signaling** statement.

## Configuring Ultimate-Hop Popping for LSPs

By default, RSVP-signaled LSPs use penultimate-hop popping (PHP). [Figure 31 on page 250](#) illustrates a penultimate-hop popping LSP between Router PE1 and Router PE2. Router CE1 forwards a packet to its next hop (Router PE1), which is also the LSP ingress. Router PE1 pushes label 1 on the packet and forwards the labeled packet to Router P1. Router P1 completes the standard MPLS label swapping operation, swapping label 1 for label 2, and forwards the packet to Router P2. Since Router P2 is the penultimate-hop router for the LSP to Router PE2, it first pops the label and then forwards the packet to Router PE2. When Router PE2 receives it, the packet can have a service label, an explicit-null label, or just be a plain IP or VPLS packet. Router PE2 forwards the unlabeled packet to Router CE2.

**Figure 44: Penultimate-Hop Popping for an LSP**

You can also configure ultimate-hop popping (UHP) (as shown in [Figure 32 on page 250](#)) for RSVP-signaled LSPs. Some network applications can require that packets arrive at the egress router (Router PE2) with a non-null outer label. For an ultimate-hop popping LSP, the penultimate router (Router P2 in [Figure 32 on page 250](#)) performs the standard MPLS label swapping operation (in this example, label 2 for label 3) before forwarding the packet to egress Router PE2. Router PE2 pops the outer label and performs a second lookup of the packet address to determine the end destination. It then forwards the packet to the appropriate destination (either Router CE2 or Router CE4).

Figure 45: Ultimate-Hop Popping for an LSP

The following network applications require that you configure UHP LSPs:

- MPLS-TP for performance monitoring and in-band OAM
- Edge protection virtual circuits

The following features do not support the UHP behavior:

- LDP-signaled LSPs
- Static LSPs
- Point-to-multipoint LSPs
- CCC
- **traceroute** command

For more information about UHP behavior, see Internet draft [draft-ietf-mpls-rsvp-te-no-php-oob-mapping-01.txt](#), *Non PHP behavior and Out-of-Band Mapping for RSVP-TE LSPs*.

For point-to-point RSVP-signaled LSPs, UHP behavior is signaled from the LSP ingress. Based on the ingress router configuration, RSVP can signal the UHP LSP with the non-PHP flag set. RSVP PATH messages carry the two flags in the LSP-ATTRIBUTES object. When the egress router receives the PATH message, it assigns a non-null label to the LSP. RSVP also creates and installs two routes in the mpls.0 routing table. S refers to the S bit of the MPLS label, which indicates whether or not the bottom of the label stack has been reached.

- Route S=0—Indicates that there are more labels in the stack. The next hop for this route points to the mpls.0 routing table, triggering a chained MPLS label lookup to discover the remaining MPLS labels in the stack.
- Route S=1—Indicates that there are no more labels. The next hop points to the inet.0 routing table if the platform supports chained and multi-family lookup. Alternatively, the label route can point to a VT interface to initiate IP forwarding.

If you enable UHP LSPs, MPLS applications such as Layer 3 VPNs, VPLS, Layer 2 VPNs, and Layer 2 circuits can use the UHP LSPs. The following explains how UHP LSPs affect the different types of MPLS applications:

- **Layer 2 VPNs and Layer 2 circuits**—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label (S=0) is the UHP label, and the inner label (S=1) is the VC label. A lookup based on the transport label results in a table handle for the mpls.0 routing table. There is an additional route in the mpls.0 routing table corresponding to the inner label. A lookup based on the inner label results in the CE router next hop.
- **Layer 3 VPN**—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label (S=0) is the UHP label, and the inner label is the VPN label (S=1). A lookup based on the transport label results in the table handle for the mpls.0 routing table. There are two cases in this scenario. By default, Layer 3 VPNs advertise the per-next hop label. A lookup based on the inner label results in the next hop toward the CE router. However, if you have configured the **vrf-table-label** statement for the Layer 3 VPN routing instance, the inner LSI label points to the VRF routing table. An IP lookup is also completed for the VRF routing table.

**NOTE:** UHP for Layer 3 VPNs configured with the **vrf-table-label** statement is supported on MX 3D Universal Edge Routers only.

- **VPLS**—A packet arrives at the PE router (egress of the UHP LSP) with two labels. The outer label is the transport label (S=0) and the inner label is the VPLS label (S=1). A lookup based on the transport label results in the table handle for the mpls.0 routing table. A lookup based on the inner label in mpls.0 routing table results in the LSI tunnel interface of the VPLS routing instance if tunnel-services is not configured (or a VT interface not available). MX 3D Series routers support chained lookup and multi-family lookup.

**NOTE:** UHP for VPLS configured with the **no-tunnel-service** statement is supported on MX 3D Series routers only.

- **IPv4 over MPLS**—A packet arrives at the PE router (egress of the UHP LSP) with one label (S=1). A lookup based on this label returns a VT tunnel interface. Another IP lookup is completed on the VT interface to determine where to forward the packet. If the routing platform supports multi-family and chained lookups (for example, MX 3D routers and PTX Series Packet Transport Routers), lookup based on label route (S=1) points to the inet.0 routing table.
- **IPv6 over MPLS**—For IPv6 tunneling over MPLS, PE routers advertise IPv6 routes to each other with a label value of 2. This is the explicit null label for IPv6. As a result, the forwarding next hops for IPv6 routes that are learned from remote PE routers normally push two labels. The inner label is 2 (it could be different if the advertising PE router is from another vendor), and the router label is the LSP label. Packets arrive at the PE router (egress of the UHP LSP) with two labels. The outer label is the transport label (S=0), and the inner label is the IPv6 explicit-null label (label 2). Lookup based on the

inner label in the mpls.0 routing table redirects back to the mpls.0 routing table. On MX 3D Series routers, the inner label (label 2) is stripped off and an IPv6 lookup is done using the inet6.0 routing table.

- Enabling both PHP and UHP LSPs—You can configure both PHP and UHP LSPs over the same network paths. You can separate PHP and UHP traffic by selecting forwarding LSP next hops using a regular expression with the **install-nexthop** statement. You can also separate traffic by simply naming the LSPs appropriately.

The following statements enable ultimate-hop popping for an LSP. You can enable this feature on a specific LSP or for all of the ingress LSPs configured on the router. Configure these statements on the router at the LSP ingress.

1. To enable ultimate-hop popping, include the **ultimate-hop-popping** statement:

**ultimate-hop-popping;**

Include this statement at the **[edit protocols mpls label-switched-path label-switched-path-name]** hierarchy level to enable ultimate-hop popping on a specific LSP. Include this statement at the **[edit protocols mpls]** hierarchy level to enable ultimate-hop popping on all of the ingress LSPs configured on the router. You can also configure the **ultimate-hop-popping** statement under the equivalent **[edit logical-routers]** hierarchy levels.

**NOTE:** When you enable ultimate-hop popping, RSVP attempts to resignal existing LSPs as ultimate-hop popping LSPs in a make-before-break fashion. If an egress router does not support ultimate-hop popping, the existing LSP is torn down (RSVP sends a PathTear message along an LSP's path, removing the path state and dependent reservation state and releasing the associated networking resources).

If you disable ultimate-hop popping, RSVP resignals existing LSPs as penultimate-hop popping LSPs in a make-before-break fashion.

2. If you want to enable both ultimate-hop-popping and chained next hops on MX 3D Series routers only, you also need to configure the **enhanced-ip** option for the **network-services** statement:

**network-services enhanced-ip;**

You configure this statement at the **[edit chassis]** hierarchy level. Once you have configured the **network-services** statement, you need to reboot the router to enable UHP behavior.

#### Related Documentation

- [MPLS Label Allocation on page 26](#)
- [Configuring Corouted Bidirectional LSPs on page 248](#)
- [network-services](#)
- [ultimate-hop-popping on page 1537](#)

## Configuring RSVP to Pop the Label on the Ultimate-Hop Router

You can control the label value advertised on the egress router of an LSP. The default advertised label is label 3 (Implicit Null label). If label 3 is advertised, the penultimate-hop router removes the label and sends the packet to the egress router. When ultimate-hop popping is enabled, label 0 (IP version 4 [IPv4] Explicit Null label) is advertised. Ultimate-hop popping ensures that any packets traversing an MPLS network include a label.

**NOTE:** Juniper Networks routers queue packets based on the incoming label. Routers from other vendors might queue packets differently. Keep this in mind when working with networks containing routers from multiple vendors.

To configure ultimate-hop popping for RSVP, include the **explicit-null** statement:

```
explicit-null;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls]**
- **[edit logical-systems *logical-system-name* protocols mpls]**

### Related Documentation

- [MPLS Label Overview on page 24](#)
- [MPLS Label Allocation on page 26](#)

## Enabling Ultimate-Hop Popping on Point-to-Multipoint LSPs

By default, for both point-to-point and point-to-multipoint LSPs, penultimate-hop popping is used for MPLS traffic. MPLS labels are removed from packets on the router just before the egress router of the LSP. The plain IP packets are then forwarded to the egress router. For ultimate-hop popping, the egress router is responsible for both removing the MPLS label and processing the plain IP packet.

It can be beneficial to enable ultimate-hop popping on point-to-multipoint LSPs, particularly when transit traffic is traversing the same egress device. If you enable ultimate-hop popping, a single copy of traffic can be sent over the incoming link, saving significant bandwidth. By default, ultimate-hop popping is disabled.

You enable ultimate-hop popping for point-to-multipoint LSPs by configuring the **tunnel-services** statement. When you enable ultimate-hop popping, the Junos OS selects one of the available virtual loopback tunnel (VT) interfaces to loop back the packets to the PFE for IP forwarding. By default, the VT interface selection process is performed automatically. Bandwidth admission control is used to limit the number of LSPs that can be used on one VT interface. Once all the bandwidth is consumed on one interface, the Junos OS selects another VT interface with sufficient bandwidth for admission control.

If an LSP requires more bandwidth than is available from any of the VT interfaces, ultimate-hop popping cannot be enabled and penultimate-hop popping is enabled instead.

For ultimate-hop popping on point-to-multipoint LSPs to function properly, the egress router must have a PIC that provides tunnel services, such as the tunnel services PIC or the adaptive services PIC. Tunnel services are needed for popping the final MPLS label and for returning packets for IP address lookups.

You can explicitly configure which VT interfaces handle the RSVP traffic by including the **devices** option for the **tunnel-services** statement. The **devices** option allows you to specify which VT interfaces are to be used by RSVP. If you do not configure this option, all of the VT interfaces available to the router can be used.

To enable ultimate-hop popping for the egress point-to-multipoint LSPs on a router, configure the **tunnel-services** statement:

```
tunnel-services {  
  devices device-names;  
}
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

To enable ultimate-hop popping for egress point-to-multipoint LSPs, you must also configure the **interface** statement with the **all** option:

```
interface all;
```

You must configure this statement at the **[edit protocols rsvp]** hierarchy level.

---

## Tracing RSVP Protocol Traffic

To trace RSVP protocol traffic, include the **traceoptions** statement:

```
traceoptions {  
  file filename <files number> <size size> <world-readable | no-world-readable>;  
  flag flag <flag-modifier> <disable>;  
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

You can specify the following RSVP-specific flags in the RSVP **traceoptions** statement:

Use the **file** statement to specify the name of the file that receives the output of the tracing operation. All files are placed in the directory **/var/log**. We recommend that you place RSVP tracing output in the file **rsvp-log**.

- **all**—All tracing operations.
- **error**—All detected error conditions
- **event**—RSVP-related events (helps to trace events related to RSVP graceful restart)
- **lmp**—RSVP-Link Management Protocol (LMP) interactions
- **packets**—All RSVP packets
- **path**—All path messages
- **pathtear**—PathTear messages
- **resv**—Resv messages
- **resvtear**—ResvTear messages
- **route**—Routing information
- **state**—Session state transitions, including when RSVP-signaled LSPs come up and go down.

**NOTE:** Use the **all** trace flag and the **detail** flag modifier with caution because these might cause the CPU to become very busy.

To view the log file generated when you enable RSVP traceoptions, issue the **show log file-name** command, where **file-name** is the file you specified using the **traceoptions** statement.

For general information about tracing and global tracing options, see the *Junos OS Routing Protocols Library*.

## Examples: Tracing RSVP Protocol Traffic

Trace RSVP path messages in detail:

```
[edit]
protocols {
  rsvp {
    traceoptions {
      file rsvp size 10m files 5;
      flag path;
    }
  }
}
```

Trace all RSVP messages:

```
[edit]
protocols {
  rsvp {
```

```

        traceoptions {
            file rsvp size 10m files 5;
            flag packets;
        }
    }
}

```

Trace all RSVP error conditions:

```

[edit]
protocols {
    rsvp {
        traceoptions {
            file rsvp size 10m files 5;
            flag error;
        }
    }
}

```

Trace RSVP state transitions:

```

[edit]
protocols {
    rsvp {
        traceoptions {
            file rsvp-data;
            flag state;
        }
    }
}

```

## RSVP Log File Output

The following is sample output generated by issuing the **show log file-name** command on a router on which RSVP traceoptions have been enabled with the **state** flag configured. The RSVP-signaled LSP E-D is shown being torn down on Mar 11 14:04:36.707092. On Mar 11 14:05:30.101492, it is shown coming back up.

```

- [Configuring Inter-AS Node and Link Protection on page 544](#)

## Link Protection

---

Link protection helps to ensure that traffic going over a specific interface to a neighboring router or switch can continue to reach this router (switch) if that interface fails. When link protection is configured for an interface and an LSP that traverses this interface, a bypass LSP is created that will handle this traffic if the interface fails. The bypass LSP uses a different interface and path to reach the same destination. The path used can be configured explicitly, or you can rely on CSPF. The RSVP metric for the bypass LSP is set in the range of 20,000 through 29,999 (this value is not user configurable).

If a link-protected interface fails, traffic is quickly switched to the bypass LSP. Note that a bypass LSP cannot share the same egress interface with the LSPs it monitors.

In [Figure 46 on page 530](#), link protection is enabled on Interface B between Router 1 and Router 2. It is also enabled on LSP A, an LSP that traverses the link between Router 1 and Router 2. If the link between Router 1 and Router 2 fails, traffic from LSP A is quickly switched to the bypass LSP generated by link protection.

**Figure 46: Link Protection Creating a Bypass LSP for the Protected Interface**

Although LSPs traversing an interface can be configured to take advantage of link protection, it is important to note that it is specifically the interface that benefits from link protection. If link protection is enabled on an interface but not on a particular LSP traversing that interface, then if the interface fails, that LSP will also fail.

**NOTE:** Link protection does not work on unnumbered interfaces.

To protect traffic over the entire route taken by an LSP, you should configure fast reroute. For more information, see [“Configuring Fast Reroute” on page 254](#).

## Multiple Bypass LSPs for Link Protection

By default, link protection relies on a single bypass LSP to provide path protection for an interface. However, you can also specify multiple bypass LSPs to provide link protection for an interface. You can individually configure each of these bypass LSPs or create a single configuration for all of the bypass LSPs. If you do not configure the bypass LSPs individually, they all share the same path and bandwidth constraints.

The following algorithm describes how and when an additional bypass LSP is activated for an LSP:

1. If any currently active bypass can satisfy the requirements of the LSP (bandwidth, link protection, or node-link protection), the traffic is directed to that bypass.
2. If no active bypass LSP is available, scan through the manual bypass LSPs in first-in, first-out (FIFO) order, skipping those that are already active (each manual bypass can only be activated once). The first inactive manual bypass that can satisfy the requirements is activated and traffic is directed to that bypass.
3. If no manual bypass LSPs are available and if the **max-bypasses** statement activates multiple bypass LSPs for link protection, determine whether an automatically configured bypass LSP can satisfy the requirements. If an automatically configured

bypass LSP is available and if the total number of active automatically configured bypass LSPs does not exceed the maximum bypass LSP limit (configured with the **max-bypasses** statement), activate another bypass LSP.

For information about how to configure multiple bypass LSPs for link protection, see [“Configuring Bypass LSPs” on page 537](#).

## Node Protection

Node protection extends the capabilities of link protection. Link protection helps to ensure that traffic going over a specific interface to a neighboring router can continue to reach this router if that interface fails. Node protection ensures that traffic from an LSP traversing a neighboring router can continue to reach its destination even if the neighboring router fails.

When you enable node protection for an LSP, you must also enable link protection. Once enabled, node protection and link protection establish the following types of bypass LSPs:

- Next-hop bypass LSP—Provides an alternate route for an LSP to reach a neighboring router. This type of bypass LSP is established when you enable either node protection or link protection.
- Next-next-hop bypass LSP—Provides an alternate route for an LSP to get around a neighboring router en route to the destination router. This type of bypass LSP is established exclusively when node protection is configured. If a next-next-hop bypass LSP cannot be created, an attempt is made to signal a next-hop bypass LSP.

In [Figure 47 on page 531](#), node protection is enabled on Interface B on Router 1. Node protection is also enabled on LSP A, an LSP that traverses the link transiting Router 1, Router 2, and Router 3. If Router 2 suffers a hardware or software failure, traffic from LSP A is switched to the next-next-hop bypass LSP generated by node protection.

**Figure 47: Node Protection Creating a Next-Next-Hop Bypass LSP**

The time needed by node protection to switch traffic to a next-next-hop bypass LSP can be significantly longer than the time needed by link protection to switch traffic to a next-hop bypass LSP. Link protection relies on a hardware mechanism to detect a link failure, allowing it to quickly switch traffic to a next-hop bypass LSP.

Node failures are often due to software problems on the node router. Node protection relies on the receipt of hello messages from a neighboring router to determine whether it is still functioning. The time it takes node protection to divert traffic partly depends on how often the node router sends hello messages and how long it takes the node-protected

router to react to having not received a hello message. However, once the failure is detected, traffic can be quickly diverted to the next-next-hop bypass LSP.

**NOTE:**

Node protection provides traffic protection in the event of an error or interruption of the physical link between two routers. It does not provide protection in the event of control plane errors. The following provides an example of a control plane error:

- A transit router changes the label of a packet due to a control plane error.
- When the ingress router receives the packet, it considers the label change to be a catastrophic event and deletes both the primary LSP and the associated bypass LSP.

## Fast Reroute, Node Protection, and Link Protection

This document discusses the following sections:

- [LSP Protection Overview on page 532](#)
- [LSP Protection Types Comparison on page 533](#)
- [One-to-One Backup Implementation on page 533](#)
- [Facility Backup Implementation on page 534](#)

### LSP Protection Overview

RSVP-TE extensions establish backup label-switched path (LSP) tunnels for local repair of LSP tunnels. These mechanisms enable immediate re-direction of traffic onto backup LSP tunnels, in the event of a failure.

RFC 4090, *Fast Reroute Extensions to RSVP-TE for LSP Tunnels*, describes two different types of traffic protection for RSVP-signaled LSPs:

- One-to-one backup—In this method, detour LSPs for each protected LSP is created at each potential point of local repair.
- Facility backup—In this method, a bypass tunnel is created to protect a set of LSPs that have similar backup constraints at a potential failure point, by taking advantage of the MPLS label stacking.

The one-to-one backup and the facility backup methods protect links and nodes during network failure, and can co-exist in a mixed network.

## LSP Protection Types Comparison

In the Junos OS, the one-to-one backup of traffic protection is provided by fast reroute. Each LSP requires a protecting LSP to be signaled at each hop except the egress router. This method of LSP protection cannot be shared.

In the facility backup method, the LSP traffic protection is provided on the node and link. Each LSP requires a protecting LSP to be signaled at each hop except the egress router. Unlike fast reroute, this protecting LSP can be shared by other LSPs.

Table 17 on page 533 summarizes the traffic protection types.

**Table 17: One-to-One Backup Compared with Facility Backup**

| Comparison                     | One-to-One Backup   | Facility Backup                                        |
|--------------------------------|---------------------|--------------------------------------------------------|
| Name of the protecting LSP     | Detour LSP          | Bypass LSP                                             |
| Sharing of the protecting LSP  | Cannot be shared    | Can be shared by multiple LSPs                         |
| Junos configuration statements | <b>fast-reroute</b> | <b>node-link-protection</b> and <b>link-protection</b> |

## One-to-One Backup Implementation

In the one-to-one backup method, the points of local repair maintain separate backup paths for each LSP passing through a facility. The backup path terminates by merging back with the primary path at a node called the merge point. In this approach, the merge point can be any node downstream from the protected facility.

In the one-to-one backup method, an LSP is established that intersects the original LSP downstream of the point of link or node failure. A separate backup LSP is established for each LSP that is backed up.

One-to-one backup is appropriate under the following circumstances:

- Protection of a small number of LSPs relative to the total number of LSPs.
- Path selection criteria, such as bandwidth, priority, and link coloring for detour paths is critical.
- Control of individual LSPs is important.

In Figure 48 on page 534, Routers R1 and R5 are the ingress and egress routers, respectively. A protected LSP is established between the two routers transiting Routers R2, R3, and R4. Router R2 provides user traffic protection by creating a partial backup LSP that merges with the protected LSP at Router R4. This partial one-to-one backup LSP is called a detour. Detours are always calculated to avoid the immediate downstream link and node, providing against both link and node failure.

Figure 48: One-to-One Backup

g042701

In the example, the protected LSP is **R1-R2-R3-R4-R5**, and the following detours are established:

- Router R1—**R1-R6-R7-R8-R3**
- Router R2—**R2-R7-R8-R4**
- Router R3—**R3-R8-R9-R5**
- Router R4—**R4-R9-R5**

To protect an LSP that traverses **N** nodes fully, there can be as many as **(N - 1)** detours. The point of local repair sends periodic refresh messages to maintain each backup path, as a result maintaining state information for backup paths protecting individual LSPs is a significant resource burden for the point of local repair. To minimize the number of LSPs in the network, it is desirable to merge a detour back to its protected LSP, when feasible. When a detour LSP intersects its protected LSP at an LSR with the same outgoing interface, it is merged.

## Facility Backup Implementation

In the facility backup approach, a point of local repair maintains a single backup path to protect a set of primary LSPs traversing the point of local repair, the facility, and the merge point. The facility backup is based on interface rather than on LSP. While fast reroute protects interfaces or nodes along the entire path of a LSP, the facility backup protection can be applied on interfaces as needed. As a result, fewer states need to be maintained and refreshed which results in a scalable solution. The facility backup method is also called many-to-one backup.

The facility backup method takes advantage of the MPLS label stack. Instead of creating a separate LSP for every backed-up LSP, a single LSP is created that serves to back up a set of LSPs. Such an LSP tunnel is called a bypass tunnel. In this method, a router immediately upstream from a link failure uses an alternate interface to forward traffic

to its downstream neighbor, and the merge point should be the node immediately downstream to the facility. This is accomplished by preestablishing a bypass path that is shared by all protected LSPs traversing the failed link. A single bypass path can safeguard a set of protected LSPs. When an outage occurs, the router immediately upstream from the link outage switches protected traffic to the bypass link, then signals the link failure to the ingress router.

The bypass tunnel must intersect the path of the original LSP(s) somewhere downstream of the point of local repair. This constrains the set of LSPs being backed up through that bypass tunnel to those that pass through some common downstream nodes. All LSPs that pass through the point of local repair and through this common node, and that do not also use the facilities involved in the bypass tunnel are candidates for this set of LSPs.

The facility backup method is appropriate in the following situations:

- The number of LSPs to be protected is large.
- Satisfying path selection criteria (priority, bandwidth, and link coloring) for bypass paths is less critical.
- Control at the granularity of individual LSPs is not required.

In [Figure 49 on page 535](#), Routers R1 and R5 are the ingress and egress routers, respectively. Router R2 has established a bypass tunnel that protects against the failure of Router R2-R3 link and Router R3 node. A bypass tunnel is established between Routers R6 and R7. There are three different protected LSPs that are using the same bypass tunnel for protection.

**Figure 49: Facility Backup**

8042700

The facility backup method provides a scalability improvement, wherein the same bypass tunnel is also used to protect LSPs from any of Routers R1, R2, or R8 to any of Routers R4, R5, or R9.

## Configuring Link Protection on Interfaces Used by LSPs

---

When you configure node protection or link protection on a router for LSPs as described in “[Configuring Node Protection or Link Protection for LSPs](#)” on page 543, you also must configure the **link-protection** statement on the RSVP interfaces used by the LSPs.

To configure link protection on the interfaces used by the LSPs, include the **link-protection** statement:

```
link-protection {  
  disable;  
  admin-group  
    exclude group-names;  
    include-all group-names;  
    include-any group-names;  
}  
bandwidth bps;  
bypass bypass-name {  
  bandwidth bps;  
  description text;  
  hop-limit number;  
  no-cspf;  
  path address <strict | loose>;  
  priority setup-priority reservation-priority;  
  to address;  
}  
class-of-service cos-value;  
hop-limit number;  
max-bypasses number;  
no-cspf;  
no-node-protection;  
optimize-timer seconds;  
path address <strict | loose>;  
priority setup-priority reservation-priority;  
subscription percent {  
  ct0 percent;  
  ct1 percent;  
  ct2 percent;  
  ct3 percent;  
}  
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name*]

All the statements under **link-protection** are optional.

The following sections describe how to configure link protection:

- [Configuring Priority and Preemption for Bypass LSPs on page 543](#)

## Configuring Bypass LSPs

You can configure specific bandwidth and path constraints for a bypass LSP. You can also individually configure each bypass LSP generated when you enable multiple bypass LSPs. If you do not configure the bypass LSPs individually, they all share the same path and bandwidth constraints (if any).

If you specify the **bandwidth**, **hop-limit**, and **path** statements for the bypass LSP, these values take precedence over the values configured at the [edit protocols rsvp **interface** *interface-name* **link-protection**] hierarchy level. The other attributes (**subscription**, **no-node-protection**, and **optimize-timer**) are inherited from the general constraints.

To configure a bypass LSP, specify a name for the bypass LSP using the **bypass** statement. The name can be up to 64 characters in length.

```
bypass bypass-name {
  bandwidth bps;
  description text;
  class-of-service cos-value;
  hop-limit number;
  no-cspf;
  path address <strict | loose>;
  priority setup-priority reservation-priority;
  to address;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* **link-protection**]

- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

### Configuring the Next-Hop or Next-Next-Hop Node Address for Bypass LSPs

---

If you configure a bypass LSP, you must also configure the **to** statement. The **to** statement specifies the address for the interface of the immediate next-hop node (for link protection) or the next-next-hop node (for node-link protection). The address specified determines whether this is a link protection bypass or a node-link protection bypass. On multiaccess networks (for example, a LAN), this address is also used to specify which next-hop node is being protected.

### Configuring Administrative Groups for Bypass LSPs

Administrative groups, also known as link coloring or resource class, are manually assigned attributes that describe the “color” of links, such that links with the same color conceptually belong to the same class. You can use administrative groups to implement a variety of policy-based LSP setups. You can configure administrative groups for bypass LSPs. For more information about configuring administrative groups, see “[Configuring Administrative Groups for LSPs](#)” on page 268.

To configure administrative groups for bypass LSPs, include the **admin-group** statement:

```
admin-group {  
  exclude group-names;  
  include-all group-names;  
  include-any group-names;  
}
```

To configure an administrative group for all of the bypass LSPs, include the **admin-group** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

To configure an administrative groups for a specific bypass LSP, include the **admin-group** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]

### Configuring the Bandwidth for Bypass LSPs

You can specify the amount of bandwidth allocated for automatically generated bypass LSPs or you can individually specify the amount of bandwidth allocated for each LSP.

If you have enabled multiple bypass LSPs, this statement is required.

To specify the bandwidth allocation, include the **bandwidth** statement:

**bandwidth** *bps*;

For automatically generated bypass LSPs, include the **bandwidth** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

For individually configured bypass LSPs, include the **bandwidth** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]

## Configuring Class of Service for Bypass LSPs

You can specify the class-of-service value for bypass LSPs by including the **class-of-service** statement:

**class-of-service** *cos-value*;

To apply a class-of-service value to all the automatically generated bypass LSPs, include the **class-of-service** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

To configure a class-of-service value for a specific bypass LSPs, include the **class-of-service** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]

## Configuring the Hop Limit for Bypass LSPs

You can specify the maximum number of hops a bypass can traverse. By default, each bypass can traverse a maximum of 255 hops (the ingress and egress routers count as one hop each, so the minimum hop limit is two).

To configure the hop limit for bypass LSPs, include the **hop-limit** statement:

**hop-limit** *number*;

For automatically generated bypass LSPs, include the **hop-limit** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]

- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

For individually configured bypass LSPs, include the **hop-limit** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]

## Configuring the Maximum Number of Bypass LSPs

You can specify the maximum number of dynamic bypass LSPs permitted for protecting an interface using the **max-bypasses** statement at the [edit protocols rsvp **interface** *interface-name* link-protection] hierarchy level. When this statement is configured, multiple bypasses for link protection are enabled. Call admission control (CAC) is also enabled.

By default, this option is disabled and only one bypass is enabled for each interface. You can configure a value of between 0 through 99 for the **max-bypasses** statement. Configuring a value of 0 prevents the creation of any dynamic bypass LSPs for the interface. If you configure a value of 0 for the **max-bypasses** statement, you need to configure one or more static bypass LSPs to enable link protection on the interface.

If you configure the **max-bypasses** statement, you must also configure the **bandwidth** statement (discussed in “[Configuring the Bandwidth for Bypass LSPs](#)” on page 538).

To configure the maximum number of bypass LSPs for a protected interface, include the **max-bypasses** statement:

```
max-bypasses number;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

## Disabling CSPF for Bypass LSPs

Under certain circumstances, you might need to disable CSPF computation for bypass LSPs and use the configured Explicit Route Object (ERO) if available. For example, a bypass LSP might need to traverse multiple OSPF areas or IS-IS levels, preventing the CSPF computation from working. To ensure that link and node protection function properly in this case, you have to disable CSPF computation for the bypass LSP.

You can disable CSPF computation for all bypass LSPs or for specific bypass LSPs.

To disable CSPF computation for bypass LSPs, include the **no-cspf** statement:

```
no-cspf;
```

For a list of hierarchy levels where you can include this statement, see the statement summary for this statement.

## Disabling Node Protection for Bypass LSPs

You can disable node protection on the RSVP interface. Link protection remains active. When this option is configured, the router can only initiate a next-hop bypass, not a next-next-hop bypass.

To disable node protection for bypass LSPs, include the **no-node-protection** statement:

```
no-node-protection;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

## Configuring the Optimization Interval for Bypass LSPs

You can configure an optimization interval for bypass LSPs using the **optimize-timer** statement. At the end of this interval, an optimization process is initiated that attempts to either minimize the number of bypasses currently in use, minimize the total amount of bandwidth reserved for all of the bypasses, or both. You can configure an optimization interval from 1 through 65,535 seconds. A default value of 0 disables bypass LSP optimization.

When you configure the **optimize-timer** statement, bypass LSPs are reoptimized automatically when you configure or change the configuration of any of the following:

- Administrative group for a bypass LSP—The configuration for an administrative group has been changed on a link along the path used by the bypass LSP. Configure an administrative group using the **admin-group** statement at the [edit protocols rsvp **interface** *interface-name* link-protection] hierarchy level.
- Fate sharing group—The configuration for a fate sharing group has been changed. Configure a fate sharing group using the **group** statement at the [edit routing-options **fate-sharing**] hierarchy level.
- IS-IS overload—The configuration for IS-IS overload has been changed on a router along the path used by the bypass LSP. Configure IS-IS overload using the **overload** statement at the [edit protocols isis] hierarchy level.
- IGP metric—The IGP metric has been changed on a link along the path used by the bypass LSP.

To configure the optimization interval for bypass LSPs, include the **optimize-timer** statement:

```
optimize-timer seconds;
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]

- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

## Configuring an Explicit Path for Bypass LSPs

By default, when you establish a bypass LSP to an adjacent neighbor, CSPF is used to discover the least-cost path. The **path** statement allows you to configure an explicit path (a sequence of strict or loose routes), giving you control over where and how the bypass LSP is established. To configure an explicit path, include the **path** statement:

```
path address <strict | loose>;
```

For automatically generated bypass LSPs, include the **path** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

For individually configured bypass LSPs, include the **path** statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]
- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection **bypass** *bypass-name*]

## Configuring the Amount of Bandwidth Subscribed for Bypass LSPs

You can configure the amount of bandwidth subscribed to bypass LSPs. You can configure the bandwidth subscription for the whole bypass LSP or for each class type that might traverse the bypass LSP. You can configure any value between 1 percent and 65,535 percent. By configuring a value less than 100 percent, you are undersubscribing the bypass LSPs. By configuring a value greater than 100 percent, you are oversubscribing the bypass LSPs.

The ability to oversubscribe the bandwidth for the bypass LSPs makes it possible to more efficiently use network resources. You can configure the bandwidth for the bypass LSPs based on the average network load as opposed to the peak load.

To configure the amount of bandwidth subscribed for bypass LSPs, include the **subscription** statement:

```
subscription percentage {  
  ct0 percentage;  
  ct1 percentage;  
  ct2 percentage;  
  ct3 percentage;  
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols rsvp **interface** *interface-name* link-protection]

- [edit logical-systems *logical-system-name* protocols rsvp **interface** *interface-name* link-protection]

## Configuring Priority and Preemption for Bypass LSPs

When there is insufficient bandwidth to establish a more important LSP, you might want to tear down a less important existing LSP to release the bandwidth. You do this by preempting the existing LSP.

For more detailed information on configuring setup priority and reservation priority for LSPs, see “[Configuring Priority and Preemption for LSPs](#)” on page 280.

To configure the bypass LSP's priority and preemption properties, include the **priority** statement:

```
priority setup-priority reservation-priority;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

---

## Configuring Node Protection or Link Protection for LSPs

When you configure node protection or link protection on a router or switch, bypass LSPs are created to the next-hop or next-next-hop routers (switches) for the LSPs traversing the router (switch). You must configure node protection or link protection for each LSP that you want protected. To extend protection along the entire path used by an LSP, you must configure protection on each router that the LSP traverses.

You can configure node protection or link protection for both static and dynamic LSPs.

To configure node protection on a router for a specified LSP, include the **node-link-protection** statement:

```
node-link-protection;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

To configure link protection on a router for a specified LSP, include the **link-protection** statement:

```
link-protection;
```

You can include this statement at the following hierarchy levels:

- [edit protocols mpls **label-switched-path** *lsp-name*]
- [edit logical-systems *logical-system-name* protocols mpls **label-switched-path** *lsp-name*]

**NOTE:** To complete the configuration of node or link protection, you must also configure link protection on all unidirectional RSVP interfaces that the LSPs traverse, as described in [“Configuring Link Protection on Interfaces Used by LSPs”](#) on page 536.

---

## Configuring Inter-AS Node and Link Protection

To interoperate with other vendors' equipment, the Junos OS supports the record route object (RRO) node ID subobject for use in inter-AS link and node protection configurations. The RRO node ID subobject is defined in RFC 4561, *Definition of a Record Route Object (RRO) Node-Id Sub-Object*. This functionality is enabled by default in Junos OS Release 9.4 and later.

If you have Juniper Networks routers running Junos OS Release 9.4 and later releases in the same MPLS-TE network as routers running Junos OS Release 8.4 and earlier releases, you might need to disable the RRO node ID subobject by configuring the **no-node-id-subobject** statement:

**no-node-id-subobject;**

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

# Configuring RSVP Graceful Restart for High Availability

- [RSVP Graceful Restart on page 545](#)
- [RSVP Graceful Restart Standard on page 545](#)
- [RSVP Graceful Restart Terminology on page 546](#)
- [RSVP Graceful Restart Operation on page 546](#)
- [Processing the Restart Cap Object on page 547](#)
- [Configuring RSVP Graceful Restart on page 548](#)

## RSVP Graceful Restart

---

RSVP graceful restart allows a router undergoing a restart to inform its adjacent neighbors of its condition. The restarting router requests a grace period from the neighbor or peer, which can then cooperate with the restarting router. The restarting router can still forward MPLS traffic during the restart period; convergence in the network is not disrupted. The restart is not visible to the rest of the network, and the restarting router is not removed from the network topology. RSVP graceful restart can be enabled on both transit routers and ingress routers. It is available for both point-to-point LSPs and point-to-multipoint LSPs.

RSVP graceful restart is described in the following sections:

- [RSVP Graceful Restart Standard on page 545](#)
- [RSVP Graceful Restart Terminology on page 546](#)
- [RSVP Graceful Restart Operation on page 546](#)
- [Processing the Restart Cap Object on page 547](#)

## RSVP Graceful Restart Standard

---

RSVP graceful restart is described in RFC 3473, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Resource ReserVation Protocol-Traffic Engineering (RSVP-TE) Extensions* (only Section 9, “Fault Handling”).

## RSVP Graceful Restart Terminology

---

### R

|                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Recovery time<br/>(in milliseconds)</b> | <p>Applies only when the control channel is up (the hello exchange is complete) before the restart time. Applies only to nodal faults.</p> <p>When a graceful restart is in progress, the time left to complete a recovery is advertised. At other times, this value is zero. The maximum advertised recovery time is 2 minutes (120,000 milliseconds).</p> <p>During the recovery time, a restarting node attempts to recover its lost states with assistance from its neighbors. The neighbor of the restarting node must send the path messages with the recovery labels to the restarting node within a period of one-half the recovery time. The restarting node considers its graceful restart complete after its advertised recovery time.</p> |
| <b>Restart time<br/>(in milliseconds)</b>  | <p>The default value is 60,000 milliseconds (1 minute). The restart time is advertised in the hello message. The time indicates how long a neighbor should wait to receive a hello message from a restarting router before declaring that router dead and purging states.</p> <p>The Junos OS can override a neighbor's advertised restart time if the time is greater than one-third the local restart time. For example, given the default restart time of 60 seconds, a router would wait 20 seconds or less to receive a hello message from a restarting neighbor. If the restart time is zero, the restarting neighbor can immediately be declared dead.</p>                                                                                     |

## RSVP Graceful Restart Operation

---

For RSVP graceful restart to function, the feature must be enabled on the global routing instance. RSVP graceful restart can be disabled at the protocol level (for RSVP alone) or at the global level for all protocols.

RSVP graceful restart requires the following of a restarting router and the router's neighbors:

- For the restarting router, RSVP graceful restart attempts to maintain the routes installed by RSVP and the allocated labels, so that traffic continues to be forwarded without disruption. RSVP graceful restart is done quickly enough to reduce or eliminate the impact on neighboring nodes.
- The neighboring routers must have RSVP graceful restart helper mode enabled, thus allowing them to assist a router attempting to restart RSVP.

An object called Restart Cap that is sent in RSVP hello messages advertises a node's restart capability. The neighboring node sends a Recover Label object to the restarting node to recover its forwarding state. This object is essentially the old label that the restarting node advertised before the node went down.

The following lists the RSVP graceful restart behaviors, which vary depending on the configuration and on which features are enabled:

- If you disable helper mode, the Junos OS does not attempt to help a neighbor restart RSVP. Any information that arrives with a Restart Cap object from a neighbor is ignored.
- When you enable graceful restart under the routing instance configuration, the router can restart gracefully with the help of its neighbors. RSVP advertises a Restart Cap object (RSVP RESTART) in hello messages in which restart and recovery times are specified (neither value is 0).
- If you explicitly disable RSVP graceful restart under the **[protocols rsvp]** hierarchy level, the Restart Cap object is advertised with restart and recovery times specified as 0. The restart of neighboring routers is supported (unless helper mode is disabled), but the router itself does not preserve the RSVP forwarding state and cannot recover its control state.
- If after a restart RSVP realizes that no forwarding state has been preserved, the Restart Cap object is advertised with restart and recovery times specified as 0.
- If graceful restart and helper mode are disabled, RSVP graceful restart is completely disabled. The router neither recognizes nor advertises the RSVP graceful restart objects.

You cannot explicitly configure values for the restart and recovery times.

Unlike other protocols, there is no way for RSVP to determine that it has completed a restart procedure, other than a fixed timeout. All RSVP graceful restart procedures are timer-based. A **show rsdp version** command might indicate that the restart is still in progress even if all RSVP sessions are back up and the routes are restored.

---

## Processing the Restart Cap Object

The following assumptions are made about a neighbor based on the Restart Cap object (assuming that a control channel failure can be distinguished unambiguously from a node restart):

- A neighbor that does not advertise the Restart Cap object in its hello messages cannot assist a router with state or label recovery, nor can it perform an RSVP graceful restart.
- After a restart, a neighbor advertising a Restart Cap object with a restart time equal to any value and a recovery time equal to 0 has not preserved its forwarding state. When a recovery time equals 0, the neighbor is considered dead and any states related to this neighbor are purged, regardless of the value of the restart time.
- After a restart, a neighbor advertising its recovery time with a value other than 0 can keep or has kept the forwarding state. If the local router is helping its neighbor with restart or recovery procedures, it sends a Recover Label object to this neighbor.

## Configuring RSVP Graceful Restart

---

The following RSVP graceful restart configurations are possible:

- Graceful restart and helper mode are both enabled (the default).
- Graceful restart is enabled but helper mode is disabled. A router configured in this way can restart gracefully, but cannot help a neighbor with its restart and recovery procedures.
- Graceful restart is disabled but helper mode is enabled. A router configured in this way cannot restart gracefully, but can help a restarting neighbor.
- Graceful restart and helper mode both are disabled. This configuration completely disables RSVP graceful restart (including restart and recovery procedures and helper mode). The router behaves like a router that does not support RSVP graceful restart.

**NOTE:** In order to turn on RSVP graceful restart, you must set the global graceful restart timer to at least 180 seconds.

The following sections describe how to configure RSVP graceful restart:

- [Enabling Graceful Restart for All Routing Protocols on page 548](#)
- [Disabling Graceful Restart for RSVP on page 548](#)
- [Disabling RSVP Helper Mode on page 549](#)
- [Configuring the Maximum Helper Recovery Time on page 549](#)
- [Configuring the Maximum Helper Restart Time on page 549](#)

### Enabling Graceful Restart for All Routing Protocols

To enable graceful restart for RSVP, you need to enable graceful restart for all the protocols that support graceful restart on the router. For more information about graceful restart, see the *Junos OS Routing Protocols Library*.

To enable graceful restart on the router, include the **graceful-restart** statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-options]**
- **[edit logical-systems *logical-system-name* routing-options]**

### Disabling Graceful Restart for RSVP

By default, RSVP graceful restart and RSVP helper mode are enabled when you enable graceful restart. However, you can disable one or both of these capabilities.

To disable RSVP graceful restart and recovery, include the **disable** statement at the **[edit protocols rsvp graceful-restart]** hierarchy level:

```
disable;
```

## Disabling RSVP Helper Mode

To disable RSVP helper mode, include the **helper-disable** statement at the **[edit protocols rsvp graceful-restart]** hierarchy level:

```
helper-disable;
```

## Configuring the Maximum Helper Recovery Time

To configure the amount of time the router retains the state of its RSVP neighbors while they undergo a graceful restart, include the **maximum-helper-recovery-time** statement at the **[edit protocols rsvp graceful-restart]** hierarchy level. This value is applied to all neighboring routers, so it should be based on the time required by the slowest RSVP neighbor to recover.

```
maximum-helper-recovery-time seconds;
```

## Configuring the Maximum Helper Restart Time

To configure the delay between when the router discovers that a neighboring router has gone down and when it declares the neighbor down, include the **maximum-helper-restart-time** statement at the **[edit protocols rsvp graceful-restart]** hierarchy level. This value is applied to all neighboring routers, so it should be based on the time required by the slowest RSVP neighbor to restart.

```
maximum-helper-restart-time seconds;
```

# Configuring RSVP LSP Tunnels

- [RSVP LSP Tunnels Overview on page 551](#)
- [Example: RSVP LSP Tunnel Configuration on page 553](#)
- [Configuring Link Management Protocol Peers on page 571](#)
- [Configuring Link Management Protocol Traffic Engineering Links on page 571](#)
- [Configuring Peer Interfaces in OSPF and RSVP on page 572](#)
- [Defining Label-Switched Paths for the FA-LSP on page 572](#)
- [Establishing FA-LSP Path Information on page 573](#)
- [Option: Tearing Down RSVP LSPs Gracefully on page 573](#)

## RSVP LSP Tunnels Overview

---

A Resource Reservation Protocol (RSVP) label-switched path (LSP) tunnel enables you to send RSVP LSPs inside other RSVP LSPs. This enables a network administrator to provide traffic engineering from one end of the network to the other. A useful application for this feature is to connect customer edge (CE) routers with provider edge (PE) routers by using an RSVP LSP, and then tunnel this edge LSP inside a second RSVP LSP traveling across the network core.

You should have a general understanding of MPLS and label switching concepts. For more information about MPLS, see the *Junos MPLS Applications Configuration Guide*.

An RSVP LSP tunnel adds the concept of a forwarding adjacency, similar to the one used for generalized Multiprotocol Label Switching (GMPLS). (For more information about GMPLS, see *Junos GMPLS Feature Guide*.)

The forwarding adjacency creates a tunneled path for sending data between peer devices in an RSVP LSP network. Once a forwarding adjacency LSP (FA-LSP) has been established, other LSPs can be sent over the FA-LSP by using Constrained Shortest Path First (CSPF), Link Management Protocol (LMP), Open Shortest Path First (OSPF), and RSVP.

To enable an RSVP LSP tunnel, the Junos OS uses the following mechanisms:

- LMP—Originally designed for GMPLS, LMP establishes forwarding adjacencies between RSVP LSP tunnel peers, and maintains and allocates resources for traffic engineering links.

- OSPF extensions—OSPF was designed to route packets to physical and logical interfaces related to a Physical Interface Card (PIC). This protocol has been extended to route packets to virtual peer interfaces defined in an LMP configuration.
- RSVP-TE extensions—RSVP-TE was designed to signal the setup of packet LSPs to physical interfaces. The protocol has been extended to request path setup for packet LSPs traveling to virtual peer interfaces defined in an LMP configuration.

**NOTE:** Beginning with Junos OS Release 15.1, multi-instance support is extended to MPLS RSVP-TE. This support is available only for virtual router instance type. A router can create and participate in multiple independent TE topology partitions, which allows each partitioned TE domain to scale independently. Multi-instance RSVP-TE provides the flexibility to hand pick the control-plane entities that need to be instance-aware, for example, a router can participate in multiple TE instances while still running a single BGP instance.

The Junos OS implementation of MPLS RSVP-TE is scaled to enhance the usability, visibility, configuration, and troubleshooting of LSPs in Junos OS Release 16.1.

These enhancements make the RSVP-TE configuration easier at scale by:

- Ensuring the LSP data-plane readiness during LSP resignaling before traffic traverses the LSP with the RSVP-TE LSP self-ping mechanism.

An LSP should not start to carry traffic unless it is known to have been programmed in the data plane. Data exchange in the LSP data plane, such as LSP ping requests, happens at the ingress router before switching traffic to an LSP, or to its MBB instance. In large networks, this traffic can overwhelm an LSP egress router, as the egress LSP needs to respond to the LSP ping requests. The LSP self-ping mechanism enables the ingress LER to create LSP ping response messages and send them over the LSP data plane. On receiving these messages, the egress LER forwards them to the ingress, indicating the liveliness of the LSP data plane. This ensures that the LSP does not start to carry traffic before the data plane has been programmed.

- Removing the current hard limit of 64K LSPs on an ingress router and scaling the total number of LSPs with RSVP-TE signaled LSPs. There can be up to 64K LSPs configured on a per-egress basis. Earlier, this limit was the aggregate number of LSPs that could be configured on the ingress LER.
- Preventing abrupt tearing down of LSPs by the ingress router because of delay in signaling the LSP at the transit routers.
- Enabling a flexible view of LSP data-sets to facilitate LSP characteristic data visualization.

The following limitations exist for LSP hierarchies:

- Circuit cross-connect (CCC)-based LSPs are not supported.
- Graceful restart is not supported.

- Link protection is not available for FA-LSPs or at the egress point of the forwarding adjacency.
- Point-to-multipoint LSPs are not supported across FA-LSPs.

## Example: RSVP LSP Tunnel Configuration

**Figure 50: RSVP LSP Tunnel Topology Diagram**

Figure 50 on page 553 shows an end-to-end RSVP LSP called **e2e\_lsp\_r0r5** that originates on Router 0 and terminates on Router 5. In transit, this LSP traverses the FA-LSP **fa\_lsp\_r1r4**. The return path is represented by the end-to-end RSVP LSP **e2e\_lsp\_r5r0** that travels over the FA-LSP **fa\_lsp\_r4r1**.

On Router 0, configure the end-to-end RSVP LSP that travels to Router 5. Use a strict path that traverses Router 1 and the LMP traffic engineering link traveling from Router 1 to Router 4.

```

}

```

On Router 1, configure an FA-LSP to reach Router 4. Establish an LMP traffic engineering link and LMP peer relationship with Router 4. Reference the FA-LSP in the traffic engineering link and add the peer interface into both OSPF and RSVP.

When the return path end-to-end LSP arrives at Router 1, the routing platform performs a routing lookup and can forward traffic to Router 0. Make sure you configure OSPF correctly between Routers 0 and 1.

```

## Verifying Your Work

To verify that your RSVP LSP tunnel is working correctly, issue the following commands:

- **show ted database (extensive)**
- **show rsvp session name (extensive)**
- **show link-management**
- **show link-management te-link name (detail)**

To see these commands used with the configuration example, see the following sections:

- [Router 0 on page 565](#)
- [Router 1 on page 569](#)

### Router 0

On Router 0, you can verify that the FA-LSPs appear as valid paths in the traffic engineering database. In this case, look for the paths from Router 1 (**10.255.41.216**) and Router 4 (**10.255.41.217**) that reference the LMP traffic engineering link addresses of **172.16.30.1** and **172.16.30.2**. You can also issue the **show rsvp session extensive** command to look for the path of the end-to-end LSP as it travels to Router 5 over the FA-LSP.

```

### Router 1

On Router 1, verify that your LMP traffic engineering link configuration is working and that the end-to-end LSP is traversing the traffic engineering link by issuing the **show**

**link-management** set of commands. You can also issue the **show rsvp session extensive** command to confirm that the FA-LSP is operational.

```
user@router1> show link-management
```

```
Peer name: r4 , System identifier: 10758
```

```

## Configuring Link Management Protocol Peers

After you set up traffic engineering links, configure LMP network peers with the **peer** *peer-name* statement at the **[edit protocols link-management]** hierarchy level. A peer is the network device with which your routing platform communicates and establishes an FA-LSP. Designate a peer name, configure the peer router ID as the address (often a loopback address), and apply the traffic engineering link to be associated with this peer. Remember to configure both sides of a peering relationship to enable bidirectional communication.

Unlike GMPLS, you must not configure a control channel for a peer. If you include a control channel, the commit operation fails.

```
[edit]
protocols {
  link-management {
    peer peer-name { # Configure the name of your network peer.
      address ip-address; # Include the router ID of the peer.
      te-link te-link-name; # Assign a TE link to this peer.
    }
  }
}
```

- Related Documentation**
- [Example: RSVP LSP Tunnel Configuration on page 553](#)

## Configuring Link Management Protocol Traffic Engineering Links

To begin your RSVP LSP tunnel configuration, configure LMP traffic engineering links on both the ingress and egress routing platforms. Because traffic engineering links define a unidirectional connection between peer devices, you must configure traffic engineering links in both directions between peers to enable the bidirectional transport of packets.

To configure traffic engineering links in LMP, include the **te-link** *te-link-name* statement at the **[edit protocols link-management]** hierarchy level. Define the traffic engineering link options shown below, especially the label-switched path to be used as the FA-LSP to reach the peer. Optionally, you can specify the traffic engineering metric for the traffic engineering link (TE link). By default, the traffic engineering metric is derived from the CSPF computation.

```
[edit]
protocols {
  link-management {
    te-link te-link-name { # Name of the TE link.
      label-switched-path lsp-name; # LSP used for the forwarding adjacency.
      local-address ip-address; # Local IP address associated with the TE link.
      remote-address ip-address; # Remote IP address mapped to the TE link.
      te-metric value; # Traffic engineering metric used for the TE link.
    }
  }
}
```

**Related Documentation** • [Example: RSVP LSP Tunnel Configuration on page 553](#)

## Configuring Peer Interfaces in OSPF and RSVP

After you establish LMP peers, you must add peer interfaces to OSPF and RSVP. A peer interface is a virtual interface used to support the control adjacency between two peers.

The peer interface name must match the **peer *peer-name*** statement configured in LMP at the **[edit protocols link-management]** hierarchy level. Because actual protocol packets are sent and received by peer interfaces, the peer interfaces can be signaled and advertised to peers like any other physical interface configured for OSPF and RSVP. To configure OSPF routing for LMP peers, include the **peer-interface** statement at the **[edit protocols ospf area *area-number*]** hierarchy level. To configure RSVP signaling for LMP peers, include the **peer-interface** statement at the **[edit protocols rsvp]** hierarchy level.

```
[edit]
protocols {
  rsvp {
    peer-interface peer-name { # Configure the name of your LMP peer.
    }
  }
  ospf {
    area area-number {
      peer-interface peer-name { # Configure the name of your LMP peer.
      }
    }
  }
}
```

**Related Documentation** • [Example: RSVP LSP Tunnel Configuration on page 553](#)

## Defining Label-Switched Paths for the FA-LSP

Next, define your FA-LSP by including the **label-switched-path** statement at the **[edit protocols mpls]** hierarchy level. Include the router ID of the peer in the **to** statement at the **[edit protocols mpls label-switched-path]** hierarchy level. Because packet LSPs are unidirectional, you must create one FA-LSP to reach the peer and a second FA-LSP to return from the peer.

```
[edit]
protocols {
  mpls {
    label-switched-path lsp-name {
      from ip-address;
      to ip-address;
      primary path-name;
      secondary path-name;
      no-cspf; # This statement to disable CSPF is optional.
    }
  }
}
```

**Related Documentation** • [Example: RSVP LSP Tunnel Configuration on page 553](#)

## Establishing FA-LSP Path Information

When you configure explicit LSP paths for an FA-LSP, you must use the traffic engineering link remote address as your next-hop address. When CSPF is supported, you can use any path option you wish. However, when CSPF is disabled with the **no-cspf** statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level, you must use strict paths.

```
[edit]
protocols {
  mpls {
    path path-name {
      next-hop-address (strict | loose);
    }
  }
}
```

**NOTE:** If the end-to-end LSP originates on the same routing platform as the FA-LSP, you must disable CSPF and use strict paths.

**Related Documentation** • [Example: RSVP LSP Tunnel Configuration on page 553](#)

## Option: Tearing Down RSVP LSPs Gracefully

You can tear down an RSVP LSP in a two-step process that gracefully withdraws the RSVP session used by the LSP. For all neighbors that support graceful teardown, a request for the teardown is sent by the routing platform to the destination endpoint for the LSP and all RSVP neighbors in the path. The request is included within the **ADMIN\_STATUS** field of the RSVP packet. When neighbors receive the request, they prepare for the RSVP session to be withdrawn. A second message is sent by the routing platform to complete the teardown of the RSVP session. If a neighbor does not support graceful teardown, the request is handled as a standard session teardown rather than a graceful one.

To perform a graceful teardown of an RSVP session, issue the **clear rsvp session gracefully** command. Optionally, you can specify the source and destination address of the RSVP session, the LSP identifier of the RSVP sender, and the tunnel identifier of the RSVP session. To use these qualifiers, include the **connection-source**, **connection-destination**, **lsp-id**, and **tunnel-id** options when you issue the **clear rsvp session gracefully** command.

You can also configure the amount of time that the routing platform waits for neighbors to receive the graceful teardown request before initiating the actual teardown by including the **graceful-deletion-timeout** statement at the **[edit protocols rsvp]** hierarchy level. The default graceful deletion timeout value is 30 seconds, with a minimum value of 1 second and a maximum value of 300 seconds. To view the current value configured for graceful deletion timeout, issue the **show rsvp version** operational mode command.

## LDP Introduction

---

The Label Distribution Protocol (LDP) is a protocol for distributing labels in non-traffic-engineered applications. LDP allows routers to establish label-switched paths (LSPs) through a network by mapping network-layer routing information directly to data link layer-switched paths.

These LSPs might have an endpoint at a directly attached neighbor (comparable to IP hop-by-hop forwarding), or at a network egress node, enabling switching through all intermediary nodes. LSPs established by LDP can also traverse traffic-engineered LSPs created by RSVP.

LDP associates a forwarding equivalence class (FEC) with each LSP it creates. The FEC associated with an LSP specifies which packets are mapped to that LSP. LSPs are extended through a network as each router chooses the label advertised by the next hop for the FEC and splices it to the label it advertises to all other routers. This process forms a tree of LSPs that converge on the egress router.

## Supported LDP Standards

---

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for LDP.

- RFC 3212, *Constraint-Based LSP Setup using LDP*
- RFC 3478, *Graceful Restart Mechanism for Label Distribution Protocol*
- Internet draft draft-napierala-mpls-targeted-mldp-01.txt, *Using LDP Multipoint Extensions on Targeted LDP Sessions*

The following RFCs do not define standards, but provide information about LDP. The IETF classifies them as “Informational.”

- RFC 3215, *LDP State Machine*
- RFC 5036, *LDP Specification*

For the following features described in the indicated sections of the RFC, Junos OS supports one of the possible modes but not the others:

- Label distribution control (section 2.6.1): Ordered mode is supported, but not Independent mode.
- Label retention (section 2.6.2): Liberal mode is supported, but not Conservative mode.
- Label advertisement (section 2.6.3): Both Downstream Unsolicited mode and Downstream on Demand mode are supported.
- RFC 5443, *LDP IGP Synchronization*
- RFC 6826, *Multipoint LDP In-Band Signaling for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*

Junos OS support limited to point-to-multipoint extensions for LDP.

## Junos OS LDP Protocol Implementation

---

The Junos OS implementation of LDP supports LDP version 1. The Junos OS supports a simple mechanism for tunneling between routers in an interior gateway protocol (IGP), to eliminate the required distribution of external routes within the core. The Junos OS allows an MPLS tunnel next hop to all egress routers in the network, with only an IGP running in the core to distribute routes to egress routers. Edge routers run BGP but do not distribute external routes to the core. Instead, the recursive route lookup at the edge

resolves to an LSP switched to the egress router. No external routes are necessary on the transit LDP routers.

## LDP Operation

You must configure LDP for each interface on which you want LDP to run. LDP creates LSP trees rooted at each egress router for the router ID address that is the subsequent BGP next hop. The ingress point is at every router running LDP. This process provides an inet.3 route to every egress router. If BGP is running, it will attempt to resolve next hops by using the inet.3 table first, which binds most, if not all, of the BGP routes to MPLS tunnel next hops.

Two adjacent routers running LDP become neighbors. If the two routers are connected by more than one interface, they become neighbors on each interface. When LDP routers become neighbors, they establish an LDP session to exchange label information. If per-router labels are in use on both routers, only one LDP session is established between them, even if they are neighbors on multiple interfaces. For this reason, an LDP session is not related to a particular interface.

LDP operates in conjunction with a unicast routing protocol. LDP installs LSPs only when both LDP and the routing protocol are enabled. For this reason, you must enable both LDP and the routing protocol on the same set of interfaces. If this is not done, LSPs might not be established between each egress router and all ingress routers, which might result in loss of BGP-routed traffic.

You can apply policy filters to labels received from and distributed to other routers through LDP. Policy filters provide you with a mechanism to control the establishment of LSPs.

For LDP to run on an interface, MPLS must be enabled on a logical interface on that interface. For more information, see the *Logical Interfaces*.

- [Logical Interfaces](#)

## LDP Message Types

LDP uses the message types described in the following sections to establish and remove mappings and to report errors. All LDP messages have a common structure that uses a type, length, and value (TLV) encoding scheme.

- [Discovery Messages on page 579](#)
- [Session Messages on page 580](#)
- [Advertisement Messages on page 580](#)
- [Notification Messages on page 580](#)

### Discovery Messages

Discovery messages announce and maintain the presence of a router in a network. Routers indicate their presence in a network by sending hello messages periodically. Hello

messages are transmitted as UDP packets to the LDP port at the group multicast address for all routers on the subnet.

LDP uses the following discovery procedures:

- Basic discovery—A router periodically sends LDP link hello messages through an interface. LDP link hello messages are sent as UDP packets addressed to the LDP discovery port. Receipt of an LDP link hello message on an interface identifies an adjacency with the LDP peer router.
- Extended discovery—LDP sessions between routers not directly connected are supported by LDP extended discovery. A router periodically sends LDP targeted hello messages to a specific address. Targeted hello messages are sent as UDP packets addressed to the LDP discovery port at the specific address. The targeted router decides whether to respond to or ignore the targeted hello message. A targeted router that chooses to respond does so by periodically sending targeted hello messages to the initiating router.

## Session Messages

Session messages establish, maintain, and terminate sessions between LDP peers. When a router establishes a session with another router learned through the hello message, it uses the LDP initialization procedure over TCP transport. When the initialization procedure is completed successfully, the two routers are LDP peers and can exchange advertisement messages.

## Advertisement Messages

Advertisement messages create, change, and delete label mappings for forwarding equivalence classes (FECs). Requesting a label or advertising a label mapping to a peer is a decision made by the local router. In general, the router requests a label mapping from a neighboring router when it needs one and advertises a label mapping to a neighboring router when it wants the neighbor to use a label.

## Notification Messages

Notification messages provide advisory information and signal error information. LDP sends notification messages to report errors and other events of interest. There are two kinds of LDP notification messages:

- Error notifications, which signal fatal errors. If a router receives an error notification from a peer for an LDP session, it terminates the LDP session by closing the TCP transport connection for the session and discarding all label mappings learned through the session.
- Advisory notifications, which pass information to a router about the LDP session or the status of some previous message received from the peer.

## Discovery Messages

---

Discovery messages announce and maintain the presence of a router in a network. Routers indicate their presence in a network by sending hello messages periodically. Hello

messages are transmitted as UDP packets to the LDP port at the group multicast address for all routers on the subnet.

LDP uses the following discovery procedures:

- Basic discovery—A router periodically sends LDP link hello messages through an interface. LDP link hello messages are sent as UDP packets addressed to the LDP discovery port. Receipt of an LDP link hello message on an interface identifies an adjacency with the LDP peer router.
- Extended discovery—LDP sessions between routers not directly connected are supported by LDP extended discovery. A router periodically sends LDP targeted hello messages to a specific address. Targeted hello messages are sent as UDP packets addressed to the LDP discovery port at the specific address. The targeted router decides whether to respond to or ignore the targeted hello message. A targeted router that chooses to respond does so by periodically sending targeted hello messages to the initiating router.

---

## Session Messages

Session messages establish, maintain, and terminate sessions between LDP peers. When a router establishes a session with another router learned through the hello message, it uses the LDP initialization procedure over TCP transport. When the initialization procedure is completed successfully, the two routers are LDP peers and can exchange advertisement messages.

---

## Advertisement Messages

Advertisement messages create, change, and delete label mappings for forwarding equivalence classes (FECs). Requesting a label or advertising a label mapping to a peer is a decision made by the local router. In general, the router requests a label mapping from a neighboring router when it needs one and advertises a label mapping to a neighboring router when it wants the neighbor to use a label.

---

## Notification Messages

Notification messages provide advisory information and signal error information. LDP sends notification messages to report errors and other events of interest. There are two kinds of LDP notification messages:

- Error notifications, which signal fatal errors. If a router receives an error notification from a peer for an LDP session, it terminates the LDP session by closing the TCP transport connection for the session and discarding all label mappings learned through the session.
- Advisory notifications, which pass information to a router about the LDP session or the status of some previous message received from the peer.

## Tunneling LDP LSPs in RSVP LSPs

You can tunnel LDP LSPs over RSVP LSPs. The following sections describe how tunneling of LDP LSPs in RSVP LSPs works:

- [Tunneling LDP LSPs in RSVP LSPs Overview on page 582](#)
- [Label Operations on page 583](#)

## Tunneling LDP LSPs in RSVP LSPs Overview

If you are using RSVP for traffic engineering, you can run LDP simultaneously to eliminate the distribution of external routes in the core. The LSPs established by LDP are tunneled through the LSPs established by RSVP. LDP effectively treats the traffic-engineered LSPs as single hops.

When you configure the router to run LDP across RSVP-established LSPs, LDP automatically establishes sessions with the router at the other end of the LSP. LDP control packets are routed hop-by-hop, rather than carried through the LSP. This routing allows you to use simplex (one-way) traffic-engineered LSPs. Traffic in the opposite direction flows through LDP-established LSPs that follow unicast routing rather than through traffic-engineered tunnels.

If you configure LDP over RSVP LSPs, you can still configure multiple OSPF areas and IS-IS levels in the traffic engineered core and in the surrounding LDP cloud.

**NOTE:** Beginning with Junos OS Release 15.1, multi-instance support is extended to LDP over RSVP tunneling for a virtual router routing instance. This allows splitting of a single routing and MPLS domain into multiple domains so that each domain can be scaled independently. BGP labeled unicast can be used to stitch these domains for service FECs. Each domain uses intra-domain LDP over RSVP LSP for MPLS forwarding.

Release History Table

| Release | Description                                                                                                                                |

- [Configuring a Hierarchy of RSVP LSPs to Tunnel Multiple RSVP LSPs Over a Single RSVP LSP on page 820](#)

## Label Operations

Figure 51 on page 583 depicts an LDP LSP being tunneled through an RSVP LSP. (For definitions of label operations, see “MPLS Label Overview” on page 24.) The shaded inner oval represents the RSVP domain, whereas the outer oval depicts the LDP domain. RSVP establishes an LSP through routers B, C, D, and E, with the sequence of labels L3, L4. LDP establishes an LSP through Routers A, B, E, F, and G, with the sequence of labels L1, L2, L5. LDP views the RSVP LSP between Routers B and E as a single hop.

When the packet arrives at Router A, it enters the LSP established by LDP, and a label (L1) is pushed onto the packet. When the packet arrives at Router B, the label (L1) is swapped with another label (L2). Because the packet is entering the traffic-engineered LSP established by RSVP, a second label (L3) is pushed onto the packet.

This outer label (L3) is swapped with a new label (L4) at the intermediate router (C) within the RSVP LSP tunnel, and when the penultimate router (D) is reached, the top label is popped. Router E swaps the label (L2) with a new label (L5), and the penultimate router for the LDP-established LSP (F) pops the last label.

Figure 51: Swap and Push When LDP LSPs Are Tunneled Through RSVP LSPs

Figure 52 on page 584 depicts a double push label operation (L1L2). A double push label operation is used when the ingress router (A) for both the LDP LSP and the RSVP LSP tunneled through it is the same device. Note that Router D is the penultimate hop for the LDP-established LSP, so L2 is popped from the packet by Router D.

Figure 52: Double Push When LDP LSPs Are Tunneled Through RSVP LSPs

## LDP Session Protection

LDP session protection is based on the LDP targeted hello functionality defined in RFC 5036, *LDP Specification*, and is supported by the Junos OS as well as the LDP implementations of most other vendors. It involves sending unicast User Datagram Protocol (UDP) hello packets to a remote neighbor address and receiving similar packets from the neighbor router.

If you configure LDP session protection on a router, the LDP sessions are maintained as follows:

1. An LDP session is established between a router and a remote neighboring router.
2. If all of the direct links between the routers go down, the LDP session remains up so long as there is IP connectivity between the routers based on another connection over the network.
3. When the direct link between the routers is reestablished, the LDP session is not restarted. The routers simply exchange LDP hellos with each other over the direct link. They can then begin forwarding LDP-signaled MPLS packets using the original LDP session.

By default, LDP targeted hellos are set to the remote neighbor so long as the LDP session is up, even if there are no more link neighbors to that router. You can also specify the duration you would like to maintain the remote neighbor connection in the absence of link neighbors. When the last link neighbor for a session goes down, the Junos OS starts an LDP session protection timer. If this timer expires before any of the link neighbors come back up, the remote neighbor connection is taken down and the LDP session is terminated. If you configure a different value for the timer while it is currently running, the Junos OS updates the timer to the specified value without disrupting the current state of the LDP session.

---

## LDP Native IPv6 Support Overview

---

IPv6 connectivity often relies on tunneling IPv6 over an IPv4 MPLS core with IPv4-signaled MPLS label-switched paths (LSPs). This requires the IPv4-signaled LSPs to be configured statically or established dynamically by IPv6 provider edge routers. Because of the growing demand of IPv6, it has become imperative to deploy an IPv6 MPLS core with an IPv6-signaled LSP to provide IPv6 connectivity. In Junos OS, LDP is supported in an IPv6 network only, and in an IPv6/IPv4 dual-stack network as described in *RFC 7552*. Apart from providing a single session for both IPv4 and IPv6 networks, Junos OS LDP supports separate IPv4 sessions for IPv4 only, and IPv6 sessions for IPv6 only.

You can configure the address family as **inet** for IPv4 or **inet6** for IPv6, or both. If the family address is not configured, then the default address of family inet is enabled. When both IPv4 and IPv6 are configured, you can use the **transport-preference** statement to configure the preferred transport to be either **IPv4** or **IPv6**. Based on the preference, LDP attempts to establish a TCP connection using IPv4 or IPv6. By default, IPv6 is selected. The **dual-transport** statement allows Junos OS LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. The **inet-lsr-id** and **inet6-lsr-id** IDs are the two LSR IDs that have to be configured to establish an LDP session over IPv4 and IPv6 TCP transport. These two IDs should be non-zero and must be configured with different values.

---

## Longest Match Support for LDP Overview

---

LDP is often used to establish MPLS label-switched paths (LSPs) throughout a complete network domain using an IGP such as OSPF or IS-IS. In such a network, all links in the domain have IGP adjacencies as well as LDP adjacencies. LDP establishes the LSPs on the shortest path to a destination as determined by IGP. In Junos OS, the LDP implementation does an exact match lookup on the IP address of the forwarding equivalence class (FEC) in the routing information base (RIB) or IGP routes for label mapping. This exact mapping requires MPLS end-to-end LDP endpoint IP addresses to be configured in all the label edge routers (LERs). This defeats the purpose of IP hierarchical design or default routing in access devices. Configuring **longest-match** allows LDP to set up LSP based on the routes aggregated or summarized across OSPF areas or IS-IS levels in the inter-domain.

## Minimum LDP Configuration

To enable LDP on a single interface, include the **ldp** statement and specify the interface using the **interface** statement. This is the minimum LDP configuration. All other LDP configuration statements are optional.

```
ldp {  
  interface interface-name;  
}
```

To enable LDP on all interfaces, specify **all** for *interface-name*.

For a list of hierarchy levels at which you can include these statements, see the statement summary sections.

---

## Enabling and Disabling LDP

LDP is routing-instance-aware. To enable LDP on a specific interface, include the following statements:

```
ldp {  
  interface interface-name;  
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections.

To enable LDP on all interfaces, specify **all** for *interface-name*.

If you have configured interface properties on a group of interfaces and want to disable LDP on one of the interfaces, include the **interface** statement with the **disable** option:

```
interface interface-name {  
  disable;  
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

## Configuring the LDP Timer for Hello Messages

LDP hello messages enable LDP nodes to discover one another and to detect the failure of a neighbor or the link to the neighbor. Hello messages are sent periodically on all interfaces where LDP is enabled.

There are two types of LDP hello messages:

- Link hello messages—Sent through the LDP interface as UDP packets addressed to the LDP discovery port. Receipt of an LDP link hello message on an interface identifies an adjacency with the LDP peer router.
- Targeted hello messages—Sent as UDP packets addressed to the LDP discovery port at a specific address. Targeted hello messages are used to support LDP sessions between routers that are not directly connected. A targeted router determines whether to respond or ignore a targeted hello message. A targeted router that chooses to respond does so by periodically sending targeted hello messages back to the initiating router.

By default, LDP sends hello messages every 5 seconds for link hello messages and every 15 seconds for targeted hello messages. You can configure the LDP timer to alter how often both types of hello messages are sent. However, you cannot configure a time for the LDP timer that is greater than the LDP hold time. For more information, see [“Configuring the Delay Before LDP Neighbors Are Considered Down”](#) on page 589.

### Configuring the LDP Timer for Link Hello Messages

To modify how often LDP sends link hello messages, specify a new link hello message interval for the LDP timer using the **hello-interval** statement:

```
hello-interval seconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

### Configuring the LDP Timer for Targeted Hello Messages

To modify how often LDP sends targeted hello messages, specify a new targeted hello message interval for the LDP timer by configuring the **hello-interval** statement as an option for the **targeted-hello** statement:

```
targeted-hello {
  hello-interval seconds;
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections for these statements.

## Configuring the Delay Before LDP Neighbors Are Considered Down

The hold time determines how long an LDP node should wait for a hello message before declaring a neighbor to be down. This value is sent as part of a hello message so that

each LDP node tells its neighbors how long to wait. The values sent by each neighbor do not have to match.

The hold time should normally be at least three times the hello interval. The default is 15 seconds for link hello messages and 45 seconds for targeted hello messages. However, it is possible to configure an LDP hold time that is close to the value for the hello interval.

**NOTE:** By configuring an LDP hold time close to the hello interval (less than three times the hello interval), LDP neighbor failures might be detected more quickly. However, this also increases the possibility that the router might declare an LDP neighbor down that is still functioning normally. For more information, see [“Configuring the LDP Timer for Hello Messages” on page 589](#).

The LDP hold time is also negotiated automatically between LDP peers. When two LDP peers advertise different LDP hold times to one another, the smaller value is used. If an LDP peer router advertises a shorter hold time than the value you have configured, the peer router’s advertised hold time is used. This negotiation can affect the LDP keepalive interval as well.

If the local LDP hold time is not shortened during LDP peer negotiation, the user-configured keepalive interval is left unchanged. However, if the local hold time is reduced during peer negotiation, the keepalive interval is recalculated. If the LDP hold time has been reduced during peer negotiation, the keepalive interval is reduced to one-third of the new hold time value. For example, if the new hold-time value is 45 seconds, the keepalive interval is set to 15 seconds.

This automated keepalive interval calculation can cause different keepalive intervals to be configured on each peer router. This enables the routers to be flexible in how often they send keepalive messages, because the LDP peer negotiation ensures they are sent more frequently than the LDP hold time.

When you reconfigure the hold-time interval, changes do not take effect until after the session is reset. The hold time is negotiated when the LDP peering session is initiated and cannot be renegotiated as long as the session is up (required by RFC 5036, *LDP Specification*). To manually force the LDP session to reset, issue the **clear ldp session** command.

## Configuring the LDP Hold Time for Link Hello Messages

To modify how long an LDP node should wait for a link hello message before declaring the neighbor down, specify a new time in seconds using the **hold-time** statement:

**hold-time** *seconds*;

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring the LDP Hold Time for Targeted Hello Messages

To modify how long an LDP node should wait for a targeted hello message before declaring the neighbor down, specify a new time in seconds using the **hold-time** statement as an option for the **targeted-hello** statement:

```
targeted-hello {  
  hold-time seconds;  
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary sections for these statements.

---

## Enabling Strict Targeted Hello Messages for LDP

Use strict targeted hello messages to prevent LDP sessions from being established with remote neighbors that have not been specifically configured. If you configure the **strict-targeted-hellos** statement, an LDP peer does not respond to targeted hello messages coming from a source that is not one of its configured remote neighbors. Configured remote neighbors can include:

- Endpoints of RSVP tunnels for which LDP tunneling is configured
- Layer 2 circuit neighbors

If an unconfigured neighbor sends a hello message, the LDP peer ignores the message and logs an error (with the **error** trace flag) indicating the source. For example, if the LDP peer received a targeted hello from the Internet address 10.0.0.1 and no neighbor with this address is specifically configured, the following message is printed to the LDP log file:

```
LDP: Ignoring targeted hello from 10.0.0.1
```

To enable strict targeted hello messages, include the **strict-targeted-hellos** statement:

```
strict-targeted-hellos;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

---

## Configuring the Interval for LDP Keepalive Messages

The keepalive interval determines how often a message is sent over the session to ensure that the keepalive timeout is not exceeded. If no other LDP traffic is sent over the session in this much time, a keepalive message is sent. The default is 10 seconds. The minimum value is 1 second.

The value configured for the keepalive interval can be altered during LDP session negotiation if the value configured for the LDP hold time on the peer router is lower than the value configured locally. For more information, see [“Configuring the Delay Before LDP Neighbors Are Considered Down” on page 589](#).

To modify the keepalive interval, include the **keepalive-interval** statement:

**keepalive-interval** *seconds*;

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

---

## Configuring the LDP Keepalive Timeout

After an LDP session is established, messages must be exchanged periodically to ensure that the session is still working. The keepalive timeout defines the amount of time that the neighbor LDP node waits before deciding that the session has failed. This value is usually set to at least three times the keepalive interval. The default is 30 seconds.

To modify the keepalive interval, include the **keepalive-timeout** statement:

**keepalive-timeout** *seconds*;

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The value configured for the **keepalive-timeout** statement is displayed as the hold time when you issue the **show ldp session detail** command.

---

## Configuring Longest Match for LDP

In order to allow LDP to learn the routes aggregated or summarized across OSPF areas or ISIS levels in inter-domain, Junos OS allows you to configure longest match for LDP based on *RFC5283*.

Before you configure longest match for LDP, you must do the following:

1. Configure the device interfaces.
2. Configure the MPLS protocol.
3. Configure the OSPF protocol.

To configure longest match for LDP, you must do the following:

1. Configure longest match for the LDP protocol.

```
[edit protocols ldp]
user@host# set longest-match
```

2. Configure the LDP protocol on the interface.

```
[edit protocols ldp]
user@host# set interface interface-name
```

For example, to configure the interfaces:

```
[edit protocols ldp]
user@host# set interface ge-0/0/2.0
user@host# set interface lo0.0
```

### Related Documentation

- [Example: Configuring Longest Match for LDP on page 593](#)
- [Longest Match Support for LDP Overview on page 585](#)

- [longest-match on page 1460](#)

## Example: Configuring Longest Match for LDP

---

This example shows how to configure longest match for LDP based on *RFC5283*. This allows LDP to learn the routes aggregated or summarized across OSPF areas or ISIS levels in inter-domain.. The longest match policy provides per prefix granularity.

- [Requirements on page 593](#)
- [Overview on page 593](#)
- [Configuration on page 594](#)
- [Verification on page 598](#)

### Requirements

This example uses the following hardware and software components:

- Six MX Series routers with OSPF protocol, and LDP enabled on the connected interfaces.
- Junos OS Release 16.1 or later running on all devices.

Before you begin:

- Configure the device interfaces.
- Configure OSPF.

### Overview

LDP is often used to establish MPLS label-switched paths (LSPs) throughout a complete network domain using an IGP such as OSPF or IS-IS. In such a network, all links in the domain have IGP adjacencies as well as LDP adjacencies. LDP establishes the LSPs on the shortest path to a destination as determined by IP forwarding. In Junos OS, the LDP implementation does an exact match lookup on the IP address of the FEC in the RIB or IGP routes for label mapping. This exact mapping requires MPLS end-to-end LDP endpoint IP addresses to be configured in all the LERs. This defeats the purpose of IP hierarchical design or default routing in access devices. Configuring **longest-match** helps to overcome this by suppressing the exact match behaviour and setup LSP based on the longest matching route on per-prefix basis.

### Topology

---

In the topology, [Figure 53 on page 594](#) shows the longest match for LDP is configured on Device R0 .

Figure 53: Example Longest Match for LDP

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

## Configuring Device R0

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device R0:

1. Configure the interfaces.
 

```

[edit interfaces]
set ge-0/0/0 unit 0 family inet address 22.22.22.1/24

set ge-0/0/1 unit 0 family inet address 15.15.15.1/24

```

```

set ge-0/0/2 unit 0 family inet address 11.11.11.1/24
set ge-0/0/2 unit 0 family iso
set ge-0/0/2 unit 0 family mpls

```

2. Assign the loopback addresses to the device.

```

[edit interfaces lo0 unit 0 family]
set inet address 10.255.112.1/32 primary
set inet address 10.255.112.1/32 preferred
set iso address 49.0002.0192.0168.0001.00

```

3. Configure the router ID.

```

[edit routing-options]
set router-id 10.255.112.1

```

4. Configure the MPLS protocol on the interface.

```

[edit protocols mpls]
set interface ge-0/0/2.0

```

5. Configure the OSPF protocol on the interface.

```

[edit protocols ospf]
set area 0.0.0.1 interface ge-0/0/2.0
set area 0.0.0.1 interface lo0.0 passive

```

6. Configure longest match for the LDP protocol.

```

[edit protocols ldp]
set longest-match

```

7. Configure the LDP protocol on the interface.

```

[edit protocols ldp]
set interface ge-0/0/2.0
set interface lo0.0

```

## Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@R0# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 22.22.22.1/24;
    }
  }
}
ge-0/0/1 {
  unit 0 {
    family inet {
      address 15.15.15.1/24;
    }
  }
}

```

```
}
ge-0/0/2 {
  unit 0 {
    family inet {
      address 11.11.11.1/24;
    }
    family iso;
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.112.1/32 {
        primary;
        preferred;
      }
    }
    family iso {
      address 49.0002.0192.0168.0001.00;
    }
  }
}

user@R0# show protocols
mpls {
  interface ge-0/0/2.0;
}
ospf {
  area 0.0.0.1 {
    interface ge-0/0/2.0;
    interface lo0.0 {
      passive;
    }
  }
}
ldp {
  longest-match;
  interface ge-0/0/2.0;
  interface lo0.0;
}

user@R0# show routing-options
router-id 10.255.112.1;
```

If you are done configuring the device, enter **commit** from the configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the Routes on page 599](#)
- [Verifying LDP Overview Information on page 603](#)
- [Verify the LDP Entries in the Internal Topology Table on page 605](#)

- [Verify Only FEC Information of LDP Route on page 607](#)
- [Verify FEC and Shadow Routes of LDP on page 607](#)

### Verifying the Routes

---

**Purpose** Verify that the expected routes are learned.

**Action** On Device R0, from operational mode, run the **show route** command to display the routes in the routing table.

```
user@R0> show route
```

```
inet.0: 62 destinations, 62 routes (62 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
10.4.0.0/16      *[Static/5] 10:08:01
                  > to 10.92.31.254 via fxp0.0
10.5.0.0/16      *[Static/5] 10:08:01
                  > to 10.92.31.254 via fxp0.0
10.6.128.0/17    *[Static/5] 10:08:01
                  > to 10.92.31.254 via fxp0.0
10.9.0.0/16      *[Static/5] 10:08:01
                  > to 10.92.31.254 via fxp0.0
10.10.0.0/16     *[Static/5] 10:08:01
                  > to 10.92.31.254 via fxp0.0
10.13.4.0/23     *[Static/5] 10:08:01
                  > to 10.92.31.254 via fxp0.0
10.13.10.0/23    *[Static/5] 10:08:01
                  > to 10.92.31.254 via fxp0.0
10.82.0.0/15     *[Static/5] 10:08:01
                  > to 10.92.31.254 via fxp0.0
10.84.0.0/16     *[Static/5] 10:08:01
                  > to 10.92.31.254 via fxp0.0
10.85.12.0/22    *[Static/5] 10:08:01
                  > to 10.92.31.254 via fxp0.0
10.92.0.0/16     *[Static/5] 10:08:01
                  > to 10.92.31.254 via fxp0.0

```

**Meaning** The output shows all the routes in the routing table of Device R0.

---

### Verifying LDP Overview Information

---

**Purpose** Display LDP overview information.

**Action** On Device R0, from operational mode, run the **show ldp overview** command to display the overview of the LDP.

```
user@R0> show ldp overview
Instance: master
  Reference count: 2
  Router ID: 10.255.112.1
  Message id: 8
  Configuration sequence: 6
  Deaggregate: disabled
  Explicit null: disabled
  IPv6 tunneling: disabled
  Strict targeted hellos: disabled
  Loopback if added: yes
  Route preference: 9
  Unicast transit LSP chaining: disabled
  P2MP transit LSP chaining: disabled
  Transit LSP statistics based on route statistics: disabled
  LDP route acknowledgement: enabled
  LDP mtu discovery: disabled
  Longest Match: enabled
  Capabilities enabled: none
  Egress FEC capabilities enabled: entropy-label-capability
  Downstream unsolicited Sessions:
    Operational: 1
    Retention: liberal
    Control: ordered
  Auto targeted sessions:
    Auto targeted: disabled
  Timers:
    Keepalive interval: 10, Keepalive timeout: 30
    Link hello interval: 5, Link hello hold time: 15
    Targeted hello interval: 15, Targeted hello hold time: 45
    Label withdraw delay: 60, Make before break timeout: 30
    Make before break switchover delay: 3
    Link protection timeout: 120
  Graceful restart:
    Restart: disabled, Helper: enabled, Restart in process: false
    Reconnect time: 60000, Max neighbor reconnect time: 120000
    Recovery time: 160000, Max neighbor recovery time: 240000
  Traffic Engineering:
    Bgp igp: disabled
    Both ribs: disabled
    Mpls forwarding: disabled
  IGP:
    Tracking igp metric: disabled
    Sync session up delay: 10
  Session protection:
    Session protection: disabled
    Session protection timeout: 0
  Interface addresses advertising:
    11.11.11.1
    10.255.112.1
    128.92.20.175
  Label allocation:
    Current number of LDP labels allocated: 5
    Total number of LDP labels allocated: 11
    Total number of LDP labels freed: 6
    Total number of LDP label allocation failure: 0
    Current number of labels allocated by all protocols: 5
```

**Meaning** The output displays the LDP overview information of Device R0

#### Verify the LDP Entries in the Internal Topology Table

**Purpose** Display the route entries in the Label Distribution Protocol (LDP) internal topology table.

**Action** On Device R0, from operational mode, run the **show ldp route** command to display the internal topology table of LDP.

```
user@R0> show ldp route
```

**Meaning** The output displays the route entries in the Label Distribution Protocol (LDP) internal topology table of Device R0.

### Verify Only FEC Information of LDP Route

**Purpose** Display only the FEC information of LDP route.

**Action** On Device R0, from operational mode, run the **show ldp route fec-only** command to display the routes in the routing table.

user@R0> **show ldp route fec-only**

| Destination     | Next-hop intf/lsp/table | Next-hop address |
|-----------------|-------------------------|------------------|

## Configuring LDP Route Preferences

When several protocols calculate routes to the same destination, route preferences are used to select which route is installed in the forwarding table. The route with the lowest preference value is selected. The preference value can be a number in the range 0 through 255. By default, LDP routes have a preference value of 9.

To modify the route preferences, include the **preference** statement:

```
preference preference;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## LDP Graceful Restart

LDP graceful restart enables a router whose LDP control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers. It also enables a router on which helper mode is enabled to assist a neighboring router that is attempting to restart LDP.

During session initialization, a router advertises its ability to perform LDP graceful restart or to take advantage of a neighbor performing LDP graceful restart by sending the graceful restart TLV. This TLV contains two fields relevant to LDP graceful restart: the reconnect time and the recovery time. The values of the reconnect and recovery times indicate the graceful restart capabilities supported by the router.

When a router discovers that a neighboring router is restarting, it waits until the end of the recovery time before attempting to reconnect. The recovery time is the length of time a router waits for LDP to restart gracefully. The recovery time period begins when an

initialization message is sent or received. This time period is also typically the length of time that a neighboring router maintains its information about the restarting router, allowing it to continue to forward traffic.

You can configure LDP graceful restart in both the master instance for the LDP protocol and for a specific routing instance. You can disable graceful restart at the global level for all protocols, at the protocol level for LDP only, and on a specific routing instance. LDP graceful restart is disabled by default, because at the global level, graceful restart is disabled by default. However, helper mode (the ability to assist a neighboring router attempting a graceful restart) is enabled by default.

The following are some of the behaviors associated with LDP graceful restart:

- Outgoing labels are not maintained in restarts. New outgoing labels are allocated.
- When a router is restarting, no label-map messages are sent to neighbors that support graceful restart until the restarting router has stabilized (label-map messages are immediately sent to neighbors that do not support graceful restart). However, all other messages (keepalive, address-message, notification, and release) are sent as usual. Distributing these other messages prevents the router from distributing incomplete information.
- Helper mode and graceful restart are independent. You can disable graceful restart in the configuration, but still allow the router to cooperate with a neighbor attempting to restart gracefully.

## Configuring LDP Graceful Restart

---

When you alter the graceful restart configuration at either the **[edit routing-options graceful-restart]** or **[edit protocols ldp graceful-restart]** hierarchy levels, any running LDP session is automatically restarted to apply the graceful restart configuration. This behavior mirrors the behavior of BGP when you alter its graceful restart configuration.

By default, graceful restart helper mode is enabled, but graceful restart is disabled. Thus, the default behavior of a router is to assist neighboring routers attempting a graceful restart, but not to attempt a graceful restart itself.

To configure LDP graceful restart, see the following sections:

- [Enabling Graceful Restart on page 610](#)
- [Disabling LDP Graceful Restart or Helper Mode on page 611](#)
- [Configuring Reconnect Time on page 612](#)
- [Configuring Recovery Time and Maximum Recovery Time on page 612](#)

### Enabling Graceful Restart

To enable LDP graceful restart, you also need to enable graceful restart on the router. To enable graceful restart, include the **graceful-restart** statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- [edit routing-options]
- [edit logical-systems *logical-system-name* routing-options]

**NOTE:** ACX Series routers do not support [edit logical-systems *logical-system-name* routing-options] hierarchy level.

The **graceful-restart** statement enables graceful restart for all protocols supporting this feature on the router. For more information about graceful restart, see the *Junos OS Routing Protocols Library*.

By default, LDP graceful restart is enabled when you enable graceful restart at both the LDP protocol level and on all the routing instances. However, you can disable both LDP graceful restart and LDP graceful restart helper mode.

## Disabling LDP Graceful Restart or Helper Mode

To disable LDP graceful restart and recovery, include the **disable** statement:

```
ldp {
  graceful-restart {
    disable;
  }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

You can disable helper mode at the LDP protocols level only. You cannot disable helper mode for a specific routing instance. To disable LDP helper mode, include the **helper-disable** statement:

```
ldp {
  graceful-restart {
    helper-disable;
  }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The following LDP graceful restart configurations are possible:

- LDP graceful restart and helper mode are both enabled.
- LDP graceful restart is disabled but helper mode is enabled. A router configured in this way cannot restart gracefully but can help a restarting neighbor.
- LDP graceful restart and helper mode are both disabled. The router does not use LDP graceful restart or the graceful restart type, length, and value (TLV) sent in the initialization message. The router behaves as a router that cannot support LDP graceful restart.

A configuration error is issued if you attempt to enable graceful restart and disable helper mode.

## Configuring Reconnect Time

After the LDP connection between neighbors fails, neighbors wait a certain amount of time for the gracefully restarting router to resume sending LDP messages. After the wait period, the LDP session can be reestablished. You can configure the wait period in seconds. This value is included in the fault tolerant session TLV sent in LDP initialization messages when LDP graceful restart is enabled.

Suppose that Router A and Router B are LDP neighbors. Router A is the restarting Router. The reconnect time is the time that Router A tells Router B to wait after Router B detects that Router A restarted.

To configure the reconnect time, include the **reconnect-time** statement:

```
graceful-restart {  
    reconnect-time seconds;  
}
```

You can set the reconnect time to a value in the range from 30 through 300 seconds. By default, it is 60 seconds.

For a list of hierarchy levels at which you can configure these statements, see the statement summary sections for these statements.

## Configuring Recovery Time and Maximum Recovery Time

The recovery time is the amount of time a router waits for LDP to restart gracefully. The recovery time period begins when an initialization message is sent or received. This period is also typically the amount of time that a neighboring router maintains its information about the restarting router, allowing it to continue to forward traffic.

To prevent a neighboring router from being adversely affected if it receives a false value for the recovery time from the restarting router, you can configure the maximum recovery time on the neighboring router. A neighboring router maintains its state for the shorter of the two times. For example, Router A is performing an LDP graceful restart. It has sent a recovery time of 900 seconds to neighboring Router B. However, Router B has its maximum recovery time configured at 400 seconds. Router B will only wait for 400 seconds before it purges its LDP information from Router A.

To configure recovery time, include the **recovery-time** statement and the **maximum-neighbor-recovery-time** statement:

```
graceful-restart {  
    maximum-neighbor-recovery-time seconds;  
    recovery-time seconds;  
}
```

For a list of hierarchy levels at which you can configure these statements, see the statement summary sections for these statements.

## Filtering Inbound LDP Label Bindings

You can filter received LDP label bindings, applying policies to accept or deny bindings advertised by neighboring routers. To configure received-label filtering, include the **import** statement:

```
import [ policy-names ];
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The named policy (configured at the **[edit policy-options]** hierarchy level) is applied to all label bindings received from all LDP neighbors. All filtering is done with **from** statements. [Table 18 on page 613](#) lists the only **from** operators that apply to LDP received-label filtering.

**Table 18: from Operators That Apply to LDP Received-Label Filtering**

| from Operator       | Description                                                                                |
|---------------------|--------------------------------------------------------------------------------------------|
| <b>interface</b>    | Matches on bindings received from a neighbor that is adjacent over the specified interface |
| <b>neighbor</b>     | Matches on bindings received from the specified LDP router ID                              |
| <b>next-hop</b>     | Matches on bindings received from a neighbor advertising the specified interface address   |
| <b>route-filter</b> | Matches on bindings with the specified prefix                                              |

If a binding is filtered, it still appears in the LDP database, but is not considered for installation as part of a label-switched path (LSP).

Generally, applying policies in LDP can be used only to block the establishment of LSPs, not to control their routing. This is because the path that an LSP follows is determined by unicast routing, and not by LDP. However, when there are multiple equal-cost paths to the destination through different neighbors, you can use LDP filtering to exclude some of the possible next hops from consideration. (Otherwise, LDP chooses one of the possible next hops at random.)

LDP sessions are not bound to interfaces or interface addresses. LDP advertises only per-router (not per-interface) labels; so if multiple parallel links exist between two routers, only one LDP session is established, and it is not bound to a single interface. When a router has multiple adjacencies to the same neighbor, take care to ensure that the filter does what is expected. (Generally, using **next-hop** and **interface** is not appropriate in this case.)

If a label has been filtered (meaning that it has been rejected by the policy and is not used to construct an LSP), it is marked as filtered in the database:

```
user@host> show ldp database
```

```
Input label database, 10.10.255.1:0-10.10.255.6:0
Label Prefix
3 10.10.255.6/32 (Filtered)
Output label database, 10.10.255.1:0-10.10.255.6:0
Label Prefix
3 10.10.255.1/32 (Filtered)
```

For more information about how to configure policies for LDP, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

## Examples: Filtering Inbound LDP Label Bindings

Accept only /32 prefixes from all neighbors:

```
[edit]
protocols {
  ldp {
    import only-32;
    ...
  }
}
policy-options {
  policy-statement only-32 {
    term first {
      from {
        route-filter 0.0.0.0/0 upto /31;
      }
      then reject;
    }
    then accept;
  }
}
```

Accept 131.108/16 or longer from router ID 10.10.255.2 and accept all prefixes from all other neighbors:

```
[edit]
protocols {
  ldp {
    import nosy-neighbor;
    ...
  }
}
policy-options {
  policy-statement nosy-neighbor {
    term first {
      from {
        neighbor 10.10.255.2;
        route-filter 131.108.0.0/16 orlonger accept;
        route-filter 0.0.0.0/0 orlonger reject;
      }
    }
    then accept;
  }
}
```

## Filtering Outbound LDP Label Bindings

You can configure export policies to filter LDP outbound labels. You can filter outbound label bindings by applying routing policies to block bindings from being advertised to neighboring routers. To configure outbound label filtering, include the **export** statement:

**export** [*policy-name*];

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The named export policy (configured at the **[edit policy-options]** hierarchy level) is applied to all label bindings transmitted to all LDP neighbors. The only **from** operator that applies to LDP outbound label filtering is **route-filter**, which matches bindings with the specified prefix. The only **to** operators that apply to outbound label filtering are the operators in [Table 19 on page 615](#).

Table 19: to Operators for LDP Outbound-Label Filtering

| to Operator      | Description                                                                          |
|------------------|--------------------------------------------------------------------------------------|
| <b>interface</b> | Matches on bindings sent to a neighbor that is adjacent over the specified interface |
| <b>neighbor</b>  | Matches on bindings sent to the specified LDP router ID                              |
| <b>next-hop</b>  | Matches on bindings sent to a neighbor advertising the specified interface address   |

If a binding is filtered, the binding is not advertised to the neighboring router, but it can be installed as part of an LSP on the local router. You can apply policies in LDP to block the establishment of LSPs, but not to control their routing. The path an LSP follows is determined by unicast routing, not by LDP.

LDP sessions are not bound to interfaces or interface addresses. LDP advertises only per-router (not per-interface) labels. If multiple parallel links exist between two routers, only one LDP session is established, and it is not bound to a single interface.

Do not use the **next-hop** and **interface** operators when a router has multiple adjacencies to the same neighbor.

Filtered labels are marked in the database:

```
user@host> show ldp database
Input label database, 10.10.255.1:0-10.10.255.3:0
Label Prefix
100007 10.10.255.2/32
3 10.10.255.3/32
Output label database, 10.10.255.1:0-10.10.255.3:0
Label Prefix
3 10.10.255.1/32
100001 10.10.255.6/32 (Filtered)
```

For more information about how to configure policies for LDP, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

## Examples: Filtering Outbound LDP Label Bindings

Block transmission of the route for **10.10.255.6/32** to any neighbors:

```
[edit protocols]
ldp {
  export block-one;
}
policy-options {
  policy-statement block-one {
    term first {
      from {
        route-filter 10.10.255.6/32 exact;
      }
      then reject;
    }
    then accept;
  }
}
```

Send only **131.108/16** or longer to router ID **10.10.255.2**, and send all prefixes to all other routers:

```
[edit protocols]
ldp {
  export limit-lsps;
}
policy-options {
  policy-statement limit-lsps {
    term allow-one {
      from {
        route-filter 131.108.0.0/16 orlonger;
      }
      to {
        neighbor 10.10.255.2;
      }
      then accept;
    }
    term block-the-rest {
      to {
        neighbor 10.10.255.2;
      }
      then reject;
    }
    then accept;
  }
}
```

## Specifying the Transport Address Used by LDP

Routers must first establish a TCP session between each other before they can establish an LDP session. The TCP session enables the routers to exchange the label advertisements needed for the LDP session. To establish the TCP session, each router must learn the other router's transport address. The transport address is an IP address used to identify the TCP session over which the LDP session will run.

To configure the LDP transport address, include the `transport-address` statement:

```
transport-address (router-id | interface);
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

If you specify the **router-id** option, the address of the router identifier is used as the transport address (unless otherwise configured, the router identifier is typically the same as the loopback address). If you specify the **interface** option, the interface address is used as the transport address for any LDP sessions to neighbors that can be reached over that interface. Note that the router identifier is used as the transport address by default.

You cannot specify the **interface** option when there are multiple parallel links to the same LDP neighbor, because the LDP specification requires that the same transport address be advertised on all interfaces to the same neighbor. If LDP detects multiple parallel links to the same neighbor, it disables interfaces to that neighbor one by one until the condition is cleared, either by disconnecting the neighbor on an interface or by specifying the **router-id** option.

- [transport-address on page 1650](#)

## Configuring the Prefixes Advertised into LDP from the Routing Table

You can control the set of prefixes that are advertised into LDP and cause the router to be the egress router for those prefixes. By default, only the loopback address is advertised into LDP. To configure the set of prefixes from the routing table to be advertised into LDP, include the **egress-policy** statement:

```
egress-policy policy-name;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

**NOTE:** If you configure an egress policy for LDP that does not include the loopback address, it is no longer advertised in LDP. To continue to advertise the loopback address, you need to explicitly configure it as a part of the LDP egress policy.

The named policy (configured at the **[edit policy-options]** or **[edit logical-systems logical-system-name policy-options]** hierarchy level) is applied to all routes in the routing

table. Those routes that match the policy are advertised into LDP. You can control the set of neighbors to which those prefixes are advertised by using the **export** statement. Only **from** operators are considered; you can use any valid **from** operator. For more information, see the *Junos OS Routing Protocols Library*.

**NOTE:** ACX Series routers do not support [edit logical-systems] hierarchy level.

---

### Example: Configuring the Prefixes Advertised into LDP

Advertise all connected routes into LDP:

```
[edit protocols]
ldp {
  egress-policy connected-only;
}
policy-options {
  policy-statement connected-only {
    from {
      protocol direct;
    }
    then accept;
  }
}
```

---

### Configuring FEC Deaggregation

When an LDP egress router advertises multiple prefixes, the prefixes are bound to a single label and aggregated into a single forwarding equivalence class (FEC). By default, LDP maintains this aggregation as the advertisement traverses the network.

Normally, because an LSP is not split across multiple next hops and the prefixes are bound into a single LSP, load-balancing across equal-cost paths does not occur. You can, however, load-balance across equal-cost paths if you configure a load-balancing policy and deaggregate the FECs.

Deaggregating the FECs causes each prefix to be bound to a separate label and become a separate LSP.

To configure deaggregated FECs, include the **deaggregate** statement:

**deaggregate;**

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

For all LDP sessions, you can configure deaggregated FECs only globally.

Deaggregating a FEC allows the resulting multiple LSPs to be distributed across multiple equal-cost paths and distributes LSPs across the multiple next hops on the egress segments but installs only one next hop per LSP.

To aggregate FECs, include the **no-deaggregate** statement:

```
no-deaggregate;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

For all LDP sessions, you can configure aggregated FECs only globally.

## Configuring Policers for LDP FECs

You can configure the Junos OS to track and police traffic for LDP FECs. LDP FEC policers can be used to do any of the following:

- Track or police the ingress traffic for an LDP FEC.
- Track or police the transit traffic for an LDP FEC.
- Track or police LDP FEC traffic originating from a specific forwarding class.
- Track or police LDP FEC traffic originating from a specific virtual routing and forwarding (VRF) site.
- Discard false traffic bound for a specific LDP FEC.

To police traffic for an LDP FEC, you must first configure a filter. Specifically, you need to configure either the **interface** statement or the **interface-set** statement at the **[edit firewall family protocol-family filter filter-name term term-name from]** hierarchy level. The **interface** statement allows you to match the filter to a single interface. The **interface-set** statement allows you to match the filter to multiple interfaces.

For more information on how to configure the **interface** statement, the **interface-set** statement, and policers for LDP FECs, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide for Routing Devices*.

Once you have configured the filters, you need to include them in the **policing** statement configuration for LDP. To configure policers for LDP FECs, include the **policing** statement:

```
policing {
  fec fec-address {
    ingress-traffic filter-name;
    transit-traffic filter-name;
  }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The **policing** statement includes the following options:

- **fec**—Specify the FEC address for the LDP FEC you want to police.
- **ingress-filter**—Specify the name of the ingress traffic filter.
- **transit-traffic**—Specify the name of the transit traffic filter.

## Configuring LDP IPv4 FEC Filtering

---

By default, when a targeted LDP session is established, the Junos OS always exchanges both the IPv4 forwarding equivalence classes (FECs) and the Layer 2 circuit FECs over the targeted LDP session. For an LDP session to an indirectly connected neighbor, you might only want to export Layer 2 circuit FECs to the neighbor if the session was specifically configured to support Layer 2 circuits or VPLS.

In a mixed vendor network where all non-BGP prefixes are advertised into LDP, the LDP database can become large. For this type of environment, it can be useful to prevent the advertisement of IPv4 FECs over LDP sessions formed because of Layer 2 circuit or LDP VPLS configuration. Similarly, it can be useful to filter any IPv4 FECs received in this sort of environment.

If all the LDP neighbors associated with an LDP session are Layer 2 only, you can configure the Junos OS to advertise only Layer 2 circuit FECs by configuring the **l2-smart-policy** statement. This feature also automatically filters out the IPv4 FECs received on this session. Configuring an explicit export or import policy that is activated for **l2-smart-policy** disables this feature in the corresponding direction.

If one of the LDP session's neighbors is formed because of a discovered adjacency or if the adjacency is formed because of an LDP tunneling configuration on one or more RSVP LSPs, the IPv4 FECs are advertised and received using the default behavior.

To prevent LDP from exporting IPv4 FECs over LDP sessions with Layer 2 neighbors only and to filter out IPv4 FECs received over such sessions, include the **l2-smart-policy** statement:

**l2-smart-policy;**

For a list of hierarchy levels at which you can configure this statement, see the statement summary for this statement.

## Configuring BFD for LDP LSPs

---

You can configure Bidirectional Forwarding Detection (BFD) for LDP LSPs. The BFD protocol is a simple hello mechanism that detects failures in a network. Hello packets are sent at a specified, regular interval. A neighbor failure is detected when the router stops receiving a reply after a specified interval. BFD works with a wide variety of network environments and topologies. The failure detection timers for BFD have shorter time limits than the failure detection mechanisms of static routes, providing faster detection.

An error is logged whenever a BFD session for a path fails. The following shows how BFD for LDP LSP log messages might appear:

```
RPD_LDP_BFD_UP: LDP BFD session for FEC 10.255.16.14/32 is up
RPD_LDP_BFD_DOWN: LDP BFD session for FEC 10.255.16.14/32 is down
```

You can also configure BFD for RSVP LSPs, as described in [“Configuring BFD for RSVP-Signaled LSPs” on page 383](#).

The BFD failure detection timers are adaptive and can be adjusted to be more or less aggressive. For example, the timers can adapt to a higher value if the adjacency fails, or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the **clear bfd adaptation** command to return BFD interval timers to their configured values. The **clear bfd adaptation** command is hitless, meaning that the command does not affect traffic flow on the routing device.

To enable BFD for LDP LSPs, include the **oam** and **bfd-liveness-detection** statements:

```
oam {
  bfd-liveness-detection {
    detection-time threshold milliseconds;
    ecmp;
    failure-action {
      remove-nexthop;
      remove-route;
    }
    holddown-interval seconds;
    ingress-policy ingress-policy-name;
    minimum-interval milliseconds;
    minimum-receive-interval milliseconds;
    minimum-transmit-interval milliseconds;
    multiplier detection-time-multiplier;
    no-adaptation;
    transmit-interval {
      minimum-interval milliseconds;
      threshold milliseconds;
    }
    version (0 | 1 | automatic);
  }
  fec fec-address {
    bfd-liveness-detection {
      detection-time threshold milliseconds;
      ecmp;
      failure-action {
        remove-nexthop;
        remove-route;
      }
      holddown-interval milliseconds;
      ingress-policy ingress-policy-name;
      minimum-interval milliseconds;
      minimum-receive-interval milliseconds;
    }
  }
}
```

```

        minimum-transmit-interval milliseconds;
        multiplier detection-time-multiplier;
        no-adaptation;
        transmit-interval {
            minimum-interval milliseconds;
            threshold milliseconds;
        }
        version (0 | 1 | automatic);
    }
    no-bfd-liveness-detection;
    periodic-traceroute {
        disable;
        exp exp-value;
        fanout fanout-value;
        frequency minutes;
        paths number-of-paths;
        retries retry-attempts;
        source address;
        ttl ttl-value;
        wait seconds;
    }
}
lsp-ping-interval seconds;
periodic-traceroute {
    disable;
    exp exp-value;
    fanout fanout-value;
    frequency minutes;
    paths number-of-paths;
    retries retry-attempts;
    source address;
    ttl ttl-value;
    wait seconds;
}
}

```

You can enable BFD for the LDP LSPs associated with a specific forwarding equivalence class (FEC) by configuring the FEC address using the **fec** option at the **[edit protocols ldp]** hierarchy level. Alternatively, you can configure an Operation Administration and Management (OAM) ingress policy to enable BFD on a range of FEC addresses. For more information, see [“Configuring OAM Ingress Policies for LDP” on page 625](#).

You cannot enable BFD LDP LSPs unless their equivalent FEC addresses are explicitly configured or OAM is enabled on the FECs using an OAM ingress policy. If BFD is not enabled for any FEC addresses, the BFD session will not come up.

You can configure the **oam** statement at the following hierarchy levels:

- **[edit protocols ldp]**
- **[edit logical-systems *logical-system-name* protocols ldp]**

**NOTE:** ACX Series routers do not support **[edit logical-systems]** hierarchy level.

The **oam** statement includes the following options:

- **fec**—Specify the FEC address. You must either specify a FEC address or configure an OAM ingress policy to ensure that the BFD session comes up.
- **lsp-ping-interval**—Specify the duration of the LSP ping interval in seconds. To issue a ping on an LDP-sigaled LSP, use the **ping mpls ldp** command. For more information, see the [CLI Explorer](#).

The **bfd-liveness-detection** statement includes the following options:

- **ecmp**—Cause LDP to establish BFD sessions for all ECMP paths configured for the specified FEC. If you configure the **ecmp** option, you must also configure the **periodic-traceroute** statement for the specified FEC. If you do not do so, the commit operation fails. You can configure the **periodic-traceroute** statement at the global hierarchy level (**[edit protocols ldp oam]**) while only configuring the **ecmp** option for a specific FEC (**[edit protocols ldp oam fec address bfd-liveness-detection]**).
- **holddown-interval**—Specify the duration the BFD session should remain up before adding the route or next hop. Specifying a time of 0 seconds causes the route or next hop to be added as soon as the BFD session comes back up.
- **minimum-interval**—Specify the minimum transmit and receive interval. If you configure the **minimum-interval** option, you do not need to configure the **minimum-receive-interval** option or the **minimum-transmit-interval** option.
- **minimum-receive-interval**—Specify the minimum receive interval. The range is from 1 through 255,000 milliseconds.
- **minimum-transmit-interval**—Specify the minimum transmit interval. The range is from 1 through 255,000 milliseconds.
- **multiplier**—Specify the detection time multiplier. The range is from 1 through 255.
- **version**—Specify the BFD version. The options are BFD version 0 or BFD version 1. By default, the Junos OS software attempts to automatically determine the BFD version.

## Configuring ECMP-Aware BFD for LDP LSPs

When you configure BFD for a FEC, a BFD session is established for only one active local next-hop for the router. However, you can configure multiple BFD sessions, one for each FEC associated with a specific equal-cost multipath (ECMP) path. For this to function properly, you also need to configure LDP LSP periodic traceroute. (See “[Configuring LDP LSP Traceroute](#)” on page 729.) LDP LSP traceroute is used to discover ECMP paths. A BFD session is initiated for each ECMP path discovered. Whenever a BFD session for one of the ECMP paths fails, an error is logged.

LDP LSP traceroute is run periodically to check the integrity of the ECMP paths. The following might occur when a problem is discovered:

- If the latest LDP LSP traceroute for a FEC differs from the previous traceroute, the BFD sessions associated with that FEC (the BFD sessions for address ranges that have

changed from previous run) are brought down and new BFD sessions are initiated for the destination addresses in the altered ranges.

- If the LDP LSP traceroute returns an error (for example, a timeout), all the BFD sessions associated with that FEC are torn down.

To configure LDP to establish BFD sessions for all ECMP paths configured for the specified FEC, include the **ecmp** statement.

```
ecmp;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Along with the **ecmp** statement, you must also include the **periodic-traceroute** statement, either in the global LDP OAM configuration (at the **[edit protocols ldp oam]** or **[edit logical-systems logical-system-name protocols ldp oam]** hierarchy level) or in the configuration for the specified FEC (at the **[edit protocols ldp oam fec address]** or **[edit logical-systems logical-system-name protocols ldp oam fec address]** hierarchy level). Otherwise, the commit operation fails.

**NOTE:** ACX Series routers do not support **[edit logical-systems]** hierarchy level.

---

## Configuring a Failure Action for the BFD Session on an LDP LSP

---

You can configure route and next-hop properties in the event of a BFD session failure event on an LDP LSP. The failure event could be an existing BFD session that has gone down or could be a BFD session that never came up. LDP adds back the route or next hop when the relevant BFD session comes back up.

You can configure one of the following failure action options for the **failure-action** statement in the event of a BFD session failure on the LDP LSP:

- **remove-nexthop**—Removes the route corresponding to the next hop of the LSP's route at the ingress node when a BFD session failure event is detected.
- **remove-route**—Removes the route corresponding to the LSP from the appropriate routing tables when a BFD session failure event is detected. If the LSP is configured with ECMP and a BFD session corresponding to any path goes down, the route is removed.

To configure a failure action in the event of a BFD session failure on an LDP LSP, include either the **remove-nexthop** option or the **remove-route** option for the **failure-action** statement:

```
failure-action {  
  remove-nexthop;  
  remove-route;  
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring the Holddown Interval for the BFD Session

You can specify the duration the BFD session should be up before adding a route or next hop by configuring the **holddown-interval** statement at either the **[edit protocols ldp oam bfd-liveness-detection]** hierarchy level or at the **[edit protocols ldp oam fec address bfd-liveness-detection]** hierarchy level. Specifying a time of 0 seconds causes the route or next hop to be added as soon as the BFD session comes back up.

**holddown-interval** *seconds*;

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring OAM Ingress Policies for LDP

Using the **ingress-policy** statement, you can configure an Operation, Administration, and Management (OAM) policy to choose which forwarding equivalence classes (FECs) need to have OAM enabled. If the FEC passes through the policy or if the FEC is explicitly configured, OAM is enabled for a FEC. For FECs chosen using a policy, the BFD parameters configured under **[edit protocols ldp oam bfd-liveness-detection]** are applied.

You configure the OAM ingress policy at the **[edit policy-options]** hierarchy level. To configure an OAM ingress policy, include the **ingress-policy** statement:

**ingress-policy** *ingress-policy-name*;

You can configure this statement at the following hierarchy levels:

- **[edit protocols ldp oam]**
- **[edit logical-systems *logical-system-name* protocols ldp oam]**

**NOTE:** ACX Series routers do not support **[edit logical-systems]** hierarchy level.

## Configuring LDP Link Protection

You can configure Label Distribution Protocol (LDP) link protection for both unicast and multicast LDP label-switched paths (LSPs) to provide resiliency during link or node failure.

Before you begin:

1. Configure the device interfaces.
2. Configure the router ID and autonomous system number for the device.
3. Configure the following protocols:
  - a. RSVP

- b. MPLS with traffic engineering capability.
- c. OSPF with traffic engineering capability.

**NOTE:** For multicast LDP link protection with loop-free alternative (LFA), enable link protection.

```
[edit protocols]
user@R0# set ospf area 0 interface all link-protection
```

To configure LDP link protection:

1. Enable point-to-multipoint LDP LSPs.

```
[edit protocols]
user@R0# set ldp p2mp
```

2. Enable LDP on all the interfaces of Router R0 (excluding the management interface) and configure link protection with dynamic RSVP bypass LSP.

```
[edit protocols]
user@R0# set ldp interface all link-protection dynamic-rsvp-lsp
user@R0# set ldp interface fxp0.0 disable
```

3. Verify and commit the configuration.

For example:

```
[edit protocols]
user@R0# show protocols
rsvp {
  interface all;
  interface fxp0.0 {
    disable;
  }
}
mpls {
  traffic-engineering;
  interface all;
  interface fxp0.0 {
    disable;
  }
}
ospf {
  traffic-engineering;
  area 0.0.0.0 {
    interface all {
      metric 1;
    }
    interface fxp0.0 {
      disable;
    }
  }
}
ldp {
  interface all {
```

```

link-protection {
    dynamic-rsvp-lsp;
}
}
interface fxp0.0 {
    disable;
}
p2mp;
}

[edit]
user@R0# commit
commit complete

```

### Introduction to LDP

The Label Distribution Protocol (LDP) is a protocol for distributing labels in non-traffic-engineered applications. LDP allows routers to establish label-switched paths (LSPs) through a network by mapping network-layer routing information directly to the data link LSPs.

These LSPs might have an endpoint at a directly attached neighbor (comparable to IP hop-by-hop forwarding) or at a network egress node, enabling switching through all intermediary nodes. LSPs established by LDP can also traverse traffic-engineered LSPs created by RSVP.

LDP associates a forwarding equivalence class (FEC) with each LSP it creates. The FEC associated with an LSP specifies which packets are mapped to that LSP. LSPs are extended through a network as each router chooses the label advertised by the next hop for the FEC and splices it to the label it advertises to all other routers. This process forms a tree of LSPs that converge on the egress router.

---

### Junos OS LDP Protocol Implementation

The Junos OS implementation of LDP supports LDP version 1. Junos OS supports a simple mechanism for tunneling between routers in an interior gateway protocol (IGP), to eliminate the required distribution of external routes within the core. Junos OS allows an MPLS tunnel next hop to all egress routers in the network, with only an IGP running in the core to distribute routes to egress routers. Edge routers run BGP but do not distribute external routes to the core. Instead, the recursive route lookup at the edge resolves to an LSP switched to the egress router. No external routes are necessary on the transit LDP routers.

---

### Understanding Multipoint Extensions to LDP

An LDP defines mechanisms for setting up point-to-point, multipoint-to-point, point-to-multipoint, and multipoint-to-multipoint LSPs in the network. The point-to-multipoint and multipoint-to-multipoint LSPs are collectively referred to as multipoint LSPs, where traffic flows from a single source to multiple destinations, and from multiple sources to multiple destinations, respectively. The destination or egress routers are called leaf nodes, and traffic from the source traverses one or more transit nodes before reaching the leaf nodes.

**NOTE:** Junos OS does not provide support for multipoint-to-multipoint LSPs.

---

By taking advantage of the MPLS packet replication capability of the network, multipoint LSPs avoid unnecessary packet replication at the ingress router. Packet replication takes place only when packets are forwarded to two or more different destinations requiring different network paths.

---

### Using Multipoint Extensions to LDP on Targeted LDP Sessions

The specification for the multipoint extensions to LDP requires that the two endpoints of an LDP session are directly connected by a Layer 2 medium, or are considered to be neighbors by the network's IGP. This is referred to as an LDP link session. When the two endpoints of an LDP session are not directly connected, the session is referred to as a targeted LDP session.

Past Junos OS implementations support multicast LDP for link sessions only. With the introduction of the LDP link protection feature, the multicast LDP capabilities are extended to targeted LDP sessions. [Figure 54 on page 629](#) shows a sample topology.

Figure 54: Multicast LDP Support for Targeted LDP Session

Routers R7 and R8 are the upstream (LSR-U) and downstream (LSR-D) label-switched routers (LSRs), respectively, and deploy multicast LDP. The core router, Router R5, has RSVP-TE enabled.

When LSR-D is setting up the point-to-multipoint LSP with root and LSP ID attributes, it determines the upstream LSR-U as a next-hop on the best path to the root (currently, this next-hop is assumed to be an IGP next hop).

With the multicast LDP support on targeted LDP sessions, you can determine if there is an LSP next hop to LSR-U which is on LSR-D's path to root, where LSR-D and LSR-U are not directly connected neighbors, but targeted LDP peers. The point-to-multipoint label advertised on the targeted LDP session between LSR-D and LSR-U is not used unless there is an LSP between LSR-D and LSR-U. Therefore, a corresponding LSP in the reverse direction from LSR-U to LSR-D is required.

Data is transmitted on the point-to-multipoint LSP using unicast replication of packets, where LSR-U sends one copy to each downstream LSR of the point-to-multipoint LSP.

The data transmission is implemented in the following ways:

1. The point-to-multipoint capabilities on the targeted LDP session are negotiated.
2. The algorithm to select the upstream LSR is changed, where if IGP next hops are unavailable, or in other words, there is no LDP link session between LSR-D and LSR-U, an RSVP LSP is used as the next hop to reach LSR-U.
3. The incoming labels received over the targeted LDP sessions are installed as a branch next hop for this point-to-multipoint FEC route with the LDP label as the inner label and the RSVP label as the outer label.

### Current Limitations of LDP Link Protection

When there is a link or node failure in an LDP network deployment, fast traffic recovery should be provided to recover impacted traffic flows for mission-critical services. In the case of multipoint LSPs, when one of the links of the point-to-multipoint tree fails, the subtrees might get detached until the IGP reconverges and the multipoint LSP is established using the best path from the downstream router to the new upstream router.

In fast reroute using local repair for LDP traffic, a backup path (repair path) is pre-installed in the Packet Forwarding Engine. When the primary path fails, traffic is rapidly moved to the backup path without having to wait for the routing protocols to converge. Loop-free alternate (LFA) is one of the methods used to provide IP fast reroute capability in the core and service provider networks.

Without LFA, when a link or a router fails or is returned to service, the distributed routing algorithms compute the new routes based on the changes in the network. The time during which the new routes are computed is referred to as routing transition. Until the routing transition is completed, the network connectivity is interrupted because the routers adjacent to a failure continue to forward the data packets through the failed component until an alternative path is identified.

However, LFA does not provide full coverage in all network deployments because of the IGP metrics. As a result, this is a limitation to the current LDP link protection schemes.

Figure 55 on page 630 illustrates a sample network with incomplete LFA coverage, where traffic flows from the source router (S) to the destination router (D) through Router R1. Assuming that each link in the network has the same metric, if the link between the Router S and Router R1 fails, Router R4 is not an LFA that protects the S-R1 link, so traffic resiliency is lost. Thus, full coverage is not achieved by using plain LFA. In typical networks, there is always some percentage of LFA coverage gap with plain LFA.

**Figure 55: Incomplete Coverage Problem with LFA**

### Using RSVP LSP as a Solution

The key to protect the traffic flowing through LDP LSPs is to have an explicit tunnel to re-route the traffic in the event of a link or node failure. The explicit path has to terminate on the next downstream router, and the traffic needs to be accepted on the explicit path, where the RPF check should pass.

RSVP LSPs help overcome the current limitations of loop-free alternate (LFA) for both point-to-point and point-to-multipoint LDP LSPs by extending the LFA coverage in the following methods:

- [Manually Configured RSVP LSPs on page 631](#)
- [Dynamically Configured RSVP LSPs on page 631](#)

#### **Manually Configured RSVP LSPs**

Considering the example used in [Figure 55 on page 630](#), when the S-R1 link fails, and Router R4 is not an LFA for that particular link, a manually created RSVP LSP is used as a patch to provide complete LFA coverage. The RSVP LSP is pre-sigaled and pre-installed in the Packet Forwarding Engine of Router S, so that it can be used as soon as Router S detects that the link has failed.

**Figure 56: Manually Configured RSVP LSP Coverage**

In this case, an RSVP LSP is created between Routers S, R4, and R3 as illustrated in [Figure 56 on page 631](#). A targeted LDP session is created between Router S and Router R3, as a result of which, when the S-R1 link fails, traffic reaches Router R3. Router R3 forwards the traffic to Router R2, as it is the shortest path to reach the destination, Router D.

#### **Dynamically Configured RSVP LSPs**

In this method, the RSVP LSPs are created automatically and pre-installed in the system so that they can be used immediately when there is a link failure. Here, the egress is the node on the other side of the link being protected, thereby improving the LFA coverage.

Considering the example used in [Figure 55 on page 630](#), in order to protect traffic against the potential failure of the S-R1 link, because Router R4 is not an LFA for that particular link, an RSVP bypass LSP is automatically created to Router R1, which is the node on the far side of the protected link as illustrated in [Figure 57 on page 632](#). From Router R1, traffic is forwarded to its original destination, Router D.

The RSVP LSP is pre-sigaled and pre-installed in the Packet Forwarding Engine of Router S so that it can be used as soon as Router S detects that the link has failed.

Figure 57: Dynamically Configured RSVP LSP Coverage

An alternative mode of operation is not to use LFA at all, and to always have the RSVP LSP created to cover all link failures.

To enable dynamic RSVP LSPs, include the **dynamic-rsvp-lsp** statement at the **[edit protocols ldp interface *interface-name* link-protection]** hierarchy level, in addition to enabling the RSVP protocol on the appropriate interfaces.

Some of the benefits of enabling dynamic RSVP LSPs include:

- Ease of configuration.
- 100 percent coverage against link failure as long as there is an alternate path to the far end of the link being protected.
- Setting up and tearing down of the RSVP bypass LSP is automatic.
- RSVP LSP only used for link protection and not for forwarding traffic while the link being protected is up.
- Reduces the total number of RSVP LSPs required on the system.

### Understanding Multicast LDP Link Protection

A point-to-multipoint LDP label-switched path (LSP) is an LDP-sigaled LSP that is point-to-multipoint, and is referred to as multicast LDP.

A multicast LDP LSP can be used to send traffic from a single root or ingress node to a number of leaf or egress nodes traversing one or more transit nodes. Multicast LDP link protection enables fast reroute of traffic carried over point-to-multipoint LDP LSPs in case of a link failure. When one of the links of the point-to-multipoint tree fails, the

subtrees might get detached until the IGP reconverges and the multipoint LSP is established using the best path from the downstream router to the new upstream router.

To protect the traffic flowing through the multicast LDP LSP, you can configure an explicit tunnel to re-route the traffic in the event of link failure. The explicit path has to terminate on the next downstream router. The reverse path forwarding for the traffic should be successful.

Multicast LDP link protection introduces the following features and functionality:

- Use of dynamic RSVP LSP as bypass tunnels

The RSVP LSP's Explicit Route Object (ERO) is calculated using Constrained Shortest Path First (CSPF) with the constraint as the link to avoid. The LSP is signaled and torn down dynamically whenever link protection is necessary.

- Make-before-break

The make-before-break feature ensures that there is minimum packet loss when attempting to signal a new LSP path before tearing down the old LSP path for the multicast LDP LSP.

- Targeted LDP session

A targeted adjacency to the downstream label-switching router (LSR) is created for two reasons:

- To keep the session up after link failure.
- To use the point-to-multipoint label received from the session to send traffic to the downstream LSR on the RSVP LSP bypass tunnel.

When the downstream LSR sets up the multicast LDP LSP with the root node and LSP ID, it uses that upstream LSR, which is on the best path toward the root.

**NOTE:** Multicast LDP link protection is not required when there are multiple link adjacencies (parallel links) to the downstream LSR.

### Different Modes for Providing LDP Link Protection

Following are three different modes of operation available for unicast and multicast LDP link protection:

- **Case A: LFA only**

Under this mode of operation, multicast LDP link protection is provided using an existing viable loop-free alternate (LFA). In the absence of a viable LFA, link protection is not provided for the multicast LDP LSP.

- **Case B: LFA and Dynamic RSVP LSP**

Under this mode of operation, multicast LDP link protection is provided using an existing viable LFA. In the absence of a viable LFA, an RSVP bypass LSP is created automatically to provide link protection for the multicast LDP LSP.

- **Case C: Dynamic RSVP LSP only**

Under this mode of operation, LFA is not used for link protection. Multicast LDP link protection is provided by using automatically created RSVP bypass LSP.

Figure 58 on page 634 is a sample topology illustrating the different modes of operation for multicast LDP link protection. Router R5 is the root connecting to two leaf nodes, Routers R3 and R4. Router R0 and Router R1 are the upstream and downstream label-switched routers (LSRs), respectively. A multicast LDP LSP runs among the root and leaf nodes.

**Figure 58: Multicast LDP Link Protection Sample Topology**

Considering that Router R0 needs to protect the multicast LDP LSP in the case that the R0-R1 link fails, the different modes of link protection operate in the following manner:

- **Case A: LFA only**

Router R0 checks if a viable LFA path exists that can avoid the R0-R1 link to reach Router R1. Based on the metrics, Router R2 is a valid LFA path for the R0-R1 link and is used to forward unicast LDP traffic. If multiple multicast LDP LSPs use the R0-R1 link, the same LFA (Router R2) is used for multicast LDP link protection.

When the R0-R1 link fails, the multicast LDP LSP traffic is moved onto the LFA path by Router R0, and the unicast LDP label to reach Router R1 (L100) is pushed on top of the multicast LDP label (L21).

- **Case B: LFA and Dynamic RSVP LSP**

Router R0 checks if a viable LFA path exists that can avoid the R0-R1 link to reach Router R1. Based on the metrics, Router R2 is a valid LFA path for the R0-R1 link and is used to forward unicast LDP traffic. If multiple multicast LDP LSPs use the R0-R1 link, the same LFA (Router R2) is used for multicast LDP link protection. When the R0-R1 link fails, the multicast LDP LSP traffic is moved onto the LFA path by Router R0.

However, if the metric on the R2-R1 link was 50 instead of 10, Router R2 is not a valid LFA for the R0-R1 link. In this case, an RSVP LSP is automatically created to protect the multicast LDP traffic traveling between Routers R0 and R1.

- **Case C: Dynamic RSVP LSP only**

An RSVP LSP is signaled automatically from Router R0 to Router R1 through Router R2, avoiding interface ge-1/1/0. If multiple multicast LDP LSPs use the R0-R1 link, the same RSVP LSP is used for multicast LDP link protection.

When the R0-R1 link fails, the multicast LDP LSP traffic is moved onto the RSVP LSP by Router R0, and the RSVP label to reach Router R1 (L100) is pushed on top of the multicast LDP label (L21).

### Label Operation for LDP Link Protection

Using the same network topology as in Figure 5, [Figure 59 on page 635](#) illustrates the label operation for unicast and multicast LDP link protection.

**Figure 59: LDP Label Operation Sample Topology**

Router R5 is the root connecting to two leaf nodes, Routers R3 and R4. Router R0 and Router R1 are the upstream and downstream label-switched routers (LSRs), respectively. A multicast LDP LSP runs among the root and leaf nodes. An unicast LDP path connects Router R1 to Router R5.

The label operation is performed differently under the following modes of LDP link protection:

- [Case A: LFA Only on page 636](#)
- [Case B: LFA and Dynamic RSVP LSP on page 639](#)
- [Case C: Dynamic RSVP LSP Only on page 641](#)

**Case A: LFA Only**

Using the **show route detail** command output on Router R0, the unicast LDP traffic and multicast LDP traffic can be derived.

```

user@R0> show route detail

          Task: LDP
          Announcement bits (1): 0-KRT
          AS path: I
          FECs bound to route: P2MP root-addr 192.168.0.5, lsp-id 99

```

Label 299840 is traffic arriving at Router R0 that corresponds to unicast LDP traffic to Router R1. Label 299856 is traffic arriving at Router 0 that corresponds to multicast LDP traffic from the root node R5 to the leaf egress nodes, R3 and R4.

The main path for both unicast and multicast LDP LSPs is through interface ge-0/0/1 (the link to Router R1), and the LFA path is through interface ge-0/0/2 (the link to Router R2). The LFA path is not used unless the ge-0/0/1 interface goes down.

In the label operation for Case A, the LFA-only mode of operation is different for unicast and multicast LDP traffic:

- Unicast label operation

For unicast LDP traffic, the FECs and associated labels are advertised on all the links in the network on which LDP is enabled. This means that in order to provide LFA action for the unicast LDP traffic to Router R4, instead of swapping the incoming label for label 299824 advertised by Router R1 for FEC R4, Router R0 simply swaps the incoming label for label 299808 advertised by Router R2 for FEC R4. This is the standard Junos OS LFA operation for unicast LDP traffic.

Figure 60 on page 637 illustrates the label operation for unicast traffic when the R0-R1 link fails. The grey boxes show the label operation for unicast LDP traffic under normal condition, and the dotted boxes show the label operation for unicast LDP traffic when the R0-R1 link fails.

Figure 60: Unicast LDP Label Operation

- Multicast label operation

The label operation for multicast LDP traffic differs from the unicast LDP label operation, because multipoint LSP labels are only advertised along the best path from the leaf node to the ingress node. As a result, Router R2 has no knowledge of the multicast LDP. To overcome this, the multicast LDP LSP traffic is simply tunneled inside the unicast LDP LSP path through Router R2 that terminates at Router R1.

In order to achieve this, Router R0 first swaps the incoming multicast LDP LSP label 299856 to label 299888 advertised by Router R1. Label 299776 is then pushed on top, which is the LDP label advertised by Router R2 for FEC R1. When the packet arrives at Router R2, the top label is popped out due to penultimate hop-popping. This means that the packet arrives at Router R1 with the multicast LDP label 299888 that Router R1 had originally advertised to Router R0.

Figure 61 on page 638 illustrates the label operation for multicast LDP traffic when the R0-R1 link fails. The blue boxes show the label operation for multicast LDP traffic under normal condition, and the dotted boxes show the label operation for multicast LDP traffic when the R0-R1 link fails.

Figure 61: Multicast LDP Label Operation

When the metric on the R2-R1 link is set to 1000 instead of 1, Router R2 is not a valid LFA for Router R0. In this case, if Router R2 receives a packet destined for Router R1, R3, or R4 before its IGP has converged, the packet is sent back to Router R0, resulting in looping packets.

Because Router R0 has no viable LFA, no backup paths are installed in the Packet Forwarding Engine. If the R0-R1 link fails, traffic flow is interrupted until the IGP and LDP converge and new entries are installed on the affected routers.

The **show route detail** command displays the state when no LFA is available for link protection.

```
user@host> show route detail

```

### Case B: LFA and Dynamic RSVP LSP

In this mode of operation, if there is a viable LFA neighbor, the label operation behavior is similar to that of Case A, LFA only mode. However, if there is no viable LFA neighbor, an RSVP bypass tunnel is automatically created.

If the metric on the link R2-R1 is set to 1000 instead of 1, Router R2 is not an LFA for Router R0. On learning that there are no LFA paths to protect the R0-R1 link failure, an RSVP bypass tunnel is automatically created with Router R1 as the egress node and follows a path that avoids the R0-R1 link (for instance, R0-R2-R1).

If the R0-R1 link fails, the unicast LDP and multicast LDP traffic is tunneled through the RSVP bypass tunnel. The RSVP bypass tunnel is not used for normal forwarding and is used only to provide link protection to LDP traffic in the case of R0-R1 link failure.

Using the **show route detail** command, the unicast and multicast LDP traffic can be derived.

```

user@host> show route detail

FECs bound to route: P2MP root-addr 192.168.0.5, lsp-id 99
```

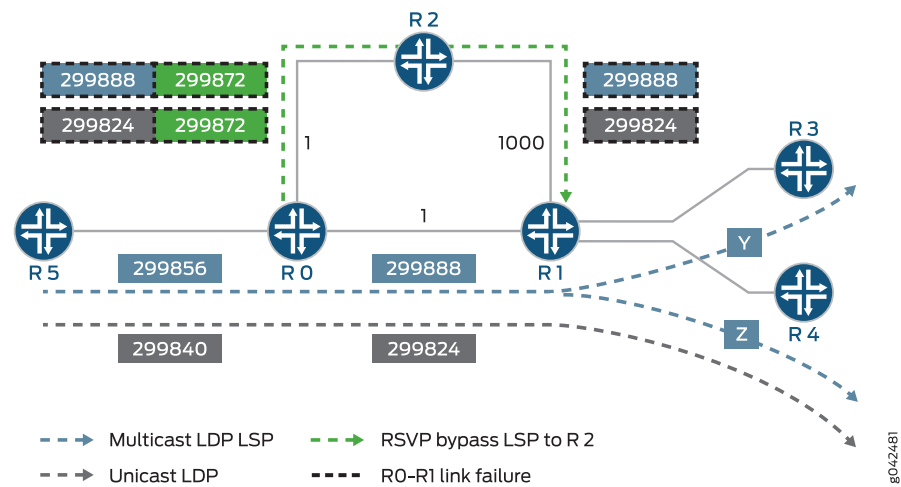

The main path for both unicast and multicast LDP LSP is through interface ge-0/0/1 (the link to Router R1), and the LFA path is through interface ge-0/0/2 (the link to Router R2). The LFA path is not used unless the ge-0/0/1 interface goes down.

Label 299840 is traffic arriving at Router R0 that corresponds to unicast LDP traffic to Router R4. Label 299856 is traffic arriving at Router 0 that corresponds to multicast LDP traffic from the root node R5 to the leaf egress nodes, R3 and R4.

As seen in the **show route detail** command output, the label operations for the protection path are the same for unicast LDP and multicast LDP traffic. The incoming LDP label at Router R0 is swapped to the LDP label advertised by Router R1 to Router R0. The RSVP label 299872 for the bypass tunnel is then pushed onto the packet. Penultimate hop-popping is used on the bypass tunnel, causing Router R2 to pop that label. Thus the packet arrives at Router R1 with the LDP label that it had originally advertised to Router R0.

[Figure 62 on page 641](#) illustrates the label operation for unicast LDP and multicast LDP traffic protected by the RSVP bypass tunnel. The grey and blue boxes represent label values used under normal conditions for unicast and multicast LDP traffic, respectively. The dotted boxes represent label values used when the R0-R1 link fails.

### Figure 62: LDP Link Protection Label Operation

### Case C: Dynamic RSVP LSP Only

In this mode of operation, LFA is not used at all. A dynamic RSVP bypass LSP is automatically created in order to provide link protection. The output from the **show route detail** command and the label operations are similar to Case B, LFA and dynamic RSVP LSP mode.

## Sample Multicast LDP Link Protection Configuration

To enable multicast LDP link protection, the following configuration is required on Router R0:

**NOTE:** In this sample, multicast LDP link protection is enabled on the ge-1/0/0 interface of Router R0 that connects to Router R1, although typically all the interfaces need to be configured for link protection.

```
Router R0      protocols {
    rsvp {
        interface all;
        interface ge-0/0/0.0 {
            disable;
        }
    }
    mpls {
        interface all;
        interface ge-0/0/0.0 {
            disable;
        }
    }
    ospf {
        traffic-engineering;
```

```
area 0.0.0.0 {
  interface lo0.0;
  interface ge-0/0/1.0 {
    link-protection;
  }
  interface ge-0/0/2.0;
  interface ge-0/0/3.0;
}
}
ldp {
  make-before-break {
    timeout seconds;
    switchover-delay seconds;
  }
  interface ge-1/1/0.0 {
    link-protection {
      disable;
      dynamic-rsvp-lsp;
    }
  }
}
}
```

The following configuration statements apply to the different modes of multicast LDP protection as follows:

- **link-protection** statement at **[edit protocols ospf interface ge-0/0/1.0]**

This configuration is applied only for Case A (LFA only) and Case B (LFA and dynamic RSVP LSP) modes of multicast LDP link protection. Configuring link protection under an IGP is not required for Case C (dynamic RSVP LSP only).

- **link-protection** statement at **[edit protocols ldp interface ge-0/0/1.0]**

This configuration is required for all modes of multicast LDP protection. However, if the only LDP traffic present is unicast, and dynamic RSVP bypasses are not required, then this configuration is not required, as the **link-protection** statement at the **[edit protocols ospf interface ge-0/0/1.0]** hierarchy level results in LFA action for the LDP unicast traffic.

- **dynamic-rsvp-lsp** statement at **[edit protocols ldp interface ge-0/0/1.0 link-protection]**

This configuration is applied only for Case B (LFA and dynamic RSVP LSP) and Case C (dynamic RSVP LSP only) modes of LDP link protection. Dynamic RSVP LSP configuration does not apply to Case A (LFA only).

---

### Make-Before-Break

The make-before-break feature is enabled by default on Junos OS and provides some benefits for point-to-multipoint LSPs.

For a point-to-multipoint LSP, a label-switched router (LSR) selects the LSR that is its next hop to the root of the LSP as its upstream LSR. When the best path to reach the root changes, the LSR chooses a new upstream LSR. During this period, the LSP might be temporarily broken, resulting in packet loss until the LSP reconverges to a new

upstream LSR. The goal of make-before-break in this case is to minimize the packet loss. In cases where the best path from the LSR to the root changes but the LSP continues to forward traffic to the previous next hop to the root, a new LSP should be established before the old LSP is withdrawn to minimize the duration of packet loss.

Taking for example, after a link failure, a downstream LSR (for instance, LSR-D) still receives and/or forwards packets to the other downstream LSRs, as it continues to receive packets from the one hop RSVP LSP. Once routing converges, LSR-D selects a new upstream LSR (LSR-U) for this point-to-multipoint LSP's FEC (FEC-A). The new LSR might already be forwarding packets for FEC-A to the downstream LSRs other than LSR-D. After LSR-U receives a label for FEC-A from LSR-D, it notifies LSR-D when it has learnt that LSP for FEC-A has been established from the root to itself. When LSR-D receives such a notification, it changes its next hop for the LSP root to LSR-U. This is a route delete and add operation on LSR-D. At this point, LSR-D does an LSP switchover, and traffic tunneled through RSVP LSP or LFA is dropped, and traffic from LSR-U is accepted. The new transit route for LSR-U is added. The RPF check is changed to accept traffic from LSR-U and to drop traffic from the old upstream LSR, or the old route is deleted and the new route is added.

The assumption is that LSR-U has received a make-before-break notification from its upstream router for the FEC-A point-to-multipoint LSP and has installed a forwarding state for the LSP. At that point it should signal LSR-D by means of make-before-break notification that it has become part of the tree identified by FEC-A and that LSR-D should initiate its switchover to the LSP. Otherwise, LSR-U should remember that it needs to send notification to LSR-D when it receives a make-before-break notification from the upstream LSR for FEC-A and installs a forwarding state for this LSP. LSR-D continues to receive traffic from the old next hop to the root node using one hop RSVP LSP or LFA path until it switches over to the new point-to-multipoint LSP to LSR-U.

The make-before-break functionality with multicast LDP link protection includes the following features:

- Make-before-break capability

An LSR advertises that it is capable of handling make-before-break LSPs using the capability advertisement. If the peer is not make-before-break capable, the make-before-break parameters are not sent to this peer. If an LSR receives a make-before-break parameter from a downstream LSR (LSR-D) but the upstream LSR (LSR-U) is not make-before-break capable, the LSR immediately sends a make-before-break notification to LSR-D, and the make-before-break capable LSP is not established. Instead, the normal LSP is established.

- Make-before-break status code

The make-before-break status code includes:

- 1—make-before-break request
- 2—make-before-break acknowledgment

When a downstream LSR sends a label-mapping message for point-to-multipoint LSP, it includes the make-before-break status code as 1 (request). When the upstream LSR updates the forwarding state for the point-to-multipoint LSP, it informs the

downstream LSR with a notification message containing the make-before-break status code as 2 (acknowledgment). At that point, the downstream LSR does an LSP switchover.

### Caveats and Limitations

---

The Junos OS implementation of the LDP link protection feature has the following caveats and limitations:

- Make-before-break is not supported for the following point-to-multipoint LSPs on an egress LSR:
  - Next-generation multicast virtual private network (MVPN) with virtual routing and forwarding (VRF) label
  - Static LSP
- The following features are not supported:
  - Nonstop active routing for point-to-multipoint LSP in Junos OS Releases 12.3, 13.1 and 13.2
  - Graceful restart switchover point-to-multipoint LSP
  - Link protection for routing instance

## Understanding Multicast-Only Fast Reroute

---

Starting in Junos OS Release 14.1, Multicast-only fast reroute (MoFRR) functionality is available, in which packet loss is minimized in PIM and multipoint LDP domains. MoFRR minimizes packet loss in a network when there is a link failure. It works by enhancing multicast routing protocols like Protocol Independent Multicast (PIM) and multipoint Label Distribution Protocol (multipoint LDP). MoFRR is supported on MX Series routers with MPC line cards. As a prerequisite, the router must be set to **network-services enhanced-ip** mode, and all the line-cards in the router must be MPCs.

With MoFRR enabled, join messages are sent on primary and backup upstream paths. Data packets are received from both the primary path and the backup paths. The redundant packets are discarded based on priority (weights that are assigned to the primary and backup paths). When a failure is detected on the primary path, the repair is made by changing the interface on which packets are accepted to the secondary interface. Because the repair is local, it is fast—greatly improving convergence times in the event of a link failure on the primary path.

Currently, the most likely real-world application for MoFRR is streaming IPTV. IPTV streams are multicast as UDP streams. Therefore, any lost packets are not retransmitted, and this can result in a less-than-satisfactory user experience. MoFRR can be used to improve this situation.

When fast reroute is applied to unicast streams, an upstream router preestablishes MPLS label-switched paths (LSPs) or precomputes an IP loop-free alternate (LFA) fast reroute backup path to handle failure of a segment in the downstream path.

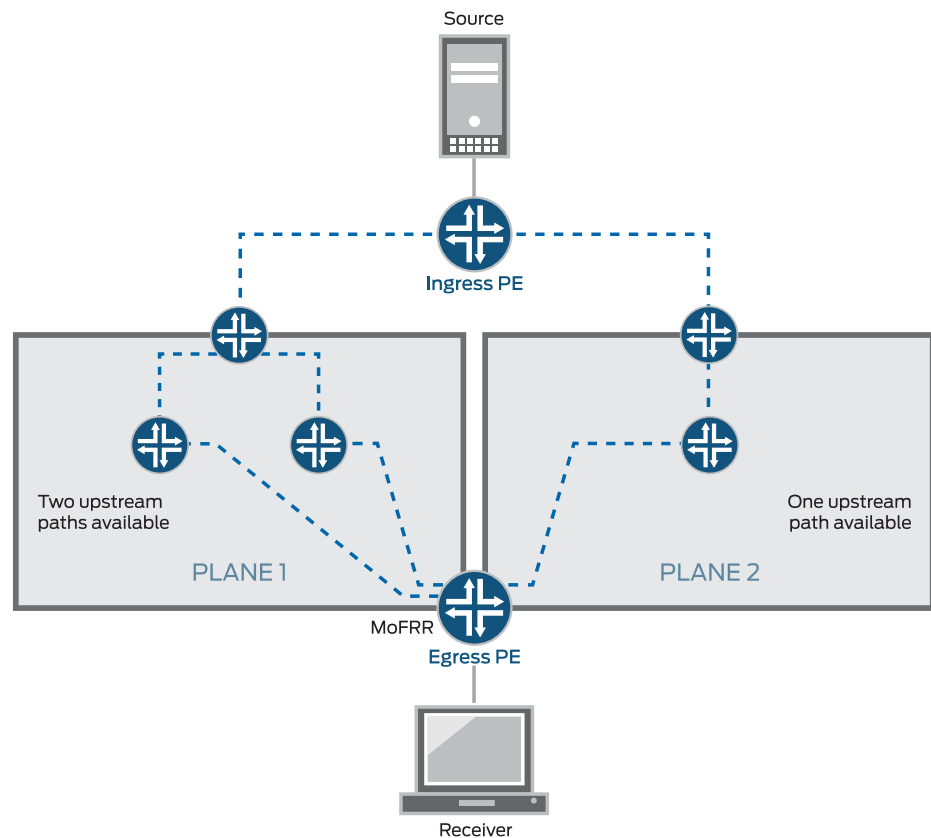

In multicast routing, the traffic distribution graphs are usually originated by the receiver. This is unlike unicast routing, which usually establishes the path from the source to the receiver. Protocols that are capable of establishing multicast distribution graphs are PIM (for IP), multipoint LDP (for MPLS), and RSVP-TE (for MPLS). Of these, PIM and multipoint LDP receivers initiate the distribution graph setup, and therefore these are the two multicast protocols for which MoFRR is supported.

In a multicast tree, performing a reactive repair upon detection of a network-component failure can lead to significant traffic loss due to delay in setting up the alternative path. MoFRR reduces traffic loss in a multicast distribution tree when a network component fails. With MoFRR, one of the downstream routers that supports this feature sets up an alternative path toward the source to receive a backup live stream of the same multicast traffic. When a failure is detected on the primary stream, the MoFRR router switches to the backup stream.

With MoFRR enabled, for each (S,G) entry, two of the available upstream interfaces are used to send a join message and to receive multicast traffic. The protocol attempts to select two disjoint paths if two such paths are available. If disjoint paths are not available, the protocol selects two nondisjoint paths. If two nondisjoint paths are not available, only a primary path is selected with no backup. MoFRR is supported for both IPv4 and IPv6 protocol families.

[Figure 63 on page 646](#) shows two paths from the egress provider edge (PE) router to the ingress PE router.

Figure 63: MoFRR Sample Topology

8041674

When enabled with MoFRR functionality, the egress router sets up two multicast trees, a primary path and a backup path, toward the multicast source for each (S,G). In other words, the egress router propagates the same (S,G) join messages toward two different upstream neighbors, thus creating two multicast trees.

One of the multicast trees goes through plane 1 and the other through plane 2, as shown in [Figure 63 on page 646](#). For each (S,G), the egress PE router forwards traffic received on the primary path and drops traffic received on the backup path.

MoFRR is supported on both equal-cost multipath (ECMP) paths and non-ECMP paths. Unicast loop-free alternate (LFA) routes need to be enabled to support MoFRR on non-ECMP paths. LFA routes are enabled with the **link-protection** statement in the interior gateway protocol (IGP) configuration. When you enable link protection on an OSPF or IS-IS interface, Junos OS creates a backup LFA path to the primary next hop for all destination routes that traverse the protected interface.

Junos OS implements MoFRR in the IP network for IP MoFRR and at the MPLS label-edge router (LER) for multipoint LDP MoFRR.

Multipoint LDP MoFRR is used at the egress node of an MPLS network, where the packets are forwarded to an IP network. In the case of multipoint LDP MoFRR, the two paths toward the upstream PE router are established for receiving two streams of MPLS packets at the LER. One of the streams (the primary) is accepted, and the other one (the backup)

is dropped at the LER. The backup stream is accepted if the primary path fails. A prerequisite for this feature is inband signaling support, as described in [“Understanding Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs” on page 692](#).

## PIM Functionality

Junos OS supports MoFRR for shortest-path tree (SPT) joins in PIM source-specific multicast (SSM) and any-source multicast (ASM). MoFRR is supported for both SSM and ASM ranges. To enable MoFRR for (\*G) joins, the `mofrr-asm-starg` configuration statement needs to be included. For each group G, either (S,G) or (\*G) (not both) will undergo MoFRR. (S,G) always takes precedence over (\*G).

With MoFRR enabled, a PIM router propagates join messages on two upstream RPF interfaces to receive multicast traffic on both links for the same join request. Preference is given to two paths that do not converge to the same immediate upstream router. PIM installs appropriate multicast routes with upstream RPF next hops with two (primary and backup) interfaces.

When the primary path fails, the backup path is upgraded to primary, and traffic is forwarded accordingly. If there are alternate paths available, a new backup path is calculated and the appropriate multicast route is updated or installed.

MoFRR can be enabled along with PIM join load balancing (with the `join-load-balance automatic` statement). However, in such cases the distribution of join messages among the links might not be even. When a new ECMP link is added, join messages on the primary path are redistributed and load-balanced. The join messages on the backup path might still follow the same path and might not be evenly redistributed.

MoFRR is enabled with a `[edit routing-options multicast stream-protection]` configuration and is managed by a set of filter policies. When an egress PIM router receives a join message or an IGMP report, the router checks for the MoFRR configuration.

If the MoFRR configuration is not present, PIM sends a join message upstream toward one upstream neighbor (for example, plane 2 in [Figure 63 on page 646](#)).

If the MoFRR configuration is present, Junos OS checks for a policy configuration.

If a policy is not present, Junos OS checks for primary and backup paths (upstream interfaces), and takes the following actions:

- If primary and backup paths are not available—PIM sends a join message upstream toward one upstream neighbor (for example, plane 2 in [Figure 63 on page 646](#)).
- If primary and backup paths are available—PIM sends the join message upstream toward two of the available upstream neighbors. Junos OS sets up primary and secondary multicast paths to receive multicast traffic (for example, plane 1 in [Figure 63 on page 646](#)).

If a policy is present, Junos OS checks whether the policy allows MoFRR for this (S,G), and takes the following actions:

- If the policy check fails—PIM sends a join message upstream toward one upstream neighbor (for example, plane 2 in [Figure 63 on page 646](#)).

- If the policy check passes—Junos OS checks for primary and backup paths (upstream interfaces).
- If the primary and backup paths are not available, PIM sends a join message upstream toward one upstream neighbor (for example, plane 2 in [Figure 63 on page 646](#)).
- If the primary and backup paths are available, PIM sends the join message upstream toward two of the available upstream neighbors. Junos OS sets up primary and secondary multicast paths to receive multicast traffic (for example, plane 1 in [Figure 63 on page 646](#)).

## Multipoint LDP Functionality

To avoid MPLS traffic duplication, the usual implementation of multipoint LDP selects only one upstream path. (See section 2.4.1.1. Determining One's 'upstream LSR' in RFC 6388, *Label Distribution Protocol Extensions for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*.)

For multipoint LDP MoFRR, the multipoint LDP node selects two separate upstream peers and sends two separate labels, one to each upstream peer. The same algorithm described in RFC 6388 is used to select the primary upstream path. The backup upstream path selection again uses the same algorithm but excludes the primary upstream LSR as a candidate. Two streams of MPLS traffic are sent to the egress node from the two different upstream peers. The MPLS traffic from only one of the upstream neighbors is selected as the primary path to accept the traffic, and the other path becomes the backup path. The traffic on the backup path is dropped. When the primary upstream path fails, the traffic from the backup path is then accepted. The multipoint LDP node selects the two upstream paths based on the interior gateway protocol (IGP) root node next hop.

A forwarding equivalency class (FEC) is a group of IP packets that are forwarded in the same manner, over the same path, and with the same forwarding treatment. Normally, the label that is put on a particular packet represents the FEC to which that packet is assigned. In MoFRR, two routes are placed into the mpls.0 table for each FEC—one route for the primary label and the other route for the backup label.

If there are parallel links toward the same immediate upstream node, both parallel links are considered to be the primary. At any point in time, the upstream node sends traffic on only one of the multiple parallel links.

A bud node is an LSR that is an egress LSR, but also has one or more directly connected downstream LSRs. In the case of a bud node, the traffic from the primary upstream path is forwarded to a downstream LSR. If the primary upstream path fails, the MPLS traffic from the backup upstream path is forwarded to the downstream LSR. This means that the downstream LSR next hop is added to both MPLS routes along with the egress next hop.

MoFRR for multipoint LDP is enabled with a **[edit routing-options multicast stream-protection]** configuration and is managed by a set of filter policies.

If the multipoint LDP point-to-multipoint FEC is enabled for MoFRR, the following additional considerations are factored into upstream path selection:

- The targeted LDP sessions are skipped if there is a nontargeted LDP session. If there is a single targeted LDP session, the targeted LDP session is selected, but the corresponding point-to-multipoint FEC loses the MoFRR capability because there is no interface associated with the targeted LDP session.
- All interfaces that belong to the same upstream LSR are considered to be the primary path.
- For any root-node route updates, the upstream path is changed based on the latest next hops from the IGP. If a better path is available, multipoint LDP attempts to switch to the better path.

## Packet Forwarding

For both PIM and multipoint LDP, multicast source stream selection is performed at the incoming interface. This prevents duplicate streams from being sent across the fabric and prevents multiple route lookups that result in drops, thus preserving fabric bandwidth and maximizing forwarding performance.

For PIM, each IP multicast stream contains the same destination address. Regardless of the interface on which the packets arrive, the packets have the same route. An interface list is attached to the route. Junos OS checks the interface upon which each packet arrives and forwards only those that are from the primary interface. If the interface matches a secondary interface, the packets are dropped. If no match is found, the packets are handled as exceptions in the control plane.

This process is shown in [Figure 64 on page 649](#).

**Figure 64: MoFRR IP Route Lookup in the Packet Forwarding Engine**

For multipoint LDP, multiple MPLS labels are used to control MoFRR stream selection. Each label represents a separate route, but each references the same interface list check. Only the primary label is forwarded while all others are dropped. Multiple interfaces can receive packets using the same label.

This process is shown in [Figure 65 on page 650](#).

Figure 65: MoFRR MPLS Route Lookup in the Packet Forwarding Engine

## Limitations and Caveats

MoFRR has the following limitations and caveats:

- MoFRR failure detection is supported for immediate link protection of the router on which MoFRR is enabled and not on all the links (end-to-end) in the multicast traffic path.
- MoFRR supports FRR on two selected disjoint paths toward the source. Two of the selected upstream neighbors cannot be on the same interface—in other words, two upstream neighbors on a LAN segment. The same is true if the upstream interface happens to be a multicast tunnel interface.
- Detection of the maximum end-to-end disjoint upstream paths is not supported. The egress router only makes sure that there is a disjoint upstream node (the immediate previous hop). PIM and multipoint LDP do not support the equivalent of explicit route objects (EROs). Hence, disjoint upstream path detection is limited to control over the immediately previous hop node. Because of this limitation, the path to the upstream node of the previous hop selected as primary and backup might be shared.
- MoFRR does not apply to multipoint LDP traffic received on an RSVP tunnel because the RSVP tunnel is not associated with any interface.
- Some traffic loss is seen in the following scenarios:
  - A better upstream path becomes available on an egress node.
  - MoFRR is enabled or disabled on the egress node while there is an active traffic stream flowing.
- PIM join load balancing for join messages for backup paths are not supported.
- For a multicast group G, MoFRR is not allowed for both (S,G) and (\*,G) join messages. (S,G) join messages have precedence over (\*,G).
- MoFRR is not supported for multicast traffic streams that use two different multicast groups. Each (S,G) combination is treated as a unique multicast traffic stream.
- The bidirectional PIM range is not supported for MoFRR.
- PIM dense-mode is not supported for MoFRR.

- Mixed upstream MoFRR is not supported. This refers to PIM multipoint LDP in-band signaling, wherein one upstream path is through multipoint LDP and the second upstream path is through PIM.
- Multicast statistics for the backup traffic stream are not maintained by PIM and therefore are not available in the operational output of **show** commands.
- Multipoint LDP labels as inner labels are not supported.
- If the source is reachable through multiple ingress provider edge (PE) routers, multipoint LDP MoFRR is not supported.
- Targeted upstream sessions are not selected as the upstream node for MoFRR.
- Rate monitoring is not supported.
- Multipoint LDP link protection on the backup path is not supported because there is no support for MoFRR inner labels.

Release History Table

## Configuring Multicast-Only Fast Reroute

You can configure multicast-only fast reroute (MoFRR) to minimize packet loss in a network when there is a link failure.

When fast reroute is applied to unicast streams, an upstream router preestablishes MPLS label-switched paths (LSPs) or precomputes an IP loop-free alternate (LFA) fast reroute backup path to handle failure of a segment in the downstream path.

In multicast routing, the traffic distribution graphs are usually originated by the receiver. This is unlike unicast routing, which usually establishes the path from the source to the receiver. Protocols that are capable of establishing multicast distribution graphs are PIM (for IP), multipoint LDP (for MPLS) and RSVP-TE (for MPLS). Of these, PIM and multipoint LDP receivers initiate the distribution graph setup, and therefore these are the two multicast protocols for which MoFRR is supported.

MoFRR is supported on MX Series routers with MPC line cards. As a prerequisite, all the line cards in the router must be MPCs.

Make sure that all of the

To configure MoFRR:

1. Set the router to enhanced IP mode.

```
[edit chassis]
user@host# set network-services enhanced-ip
```

2. Enable MoFRR.

```
[edit routing-options multicast]
user@host# set stream-protection
```

3. (Optional) Configure a routing policy that filters for a restricted set of multicast streams to be affected by your MoFRR configuration.

You can apply filters that are based on source or group addresses.

For example:

```
[edit policy-options]
policy-statement mofrr-select {
  term A {
    from {
      source-address-filter 225.1.1.1/32 exact;
    }
    then {
      accept;
    }
  }
  term B {
    from {
      source-address-filter 226.0.0.0/8 orlonger;
    }
    then {
      accept;
    }
  }
  term C {
    from {
      source-address-filter 227.1.1.0/24 orlonger;
      source-address-filter 227.4.1.0/24 orlonger;
      source-address-filter 227.16.1.0/24 orlonger;
    }
    then {
      accept;
    }
  }
  term D {
    from {
      source-address-filter 227.1.1.1/32 exact
    }
    then {
      reject; #MoFRR disabled
    }
  }
  ...
}
```

4. (Optional) If you configured a routing policy to filter the set of to be affected by your MoFRR configuration, apply the policy.

```
[edit routing-options multicast stream-protection]
user@host# set policy policy-name
```

For example:

```
routing-options {
  multicast {
    stream-protection {
      policy mofrr-select
    }
  }
}
```

5. (Optional) In a PIM domain with MoFRR, allow MoFRR to be applied to any-source multicast (ASM) (\*,G) joins.

This is not supported for multipoint LDP MoFRR.

```
[edit routing-options multicast stream-protection]
user@host# set mofrr-asm-starg
```

6. (Optional) In a PIM domain with MoFRR, allow only a disjoint RPF (an RPF on a separate plane) to be selected as the backup RPF path.

This is not supported for multipoint LDP MoFRR. In a multipoint LDP MoFRR domain, the same label is shared between parallel links to the same upstream neighbor. This is not the case in a PIM domain, where each link forms a neighbor. The **mofrr-disjoint-upstream-only** statement does not allow a backup RPF path to be selected if the path goes to the same upstream neighbor as that of the primary RPF path. This ensures that MoFRR is triggered only on a topology that has multiple RPF upstream neighbors.

```
[edit routing-options multicast stream-protection]
user@host# set mofrr-disjoint-upstream-only
```

7. (Optional) In a PIM domain with MoFRR, prevent sending join messages on the backup path, but retain all other MoFRR functionality.

This is not supported for multipoint LDP MoFRR.

```
[edit routing-options multicast stream-protection]
user@host# set mofrr-no-backup-join
```

8. (Optional) In a PIM domain with MoFRR, allow new primary path selection to be based on the unicast gateway selection for the unicast route to the source and to change when there is a change in the unicast selection, rather than having the backup path be promoted as primary. This ensures that the primary RPF hop is always on the best path.

When you include the **mofrr-primary-selection-by-routing** statement, the backup path is not guaranteed to get promoted to be the new primary path when the primary path goes down.

This is not supported for multipoint LDP MoFRR.

```
[edit routing-options multicast stream-protection]
```

```
user@host# set mofrr-primary-path-selection-by-routing
```

## Example: Configuring Multicast-Only Fast Reroute in a Multipoint LDP Domain

---

This example shows how to configure multicast-only fast reroute (MoFRR) to minimize packet loss in a network when there is a link failure.

Multipoint LDP MoFRR is used at the egress node of an MPLS network, where the packets are forwarded to an IP network. In the case of multipoint LDP MoFRR, the two paths toward the upstream provider edge (PE) router are established for receiving two streams of MPLS packets at the label-edge router (LER). One of the streams (the primary) is accepted, and the other one (the backup) is dropped at the LER. The backup stream is accepted if the primary path fails.

### Requirements

No special configuration beyond device initialization is required before configuring this example.

In a multipoint LDP domain, for MoFRR to work, only the egress PE router needs to have MoFRR enabled. The other routers do not need to support MoFRR.

MoFRR is supported on MX Series platforms with MPC line cards. As a prerequisite, the router must be set to **network-services enhanced-ip** mode, and all the line-cards in the platform must be MPCs.

This example requires Junos OS Release 14.1 or later on the egress PE router.

### Overview

In this example, Device R3 is the egress edge router. MoFRR is enabled on this device only.

OSPF is used for connectivity, though any interior gateway protocol (IGP) or static routes can be used.

For testing purposes, routers are used to simulate the source and the receiver. Device R4 and Device R8 are configured to statically join the desired group by using the **set protocols**

**igmp interface interface-name static group group** command. In the case when a real multicast receiver host is not available, as in this example, this static IGMP configuration is useful. On the receivers, to make them listen to the multicast group address, this example uses **set protocols sap listen group**.

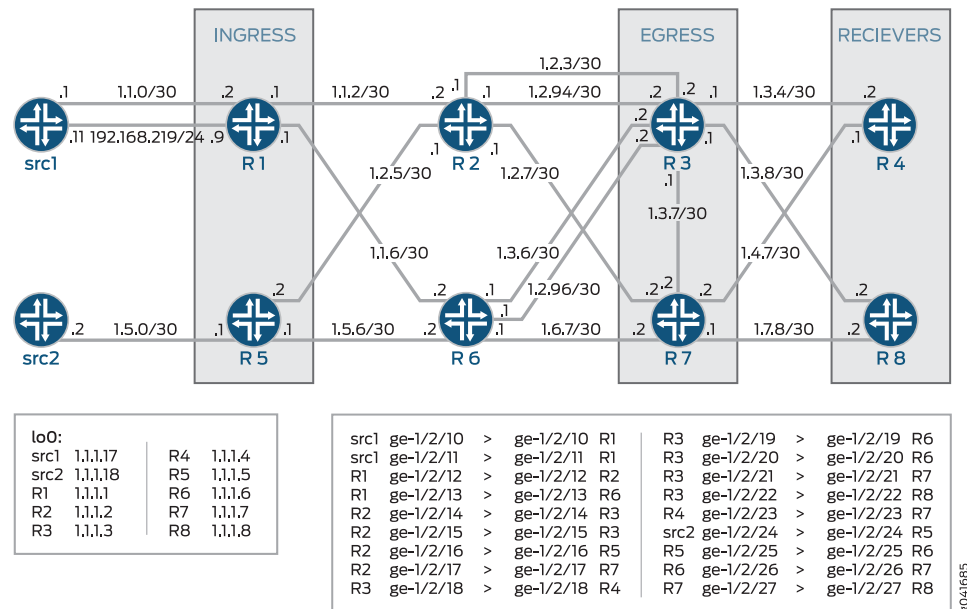

MoFRR configuration includes a policy option that is not shown in this example, but is explained separately. The option is configured as follows:

```
stream-protection {
  policy policy-name;
}
```

### Topology

Figure 66 on page 655 shows the sample network.

Figure 66: MoFRR in a Multipoint LDP Domain

“CLI Quick Configuration” on page 655 shows the configuration for all of the devices in Figure 66 on page 655.

The section “Configuration” on page 661 describes the steps on Device R3.

### CLI Quick Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

**Device src1**

## Configuration

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device R3:

1. Enable enhanced IP mode.
 

```

[edit chassis]
user@R3# set network-services enhanced-ip

```
2. Configure the device interfaces.
 

```

[edit interfaces]
user@R3# set ge-1/2/14 unit 0 description R3-to-R2
user@R3# set ge-1/2/14 unit 0 family inet address 1.2.3.2/30
user@R3# set ge-1/2/14 unit 0 family mpls

user@R3# set ge-1/2/18 unit 0 description R3-to-R4
user@R3# set ge-1/2/18 unit 0 family inet address 1.3.4.1/30
user@R3# set ge-1/2/18 unit 0 family mpls

```

```
user@R3# set ge-1/2/19 unit 0 description R3-to-R6
user@R3# set ge-1/2/19 unit 0 family inet address 1.3.6.2/30
user@R3# set ge-1/2/19 unit 0 family mpls
```

```
user@R3# set ge-1/2/21 unit 0 description R3-to-R7
user@R3# set ge-1/2/21 unit 0 family inet address 1.3.7.1/30
user@R3# set ge-1/2/21 unit 0 family mpls
```

```
user@R3# set ge-1/2/22 unit 0 description R3-to-R8
user@R3# set ge-1/2/22 unit 0 family inet address 1.3.8.1/30
user@R3# set ge-1/2/22 unit 0 family mpls
```

```
user@R3# set ge-1/2/15 unit 0 description R3-to-R2
user@R3# set ge-1/2/15 unit 0 family inet address 1.2.94.2/30
user@R3# set ge-1/2/15 unit 0 family mpls
```

```
user@R3# set ge-1/2/20 unit 0 description R3-to-R6
user@R3# set ge-1/2/20 unit 0 family inet address 1.2.96.2/30
user@R3# set ge-1/2/20 unit 0 family mpls
```

```
user@R3# set lo0 unit 0 family inet address 1.1.1.3/32 primary
```

3. Configure the autonomous system (AS) number.

```
user@R3# set routing-options autonomous-system 10
```

4. Configure the routing policies.

```
[edit policy-options policy-statement mldppim-ex]
user@R3# set term B from source-address-filter 192.168.0.0/24 orlonger
user@R3# set term B from source-address-filter 192.168.219.11/32 orlonger
user@R3# set term B then accept
user@R3# set term A from source-address-filter 1.1.0.1/30 orlonger
user@R3# set term A then accept
```

```
[edit policy-options policy-statement static-route-tobgp]
user@R3# set term static from protocol static
user@R3# set term static from protocol direct
user@R3# set term static then accept
```

5. Configure PIM.

```
[edit protocols pim]
user@R3# set mldp-inband-signalling policy mldppim-ex
user@R3# set interface lo0.0
user@R3# set interface ge-1/2/18.0
user@R3# set interface ge-1/2/22.0
```

6. Configure LDP.

```
[edit protocols ldp]
user@R3# set interface all
user@R3# set p2mp
```

7. Configure an IGP or static routes.

```
[edit protocols ospf]
```

```

user@R3# set traffic-engineering
user@R3# set area 0.0.0.0 interface all
user@R3# set area 0.0.0.0 interface fxp0.0 disable
user@R3# set area 0.0.0.0 interface lo0.0 passive

```

8. Configure internal BGP.

```

[edit protocols bgp group ibgp]
user@R3# set local-address 1.1.1.3
user@R3# set peer-as 10
user@R3# set neighbor 1.1.1.1
user@R3# set neighbor 1.1.1.5

```

9. Configure MPLS and, optionally, RSVP.

```

[edit protocols mpls]
user@R3# set interface all

```

```

[edit protocols rsvp]
user@R3# set interface all

```

10. Enable MoFRR.

```

[edit routing-options multicast]
user@R3# set stream-protection

```

**Results** From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@R3# show chassis
network-services enhanced-ip;

user@R3# show interfaces

    stream-protection;  
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Checking the LDP Point-to-Multipoint Forwarding Equivalency Classes on page 666](#)
- [Examining the Label Information on page 666](#)
- [Checking the Multicast Routes on page 668](#)
- [Checking the LDP Point-to-Multipoint Traffic Statistics on page 669](#)

---

### Checking the LDP Point-to-Multipoint Forwarding Equivalency Classes

**Purpose** Make sure the MoFRR is enabled, and determine what labels are being used.

**Action** user@R3> show ldp p2mp fec

```
LDP P2MP FECs:  
P2MP root-addr 1.1.1.1, grp: 232.1.1.1, src: 192.168.219.11  
  MoFRR enabled  
  Fec type: Egress (Active)  
  Label: 301568  
P2MP root-addr 1.1.1.1, grp: 232.1.1.2, src: 192.168.219.11  
  MoFRR enabled  
  Fec type: Egress (Active)  
  Label: 301600
```

**Meaning** The output shows that MoFRR is enabled, and it shows that the labels 301568 and 301600 are being used for the two multipoint LDP point-to-multipoint LSPs.

---

### Examining the Label Information

**Purpose** Make sure that the egress device has two upstream interfaces for the multicast group join.

**Action** user@R3> show route label 301568 detail

```

mpls.0: 18 destinations, 18 routes (18 active, 0 holddown, 0 hidden)

(Active)
P2MP path type: Transit/Egress
  Output Session (label): 1.1.1.2:0 (301616) (Backup)
  Egress Nexthops: Interface ge-1/2/18.0
                   Interface ge-1/2/22.0
  RPF Nexthops:   Interface ge-1/2/15.0, 1.2.94.1, 301616, 65534
                   Interface ge-1/2/20.0, 1.2.96.1, 301600, 1
                   Interface ge-1/2/14.0, 1.2.3.1, 301616, 65534
                   Interface ge-1/2/19.0, 1.3.6.1, 301600, 1
  Attached FECs:  P2MP root-addr 1.1.1.1, grp: 232.1.1.2, src: 192.168.219.11
(Active)

```

**Meaning** The output shows primary and backup sessions, and RPF next hops.

### Checking the LDP Point-to-Multipoint Traffic Statistics

**Purpose** Make sure that both primary and backup statistics are listed.

**Action** user@R3> `show ldp traffic-statistics p2mp`

P2MP FEC Statistics:

| FEC(root_addr:lsp_id/grp,src)                                 | Nexthop | Packets | Bytes |
|---------------------------------------------------------------|---------|---------|-------|
| Shared                                                        |         |         |       |
| 1.1.1.1:232.1.1.1,192.168.219.11, Label: 301568               | 1.3.8.2 | 0       | 0     |
| No                                                            | 1.3.4.2 | 0       | 0     |
| No                                                            |         |         |       |
| 1.1.1.1:232.1.1.1,192.168.219.11, Label: 301584, Backup route | 1.3.4.2 | 0       | 0     |
| No                                                            | 1.3.8.2 | 0       | 0     |
| No                                                            |         |         |       |
| 1.1.1.1:232.1.1.2,192.168.219.11, Label: 301600               | 1.3.8.2 | 0       | 0     |
| No                                                            | 1.3.4.2 | 0       | 0     |
| No                                                            |         |         |       |
| 1.1.1.1:232.1.1.2,192.168.219.11, Label: 301616, Backup route | 1.3.4.2 | 0       | 0     |
| No                                                            | 1.3.8.2 | 0       | 0     |
| No                                                            |         |         |       |

**Meaning** The output shows both primary and backup routes with the labels.

## Example: Configuring LDP Downstream on Demand

This example shows how to configure LDP downstream on demand. LDP is commonly configured using downstream unsolicited advertisement mode, meaning label advertisements for all routes are received from all LDP peers. As service providers integrate the access and aggregation networks into a single MPLS domain, LDP downstream on demand is needed to distribute the bindings between the access and aggregation networks and to reduce the processing requirements for the control plane.

Downstream nodes could potentially receive tens of thousands of label bindings from upstream aggregation nodes. Instead of learning and storing all label bindings for all possible loopback addresses within the entire MPLS network, the downstream aggregation node can be configured using LDP downstream on demand to only request the label bindings for the FECs corresponding to the loopback addresses of those egress nodes on which it has services configured.

- [Verification on page 674](#)

## Requirements

This example uses the following hardware and software components:

- M Series router
- Junos OS 12.2

## Overview

You can enable LDP downstream on demand label advertisement for an LDP session by including the **downstream-on-demand** statement at the **[edit protocols ldp session]** hierarchy level. If you have configured downstream on demand, the Juniper Networks router advertises the downstream on demand request to its peer routers. For a downstream on demand session to be established between two routers, both have to advertise downstream on demand mode during LDP session establishment. If one router advertises downstream unsolicited mode and the other advertises downstream on demand, downstream unsolicited mode is used.

## Configuration

### Configuring LDP Downstream on Demand

#### Step-by-Step Procedure

To configure a LDP downstream on demand policy and then configure that policy and enable LDP downstream on demand on the LDP session:

1. Configure the downstream on demand policy (DOD-Request-Loopbacks in this example).

This policy causes the router to forward label request messages only to the FECs that are matched by the DOD-Request-Loopbacks policy.

```
[edit policy-options]
user@host# set prefix-list Request-Loopbacks 10.1.1.1/32
user@host# set prefix-list Request-Loopbacks 10.1.1.2/32
user@host# set prefix-list Request-Loopbacks 10.1.1.3/32
user@host# set prefix-list Request-Loopbacks 10.1.1.4/32
user@host# set policy-statement DOD-Request-Loopbacks term 1 from prefix-list
Request-Loopbacks
user@host# set policy-statement DOD-Request-Loopbacks term 1 then accept
```

2. Specify the DOD-Request-Loopbacks policy using the **dod-request-policy** statement at the **[edit protocols ldp]** hierarchy level.

The policy specified with the **dod-request-policy** statement is used to identify the prefixes to send label request messages. This policy is similar to an egress policy or an import policy. When processing routes from the inet.0 routing table, the Junos OS software checks for routes matching the **DOD-Request-Loopbacks** policy (in this example). If the route matches the policy and the LDP session is negotiated with DOD advertisement mode, label request messages are sent to the corresponding downstream LDP session.

```
[edit protocols ldp]
user@host# set dod-request-policy DOD-Request-Loopbacks
```

3. Include the **downstream-on-demand** statement in the configuration for the LDP session to enable downstream on demand distribution mode.

```
[edit protocols ldp]
user@host# set session 1.1.1.1 downstream-on-demand
```

### Distributing LDP Downstream on Demand Routes into Labeled BGP

**Step-by-Step Procedure** To distribute LDP downstream on demand routes into labeled BGP, use a BGP export policy.

1. Configure the LDP route policy (**redistribute\_ldp** in this example).

```
[edit policy-options]
user@host# set policy-statement redistribute_ldp term 1 from protocol ldp
user@host# set policy-statement redistribute_ldp term 1 from tag 1000
user@host# set policy-statement redistribute_ldp term 1 then accept
```

2. Include the LDP route policy, **redistribute\_ldp** in the BGP configuration (as a part of the BGP group configuration **ebgp-to-abr** in this example).

BGP forwards the LDP routes based on the **redistribute\_ldp** policy to the remote PE router

```
[edit protocols bgp]
user@host# set group ebgp-to-abr type external
user@host# set group ebgp-to-abr local-address 192.168.0.1
user@host# set group ebgp-to-abr peer-as 65319
user@host# set group ebgp-to-abr local-as 65320
user@host# set group ebgp-to-abr neighbor 192.168.6.1 family inet unicast
user@host# set group ebgp-to-abr neighbor 192.168.6.1 family inet labeled-unicast
rib inet.3
user@host# set group ebgp-to-abr neighbor 192.168.6.1 export redistribute_ldp
```

**Step-by-Step Procedure** To restrict label propagation to other routers configured in downstream unsolicited mode (instead of downstream on demand), configure the following policies:

1. Configure the **dod-routes** policy to accept routes from LDP.

```
user@host# set policy-options policy-statement dod-routes term 1 from protocol ldp
user@host# set policy-options policy-statement dod-routes term 1 from tag 1145307136
user@host# set policy-options policy-statement dod-routes term 1 then accept
```

2. Configure the **do-not-propagate-du-sessions** policy to not forward routes to neighbors 1.1.1.1, 2.2.2.2, and 3.3.3.3.

```
user@host# set policy-options policy-statement do-not-propagate-du-sessions term 1 to neighbor 1.1.1.1
user@host# set policy-options policy-statement do-not-propagate-du-sessions term 1 to neighbor 2.2.2.2
user@host# set policy-options policy-statement do-not-propagate-du-sessions term 1 to neighbor 3.3.3.3
```

```
user@host# set policy-options policy-statement do-not-propagate-du-sessions
term 1 then reject
```

3. Configure the **filter-dod-on-du-sessions** policy to prevent the routes examined by the **dod-routes** policy from being forwarded to the neighboring routers defined in the **do-not-propagate-du-sessions** policy.

```
user@host# set policy-options policy-statement filter-dod-routes-on-du-sessions
term 1 from policy dod-routes
user@host# set policy-options policy-statement filter-dod-routes-on-du-sessions
term 1 to policy do-not-propagate-du-sessions
```

4. Specify the **filter-dod-routes-on-du-session** policy as the export policy for BGP group **ebgp-to-abr**.

```
[edit protocols bgp]
user@host# set group ebgp-to-abr neighbor 192.168.6.2 export
filter-dod-routes-on-du-sessions
```

**Results** From configuration mode, confirm your configuration by entering the **show policy-options** and **show protocols ldp** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host#
show policy-options
prefix-list Request-Loopbacks {
  10.1.1.1/32;
  10.1.1.2/32;
  10.1.1.3/32;
  10.1.1.4/32;
}
policy-statement DOD-Request-Loopbacks {
  term 1 {
    from {
      prefix-list Request-Loopbacks;
    }
    then accept;
  }
}
policy-statement redistribute_ldp {
  term 1 {
    from {
      protocol ldp;
      tag 1000;
    }
    then accept;
  }
}

user@host#
show protocols ldp
dod-request-policy DOD-Request-Loopbacks;
session 1.1.1.1 {
  downstream-on-demand;
}

user@host#
```

```
show protocols bgp
group ebgp-to-abr {
  type external;
  local-address 192.168.0.1;
  peer-as 65319;
  local-as 65320;
  neighbor 192.168.6.1 {
    family inet {
      unicast;
      labeled-unicast {
        rib {
          inet.3;
        }
      }
    }
  }
  export redistribute_ldp;
}
```

## Verification

### Verifying Label Advertisement Mode

---

**Purpose** Confirm that the configuration is working properly.

Use the **show ldp session** command to verify the status of the label advertisement mode for the LDP session.

**Action** Issue the `show ldp session` and `show ldp session detail` commands:

- The following command output for the `show ldp session` command indicates that the **Adv. Mode** (label advertisement mode) is **DOD** (meaning the LDP downstream on demand session is operational):

```
user@host> show ldp session
  Address          State      Connection    Hold time  Adv. Mode
  1.1.1.2          Operational Open          22         DOD
```

- The following command output for the `show ldp session detail` command indicates that the **Local Label Advertisement mode** is **Downstream unsolicited**, the default value (meaning downstream on demand is not configured on the local session). Conversely, the **Remote Label Advertisement mode** and the **Negotiated Label Advertisement mode** both indicate that **Downstream on demand** is configured on the remote session

```
user@host> show ldp session detail
Address: 1.1.1.2, State: Operational, Connection: Open, Hold time: 24
Session ID: 1.1.1.1:0--1.1.1.2:0
Next keepalive in 4 seconds
Passive, Maximum PDU: 4096, Hold time: 30, Neighbor count: 1
Neighbor types: configured-tunneled
Keepalive interval: 10, Connect retry interval: 1
Local address: 1.1.1.1, Remote address: 1.1.1.2
Up for 17:54:52
Capabilities advertised: none
Capabilities received: none
Protection: disabled
Local - Restart: disabled, Helper mode: enabled,
Remote - Restart: disabled, Helper mode: enabled
Local maximum neighbor reconnect time: 120000 msec
Local maximum neighbor recovery time: 240000 msec
Local Label Advertisement mode: Downstream unsolicited
Remote Label Advertisement mode: Downstream on demand
Negotiated Label Advertisement mode: Downstream on demand
Nonstop routing state: Not in sync
Next-hop addresses received:
  1.1.1.2
```

## Configuring LDP Native IPv6 Support

LDP is supported in an IPv6-only network, and in an IPv6 or IPv4 dual-stack network as described in *RFC 7552*. Configure the address family as **inet** for IPv4 or **inet6** for IPv6 or both, and the transport preference to be either **IPv4** or **IPv6**. The **dual-transport** statement allows Junos OS LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. The **inet-lsr-id** and **inet6-lsr-id** IDs are the two LSR IDs that have to be configured to establish an LDP session over IPv4 and IPv6 TCP transport. These two IDs should be non-zero and must be configured with different values.

Before you configure IPv6 as dual-stack, be sure you configure the routing and signaling protocols.

To configure LDP native IPv6 support, you must do the following:

1. Enable forwarding equivalence class (FEC) deaggregation in order to use different labels for different address families.

```
[edit protocols ldp]  
set deaggregate
```

2. Configure LDP address families.

```
[edit protocols ldp]  
set family inet6  
set family inet
```

3. Configure the **transport-preference** statement to select the preferred transport for the TCP connection when both IPv4 and IPv6 are enabled. By default, IPv6 is used as the TCP transport for establishing an LDP connection.

```
[edit protocols ldp]  
set transport-preference ipv4
```

4. (Optional) Configure dual-transport to allow LDP to establish a separate IPv4 session with an IPv4 neighbor, and an IPv6 session with an IPv6 neighbor. Configure **inet-lsr-id** as the LSR ID for IPv4, and **inet6-lsr-id** as the LSR ID for IPv6.

```
[edit protocols ldp dual-transport]  
set inet-lsr-id inet-lsr-id  
set inet6-lsr-id inet6-lsr-id
```

For example, configure **inet-lsr-id** as 10.255.0.1, and **inet6-lsr-id** as 1.1.1.1.

```
[edit protocols ldp dual-transport]  
set inet-lsr-id 10.255.0.1  
set inet6-lsr-id 1.1.1.1
```

---

## Example: Configuring LDP Native IPv6 Support

This example shows how to allow the Junos OS Label Distribution Protocol (LDP) to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. This helps avoid tunneling of IPv6 over IPv4 MPLS core with IPv4-signaled MPLS label-switched paths (LSPs).

- [Requirements on page 676](#)
- [Overview on page 677](#)
- [Configuration on page 677](#)

### Requirements

This example uses the following hardware and software components:

- Two MX Series routers

- Before you configure IPv6 as dual-stack, be sure you configure the routing and signaling protocols.

LDP is supported in an IPv6 only network, and in an IPv6 or IPv4 dual-stack network as described in *RFC 7552*. Configure the address family as **inet** for IPv4 or **inet6** for IPv6. By default, IPv6 is used as the TCP transport for the LDP session with its peers when both IPv4 and IPv6 are enabled. The dual-transport statement allows Junos LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR. The **inet-lsr-id** and **inet6-lsr-id** are the two LSR IDs that have to be configured to establish an LDP session over IPv4 and IPv6 TCP transport. These two IDs should be non-zero and must be configured with different values.

Figure 67 on page 677 shows the LDP IPv6 configured as dual-stack on Device R1 and Device R2.

### Figure 67: Example LDP Native IPv6 Support

## Configuration

## CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
R1      set interfaces ge-1/0/0 unit 0 family inet address 192.168.12.1/24
        set interfaces ge-1/0/0 unit 0 family iso
        set interfaces ge-1/0/0 unit 0 family inet6 address 2001:db8:0:12::/64 eui-64
        set interfaces ge-1/0/0 unit 0 family mpls
        set interfaces lo0 unit 0 family inet address 10.255.0.1/32
        set interfaces lo0 unit 0 family iso address 49.0001.1720.1600.1010.00
        set interfaces lo0 unit 0 family inet6 address 2001:db8::1/128
        set protocols isis interface ge-1/0/0.0
        set protocols isis interface lo0.0
        set protocols mpls interface ge-1/0/0.0
        set protocols ldp deaggregate
        set protocols ldp interface ge-1/0/0.0
        set protocols ldp interface lo0.0
        set protocols ldp family inet6
        set protocols ldp family inet

R2      set interfaces ge-1/0/1 unit 0 family inet address 192.168.12.2/24
        set interfaces ge-1/0/1 unit 0 family iso
        set interfaces ge-1/0/1 unit 0 family inet6 address 2001:db8:0:12::/64 eui-64
```

```
set interfaces ge-1/0/1 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 10.255.0.2/32
set interfaces lo0 unit 0 family iso address 49.0001.1720.1600.2020.00
set interfaces lo0 unit 0 family inet6 address 2001:db8::2/128
set protocols isis interface ge-1/0/1.0
set protocols isis interface lo0.0
set protocols mpls interface ge-1/0/1.0
set protocols ldp deaggregate
set protocols ldp interface ge-1/0/1.0
set protocols ldp interface lo0.0
set protocols ldp family inet6
set protocols ldp family inet
```

---

### Configuring R1

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see “Using the CLI Editor in Configuration Mode” in the *CLI User Guide*.

To configure Device R1:

1. Configure the interfaces.  

```
[edit interfaces]
set ge-1/0/0 unit 0 family inet address 192.168.12.1/24
set ge-1/0/0 unit 0 family iso
set ge-1/0/0 unit 0 family inet6 address 2001:db8:0:12::/64 eui-64
set ge-1/0/0 unit 0 family mpls
```
2. Assign a loopback address to the device.  

```
[edit interfaces lo0 unit 0]
set family inet address 10.255.0.1/32
set family iso address 49.0001.1720.1600.1010.00
set family inet6 address 2001:db8::1/128
```
3. Configure the IS-IS interfaces.  

```
[edit protocols isis]
set interface ge-1/0/0.0
set interface lo0.0
```
4. Configure MPLS to use LDP interfaces on the device.  

```
[edit protocols mpls]
set protocols mpls interface ge-1/0/0.0
set interface ge-1/0/0.0
set interface lo0.0
```
5. Enable forwarding equivalence class (FEC) deaggregation in order to use different labels for different address families.  

```
[edit protocols ldp]
set deaggregate
```
6. Configure LDP address families.  

```
[edit protocols ldp]
set family inet6
```

**set family inet**

**Results** From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@R1# show interfaces
ge-1/0/0 {
  unit 0 {
    family inet {
      address 192.168.12.1/24;
    }
    family iso;
    family inet6 {
      address 2001:db8:0:12::/64 {
        eui-64;
      }
    }
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.255.0.1/32;
    }
    family iso {
      address 49.0001.1720.1600.1010.00
    }
    family inet6 {
      address 2001:db8::1/128;
    }
  }
}

user@R1# show protocols
mpls {
  interface ge-1/0/0.0;
}
isis {
  interface ge-1/0/0.0;
  interface lo0.0;
}
ldp {
  deaggregate;
  interface ge-1/0/0.0;
  interface lo0.0;
  family {
    inet6;
    inet;
  }
}

```

## Verification

Confirm that the configuration is working properly.

- [Verifying the Route Entries in the mpls.0 Table on page 680](#)
- [Verifying the Route Entries in the inet.3 Table on page 680](#)
- [Verifying the Route Entries in the inet6.3 Table on page 681](#)
- [Verifying the LDP Database on page 681](#)
- [Verifying the LDP Neighbor Information on page 682](#)
- [Verifying the LDP Session Information on page 683](#)

### *Verifying the Route Entries in the mpls.0 Table*

**Purpose** Display mpls.0 route table information.

**Action** On Device R1, from operational mode, run the **show route table mpls.0** command to display mpls.0 route table information.

```
user@R1> show route table mpls.0
mpls.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                *[MPLS/0] 05:19:58, metric 1
                  Receive
1                *[MPLS/0] 05:19:58, metric 1
                  Receive
2                *[MPLS/0] 05:19:58, metric 1
                  Receive
13               *[MPLS/0] 05:19:58, metric 1
                  Receive
299824           *[LDP/9] 04:28:45, metric 1
                  > to fe80::21f:1200:cb6:4c8d via ge-1/0/0.0, Pop
299824(S=0)      *[LDP/9] 04:28:45, metric 1
                  > to fe80::21f:1200:cb6:4c8d via ge-1/0/0.0, Pop
299888           *[LDP/9] 00:56:12, metric 1
                  > to 192.168.12.2 via ge-1/0/0.0, Pop
299888(S=0)      *[LDP/9] 00:56:12, metric 1
                  > to 192.168.12.2 via ge-1/0/0.0, Pop
```

**Meaning** The output shows the mpls.0 route table information.

### *Verifying the Route Entries in the inet.3 Table*

**Purpose** Display inet.3 route table information.

**Action** On Device R1, from operational mode, run the **show route table inet.3** command to display inet.3 route table information.

```
user@R1> show route table inet.3
inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.255.0.2/32      *[LDP/9] 00:58:38, metric 1
                  > to 192.168.12.2 via ge-1/0/0.0
```

**Meaning** The output shows the inet.3 route table information.

#### *Verifying the Route Entries in the inet6.3 Table*

**Purpose** Display inet6.3 route table information.

**Action** On Device R1, from operational mode, run the **show route table inet6.3** command to display inet6.3 route table information.

```
user@R1> show route table inet6.3

inet6.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

2001:db8::2/128   *[LDP/9] 04:31:17, metric 1
                  > to fe80::21f:1200:cb6:4c8d via ge-1/0/0.0
```

**Meaning** The output shows the inet6.3 route table information.

#### *Verifying the LDP Database*

**Purpose** Display the LDP database information.

**Action** On Device R1, from operational mode, run the **show ldp database** command to display LDP database information.

```
user@R1> show ldp database
```

```
Input label database, 10.255.0.1:0--10.255.0.2:0  
Labels received: 3
```

| Label  | Prefix          |
|--------|-----------------|
| 299840 | 10.255.0.1/32   |
| 3      | 10.255.0.2/32   |
| 299808 | 2001:db8::1/128 |
| 3      | 2001:db8::2/128 |

```
Output label database, 10.255.0.1:0--10.255.0.2:0  
Labels advertised: 3
```

| Label  | Prefix          |
|--------|-----------------|
| 3      | 10.255.0.1/32   |
| 299888 | 10.255.0.2/32   |
| 3      | 2001:db8::1/128 |
| 299824 | 2001:db8::2/128 |

**Meaning** The output shows the entries in the LDP database.

#### *Verifying the LDP Neighbor Information*

**Purpose** Display the LDP neighbor information.

**Action** On Device R1, from operational mode, run the **show ldp neighbor** and **show ldp neighbor extensive** commands to display LDP neighbor information.

```
user@R1> show ldp neighbor
```

| Address                 | Interface  | Label space ID | Hold time |
|-------------------------|------------|----------------|-----------|
| fe80::21f:1200:cb6:4c8d | ge-1/0/0.0 | 10.255.0.2:0   | 12        |
| 192.168.12.2            | ge-1/0/0.0 | 10.255.0.2:0   | 11        |

```
user@R1> show ldp neighbor extensive
```

| Address      | Interface  | Label space ID | Hold time |
|--------------|------------|----------------|-----------|
| 192.168.12.2 | ge-1/0/0.0 | 10.255.0.2:0   | 11        |

Transport address: 10.255.0.2, Transport preference: IPv6, Configuration sequence: 10  
Up for 00:04:35  
Reference count: 1  
Hold time: 15, Proposed local/peer: 15/15  
Hello flags: none  
Neighbor types: discovered

| Address                 | Interface  | Label space ID | Hold time |
|-------------------------|------------|----------------|-----------|
| fe80::21f:1200:cb6:4c8d | ge-1/0/0.0 | 10.255.0.2:0   | 14        |

Transport address: 2001:db8::2, Transport preference: IPv6, Configuration sequence: 10  
Up for 00:04:35  
Reference count: 1  
Hold time: 15, Proposed local/peer: 15/15  
Hello flags: none  
Neighbor types: discovered

**Meaning** The output shows LDP neighbor information of both IPv4 and IPv6 addresses.

### *Verifying the LDP Session Information*

**Purpose** Display the LDP session information.

**Action** On Device R1, from operational mode, run the **show ldp session** and **show ldp session extensive** commands to display LDP session information.

```
user@R1> show ldp session
```

```
session
```

| Address     | State       | Connection | Hold time | Adv. Mode |
|-------------|-------------|------------|-----------|-----------|
| 2001:db8::2 | Operational | Open       | 20        | DU        |

```
user@R1> show ldp session extensive
```

```
Address: 2001:db8::2, State: Operational, Connection: Open, Hold time: 29
```

```
Session ID: 10.255.0.1:0--10.255.0.2:0
```

```
Next keepalive in 9 seconds
```

```
Passive, Maximum PDU: 4096, Hold time: 30, Neighbor count: 1
```

```
Neighbor types: discovered
```

```
Keepalive interval: 10, Connect retry interval: 1
```

```
Local address: 2001:db8::1, Remote address: 2001:db8::2
```

```
Up for 00:05:31
```

```

fe80::21f:1200:cb6:4c8d
```

```
Queue depth: 0
```

| Message type     | Total |          | Last 5 seconds |          |
|------------------|-------|----------|----------------|----------|
|                  | Sent  | Received | Sent           | Received |
| Initialization   | 1     | 1        | 0              | 0        |
| Keepalive        | 34    | 34       | 0              | 0        |
| Notification     | 0     | 0        | 0              | 0        |
| Address          | 1     | 1        | 0              | 0        |
| Address withdraw | 0     | 0        | 0              | 0        |
| Label mapping    | 3     | 3        | 0              | 0        |
| Label request    | 0     | 0        | 0              | 0        |
| Label withdraw   | 0     | 0        | 0              | 0        |
| Label release    | 0     | 0        | 0              | 0        |
| Label abort      | 0     | 0        | 0              | 0        |

**Meaning** The output displays information for the LDP session using IPv6 as the TCP transport.

### Configure transport-preference to Select the Preferred Transport

**CLI Quick Configuration** You can configure the **transport-preference** statement to select the preferred transport for a TCP connection when both IPv4 and IPv6 are enabled. By default, IPv6 is used as TCP transport for establishing an LDP connection.

- (Optional) Configure the transport preference for an LDP connection.

```
[edit protocols ldp]
set transport-preference ipv4
```

**Results** From configuration mode, confirm your configuration by entering the **show protocols** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show protocols
  mpls {
    interface ge-1/0/0.0;
  }
  isis {
    interface ge-1/0/0.0;
    interface lo0.0;
  }
  ldp {
    deaggregate;
    interface ge-1/0/0.0;
    interface lo0.0;
    family {
      inet6;
      inet;
    }
    transport-preference ipv4;
  }
```

### Verification

Confirm that the configuration is working properly.

| Initialization   | 1     | 1        | 0              | 0        |
| Keepalive        | 33    | 33       | 1              | 1        |
| Notification     | 0     | 0        | 0              | 0        |
| Address          | 2     | 2        | 0              | 0        |
| Address withdraw | 0     | 0        | 0              | 0        |
| Label mapping    | 6     | 6        | 0              | 0        |
| Label request    | 0     | 0        | 0              | 0        |
| Label withdraw   | 0     | 0        | 0              | 0        |
| Label release    | 0     | 0        | 0              | 0        |
| Label abort      | 0     | 0        | 0              | 0        |

**Meaning** The output displays information for the LDP session using IPv6 as the TCP transport.

### Configure dual-transport to Establish Separate Sessions for IPv4 with an IPv4 Neighbor and IPv6 with an IPv6 Neighbor

**Step-by-Step Procedure** You can configure the **dual-transport** statement to allow LDP to establish a separate IPv4 session with an IPv4 neighbor, and an IPv6 session with an IPv6 neighbor. This requires the configuration of **inet-lsr-id** as the LSR ID for IPv4, and **inet6-lsr-id** as the LSR ID for IPv6.

- (Optional) Configure dual-transport to allow LDP to establish the TCP connection over IPv4 with IPv4 neighbors, and over IPv6 with IPv6 neighbors as a single-stack LSR.

```
[edit protocols ldp dual-transport]
set inet-lsr-id 10.255.0.1
set inet6-lsr-id 1.1.1.1
```

**Results** From configuration mode, confirm your configuration by entering the **show protocols** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R1# show protocols
mpls {
  interface ge-1/0/0.0;
}
isis {
  interface ge-1/0/0.0;
  interface lo0.0;
}
ldp {
  deaggregate;
  interface ge-1/0/0.0;
  interface lo0.0;
  family {
    inet6;
    inet;
  }
  dual-transport {
    inet-lsr-id 10.255.0.1;
    inet6-lsr-id 1.1.1.1;
  }
}
```

## Understanding Multipoint LDP Inband Signaling for Point-to-Multipoint LSPs

The Multipoint Label Distribution Protocol (M-LDP) for point-to-multipoint label-switched paths (LSPs) with in-band signaling is useful in a deployment with an existing IP/MPLS backbone, in which you need to carry multicast traffic, for IPTV for example.

For years, the most widely used solution for transporting multicast traffic has been to use native IP multicast in the service provider core with multipoint IP tunneling to isolate customer traffic. A multicast routing protocol, usually Protocol Independent Multicast (PIM), is deployed to set up the forwarding paths. IP multicast routing is used for forwarding, using PIM signaling in the core. For this model to work, the core network has to be multicast enabled. This allows for effective and stable deployments even in inter-autonomous system (AS) scenarios.

However, in an existing IP/MPLS network, deploying PIM might not be the first choice. Some service providers are interested in replacing IP tunneling with MPLS label encapsulation. The motivations for moving to MPLS label switching is to leverage MPLS traffic engineering and protection features and to reduce the amount of control traffic overhead in the provider core.

To do this, service providers are interested in leveraging the extension of the existing deployments to allow multicast traffic to pass through. The existing multicast extensions for IP/MPLS are point-to-multipoint extensions for RSVP-TE and point-to-multipoint and multipoint-to-multipoint extensions for LDP. These deployment scenarios are discussed in RFC 6826, *Multipoint LDP In-Band Signaling for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths*. This feature overview is limited to point-to-multipoint extensions for LDP.

## How M-LDP Works

- [Label Bindings in M-LDP Signaling on page 693](#)
- [M-LDP in PIM-Free MPLS Core on page 693](#)
- [M-LDP in PIM-Enabled MPLS Core on page 695](#)

### Label Bindings in M-LDP Signaling

The multipoint extension to LDP uses point-to-multipoint and multipoint-to-multipoint forwarding equivalence class (FEC) elements (defined in RFC 5036, *LDP Specification*) along with capability advertisements, label mapping, and signaling procedures. The FEC elements include the idea of the LSP root, which is an IP address, and an “opaque” value, which is a selector that groups together the leaf nodes sharing the same opaque value. The opaque value is transparent to the intermediate nodes, but has meaning for the LSP root. Every LDP node advertises its local incoming label binding to the upstream LDP node on the shortest path to the root IP address found in the FEC. The upstream node receiving the label bindings creates its own local label and outgoing interfaces. This label allocation process might result in packet replication, if there are multiple outgoing branches. As shown in [Figure 68 on page 693](#), an LDP node merges the label bindings for the same opaque value if it finds downstream nodes sharing the same upstream node. This allows for effective building of point-to-multipoint LSPs and label conservation.

### Figure 68: Label Bindings in M-LDP Signaling

### *M-LDP in PIM-Free MPLS Core*

Figure 69 on page 694 shows a scaled-down deployment scenario. Two separate PIM domains are interconnected by a PIM-free core site. The border routers in this core site support PIM on the border interfaces. Further, these border routers collect and distribute the routing information from the adjacent sites to the core network. The edge routers in Site C run BGP for root-node discovery. Interior gateway protocol (IGP) routes cannot be used for ingress discovery because in most cases the forwarding next hop provided by the IGP would not provide information about the ingress device toward the source. M-LDP inband signaling has a one-to-one mapping between the point-to-multipoint LSP and the (S,G) flow. With in-band signaling, PIM messages are directly translated into M-LDP FEC bindings. In contrast, out-of-band signaling is based on manual

configuration. One application for M-LDP inband signaling is to carry IPTV multicast traffic in an MPLS backbone.

**Figure 69: Sample M-LDP Topology in PIM-Free MPLS Core**

### Configuration

The configuration statement **mldp-inband-signalling** on the label-edge router (LER) enables PIM to use M-LDP in-band signaling for the upstream neighbors when the LER does not detect a PIM upstream neighbor. Static configuration of the MPLS LSP root is included in the PIM configuration, using policy. This is needed when IBGP is not available in the core site or to override IBGP-based LSP root detection.

For example:

```
protocols {
  pim {
    mldp-inband-signalling {
      policy lsp-mapping-policy-example;
    }
  }
}

policy-options {
  policy-statement lsp-mapping-policy-example {
    term channel1 {
      from {
        source-address-filter ip-prefix</prefix-length>; #policy filter for channel1
      }
      then {
        p2mp-lsp-root {
          # Statically configured ingress address of edge
          # used by channel1
        }
      }
    }
  }
}
```

```

        address ip-address;
    }
    accept;
}
}
}
}

```

### M-LDP in PIM-Enabled MPLS Core

Starting in Junos OS Release 14.1, in order to migrate existing IPTV services from native IP multicast to MPLS multicast, you need to smoothly transition from PIM to M-LDP point-to-multipoint LSPs with minimal outage. Figure 70 on page 695 shows a similar M-LDP topology as Figure 69 on page 694, but with a different scenario. The core is enabled with PIM, with one source streaming all the IPTV channels. The TV channels are sent as ASM streams with each channel identified by its group address. Previously, these channels were streamed on the core as IP streams and signaled using PIM.

Figure 70: Sample M-LDP Topology in PIM-Enabled MPLS Core

By configuring the **mldp-inband-signaling** in this scenario, M-LDP signaling is initiated only when there is no PIM neighbor towards the source. However, because there is always a PIM neighbor towards the source unless PIM is deactivated on the upstream interfaces of the egress PE, PIM takes precedence over M-LDP and M-LDP does not take effect.

### Configuration

To progressively migrate channel by channel to M-LDP MPLS core with few streams using M-LDP upstream and other streams using existing PIM upstream, include the **selected-mldp-egress** configuration statement along with group based filters in the policy filter for M-LDP inband signaling.

**NOTE:** The M-LDP inband signaling policy filter can include either the `source-address-filter` statement or the `route-filter` statement, or a combination of both.

For example:

```
protocols {
  pim {
    mldp-inband-signalling {
      policy lsp-mapping-policy-example;
    }
  }
}

policy-options {
  policy-statement lsp-mapping-policy-example {
    term channel1 {
      from {
        source-address-filter ip-prefix</prefix-length>; #policy filter for channel1
      }
      then {
        selected-mldp-egress;
        accept;
      }
    }
    term channel2 {
      from {
        source-address-filter ip-prefix</prefix-length>; #policy filter for channel2
        route-filter ip-prefix</prefix-length>; #policy filter on multicast group address
      }
      then {
        selected-mldp-egress;
        p2mp-lsp-root {
          # Statically configured ingress address of edge
          # used by channel2
          address ip-address;
        }
        accept;
      }
    }
    term channel3 {
      from {
        route-filter ip-prefix</prefix-length>; #policy filter on multicast group address
      }
      then {
        selected-mldp-egress;
        accept;
      }
    }
  }
}
```

**NOTE:**

Some of the limitations of the above configuration are as follows:

- The `selected-mldp-egress` statement should be configured only on the LER. Configuring the `selected-mldp-egress` statement on non-egress PIM routers can cause path setup failures.
- When policy changes are made to switch traffic from PIM upstream to M-LDP upstream and vice-versa, packet loss can be expected as break-and-make mechanism is performed at the control plane.

### Terminology

The following terms are important for an understanding of M-LDP in-band signaling for multicast traffic.

**Point-to-point LSP**—An LSP that has one ingress label-switched router (LSR) and one egress LSR.

**Multipoint LSP**—Either a point-to-multipoint or a multipoint-to-multipoint LSP.

**Point-to-multipoint LSP**—An LSP that has one ingress LSR and one or more egress LSRs.

**Multipoint-to-point LSP**—An LSP that has one or more ingress LSRs and one unique egress LSR.

**Multipoint-to-multipoint LSP**—An LSP that connects a set of nodes, such that traffic sent by any node in the LSP is delivered to all others.

**Ingress LSR**—An ingress LSR for a particular LSP is an LSR that can send a data packet along the LSP. Multipoint-to-multipoint LSPs can have multiple ingress LSRs. Point-to-multipoint LSPs have only one, and that node is often referred to as the root node.

**Egress LSR**—An egress LSR for a particular LSP is an LSR that can remove a data packet from that LSP for further processing. Point-to-point and multipoint-to-point LSPs have only a single egress node. Point-to-multipoint and multipoint-to-multipoint LSPs can have multiple egress nodes.

**Transit LSR**—An LSR that has reachability to the root of the multipoint LSP through a directly connected upstream LSR and one or more directly connected downstream LSRs.

**Bud LSR**—An LSR that is an egress but also has one or more directly connected downstream LSRs.

**Leaf node**—Either an egress or bud LSR in the context of a point-to-multipoint LSP. In the context of a multipoint-to-multipoint LSP, an LSR is both ingress and egress for the same multipoint-to-multipoint LSP and can also be a bud LSR.

### Ingress Join Translation and Pseudo Interface Handling

---

At the ingress LER, LDP notifies PIM about the (S,G) messages that are received over the in-band signaling. PIM associates each (S,G) message with a pseudo interface. Subsequently, a shortest-path-tree (SPT) join message is initiated toward the source. PIM treats this as a new type of local receiver. When the LSP is torn down, PIM removes this local receiver based on notification from LDP.

### Ingress Splicing

---

LDP provides PIM with a next hop to be associated with each (S,G) entry. PIM installs a PIM (S,G) multicast route with the LDP next hop and other PIM receivers. The next hop is a composite next hop of local receivers + the list of PIM downstream neighbors + a sub-level next hop for the LDP tunnel.

### Reverse Path Forwarding

---

PIM's reverse-path-forwarding (RPF) calculation is performed at the egress node.

PIM performs M-LDP in-band signaling when all of the following conditions are true:

- There are no PIM neighbors toward the source.
- The M-LDP in-band signaling statement is configured.
- The next hop is learned through BGP, or is present in the static mapping (specified in an M-LDP in-band signaling policy).

Otherwise, if LSP root detection fails, PIM retains the (S,G) entry with an RPF state of unresolved.

PIM RPF registers this source address each time unicast routing information changes. Therefore, if the route toward the source changes, the RPF recalculation recurs. BGP protocol next hops toward the source too are monitored for changes in the LSP root. Such changes might cause traffic disruption for short durations.

### LSP Root Detection

---

If the RPF operation detects the need for M-LDP in-band signaling upstream, the LSP root (ingress) is detected. This root is a parameter for LDP LSP signaling.

The root node is detected as follows:

1. If the existing static configuration specifies the source address, the root is taken as given in configuration.
2. A lookup is performed in the unicast routing table. If the source address is found, the protocol next hop toward the source is used as the LSP root.

Prior to Junos OS Release 16.1, M-LDP point-to-multipoint LSP is signaled from an egress to ingress using the root address of the ingress LSR. This root address is reachable through IGP only, thereby confining the M-LDP point-to-multipoint LSP to a single autonomous system. If the root address is not reachable through an IGP, but reachable through BGP, and if that BGP route is recursively resolved over an MPLS

LSP, then the point-to-multipoint LSP is not signaled further from that point towards the ingress LSR root address.

There is a need for these non-segmented point-to-multipoint LSPs to be signaled across multiple autonomous systems, which can be used for the following applications:

- Inter-AS MVPN with non-segmented point-to-multipoint LSPs.
- Inter-AS M-LDP inband signaling between client networks connected by an MPLS core network.
- Inter-area MVPN or M-LDP inband signaling with non-segmented point-to-multipoint LSPs (seamless MPLS multicast).

Starting from Junos OS Release 16.1, M-LDP can signal point-to-multipoint LSPs at ASBR or transit or egress when root address is a BGP route which is further recursively resolved over an MPLS LSP.

---

### Egress Join Translation and Pseudo Interface Handling

At the egress LER, PIM notifies LDP of the (S,G) message to be signaled along with the LSP root. PIM creates a pseudo interface as the upstream interface for this (S,G) message. When an (S,G) prune message is received, this association is removed.

---

### Egress Splicing

At the egress node of the core network, where the (S,G) join message from the downstream site is received, this join message is translated to M-LDP in-band signaling parameters and LDP is notified. Further, LSP teardown occurs when the (S,G) entry is lost, when the LSP root changes, or when the (S,G) entry is reachable over a PIM neighbor.

---

### Supported Functionality

For M-LDP in-band signaling, Junos OS supports the following functionality:

- Egress splicing of the PIM next hop with the LDP route
- Ingress splicing of the PIM route with the LDP next hop
- Translation of PIM join messages to LDP point-to-multipoint LSP setup parameters
- Translation of M-LDP in-band LSP parameters to set up PIM join messages
- Statically configured and BGP protocol next hop-based LSP root detection
- PIM (S,G) states in the PIM source-specific multicast (SSM) and anysource multicast (ASM) ranges
- Configuration statements on ingress and egress LERs to enable them to act as edge routers
- IGMP join messages on LERs
- Carrying IPv6 source and group address as opaque information toward an IPv4 root node
- Static configuration to map an IPv6 (S,G) to an IPv4 root address

### Unsupported Functionality

---

For M-LDP in-band signaling, Junos OS does *not* support the following functionality:

- Full support for PIM ASM
- The **mpls lsp point-to-multipoint ping** command with an (S,G) option
- Nonstop active routing (NSR)
- Make-before-break (MBB) for PIM
- IPv6 LSP root addresses (LDP does not support IPv6 LSPs.)
- Neighbor relationship between PIM speakers that are not directly connected
- Graceful restart
- PIM dense mode
- PIM bidirectional mode

### LDP Functionality

---

The PIM (S,G) information is carried as M-LDP opaque type-length-value (TLV) encodings. The point-to-multipoint FEC element consists of the root-node address. In the case of next-generation multicast VPNs (NGEN MVPNs), the point-to-multipoint LSP is identified by the root node address and the LSP ID.

### Egress LER Functionality

---

On the egress LER, PIM triggers LDP with the following information to create a point-to-multipoint LSP:

- Root node
- (S,G)
- Next hop

PIM finds the root node based on the source of the multicast tree. If the root address is configured for this (S,G) entry, the configured address is used as the point-to-multipoint LSP root. Otherwise, the routing table is used to look up the route to the source. If the route to the source of the multicast tree is a BGP-learned route, PIM retrieves the BGP next hop address and uses it as the root node for the point-to-multipoint LSP.

LDP finds the upstream node based on the root node, allocates a label, and sends the label mapping to the upstream node. LDP does not use penultimate hop popping (PHP) for in-band M-LDP signaling.

If the root addresses for the source of the multicast tree changes, PIM deletes the point-to-multipoint LSP and triggers LDP to create a new point-to-multipoint LSP. When this happens, the outgoing interface list becomes NULL, PIM triggers LDP to delete the point-to-multipoint LSP, and LDP sends a label withdraw message to the upstream node.

### Transit LSR Functionality

The transit LSR advertises a label to the upstream LSR toward the source of the point-to-multipoint FEC and installs the necessary forwarding state to forward the packets. The transit LSR can be any M-LDP capable router.

### Ingress LER Functionality

On the ingress LER, LDP provides the following information to PIM upon receiving the label mapping:

- (S,G)
- Flood next hop

Then PIM installs the forwarding state. If the new branches are added or deleted, the flood next hop is updated accordingly. If all branches are deleted due to a label being withdrawn, LDP sends updated information to PIM. If there are multiple links between the upstream and downstream neighbors, the point-to-multipoint LSP is not load balanced.

## Example: Configuring Multipoint LDP In-Band Signaling for Point-to-Multipoint LSPs

This example shows how to configure multipoint LDP (M-LDP) in-band signaling for multicast traffic, as an extension to the Protocol Independent Multicast (PIM) protocol or as a substitute for PIM.

- [Requirements on page 701](#)
- [Overview on page 702](#)
- [Configuration on page 702](#)
- [Verification on page 711](#)

### Requirements

This example can be configured using the following hardware and software components:

- Junos OS Release 13.2 or later
- MX Series 3D Universal Edge Routers or M Series Multiservice Edge Routers for the Provider Edge (PE) Routers
- PTX Series Packet Transport Routers acting as transit label-switched routers
- T Series Core Routers for the Core Routers

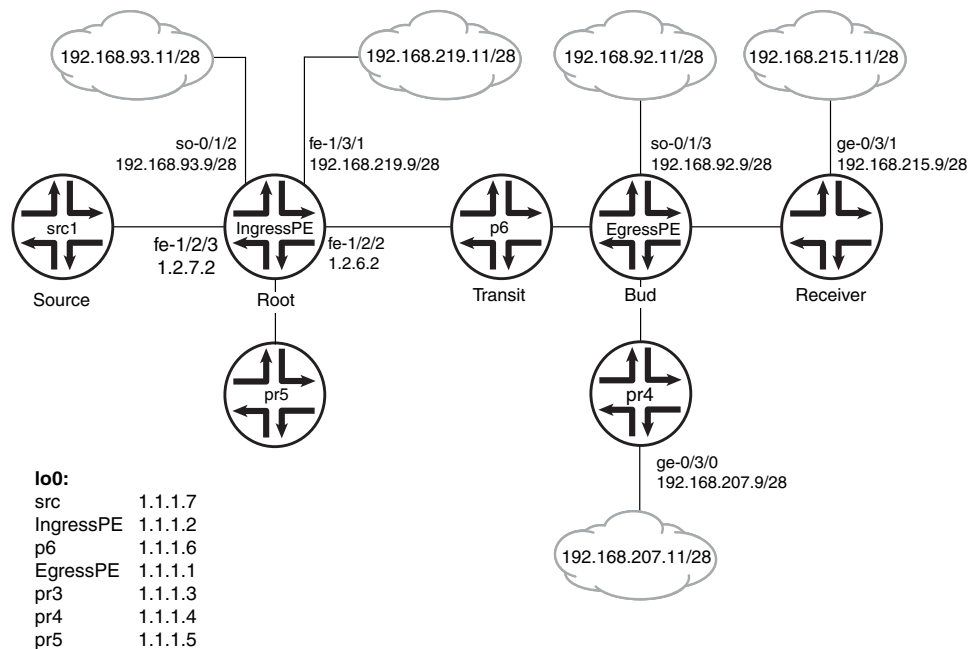

**NOTE:** The PE routers could also be T Series Core Routers but that is not typical. Depending on your scaling requirements, the core routers could also be MX Series 3D Universal Edge Routers or M Series Multiservice Edge Routers. The Customer Edge (CE) devices could be other routers or switches from Juniper Networks or another vendor.

No special configuration beyond device initialization is required before configuring this example.

### Overview

"CLI Quick Configuration" on page 702 shows the configuration for all of the devices in Figure 71 on page 702. The section "Step-by-Step Procedure" on page 706 describes the steps on Device EgressPE.

Figure 71: M-LDP In-Band Signaling for Point-to-Multipoint LSPs Example Topology

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

#### Device src1

```
set logical-systems src1 interfaces fe-1/2/0 unit 0 family inet address 1.2.7.7/24
set logical-systems src1 interfaces lo0 unit 0 family inet address 1.1.1.7/32
set logical-systems src1 protocols ospf area 0.0.0.0 interface all
```

#### Device IngressPE

```
set interfaces so-0/1/2 unit 0 family inet address 192.168.93.9/28
set interfaces fe-1/2/0 unit 0 family inet address 1.2.3.2/24
set interfaces fe-1/2/0 unit 0 family mpls
set interfaces fe-1/2/1 unit 0 family inet address 1.2.5.2/24
set interfaces fe-1/2/2 unit 0 family inet address 1.2.6.2/24
set interfaces fe-1/2/2 unit 0 family mpls
set interfaces fe-1/2/3 unit 0 family inet address 1.2.7.2/24
set interfaces fe-1/3/1 unit 0 family inet address 192.168.219.9/28
set interfaces lo0 unit 0 family inet address 1.1.1.2/32
```

```

set protocols igmp interface fe-1/2/1.0 version 3

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device EgressPE:

1. Configure the interfaces.

Enable MPLS on the core-facing interfaces. On the egress next hops, you do not need to enable MPLS.

```
[edit interfaces]
```

```
user@EgressPE# set fe-1/2/0 unit 0 family inet address 1.1.3.1/24
```

```
user@EgressPE# set fe-1/2/0 unit 0 family mpls
```

```
user@EgressPE# set fe-1/2/2 unit 0 family inet address 1.1.6.1/24
```

```
user@EgressPE# set fe-1/2/2 unit 0 family mpls
```

```
user@EgressPE# set so-0/1/3 unit 0 point-to-point
```

```
user@EgressPE# set so-0/1/3 unit 0 family inet address 192.168.92.9/28
```

```
user@EgressPE# set fe-1/2/1 unit 0 family inet address 1.1.4.1/24
```

```
user@EgressPE# set fe-1/3/0 unit 0 family inet address 192.168.209.9/28
```

```
user@EgressPE# set lo0 unit 0 family inet address 1.1.1.1/32
```

2. Configure IGMP on the egress interfaces.

For testing purposes, this example includes static group and source addresses.

```
[edit protocols igmp]
```

```
user@EgressPE# set interface fe-1/3/0.0 version 3
```

```
user@EgressPE# set interface fe-1/3/0.0 static group 232.1.1.1 group-count 3
```

```
user@EgressPE# set interface fe-1/3/0.0 static group 232.1.1.1 source 192.168.219.11
```

```
user@EgressPE# set interface fe-1/3/0.0 static group 227.1.1.1
```

```
user@EgressPE# set interface so-0/1/3.0 version 3
```

```
user@EgressPE# set interface so-0/1/3.0 static group 232.1.1.1 group-count 2
```

```
user@EgressPE# set interface so-0/1/3.0 static group 232.1.1.1 source 192.168.219.11
```

```
user@EgressPE# set interface so-0/1/3.0 static group 232.2.2.2 source 1.2.7.7
```

3. Configure MPLS on the core-facing interfaces.

```
[edit protocols mpls]
```

```
user@EgressPE# set interface fe-1/2/0.0
```

```
user@EgressPE# set interface fe-1/2/2.0
```

4. Configure BGP.

BGP is a policy-driven protocol, so also configure and apply any needed routing policies.

For example, you might want to export static routes into BGP.

```
[edit protocols bgp group ibgp]
```

- ```

user@EgressPE# set type internal
user@EgressPE# set local-address 1.1.1.1
user@EgressPE# set family inet any
user@EgressPE# set neighbor 1.1.1.2

```
5. (Optional) Configure an MSDP peer connection with Device pr5 in order to interconnect the disparate PIM domains, thus enabling redundant RPs.
 

```

[edit protocols msdp]
user@EgressPE# set local-address 1.1.1.1
user@EgressPE# set peer 1.1.1.5

```
  6. Configure OSPF.
 

```

[edit protocols ospf area 0.0.0.0]
user@EgressPE# set interface all
user@EgressPE# set interface fxp0.0 disable

```
  7. Configure LDP on the core-facing interfaces and on the loopback interface.
 

```

[edit protocols ldp]
user@EgressPE# set interface fe-1/2/0.0
user@EgressPE# set interface fe-1/2/2.0
user@EgressPE# set interface lo0.0

```
  8. Enable point-to-multipoint MPLS LSPs.
 

```

[edit protocols ldp]
user@EgressPE# set p2mp

```
  9. Configure PIM on the downstream interfaces.
 

```

[edit protocols pim]
user@EgressPE# set interface lo0.0
user@EgressPE# set interface fe-1/3/0.0
user@EgressPE# set interface fe-1/2/1.0
user@EgressPE# set interface so-0/1/3.0

```
  10. Configure the RP settings because this device serves as the PIM rendezvous point (RP).
 

```

[edit protocols pim]
user@EgressPE# set rp local address 1.1.1.1
user@EgressPE# set rp local group-ranges 227.0.0.0/8
user@EgressPE# set rp static address 1.1.1.4
user@EgressPE# set rp static address 1.2.7.7 group-ranges 226.0.0.0/8

```
  11. Enable M-LDP in-band signaling and set the associated policy.
 

```

[edit protocols pim]
user@EgressPE# set mldp-inband-signalling policy mldppim-ex

```
  12. Configure the routing policy that specifies the root address for the point-to-multipoint LSP and the associated source addresses.
 

```

[edit policy-options policy-statement mldppim-ex]
user@EgressPE# set term B from source-address-filter 192.168.0.0/24 orlonger
user@EgressPE# set term B from source-address-filter 192.168.219.11/32 orlonger
user@EgressPE# set term B then p2mp-lsp-root address 1.1.1.2
user@EgressPE# set term B then accept

```

```
user@EgressPE# set term A from source-address-filter 1.2.7.0/24 orlonger
user@EgressPE# set term A then accept
```

13. Configure the autonomous system (AS) ID.

```
[edit routing-options]
user@EgressPE# set autonomous-system 64510
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

- [Looking Up the Route Information for the MPLS Label on page 720](#)
- [Checking the LDP Traffic Statistics on page 721](#)

#### *Checking the PIM Join States*

**Purpose** Display information about PIM join states to verify the M-LDP in-band upstream and downstream details. On the ingress device, the **show pim join extensive** command displays **Pseudo-MLDP** for the downstream interface. On the egress, the **show pim join extensive** command displays **Pseudo-MLDP** for the upstream interface.

**Action** From operational mode, enter the **show pim join extensive** command.

```
user@IngressPE> show pim join extensive
```

### ***Checking the PIM Sources***

**Purpose** Verify that the PIM sources have the expected M-LDP in-band upstream and downstream details.

**Action** From operational mode, enter the **show pim source** command.

```
user@IngressPE> show pim source
```

```
Instance: PIM.master Family: INET
```

```
Source 1.1.1.1
  Prefix 1.1.1.1/32
  Upstream interface Local
  Upstream neighbor Local

Source 1.2.7.7
  Prefix 1.2.7.0/24
  Upstream protocol MLDP
  Upstream interface Pseudo MLDP
  Upstream neighbor MLDP LSP root <1.1.1.2>

Source 192.168.219.11
  Prefix 192.168.219.0/28
  Upstream protocol MLDP
  Upstream interface Pseudo MLDP
  Upstream neighbor MLDP LSP root <1.1.1.2>
```

```
user@EgressPE> show pim source
```

```
Instance: PIM.master Family: INET
```

```
Source 1.2.7.7
  Prefix 1.2.7.0/24
  Upstream interface fe-1/2/3.0
  Upstream neighbor 1.2.7.2

Release History Table

Release	Description
16.1	Starting from Junos OS Release 16.1, M-LDP can signal point-to-multipoint LSPs at ASBR or transit or egress when root address is a BGP route which is further recursively resolved over an MPLS LSP.
14.1	Starting in Junos OS Release 14.1, in order to migrate existing IPTV services from native IP multicast to MPLS multicast, you need to smoothly transition from PIM to M-LDP point-to-multipoint LSPs with minimal outage.

## Configuring Miscellaneous LDP Properties

The following sections describe how to configure a number of miscellaneous LDP properties:

- [Configuring LDP to Use the IGP Route Metric on page 723](#)
- [Preventing Addition of Ingress Routes to the inet.0 Routing Table on page 723](#)
- [Multiple-Instance LDP and Carrier-of-Carriers VPNs on page 723](#)
- [Configuring MPLS and LDP to Pop the Label on the Ultimate-Hop Router on page 724](#)
- [Enabling LDP over RSVP-Established LSPs on page 724](#)
- [Enabling LDP over RSVP-Established LSPs in Heterogeneous Networks on page 724](#)
- [Configuring the TCP MD5 Signature for LDP Sessions on page 725](#)

- [Configuring LDP Session Protection on page 726](#)
- [Disabling SNMP Traps for LDP on page 727](#)
- [Configuring LDP Synchronization with the IGP on LDP Links on page 727](#)
- [Configuring LDP Synchronization with the IGP on the Router on page 728](#)
- [Configuring the Label Withdrawal Timer on page 728](#)
- [Ignoring the LDP Subnet Check on page 728](#)

## Configuring LDP to Use the IGP Route Metric

Use the **track-igp-metric** statement if you want the interior gateway protocol (IGP) route metric to be used for the LDP routes instead of the default LDP route metric (the default LDP route metric is 1).

To use the IGP route metric, include the **track-igp-metric** statement:

```
track-igp-metric;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Preventing Addition of Ingress Routes to the inet.0 Routing Table

By configuring the **no-forwarding** statement, you can prevent ingress routes from being added to the **inet.0** routing table instead of the **inet.3** routing table even if you enabled the **traffic-engineering bgp-igp** statement at the **[edit protocols mpls]** or the **[edit logical-systems logical-system-name protocols mpls]** hierarchy level. By default, the **no-forwarding** statement is disabled.

**NOTE:** ACX Series routers do not support **[edit logical-systems]** hierarchy level.

To omit ingress routes from the **inet.0** routing table, include the **no-forwarding** statement:

```
no-forwarding;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Multiple-Instance LDP and Carrier-of-Carriers VPNs

By configuring multiple LDP routing instances, you can use LDP to advertise labels in a carrier-of-carriers VPN from a service provider provider edge (PE) router to a customer carrier customer edge (CE) router. This is especially useful when the carrier customer is a basic Internet service provider (ISP) and wants to restrict full Internet routes to its PE routers. By using LDP instead of BGP, the carrier customer shields its other internal routers from the Internet. Multiple-instance LDP is also useful when a carrier customer wants to provide Layer 2 or Layer 3 VPN services to its customers.

For an example of how to configure multiple LDP routing instances for carrier-of-carriers VPNs, see the *Multiple Instances for Label Distribution Protocol Feature Guide*.

## Configuring MPLS and LDP to Pop the Label on the Ultimate-Hop Router

The default advertised label is label 3 (Implicit Null label). If label 3 is advertised, the penultimate-hop router removes the label and sends the packet to the egress router. If ultimate-hop popping is enabled, label 0 (IPv4 Explicit Null label) is advertised. Ultimate-hop popping ensures that any packets traversing an MPLS network include a label.

To configure ultimate-hop popping, include the **explicit-null** statement:

```
explicit-null;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

**NOTE:** Juniper Networks routers queue packets based on the incoming label. Routers from other vendors might queue packets differently. Keep this in mind when working with networks containing routers from multiple vendors.

For more information about labels, see [“MPLS Label Overview” on page 24](#) and [“MPLS Label Allocation” on page 26](#).

## Enabling LDP over RSVP-Established LSPs

You can run LDP over LSPs established by RSVP, effectively tunneling the LDP-established LSP through the one established by RSVP. To do so, enable LDP on the lo0.0 interface (see [“Enabling and Disabling LDP” on page 588](#)). You must also configure the LSPs over which you want LDP to operate by including the **ldp-tunneling** statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level:

```
[edit]
protocols {
  mpls {
    label-switched-path lsp-name {
      from source;
      to destination;
      ldp-tunneling;
    }
  }
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

**Related Documentation** • [Tunneling LDP LSPs in RSVP LSPs Overview on page 582](#)

## Enabling LDP over RSVP-Established LSPs in Heterogeneous Networks

Some other vendors use an OSPF metric of 1 for the loopback address. Juniper Networks routers use an OSPF metric of 0 for the loopback address. This might require that you

manually configure the RSVP metric when deploying LDP tunneling over RSVP LSPs in heterogeneous networks.

When a Juniper Networks router is linked to another vendor's router through an RSVP tunnel, and LDP tunneling is also enabled, by default the Juniper Networks router might not use the RSVP tunnel to route traffic to the LDP destinations downstream of the other vendor's egress router if the RSVP path has a metric of 1 larger than the physical OSPF path.

To ensure that LDP tunneling functions properly in heterogeneous networks, you can configure OSPF to ignore the RSVP LSP metric by including the **ignore-lsp-metrics** statement:

```
ignore-lsp-metrics;
```

You can configure this statement at the following hierarchy levels:

- [edit protocols ospf traffic-engineering shortcuts]
- [edit logical-systems *logical-system-name* protocols ospf traffic-engineering shortcuts]

**NOTE:** ACX Series routers do not support [edit logical-systems] hierarchy level.

To enable LDP over RSVP LSPs, you also still need to complete the procedure in Section “Enabling LDP over RSVP-Established LSPs” on page 724.

## Configuring the TCP MD5 Signature for LDP Sessions

You can configure an MD5 signature for an LDP TCP connection to protect against the introduction of spoofed TCP segments into LDP session connection streams.

A router using the MD5 signature option is configured with a password for each peer for which authentication is required. The password is stored encrypted.

LDP hello adjacencies can still be created even when peering interfaces are configured with different security signatures. However, the TCP session cannot be authenticated and is never established.

To configure an MD5 signature for an LDP TCP connection, include the **session** and **authentication-key** statement:

```
session address {
  authentication-key md5-authentication-key;
}
```

For a list of hierarchy levels at which you can include these statements, see the statement summary section for the **session** statement.

Use the **session** statement to configure the address for the remote end of the LDP session.

The **md5-authentication-key** (password) can be up to 69 characters long. Characters can include any ASCII strings. If you include spaces, enclose all characters in quotation marks.

You can also configure an authentication key update mechanism for the LDP routing protocol. This mechanism allows you to update authentication keys without interrupting associated routing and signaling protocols such as Open Shortest Path First (OSPF) and Resource Reservation Setup Protocol (RSVP).

To configure the authentication key update mechanism, include the **key-chain** statement at the **[edit security authentication-key-chains]** hierarchy level, and specify the **key** option to create a keychain consisting of several authentication keys.

```
[edit security authentication-key-chains]
key-chain key-chain-name {
  key key {
    secret secret-data;
    start-time yyyy-mm-dd.hh:mm:ss;
  }
}
```

To configure the authentication key update mechanism for the LDP routing protocol, include the **authentication-key-chain** statement at the **[edit protocols ldp]** hierarchy level to associate the protocol with the **[edit security authentication-key-chains]** authentication keys. You must also configure the authentication algorithm by including the **authentication-algorithm** *algorithm* statement the **[edit protocols ldp]** hierarchy level.

```
[edit protocols ldp]
group group-name {
  neighbor address {
    authentication-algorithm algorithm;
    authentication-key-chain key-chain-name;
  }
}
```

For more information about the authentication key update feature, see *Configuring the Authentication Key Update Mechanism for BGP and LDP Routing Protocols*.

## Configuring LDP Session Protection

An LDP session is normally created between a pair of routers that are connected by one or more links. The routers form one hello adjacency for every link that connects them and associate all the adjacencies with the corresponding LDP session. When the last hello adjacency for an LDP session goes away, the LDP session is terminated. You might want to modify this behavior to prevent an LDP session from being unnecessarily terminated and reestablished.

You can configure the Junos OS to leave the LDP session between two routers up even if there are no hello adjacencies on the links connecting the two routers by configuring the **session-protection** statement. You can optionally specify a time in seconds using the **timeout** option. The session remains up for the duration specified as long as the routers maintain IP network connectivity.

```
session-protection {
  timeout seconds;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section.

## Disabling SNMP Traps for LDP

Whenever an LDP LSP makes a transition from up to down, or down to up, the router sends an SNMP trap. However, it is possible to disable the LDP SNMP traps on a router, logical system, or routing instance.

For information about the LDP SNMP traps and the proprietary LDP MIB, see the [SNMP MIB Explorer](#) and *Interpreting the Enterprise-Specific LDP MIB*.

To disable SNMP traps for LDP, specify the **trap disable** option for the **log-updown** statement:

```
log-updown {
  trap disable;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring LDP Synchronization with the IGP on LDP Links

LDP is a protocol for distributing labels in non-traffic-engineered applications. Labels are distributed along the best path determined by the IGP. If synchronization between LDP and the IGP is not maintained, the LSP goes down. When LDP is not fully operational on a given link (a session is not established and labels are not exchanged), the IGP advertises the link with the maximum cost metric. The link is not preferred but remains in the network topology.

LDP synchronization is supported only on active point-to-point interfaces and LAN interfaces configured as point-to-point under the IGP. LDP synchronization is not supported during graceful restart.

To advertise the maximum cost metric until LDP is operational for synchronization, include the **ldp-synchronization** statement:

```
ldp-synchronization {
  disable;
  hold-time seconds;
}
```

To disable synchronization, include the **disable** statement. To configure the time period to advertise the maximum cost metric for a link that is not fully operational, include the **hold-time** statement.

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

## Configuring LDP Synchronization with the IGP on the Router

You can configure the time the LDP waits before informing the IGP that the LDP neighbor and session for an interface are operational. For large networks with numerous FECs, you might need to configure a longer value to allow enough time for the LDP label databases to be exchanged.

To configure the time the LDP waits before informing the IGP that the LDP neighbor and session are operational, include the **igp-synchronization** statement and specify a time in seconds for the **holddown-interval** option:

```
igp-synchronization holddown-interval seconds;
```

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

## Configuring the Label Withdrawal Timer

The label withdrawal timer delays sending a label withdrawal message for a FEC to a neighbor. When an IGP link to a neighbor fails, the label associated with the FEC has to be withdrawn from all the upstream routers if the neighbor is the next hop for the FEC. After the IGP converges and a label is received from a new next hop, the label is readvertised to all the upstream routers. This is the typical network behavior. By delaying label withdrawal by a small amount of time (for example, until the IGP converges and the router receives a new label for the FEC from the downstream next hop), the label withdrawal and sending a label mapping soon could be avoided. The **label-withdrawal-delay** statement allows you to configure this delay time. By default, the delay is 60 seconds.

If the router receives the new label before the timer runs out, the label withdrawal timer is canceled. However, if the timer runs out, the label for the FEC is withdrawn from all of the upstream routers.

By default, LDP waits for 60 seconds before withdrawing labels to avoid resignaling LSPs multiple times while the IGP is reconverging. To configure the label withdrawal delay time in seconds, include the **label-withdrawal-delay** statement:

```
label-withdrawal-delay seconds;
```

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

## Ignoring the LDP Subnet Check

In Junos OS Release 8.4 and later releases, an LDP source address subnet check is performed during the neighbor establishment procedure. The source address in the LDP link hello packet is matched against the interface address. This causes an interoperability issue with some other vendors' equipment.

To disable the subnet check, include the **allow-subnet-mismatch** statement:

```
allow-subnet-mismatch;
```

This statement can be included at the following hierarchy levels:

- [edit protocols ldp **interface** *interface-name*]
- [edit logical-systems *logical-system-name* protocols ldp **interface** *interface-name*]

**NOTE:** ACX Series routers do not support [edit logical-systems] hierarchy level.

## Configuring LDP LSP Traceroute

You can trace the route followed by an LDP-sigaled LSP. LDP LSP traceroute is based on RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*. This feature allows you to periodically trace all paths in a FEC. The FEC topology information is stored in a database accessible from the CLI.

A topology change does not automatically trigger a trace of an LDP LSP. However, you can manually initiate a traceroute. If the traceroute request is for an FEC that is currently in the database, the contents of the database are updated with the results.

The periodic traceroute feature applies to all FECs specified by the **oam** statement configured at the [edit protocols ldp] hierarchy level. To configure periodic LDP LSP traceroute, include the **periodic-traceroute** statement:

```
periodic-traceroute {
  disable;
  exp exp-value;
  fanout fanout-value;
  frequency minutes;
  paths number-of-paths;
  retries retry-attempts;
  source address;
  ttl ttl-value;
  wait seconds;
}
```

You can configure this statement at the following hierarchy levels:

- [edit protocols ldp **oam**]
- [edit protocols ldp **oam** *fec address*]

You can configure the **periodic-traceroute** statement by itself or with any of the following options:

- **exp**—Specify the class of service to use when sending probes.
- **fanout**—Specify the maximum number of next hops to search per node.
- **frequency**—Specify the interval between traceroute attempts.
- **paths**—Specify the maximum number of paths to search.

- **retries**—Specify the number of attempts to send a probe to a specific node before giving up.
- **source**—Specify the IPv4 source address to use when sending probes.
- **ttl**—Specify the maximum time-to-live value. Nodes that are beyond this value are not traced.
- **wait**—Specify the wait interval before resending a probe packet.

## Collecting LDP Statistics

LDP traffic statistics show the volume of traffic that has passed through a particular FEC on a router.

When you configure the **traffic-statistics** statement at the **[edit protocols ldp]** hierarchy level, the LDP traffic statistics are gathered periodically and written to a file. You can configure how often statistics are collected (in seconds) by using the **interval** option. The default collection interval is 5 minutes. You must configure an LDP statistics file; otherwise, LDP traffic statistics are not gathered. If the LSP goes down, the LDP statistics are reset.

To collect LDP traffic statistics, include the **traffic-statistics** statement:

```
traffic-statistics {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  interval interval;
  no-penultimate-hop;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

This section includes the following topics:

- [LDP Statistics Output on page 730](#)
- [Disabling LDP Statistics on the Penultimate-Hop Router on page 731](#)
- [LDP Statistics Limitations on page 732](#)

## LDP Statistics Output

The following sample output is from an LDP statistics file:

FEC	Type	Packets	Bytes	Shared
10.255.350.448/32	Transit	0	0	No
	Ingress	0	0	No
10.255.350.450/32	Transit	0	0	Yes
	Ingress	0	0	No
10.255.350.451/32	Transit	0	0	No
	Ingress	0	0	No
220.220.220.1/32	Transit	0	0	Yes
	Ingress	0	0	No
220.220.220.2/32	Transit	0	0	Yes
	Ingress	0	0	No
220.220.220.3/32	Transit	0	0	Yes
	Ingress	0	0	No

May 28 15:02:05, read 12 statistics in 00:00:00 seconds

The LDP statistics file includes the following columns of data:

- **read**—Number of bytes of data passed by the FEC since its LSP came up.
- **read**—FEC for which LDP traffic statistics are collected.
- **read**—Number of packets passed by the FEC since its LSP came up.
- **read**—This number (which appears next to the date and time) might differ from the actual number of the statistics displayed. Some of the statistics are summarized before being displayed.
- **Shared**—A **Yes** value indicates that several prefixes are bound to the same label (for example, when several prefixes are advertised with an egress policy). The LDP traffic statistics for this case apply to all the prefixes and should be treated as such.
- **Type**—Type of traffic originating from a router, either **Ingress** (originating from this router) or **Transit** (forwarded through this router).

## Disabling LDP Statistics on the Penultimate-Hop Router

Gathering LDP traffic statistics at the penultimate-hop router can consume excessive system resources, on next-hop routes in particular. This problem is exacerbated if you have configured the **deaggregate** statement in addition to the **traffic-statistics** statement. For routers reaching their limit of next-hop route usage, we recommend configuring the **no-penultimate-hop** option for the **traffic-statistics** statement:

```
traffic-statistics {
  no-penultimate-hop;
}
```

For a list of hierarchy levels at which you can configure the **traffic-statistics** statement, see the statement summary section for this statement.

**NOTE:** When you configure the **no-penultimate-hop** option, no statistics are available for the FECs that are the penultimate hop for this router.

Whenever you include or remove this option from the configuration, the LDP sessions are taken down and then restarted.

The following sample output is from an LDP statistics file showing routers on which the **no-penultimate-hop** option is configured:

FEC	Type	Packets	Bytes	Shared
10.255.245.218/32	Transit	0	0	No
	Ingress	4	246	No
10.255.245.221/32	Transit	statistics disabled		
	Ingress	statistics disabled		
13.1.1.0/24	Transit	statistics disabled		
	Ingress	statistics disabled		
13.1.3.0/24	Transit	statistics disabled		
	Ingress	statistics disabled		

## LDP Statistics Limitations

The following are issues related to collecting LDP statistics by configuring the **traffic-statistics** statement:

- You cannot clear the LDP statistics.
- If you shorten the specified interval, a new LDP statistics request is issued only if the statistics timer expires later than the new interval.
- A new LDP statistics collection operation cannot start until the previous one has finished. If the interval is short or if the number of LDP statistics is large, the time gap between the two statistics collections might be longer than the interval.

When an LSP goes down, the LDP statistics are reset.

---

## Tracing LDP Protocol Traffic

The following sections describe how to configure the trace options to examine LDP protocol traffic:

- [Tracing LDP Protocol Traffic at the Protocol and Routing Instance Levels on page 732](#)
- [Tracing LDP Protocol Traffic Within FECs on page 733](#)
- [Examples: Tracing LDP Protocol Traffic on page 734](#)

### Tracing LDP Protocol Traffic at the Protocol and Routing Instance Levels

To trace LDP protocol traffic, you can specify options in the global **traceoptions** statement at the **[edit routing-options]** hierarchy level, and you can specify LDP-specific options by including the **traceoptions** statement:

```
traceoptions {  
  file filename <files number> <size size> <world-readable | no-world-readable>;  
  flag flag <flag-modifier> <disable>;  
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Use the **file** statement to specify the name of the file that receives the output of the tracing operation. All files are placed in the directory `/var/log`. We recommend that you place LDP-tracing output in the file **ldp-log**.

The following trace flags display the operations associated with the sending and receiving of various LDP messages. Each can carry one or more of the following modifiers:

- **address**—Trace the operation of address and address withdrawal messages.
- **binding**—Trace label-binding operations.
- **error**—Trace error conditions.
- **event**—Trace protocol events.

- **initialization**—Trace the operation of initialization messages.
- **label**—Trace the operation of label request, label map, label withdrawal, and label release messages.
- **notification**—Trace the operation of notification messages.
- **packets**—Trace the operation of address, address withdrawal, initialization, label request, label map, label withdrawal, label release, notification, and periodic messages. This modifier is equivalent to setting the **address**, **initialization**, **label**, **notification**, and **periodic** modifiers.

You can also configure the **filter** flag modifier with the **match-on address** sub-option for the **packets** flag. This allows you to trace based on the source and destination addresses of the packets.

- **path**—Trace label-switched path operations.
- **path**—Trace label-switched path operations.
- **periodic**—Trace the operation of hello and keepalive messages.
- **route**—Trace the operation of route messages.
- **state**—Trace protocol state transitions.

## Tracing LDP Protocol Traffic Within FECs

LDP associates a forwarding equivalence class (FEC) with each LSP it creates. The FEC associated with an LSP specifies which packets are mapped to that LSP. LSPs are extended through a network as each router chooses the label advertised by the next hop for the FEC and splices it to the label it advertises to all other routers.

You can trace LDP protocol traffic within a specific FEC and filter LDP trace statements based on an FEC. This is useful when you want to trace or troubleshoot LDP protocol traffic associated with an FEC. The following trace flags are available for this purpose: **route**, **path**, and **binding**.

The following example illustrates how you might configure the LDP **traceoptions** statement to filter LDP trace statements based on an FEC:

```
[edit protocols ldp traceoptions]
set flag route filter match-on fec policy "filter-policy-for-ldp-fec";
```

This feature has the following limitations:

- The filtering capability is only available for FECs composed of IP version 4 (IPv4) prefixes.
- Layer 2 circuit FECs cannot be filtered.
- When you configure both route tracing and filtering, MPLS routes are not displayed (they are blocked by the filter).

- Filtering is determined by the policy and the configured value for the **match-on** option. When configuring the policy, be sure that the default behavior is always **reject**.
- The only **match-on** option is **fec**. Consequently, the only type of policy you should include is a route-filter policy.

## Examples: Tracing LDP Protocol Traffic

Trace LDP path messages in detail:

```
[edit]
protocols {
  ldp {
    traceoptions {
      file ldp size 10m files 5;
      flag path;
    }
  }
}
```

Trace all LDP outgoing messages:

```
[edit]
protocols {
  ldp {
    traceoptions {
      file ldp size 10m files 5;
      flag packets;
    }
  }
}
```

Trace all LDP error conditions:

```
[edit]
protocols {
  ldp {
    traceoptions {
      file ldp size 10m files 5;
      flag error;
    }
  }
}
```

Trace all LDP incoming messages and all label-binding operations:

```
[edit]
protocols {
  ldp {
    traceoptions {
      file ldp size 10m files 5 world-readable;
      flag packets receive;
      flag binding;
    }
    interface all {
    }
  }
}
```

```
}
```

Trace LDP protocol traffic for an FEC associated with the LSP:

```
[edit]
protocols {
  ldp {
    traceoptions {
      flag route filter match-on fec policy filter-policy-for-ldp-fec;
    }
  }
}
```

## CHAPTER 16

# CCC and TCC Overview

- [CCC Overview on page 739](#)
- [Transmitting Nonstandard BPDUs on page 740](#)
- [TCC Overview on page 740](#)

### CCC Overview

---

Circuit cross-connect (CCC) allows you to configure transparent connections between two circuits, where a circuit can be a Frame Relay data-link connection identifier (DLCI), an Asynchronous Transfer Mode (ATM) virtual circuit (VC), a Point-to-Point Protocol (PPP) interface, a Cisco High-Level Data Link Control (HDLC) interface, or an MPLS label-switched path (LSP). Using CCC, packets from the source circuit are delivered to the destination circuit with, at most, the Layer 2 address being changed. No other processing—such as header checksums, time-to-live (TTL) decrementing, or protocol processing—is done.

CCC circuits fall into two categories: logical interfaces, which include DLCIs, VCs, virtual local area network (VLAN) IDs, PPP and Cisco HDLC interfaces, and LSPs. The two circuit categories provide three types of cross-connect:

- **Layer 2 switching**—Cross-connects between logical interfaces provide what is essentially Layer 2 switching. The interfaces that you connect must be of the same type.
- **MPLS tunneling**—Cross-connects between interfaces and LSPs allow you to connect two distant interface circuits of the same type by creating MPLS tunnels that use LSPs as the conduit.
- **LSP stitching**—Cross-connects between LSPs provide a way to “stitch” together two label-switched paths, including paths that fall in two different traffic engineering database areas.

For Layer 2 switching and MPLS tunneling, the cross-connect is bidirectional, so packets received on the first interface are transmitted out the second interface, and those received on the second interface are transmitted out the first. For LSP stitching, the cross-connect is unidirectional.

You can police (control) the amount of traffic flowing over CCC circuits. For more information, see the *Junos OS VPNs Library for Routing Devices*.

It is also possible to use the **ping** command to check the integrity of CCC LSPs. See [“Pinging CCC LSPs” on page 389](#) for more information.

## Transmitting Nonstandard BPDUs

CCC protocol (and Layer 2 Circuit and Layer 2 VPN) configurations can transmit nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment. This is the default behavior on all supported PICs and requires no additional configuration.

The following PICs are supported on M320 and T Series routers:

- 1-port Gigabit Ethernet PIC
- 2-port Gigabit Ethernet PIC
- 4-port Gigabit Ethernet PIC
- 10-port Gigabit Ethernet PIC

## TCC Overview

Translational cross-connect (TCC) is a switching concept that enables you to establish interconnections between a variety of Layer 2 protocols or circuits. It is similar to CCC. However, whereas CCC requires the same Layer 2 encapsulations on each side of a Juniper Networks router (such as PPP-to-PPP or Frame Relay-to-Frame Relay), TCC enables you to connect different types of Layer 2 protocols interchangeably. When you use TCC, combinations such as PPP-to-ATM (see [Figure 72 on page 740](#)) and Ethernet-to-Frame Relay connections are possible.

Figure 72: TCC Example

The Layer 2 circuits and encapsulation types that can be interconnected by TCC are:

- Ethernet
- Extended VLANs
- PPP
- HDLC
- ATM
- Frame Relay

TCC works by removing the Layer 2 header when frames enter the router and adding a different Layer 2 header on the frames before they leave the router. In [Figure 72 on page 740](#), the PPP encapsulation is stripped from the frames arriving at Router B, and the ATM encapsulation is added before the frames are sent to Router C.

Note that all control traffic is terminated at the interconnecting router (Router B). Examples of traffic controllers include the Link Control Protocol (LCP) and the Network Control Protocol (NCP) for PPP, keepalives for HDLC, and Local Management Interface (LMI) for Frame Relay.

TCC functionality is different from standard Layer 2 switching. TCC only swaps Layer 2 headers. No other processing, such as header checksums, TTL decrementing, or protocol handling is performed. TCC is supported for IPv4 only.

Address Resolution Protocol (APR) packet policing on TCC Ethernet interfaces is effective for releases 10.4 and onwards.

You can configure TCC for interface switching and for Layer 2 VPNs. For more information about using TCC for virtual private networks (VPNs), see the *Junos OS VPNs Library for Routing Devices*.

# Configuring CCC and TCC

- [Configuring CCC and TCC Graceful Restart on page 761](#)
- [Configuring CCC Switching for Point-to-Multipoint LSPs on page 761](#)

## Configuring Layer 2 Switching Cross-Connects Using CCC

Layer 2 switching cross-connects join logical interfaces to form what is essentially Layer 2 switching. The interfaces that you connect must be of the same type.

[Figure 73 on page 743](#) illustrates a Layer 2 switching cross-connect. In this topology, Router A and Router C have Frame Relay connections to Router B, which is a Juniper Networks router. Circuit cross-connect (CCC) allows you to configure Router B to act as a Frame Relay (Layer 2) switch.

To configure Router B to act as a Frame Relay switch, you configure a circuit from Router A to Router C that passes through Router B, effectively configuring Router B as a Frame Relay switch with respect to these routers. This configuration allows Router B to transparently switch packets (frames) between Router A and Router C without regard to the packets' contents or the Layer 3 protocols. The only processing that Router B performs is to translate DLCI 600 to 750.

**Figure 73: Layer 2 Switching Cross-Connect**

If the Router A-to-Router B and Router B-to-Router C circuits were PPP, for example, the Link Control Protocol and Network Control Protocol exchanges occur between Router A and Router C. These messages are handled transparently by Router B, allowing Router A and Router C to use various PPP options (such as header or address compression and authentication) that Router B might not support. Similarly, Router A and Router C exchange keepalives, providing circuit-to-circuit connectivity status.

You can configure Layer 2 switching cross-connects on PPP, Cisco HDLC, Frame Relay, Ethernet, and ATM circuits. In a single cross-connect, only like interfaces can be connected.

To configure Layer 2 switching cross-connects, you must configure the following on the router that is acting as the switch (Router B in [Figure 73 on page 743](#)):

- [Configuring the CCC Encapsulation for Layer 2 Switching Cross-Connects on page 744](#)
- [Configuring the CCC Connection for Layer 2 Switching Cross-Connects on page 748](#)
- [Configuring MPLS for Layer 2 Switching Cross-Connects on page 748](#)
- [Example: Configuring a Layer 2 Switching Cross-Connect on page 749](#)

## Configuring the CCC Encapsulation for Layer 2 Switching Cross-Connects

To configure Layer 2 switching cross-connects, configure the CCC encapsulation on the router that is acting as the switch (Router B in [Figure 73 on page 743](#)).

**NOTE:** You cannot configure families on CCC interfaces; that is, you cannot include the family statement at the [edit interfaces *interface-name* unit *logical-unit-number*] hierarchy level.

For instructions for configuring the encapsulation for Layer 2 switching cross-connects, see the following sections:

- [Configuring ATM Encapsulation for Layer 2 Switching Cross-Connects on page 744](#)
- [Configuring Ethernet Encapsulation for Layer 2 Switching Cross-Connects on page 745](#)
- [Configuring Ethernet VLAN Encapsulation for Layer 2 Switching Cross-Connects on page 745](#)
- [Configuring Aggregated Ethernet Encapsulation for Layer 2 Switching Cross-Connects on page 746](#)
- [Configuring Frame Relay Encapsulation for Layer 2 Switching Cross-Connects on page 747](#)
- [Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching Cross-Connects on page 748](#)

---

## Configuring ATM Encapsulation for Layer 2 Switching Cross-Connects

For ATM circuits, specify the encapsulation when configuring the virtual circuit (VC). Configure each VC as a circuit or a regular logical interface by including the following statements:

```
at-fpc/pic/port {
  atm-options {
    vpi vpi-identifier maximum-vcs maximum-vcs;
  }
  unit logical-unit-number {
    encapsulation encapsulation-type;
    point-to-point; # Default interface type
    vci vpi-identifier.vci-identifier;
```

```
}
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

### Configuring Ethernet Encapsulation for Layer 2 Switching Cross-Connects

For Ethernet circuits, specify **ethernet-ccc** in the **encapsulation** statement. This statement configures the entire physical device. For these circuits to work, you must also configure a logical interface (unit 0).

Ethernet interfaces with standard Tag Protocol Identifier (TPID) tagging can use Ethernet CCC encapsulation. On M Series Multiservice Edge Routers, except the M320, one-port Gigabit Ethernet, two-port Gigabit Ethernet, four-port Gigabit Ethernet, and four-port Fast Ethernet PICs can use Ethernet CCC encapsulation. On T Series Core Routers and M320 routers, one-port Gigabit Ethernet and two-port Gigabit Ethernet PICs installed in FPC2 can use Ethernet CCC encapsulation. When you use this encapsulation type, you can configure the **ccc** family only.

```
fe-fpc/pic/port {
  encapsulation ethernet-ccc;
  unit 0;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

### Configuring Ethernet VLAN Encapsulation for Layer 2 Switching Cross-Connects

An Ethernet virtual LAN (VLAN) circuit can be configured using either the **vlan-ccc** or **extended-vlan-ccc** encapsulation. If you configure the **extended-vlan-ccc** encapsulation on the physical interface, you cannot configure the **inet** family on the logical interfaces. Only the **ccc** family is allowed. If you configure the **vlan-ccc** encapsulation on the physical interface, both the **inet** and **ccc** families are supported on the logical interfaces. Ethernet interfaces in VLAN mode can have multiple logical interfaces.

For encapsulation type **vlan-ccc**, VLAN IDs from 512 through 4094 are reserved for CCC VLANs. For the **extended-vlan-ccc** encapsulation type, all VLAN IDs 1 and higher are valid. VLAN ID 0 is reserved for tagging the priority of frames.

**NOTE:** Some vendors use the proprietary TPIDs 0x9100 and 0x9901 to encapsulate a VLAN-tagged packet into a VLAN-CCC tunnel to interconnect a geographically separated metro Ethernet network. By configuring the **extended-vlan-ccc** encapsulation type, a Juniper Networks router can accept all three TPIDs (0x8100, 0x9100, and 0x9901).

Configure an Ethernet VLAN circuit with the **vlan-ccc** encapsulation as follows:

```
interfaces {  
  type-fpc/pic/port {  
    vlan-tagging;  
    encapsulation vlan-ccc;  
    unit logical-unit-number {  
      encapsulation vlan-ccc;  
      vlan-id vlan-id;  
    }  
  }  
}
```

You can configure these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems *logical-system-name* interfaces]**

Configure an Ethernet VLAN circuit with the **extended-vlan-ccc** encapsulation statement as follows:

```
interfaces {  
  type-fpc/pic/port {  
    vlan-tagging;  
    encapsulation extended-vlan-ccc;  
    unit logical-unit-number {  
      vlan-id vlan-id;  
      family ccc;  
    }  
  }  
}
```

You can configure these statements at the following hierarchy levels:

- **[edit interfaces]**
- **[edit logical-systems *logical-system-name* interfaces]**

Whether you configure the encapsulation as **vlan-ccc** or **extended-vlan-ccc**, you must enable VLAN tagging by including the **vlan-tagging** statement.

### Configuring Aggregated Ethernet Encapsulation for Layer 2 Switching Cross-Connects

---

You can configure aggregated Ethernet interfaces for CCC connections and for Layer 2 virtual private networks (VPNs).

Aggregated Ethernet interfaces configured with VLAN tagging can be configured with multiple logical interfaces. The only encapsulation available for aggregated Ethernet logical interfaces is **vlan-ccc**. When you configure the **vlan-id** statement, you are limited to VLAN IDs 512 through 4094.

Aggregated Ethernet interfaces configured without VLAN tagging can be configured only with the **ethernet-ccc** encapsulation. All untagged Ethernet packets received are forwarded based on the CCC parameters.

To configure aggregated Ethernet interfaces for CCC connections, include the **ae0** statement at the **[edit interfaces]** hierarchy level:

```
[edit interfaces]
ae0 {
  encapsulation (ethernet-ccc | extended-vlan-ccc | vlan-ccc);
  vlan-tagging;
  aggregated-ether-options {
    minimum-links links;
    link-speed speed;
  }
  unit logical-unit-number {
    encapsulation vlan-ccc;
    vlan-id identifier;
    family ccc;
  }
}
```

Be aware of the following limitations when configuring CCC connections over aggregated Ethernet interfaces:

- If you configured load balancing between child links, be aware that a different hash key is used to distribute packets among the child links. Standard aggregated interfaces have family inet configured. An IP version 4 (IPv4) hash key (based on the Layer 3 information) is used to distribute packets among the child links. A CCC connection over an aggregated Ethernet interface has family ccc configured instead. Instead of an IPv4 hash key, an MPLS hash key (based on the destination media access control [MAC] address) is used to distributed packets among the child links.
- The extended-vlan-ccc encapsulation is not supported on the 12-port Fast Ethernet PIC and the 48-port Fast Ethernet PIC.
- The Junos OS does not support the Link Aggregation Control Protocol (LACP) when an aggregated interface is configured as a VLAN (with vlan-ccc encapsulation). LACP can be configured only when the aggregated interface is configured with the ethernet-ccc encapsulation.

For more information about how to configure aggregated Ethernet interfaces, see the *Junos OS Network Interfaces Library for Routing Devices*.

### Configuring Frame Relay Encapsulation for Layer 2 Switching Cross-Connects

For Frame Relay circuits, specify the encapsulation when configuring the DLCI. Configure each DLCI as a circuit or a regular logical interface. The DLCI for regular interfaces must be from 1 through 511. For CCC interfaces, it must be from 512 through 4094.

```
interfaces {
  type-fpc/pic/port {
    unit logical-unit-number {
      dlci dlci-identifier;
      encapsulation encapsulation-type;
      point-to-point; # Default interface type
    }
  }
}
```

You can configure these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

### Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching Cross-Connects

---

For PPP and Cisco HDLC circuits, specify the encapsulation in the **encapsulation** statement. This statement configures the entire physical device. For these circuits to work, you must configure a logical interface (unit 0).

```
interfaces type-fpc/pic/port {  
  encapsulation encapsulation-type;  
  unit 0;  
}
```

You can configure these statements at the following hierarchy levels:

- [edit interfaces *type-fpc/pic/port*]
- [edit logical-systems *logical-system-name* interfaces *type-fpc/pic/port*]

### Configuring the CCC Connection for Layer 2 Switching Cross-Connects

To configure Layer 2 switching cross-connects, define the connection between the two circuits by including the **interface-switch** statement. You configure this connection on the router that is acting as the switch (Router B in [Figure 73 on page 743](#)). The connection joins the interface that comes from the circuit's source to the interface that leads to the circuit's destination. When you specify the interface names, include the logical portion of the name, which corresponds to the logical unit number. The cross-connect is bidirectional, so packets received on the first interface are transmitted out the second interface, and those received on the second interface are transmitted out the first.

```
interface-switch connection-name {  
  interface interface-name.unit-number;  
  interface interface-name.unit-number;  
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

### Configuring MPLS for Layer 2 Switching Cross-Connects

For Layer 2 switching cross-connects to work, you must enable MPLS on the router by including at least the following statements. This minimum configuration enables MPLS on a logical interface for the switching cross-connect.

Include the **family mpls** statement:

```
family mpls;
```

You can configure this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

You can then specify this logical interface in the MPLS protocol configuration:

```
mpls {
  interface interface-name; # Required to enable MPLS on the interface
}
```

You can configure these statements at the following hierarchy levels:

- [edit protocols]
- [edit logical-systems *logical-system-name* protocols]

### Example: Configuring a Layer 2 Switching Cross-Connect

Configure a full-duplex Layer 2 switching cross-connect between Router A and Router C, using a Juniper Networks router, Router B, as the virtual switch. See the topology in [Figure 74 on page 749](#) and [Figure 75 on page 750](#).

Figure 74: Topology of a Frame Relay Layer 2 Switching Cross-Connect

```
[edit]
interfaces {
  so-1/0/0 {
    encapsulation frame-relay-ccc;
    unit 1 {
      point-to-point;
      encapsulation frame-relay-ccc;
      dlci 600;
    }
  }
  so-2/0/0 {
    encapsulation frame-relay-ccc;
    unit 2 {
      point-to-point;
      encapsulation frame-relay-ccc;
      dlci 750;
    }
  }
}
protocols {
  connections {
    interface-switch router-a-to-router-c {
      interface so-1/0/0.1;
    }
  }
}
```

```

        interface so-2/0/0.2;
    }
}
mpls {
    interface all;
}
}

```

Figure 75: Sample Topology of a VLAN Layer 2 Switching Cross-Connect

```

[edit]
interfaces {
    ge-2/1/0 {
        vlan-tagging;
        encapsulation vlan-ccc;
        unit 0 {
            encapsulation vlan-ccc;
            vlan-id 600;
        }
    }
    ge-2/2/0 {
        vlan-tagging;
        encapsulation vlan-ccc;
        unit 0 {
            encapsulation vlan-ccc;
            vlan-id 600;
        }
        unit 1 {
            family inet {
                vlan-id 1;
                address 10.9.200.1/24;
            }
        }
    }
}
protocols {
    mpls {
        interface all;
    }
    connections {
        interface-switch layer2-sw {
            interface ge-2/1/0.0;
            interface ge-2/2/0.0;
        }
    }
}
}

```

## Configuring MPLS LSP Tunnel Cross-Connects Using CCC

MPLS tunnel cross-connects between interfaces and LSPs allow you to connect two distant interface circuits of the same type by creating MPLS tunnels that use LSPs as the conduit. The topology in [Figure 76 on page 751](#) illustrates an MPLS LSP tunnel cross-connect. In this topology, two separate networks, in this case ATM access networks, are connected through an IP backbone. CCC allows you to establish an LSP tunnel between the two domains. With LSP tunneling, you tunnel the ATM traffic from one network across a SONET backbone to the second network by using an MPLS LSP.

**Figure 76: MPLS Tunnel Cross-Connect**

When traffic from Router A (VC 234) reaches Router B, it is encapsulated and placed into an LSP, which is sent through the backbone to Router C. At Router C, the label is removed, and the packets are placed onto the ATM permanent virtual circuit (PVC) (VC 591) and sent to Router D. Similarly, traffic from Router D (VC 591) is sent over an LSP to Router B, then placed on VC 234 to Router A.

You can configure LSP tunnel cross-connect on PPP, Cisco HDLC, Frame Relay, and ATM circuits. In a single cross-connect, only like interfaces can be connected.

When you use MPLS tunnel cross-connects to support IS-IS, you must ensure that the LSP's maximum transmission unit (MTU) can, at a minimum, accommodate a 1492-octet IS-IS protocol data unit (PDU) in addition to the link-level overhead associated with the technology being connected.

For the tunnel cross-connects to work, the IS-IS frame size on the edge routers (Routers A and D in [Figure 77 on page 754](#)) must be smaller than the LSP's MTU.

**NOTE:** Frame size values do not include the frame check sequence (FCS) or delimiting flags.

To determine the LSP MTU required to support IS-IS, use the following calculation:

$$\text{IS-IS MTU (minimum 1492, default 1497) + frame overhead + 4 (MPLS shim header) = Minimum LSP MTU}$$

The framing overhead varies based on the encapsulation being used. The following lists the IS-IS encapsulation overhead values for various encapsulations:

- ATM
  - AAL5 multiplex—8 bytes (RFC 1483)

- VC multiplex—0 bytes
- Frame Relay
  - Multiprotocol—2 bytes (RFCs 1490 and 2427)
  - VC multiplex—0 bytes
- HDLC—4 bytes
- PPP—4 bytes
- VLAN—21 bytes (802.3/LLC)

For IS-IS to work over VLAN-CCC, the LSP's MTU must be at least 1513 bytes (or 1518 for 1497-byte PDUs). If you increase the size of a Fast Ethernet MTU above the default of 1500 bytes, you might need to explicitly configure jumbo frames on intervening equipment.

To modify the MTU, include the **mtu** statement when configuring the logical interface family at the **[edit interfaces *interface-name* unit *logical-unit-number* encapsulation *family*]** hierarchy level. For more information about setting the MTU, see the *Junos OS Network Interfaces Library for Routing Devices*.

To configure an LSP tunnel cross-connect, you must configure the following on the interdomain router (Router B in [Figure 77 on page 754](#)):

- [Configuring the CCC Encapsulation for LSP Tunnel Cross-Connects on page 752](#)
- [Configuring the CCC Connection for LSP Tunnel Cross-Connects on page 753](#)
- [Example: Configuring an LSP Tunnel Cross-Connect on page 754](#)

## Configuring the CCC Encapsulation for LSP Tunnel Cross-Connects

To configure LSP tunnel cross-connects, you must configure the CCC encapsulation on the ingress and egress routers (Router B and Router C, respectively, in [Figure 77 on page 754](#)).

**NOTE:** You cannot configure families on CCC interfaces; that is, you cannot include the **family** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

For PPP or Cisco HDLC circuits, include the **encapsulation** statement to configure the entire physical device. For these circuits to work, you must configure logical unit 0 on the interface.

```
type-fpc/pic/port {
  encapsulation (ppp-ccc | cisco-hdlc-ccc);
  unit 0;
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces]**

- [edit logical-systems *logical-system-name* interfaces]

For ATM circuits, specify the encapsulation when configuring the VC by including the following statements. For each VC, you configure whether it is a circuit or a regular logical interface.

```
at-fpc/pic/port {
  atm-options {
    vpi vpi-identifier maximum-vcs maximum-vcs;
  }
  unit logical-unit-number {
    point-to-point; # Default interface type
    encapsulation atm-ccc-vc-mux;
    vci vpi-identifier.vci-identifier;
  }
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

For Frame Relay circuits, include the following statements to specify the encapsulation when configuring the DLCI. For each DLCI, you configure whether it is a circuit or a regular logical interface. The DLCI for regular interfaces must be in the range 1 through 511. For CCC interfaces, it must be in the range 512 through 1022.

```
type-fpc/pic/port {
  encapsulation frame-relay-ccc;
  unit logical-unit-number {
    point-to-point; # default interface type
    encapsulation frame-relay-ccc;
    dlci dlci-identifier;
  }
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces]
- [edit logical-systems *logical-system-name* interfaces]

For more information about the **encapsulation** statement, see the *Junos OS Network Interfaces Library for Routing Devices*.

## Configuring the CCC Connection for LSP Tunnel Cross-Connects

To configure LSP tunnel cross-connects, include the **remote-interface-switch** statement to define the connection between the two circuits on the ingress and egress routers (Router B and Router C, respectively, in [Figure 77 on page 754](#)). The connection joins the interface or LSP that comes from the circuit's source to the interface or LSP that leads to the circuit's destination. When you specify the interface name, include the logical portion of the name, which corresponds to the logical unit number. For the cross-connect to be bidirectional, you must configure cross-connects on two routers.

```

remote-interface-switch connection-name {
  interface interface-name.unit-number;
  transmit-lsp label-switched-path;
  receive-lsp label-switched-path;
}

```

You can include these statements at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

### Example: Configuring an LSP Tunnel Cross-Connect

Configure a full-duplex MPLS LSP tunnel cross-connect from Router A to Router D, passing through Router B and Router C. See the topology in [Figure 77 on page 754](#).

Figure 77: Example Topology of MPLS LSP Tunnel Cross-Connect

On Router B:

```

[edit]
interfaces {
  at-7/1/1 {
    atm-options {
      vpi 1 maximum-vcs 600;
    }
    unit 1 {
      point-to-point; # default interface type
      encapsulation atm-ccc-vc-mux;
      vci 1.234;
    }
  }
}
protocols {
  connections {
    remote-interface-switch router-b-to-router-c {
      interface at-7/1/1.1;
      transmit-lsp lsp1;
      receive-lsp lsp2;
    }
  }
}

```

On Router C:

```

[edit]
interfaces {
  at-3/0/0 {
    atm-options {

```

```

    vpi 2 maximum-vcs 600;
  }
  unit 2 {
    point-to-point; # default interface type
    encapsulation atm-ccc-vc-mux;
    vci 2.591;
  }
}
protocols {
  connections {
    remote-interface-switch router-b-to-router-c {
      interface at-3/0/0.2;
      transmit-lsp lsp2;
      receive-lsp lsp1;
    }
  }
}

```

## Configuring TCC

This section describes how to configure translational cross-connect (TCC). Extensive examples on how to configure TCC for interface switching and for Layer 2.5 VPNs are available in the *Junos OS, Release 15.1*.

To configure TCC, you must perform the following tasks on the router that is acting as the switch:

- [Configuring the Encapsulation for Layer 2 Switching TCCs on page 755](#)
- [Configuring the Connection for Layer 2 Switching TCCs on page 759](#)
- [Configuring MPLS for Layer 2 Switching TCCs on page 759](#)

### Configuring the Encapsulation for Layer 2 Switching TCCs

To configure a Layer 2 switching TCC, specify the TCC encapsulation on the desired interfaces of the router that is acting as the switch.

**NOTE:** You cannot configure standard protocol families on TCC or CCC interfaces. Only the CCC family is allowed on CCC interfaces, and only the TCC family is allowed on TCC interfaces.

For Ethernet circuits and Ethernet extended VLAN circuits, you must also configure the Address Resolution Protocol (ARP). See [“Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations” on page 758](#).

- [Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching TCCs on page 756](#)
- [Configuring ATM Encapsulation for Layer 2 Switching TCCs on page 756](#)
- [Configuring Frame Relay Encapsulation for Layer 2 Switching TCCs on page 756](#)
- [Configuring Ethernet Encapsulation for Layer 2 Switching TCCs on page 757](#)

- [Configuring Ethernet Extended VLAN Encapsulation for Layer 2 Switching TCCs on page 757](#)
- [Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations on page 758](#)

### [Configuring PPP and Cisco HDLC Encapsulation for Layer 2 Switching TCCs](#)

---

For PPP and Cisco HDLC circuits, configure the encapsulation type for the entire physical device by specifying the appropriate value for the **encapsulation** statement. For these circuits to work, you must also configure the logical interface **unit 0**.

```
encapsulation (ppp-tcc | cisco-hdlc-tcc);
unit 0{...}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name*]
- [edit logical-systems *logical-system-name* interfaces *interface-name*]

### [Configuring ATM Encapsulation for Layer 2 Switching TCCs](#)

---

For ATM circuits, configure the encapsulation type by specifying the appropriate value for the **encapsulation** statement in the virtual circuit (VC) configuration. Specify whether each VC is a circuit or a regular logical interface.

```
atm-options {
  vpi vpi-identifier maximum-vcs maximum-vcs;
}
unit logical-unit-number {
  encapsulation (atm-tcc-vc-mux | atm-tcc-snap);
  point-to-point;
  vci vpi-identifier.vci-identifier;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *at-fpc/pic/port*]
- [edit logical-systems *logical-system-name* interfaces *at-fpc/pic/port*]

### [Configuring Frame Relay Encapsulation for Layer 2 Switching TCCs](#)

---

For Frame Relay circuits, configure the encapsulation type by specifying the value **frame-relay-tcc** for the **encapsulation** statement when configuring the data-link connection identifier (DLCI). You configure each DLCI as a circuit or a regular logical interface. The DLCI for regular interfaces must be in the range from 1 through 511, but for TCC and CCC interfaces it must be in the range from 512 through 1022.

```
encapsulation frame-relay-tcc;
unit logical-unit-number {
  dlci dlci-identifier;
  encapsulation frame-relay-tcc;
  point-to-point;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name*]
- [edit logical-systems *logical-system-name* interfaces *interface-name*]

### Configuring Ethernet Encapsulation for Layer 2 Switching TCCs

For Ethernet TCC circuits, configuring the encapsulation type for the entire physical device by specifying the value **ethernet-tcc** for the **encapsulation** statement.

You must also specify static values for a remote address and a proxy address at the [edit interfaces *interface-name* unit *unit-number* family **tcc**] or [edit logical-systems *logical-system-name* interfaces *interface-name* unit *unit-number* family **tcc**] hierarchy level.

The remote address is associated with the TCC switching router's Ethernet neighbor; in the **remote** statement you must specify both the IP address and the media access control (MAC) address of the Ethernet neighbor. The proxy address is associated with the TCC router's other neighbor connected by the unlike link; in the **proxy** statement you must specify the IP address of the non-Ethernet neighbor.

You can configure Ethernet TCC encapsulation for the interfaces on 1-port Gigabit Ethernet, 2-port Gigabit Ethernet, 4-port Fast Ethernet, and 4-port Gigabit Ethernet PICs.

```
encapsulation ethernet-tcc;
unit logical-unit-number {
  family tcc {
    proxy {
      inet-address ip-address;
    }
    remote {
      inet-address ip-address;
      mac-address mac-address;
    }
  }
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces (fe | ge)-*fpc/pic/port*]
- [edit logical-systems *logical-system-name* interfaces (fe | ge)-*fpc/pic/port*]

**NOTE:** For Ethernet circuits, you must also configure the Address Resolution Protocol (ARP). See “Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations” on page 758.

### Configuring Ethernet Extended VLAN Encapsulation for Layer 2 Switching TCCs

For Ethernet extended VLAN circuits, configure the encapsulation type for the entire physical device by specifying the value **extended-vlan-tcc** for the **encapsulation** statement.

You must also enable VLAN tagging. Ethernet interfaces in VLAN mode can have multiple logical interfaces. With encapsulation type **extended-vlan-tcc**, all VLAN IDs from 0 through

4094 are valid, up to a maximum of 1024 VLANs. As with Ethernet circuits, you must also specify a proxy address and a remote address at the `[edit interfaces interface-name unit logical-unit-number family tcc]` or `[edit logical-systems logical-system-name interfaces interface-name unit unit-number family tcc]` hierarchy level (see “[Configuring Ethernet Encapsulation for Layer 2 Switching TCCs](#)” on page 757).

```
encapsulation extended-vlan-tcc;
vlan-tagging;
unit logical-unit-number {
  vlan-id identifier;
  family tcc;
  proxy {
    inet-address ip-address;
  }
  remote {
    inet-address ip-address;
    mac-address mac-address;
  }
}
```

You can configure these statements at the following hierarchy levels:

- `[edit interfaces interface-name]`
- `[edit logical-systems logical-system-name interfaces interface-name]`

**NOTE:** For Ethernet extended VLAN circuits, you must also configure the Address Resolution Protocol (ARP). See “[Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations](#)” on page 758.

### Configuring ARP for Ethernet and Ethernet Extended VLAN Encapsulations

For Ethernet and Ethernet extended VLAN circuits with TCC encapsulation, you must also configure ARP. Because TCC simply removes one Layer 2 header and adds another, the default form of dynamic ARP is not supported; you must configure static ARP.

Because remote and proxy addresses are specified on the router performing TCC switching, you must apply the static ARP statement to the Ethernet-type interfaces of the routers that connect to the TCC-switched router. The `arp` statement must specify the IP address and the MAC address of the remotely connected neighbor by use of the unlike Layer 2 protocol on the far side of the TCC switching router.

```
arp ip-address mac mac-address;
```

You can include this statement at the following hierarchy levels:

- `[edit interfaces interface-name unit logical-unit-number family inet address ip-address]`
- `[edit logical-systems logical-system-name interfaces interface-name unit logical-unit-number family inet address ip-address]`

## Configuring the Connection for Layer 2 Switching TCCs

You must configure the connection between the two circuits of the Layer 2 switching TCC on the router acting as the switch. The connection joins the interface coming from the circuit's source to the interface leading to the circuit's destination. When you specify the interface names, include the logical portion of the name, which corresponds to the logical unit number. The cross-connect is bidirectional, so packets received on the first interface are transmitted from the second interface, and those received on the second interface are transmitted from the first.

To configure a connection for a local interface switch, include the following statements:

```
interface-switch connection-name {
    interface interface-name.unit-number;
}
lsp-switch connection-name {
    transmit-lsp lsp-number;
    receive-lsp lsp-number;
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

To configure a connection for a remote interface switch, include the following statements:

```
remote-interface-switch connection-name {
    interface interface-name.unit-number;
    interface interface-name.unit-number;
    transmit-lsp lsp-number;
    receive-lsp lsp-number;
}
```

You can include these statements at the following hierarchy levels:

- [edit protocols connections]
- [edit logical-systems *logical-system-name* protocols connections]

## Configuring MPLS for Layer 2 Switching TCCs

For a Layer 2 switching TCC to work, you must enable MPLS on the router by including at least the following statements. This minimum configuration enables MPLS on a logical interface for the switching cross-connect.

Include the **family mpls** statement:

```
family mpls;
```

You can configure this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]

- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

You can then specify this logical interface in the MPLS protocol configuration:

```
mpls {
  interface interface-name; # Required to enable MPLS on the interface
}
```

You can configure these statements at the following hierarchy levels:

- [edit protocols]
- [edit logical-systems *logical-system-name* protocols]

**NOTE:** MPLS LSP link protection does not support TCC.

## CCC and TCC Graceful Restart

CCC and TCC graceful restart allows Layer 2 connections between customer edge (CE) routers to restart gracefully. These Layer 2 connections are configured with the **remote-interface-switch** or **lsp-switch** statements. Because these CCC and TCC connections have an implicit dependency on RSVP LSPs, graceful restart for CCC and TCC uses the RSVP graceful restart capabilities.

RSVP graceful restart must be enabled on the PE routers and P routers to enable graceful restart for CCC and TCC. Also, because RSVP is used as the signaling protocol for signaling label information, the neighboring router must use helper mode to assist with the RSVP restart procedures.

Figure 78 on page 760 illustrates how graceful restart might work on a CCC connection between two CE routers.

**Figure 78: Remote Interface Switch Connecting Two CE Routers Using CCC**

PE Router A is the ingress for the transmit LSP from PE Router A to PE Router B and the egress for the receive LSP from PE Router B to PE Router A. With RSVP graceful restart enabled on all the PE and P routers, the following occurs when PE router A restarts:

- PE Router A preserves the forwarding state associated with the CCC routes (those from CCC to MPLS and from MPLS to CCC).
- Traffic flows without disruption from CE router to CE router.
- After the restart, PE Router A preserves the label for the LSP for which PE Router A is the egress (the receive LSP, for example). The transmit LSP from PE Router A to PE Router B can derive new label mappings, but should not cause any traffic disruption.

## Configuring CCC and TCC Graceful Restart

---

To enable CCC and TCC graceful restart, include the **graceful-restart** statement:

```
graceful-restart;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-options]**
- **[edit logical-systems *logical-system-name* routing-options]**

The **graceful-restart** statement enables graceful restart for all protocols supporting this feature on the router. For more information about graceful restart, see the *Junos OS Routing Protocols Library*.

CCC and TCC graceful restart depend on RSVP graceful restart. If you disable RSVP graceful restart, CCC and TCC graceful restart will not work. For more information about RSVP graceful restart, see [“RSVP Graceful Restart” on page 545](#) and [“Configuring RSVP Graceful Restart” on page 548](#).

## Configuring CCC Switching for Point-to-Multipoint LSPs

---

You can configure circuit cross-connect (CCC) between two circuits to switch traffic from interfaces to point-to-multipoint LSPs. This feature is useful for handling multicast or broadcast traffic (for example, a digital video stream).

To configure CCC switching for point-to-multipoint LSPs, you do the following:

- On the ingress provider edge (PE) router, you configure CCC to switch traffic from an incoming interface to a point-to-multipoint LSP.
- On the egress PE, you configure CCC to switch traffic from an incoming point-to-multipoint LSP to an outgoing interface.

The CCC connection for point-to-multipoint LSPs is unidirectional.

For more information about point-to-multipoint LSPs, see [“Point-to-Multipoint LSPs Overview” on page 309](#).

To configure a CCC connection for a point-to-multipoint LSP, complete the steps in the following sections:

- [Configuring the Point-to-Multipoint LSP Switch on Ingress PE Routers on page 762](#)
- [Configuring Local Receivers on a Point-to-Multipoint CCC LSP Switch on Ingress PE Routers on page 762](#)
- [Configuring the Point-to-Multipoint LSP Switch on Egress PE Routers on page 763](#)

## Configuring the Point-to-Multipoint LSP Switch on Ingress PE Routers

To configure the ingress PE router with a CCC switch for a point-to-multipoint LSP, include the **p2mp-transmit-switch** statement:

```
p2mp-transmit-switch switch-name {  
    input-interface input-interface-name.unit-number;  
    transmit-p2mp-lsp transmitting-lsp;  
}
```

You can include the **p2mp-transmit-switch** statement at the following hierarchy levels:

- **[edit protocols connections]**
- **[edit logical-systems *logical-system-name* protocols connections]**

***switch-name*** specifies the name of the ingress CCC switch.

**input-interface *input-interface-name.unit-number*** specifies the name of the ingress interface.

**transmit-p2mp-lsp *transmitting-lsp*** specifies the name of the transmitting point-to-multipoint LSP.

## Configuring Local Receivers on a Point-to-Multipoint CCC LSP Switch on Ingress PE Routers

In addition to configuring an incoming CCC interface to a point-to-multipoint LSP on an ingress PE router, you can also configure CCC to switch traffic on an incoming CCC interface to one or more outgoing CCC interfaces by configuring output interfaces as local receivers.

To configure output interfaces, include the **output-interface** statement at the **[edit protocols connections p2mp-transmit-switch *p2mp-transmit-switch-name*]** hierarchy level.

```
[edit protocols connections]  
p2mp-transmit-switch pc-ccc {  
    input-interface fe-1/3/1.0;  
    transmit-p2mp-lsp myp2mp;  
    output-interface [fe-1/3/2.0 fe-1/3/3.0];  
}
```

You can configure one or more output interfaces as local receivers on the ingress PE router using this statement.

Use the **show connections p2mp-transmit-switch (extensive | history | status)**, **show route ccc <interface-name> (detail | extensive)**, and **show route forwarding-table ccc**

`<interface-name> (detail | extensive)` commands to view details of the local receiving interfaces on the ingress PE router.

## Configuring the Point-to-Multipoint LSP Switch on Egress PE Routers

To configure the CCC switch for a point-to-multipoint LSP on the egress PE router, include the `p2mp-receive-switch` statement.

```
p2mp-receive-switch switch-name {  
    output-interface [ output-interface-name.unit-number ];  
    receive-p2mp-lsp receptive-lsp;  
}
```

You can include this statement at the following hierarchy levels:

- `[edit protocols connections]`
- `[edit logical-systems logical-system-name protocols connections]`

*switch-name* specifies the name of the egress CCC switch.

`output-interface [ output-interface-name.unit-number ]` specifies the name of one or more egress interfaces.

`receive-p2mp-lsp receptive-lsp` specifies the name of the receptive point-to-multipoint LSP.

- [GMPLS Features on page 772](#)

### Introduction to GMPLS

---

Traditional MPLS is designed to carry Layer 3 IP traffic using established IP-based paths and associating these paths with arbitrarily assigned labels. These labels can be configured explicitly by a network administrator, or can be dynamically assigned by means of a protocol such as LDP or RSVP.

GMPLS generalizes MPLS in that it defines labels for switching varying types of Layer 1, Layer 2, or Layer 3 traffic. GMPLS nodes can have links with one or more of the following switching capabilities:

- Fiber-switched capable (FSC)
- Lambda-switched capable (LSC)
- Time-division multiplexing (TDM) switched-capable (TSC)
- Packet-switched capable (PSC)

Label-switched paths (LSPs) must start and end on links with the same switching capability. For example, routers can establish packet-switched LSPs with other routers. The LSPs might be carried over a TDM-switched LSP between SONET add/drop multiplexers (ADMs), which in turn might be carried over a lambda-switched LSP.

The result of this extension of the MPLS protocol is an expansion in the number of devices that can participate in label switching. Lower-layer devices, such as OXCs and SONET ADMs, can now participate in GMPLS signaling and set up paths to transfer data. A router can participate in signaling optical paths across a transport network.

Two service models determine the visibility that a client node (a router, for example) has into the optical core or transport network. The first is through a user-to-network interface (UNI), which is often referred to as the overlay model. The second is known as the peer model. Juniper Networks supports both models.

**NOTE:** There is not necessarily a one-to-one correspondence between a physical interface and a GMPLS interface. If a GMPLS connection uses a nonchannelized physical connector, the GMPLS label can use the physical port ID. However, the label for channelized interfaces often is based on a channel or time slot. Consequently, it is best to refer to GMPLS labels as identifiers for a resource on a traffic engineering link.

To establish LSPs, GMPLS uses the following mechanisms:

- An out-of-band control channel and a data channel—RSVP messages for LSP setup are sent over an out-of-band control network. Once the LSP setup is complete and the path is provisioned, the data channel is up and can be used to carry traffic. The Link Management Protocol (LMP) is used to define and manage the data channels between a pair of nodes. You can optionally use LMP to establish and maintain LMP control channels between peers running the same Junos OS Release.
- RSVP-TE extensions for GMPLS—RSVP-TE is already designed to signal the setup of packet LSPs. This has been extended for GMPLS to be able to request path setup for various kinds of LSPs (nonpacket) and request labels like wavelengths, time slots, and fibers as label objects.
- Bidirectional LSPs—Data can travel both ways between GMPLS devices over a single path, so nonpacket LSPs are signaled to be bidirectional.

---

## GMPLS Terms and Acronyms

### F

**Forwarding adjacency**     A forwarding path for sending data between GMPLS-enabled devices.

### G

**Generalized MPLS (GMPLS)**     An extension to MPLS that allows data from multiple layers to be switched over label-switched paths (LSPs). GMPLS LSP connections are possible between similar Layer 1, Layer 2, and Layer 3 devices.

**GMPLS label**     Layer 3 identifiers, fiber port, time-division multiplexing (TDM) time slot, or dense wavelength-division multiplexing (DWDM) wavelength of a GMPLS-enabled device used as a next-hop identifier.

- GMPLS LSP types**      The four types of GMPLS LSPs are:
- Fiber-switched capable (FSC)—LSPs are switched between two fiber-based devices, such as optical cross-connects (OXCs) that operate at the level of individual fibers.
  - Lambda-switched capable (LSC)—LSPs are switched between two DWDM devices, such as OXCs that operate at the level of individual wavelengths.
  - TDM-switched capable (TDM)—LSPs are switched between two TDM devices, such as SONET ADMs.
  - Packet-switched capable (PSC)—LSPs are switched between two packet-based devices, such as routers or ATM switches.

## L

- Link Management Protocol**      A protocol used to define a forwarding adjacency between peers and to maintain and allocate resources on the traffic engineering links.

## T

- Traffic engineering link**      A logical connection between GMPLS-enabled devices. Traffic engineering links can have addresses or IDs and are associated with certain resources or interfaces. They also have certain attributes (encoding-type, switching capability, bandwidth, and so on). The logical addresses can be routable, although this is not required because they are acting as link identifiers. Each traffic engineering link represents a forwarding adjacency between a pair of devices.

## Supported GMPLS Standards

Junos OS substantially supports the following RFCs and Internet drafts, which define standards for Generalized MPLS (GMPLS).

- RFC 3471, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Functional Description*

Only the following features are supported:

- Bidirectional LSPs (upstream label only)
- Control channel separation
- Generalized label (suggested label only)
- Generalized label request (bandwidth encoding only)
- RFC 3473, *Generalized Multi-Protocol Label Switching (GMPLS) Signaling Resource Reservation Protocol-Traffic Engineering (RSVP-TE) Extensions*  
Only Section 9, "Fault Handling," is supported.
- RFC 4202, *Routing Extensions in Support of Generalized Multi-Protocol Label Switching*  
Only interface switching is supported.
- RFC 4206, *Label Switched Paths (LSP) Hierarchy with Generalized Multi-Protocol Label Switching (GMPLS) Traffic Engineering (TE)*

- Internet draft draft-ietf-ccamp-gmpls-rsvp-te-ason-02.txt, *Generalized MPLS (GMPLS) RSVP-TE Signalling in support of Automatically Switched Optical Network (ASON)* (expires January 2005)

- Internet draft draft-ietf-ccamp-gmpls-sonet-sdh-08.txt, *Generalized Multi-Protocol Label Switching Extensions for SONET and SDH Control*

Only S,U,K,L,M-format labels and SONET traffic parameters are supported.

- Internet draft draft-ietf-ccamp-lmp-10.txt, *Link Management Protocol (LMP)*

- Internet draft draft-ietf-ccamp-ospf-gmpls-extensions-12.txt, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching*

The following sub-TLV types for the Link type, link, value (TLV) are not supported:

- Link Local/Remote Identifiers (type 11)
- Link Protection Type (type 14)
- Shared Risk Link Group (SRLG) (type 16)

The features described in Section 2 of the draft, “Implications on Graceful Restart,” are also not supported.

The Interface Switching Capability Descriptor (type 15) sub-TLV type is implemented, but only for packet switching.

- Internet draft draft-ietf-mpls-bundle-04.txt, *Link Bundling in MPLS Traffic Engineering*

---

## **GMPLS Operation**

The basic functionality of GMPLS requires close interaction between RSVP and LMP. It works in the following sequence:

1. LMP notifies RSVP of the new entities:
  - Traffic engineering link (forwarding adjacency)
  - Resources available for the traffic engineering link
  - Control peer
2. GMPLS extracts the LSP attributes from the configuration and requests RSVP to signal one or more specific paths, which are specified by the traffic engineering link addresses.
3. RSVP determines the local traffic engineering link, corresponding control adjacency and active control channel, and transmission parameters (such as IP destination). It

requests that LMP allocate a resource from the traffic engineering link with the specified attributes. If LMP finds a resource matching the attributes, label allocation succeeds. RSVP sends a PathMsg hop by hop until it reaches the target router.

4. When the target router receives the PathMsg, RSVP again requests that LMP allocate a resource based on the signaled parameters. If label allocation succeeds, the router sends back a ResvMsg.
5. If the signaling is successful, a bidirectional optical path is provisioned.

## GMPLS and OSPF

---

You can configure OSPF for GMPLS. OSPF is an interior gateway protocol (IGP) that routes packets within a single autonomous system (AS). OSPF uses link-state information to make routing decisions.

## GMPLS and CSPF

---

GMPLS introduces extra constraints for computing paths for GMPLS LSPs that use CSPF. These additional constraints affect the following link attributes:

- Signal type (minimum LSP bandwidth)
- Encoding type
- Switching type

These new constraints are populated in the traffic engineering database with the exchange of an interface-switching capability descriptor type, length, value (TLV) through an IGP.

The ignored constraints that are exchanged through the interface switching capability descriptor include:

- Maximum LSP bandwidth
- Maximum transmission unit (MTU)

The CSPF path computation is the same as in non-GMPLS environments, except that the links are also limited by GMPLS constraints.

Each link can have multiple interface-switching capability descriptors. All the descriptors are checked before a link is rejected.

The constraints are checked in the following order:

1. The signal type configured for the GMPLS LSP signifies the amount of bandwidth requested. If the desired bandwidth is less than the minimum LSP bandwidth, the interface-switching descriptor is rejected.
2. The encoding type of the link for the ingress and the egress interfaces should match. The encoding type is selected and stored at the ingress node after all the constraints are satisfied by the link and is used to select the link on the egress node.

3. The switching type of the links of the intermediate switches should match that of the GMPLS LSP specified in the configuration.

## GMPLS Features

---

The Junos OS includes the following GMPLS functionality:

- An out-of-band control plane makes it possible to signal LSP path setup.
- RSVP-TE extensions support additional objects beyond Layer 3 packets, such as ports, time slots, and wavelengths.
- The LMP protocol creates and maintains a database of traffic engineering links and peer information. Only the static version of this protocol is supported in the Junos OS. You can optionally configure LMP to establish and maintain LMP control channels between peers running the same Junos OS Release.
- Bidirectional LSPs are required between devices.
- Several GMPLS label types that are defined in RFC 3471, *Generalized MPLS—Signaling Functional Description*, such as MPLS, Generalized, SONET/SDH, Suggested, and Upstream, are supported. Generalized labels do not contain a type field, because the nodes should know from the context of their connection what type of label to expect.
- Traffic parameters facilitate GMPLS bandwidth encoding and SONET/SDH formatting.
- Other supported attributes include interface identification and errored interface identification, user-to-network (UNI)-style signaling, and secondary LSP paths.

# Configuring GMPLS

- [Example: Configuring GMPLS RSVP-TE VLAN LSP Signaling on page 794](#)

## LMP Configuration Overview

---

You need to configure the Link Management Protocol (LMP) to define the data channel connection and the control channel connection between devices. Include the following statements at the **[edit protocols link-management]** hierarchy level:

```
[edit protocols link-management]
peer peer-name {
  address address;
  control-channel control-channel-name;
  lmp-control-channel control-channel-interface {
    remote-address ip-address;
  }
  lmp-protocol {
    hello-dead-interval milliseconds;
    hello-interval milliseconds;
    retransmission-interval milliseconds;
    retry-limit number;
    passive;
  }
  te-link te-link-name;
}
te-link te-link-name {
  disable;
  interface interface-name {
    disable;
```

```

    local-address ip-address;
    remote-address ip-address;
    remote-id id-number;
}
label-switched-path lsp-name;
local-address ip-address;
remote-address ip-address;
remote-id id-number;
}
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}

```

**NOTE:** Although you can include GMPLS configuration statements at the [edit logical-systems *logical-system-name*] hierarchy level, GMPLS is not supported on logical systems.

For information about configuring LMP, see the following sections:

- [Configuring LMP Traffic Engineering Links on page 774](#)
- [Configuring LMP Peers on page 776](#)
- [Configuring RSVP and OSPF for LMP Peer Interfaces on page 781](#)
- [Configuring MPLS Paths for GMPLS on page 782](#)
- [Tracing LMP Traffic on page 783](#)

## Configuring LMP Traffic Engineering Links

An LMP traffic engineering link acts as a data channel connection between GMPLS devices.

To configure a traffic engineering link, include the **te-link** statement at the [edit protocols link-management] hierarchy level:

```

[edit protocols link-management]
te-link te-link-name {
  disable;
  interface interface-name {
    local-address ip-address;
    remote-address ip-address;
    remote-id id-number;
  }
  label-switched-path lsp-name;
  local-address ip-address;
  remote-address ip-address;
  remote-id id-number;
}

```

Complete the procedures in the following sections to configure an LMP traffic engineering link:

- [Configuring the Local IP Address for Traffic Engineering Links on page 775](#)
- [Configuring the Remote IP Address for Traffic Engineering Links on page 775](#)
- [Configuring the Remote ID for Traffic Engineering Links on page 776](#)

When you configure a traffic engineering link that contains interfaces for an LMP peer, you must also configure a control channel. However, no control channel is required for a traffic engineering link that contains an LSP. For information about configuring control channels, see [“Configuring LMP Peers” on page 776](#).

## Configuring the Local IP Address for Traffic Engineering Links

Use the **local-address** statement to configure the local IP address associated with the traffic engineering link.

We recommend that you configure an IP address subnet for your traffic engineering link addresses that is different from the subnet configured for your physical interfaces. This configuration enables you to identify which addresses are physical and which addresses belong to the traffic engineering link.

To configure the local IP address for the traffic engineering link, include the **local-address** statement:

```
te-link te-link-name {
  interface interface-name {
    local-address ip-address;
  }
  local-address ip-address;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring the Remote IP Address for Traffic Engineering Links

You need to specify the address of the remote end of the data channel for each traffic engineering link. Use the **remote-address** statement to configure the remote IP address.

We recommend that you configure an IP address subnet for your traffic engineering link addresses that is different from the subnet configured for your physical interfaces. This enables you to identify which addresses are physical and which addresses belong to the traffic engineering link.

To configure the remote IP address for the traffic engineering link, include the **remote-address** statement:

```
te-link te-link-name {
  interface interface-name {
    remote-address ip-address;
  }
  remote-address ip-address;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring the Remote ID for Traffic Engineering Links

The local ID for the traffic engineering link is automatically assigned by LMP. The port identifier and labels for the interfaces (resources) in the traffic engineering link are also assigned automatically. However, you need to explicitly configure the remote ID for the traffic engineering link and the remote ID traffic engineering link interface. The remote ID for the interface must be based on the post-ID assignment of the peer node. The remote IDs are needed for static mapping of remote labels to local labels.

Before you can obtain the remote IDs for the traffic engineering link and traffic engineering link interface on the peer node, you must first configure the LMP peer, as described in [“Configuring LMP Peers” on page 776](#). Once you have configured the LMP peer, you can obtain the traffic engineering link local ID and interface local ID by issuing the **show link-management te-link** command. Once you have these IDs, you can configure them as the remote IDs on the peer node.

To configure the remote ID for a traffic engineering link and for the traffic engineering link interface, include the **remote-id** statement:

```
te-link te-link-name {  
  interface interface-name {  
    remote-id id-number;  
  }  
  remote-id id-number;  
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

---

## Configuring LMP Peers

You need to configure network peers for GMPLS. A peer is a network device that your router communicates with when setting up the control and data channels. The peer is often an optical cross-connect (OXC).

To configure an LMP peer name, include the **peer** statement at the **[edit protocols link-management]** hierarchy level:

```
peer peer-name {  
  address ip-address;  
  control-channel control-channel-interface;  
  lmp-control-channel control-channel-interface {  
    remote-address ip-address;  
  }  
  lmp-protocol {  
    hello-dead-interval milliseconds;  
    hello-interval milliseconds;  
    retransmission-interval milliseconds;  
    retry-limit number;  
    passive;  
  }  
}
```

```
te-link te-link-name;  
}
```

The following sections describe how to configure an LMP peer:

- [Configuring the ID for LMP Peers on page 777](#)
- [Configuring the Interface for Control Channels Between LMP Peers on page 777](#)
- [Configuring the LMP Control Channel Interface for the Peer on page 777](#)
- [Configuring the Remote IP Address for LMP Control Channels on page 778](#)
- [Configuring Hello Message Intervals for LMP Control Channels on page 779](#)
- [Controlling Message Exchange for LMP Control Channels on page 780](#)
- [Preventing the Local Peer from Initiating LMP Negotiation on page 780](#)
- [Associating Traffic Engineering Links with LMP Peers on page 780](#)
- [Disabling the Traffic Engineering Link for LMP Peers on page 781](#)

## Configuring the ID for LMP Peers

To configure the LMP peer ID, include the **address** statement at the **[edit protocols link-management peer *peer-name*]** hierarchy level. The default value for the LMP peer ID is the loopback address.

```
[edit protocols link-management peer peer-name]  
address ip-address;
```

## Configuring the Interface for Control Channels Between LMP Peers

You must configure one or more control channels between the LMP peers. The control channels must travel across either a point-to-point link or a tunnel.

To configure the interface for the control channel, include the **control-channel** statement at the **[edit protocols link-management peer *peer-name*]** hierarchy level:

```
[edit protocols link-management peer peer-name]  
control-channel [ interface-names ];
```

You can configure a generic routing encapsulation (GRE) interface (*gre-x/y/z*) for the control channel. This type of interface does not require a Tunnel PIC.

**NOTE:** You can configure GRE interfaces (*gre-x/y/z*) only for GMPLS control channels. GRE interfaces are not supported or configurable for other applications. For more information, see the *Junos OS Network Interfaces Library for Routing Devices*.

## Configuring the LMP Control Channel Interface for the Peer

In an environment that uses LMP to establish and maintain an LMP control channel between peers, you can configure a number of attributes associated with LMP. To configure the interface to be associated with the LMP control channel for the peer, include the **lmp-control-channel** statement:

**lmp-control-channel** *control-channel-interface*;

You can configure this statement at the following hierarchy levels:

- [edit protocols link-management **peer** *peer-name*]
- [edit logical-systems *logical-system-name* protocols link-management **peer** *peer-name*]

You can configure a GRE interface for the LMP control channel. This type of interface does not require a Tunnel PIC.

**NOTE:** You can configure GRE interfaces only for GMPLS control channels. GRE interfaces are not supported or configurable for other applications. For more information, see the *Junos OS Network Interfaces Library for Routing Devices*.

When this LMP control channel interface comes up, the peers use LMP to negotiate channel parameters and configure the control channel.

The local peer repeatedly sends a Config message to the remote peer. The Config message contains the local control channel ID, the local peer's node ID, a message ID, and a CONFIG object that includes hello message attributes (the hello interval and the hello dead interval).

The channel is activated when the remote peer responds with a ConfigAck message. The remote peer does so only when its own configured hello interval and hello dead interval match the values in the received Config message or the default values. If these values do not match, the remote peer responds with a ConfigNack message. The local peer logs this event and resends the Config message until the message retry limit is reached. When the message retry limit is reached, the local peer logs that event and restarts the configuration process.

## Configuring the Remote IP Address for LMP Control Channels

You need to specify the address of the remote end of the LMP control channel.

To configure the remote IP address for the LMP control channel, include the **remote-address** statement:

**remote-address** *address*;

You can configure this statement at the following hierarchy levels:

- [edit protocols link-management **peer** *peer-name* **lmp-control-channel** *control-channel-interface*]
- [edit logical-systems *logical-system-name* protocols link-management **peer** *peer-name* **lmp-control-channel** *control-channel-interface*]

## Configuring Hello Message Intervals for LMP Control Channels

Hello messages are exchanged between LMP peers to maintain the control channel after LMP has activated the control channel. The LMP control channel is considered to be up only when the hello negotiation is successful. Successful negotiation consists of the local peer sending a hello message to the remote peer and receiving a hello message in response.

The LMP peers continue to exchange hello messages after the LMP control channel is up in order to maintain the channel.

The hello interval specifies the interval between periodic hello messages. The hello dead interval specifies how long the local peer waits for a hello response before it declares the LMP control channel to be down. When the channel goes down, the local peer restarts the LMP control channel negotiation and configuration process.

You can specify a hello interval from 150 through 300,000 milliseconds. The default hello interval is 150 milliseconds.

You can specify a hello dead interval from 500 through 300,000 milliseconds. The default hello dead interval is 500 milliseconds.

To configure the attributes for hello messages exchanged between LMP peers, include the **hello-interval** and **hello-dead-interval** statements:

```
hello-dead-interval milliseconds;
hello-interval milliseconds;
```

You can configure these statements at the following hierarchy levels:

- [edit protocols link-management **peer peer-name lmp-protocol**]
- [edit logical-systems *logical-system-name* protocols link-management **peer peer-name lmp-protocol**]

When an LMP control channel comes up after a successful exchange of hello messages between LMP peers, LMP uses link property correlation to verify the traffic engineering and data link information on both sides of a link. To do so, the local peer sends a LinkSummary message for each traffic engineering link governed by the LMP control channel. The LinkSummary message contains information that characterizes the traffic engineering link and each data link in the traffic engineering link.

The local peer continues sending a LinkSummary message for each link until the remote peer responds with a LinkSummaryAck message or until the message retry limit is reached. When the message retry limit is reached, the local peer logs that event and restarts the link property correlation process.

When the remote peer receives a LinkSummary message, it examines its own link information. If this information agrees with that in the LinkSummary message, the remote peer responds with a LinkSummaryAck message. If the information is different, the remote peer responds with a LinkSummaryNack message.

## Controlling Message Exchange for LMP Control Channels

You can configure message attributes that control the exchange of LMP Config and LinkSummary messages. The retransmission interval specifies the interval between resubmitted LMP messages. The retry limit specifies how many times LMP sends a message before restarting the process.

You can specify a retransmission interval from 500 through 300,000 milliseconds. The default retransmission interval is 500 milliseconds.

You can specify a retry limit from 3 through 1000 attempts. The default number of retry attempts is three.

To configure attributes governing the exchange of LMP messages between peers, include the **retransmission-interval** and **retry-limit** statements:

```
retransmission-interval milliseconds;  
retry-limit number;
```

You can configure these statements at the following hierarchy levels:

- [edit protocols link-management **peer** *peer-name* **lmp-protocol**]
- [edit logical-systems *logical-system-name* protocols link-management **peer** *peer-name* **lmp-protocol**]

## Preventing the Local Peer from Initiating LMP Negotiation

You can specify that the local peer does not initiate LMP negotiation. Instead, the local peer waits for the remote peer to configure the LMP control channel.

To configure the local peer to wait for the remote peer to configure the LMP control channel, include the **passive** statement:

```
passive;
```

You can configure this statement at the following hierarchy levels:

- [edit protocols link-management **peer** *peer-name* **lmp-protocol**]
- [edit logical-systems *logical-system-name* protocols link-management **peer** *peer-name* **lmp-protocol**]

## Associating Traffic Engineering Links with LMP Peers

To specify the name of a traffic engineering link to be associated with this peer, include the **te-link** statement at the [edit protocols link-management **peer** *peer-name*] hierarchy level:

```
[edit protocols link-management peer peer-name]  
te-link te-link-name;
```

For information about how to configure a traffic engineering link, see [“Configuring LMP Traffic Engineering Links” on page 774](#).

## Disabling the Traffic Engineering Link for LMP Peers

To disable a specific traffic engineering link, include the **disable** statement:

```
disable;
```

You can configure this statement at the following hierarchy levels:

- [edit protocols link-management **te-link** *te-link-name*]
- [edit logical-systems *logical-system-name* protocols link-management **te-link** *te-link-name*]

## Configuring RSVP and OSPF for LMP Peer Interfaces

After you have configured the LMP peers as described in “Configuring LMP Peers” on page 776, add the peer interfaces to RSVP and OSPF. The peer interface name must match the peer name configured in LMP. Once the peer interfaces are added to the protocols, the traffic engineering link local and remote addresses can be signaled and advertised to peers like any other interface enabled for RSVP and OSPF. These addresses act as virtual interfaces for GMPLS.

**NOTE:** When adding the virtual peer interfaces to RSVP and OSPF, do not configure the corresponding physical control channel interface in either protocol. If you include the **interface all** statement, you must disable RSVP and OSPF protocols manually on the control channel interface.

To configure peer interfaces in RSVP and OSPF, complete the procedures in the following sections:

- [Configuring RSVP Signaling for LMP Peer Interfaces on page 781](#)
- [Configuring OSPF Routing for LMP Peer Interfaces on page 782](#)
- [Configuring the Hello Interval for LMP Peer Interfaces on page 782](#)

## Configuring RSVP Signaling for LMP Peer Interfaces

To configure RSVP signaling for LMP peers, configure the LMP peer interface by including the **peer-interface** statement at the [edit protocols **rsvp**] hierarchy level:

```
[edit protocols rsvp]
peer-interface peer-interface-name {
  (aggregate | no-aggregate);
  authentication-key key;
  disable;
  hello-interval seconds;
  (reliable | no-reliable);
}
```

The statements configured at the `[edit protocols rsvp peer-interface peer-interface-name]` hierarchy level have the same functionality as the statements configured at the `[edit protocols rsvp interface interface-name]` hierarchy level.

## Configuring OSPF Routing for LMP Peer Interfaces

To configure OSPF routing for LMP peers, configure the name of the LMP peer by including the `peer-interface` statement at the `[edit protocols ospf area area-number]` hierarchy level:

```
[edit protocols ospf area area-number]  
peer-interface peer-interface-name {  
  dead-interval seconds;  
  disable;  
  hello-interval seconds;  
  retransmit-interval seconds;  
  transit-delay seconds;  
}
```

For information about how to configure OSPF statements, see the *Junos OS Routing Protocols Library*.

## Configuring the Hello Interval for LMP Peer Interfaces

Hello packets are used to indicate to neighboring routers that the peer interface is still up and running. The hello interval must be the same for all routers on a shared logical IP network. You can specify a hello interval from 1 through 255 seconds. The default hello interval is normally 10 seconds. For nonbroadcast networks, the default hello interval is 120 seconds.

To specify how often the router sends hello packets out the peer interface, configure the `hello-interval` statement:

```
hello-interval seconds;
```

You can configure this statement at the following hierarchy levels:

- `[edit protocols ospf area area-number peer-interface peer-interface-name]`
- `[edit logical-systems logical-system-name protocols ospf area area-number peer-interface peer-interface-name]`

---

## Configuring MPLS Paths for GMPLS

As part of the configuration for GMPLS, you need to establish an MPLS path for each unique device connected through GMPLS. Configure the traffic engineering link remote address as the address at the `[edit protocols mpls path path-name]` hierarchy level. Constrained Shortest Path First (CSPF) is supported so you can choose either the `strict` or `loose` option with the address.

See “[LMP Configuration Overview](#)” on page 773 for information about how to obtain a traffic engineering link remote address.

To configure the MPLS path, include the `path` statement at the `[edit protocols mpls]` hierarchy level:

```
[edit protocols mpls]
path path-name {
  next-hop-address (strict | loose);
}
```

For information about how to configure MPLS paths, see [“Creating Named Paths” on page 60](#).

## Tracing LMP Traffic

To trace LMP protocol traffic, include the **traceoptions** statement at the **[edit protocols link-management]** hierarchy level:

```
[edit protocols link-management]
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

Use the **file** statement to specify the name of the file that receives the output of the tracing operation. All files are placed in the directory `/var/log`.

The following trace flags display the operations associated with the sending and receiving of various LMP messages:

- **all**—Trace all available operations
- **hello-packets**—Trace hello packets on any LMP control channel
- **init**—Output from the initialization messages
- **packets**—Trace all packets other than hello packets on any LMP control channel
- **parse**—Operation of the parser
- **process**—Operation of the general configuration
- **route-socket**—Operation of route socket events
- **routing**—Operation of the routing protocols
- **server**—Server processing operations
- **show**—Servicing operations for **show** commands
- **state**—Trace state transitions of the LMP control channels and traffic engineering links

Each flag can carry one or more of the following flag modifiers:

- **detail**—Provide detailed trace information
- **receive**—Packets being received
- **send**—Packets being transmitted

## Configuring MPLS LSPs for GMPLS

---

To enable the proper GMPLS switching parameters, configure the label-switched path (LSP) attributes that are appropriate for your network connection. The default value for **switching-type** is **psc-1**, which is also appropriate for standard MPLS.

To configure the LSP attributes, include the **lsp-attributes** statement at the **[edit protocols mpls label-switched-path *lsp-name*]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name]  
lsp-attributes {  
  encoding-type type;  
  gp-id gp-id;  
  signal-bandwidth type;  
  switching-type type;  
}
```

If you include the **no-cspf** statement in the label-switched path configuration, you must also configure primary and secondary paths, or the configuration cannot be committed.

The following sections describe how to configure each of the LSP attributes for a GMPLS LSP:

- [Configuring the Encoding Type on page 784](#)
- [Configuring the GPID on page 785](#)
- [Configuring the Signal Bandwidth Type on page 785](#)
- [Configuring GMPLS Bidirectional LSPs on page 785](#)
- [Allowing Nonpacket GMPLS LSPs to Establish Paths Through Routers Running Junos OS on page 786](#)

### Configuring the Encoding Type

You need to specify the encoding type of the payload carried by the LSP. It can be any of the following:

- **ethernet**—Ethernet
- **packet**—Packet
- **pdh**—Plesiochronous digital hierarchy (PDH)
- **sonet-sdh**—SONET/SDH

The default value is **packet**.

To configure the encoding type, include the **encoding-type** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]  
encoding-type type;
```

## Configuring the GPID

You need to specify the type of payload carried by the LSP. The payload is the type of packet underneath the MPLS label. The payload is specified by the generalized payload identifier (GPID).

You can specify the GPID with any of the following values:

- **hdlc**—High-Level Data Link Control (HDLC)
- **ethernet**—Ethernet
- **ipv4**—IP version 4 (default)
- **pos-scrambling-crc-16**—For interoperability with other vendors' equipment
- **pos-no-scrambling-crc-16**—For interoperability with other vendors' equipment
- **pos-scrambling-crc-32**—For interoperability with other vendors' equipment
- **pos-no-scrambling-crc-32**—For interoperability with other vendors' equipment
- **ppp**—Point-to-Point Protocol (PPP)

To configure the GPID, include the **gpid** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
  gpid gpid;
```

## Configuring the Signal Bandwidth Type

The signal bandwidth type is the encoding used for path computation and admission control. To configure the signal bandwidth type, include the **signal-bandwidth** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
  signal-bandwidth type;
```

## Configuring GMPLS Bidirectional LSPs

Because MPLS and GMPLS use the same configuration hierarchy for LSPs, it is helpful to know which LSP attributes control LSP functionality. Standard MPLS packet-switched LSPs are unidirectional, whereas GMPLS nonpacket LSPs are bidirectional.

If you use the default packet-switching type of **psc-1**, your LSP becomes unidirectional. To enable a GMPLS bidirectional LSP, you must select a non-packet-switching type option, such as **lambda**, **fiber**, or **ethernet**. Include the **switching-type** statement at the **[edit protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level:

```
[edit protocols mpls label-switched-path lsp-name lsp-attributes]
  switching-type (lambda | fiber | ethernet);
```

## Allowing Nonpacket GMPLS LSPs to Establish Paths Through Routers Running Junos OS

By setting the A-bit in the Admin Status object, you can enable nonpacket GMPLS LSPs to establish paths through routers that run Junos. When an ingress router sends an RSVP PATH message with the Admin Status A-bit set, an external device (not a router running the Junos OS) can either perform a Layer 1 path setup test or help bring up an optical cross-connect.

When set, the A-bit in the Admin Status object indicates the administrative down status for a GMPLS LSP. This feature is used specifically by nonpacket GMPLS LSPs. It does not affect control path setup or data forwarding for packet LSPs.

Junos does not distinguish between the control path setup and data path setup. Other nodes along the network path use RSVP PATH signaling using the A-bit in a meaningful way.

To configure the Admin Status object for a GMPLS LSP, include the **admin-down** statement:

```
admin-down;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols mpls label-switched-path *lsp-name*]**
- **[edit logical-systems *logical-system-name* protocols mpls label-switched-path *lsp-name*]**

---

## Gracefully Tearing Down GMPLS LSPs

You can gracefully tear down nonpacket GMPLS LSPs. An LSP that is torn down abruptly, a common process in a packet-switched network, can cause stability problems in nonpacket-switched networks. To maintain the stability of nonpacket-switched networks, it might be necessary to tear down LSPs gracefully.

The following sections describe how to tear down GMPLS LSPs gracefully:

- [Temporarily Deleting GMPLS LSPs on page 786](#)
- [Permanently Deleting GMPLS LSPs on page 787](#)
- [Configuring the Graceful Deletion Timeout Interval on page 787](#)

### Temporarily Deleting GMPLS LSPs

You can gracefully tear down a GMPLS LSP using the **clear rsvp session gracefully** command.

This command gracefully tears down an RSVP session for a nonpacket LSP in two passes. In the first pass, the Admin Status object is signaled along the path to the endpoint of the LSP. During the second pass, the LSP is taken down. Using this command, the LSP is taken down temporarily. After the appropriate interval, the GMPLS LSP is resignaled and then reestablished.

The **clear rsvp session gracefully** command has the following properties:

- It only works on the ingress and egress routers of an RSVP session. If used on a transit router, it has the same behavior as the **clear rsvp session** command.
- It only works for nonpacket LSPs. If used with packet LSPs, it has the same behavior as the **clear rsvp session** command.

For more information, see the [CLI Explorer](#).

## Permanently Deleting GMPLS LSPs

When you disable an LSP in the configuration, the LSP is permanently deleted. By configuring the **disable** statement, you can disable a GMPLS LSP permanently. If the LSP being disabled is a nonpacket LSP, then the graceful LSP tear-down procedures that use the Admin Status object are used. If the LSP being disabled is a packet LSP, then the regular signaling procedures for LSP deletion are used.

To disable a GMPLS LSP, include the **disable** statement at any of the following hierarchy levels:

- **[edit protocols mpls label-switched-path *lsp-name*]**—Disable the LSP.
- **[edit protocols link-management *te-link te-link-name*]**—Disable a traffic engineering link.
- **[edit protocols link-management *te-link te-link-name interface interface-name*]**—Disable an interface used by a traffic engineering link.

## Configuring the Graceful Deletion Timeout Interval

The router that initiates the graceful deletion procedure for an RSVP session waits for the graceful deletion timeout interval to ensure that all routers along the path (especially the ingress and egress routers) have prepared for the LSP to be taken down.

The ingress router initiates the graceful deletion procedure by sending the Admin Status object in the path message with the **D** bit set. The ingress router expects to receive an Resv message with the **D** bit set from the egress router. If the ingress router does not receive this message within the time specified by the graceful deletion timeout interval, it initiates a forced tear-down of the LSP by sending a PathTear message.

To configure the graceful deletion timeout interval, include the **graceful-deletion-timeout** statement at the **[edit protocols rsvp]** hierarchy level. You can configure a time between 1 through 300 seconds. The default value is 30 seconds.

**graceful-deletion-timeout** *seconds*;

You can configure this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

You can use the **show rsvp version** command to determine the current value configured for the graceful deletion timeout.

### Understanding GMPLS RSVP-TE Signaling

Signaling is the process of exchanging messages within the control plane to set up, maintain, modify, and terminate data paths (label-switched paths (LSPs)) in the data plane. Generalized MPLS (GMPLS) is a protocol suite that extends the existing control plane of MPLS to manage further classes of interfaces and to support other forms of label switching, such as time-division multiplexing (TDM), fiber (port), Lambda, and so on.

GMPLS extends intelligent IP/MPLS connections from Layer 2 and Layer 3 all the way to Layer 1 optical devices. Unlike MPLS, which is supported mainly by routers and switches, GMPLS can also be supported by optical platforms, including SONET/SDH, optical cross-connects (OXC), and dense wave division multiplexing (DWDM).

In addition to labels, which are primarily used to forward data in MPLS, other physical entries, such as wavelengths, time slots, and fibers can be used as label objects to forward data in GMPLS, thereby leveraging the existing control plane mechanisms to signal different kinds of LSPs. GMPLS uses RSVP-TE to be able to request the other label objects to signal the various kinds of LSPs (nonpacket). Bidirectional LSPs and an out-of-band control channel and a data channel using the Link Management Protocol (LMP) are the other mechanisms that are used by GMPLS to establish LSPs.

### Need for GMPLS RSVP-TE VLAN LSP Signaling

The traditional Layer 2 point-to-point services use Layer 2 circuits and Layer 2 VPN technologies that are based on LDP and BGP. In the traditional deployment, the customer edge (CE) devices do not participate in the signaling of the Layer 2 service. The provider edge (PE) devices manage and provision the Layer 2 service to provide end-to-end connectivity between the CE devices.

One of the biggest challenges of having the PE devices provision the Layer 2 services for each Layer 2 circuit between a pair of CE devices is the network management burden on the provider network.

Figure 79 on page 789 illustrates how the Layer 2 service is set up and used by the CE routers in a LDP/BGP-based Layer 2 VPN technology. Two CE routers CE1 and CE2 are connected to a provider MPLS network through the PE routers PE1 and PE2 respectively. The CE routers are connected to the PE routers by Ethernet links. Routers CE1 and CE2 are configured with VLAN1 and VLAN2 logical Layer 3 interfaces, so they appear to be directly connected. Routers PE1 and PE2 are configured with Layer 2 circuit (pseudowire) to carry the Layer 2 VLAN traffic between the CE routers. The PE routers use packet MPLS LSPs within the provider MPLS network to carry the Layer 2 VLAN traffic.

**Figure 79: Traditional Layer 2 Point-to-Point Services**

With the introduction of GMPLS-based VLAN LSP signaling, the need for the PE (also called server-layer) network to provision each individual Layer 2 connection between the CE (also called client) devices is minimized. The client router requests the server-layer router to which it is directly connected, for setting up the Layer 2 service to connect with a remote client router through GMPLS signaling.

The server-layer devices extend the signaling through the server-layer network to connect with the remote client routers. In the process, the server-layer device sets up the data plane for the Layer 2 service at the server-client border, and sets up the data plane for carrying the Layer 2 traffic within the server-layer network. With the Layer 2 service setup, the client routers can run IP/MPLS directly on top of the Layer 2 service and have IP/MPLS adjacency with each other.

In addition to reducing the provisioning activity needed on the server-layer devices, GMPLS signaling also provides the client routers with the flexibility of bringing up the Layer 2 circuits on an on-demand basis without depending on the server-layer administration for the provisioning of the Layer 2 service.

Using the same topology as in Figure 1, Figure 80 on page 790 illustrates how the Layer 2 service is set up and used by the client routers in GMPLS RSVP-TE-based Layer 2 VPN technology.

Figure 80: GMPLS RSVP-TE VLAN LSP

804277

In [Figure 80 on page 790](#), instead of configuring a pseudowire to carry the Layer 2 VLAN traffic between the client routers, Routers PE1 and PE2 are configured with an IP-based communication channel and other GMPLS-specific configurations (identification of Ethernet links as TE-links) for allowing the exchange of GMPLS RSVP-TE signaling messages with the client routers. Routers CE1 and CE2 are also configured with an IP-based communication channel and relevant GMPLS configuration for exchanging the GMPLS RSVP-TE signaling messages with the server-layer routers. Routers CE1 and CE2 establish an IP/MPLS adjacency on top of this Layer 2 service.

### GMPLS RSVP-TE VLAN LSP Signaling Functionality

Based on [Figure 80 on page 790](#), the client router establishes the Layer 2 service in the server-layer network as follows:

1. Router CE1 initiates GMPLS RSVP-TE signaling with Router PE1. In this signaling message, Router CE1 indicates the VLAN on the Ethernet link for which it needs the Layer 2 service and the remote CE router, Router CE2, with which the VLAN should be connected.  
  
Router CE1 also indicates the remote PE router, Router PE2, to which Router CE2 is connected, and the exact Ethernet link connecting Router CE2 to Router PE2 on which the Layer 2 service is required in the signaling message.
2. Router PE1 uses the information from Router CE1 in the signaling message and determines the remote PE router, Router PE2, with which Router CE2 is attached. Router PE1 then establishes a packet MPLS LSP (associated bidirectional) through the server-layer MPLS network for carrying the VLAN traffic and then passes the GMPLS RSVP-TE signaling message to Router PE2 using the LSP hierarchy mechanism.
3. Router PE2 propagates the GMPLS RSVP-TE signaling message to Router CE2 with the VLAN to be used on the PE2-CE2 Ethernet link.
4. Router CE2 responds with an acknowledgment to the GMPLS RSVP-TE signaling message to Router PE2. Router PE2 then propagates it to Router PE1, which in turn propagates it to Router CE1.
5. As part of this message propagation, Routers PE1 and PE2 set up the forwarding plane to enable bidirectional flow of VLAN Layer 2 traffic between Routers CE1 and CE2.

## LSP Hierarchy with GMPLS RSVP-TE VLAN LSP

The Layer 2 service in GMPLS RSVP-TE VLAN LSP signaling is brought up using a hierarchy mechanism in which two different RSVP LSPs are created for the Layer 2 service:

- An end-to-end VLAN LSP that has state information at the client and server-layer routers.
- An associated bidirectional packet transport LSP that is present in the server-layer routers (PE and P) of the server-layer network.

The LSP hierarchy avoids sharing information about technology-specific LSP characteristics with the core nodes of the server-layer network. This solution cleanly separates the VLAN LSP state and the transport LSP state, and ensures that the VLAN LSP state is only present on the nodes (PE, CE) where it is needed.

## Path Specification for GMPLS RSVP-TE VLAN LSP

The path for the GMPLS RSVP-TE LSP is configured as an Explicit Route Object (ERO) at the initiating client router. As this LSP traverses different network domains (initiating, terminating at client network, and traversing the server-layer network), the LSP setup falls under the category of an interdomain LSP setup. In an interdomain scenario, one network domain generally does not have full visibility into the topology of the other network domain. Hence, the ERO that gets configured at the initiating client router does not have full hop information for the server-layer portion. This feature requires that the ERO configured at the CE router has three hops, with the first hop being a strict hop identifying the CE1-PE1 Ethernet link, the second hop being a loose hop identifying the egress PE router (PE2), and the third hop being a strict hop identifying the CE2-PE2 Ethernet link.

## GMPLS RSVP-TE VLAN LSP Configuration

The configuration required to set up a GMPLS VLAN LSP at the client and server routers uses the existing GMPLS configuration model with some extensions. The Junos OS GMPLS configuration model for nonpacket LSPs is targeted toward bringing the physical interfaces up and running through GMPLS RSVP-TE signaling, whereas signaling a GMPLS RSVP-TE VLAN LSP aims at bringing up individual VLANs on top of a physical interface. The **ethernet-vlan** configuration statement under the **[edit protocols link-management te-link]** hierarchy enables this.

The client router has physical interfaces connected to a server network, and the server network provides a point-to-point connection between two client routers over the attached physical interfaces. The physical interface is brought into an operational state by GMPLS RSVP-TE as follows:

1. The client router maintains a routing or signaling adjacency with the server network node to which the physical interface is connected, typically through a control channel different from the physical interface, because the physical interface itself is brought up and running only after the signaling.
2. The client router and the server network node identify the physical interfaces connecting them using the TE-link mechanism.

3. The client router and the server network node use the TE-link identifier (IP address) as the GMPLS RSVP hop and the physical interface identifier as the GMPLS label values in the GMPLS RSVP-TE signaling messages to bring the physical interface into an operational state.

In the existing GMPLS configuration, the server and client network nodes use the **protocols link-management peer *peer-name*** configuration statement to specify the adjacent peer node. Because a client router can have one or more physical interfaces connected to the server network node, these physical interfaces are grouped and identified by an IP address through the **protocols link-management te-link *link-name*** configuration statement. The TE-link is assigned a local IP address, a remote IP address, and a list of physical interfaces. The TE-link is then associated with the **protocols link-management peer *peer-name* te-link *te-link-list*** configuration statement.

The out-of-band control channel that is required for exchanging signaling messages is specified using the **protocols link-management peer *peer-name* control-channel *interface-name*** configuration statement. The existence of the server or client network node is made visible to the RSVP and IGP (OSPF) protocols through the **peer-interface *interface-name*** configuration statement under the **[edit protocols *rsvp*]** and **[edit protocols *ospf*]** hierarchy levels.

In the existing GMPLS configuration, the label (upstream label and resv label) that is carried in the signaling message is an integer identifier that identifies the physical interface that is required to be brought up. As the label is used to identify the physical interface, the existing GMPLS configuration allows multiple interfaces to be grouped under a single TE-link. In the existing GMPLS configuration, there is sufficient information in the GMPLS RSVP-TE signaling message, such as TE-link address and label value, to identify the physical interface that is required to be brought up. In contrast, for GMPLS RSVP-TE VLAN LSP configuration, the VLAN ID value is used as the label in the signaling message.

In the GMPLS RSVP-TE VLAN LSP configuration, if multiple interfaces are allowed to be configured under a single TE-link, using VLAN ID as the label value in the signaling message can cause ambiguity as to which physical interface on which the VLAN has to be provisioned. Therefore, the TE-link is configured with the **ethernet-vlan** configuration statement, if the number of physical interfaces that can be configured under the TE-link is restricted to only one.

In the existing GMPLS configuration, the bandwidth for a nonpacket LSP is a discrete quantity that corresponds to the bandwidth of the physical interface that needs to be brought up. So, the GMPLS LSP configuration does not allow any bandwidth to be specified, but allows the bandwidth to be specified only through the **signal-bandwidth** configuration statement under the **[protocols mpls label-switched-path *lsp-name* lsp-attributes]** hierarchy level. In the GMPLS VLAN LSP configuration, bandwidth is specified similar to that of a packet LSP. In the GMPLS VLAN LSP configuration, the **bandwidth** option is supported and **signal-bandwidth** is not supported.

## Associated Bidirectional Packet LSP

The GMPLS RSVP-TE VLAN LSP is carried on an associated bidirectional transport LSP within the server-layer network, which is a single-sided provisioned LSP. The transport LSP signaling is initiated as a unidirectional LSP from the source router to the destination

router in the forward direction, and the destination router in turn initiates the signaling of the unidirectional LSP in the reverse direction back to the source router.

### Make-Before-Break for Associated Bidirectional Packet and GMPLS RSVP-TE VLAN LSP

The make-before-break support for an associated bidirectional transport LSP follows a similar model, where the destination router for the forward direction of the bidirectional LSP does not perform any make-before-break operations on the reverse direction of the bidirectional LSP. It is the source router (initiator of the associated bidirectional LSP) that initiates the make-before-break newer instance of the associated bidirectional LSP, and the destination router in turn initiates the make-before-break newer instance in the other direction.

For instance, in [Figure 80 on page 790](#), the unidirectional transport LSP is initiated from Router PE1 to Router PE2 in the forwarding direction, and in turn Router PE2 initiates the transport LSP to Router PE1 in the reverse direction. When a make-before-break instance occurs, only Router PE1 as the initiating client router can establish a new instance of the associated bidirectional LSP. Router PE2 in turn initiates the make-before-break newer instance in the reverse direction.

The make-before-break support for the associated bidirectional transport LSP is used only in scenarios where the transport LSP gets into a state of being locally protected due to link or node failure on the path of the LSP. The GMPLS RSVP-TE VLAN LSP uses the make-before-break mechanism for adjusting seamless bandwidth changes.

**NOTE:** Periodic re-optimization is not enabled for the associated bidirectional transport LSPs.

The newer make-before-break instance of the GMPLS VLAN LSP is supported under the following constraints:

- It should originate from the same client router as the older instance and be destined to the same client router as the older instance.
- It should use the same server-client links at both the server-client ends as the older instance.
- It should use the same VLAN label at the server-client links as the older instance.
- The GMPLS VLAN LSP should be configured as **adaptive** when the bandwidth change is initiated from the CLI, or else the current instance of the VLAN LSP is torn down and a new VLAN LSP instance is established.

The make-before-break operation for the GMPLS VLAN LSP on the server-layer edge router is rejected if these constraints are not met.

On the server-layer edge routers, when a make-before-break instance of the GMPLS VLAN LSP is seen, a completely new, separate associated bidirectional transport LSP is created to support this make-before-break instance. The existing associated bidirectional LSP (supporting the older instance) is not triggered to initiate a make-before-break instance at the transport LSP level. An implication of this choice (of initiating a new

transport LSP) is that at the server-layer resource/bandwidth sharing does not happen when a make-before-break operation is performed for the GMPLS VLAN LSP.

## Supported and Unsupported Features

Junos OS supports the following features with the GMPLS RSVP-TE VLAN LSP:

- Request for specific bandwidth and local protection for the VLAN LSP on the client router to the server-layer router.
- Nonstop active routing (NSR) support for the GMPLS VLAN LSP at the client routers, server-layer edge routers, and associated bidirectional transport LSP at the server-layer edge routers.
- Multichassis support.

Junos OS does **not** support the following GMPLS RSVP-TE VLAN LSP functionality:

- Graceful restart support for associated bidirectional packet LSP and GMPLS VLAN LSP.
- End-to-end path computation for GMPLS VLAN LSP using CSPF algorithm at the client router.
- Non-CSPF routing-based discovery of next-hop routers by the different client, server-layer edge routers.
- Automatic provisioning of the client Layer 3 VLAN interfaces upon the successful setup of the VLAN LSP at the client routers.
- MPLS OAM (LSP-ping, BFD).
- Packet MPLS applications, such as next-hop in static route and in IGP shortcuts.
- Local cross connect mechanism, where a client router connects to a remote client router which is connected to the same server router.
- Junos OS Services Framework.
- IPv6 support.
- Logical systems.
- Aggregated Ethernet/SONET/IRB interfaces at the server-client link.

## Example: Configuring GMPLS RSVP-TE VLAN LSP Signaling

This example shows how to configure GMPLS RSVP-TE VLAN LSP signaling on the client routers to enable one client router to connect with a remote client router through a server-layer network using the LSP hierarchy. This enables the client routers to establish, maintain, and provision the Layer 2 services, without depending on the server-layer

administration, thereby reducing the burden on the operational expenses of the provider network.

- [Requirements on page 795](#)
- [Overview on page 795](#)
- [Configuration on page 801](#)
- [Verification on page 811](#)

## Requirements

This example uses the following hardware and software components:

- Six routers that can be a combination of M Series Multiservice Edge Routers, MX Series 3D Universal Edge Routers, T Series Core Routers, and PTX Series Packet Transport Routers
- Junos OS Release 14.2 or later running on the client routers and server-layer edge routers

Before you begin:

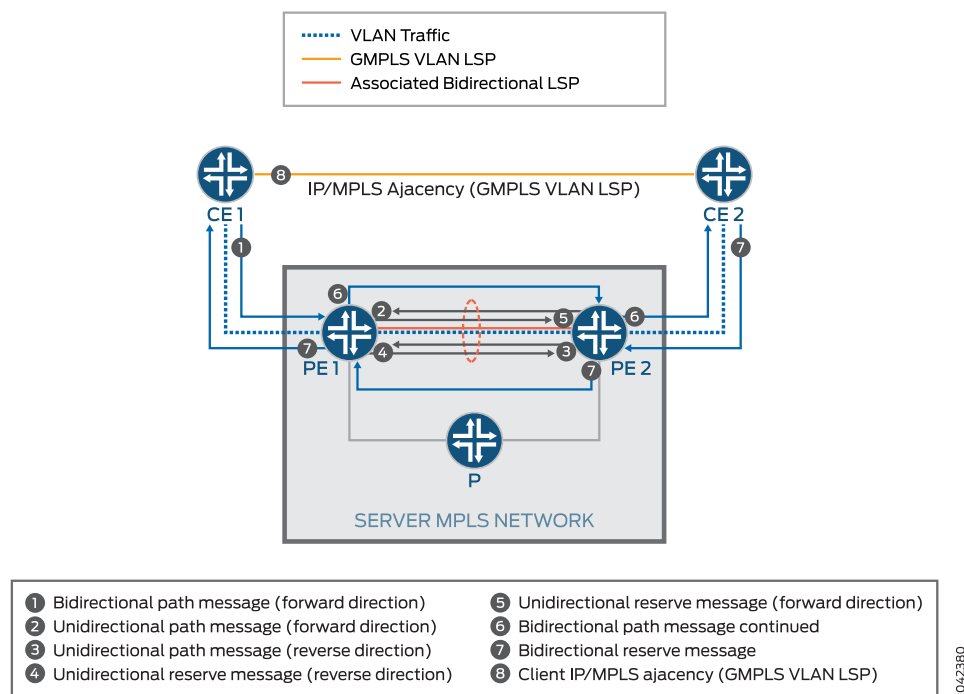

1. Configure the device interfaces.
2. Configure the interface-associated VLANs.
3. Configure the following routing protocols:
  - RSVP
  - MPLS
  - LMP

## Overview

Starting with Junos OS Release 14.2, the Layer 2 services between two client routers across an external/third-party server-layer network are set up by the client routers on an on-demand basis through GMPLS RSVP-TE signaling. This feature provides the client routers the flexibility to establish, maintain, and provision the Layer 2 services, without depending on the server-layer administration, thereby reducing the burden on the operational expenses of the provider network. In traditional Layer 2 VPN technology based on LDP and BGP, the provider network handled the provisioning activity for each Layer 2 circuit established between two client routers.

[Figure 81 on page 796](#) illustrates the setting up and signaling of the GMPLS VLAN LSP between two client routers, CE1 and CE2, across a server-layer network with two server-layer edge routers, PE1 and PE2, and one server-layer core router, P.

Figure 81: Setting Up a GMPLS VLAN LSP

The signaling of GMPLS VLAN LSP is executed as follows:

#### 1. Initiating GMPLS VLAN LSP at CE1

Router CE1 initiates the GMPLS VLAN LSP setup by sending the GMPLS RSVP-TE path message to Router PE1. The signaling between CE1 and PE1 is over an out-of-band control channel, which is a separate control VLAN configured on the Ethernet link connecting the two routers.

The GMPLS RSVP-TE path message initiated by Router CE1 is used to perform the following:

- Identify the Ethernet link on which the VLAN is active.
- Abstract the Ethernet link as a TE-link and assign an IP address to identify the Ethernet link.
- Allocate a VLAN ID from the pool of free VLANs managed by Router CE1 for every Ethernet link connecting Router PE1 to the identified Ethernet link.

This VLAN ID can also be used for the GMPLS VLAN LSP at the CE2-PE2 Ethernet link.

- Identify the VLAN for which the Layer 2 service is required to be set up using the allocated VLAN ID as the upstream label object and the upstream direction label value.

- e. Include an ERO object that helps Router PE1 in establishing the VLAN LSP through the server-layer network to the remote client router, CE2. The ERO object in the path message includes three hops:
  - First hop—Strict hop identifying the initiating client-server Ethernet link, PE1-CE1.
  - Second hop—Loose hop identifying the remote server-layer router, PE2.
  - Third hop—Strict hop identifying the remote client-server Ethernet link, PE2-CE2.
- f. Include the bandwidth required for the GMPLS VLAN LSP.
- g. Include any local-protection required within the server-layer network for the VLAN LSP.

## 2. Initiating Associated Bidirectional Transport LSP at PE1

After Router PE1 receives the path message from Router CE1, the message is validated to check the availability of the Ethernet link and VLAN ID. In the server-layer network, the Layer 2 services between the server-layer routers, PE1 and PE2, are provided at the data plane in a manner similar to Layer 2 circuits. Router PE1 brings up a transport LSP to Router PE2 and then extends the GMPLS VLAN LSP as a hierarchical LSP running on top of the PE1-PE2 transport LSP. The PE1-PE2 transport LSP is a packet LSP and is bidirectional in nature. This is because the GMPLS VLAN LSP is bidirectional and each server-layer router needs to be able to do the following:

- Receive traffic from the server-client Ethernet link (for example, the PE1-CE1 link) and send it to the remote server-layer router, PE2.
- Receive traffic from remote Router PE2 and send it on the PE1-CE1 Ethernet link.

For each GMPLS VLAN LSP, a packet transport LSP is set up within the server-layer network. The transport LSP is exclusively used to carry traffic of the GMPLS VLAN LSP for which it was created. The transport LSP is dynamically created at the time of receiving the GMPLS VLAN LSP; thus, no configuration is required to trigger its creation. The transport LSP established for the VLAN LSP inherits the bandwidth and the local-protection attributes from the VLAN LSP.

Router PE1 signals the PE1-PE2 transport LSP to Router PE2. Router PE1 determines the destination for the transport LSP from the loose hop specified in the ERO object of the GMPLS RSVP-TE path message from Router CE1 and then signals the VLAN LSP. However, if the PE1-PE2 transport LSP fails to establish, Router PE1 sends back a path error message to Router CE1, and the GMPLS VLAN LSP is not established as well.

## 3. Setting Up the Associated Bidirectional Transport LSP Between the Server-Layer Routers

The associated bidirectional LSP between routers PE1 and PE2 consists of two unidirectional packet LSPs:

- PE1-to-PE2
- PE2-to-PE1

Router PE1 initiates signaling of a unidirectional packet LSP to Router PE2. This unidirectional packet LSP constitutes the forward direction (PE1-to-PE2) of the

associated bidirectional LSP, and the path message carries the Extended Association Object indicating this is a single-sided provisioning model. On receiving the path message for the LSP, Router PE2 responds with a Resv message and triggers the signaling of a unidirectional packet LSP to Router PE1 with the same path as (PE1-to-PE2) in the reverse direction. This unidirectional packet LSP uses the PE2-to-PE1 direction of the associated bidirectional LSP, and this path message carries the same Extended Association Object seen in the PE1-to-PE2 path message.

When Router PE1 receives the Resv message for the PE1-to-PE2 unidirectional LSP and the path message for the PE2-to-PE1 unidirectional LSP, PE1 binds the PE1-to-PE2 and PE2-to-PE1 unidirectional LSPs by matching the Extended Association Objects carried in the respective path messages. For the path message for the PE2-to-PE1 unidirectional LSP, Router PE1 responds with the Resv Message. On receiving the Resv message for the PE1-to-PE2 LSP and the path message for the PE2-to-PE1 LSP, Router PE1 has established the associated bidirectional packet transport LSP.

#### **4. Setting Up the GMPLS VLAN LSP at Router PE1**

After successfully establishing the transport LSP, Router PE1 triggers the signaling of the GMPLS VLAN LSP. Router PE1 sends the GMPLS RSVP-TE path message corresponding to the VLAN LSP directly to Router PE2, which is bidirectional in nature and includes the upstream label object.

Router PE2 is not aware of the association between the transport LSP and the VLAN LSP. This association is indicated to Router PE2 by Router PE1.

#### **5. Setting Up the GMPLS VLAN LSP at Router PE2**

On receiving the VLAN LSP path message from Router PE1, Router PE2 verifies the availability of the transport LSP. If the transport LSP is not available or the LSP setup is in progress, the VLAN LSP processing is put on hold. When the transport LSP is available, Router PE2 processes the VLAN LSP path message. The ERO object in this path message indicates that the next hop is a strict hop identifying the PE2-to-CE2 Ethernet link. The ERO object can indicate the VLAN ID to be used on the PE2-to-CE2 Ethernet link by Router PE2.

Router PE2 appropriately allocates the VLAN ID to be sent as the upstream label in the VLAN LSP path message to Router CE2, and sends it through an out-of-band control channel.

#### **6. Processing the GMPLS VLAN LSP at Router CE2**

On receiving the GMPLS RSVP-TE LSP from Router PE2, Router CE2 validates the availability of VLAN ID for allocation on the PE2-to-CE2 link. Router CE2 then allocates the VLAN ID for this VLAN LSP and sends back a Resv message to Router PE2 with the VLAN ID as the label object in the Resv message.

#### **7. Processing the GMPLS VLAN LSP at Router PE2**

On receiving the Resv message from Router CE2, Router PE2 validates that the label object in the Resv message has the same VLAN ID as in the path message. Router PE2 then allocates a 20-bit MPLS label, which is included in the Resv message sent to Router PE1.

Router PE2 then programs the forwarding plane with the entries to provide the Layer 2 service functionality.

**NOTE:** For all the VLAN IDs that can be allocated as labels on the PE1-to-CE1 and PE2-CE2 Ethernet links, you must manually configure logical interfaces for circuit cross-connect (CCC) purposes on the server-layer edge routers and not for other families, such as IPv4, IPv6, or MPLS.

#### 8. Processing the GMPLS VLAN LSP at Router PE1

On receiving the Resv message for the VLAN LSP from Router PE2, Router PE1 sends a Resv message to Router CE1 with the same VLAN ID it received as the upstream label from Router CE1. Router PE1 programs the forwarding plane with the entries to provide the Layer 2 service functionality as Router PE2.

#### 9. Processing the GMPLS VLAN LSP at Router CE1

On receiving the Resv message from Router PE1, Router CE1 validates that the VLAN ID received in the Resv message matches the VLAN ID in the upstream label in the path message it sent. This completes the setup of the GMPLS VLAN LSP from Router CE1 to Router CE2.

**NOTE:**

- The GMPLS VLAN LSP setup does not result in the addition of any forwarding plane entries at the client routers, CE1 and CE2. Only the server-layer routers, PE1 and PE2, add the forwarding plane entries for the GMPLS VLAN LSP.
- There is no routing information exchange between the client and the server-layer routers. The client and server-layer routers do not exchange their network topology information with each other.

#### 10. Accounting for Bandwidth of the GMPLS VLAN LSP

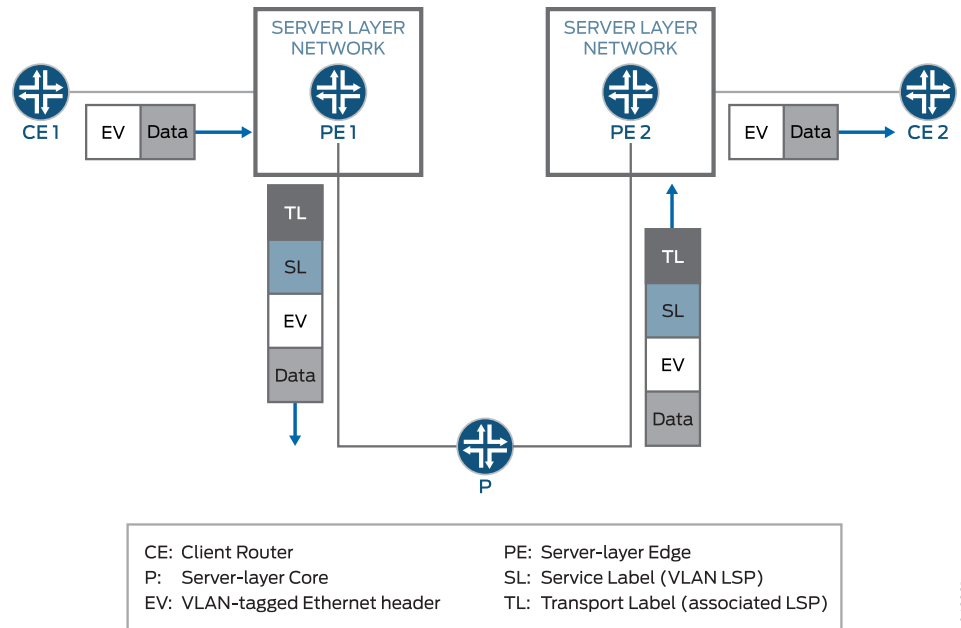

On successfully setting up the GMPLS VLAN LSP, both the client and server-layer routers reduce the amount of available bandwidth on the server-client Ethernet links by the bandwidth amount allocated for the GMPLS VLAN LSP. This bandwidth accounting information is used for admission control purposes when additional GMPLS VLAN LSPs are brought up on the server-client Ethernet links.

#### 11. Using GMPLS VLAN LSP by the Client Routers

After successfully setting up the GMPLS VLAN LSP, the client routers – CE1 and CE2 – need to be manually configured with the VLAN logical interface on top of the server-client Ethernet links with the signaled VLAN ID. This logical interface needs to be configured with the IP address and needs to be included in the IGP protocol. As a result of this configuration, Routers CE1 and CE2 establish IGP adjacency and exchange data traffic over the Layer 2 service established through the GMPLS signaling.

Figure 82 on page 800 illustrates the data traffic flow of the GMPLS VLAN LSP from Router CE1 to Router CE2 after the LSP setup is complete and the necessary CE1-to-CE2 IGP/MPLS adjacency has been established. The server-layer transport LSP originates from Router PE1, traverses a single server-layer core router, Router P, and reaches Router PE2. The server-layer transport LSP is shown as a penultimate-hop pop LSP, where Router P pops off the transport LSP label, and only the service label is present on the P-to-PE2 link.

**Figure 82: Data Traffic Flow of GMPLS VLAN LSP**

### Topology

In Figure 83 on page 801, GMPLS RSVP-TE VLAN LSP signaling is used to establish the Layer 2 services between the client routers, Router CE1 and Router CE2. The server routers, Router PE1 and Router PE2, have a GRE tunnel established with each of the directly connected client routers. Routers P1 and P2 are also server routers in the server-layer network.

### Configuring the Client Router

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router CE1:

**NOTE:** Repeat this procedure for Router CE2 in the server-layer network, after modifying the appropriate interface names, addresses, and any other parameters for the router.

1. Configure the interface connecting Router CE1 to Router PE1.  

```

[edit interfaces]
user@CE1# set ge-0/0/0 vlan-tagging

```
2. Configure the control VLAN for the ge-0/0/0 interface.  

```

[edit interfaces]
user@CE1# set ge-0/0/0 unit 1 vlan-id 1
user@CE1# set ge-0/0/0 unit 1 family inet address 1.1.1.1/30
user@CE1# set ge-0/0/0 unit 1 family mpls

```
3. Configure the LSP VLAN on the ge-0/0/0 interface.  

```

[edit interfaces]
user@CE1# set ge-0/0/0 unit 10 vlan-id 10
user@CE1# set ge-0/0/0 unit 10 family inet address 10.10.10.1/24
user@CE1# set ge-0/0/0 unit 10 family mpls

```
4. Configure the GRE tunnel as the controlling interface for Router CE1.

- ```
[edit interfaces]
user@CE1# set gre unit 0 tunnel source 1.1.1.1
user@CE1# set gre unit 0 tunnel destination 1.1.1.2
user@CE1# set gre unit 0 family inet address 10.35.100.25/30
```
5. Configure the loopback interface of Router CE1.
 

```
[edit interfaces]
user@CE1# set lo0 unit 0 family inet address 10.255.10.1/32
```
  6. Configure the loopback address of Router CE1 as its router ID.
 

```
[edit routing-options]
user@CE1# set router-id 10.255.10.1
```
  7. Enable RSVP on all the interfaces of Router CE1, excluding the management interface.
 

```
[edit protocols]
user@CE1# set rsvp interface all
user@CE1# set rsvp interface fxp0.0 disable
```
  8. Configure the RSVP peer interface for Router CE1.
 

```
[edit protocols]
user@CE1# set rsvp peer-interface PE1
```
  9. Disable automatic path computation for label-switched paths (LSPs).
 

```
[edit protocols]
user@CE1# set mpls no-cspf
```
  10. Configure the LSP to connect Router CE1 to Router CE2.
 

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 from 10.255.10.1
user@CE1# set mpls label-switched-path CE1-to-CE2 to 10.255.10.6
```
  11. Configure the CE1-to-CE2 LSP attributes.
 

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 lsp-attributes switching-type
    ethernet-vlan
user@CE1# set mpls label-switched-path CE1-to-CE2 lsp-attributes upstream-label
    vlan-id 10
user@CE1# set mpls label-switched-path CE1-to-CE2 bandwidth 100m
```
  12. Configure the CE1-to-CE2 LSP path and path parameters.
 

```
[edit protocols]
user@CE1# set mpls label-switched-path CE1-to-CE2 primary path1
user@CE1# set mpls path path1 10.35.1.2 strict
user@CE1# set mpls path path1 10.255.10.5 loose
user@CE1# set mpls path path1 10.36.1.1 strict
```
  13. Enable MPLS on all the interfaces of Router CE1, excluding the management interface.
 

```
[edit protocols]
user@CE1# set mpls interface all
user@CE1# set mpls interface fxp0.0 disable
```

14. Configure a traffic engineering link, and assign addresses for the local and remote end of the link.  

```
[edit protocols]
user@CE1# set link-management te-link link10 local-address 10.35.1.1
user@CE1# set link-management te-link link10 remote-address 10.35.1.2
```
15. Enable setting up of Layer 2 VLAN LSP on the link10 traffic engineering link.  

```
[edit protocols]
user@CE1# set link-management te-link link10 ethernet-vlan
```
16. Configure the Router CE1 interface as the member interface of the link10 traffic engineering link.  

```
[edit protocols]
user@CE1# set link-management te-link link10 interface ge-0/0/0
```
17. Configure Router PE1 as the Link Management Protocol (LMP) peer for Router CE1, and configure the peer attributes.  

```
[edit protocols]
user@CE1# set link-management peer PE1 address 10.255.10.2
user@CE1# set link-management peer PE1 control-channel gre.0
user@CE1# set link-management peer PE1 te-link link10
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE1# show interfaces
ge-0/0/0 {

### Configuring the Server Router

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Router PE1:

**NOTE:** Repeat this procedure for Router PE2 in the server-layer network, after modifying the appropriate interface names, addresses, and any other parameters for the router.

1. Configure the interface connecting Router PE1 to Router CE1.  

```
[edit interfaces]
user@PE1# set ge-0/0/0 vlan-tagging
user@PE1# set ge-0/0/0 encapsulation flexible-ethernet-services
```
2. Configure the control VLAN for the ge-0/0/0 interface.  

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 1 vlan-id 1
user@PE1# set ge-0/0/0 unit 1 family inet address 1.1.1.2/30
user@PE1# set ge-0/0/0 unit 1 family mpls
```
3. Configure the LSP VLAN on the ge-0/0/0 interface.  

```
[edit interfaces]
user@PE1# set ge-0/0/0 unit 10 encapsulation vlan-ccc
user@PE1# set ge-0/0/0 unit 10 vlan-id 10
```
4. Configure the interface connecting Router PE1 to the core routers (Router P1 and Router P2).  

```
[edit interfaces]
user@PE1# set ge-0/0/1 unit 0 family inet address 70.70.70.1/30
user@PE1# set ge-0/0/1 unit 0 family mpls

user@PE1# set ge-0/0/2 unit 0 family inet address 20.20.20.1/30
user@PE1# set ge-0/0/2 unit 0 family mpls
```
5. Configure the GRE tunnel as the controlling interface for Router PE1.  

```
[edit interfaces]
user@PE1# set gre unit 0 tunnel source 1.1.1.2
user@PE1# set gre unit 0 tunnel destination 1.1.1.1
user@PE1# set gre unit 0 family inet address 10.35.100.26/30
```
6. Configure the loopback interface of Router PE1.  

```
[edit interfaces]
user@PE1# set lo0 unit 0 family inet address 10.255.10.2/32
```
7. Configure the loopback address of Router PE1 as its router ID.

- ```
[edit routing-options]
user@PE1# set router-id 10.255.10.2
```
8. Configure an associated bidirectional LSP, and enable unidirectional reverse LSP setup for single-sided provisioned forward LSP.
 

```
[edit protocols]
user@PE1# set rsvp associated-bidirectional-lsp single-sided-provisioning
```
  9. Enable RSVP on all the interfaces of Router PE1, excluding the management interface.
 

```
[edit protocols]
user@PE1# set rsvp interface all
user@PE1# set rsvp interface fxp0.0 disable
```
  10. Configure the RSVP peer interface for Router PE1, and enable dynamic setup of bidirectional packet LSP for transporting nonpacket GMPLS LSP.
 

```
[edit protocols]
user@PE1# set rsvp peer-interface CE1 dynamic-bidirectional-transport
```
  11. Enable MPLS on all the interfaces of Router PE1, excluding the management interface.
 

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```
  12. Configure OSPF with traffic engineering capabilities.
 

```
[edit protocols]
user@PE1# set ospf traffic-engineering
```
  13. Enable OSPF area 0 on all the interfaces of Router PE1, excluding the management interface.
 

```
[edit protocols]
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```
  14. Configure a traffic engineering link, and assign addresses for the local and remote end of the link.
 

```
[edit protocols]
user@PE1# set link-management te-link link1 local-address 10.35.1.2
user@PE1# set link-management te-link link1 remote-address 10.35.1.1
```
  15. Enable setting up of a Layer 2 VLAN LSP for a specific range of VLANs on the link1 traffic engineering link.
 

```
[edit protocols]
user@PE1# set link-management te-link link1 ethernet-vlan vlan-id-range 1-1000
```
  16. Configure the Router PE1 interface as the member interface of the link1 traffic engineering link.
 

```
[edit protocols]
user@CE1# set link-management te-link link1 interface ge-0/0/0
```
  17. Configure Router CE1 as the LMP peer for Router PE1, and configure the peer attributes.

```
[edit protocols]
user@CE1# set link-management peer CE1 address 10.255.10.1
user@CE1# set link-management peer CE1 control-channel gre.0
user@CE1# set link-management peer CE1 te-link link1
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces

}
}

```

## Verification

Confirm that the configuration is working properly.

- [Verifying the Traffic Engineering Link Status on the Client Routers on page 812](#)
- [Verifying the RSVP Session Status on the Client Routers on page 814](#)

- [Verifying the LSP Status on the Server Router on page 814](#)
- [Verifying the CCC Entries in the MPLS Routing Table of the Server Routers on page 815](#)
- [Verifying End-to-End Connectivity on page 816](#)

#### [Verifying the Traffic Engineering Link Status on the Client Routers](#)

**Purpose** Verify the status of the traffic engineering link configured between Router CE1 and Router CE2.

**Action** From operational mode, run the **show link-management** and the **show link-management te-link detail** commands.

```

user@CE1> show link-management

```

**Meaning** The Link Management Protocol (LMP) peering has been established between the client routers, and the traffic engineering link is up on both Routers CE1 and CE2.

#### Verifying the RSVP Session Status on the Client Routers

**Purpose** Verify the status of the RSVP sessions between Router CE1 and Router CE2.

**Action** From operational mode, run the **show rsvp session** command.

```
user@CE1> show rsvp session
Ingress RSVP: 1 sessions
  To          From          State   Rt  Style  Labelin Labelout LSPname
  10.255.10.6 10.255.10.1 Up      0  1 FF    -      10 CE1-to-CE2 Bidir
Total 1 displayed, Up 1, Down 0

Egress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

user@CE2> show rsvp session
Ingress RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0

Egress RSVP: 1 sessions

  10.255.10.6 10.255.10.1 Up      0  1 FF    10      - CE1-to-CE2 Bidir
Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

**Meaning** The RSVP sessions are established between the ingress router, Router CE1, and the egress router, Router CE2.

#### Verifying the LSP Status on the Server Router

**Purpose** Verify the status of the MPLS LSP on Router PE1.

**Action** From operational mode, run the **show mpls lsp** command.

```
user@PE1> show mpls lsp
Ingress LSP: 1 sessions
  To          From          State Rt P    ActivePath    LSPName
10.255.10.5   10.255.10.2   Up    0 *
vlan:0:10:8176:10.255.10.2->10.255.10.5 Assoc-Bidir
Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions
  To          From          State Rt Style Labelin Labelout LSPName
10.255.10.2   10.255.10.5   Up    0 1 FF      3      -
vlan:0:10:8176:10.255.10.2->10.255.10.5:rev
Total 1 displayed, Up 1, Down 0

Transit LSP: 1 sessions
  To          From          State Rt Style Labelin Labelout LSPName
10.255.10.6   10.255.10.1   Up    0 1 FF      10    299808 CE1-to-CE2 Bidir
Total 1 displayed, Up 1, Down 0
```

**Meaning** The CE1-to-CE2 LSP is established, and the output displays the LSP attributes.

#### Verifying the CCC Entries in the MPLS Routing Table of the Server Routers

**Purpose** Verify the circuit cross-connect (CCC) interface entries in the MPLS routing table.

**Action** From operational mode, run the **show route table mpls.0** and the **show route forwarding-table ccc ccc-interface** commands.

```
user@PE1> show route table mpls.0
mpls.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0                *[MPLS/0] 1d 22:14:51, metric 1
                  Receive
1                *[MPLS/0] 1d 22:14:51, metric 1
                  Receive
2                *[MPLS/0] 1d 22:14:51, metric 1
                  Receive
13               *[MPLS/0] 1d 22:14:51, metric 1
                  Receive
299824           *[RSVP/7/1] 17:32:07, metric 1
                  > via ge-0/0/0.10, Pop
ge-0/0/0.10      *[RSVP/7/1] 17:32:07, metric 1
                  > to 20.20.20.2 via ge-0/0/2.0, label-switched-path CE1-to-CE2

user@PE1> show route forwarding-table ccc ge-0/0/0.10
Routing table: default.mpls
MPLS:
Destination      Type RtRef Next hop          Type Index  NhRef Netif
ge-0/0/0.10      (CCC) user    0 20.20.20.2      Push 299808, Push 299872(top)
581              2 ge-0/0/2.0

Routing table: __mpls-oam__.mpls
MPLS:
Destination      Type RtRef Next hop          Type Index  NhRef Netif
default          perm      0                      dscd    534    1
```

**Meaning** The output displays the CCC interface that is the client-router-facing interface and the next-hop details for that interface.

### Verifying End-to-End Connectivity

**Purpose** Verify the connectivity between Router CE1 and the remote client router, Router CE2.

**Action** From operational mode, run the **ping** command.

```
user@CE1> ping 10.10.10.2
PING 10.10.10.2 (10.10.10.2): 56 data bytes
64 bytes from 10.10.10.2: icmp_seq=0 ttl=64 time=15.113 ms
64 bytes from 10.10.10.2: icmp_seq=1 ttl=64 time=13.353 ms
64 bytes from 10.10.10.2: icmp_seq=2 ttl=64 time=13.769 ms
64 bytes from 10.10.10.2: icmp_seq=3 ttl=64 time=10.341 ms
64 bytes from 10.10.10.2: icmp_seq=4 ttl=64 time=12.597 ms
^C
--- 10.10.10.2 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max/stddev = 10.341/13.035/15.113/1.575 ms
```

**Meaning** The ping from Router CE1 to Router CE2 is successful.

## Hierarchy of RSVP LSPs Overview

---

This chapter provides overview information and configuration instructions for hierarchies of RSVP label-switched paths (LSPs), which enable you to tunnel multiple RSVP LSPs over a single RSVP LSP.

The following sections provide an overview of how a hierarchy of RSVP LSPs functions:

- [Hierarchy of RSVP LSPs on page 820](#)
- [Advertising the Forwarding Adjacency with OSPF on page 820](#)

## Hierarchy of RSVP LSPs Terminology

---

### F

<b>Forwarding adjacency</b>	A traffic engineering link created by a forwarding adjacency LSP. You can create a forwarding adjacency between two routers in a network by configuring a forwarding adjacency LSP. Forwarding adjacencies can only be statically configured. However, you can configure OSPF to advertise the forwarding adjacency to other routers. When an RSVP LSP traverses a forwarding adjacency, existing MPLS features such as fast reroute continue to function.
<b>Forwarding adjacency LSP</b>	An RSVP LSP used to tunnel other RSVP LSPs; forms the basis for a forwarding adjacency.

## Hierarchy of RSVP LSPs Standard

---

For more information on how a hierarchy of RSVP LSPs functions, see RFC 4206, *Label Switched Paths (LSP) Hierarchy with Generalized Multi-Protocol Label Switching (GMPLS) Traffic Engineering (TE)*.

## Hierarchy of RSVP LSPs

---

Forwarding adjacencies are configured and managed as point-to-point traffic engineering links by including statements at the **[edit protocols link-management]** hierarchy level. For the forwarding adjacency to function properly, you also need to make RSVP aware of the forwarding adjacency by configuring the corresponding peer interface at the **[edit protocols rsvp]** hierarchy level.

Although forwarding adjacency LSPs are configured and managed as traffic engineering links on the local router, it is not necessary to advertise these traffic engineering links to other routers in the network. However, if you want to automatically forward MPLS traffic over the forwarding adjacency or want other routers to compute paths over the forwarding adjacency, you must configure OSPF to advertise the forwarding adjacency to the other routers in the network and add the forwarding adjacency to the traffic engineering database. OSPF is the only supported interior gateway protocol (IGP).

## Advertising the Forwarding Adjacency with OSPF

---

Once a forwarding adjacency LSP and the corresponding traffic engineering link you have configured, you can configure OSPF to advertise the forwarding adjacency. Unlike regular traffic engineering links, OSPF hellos are not exchanged between the forwarding adjacency LSP endpoints and therefore no routing adjacency is created between the forwarding adjacency endpoints. If you issue a **show ospf neighbor** command on an ingress forwarding adjacency, the command displays the egress router of the forwarding adjacency LSP as a neighbor. However, no real OSPF adjacency is established (no OSPF hellos are exchanged) between the ingress and egress routers. For display purposes only, OSPF creates a pseudo-neighbor corresponding to the peer.

You can configure forwarding adjacencies over existing MPLS networks. A forwarding adjacency LSP is signaled as a regular MPLS LSP without generalized MPLS (GMPLS) extensions. When the forwarding adjacency LSP is advertised as a traffic engineering link in OSPF, the corresponding traffic engineering link in OSPF is also advertised as a regular MPLS traffic engineering link without GMPLS extensions.

## Configuring a Hierarchy of RSVP LSPs to Tunnel Multiple RSVP LSPs Over a Single RSVP LSP

---

The following sections describe how to configure a hierarchy of RSVP LSPs:

- [Configuring an RSVP LSP on Ingress Routers on page 821](#)
- [Configuring Forwarding Adjacencies on page 821](#)

- [Configuring RSVP for Forwarding Adjacencies on page 822](#)
- [Advertising Forwarding Adjacencies Using OSPF on page 823](#)

## Configuring an RSVP LSP on Ingress Routers

Configure a standard RSVP LSP on the ingress router to be used as the forwarding adjacency LSP (see [label-switched-path](#)). This LSP requires no special configuration to function as a forwarding adjacency LSP.

## Configuring Forwarding Adjacencies

A forwarding adjacency is a type of GMPLS traffic engineering link. It requires that you configure local and remote addresses to identify the link. A forwarding adjacency is associated with a specific peer router. You could configure multiple forwarding adjacencies to the same peer router.

To configure a forwarding adjacency, you need to configure the **te-link** statement at the **[edit protocols link-management]** hierarchy level:

```
[edit protocols link-management]
te-link te-link-name {
  label-switched-path lsp-name;
  local-address ip-address;
  remote-address ip-address;
}
```

For more information on how to configure GMPLS traffic engineering links, see “[Configuring LMP Traffic Engineering Links](#)” on page 774.

**NOTE:** Do not configure the control channel for a forwarding adjacency peer router. Configuring a control channel causes the commit operation to fail.

The following sections describe how to configure the **te-link** statement for a forwarding adjacency:

- [Configuring the Local IP Address for Forwarding Adjacencies on page 821](#)
- [Configuring the Remote IP Address for Forwarding Adjacencies on page 822](#)
- [Configuring the LSP for Forwarding Adjacencies on page 822](#)

### Configuring the Local IP Address for Forwarding Adjacencies

---

To configure the local IP address for the forwarding adjacency, include the **local-address** statement:

```
local-address ip-address;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

**NOTE:** If you configure **local-address**, you must also configure **remote-address**.

### Configuring the Remote IP Address for Forwarding Adjacencies

---

The address of the peer router is the node ID for the forwarding adjacency LSP egress node. You configure this node ID for the forwarding adjacency using the **remote-address** statement:

```
remote-address ip-address;
```

You can include this statement at the following hierarchy levels:

- [edit protocols link-management **te-link** *te-link-name*]
- [edit logical-systems *logical-system-name* protocols link-management **te-link** *te-link-name*]

NOTE: If you configure **remote-address**, you must also configure **local-address**.

---

### Configuring the LSP for Forwarding Adjacencies

---

To configure a router to function as a forwarding adjacency, use the **label-switched-path** statement and specify the LSP configured in “Configuring a Hierarchy of RSVP LSPs to Tunnel Multiple RSVP LSPs Over a Single RSVP LSP” on page 820:

```
label-switched-path label-switched-path-name;
```

You can include this statement at the following hierarchy levels:

- [edit protocols link-management **te-link** *te-link-name*]
- [edit logical-systems *logical-system-name* protocols link-management **te-link** *te-link-name*]

## Configuring RSVP for Forwarding Adjacencies

For the forwarding adjacency to function properly, RSVP must be made aware of it. Do this by specifying the name of the peer interface corresponding to the link-management peer associated with the forwarding adjacency. Including the **peer-interface** statement at the [edit protocols **rsvp**] hierarchy level enables RSVP to use all of the traffic engineering links configured for that peer. You can also configure RSVP control-plane parameters such as the hello interval and refresh reduction.

To configure RSVP to recognize a forwarding adjacency, include the **peer-interface** statement:

```
peer-interface peer-interface-name {  
  disable;  
  (aggregate | no-aggregate);  
  authentication-key key;  
  hello-interval seconds;  
  (reliable | no-reliable);  
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols rsvp]**
- **[edit logical-systems *logical-system-name* protocols rsvp]**

For more information on how to configure the **peer-interface** statement, see [“Configuring RSVP and OSPF for LMP Peer Interfaces” on page 781](#).

## Advertising Forwarding Adjacencies Using OSPF

You can allow other routers to dynamically signal paths over a forwarding adjacency LSP by configuring OSPF. This configuration is optional.

If you configure OSPF to advertise a forwarding adjacency LSP, the LSP is added to the traffic engineering database on each router in the traffic engineering domain. Because the forwarding adjacency LSP is unidirectional, the corresponding traffic engineering link (forwarding adjacency) is also unidirectional. The forwarding adjacency LSP appears as a standard traffic engineering database half-link to all routers in the traffic engineering domain.

Constrained Shortest Path First (CSPF) performs a bidirectional link check to ensure that traffic can flow in both directions. CSPF checks for a reverse link, either the exact reverse forwarding adjacency or another reverse link. If there is no reverse link from the forwarding adjacency LSP egress router to the forwarding adjacency LSP ingress router, the CSPF check fails.

CSPF might find another parallel reverse link. However, the LSP cannot function properly over the forwarding adjacency unless you have explicitly configured a corresponding forwarding adjacency LSP to handle the traffic flowing in the opposite direction on the forwarding adjacency LSP egress router.

To advertise the traffic engineering properties of a forwarding adjacency to a specific peer router, include the **peer-interface** statement:

```
peer-interface peer-interface-name {  
  dead-interval seconds;  
  disable;  
  hello-interval seconds;  
  retransmit-interval seconds;  
  transit-delay seconds;  
}
```

You can configure this statement at the following hierarchy levels:

- **[edit protocols ospf area *area-name*]**
- **[edit logical-systems *logical-system-name* protocols ospf area *area-name*]**

For more information on how to configure the **peer-interface** statement, see [“Configuring RSVP and OSPF for LMP Peer Interfaces” on page 781](#).

## PART 7

# Configuring Path Computation Element Protocol (PCEP)

- [PCEP Overview on page 827](#)
- [Configuring PCEP on page 843](#)

# PCEP Overview

- [PCEP Overview on page 827](#)
- [Support of the Path Computation Element Protocol for RSVP-TE Overview on page 828](#)

## PCEP Overview

A Path Computation Element (PCE) is an entity (component, application, or network node) that is capable of computing a network path or route based on a network graph and applying computational constraints. A Path Computation Client (PCC) is any client application requesting a path computation to be performed by a PCE. The Path Computation Element Protocol (PCEP) enables communications between a PCC and a PCE, or between two PCEs (defined in RFC 5440).

PCEP is a TCP-based protocol defined by the IETF PCE Working Group, and defines a set of messages and objects used to manage PCEP sessions and to request and send paths for multidomain traffic engineered LSPs (TE LSPs). It provides a mechanism for a PCE to perform path computation for a PCC's external LSPs. The PCEP interactions include LSP status reports sent by the PCC to the PCE, and PCE updates for the external LSPs.

[Figure 84 on page 827](#) illustrates the role of PCEP in the client-side implementation of a stateful PCE architecture in an MPLS RSVP-TE enabled network.

**Figure 84: PCEP Session**

A TCP-based PCEP session connects a PCC to an external PCE. The PCC initiates the PCEP session and stays connected to the PCE for the duration of the PCEP session.

During the PCEP session, the PCC requests LSP parameters from the stateful PCE. On receiving one or more LSP parameters from the PCE, the PCC re-signals the TE LSP. When the PCEP session is terminated, the underlying TCP connection is closed immediately, and the PCC attempts to re-establish the PCEP session.

Thus, the PCEP functions include:

- LSP tunnel state synchronization between a PCC and a stateful PCE—When an active stateful PCE connection is detected, a PCC tries to delegate all LSPs to this PCE in a procedure called LSP state synchronization. PCEP enables synchronization of the PCC LSP state to the PCE.
- Delegation of control over LSP tunnels to a stateful PCE—An active stateful PCE controls one or more LSP attributes for computing paths, such as bandwidth, path (ERO), and priority (setup and hold). PCEP enables such delegation of LSPs for path computation.
- Stateful PCE control of timing and sequence of path computations within and across PCEP sessions—An active stateful PCE modifies one or more LSP attributes, such as bandwidth, path (ERO), and priority (setup and hold). PCEP communicates these new LSP attributes from the PCE to the PCC, after which the PCC re-signals the LSP in the specified path.

### Understanding MPLS RSVP-TE

Traffic engineering (TE) deals with performance optimization of operational networks, mainly mapping traffic flows onto an existing physical topology. Traffic engineering provides the ability to move traffic flow away from the shortest path selected by the

interior gateway protocol (IGP) and onto a potentially less congested physical path across a network.

For traffic engineering in large, dense networks, MPLS capabilities can be implemented because they potentially provide most of the functionality available from an overlay model, in an integrated manner, and at a lower cost than the currently competing alternatives. The primary reason for implementing MPLS traffic engineering is to control paths along which traffic flows through a network. The main advantage of implementing MPLS traffic engineering is that it provides a combination of the traffic engineering capabilities of ATM, along with the class-of-service (CoS) differentiation of IP.

In an MPLS network, data plane information is forwarded using label switching. A packet arriving on a provider edge (PE) router from the customer edge (CE) router has labels applied to it, and it is then forwarded to the egress PE router. The labels are removed at the egress router and it is then forwarded out to the appropriate destination as an IP packet. The label-switching routers (LSRs) in the MPLS domain use label distribution protocols to communicate the meaning of labels used to forward traffic between and through the LSRs. RSVP-TE is one such label distribution protocol that enables an LSR peer to learn about the label mappings of other peers.

When both MPLS and RSVP are enabled on a router, MPLS becomes a client of RSVP. The primary purpose of the Junos OS RSVP software is to support dynamic signaling within label-switched paths (LSPs). RSVP reserves resources, such as for IP unicast and multicast flows, and requests quality-of-service (QoS) parameters for applications. The protocol is extended in MPLS traffic engineering to enable RSVP to set up LSPs that can be used for traffic engineering in MPLS networks.

When MPLS and RSVP are combined, labels are associated with RSVP flows. Once an LSP is established, the traffic through the path is defined by the label applied at the ingress node of the LSP. The mapping of label to traffic is accomplished using different criteria. The set of packets that are assigned the same label value by a specific node belong to the same forwarding equivalence class (FEC), and effectively define the RSVP flow. When traffic is mapped onto an LSP in this way, the LSP is called an LSP tunnel.

LSP tunnels are a way to establish unidirectional label-switched paths. RSVP-TE builds on the RSVP core protocol by defining new objects and modifying existing objects used in the PATH and RESV objects for LSP establishment. The new objects—LABEL-REQUEST object (LRO), RECORD-ROUTE object (RRO), LABEL object, and EXPLICIT-ROUTE object (ERO)—are optional with respect to the RSVP protocol, except for the LRO and LABEL objects, which are both mandatory for establishing LSP tunnels.

In general, RSVP-TE establishes a label-switched path that ensures frame delivery from ingress to egress router. However, with the new traffic engineering capabilities, the following functions are supported in an MPLS domain:

- Possibility to establish a label-switched path using either a full or partial explicit route (RFC 3209).
- Constraint-based LSP establishment over links that fulfill requirements, such as bandwidth and link properties.

- Endpoint control, which is associated with establishing and managing LSP tunnels at the ingress and egress routers.
- Link management, which manages link resources to do resource-aware routing of traffic engineering LSPs and to program MPLS labels.
- MPLS fast reroute (FRR), which manages the LSPs that need protection and assigns backup tunnel information to these LSPs.

### Current MPLS RSVP-TE Limitations

Although the RSVP extensions for traffic engineering enable better network utilization and meet requirements of classes of traffic, today's MPLS RSVP-TE protocol suite has several issues inherent to its distributed nature. This causes a number of issues during contention for bisection capacity, especially within an LSP priority class where a subset of LSPs share common setup and hold priority values. The limitations of RSVP-TE include:

- Lack of visibility of individual per-LSP, per-device bandwidth demands—The ingress routers in an MPLS RSVP-TE network establish LSPs without having a global view of the bandwidth demand on the network. Information about network resource utilization is only available as total reserved capacity by traffic class on a per interface basis. Individual LSP state is available locally on each label edge router (LER) for its own LSPs only. As a result, a number of issues related to demand pattern arise, particularly within a common setup and hold priority.
- Asynchronous and independent nature of RSVP signaling—In RSVP-TE, the constraints for path establishment are controlled by an administrator. As such, bandwidth reserved for an LSP tunnel is set by the administrator and does not automatically imply any limit on the traffic sent over the tunnel. Therefore, bandwidth available on a traffic engineering link is the bandwidth configured for the link, excluding the sum of all reservations made on the link. Thus, the unsignaled demands on an LSP tunnel lead to service degradation of the LSP requiring excess bandwidth, as well as the other LSPs that comply with the bandwidth requirements of the traffic engineering link.
- LSPs established based on dynamic or explicit path options in the order of preference—The ingress routers in an MPLS RSVP-TE network establish LSPs for demands based on the order of arrival. Because the ingress routers do not have a global view of the bandwidth demand on the network, using the order of preference to establish LSPs can cause traffic to be dropped or LSPs not being established at all when there is an excess of bandwidth demand.

As an example, [Figure 85 on page 831](#) is configured with MPLS RSVP-TE, in which A and G are the label edge routers (LERs). These ingress routers establish LSPs independently based on the order of demands and have no knowledge or control over each other's LSPs. Routers B, C, and D are intermediate or transit routers that connect to the egress routers E and F.

Figure 85: Example MPLS Traffic Engineering

The ingress routers establish LSPs based on the order in which the demands arrive. If Router G receives two demands of capacity 5 each for G-F, then G signals two LSPs – LSP1 and LSP2 – through G-B-D-F. In the same way, when Router A receives the third demand of capacity 10 for A-E, then it signals an LSP, LSP3, through A-B-C-E. However, if the demand on the A-E LSP increases from 10 to 15, Router A cannot signal LSP3 using the same (A-B-C-E) path, because the B-C link has a lower capacity.

Router A should have signaled the increased demand on LSP3 using the A-B-D-E path. Since LSP1 and LSP2 have utilized the B-D link based on the order of demands received, LSP3 is not signaled.

Thus, although adequate max-flow bandwidth is available for all the LSPs, LSP3 is subject to potentially prolonged service degradation. This is due to Router A's lack of global demand visibility and the lack of systemic coordination in demand placement by the ingress routers A and G.

## Use of an External Path Computing Entity

As a solution to the current limitations found in the MPLS RSVP-TE path computation, an external path computing entity with a global view of per-LSP, per-device demand in the network independent of available capacity is required.

Currently, only online and real-time constraint-based routing path computation is provided in an MPLS RSVP-TE network. Each router performs constraint-based routing calculations independent of the other routers in the network. These calculations are based on currently available topology information—information that is usually recent, but not completely accurate. LSP placements are locally optimized, based on current network status. The MPLS RSVP-TE tunnels are set up using the CLI. An operator configures the TE LSP, which is then signaled by the ingress router.

In addition to the existing traffic engineering capabilities, the MPLS RSVP-TE functionality is extended to include an external path computing entity, called the Path Computation Element (PCE). The PCE computes the path for the TE LSPs of ingress routers that have

been configured for external control. The ingress router that connects to a PCE is called a Path Computation Client (PCC). The PCC is configured with the Path Computation Client Protocol (PCEP) to facilitate external path computing by a PCE.

For more information, see [“Components of External Path Computing” on page 832](#).

To enable external path computing for a PCC's TE LSPs, include the **`lsp-external-controller pccd`** statement at the **`[edit mpls]`** and **`[edit mpls lsp lsp-name]`** hierarchy levels.

## Components of External Path Computing

The components that make up an external path computing system are:

- [Path Computation Element on page 832](#)
- [Path Computation Client on page 833](#)
- [Path Computation Element Protocol on page 833](#)

### Path Computation Element

---

A Path Computation Element (PCE) can be any entity (component, application, or network node) that is capable of computing a network path or route based on a network graph and applying computational constraints. However, a PCE can compute the path for only those TE LSPs of a PCC that have been configured for external control.

A PCE can either be stateful or stateless.

- **Stateful PCE**—A stateful PCE maintains strict synchronization between the PCE and network states (in terms of topology and resource information), along with the set of computed paths and reserved resources in use in the network. In other words, a stateful PCE utilizes information from the traffic engineering database as well as information about existing paths (for example, TE LSPs) in the network when processing new requests from the PCC.

A stateful PCE is of two types:

- **Passive stateful PCE**—Maintains synchronization with the PCC and learns the PCC LSP states to better optimize path calculations, but does not have control over them.
- **Active stateful PCE**—Actively modifies the PCC LSPs, in addition to learning about the PCC LSP states.

**NOTE:** In a redundant configuration with main and backup active stateful PCEs, the backup active stateful PCE cannot modify the attributes of delegated LSPs until it becomes the main PCE at the time of a failover. There is no preempting of PCEs in the case of a switchover. The main PCE is backed by a backup PCE, and when the main PCE goes down, the backup PCE assumes the role of the main PCE and remains the main PCE even after the PCE that was previously the main PCE is operational again.

---

A stateful PCE provides the following functions:

- Offers offline LSP path computation.
- Triggers LSP re-route when there is a need to re-optimize the network.
- Changes LSP bandwidth when there is an increase in bandwidth demand from an application.
- Modifies other LSP attributes on the router, such as ERO, setup priority, and hold priority.

A PCE has a global view of the bandwidth demand in the network and maintains a traffic-engineered database to perform path computations. It performs statistics collection from all the routers in the MPLS domain using SNMP and NETCONF. This provides a mechanism for offline control of the PCC's TE LSPs. Although an offline LSP path computation system can be embedded in a network controller, the PCE acts like a full-fledged network controller that provides control over the PCC's TE LSPs, in addition to computing paths.

Although a stateful PCE allows for optimal path computation and increased path computation success, it requires reliable state synchronization mechanisms, with potentially significant control plane overhead and the maintenance of a large amount of data in terms of states, as in the case of a full mesh of TE LSPs.

- Stateless PCE—A stateless PCE does not remember any computed path, and each set of requests is processed independently of each other (RFC 5440).

### Path Computation Client

A Path Computation Client (PCC) is any client application requesting a path computation to be performed by a PCE.

A PCC can connect to a maximum of 10 PCEs at one time. The PCC to PCE connection can be a configured static route or a TCP connection that establishes reachability. The PCC assigns each connected PCE a priority number. It sends a message to all the connected PCEs with information about its current LSPs, in a process called LSP state synchronization. For the TE LSPs that have external control enabled, the PCC delegates those LSPs to the main PCE. The PCC elects, as the main PCE, a PCE with the lowest priority number, or the PCE that it connects to first in the absence of a priority number.

The PCC re-signals an LSP based on the computed path it receives from a PCE. When the PCEP session with the main PCE is terminated, the PCC elects a new main PCE, and all delegated LSPs to the previously main PCE are delegated to the newly available main PCE.

### Path Computation Element Protocol

The Path Computation Element Protocol (PCEP) is used for communication between PCC and PCE (as well as between two PCEs) (RFC 5440). PCEP is a TCP-based protocol defined by the IETF PCE Working Group, and defines a set of messages and objects used to manage PCEP sessions and to request and send paths for multidomain TE LSPs. The PCEP interactions include PCC messages, as well as notifications of specific states

related to the use of a PCE in the context of MPLS RSVP-TE. When PCEP is used for PCE-to-PCE communication, the requesting PCE assumes the role of a PCC.

Thus, the PCEP functions include:

- LSP tunnel state synchronization between PCC and a stateful PCE.
- Delegation of control over LSP tunnels to a stateful PCE.

## Interaction Between a PCE and a PCC Using PCEP

Figure 86 on page 834 illustrates the relationship between a PCE, PCC, and the role of PCEP in the context of MPLS RSVP-TE.

Figure 86: PCC and RSVP-TE

The PCE to PCC communication is enabled by the TCP-based PCEP. The PCC initiates the PCEP session and stays connected to a PCE for the duration of the PCEP session.

**NOTE:** Starting with Junos OS Release 16.1, you can secure a PCEP session using TCP-MD5 authentication as per RFC 5440. To enable the MD5 security mechanism for a PCEP session, it is recommended that you define and bind the MD5 authentication key at the `[edit protocols pcep pce pce-id]` hierarchy level for a PCEP session. You can, however, also use a predefined keychain from the `[edit security authentication-key-chains key-chain]` hierarchy level to secure a PCEP session. In this case, you should bind the predefined keychain into the PCEP session at the `[edit protocols pcep pce pce-id]` hierarchy level.

The PCE and PCC use the same key to verify the authenticity of each segment sent on the TCP connection of the PCEP session, thereby securing the PCEP communication between the devices, which might be subject to attacks and can disrupt services on the network.

For more information on securing PCEP sessions using MD5 authentication, see [“TCP-MD5 Authentication for PCEP Sessions” on page 840](#).

Once the PCEP session is established, the PCC performs the following tasks:

1. LSP state synchronization—The PCC sends information about all the LSPs (local and external) to all connected PCEs. For external LSPs, the PCC sends information about any configuration change, RRO change, state change, and so on, to the PCE.

For PCE-initiated LSPs, there is no LSP configuration present on the PCC. The PCE initiating the LSP sends the LSP parameters to the PCC that has indicated its capability of supporting PCE-initiated LSPs.

**NOTE:** Support for PCE-initiated LSPs is provided in Junos OS Release 13.3 and later releases.

2. LSP delegation—After the LSP state information is synchronized, the PCC then delegates the external LSPs to one PCE, which is the main active stateful PCE. Only the main PCE can set parameters for the external LSP. The parameters that the main PCE modifies include bandwidth, path (ERO), and priority (setup and hold). The parameters specified in the local configuration are overridden by the parameters that are set by the main PCE.

**NOTE:** When the PCEP session with the main PCE is terminated, the PCC elects a new main PCE, and all delegated LSPs to the previously main PCE are delegated to the newly available main PCE.

In the case of PCE-initiated LSPs, the PCC creates the LSP using the parameters received from the PCE. The PCC assigns the PCE-initiated LSP a unique LSP-ID, and automatically delegates the LSP to the PCE. A PCC cannot revoke the delegation for the PCE-initiated LSPs for an active PCEP session.

When a PCEP session terminates, the PCC starts two timers without immediately deleting the PCE-initiated LSPs – **delegation cleanup timeout** and **lsp cleanup timer** – to avoid disruption of services. During this time, an active stateful PCE can acquire control of the LSPs provisioned by the failed PCE, by sending a create request for the LSP.

Control over PCE-initiated LSPs reverts to the PCC at the expiration of the **delegation cleanup timeout**. When the **delegation cleanup timeout** expires, and no other PCE has acquired control over the LSP from the failed PCE, the PCC takes local control of the non-delegated PCE-initiated LSP. Later, when the original or a new active stateful PCE wishes to acquire control of the locally controlled PCE-initiated LSPs, the PCC delegates these LSPs to the PCE and the **lsp cleanup timer** timer is stopped.

A PCE may return the delegation of the PCE-initiated LSP to the PCC to allow LSP transfer between PCEs. This triggers the **lsp cleanup timer** for the PCE-initiated LSP. The PCC waits for the LSP cleanup timer to expire before removing the non-delegated PCE-initiated LSPs from the failed PCE.

When the **lsp cleanup timer** expires, and no other PCE has acquired control over the LSPs from the failed PCE, the PCC deletes all the LSPs provisioned by the failed PCE.

3. LSP signaling—On receiving one or more LSP parameters from the main active stateful PCE, the PCC re-signals the TE LSP based on the PCE provided path. If the PCC fails to set up the LSP, it notifies the PCE of the setup failure and waits for the main PCE to provide new parameters for that LSP, and then re-signals it.

When the PCE specifies a path that is incomplete or has loose hops where only the path endpoints are specified, the PCC does not perform local constraint-based routing to find out the complete set of hops. Instead, the PCC provides RSVP with the PCE provided path, as it is, for signaling, and the path gets set up using IGP hop-by-hop routing.

Considering the topology used in [Figure 85 on page 831](#), [Figure 87 on page 836](#) illustrates the partial client-side PCE implementation in the MPLS RSVP-TE enabled network. The ingress routers A and G are the PCCs that are configured to connect to the external stateful PCE through a TCP connection.

The PCE has a global view of the bandwidth demand in the network and performs external path computations after looking up the traffic engineering database. The active stateful PCE then modifies one or more LSP attributes and sends an update to the PCC. The PCC uses the parameters it receives from the PCE to re-signal the LSP.

**Figure 87: Example PCE for MPLS RSVP-TE**

This way, the stateful PCE provides a cooperative operation of distributed functionality used to address specific challenges of a shortest interdomain constrained path computation. It eliminates congestion scenarios in which traffic streams are inefficiently mapped onto available resources, causing overutilization of some subsets of network resources, while other resources remain underutilized.

## LSP Behavior with External Computing

- [LSP Types on page 837](#)
- [LSP Control Mode on page 838](#)

## LSP Types

In a client-side PCE implementation, there are three types of TE LSPs:

- CLI-controlled LSPs—The LSPs that do not have the **`lsp-external-controller pccd`** statement configured are called CLI-controlled LSPs. Although these LSPs are under local control, the PCC updates the connected PCEs with information about the CLI-controlled LSPs during the initial LSP synchronization process. After the initial LSP synchronization, the PCC informs the PCE of any new and deleted LSPs as well.
- PCE-controlled LSPs—The LSPs that have the **`lsp-external-controller pccd`** statement configured are called PCE-controlled LSPs. The PCC delegates the PCC-initiated LSPs to the main PCE for external path computation.

The PCC informs the PCE about the configured parameters of a PCE-controlled LSP, such as bandwidth, ERO, and priorities. It also informs the PCE about the actual values used for these parameters to set up the LSP including the RRO, when available.

The PCC sends such LSP status reports to the PCE only when a reconfiguration has occurred or when there is a change in the ERO, RRO, or status of the PCE-controlled LSPs under external control.

There are two types of parameters that come from the CLI configuration of an LSP for a PCE:

- Parameters that are not overridden by a PCE, and that are applied immediately.
- Parameters that are overridden by a PCE. These parameters include bandwidth, path, and priority (setup and hold values). When the control mode switches from external to local, the CLI-configured values for these parameters are applied at the next opportunity to re-signal the LSP. The values are not applied immediately.
- Externally-provisioned LSPs (or PCE-initiated LSPs)—The LSPs that have the **`lsp-provisioning`** statement configured are called PCE-initiated LSPs. A PCE-initiated LSP is dynamically created by an external PCE; as a result, there is no LSP configuration present on the PCC. The PCC creates the PCE-initiated LSP using the parameters provided by the PCE, and automatically delegates the LSP to the PCE.

**NOTE:** Support for PCE-initiated LSPs is provided in Junos OS Release 13.3 and later releases.

The CLI-controlled LSPs, PCE-controlled LSPs, and PCE-initiated LSPs can coexist on a PCC.

The CLI-controlled LSPs and PCE-controlled LSPs can coexist on a PCC.

## LSP Control Mode

In a client-side PCE implementation, there are two types of control modes for a PCC-controlled LSP:

- **External**—By default, all PCE-controlled LSPs are under external control. When an LSP is under external control, the PCC uses the PCE-provided parameters to set up the LSP.
- **Local**—A PCE-controlled LSP can come under local control. When the LSP switches from external control to local control, path computation is done using the CLI-configured parameters and constraint-based routing. Such a switchover happens only when there is a trigger to re-signal the LSP. Until then, the PCC uses the PCE-provided parameters to signal the PCE-controlled LSP, although the LSP remains under local control.

A PCE-controlled LSP switches to local control from its default external control mode in cases such as no connectivity to a PCE or when a PCE returns delegation of LSPs back to the PCC.

For more information about CLI-controlled LSPs and PCE-controlled LSPs, see [“LSP Types” on page 837](#).

## Configuration Statements Supported for External Computing

[Table 20 on page 838](#) lists the MPLS and existing LSP configuration statements that apply to a PCE-controlled LSP.

**Table 20: Applicability of MPLS and Existing LSP Configurations to a PCE-Controlled LSP**

Support for PCE-Controlled LSP	Applicable LSP Configuration Statements	Applicable MPLS Configuration Statements
These configuration statements can be configured along with the PCE configuration. However, they take effect only when the local configuration is in use. During PCE control, these configuration statements remain inactive.	<ul style="list-style-type: none"> <li>• admin-group</li> <li>• auto-bandwidth</li> <li>• hop-limit</li> <li>• least-fill</li> <li>• most-fill</li> <li>• random</li> </ul>	<ul style="list-style-type: none"> <li>• admin-group</li> <li>• admin-groups</li> <li>• admin-group-extended</li> <li>• hop-limit</li> <li>• no-cspf</li> <li>• smart-optimize-timer</li> </ul>
These configuration statements can be configured along with the PCE configuration, but are overridden by the PCE-controlled LSP attributes. However, when the local configuration is in use, the configured values for these configuration statements are applied.	<ul style="list-style-type: none"> <li>• bandwidth</li> <li>• primary</li> <li>• priority</li> </ul>	<ul style="list-style-type: none"> <li>• priority</li> </ul>
<p><b>NOTE:</b> Changes to the local configuration using the CLI while the LSP is under the control of a stateful PCE do not have any effect on the LSP. These changes come into effect only when the local configuration is applied.</p>		

**Table 20: Applicability of MPLS and Existing LSP Configurations to a PCE-Controlled LSP (*continued*)**

Support for PCE-Controlled LSP	Applicable LSP Configuration Statements	Applicable MPLS Configuration Statements
These configuration statements cannot be configured along with the PCE configuration.	<ul style="list-style-type: none"> <li>p2mp</li> <li>template</li> </ul>	<ul style="list-style-type: none"> <li>p2mp-lsp-next-hop</li> </ul>

The rest of the LSP configuration statements are applicable in the same way as for existing LSPs. On configuring any of the above configuration statements for a PCE-controlled LSP, an MPLS log message is generated to indicate when the configured parameters take effect.

### PCE-Controlled LSP Protection

The protection paths, including fast reroute and bypass LSPs, are locally computed by the PCC using constraint-based routing. A stateful PCE specifies the primary path (ERO) only. A PCE can also trigger a non-standby secondary path, even if the local configuration does not have a non-standby secondary path for LSP protection.

### PCE Controlled Point-to-Multipoint RSVP-TE LSPs

After a PCEP session is established between a PCE and a PCC, the PCC reports all the LSPs in the system to the PCE for LSP state synchronization. This includes PCC-controlled, PCE-delegated, and PCE-initiated point-to-point LSPs. Starting with Junos OS Release 15.1F6 and 16.1R1, this capability is extended to report point-to-multipoint LSPs as well. For a PCE, the point-to-multipoint LSP is similar to that of RSVP point-to-multipoint LSP, where the point-to-multipoint LSP is treated as collection of point-to-point LSPs grouped under a point-to-multipoint identifier.

By default, PCE control of point-to-multipoint LSPs is not supported on a PCC. To add this capability, include the **p2mp-lsp-report-capability** statement at the **[edit protocols pcep pce pce-name]** or **[edit protocols pcep pce-group group-id]** hierarchy levels. After the point-to-multipoint report capability is configured on a PCC, the PCC advertises this capability to the PCE. If the PCE advertises the same point-to-multipoint report capability in return, then the PCC reports the complete point-to-multipoint LSP tree to the PCE for LSP state synchronization.

A PCC with the point-to-multipoint TE LSP capability supports reporting of point-to-multipoint TE LSPs for stateful PCEs, point-to-multipoint update, and LSP database supporting point-to-multipoint LSP name as key. However, the following features and functions are not supported for Junos OS Release 15.1F6 and 16.1:

- Static point-to-multipoint LSPs
- PCE-delegated and PCE-initiated point-to-multipoint LSPs
- Auto-bandwidth
- TE++
- PCE request and reply message

- Creation of point-to-multipoint LSPs using templates
- Configuring forward entry on the PCE-initiated point-to-multipoint LSPs
- Configuring forward entry on the router pointing to a provisioned LSP.

## Auto-Bandwidth and PCE-Controlled LSP

The auto-bandwidth option does not apply to PCE-controlled LSPs, although LSPs under the control of auto-bandwidth and constraint-based routing can coexist with PCE-controlled LSPs. The statistics collection for auto-bandwidth takes effect only when the control mode of a PCE-controlled LSP changes from external to local. This can happen in cases such as no connectivity to a PCE or when a PCE returns delegation of LSPs back to the PCC.

## TCP-MD5 Authentication for PCEP Sessions

A stateful PCE server automates the creation of traffic engineering paths across the network, increasing network utilization and enabling a customized programmable networking experience with the use of PCEP communication with a PCC. A PCC sends LSP reports to a PCE server, and the PCE updates or provisions LSPs back to the PCC. The data sent over a PCEP session is crucial for a PCE server to perform external path computing. As a result, an attack on the PCEP communication can disrupt network services. If altered PCEP messages are sent to a PCC, inappropriate LSPs can be set up. Similarly, if altered PCEP messages are sent to a PCE, an incorrect view of the network is learned by the PCE.

Considering the significance of the PCEP communication between a PCE and PCC in executing the PCE functionalities effectively, Junos OS Release 16.1 introduces the feature of securing a PCEP session using TCP-MD5 authentication as per RFC 5440. This feature protects the communication between a PCE and PCC over a PCEP session, which might be subject to an attack, and can disrupt network services.

To enable the MD5 security mechanism for a PCEP session, it is recommended that you define and bind the MD5 authentication key at the **[edit protocols pcep pce pce-id]** hierarchy level for a PCEP session. You can, however, also use a predefined keychain from the **[edit security authentication-key-chains key-chain]** hierarchy level to secure a PCEP session. In this case, you should bind the predefined keychain into the PCEP session at the **[edit protocols pcep pce pce-id]** hierarchy level.

The following configuration is executed on the PCC to establish a secure PCEP session with a PCE:

- Using MD5 authentication key:

```
[edit protocols pcep pce pce-id]
user@PCC# set authentication-key key
```

- Using predefined authentication keychain:

```
[edit protocols pcep pce pce-id]
user@PCC# set authentication-key-chain key-chain
user@PCC# set authentication-algorithm md5
```

For secure PCEP sessions to be established successfully, the MD5 authentication should be configured with the pre-shared authentication key on both the PCE server and the PCC. The PCE and PCC use the same key to verify the authenticity of each segment sent on the TCP connection of the PCEP session.

NOTE:

- Junos OS Release 16.1 supports only TCP-MD5 authentication for PCEP sessions, without extending support for TLS and TCP-AO, such as protection against eavesdropping, tampering, and message forgery.
- Initial application of security mechanism to a PCEP session causes the session to reset.
- If MD5 is misconfigured or not configured on one side of the PCEP session, the session does not get established. Verify that the configurations on the PCC and PCE are matching.
- This feature does not provide support for any session authentication mechanism.
- To view the authentication keychain used by the PCEP session, use the `show path-computation-client status` and `show protocols pcep` command outputs.
- Use the `show system statistics tcp | match auth` command to view the number of packets that get dropped by TCP because of authentication errors.
- Operation of the keychain can be verified by using the `show security keychain detail` command output.

## Impact of Client-Side PCE Implementation on Network Performance

The maintenance of a stateful database can be non-trivial. In a single centralized PCE environment, a stateful PCE simply needs to remember all the TE LSPs that the PCE has computed, the TE LSPs that were actually set up (if this can be known), and when the TE LSPs were torn down. However, these requirements cause substantial control protocol overhead in terms of state, network usage and processing, and optimizing links globally across the network. Thus, the concerns of a stateful PCE implementation include:

- Any reliable synchronization mechanism results in significant control plane overhead. PCEs might synchronize state by communicating with each other, but when TE LSPs are set up using distributed computation performed among several PCEs, the problems of synchronization and race condition avoidance become larger and more complex.
- Out-of-band traffic engineering database synchronization can be complex with multiple PCEs set up in a distributed PCE computation model, and can be prone to race conditions, scalability concerns, and so on.
- Path calculations incorporating total network state is highly complex, even if the PCE has detailed information on all paths, priorities, and layers.

In spite of the above concerns, the partial client-side implementation of the stateful PCE is extremely effective in large traffic engineering systems. It provides rapid convergence and significant benefits in terms of optimal resource usage, by providing the requirement for global visibility of a TE LSP state and for ordered control of path reservations across devices within the system being controlled.

**Release History Table**

Release	Description
16.1	Starting with Junos OS Release 16.1, you can secure a PCEP session using TCP-MD5 authentication as per RFC 5440.
16.1	Junos OS Release 16.1 introduces the feature of securing a PCEP session using TCP-MD5 authentication as per RFC 5440.

### Example: Configuring the Path Computation Element Protocol for MPLS RSVP-TE

This example shows how to enable external path computing by a Path Computation Element (PCE) for traffic engineered label-switched paths (TE LSPs) on a Path Computation Client (PCC). It also shows how to configure the Path Computation Element Protocol (PCEP) on the PCC to enable PCE to PCC communication.

- [Requirements on page 843](#)
- [Overview on page 844](#)
- [Configuration on page 846](#)
- [Verification on page 851](#)

## Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of M Series Multiservice Edge Routers, MX Series 3D Universal Edge Routers, T Series Core Routers, or PTX Series Transport Router, one of which is configured as a PCC.
- A TCP connection to an external stateful PCE from the PCC.
- Junos OS Release 12.3 or later running on the PCC along with the JSDN add-on package.

**NOTE:** The JSDN add-on package is required to be installed along with the core Junos OS installation package.

Before you begin:

1. Configure the device interfaces.
2. Configure MPLS and RSVP-TE.
3. Configure IS-IS or any other IGP protocol.

## Overview

Starting with Junos OS Release 12.3, the MPLS RSVP-TE functionality is extended to provide a partial client-side implementation of the stateful PCE architecture (draft-ietf-pce-stateful-pce) on a PCC.

**NOTE:** The partial client-side implementation of the stateful PCE architecture is based on version 2 of Internet draft draft-ietf-pce-stateful-pce. Starting with Junos OS Release 16.1, this implementation is upgraded to support version 7, as defined in Internet draft draft-ietf-pce-stateful-pce-07. Releases prior to 16.1 support the older version of the PCE draft, causing interoperability issues between a PCC running a previous release and a stateful PCE server that adheres to Internet draft draft-ietf-pce-stateful-pce-07.

To enable external path computing by a PCE, include the **lsp-external-controller** statement on the PCC at the **[edit mpls]** and **[edit mpls lsp lsp-name]** hierarchy levels.

```
lsp-external-controller pccd;
```

An LSP configured with the **lsp-external-controller** statement is referred to as a PCE-controlled LSP and is under the external control of a PCE by default. An active stateful PCE can override the parameters set from the CLI, such as bandwidth, path (ERO), and priority, for such PCE-controlled LSPs of the PCC.

To enable PCE to PCC communication, configure PCEP on the PCC at the **[edit protocols]** hierarchy level.

```
pcep { ... }
```

When configuring PCEP on a PCC, be aware of the following considerations:

- The JSDN add-on package is required to be installed along with the core Junos OS installation package.
- Junos OS Release 12.3 supports only stateful PCEs.
- A PCC can connect to a maximum of 10 stateful PCEs. At any given point in time, there can be only one main PCE (the PCE with the lowest priority value, or the PCE that connects to the PCC first in the absence of a PCE priority) to which the PCC delegates LSPs for path computation.
- For Junos OS Release 12.3, the PCC always initiates the PCEP sessions. PCEP sessions initiated by remote PCEs are not accepted by the PCC.

- Existing LSP features, such as LSP protection and make-before-break, work for PCE-controlled LSPs.
- The auto-bandwidth option is turned off for PCE-controlled LSPs, although LSPs under the control of auto-bandwidth and constraint-based routing can coexist with PCE-controlled LSPs.
- PCE-controlled LSPs can be referred to by other CLI configurations, such as `lsp-nexthop` to routes, forwarding adjacencies, CCC connections, and logical tunnels.
- PCE-controlled LSPs do not support GRES.
- PCE-controlled LSPs under logical-systems are not supported.
- PCE-controlled LSPs cannot be point-to-multipoint LSPs.
- Bidirectional LSPs are not supported.
- PCE-controlled LSPs cannot have secondary paths without a primary path.
- PCE-controlled LSPs depend on external path computation, which impacts overall setup time, reroutes, and make-before-break features.
- Setup time and convergence time (reroute, MBB) for existing LSPs is the same as in previous releases, in the absence of PCE-controlled LSPs. However, a small impact is seen in the presence of PCE-controlled LSPs.
- ERO computation time is expected to be significantly higher than local-CSPF.

### Topology

Figure 88: Configuring PCEP for MPLS RSVP-TE

In this example, PCC is the ingress router that connects to the external active stateful PCE.

The external LSPs of Router PCC are computed as follows:

1. Router PCC receives the LSP tunnel configuration that was set up using the CLI. Assuming that the received configuration is enabled with external path computing, Router PCC becomes aware that some of the LSP attributes – bandwidth, path, and priority – are under the control of the stateful PCE and delegates the LSP to the PCE.

In this example, the external LSP is called **PCC-to-R2** and it is being set up from Router PCC to Router R2. The CLI-configured ERO for **PCC-to-R2** is PCC-R0-R1-R2. The bandwidth for **PCC-to-R2** is 10m, and both the setup and hold priority values are 4.

2. Router PCC tries to retrieve the PCE-controlled LSP attributes. To do this, Router PCC sends out a PCRpt message to the stateful PCE stating that the LSP has been configured. The PCRpt message communicates the status of the LSP and contains the local configuration parameters of the LSP.
3. The stateful PCE modifies one or more of the delegated LSP attributes and sends the new LSP parameters to Router PCC through the PCUpd message.
4. On receiving the new LSP parameters, Router PCC sets up a new LSP and re-signals it using the PCE-provided path.

In this example, the PCE-provided ERO for **PCC-to-R2** is PCC-R3-R2. The bandwidth for **PCC-to-R2** is 8m, and both the setup and hold priority values are 3.

5. Router PCC sends a PCRpt with the new RRO to the stateful PCE.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
PCC
set interfaces ge-1/0/1 unit 0 family inet address 20.31.4.1/24
set interfaces ge-1/0/1 unit 0 family iso
set interfaces ge-1/0/1 unit 0 family mpls

      set protocols isis interface lo0.0

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router PCC:

**NOTE:** Repeat this procedure for every Juniper Networks ingress router in the MPLS domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Configure the interfaces.

To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

**[edit interfaces]**

```

user@PCC# set ge-1/0/1 unit 0 family inet address 20.31.4.1/24
user@PCC# set ge-1/0/1 unit 0 family iso
user@PCC# set ge-1/0/1 unit 0 family mpls

```

```

user@PCC# set ge-1/1/1 unit 0 family inet address 20.31.1.1/24
user@PCC# set ge-1/1/1 unit 0 family iso
user@PCC# set ge-1/1/1 unit 0 family mpls

```

```

user@PCC# set lo0 unit 0 family inet address 10.255.179.95/32

```

2. Enable RSVP on all interfaces of Router PCC, excluding the management interface.

**[edit protocols]**

```

user@PCC# set rsvp interface all
user@PCC# set rsvp interface fxp0.0 disable

```

3. Configure the label-switched path (LSP) from Router PCC to Router R2 and enable external control of LSPs by the PCE.

**[edit protocols]**

```

user@PCC# set mpls lsp-external-controller pccd

```

```

user@PCC# set mpls label-switched-path PCC-to-R2 to 10.255.179.98/32
user@PCC# set mpls label-switched-path PCC-to-R2 bandwidth 10m
user@PCC# set protocols mpls label-switched-path PCC-to-R2 priority 4 4
user@PCC# set protocols mpls label-switched-path PCC-to-R2 primary to-R2-path
user@PCC# set protocols mpls label-switched-path PCC-to-R2
lsp-external-controller pccd

```

4. Configure the LSP from Router PCC to Router R2, which has local control and is overridden by the PCE-provided LSP parameters.

```

[edit protocols]
user@PCC# set mpls path to-R2-path 20.31.1.2/30 strict
user@PCC# set mpls path to-R2-path 20.31.2.2/30 strict

```

5. Enable MPLS on all interfaces of Router PCC, excluding the management interface.

```

[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable

```

6. Configure IS-IS on all interfaces of Router PCC, excluding the management interface.

```

[edit protocols]
user@PCC# set isis level 1 disable
user@PCC# set isis interface all
user@PCC# set isis interface fxp0.0 disable
user@PCC# set isis interface lo0.0

```

7. Define the PCE that Router PCC connects to, and configure the IP address of the PCE.

```

[edit protocols]
user@PCC# set pcep pce pce1 destination-ipv4-address 10.209.57.166

```

8. Configure the destination port for Router PCC that connects to a PCE using the TCP-based PCEP.

```

[edit protocols]
user@PCC# set pcep pce pce1 destination-port 4189

```

9. Configure the PCE type.

```

[edit protocols]
user@PCC# set pcep pce pce1 pce-type active
user@PCC# set pcep pce pce1 pce-type stateful

```

## Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@PCC# show interfaces
ge-1/0/1 {
  unit 0 {
    family inet {
      address 20.31.4.1/24;
    }
    family iso;
  }
}

```

```
        family mpls;
    }
}
ge-1/1/1 {
    unit 0 {
        family inet {
            address 20.31.1.1/24;
        }
        family iso;
        family mpls;
    }
}
lo0 {
    unit 0 {
        family inet {
            address 10.255.179.95/32;
        }
    }
}

user@PCC# show protocols
rsvp {
    interface all;
    interface fxp0.0 {
        disable;
    }
}
mpls {
    lsp-external-controller pccd;
    label-switched-path PCC-to-R2 {
        to 10.255.179.98;
        bandwidth 10m;
        priority 4 4;
        primary to-R2-path;
        lsp-external-controller pccd;
    }
    path to-R2-path {
        20.31.1.2 strict;
        20.31.2.2 strict;
    }
    interface all;
    interface fxp0.0 {
        disable;
    }
}
isis {
    level 1 disable;
    interface all;
    interface fxp0.0 {
        disable;
    }
    interface lo0.0;
}
pcep {
    pce pce1 {
        destination-ipv4-address 10.209.57.166;
```

```

        destination-port 4189;
        pce-type active stateful;
    }
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the PCEP Session Status on page 851](#)
- [Verifying the PCE-Controlled LSP Status When LSP Control Is External on page 852](#)
- [Verifying the PCE-Controlled LSP Status When LSP Control Is Local on page 853](#)

### Verifying the PCEP Session Status

**Purpose** Verify the PCEP session status between the PCE and Router PCC when the PCE status is up.

**Action** From operational mode, run the **show path-computation-client active-pce** command.

```
user@PCC> show path-computation-client active-pce
```

```
PCE pce1
```

```
General
```

```

IP address           : 10.209.57.166
Priority              : 0
PCE status            : PCE_STATE_UP
Session type          : PCE_TYPE_STATEFULACTIVE
PCE-mastership        : main

```

```
Counters
```

PCReqs	Total: 0	last 5min: 0	last hour: 0
PCReps	Total: 0	last 5min: 0	last hour: 0
PCRpts	Total: 5	last 5min: 5	last hour: 5
PCUpdates	Total: 1	last 5min: 1	last hour: 1

```
Timers
```

Local	Keepalive timer:	30 [s]	Dead timer:	120 [s]
Remote	Keepalive timer:	30 [s]	Dead timer:	120 [s]

```
Errors
```

```

PCErr-recv
PCErr-sent
PCE-PCC-NTFS
PCC-PCE-NTFS

```

**Meaning** The output displays information about the current active stateful PCE that Router PCC is connected to. The **PCE status** output field indicates the current status of the PCEP session between the PCE and Router PCC.

For **pce1**, the status of the PCEP session is **PCE\_STATE\_UP**, which indicates that the PCEP session has been established between the PCEP peers.

The statistics of **PCRpts** indicate the number of messages sent by Router PCC to the PCE to report the current status of LSPs. The **PCUpdates** statistics indicate the number of messages received by Router PCC from the PCE. The **PCUpdates** messages include the PCE modified parameters for the PCE-controlled LSPs.

### Verifying the PCE-Controlled LSP Status When LSP Control Is External

**Purpose** Verify the status of the PCE-controlled LSP from Router PCC to Router R2 when the LSP is under external control.

**Action** From operational mode, run the **show mpls lsp name PCC-to-R2 extensive** command.

```
user@PCC> show mpls lsp name PCC-to-R2 extensive
Ingress LSP: 1 sessions
```

```

```

**Meaning** In the output, the **LSP Control Status** output field shows that the LSP is under local control. Although the PCE-controlled LSP is under local control, Router PCC continues to use the PCE-provided parameters, until the next opportunity to re-signal the LSP.

The output now displays the LSP parameters that were configured using the CLI along with the PCE-provided parameters used to establish the LSP as the actual values in use.

- Bandwidth—10Mbps (ActualBandwidth: 8Mbps)
- Priorities—4 4 (ActualPriorities 3 3)

On the trigger to re-signal the LSP, Router PCC uses the local configuration parameters to establish the PCE-controlled LSP.

## Example: Configuring Path Computation Element Protocol with Support of PCE-Initiated LSPs

---

This example shows how to configure the Path Computation Client (PCC) with the capability of supporting Path Computation Element (PCE)-initiated traffic-engineered label-switched paths (LSPs).

- [Requirements on page 856](#)
- [Overview on page 856](#)
- [Configuration on page 859](#)
- [Verification on page 862](#)

### Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of M Series, MX Series, or T Series routers.
- A TCP connection to two external stateful PCEs from the ingress router (PCC).
- Junos OS Release 16.1 or later running on the PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE (RSVP-Traffic Engineering).
- Configure OSPF or any other IGP protocol.

### Overview

Starting with Junos OS Release 16.1, the PCEP functionality is extended to allow a stateful PCE to initiate and provision traffic engineering LSPs through a PCC. Earlier, the LSPs were configured on the PCC and the PCC delegated control over the external LSPs to a PCE. The ownership of the LSP state was maintained by the PCC. With the introduction of the PCE-initiated LSPs, a PCE can initiate and provision a traffic engineering LSP

dynamically without the need for a locally configured LSP on the PCC. On receiving a PCCreate message from a PCE, the PCC creates the PCE-initiated LSP and automatically delegates the LSP to the PCE.

By default, a PCC rejects the request for provisioning PCE-initiated LSPs from a PCE. To enable support of PCE-initiated LSPs on the PCC, include the *lsp-provisioning* statement at the **[edit protocols pcep pce pce-id]** or **[edit protocols pcep pce-group group-id]** hierarchy levels.

A PCC indicates its capability of supporting PCE-initiated LSPs while establishing the Path Computation Element Protocol (PCEP) session with the PCE. A PCE selects a PCC with this capability to initiate an LSP. The PCE provides the PCC with the PCE-initiated LSP parameters. On receiving the PCE-initiated LSP parameters, the PCC sets up the LSP, assigns an LSP ID, and automatically delegates the LSP to the PCE.

When the PCE initiating the LSP does not provide the PCE-initiated LSP parameters, the PCC uses the default parameters. An optional LSP template may also be configured to specify values for the PCE-initiated LSP when the LSP parameters are not provided by the PCE. To configure an LSP template for PCE-initiated LSPs on the PCC, include the *label-switched-path-template* statement at the **[edit protocols mpls lsp-external-controller lsp-external-controller]** hierarchy level.

When a PCEP session terminates, the PCC starts two timers without immediately deleting the PCE-initiated LSPs—**delegation cleanup timeout** and **lsp cleanup timer**—to avoid disruption of services. During this time, an active stateful PCE can acquire control of the LSPs provisioned by the failed PCE.

A PCE may return the delegation of the PCE-initiated LSP to the PCC to allow LSP transfer between PCEs. Control over PCE-initiated LSPs reverts to the PCC at the expiration of the delegation cleanup timeout. When the delegation cleanup timeout expires, and no other PCE has acquired control over the LSP from the failed PCE, the PCC takes local control of the non-delegated PCE-initiated LSP. Later, when the original or a new active stateful PCE wishes to acquire control of the locally controlled PCE-initiated LSPs, the PCC delegates these LSPs to the PCE and the LSP cleanup timer is stopped.

The PCC waits for the LSP cleanup timer to expire before deleting the non-delegated PCE-initiated LSPs from the failed PCE. When the LSP cleanup timer expires, and no other PCE has acquired control over the LSPs from the failed PCE, the PCC deletes all the LSPs provisioned by the failed PCE.

When configuring the support of PCE-initiated LSPs for a PCC, be aware of the following considerations:

- Junos OS Release 13.3 supports only stateful PCEs.
- For Junos OS Release 13.3, the PCC always initiates the PCEP sessions. PCEP sessions initiated by remote PCEs are not accepted by the PCC.
- Existing LSP features, such as LSP protection and make-before-break, work for PCE-initiated LSPs.
- PCE-initiated LSPs do not support graceful Routing Engine switchover (GRES).

- PCE-initiated LSPs under logical systems are not supported.
- PCE-initiated LSPs cannot be point-to-multipoint LSPs.
- Bidirectional LSPs are not supported.
- RSVP-TE for unnumbered links is not supported. PCE-initiated LSPs support only numbered links.

## Topology

**Figure 89: Example PCE-Initiated LSP for MPLS RSVP-TE**

In this example, PCC is the ingress router that connects to two external stateful PCEs: PCE1 and PCE2.

When there is a new demand, the active stateful PCE dynamically initiates an LSP to meet the requirement. Since PCC is configured with the capability of supporting the PCE-initiated LSP, path computation on PCC is performed as follows:

1. A PCE sends a PCCreate message to the PCC to initiate and provision an LSP. The PCC sets up the PCE-initiated LSP using the parameters received from the PCE, and automatically delegates the PCE-initiated LSP to the PCE that initiated it.  
In this example, PCE1 is the active stateful PCE that initiates and provisions the PCE-initiated LSP on PCC. On receiving the PCE-initiated LSP parameters, PCC sets up the LSP and automatically delegates the PCE-initiated LSP to PCE1.
2. When the PCEP session between PCC and PCE1 is terminated, PCC starts two timers for the PCE1-initiated LSP: delegation cleanup timeout and the LSP cleanup timer. During this time, PCE1 or PCE2 can acquire control of the PCE-initiated LSP.
3. If PCE2 acquires control over the PCE-initiated LSP before the expiration of the LSP cleanup timer, PCC delegates the PCE-initiated LSP to PCE2, and the LSP cleanup timer and the delegation cleanup timeout are stopped.
4. If the delegation cleanup timeout expired, and neither PCE1 nor PCE2 acquired control over the PCE-initiated LSP, PCC takes local control of the non-delegated PCE-initiated LSP until the expiration of the LSP cleanup timer.
5. After the expiration of the LSP cleanup timer, PCC deletes the PCE-initiated LSP provisioned by PCE1.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
PCC

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the PCC router:

**NOTE:** Repeat this procedure for every Juniper Networks ingress router in the MPLS domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Configure the interfaces.

To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

**[edit interfaces]**

```

user@PCC# set ge-0/1/1 unit 0 family inet address 10.0.102.9/24
user@PCC# set ge-0/1/1 unit 0 family iso
user@PCC# set ge-0/1/1 unit 0 family mpls

```

```

user@PCC# set ge-0/1/3 unit 0 family inet address 10.0.112.14/24
user@PCC# set ge-0/1/3 unit 0 family iso
user@PCC# set ge-0/1/3 unit 0 family mpls

```

```

user@PCC# set lo0 unit 0 family inet address 192.168.12.1/32

```

2. Enable RSVP on all interfaces of the PCC, excluding the management interface.

**[edit protocols]**

```

user@PCC# set rsvp interface all
user@PCC# set rsvp interface fxp0.0 disable

```

3. Enable external control of LSPs by the PCEs.

**[edit protocols]**

```

user@PCC# set mpls lsp-external-controller pccd

```

4. Enable MPLS on all interfaces of the PCC, excluding the management interface.

**[edit protocols]**

```

user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable

```

5. Configure OSPF on all interfaces of the PCC, excluding the management interface.

**[edit protocols]**

```

user@PCC# set ospf traffic-engineering

```

```

user@PCC# set ospf area 0.0.0.0 interface all
user@PCC# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PCC# set ospf interface lo0.0

```

6. Define the PCE group and enable support of PCE-initiated LSPs for the PCE group.

```

[edit protocols]
user@PCC# set protocols pcep pce-group PCEGROUP pce-type active
user@PCC# set protocols pcep pce-group PCEGROUP pce-type stateful
user@PCC# set protocols pcep pce-group PCEGROUP lsp-provisioning
user@PCC# set protocols pcep pce-group PCEGROUP lsp-cleanup-timer 30

```

7. Define the PCEs that connect to the PCC.

```

[edit protocols]
user@PCC# set pcep pce PCE1 destination-ipv4-address 192.168.69.58
user@PCC# set pcep pce PCE1 destination-port 4189
user@PCC# set pcep pce PCE1 pce-group PCEGROUP

user@PCC# set pcep pce PCE2 destination-ipv4-address 192.168.70.65
user@PCC# set pcep pce PCE2 destination-port 4189
user@PCC# set pcep pce PCE2 pce-group PCEGROUP

```

## Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@PCC# show interfaces
ge-0/1/1 {
  unit 0 {
    family inet {
      address 10.0.102.9/24;
    }
    family iso;
    family mpls;
  }
}
ge-0/1/3 {
  unit 0 {
    family inet {
      address 10.0.112.14/24;
    }
    family iso;
    family mpls;
  }
}
lo0 {
  unit 0 {
    family inet {
      address 192.168.12.1/32;
    }
  }
}

```

```
user@PCC# show protocols
rsvp {
  interface all;
}
interface fxp0.0 {
  disable;
}
mpls {
  lsp-external-controller pccd;
  interface all;
  interface fxp0.0 {
    disable;
  }
}
ospf {
  traffic-engineering;
  area 0.0.0.0 {
    interface all;
    interface fxp0.0 {
      disable;
    }
  }
}
pce-group PCEGROUP {
  pce-type active stateful;
  lsp-provisioning;
  lsp-cleanup-timer 30;
}
pce PCE1 {
  destination-ipv4-address 192.168.69.58;
  destination-port 4189;
  pce-group PCEGROUP;
}
pce PCE2 {
  destination-ipv4-address 192.168.70.65;
  destination-port 4189;
  pce-group PCEGROUP;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying PCC Status on page 863](#)
- [Verifying PCE1 Status on page 863](#)
- [Verifying the PCE-Initiated LSP Status When the LSP Is Externally Provisioned on page 865](#)

### Verifying PCC Status

**Purpose** Verify the PCEP session status and LSP summary between the PCC and the connected PCEs.

**Action** From operational mode, run the **show path-computation-client status** command.

```
user@PCC# show path-computation-client status
Session          Type          Provisioning    Status
PCE1             Stateful Active        On             Up
PCE2             Stateful Active        On             Up

LSP Summary
Total number of LSPs      : 1
Static LSPs               : 0
Externally controlled LSPs : 0
Externally provisioned LSPs : 1/16000 (current/limit)
Orphaned LSPs             : 0

PCE1 (main)
  Delegated               : 1
  Externally provisioned : 1
PCE2
  Delegated               : 0
  Externally provisioned : 0
```

**Meaning** The output displays the status of the PCEP session between the active stateful PCEs and the PCC. It also displays information about the different types of LSPs on the PCC, and the number of LSPs provisioned by the connected PCEs and delegated to them.

PCE1 is the main active PCE and has one PCE-initiated LSP that has been automatically delegated to it by the PCC.

### Verifying PCE1 Status

**Purpose** Verify the status of the main active stateful PCE.

**Action** From operational mode, run the **show path-computation-client active-pce detail** command.

```

user@PCC# show path-computation-client active-pce
PCE PCE1

Errors
  PCErr-recv
  PCErr-sent
  PCE-PCC-NTFS
  PCC-PCE-NTFS

```

**Meaning** The output displays information about the current active stateful PCE to which the PCC is connected. The **PCE status** output field indicates the current status of the PCEP session between a PCE and PCC.

For PCE1, the status of the PCEP session is **PCE\_STATE\_UP**, which indicates that the PCEP session has been established with the PCC.

### Verifying the PCE-Initiated LSP Status When the LSP Is Externally Provisioned

**Purpose** Verify the status of the PCE-initiated LSP.

**Action** From operational mode, run the **show mpls lsp externally-provisioned detail** command.

```
user@PCC# show mpls lsp externally-provisioned detail
Ingress LSP: 1 sessions

10.0.101.10
  From: 10.0.102.9, State: Up, ActiveRoute: 0, LSPname: lsp15
  ActivePath: path1 (primary)
  Link protection desired
  LSPtype: Externally Provisioned, Penultimate hop popping
  LSP Control Status: Externally controlled
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  *Primary path1 State: Up
    Priorities: 7 0
    Bandwidth: 8Mbps
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 3)
    10.0.102.10 S 10.0.101.9 S
    Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node
    10=SoftPreempt 20=Node-ID):
    10.0.102.10 S 10.0.101.9 S
```

**Meaning** In the output, the **LSPtype** output field shows that the LSP is externally provisioned.

The PCEP session between PCC and PCE1 is up, and the PCC receives the following PCE-initiated LSP parameters:

- ERO (path)—10.0.102.10 and 10.0.101.9
- Bandwidth—8 Mbps
- Priority—7 0 (setup and hold values)

## Configuring Path Computation Element Protocol with Support of PCE Initiated LSPs for MPLS RSVP TE

---

You can configure a Path Computation Client (PCC) with the capability of supporting dynamically created label switched paths (LSPs) from a centralized external path computing entity. A stateful Path Computaiton Element (PCE) can be used to perform external path computation and generate dynamic LSPs when there is an increase in demand.

A PCC creates the PCE-initiated LSP using the PCE-provided LSP parameters, or parameters from a pre-configured LSP template when the PCE does not provision the LSP, and automatically delegates the PCE-initiated LSP to the respective PCE. As a result, for PCE-initiated LSPs, there is no need for a locally configured LSP on the PCC.

A CLI-controlled LSP, PCE-controlled LSP, and PCE-initiated LSP can coexist with each other on a PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE.
- Configure OSPF or any other IGP protocol.

To configure PCC to support PCE-initiated LSPs, complete the following tasks:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@PCC# edit protocols pcep
```

2. Specify the number of messages per minute that the PCC can receive at maximum.

```
[edit protocols pcep]
user@PCC# set message-rate-limit messages-per-minute
```

3. Specify the number of externally provisioned label switched paths (LSPs) over all connected PCEs that the PCC can accept at maximum.

```
[edit protocols pcep]
user@PCC# set max-provisioned-lsps max-count
```

4. Specify the unique user defined ID for the connected PCE to configure the PCE parameters.

```
[edit protocols pcep]
user@PCC# edit pce pce-id
```

5. Specify the amount of time (in seconds) that the PCC must wait before returning control of LSPs to the routing protocol process after a PCEP session is disconnected.

```
[edit protocols pcep pce pce-id]
user@PCC# set delegation-cleanup-timeout seconds
```

6. Specify the IPv4 address of the PCE to connect with.

```
[edit protocols pcep pce pce-id]
```

```
user@PCC# set destination-ipv4-address ipv4-address
```

7. Specify the TCP port number that the PCE is using

```
[edit protocols pcep pce pce-id]
user@PCC# set destination-port port-number
```

The value can range from 1 through 65535 and the default value is 4189.

8. Specify the amount of time (in seconds) that the PCC must wait before deleting any non-delegated PCE-initiated LSPs from the failed PCE after a PCEP session terminates.

```
[edit protocols pcep pce pce-id]
user@PCC# set lsp-cleanup-timer seconds
```

9. Configure the PCC to accept SPs that are externally provisioned by connected PCEs. By default, the PCC rejects PCE-initiated LSPs.

```
[edit protocols pcep pce pce-id]
user@PCC# set lsp-provisioning
```

10. Specify the number of unknown messages per minute that the PCC can receive at maximum after which the PCEP session is closed.

```
[edit protocols pcep pce pce-id]
user@PCC# set max-unknown-messages messages-per-minute
```

The value can range from 1 through 16384, and the default value is 0 (disabled or no limit).

11. Specify the number of unknown requests per minute that the PCC can receive at maximum after which the PCEP session is terminated.

```
[edit protocols pcep pce pce-id]
user@PCC# set max-unknown-requests requests-per-minute
```

The value can range from 0 through 16384, and the default value is 5. A value of 0 disables this statement.

12. Configure the PCE type.

```
[edit protocols pcep pce pce-id]
user@PCC# set pce-type active stateful
```

13. Specify the amount of time (in seconds) that the PCC must wait for a reply before resending a request.

```
[edit protocols pcep pce pce-id]
user@PCC# set request-timer seconds
```

The value can range from 0 through 65535 seconds.

14. Verify and commit the configuration.

```
user@PCC# show
user@PCC# commit
```

## Sample Output

```
[edit]
user@PCC# edit protocols pcep

[edit protocols pcep]
```

```
user@PCC# set message-rate-limit 50

[edit protocols pcep]
user@PCC# set max-provisioned-lsps 16000

[edit protocols pcep]
user@PCC# edit pce PCE

[edit protocols pcep pce PCE]
user@PCC# set delegation-cleanup-timeout 20

[edit protocols pcep pce PCE]
user@PCC# set destination-ipv4-address 192.168.69.58

[edit protocols pcep pce PCE]
user@PCC# set destination-port 4189

[edit protocols pcep pce PCE]
user@PCC# set lsp-cleanup-timer 50

[edit protocols pcep pce PCE]
user@PCC# set lsp-provisioning

[edit protocols pcep pce PCE]
user@PCC# set max-unknown-messages 5

[edit protocols pcep pce PCE]
user@PCC# set max-unknown-requests 5

[edit protocols pcep pce PCE]
user@PCC# set request-timer 50

[edit protocols pcep pce PCE]
user@PCC# up

[edit protocols pcep]
user@PCC# show
message-rate-limit 50;
max-provisioned-lsps 16000;
pce PCE {
    destination-ipv4-address 192.168.69.58;
    destination-port 4189;
    lsp-provisioning;
    lsp-cleanup-timer 50;
    request-timer 50;
    max-unknown-requests 5;
    max-unknown-messages 5;
    delegation-cleanup-timeout 20;
}

[edit protocols pcep]
user@PCC# commit
commit complete
```

## Example: Configuring Path Computation Element Protocol with Support for PCE Controlled Point-to-Multipoint RSVP-TE LSPs

---

This example shows how to configure the Path Computation Client (PCC) with the capability of reporting point-to-multipoint traffic engineered label-switched paths (TE LSPs) to a Path Computation Element (PCE).

- [Requirements on page 869](#)
- [Overview on page 869](#)
- [Configuration on page 870](#)
- [Verification on page 880](#)

### Requirements

This example uses the following hardware and software components:

- Three routers that can be a combination of M Series, MX Series, or T Series routers.
- One virtual machine configured with Virtual Route Reflector (VRR) feature.
- A TCP connection to an external stateful PCE from the VRR.
- Junos OS Release 16.1 or later running on the PCC.

Before you begin:

- Configure the device interfaces.
- Configure MPLS and RSVP-TE.
- Configure OSPF or any other IGP protocol.

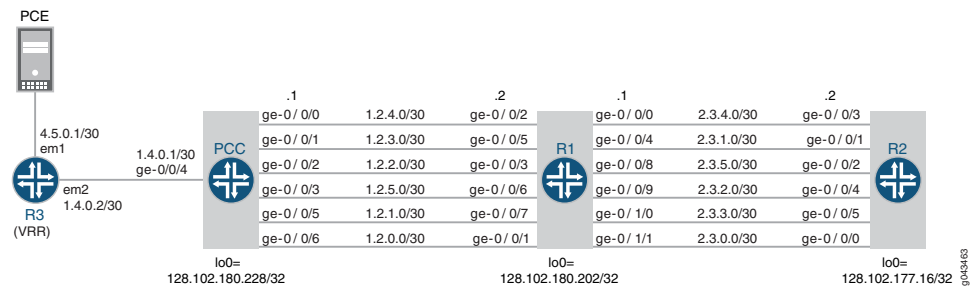

### Overview

After a PCEP session is established between a PCE and a PCC, the PCC reports all the LSPs in the system to the PCE for LSP state synchronization. This includes PCC-controlled, PCE-delegated, and PCE-initiated point-to-point LSPs. Starting with Junos OS Release 15.1F6 and 16.1R1, this capability is extended to report point-to-multipoint LSPs as well.

By default, PCE control of point-to-multipoint LSPs is not supported on a PCC. To add this capability, include the **p2mp-lsp-report-capability** statement at the **[edit protocols pcep pce *pce-name*]** or **[edit protocols pcep pce-group *group-id*]** hierarchy levels.

## Topology

Figure 90: Example PCE-Controlled Point-to-Multipoint LSPs

In this example, PCC is the ingress router, Router R1 is the transit router, and Router R2 is the egress router. PCC is connected to a Virtual Route Reflector (VRR) that is connected to a PCE. There are many point-to-multipoint interfaces between PCC, Router R1, and Router R2.

The reporting of point-to-multipoint LSPs is executed as follows:

1. If Router PCC is configured with point-to-point and point-to-multipoint LSPs without the support for point-to-multipoint reporting capability, only the point-to-point LSPs are reported to the connected PCE. By default, a PCC does not support point-to-multipoint LSP reporting capability.
2. When Router PCC is configured with point-to-multipoint LSP reporting capability, PCC first advertises this capability to PCE through a report message.
3. By default, a PCE provides support for point-to-multipoint LSP capability. On receiving the PCC's advertisement for point-to-multipoint LSP capability, the PCE in return advertises its capability to the PCC.
4. On receiving the PCE's advertisement of the point-to-multipoint capability, PCC reports all branches of point-to-multipoint LSPs to the PCE using the update message.
5. Once all the LSPs are reported to the PCE, LSP state is synchronized between the PCE and PCC.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
PCC
set interfaces ge-0/0/0 unit 0 family inet address 1.2.4.1/30
set interfaces ge-0/0/0 unit 0 family mpls

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the PCC router:

1. Configure the interfaces of Router PCC. To enable MPLS, include the protocol family on the interface so that the interface does not discard incoming MPLS traffic.

[edit interfaces]

```
user@PCC# set ge-0/0/0 unit 0 family inet address 1.2.4.1/30
user@PCC# set ge-0/0/0 unit 0 family mpls
```

```
user@PCC# set ge-0/0/1 unit 0 family inet address 1.2.3.1/30
user@PCC# set ge-0/0/1 unit 0 family mpls
```

```
user@PCC# set ge-0/0/2 unit 0 family inet address 1.2.2.1/30
user@PCC# set ge-0/0/2 unit 0 family mpls
```

```
user@PCC# set ge-0/0/3 unit 0 family inet address 1.2.5.1/30
user@PCC# set ge-0/0/3 unit 0 family mpls
```

```
user@PCC# set ge-0/0/4 unit 0 family inet address 1.4.0.1/30
user@PCC# set ge-0/0/4 unit 0 family mpls
```

```
user@PCC# set ge-0/0/5 unit 0 family inet address 1.2.1.1/30
user@PCC# set ge-0/0/5 unit 0 family mpls
```

```
user@PCC# set ge-0/0/6 unit 0 family inet address 1.2.0.1/30
user@PCC# set ge-0/0/6 unit 0 family mpls
```

2. Configure the autonomous system number for Router PCC.

[edit routing-options]

```
user@PCC# set autonomous-system 100
```

3. Enable RSVP on all interfaces of Router PCC, excluding the management interface.

[edit protocols]

```
user@PCC# set rsvp interface all
user@PCC# set rsvp interface fxp0.0 disable
```

4. Enable MPLS on all the interfaces of Router PCC, excluding the management interface.

```
[edit protocols]
user@PCC# set mpls interface all
user@PCC# set mpls interface fxp0.0 disable
```

5. Configure a dynamic LSP and disable automatic path computation for the LSP.

```
[edit protocols]
user@PCC# set mpls label-switched-path lsp_template_no_cspf template
user@PCC# set mpls label-switched-path lsp_template_no_cspf no-cspf
```

6. Configure point-to-multipoint LSPs and define external path computing entity for the LSP.

```
[edit protocols]
user@PCC# set mpls label-switched-path lsp1-pcc to 128.102.177.16
user@PCC# set mpls label-switched-path lsp2-pcc to 128.102.177.16
user@PCC# set mpls label-switched-path lsp2-pcc lsp-external-controller pccd
```

7. Enable external path computing for the MPLS LSPs and assign a template for externally provisioned LSPs.

```
[edit protocols]
user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp
pcc_delegated_no_cspf_* label-switched-path-template lsp_template_no_cspf
user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp
pce_initiated_no_ero_no_cspf_* label-switched-path-template
lsp_template_no_cspf
user@PCC# set mpls lsp-external-controller pccd pce-controlled-lsp
pce_initiated_loose_ero_no_cspf_* label-switched-path-template
lsp_template_no_cspf
```

8. Configure the LSPs that have local control and are overridden by the PCE-provided LSP parameters.

```
[edit protocols]
user@PCC# set mpls path loose-path 1.2.3.2 loose
user@PCC# set mpls path strict-path 1.2.3.2 strict
user@PCC# set mpls path strict-path 2.3.3.2 strict
user@PCC# set mpls path path-B
user@PCC# set mpls path path-C
```

9. Configure MPLS administrative group policies for constrained-path LSP computation.

```
[edit protocols]
user@PCC# set mpls admin-groups violet 1
user@PCC# set mpls admin-groups indigo 2
user@PCC# set mpls admin-groups blue 3
user@PCC# set mpls admin-groups green 4
user@PCC# set mpls admin-groups yellow 5
user@PCC# set mpls admin-groups orange 6
```

10. Assign the configured administrative group policies to Router PCC interfaces.

```
[edit protocols]
user@PCC# set mpls interface ge-0/0/6.0 admin-group violet
user@PCC# set mpls interface ge-0/0/5.0 admin-group indigo
user@PCC# set mpls interface ge-0/0/2.0 admin-group blue
```

- ```

user@PCC# set mpls interface ge-0/0/1.0 admin-group green
user@PCC# set mpls interface ge-0/0/0.0 admin-group yellow
user@PCC# set mpls interface ge-0/0/3.0 admin-group orange

```
11. Configure a traffic engineering database (TED) import policy.
 

```

[edit protocols]
user@PCC# set mpls traffic-engineering database import policy TE

```
  12. Configure a BGP internal group.
 

```

[edit protocols]
user@PCC# set bgp group northstar type internal
user@PCC# set bgp group northstar local-address 128.102.180.228
user@PCC# set bgp group northstar neighbor 128.102.180.215

```
  13. Configure traffic engineering for BGP and assign the export policy.
 

```

[edit protocols]
user@PCC# set bgp group northstar family traffic-engineering unicast
user@PCC# set bgp group northstar export TE

```
  14. Configure OSPF area 0 on all the point-to-multipoint interfaces of Router PCC.
 

```

[edit protocols]
user@PCC# set ospf area 0.0.0.0 interface lo0.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/6.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/5.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/2.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/1.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/0.0
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/3.0

```
  15. Configure OSPF area 0 on the point-to-point interface of Router PCC.
 

```

[edit protocols]
user@PCC# set ospf area 0.0.0.0 interface ge-0/0/4.0 interface-type p2p

```
  16. Enable traffic engineering for OSPF.
 

```

[edit protocols]
user@PCC# set ospf traffic-engineering

```
  17. Define the PCE that Router PCC connects to, and configure the the PCE parameters.
 

```

[edit protocols]
user@PCC# set pcep pce pce1 local-address 10.102.180.228
user@PCC# set pcep pce pce1 destination-ipv4-address 10.102.180.246
user@PCC# set pcep pce pce1 destination-port 4189
user@PCC# set pcep pce pce1 pce-type active
user@PCC# set pcep pce pce1 pce-type stateful
user@PCC# set pcep pce pce1 lsp-provisioning
user@PCC# set pcep pce pce1 lsp-cleanup-timer 0
user@PCC# set pcep pce pce1 delegation-cleanup-timeout 60

```
  18. Configure Router PCC to enable point-to-multipoint LSP capability for external path computing.
 

```

[edit protocols]
set pcep pce pce1 p2mp-lsp-report-capability

```
  19. Configure the traffic engineering policy.

```
[edit policy-options]
user@PCC# set policy-statement TE term 1 from family traffic-engineering
user@PCC# set policy-statement TE term 1 then accept
```

## Results

From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PCC# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
      address 1.2.4.1/30;
    }
    family mpls;

## Verification

Confirm that the configuration is working properly.

- [Verifying LSP Configuration on the PCC on page 880](#)
- [Verifying PCE Configuration on the PCC on page 883](#)

### Verifying LSP Configuration on the PCC

---

**Purpose** Verify the LSP type and running state of the point-to-multipoint LSP.

**Action** From operational mode, run the **show mpls lsp extensive** command.

```

user@PCC> show mpls lsp extensive
Ingress LSP: 2 sessions

128.102.177.16
  From: 128.102.180.228, State: Up, ActiveRoute: 0, LSPname: lsp1-pcc
  ActivePath: (primary)
  LSPtype: Static Configured, Penultimate hop popping
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  *Primary                               State: Up

## Verify MPLS Interfaces

- Purpose** If the MPLS protocol is not configured correctly on the routers in your network, the interfaces are not able to perform MPLS switching.
- Action** To verify MPLS interfaces, enter the following Junos OS command-line interface (CLI) operational mode command:
- ```
user@host> show mpls interface
```

## Sample Output 1

The following sample output is for all routers in the network shown in *MPLS Network Topology*.

```
user@R1> show mpls interface
Interface      State      Administrative groups
so-0/0/0.0     Up         <none>
so-0/0/1.0     Up         <none>
so-0/0/2.0     Up         <none>

user@R2> show mpls interface
Interface      State      Administrative groups
so-0/0/0.0     Up         <none>
so-0/0/1.0     Up         <none>
so-0/0/2.0     Up         <none>
so-0/0/3.0     Up         <none>
```

```

user@R3> show mpls interface
Interface      State      Administrative groups
so-0/0/0.0     Up         <none>
so-0/0/1.0     Up         <none>
so-0/0/2.0     Up         <none>
so-0/0/3.0     Up         <none>

```

```

user@R4> show mpls interface
Interface      State      Administrative groups
so-0/0/0.0     Up         <none>
so-0/0/1.0     Up         <none>
so-0/0/2.0     Up         <none>
so-0/0/3.0     Up         <none>

```

```

user@R5> show mpls interface
Interface      State      Administrative groups
so-0/0/0.0     Up         <none>
so-0/0/1.0     Up         <none>
so-0/0/2.0     Up         <none>

```

```

user@R6> show mpls interface
Interface      State      Administrative groups
so-0/0/0.0     Up         <none>
so-0/0/1.0     Up         <none>
so-0/0/2.0     Up         <none>
so-0/0/3.0     Up         <none>

```

## Sample Output 2

```

user@R6> show mpls interface
Interface      State      Administrative groups
so-0/0/0.0     Up         <none>
so-0/0/1.0     Up         <none>
so-0/0/3.0     Up         <none>          # so-0/0/2.0 is missing

```

## Sample Output 3

```

user@host> show mpls interface
MPLS not configured

```

**Meaning** Sample Output 1 shows that all MPLS interfaces on all routers in the network are enabled (**Up**) and can perform MPLS switching. If you fail to configure the correct interface at the `[edit protocols mpls]` hierarchy level or include the **family mpls** statement at the `[edit interfaces type-fpc/pic/port unit number]` hierarchy level, the interface cannot perform MPLS switching, and does not appear in the output for the **show mpls interface** command.

Administrative groups are not configured on any of the interfaces shown in the example network in *MPLS Network Topology*. However, if they were, the output would indicate which affinity class bits are enabled on the router.

Sample Output 2 shows that interface **so-0/0/2.0** is missing and therefore might be incorrectly configured. For example, the interface might not be included at the `[edit protocols mpls]` hierarchy level, or the **family mpls** statement might not be included at the `[edit interfaces type-fpc/pic/port unit number]` hierarchy level. If the interface is configured correctly, RSVP might not have signaled over this interface yet. For more

information on determining which interface is incorrectly configured, see [“Verify Protocol Families” on page 1162](#).

Sample Output 3 shows that the MPLS protocol is not configured at the `[edit protocols mpls]` hierarchy level.

## Verify the MPLS Configuration

**Purpose** After you have checked the transit and ingress routers, use the `traceroute` command to verify the BGP next hop, and used the `ping` command to verify the active path, you can check for problems with the MPLS configuration at the `[edit protocols mpls]` and `[edit interfaces]` hierarchy levels.

**Action** To verify the MPLS configuration, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show configuration protocols mpls
user@host> show configuration interfaces
```

### Sample Output 1

```
user@R1> show configuration protocols mpls
label-switched-path R1-to-R6 {
    to 10.0.0.6;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

user@R3> show configuration protocols mpls
interface fxp0.0 {
    disable;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface so-0/0/3.0;

user@R6> show configuration protocols mpls
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured
```

### Sample Output 2

```
user@R6> show configuration interfaces
so-0/0/0 {
    unit 0 {
        family inet {
            address 10.1.56.2/30;
```

```

    }
    family iso;
    family mpls;
  }
}
so-0/0/1 {
  unit 0 {
    family inet {
      address 10.1.46.2/30;
    }
    family iso;
    family mpls;
  }
}
so-0/0/2 {
  unit 0 {
    family inet {
      address 10.1.26.2/30;
    }
    family iso;
    family mpls;
  }
}
so-0/0/3 {
  unit 0 {
    family inet {
      address 10.1.36.2/30;
    }
    family iso;
    family mpls;
  }
}
fxp0 {
  unit 0 {
    family inet {
      address 192.168.70.148/21;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.0.0.6/32;
      address 127.0.0.1/32;
    }
    family iso {
      address 49.0003.1000.0000.0006.00;
    }
  }
}
}

```

**Meaning** Sample Output 1 from the ingress, transit, and egress routers shows that the configuration of interfaces on egress router **R6** is incorrect. Interface **so-0/0/3.0** is included as inactive at the **[edit protocols mpls]** hierarchy level, when it should be active because it is the interface through which the LSP travels.

Sample Output 2 shows that interfaces are correctly configured for MPLS on egress router **R6**. The interfaces are also correctly configured on the ingress and transit routers (not shown).

## Verify That Node-Link Protection Is Up

**Purpose** After you configure node-link protection, you must check that bypass paths are up. You can also check the number of LSPs protected by the bypass paths. In the network shown in [Figure 91 on page 904](#), two bypass paths should be up: one next-hop bypass path protecting the link between **R1** and **R2** (or next-hop **10.0.12.14**), and a next-next-hop bypass path avoiding **R2**.

**Action** To verify node-link protection (many-to-one backup), enter the following Junos OS CLI operational mode commands on the ingress router. You can also issue the commands on transit routers and other routers used in the bypass path for slightly different information.

```
show mpls lsp (See Sample Output on page ?)
show mpls lsp extensive (See Sample Output on page 898)
show rsvp interface (See Sample Output on page 899)
show rsvp interface extensive (See Sample Output on page 900)
show rsvp session detail (See Sample Output on page 901)
```

## Sample Output

```
user@R1> show mpls lsp
Ingress LSP: 1 sessions
To          From          State Rt ActivePath      P      LSPname
192.168.5.1  192.168.1.1  Up    0  via-r2          *      lsp2-r1-to-r5
Total 1 displayed, Up 1 , Down 0

Egress LSP: 1 sessions
To          From          State Rt Style Labelin Labelout LSPname
192.168.1.1  192.168.5.1  Up    0  1 FF          3      - r5-to-r1
Total 1 displayed, Up 1 , Down 0

Transit LSP: 2 sessions
To          From          State Rt Style Labelin Labelout LSPname
192.168.0.1  192.168.6.1  Up    0  1 FF 100464 101952 lsp1-r6-to-r0
192.168.6.1  192.168.0.1  Up    0  1 FF 100448      3  r0-to-t6
Total 2 displayed, Up 2, Down 0
```

**Meaning** Sample output from **R1** for the **show mpls lsp** command shows a brief description of the state of configured and active LSPs for which **R1** is the ingress, transit, and egress router. All LSPs are up. **R1** is the ingress router for **lsp2-r1-to-r5**, and the egress router for return LSP **r5-to-r1**. Two LSPs transit **R1**, **lsp1-r6-to-r0** and the return LSP **r0-to-t6**. For more detailed information about the LSP, include the **extensive** option when you issue the **show mpls lsp** command.

```

Sample Output user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

```

**Meaning** Sample output from R1 for the **show mpls lsp extensive** command shows detailed information about all LSPs for which R1 is the ingress, egress, or transit router, including all past state history and the reason why an LSP failed. All LSPs are up. The main two LSPs **lsp2-r1-to-r5** and **lsp1-r6-to-r0** have node-link protection as indicated by the **Node/Link protection desired** field in the ingress and transit sections of the output. In the ingress section of the output, the **Link-protection Up** field shows that **lsp2-r1-to-r5** has link protection up. In the transit section of the output, the **Type: Node/Link protected LSP** field shows that **lsp1-r6-to-r0** has node-link protection up, and in case of failure will use the bypass **LSP Bypass->10.0.12.14->10.0.24.2**.

**Sample Output**

```

user@R1> show rsvp interface
RSVP interface: 4 active

```

Interface	State	Active resv	Subscr-ption	Static BW	Available BW	Reserved BW	Highwater mark
fe-0/1/0.0	Up	2	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/1.0	Up	1	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/2.0	Up	0	100%	100Mbps	100Mbps	0bps	0bps
so-0/0/3.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps

**Meaning** Sample output from R1 for the **show rsvp interface** command shows four interfaces enabled with RSVP (**Up**). Interface **fe-0/1/0.0** has two active RSVP reservations (**Active resv**) that might indicate sessions for the two main LSPs, **lsp1-r6-to-r0** and **lsp2-r1-to-r5**. Interface **fe-0/1/0.0** is the connecting interface between R1 and R2, and both LSPs are configured with a strict path through **fe-0/1/0.0**. For more detailed information about what is happening on interface **fe-0/1/0.0**, issue the **show rsvp interface extensive** command.

**Sample Output**    user@R1> show rsvp interface extensive

```

[...Output truncated...]
```

**Meaning**    Sample output from R1 for the **show rsvp interface extensive** command shows more detailed information about the activity on all RSVP interfaces (3). However, only output for **fe-0/1/0.0** is shown. Protection is enabled (**Protection: On**), with two bypass paths (**Bypass: 2**) protecting two LSPs (**Protected LSP: 2**). All LSPs are protected, as indicated by the **Unprotected LSP: 0** field. The first bypass **Bypass->10.0.12.14** is a link protection bypass path (**Type: LP**), protecting the link between R1 and R2 **fe-0/1/0.0**. The second bypass path **10.0.12.14->10.0.24.2** is a node-link protected LSP, avoiding R2 in case of node failure.

```

**Meaning** Sample output from **R1** shows detailed information about the RSVP sessions active on **R1**. All sessions are up, with two ingress sessions, one egress session, and two transit sessions.

Within the ingress section, the first session is a bypass path, as indicated by the **Type: Bypass LSP** field; and the second session is a protected LSP (**lsp2-r1-to-r5**) originating on **R1**, as indicated by the **Type: Node/Link protected LSP** field.

**Conclusion** Multiprotocol Label Switching (MPLS) label-switched path (LSP) link protection and node-link protection are facility-based methods used to reduce the amount of time needed to reroute LSP traffic. These protection methods are often compared to fast reroute—the other Junos OS LSP protection method.

While fast reroute protects LSPs on a one-to-one basis, link protection and node-link protection protect multiple LSPs by using a single, logical bypass LSP. Link protection provides robust backup support for a link, node-link protection bypasses a node or a link, and both types of protection are designed to interoperate with other vendor equipment.

Such functionality makes link protection and node-link protection excellent choices for scalability, redundancy, and performance in MPLS-enabled networks.

---

## Node-Link Protection Overview

Node-link protection (many-to-one or facility backup) extends the capabilities of link protection and provides slightly different protection from fast reroute. While link protection is useful for selecting an alternate path to the same router when a specific link fails, and fast reroute protects interfaces or nodes along the entire path of an LSP, node-link protection establishes a bypass path that avoids a particular node in the LSP path.

When you enable node-link protection for an LSP, you must also enable link protection on all RSVP interfaces in the path. Once enabled, the following types of bypass paths are established:

- Next-hop bypass LSP—Provides an alternate route for an LSP to reach a neighboring router. This type of bypass path is established when you enable either node-link protection or link protection.
- Next-next-hop bypass LSP—Provides an alternate route for an LSP through a neighboring router en route to the destination router. This type of bypass path is established exclusively when node-link protection is configured.

[Figure 91 on page 904](#) illustrates the example MPLS network topology used in this topic. The example network uses OSPF as the interior gateway protocol (IGP) and a policy to create traffic.

Figure 91: Node-Link Protection

The MPLS network in [Figure 91 on page 904](#) illustrates a router-only network that consists of unidirectional LSPs between R1 and R5, (*lsp2-r1-to-r5*) and between R6 and R0 (*lsp1-r6-to-r0*). Both LSPs have strict paths configured that go through interface *fe-0/1/0*.

In the network shown in [Figure 91 on page 904](#), both types of bypass paths are preestablished around the protected node (R2). A next-hop bypass path avoids interface *fe-0/1/0* by going through R7, and a next-next-hop bypass path avoids R2 altogether by going through R7 and R9 to R4. Both bypass paths are shared by all protected LSPs traversing the failed link or node (many LSPs protected by one bypass path).

Node-link protection (many-to-one or facility backup) allows a router immediately upstream from a node failure to use an alternate node to forward traffic to its downstream neighbor. This is accomplished by preestablishing a bypass path that is shared by all protected LSPs traversing the failed link.

When an outage occurs, the router immediately upstream from the outage switches protected traffic to the bypass node, and then signals the failure to the ingress router. Like fast reroute, node-link protection provides local repair, restoring connectivity faster than the ingress router can establish a standby secondary path or signal a new primary LSP.

Node-link protection is appropriate in the following situations:

- Protection of the downstream link and node is required.
- The number of LSPs to be protected is large.
- Satisfying path selection criteria (priority, bandwidth, and link coloring) for bypass paths is less critical.
- Control at the granularity of individual LSPs is not required.

## Verify That Link Protection Is Up

**Purpose** When you verify link protection, you must check that the bypass LSP is up. You can also check the number of LSPs protected by the bypass. In the network shown in [Figure 92 on page 909](#), a bypass path should be up to protect the link between **R1** and **R2**, or next-hop **10.0.12.14**, and the two LSPs traversing the link, **lsp2-r1-to-r5** and **lsp1-r6-to-r0**.

**Action** To verify link protection (many-to-one backup), enter the following Junos OS CLI operational mode commands on the ingress router:

```
user@host> show mpls lsp extensive
user@host> show rsvp session detail
user@host> show rsvp interface
```

## Sample Output

```

**Meaning** The sample output from ingress router **R1** shows the ingress, egress, and transit LSPs for **R1**. Some information is similar to that found in the **show mpls lsp** command. However, because link protection is an RSVP feature, information about bypass paths is provided. The bypass path appears as a separate RSVP ingress session for the protected interface, as indicated by the **Type** field.

The bypass path name is automatically generated. By default, the name appears as **Bypass > interface-address**, where the interface address is the next downstream router's interface (**10.0.12.14**). The explicit route **10.0.17.14 10.0.27.1** for the session shows **R7** as the transit node and **R2** as the egress node.

Within the ingress RSVP section of the output, the LSP originating at **R1** (**lsp2-r1-to-r5**) is shown requesting link protection. Since a bypass path is in place to protect the downstream link, **lsp2-r1-to-r5** is associated with the bypass, as indicated by the **Link protected LSP** field.

The egress section of the output shows the return LSP **r5-to-r1**, which is not protected.

The transit section of the output shows link protection requested by **lsp1-r6-to-r0**. Since a bypass path is in place to protect the downstream link, **lsp1-r6-to-r0** is associated with the bypass, as indicated by the **Link protected LSP** field. Also included in the transit section of the output is the return LSP **r0-to-r6**, which is not protected.

**Sample Output** user@R1> show rsvp interface  
RSVP interface: 4 active

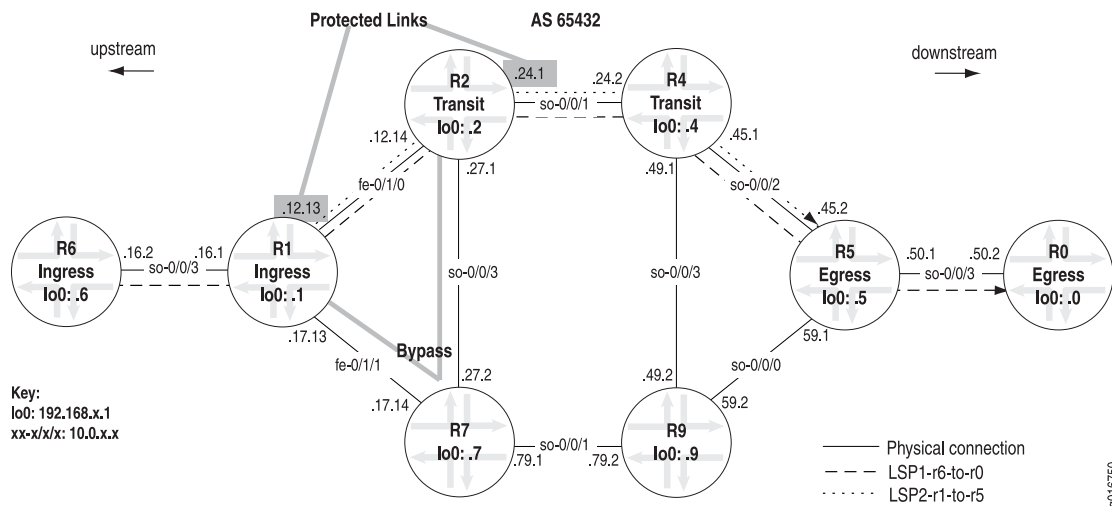

Interface	State	Active resv	Subscr-ption	Static BW	Available BW	Reserved BW	Highwater mark
fe-0/1/0.0	Up	2	100%	100Mbps	100Mbps	0bps	35Mbps
fe-0/1/1.0	Up	1	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/2.0	Up	0	100%	100Mbps	100Mbps	0bps	0bps
so-0/0/3.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps

**Meaning** The sample output from ingress router **R1** shows the number of LSPs going through the interfaces configured on **R1**. The **Active resv** field shows the number of LSPs for each interface. For example, interface **fe-0/1/0.0** between **R1** and **R2** has two active reservations, **lsp1-r6-to-r0** and **lsp2-r1-to-r5**; interface **fe-0/1/1.0** between **R1** and **R7** has one, the bypass (**10.0.12.14**); interface **fe-0/1/2.0** between **R6** and **R1** has no LSP reservations; and interface **so-0/0/3.0** between **R6** and **R1** has one LSP reservation, **lsp1-r6-to-r0**.

## Many-to-One Link Protection (Facility Backup) Overview

Many-to-one (facility backup) is based on interface rather than on LSP. While fast reroute protects interfaces or nodes along the entire path of a LSP, many-to-one protection can be applied on interfaces as needed, as shown in [Figure 92 on page 909](#). In [Figure 92 on page 909](#), a bypass path is set up around the link to be protected (**10.0.12.14**) using an alternate interface to forward traffic. The bypass path is shared by all protected LSPs traversing the failed link (many LSPs protected by one bypass path).

**Figure 92: Many-to-One or Link Protection**

In [Figure 92 on page 909](#), two LSPs (**lsp1-r6-to-r0** and **lsp2-r1-to-r5**) are protected by one preestablished bypass path from **R1** to **R2** through **R7**. Both LSPs have strict paths configured that go through interface **fe-0/1/0**. On **R1**, the interface **10.0.12.13** has link protection configured that protects the next hop **10.0.12.14**.

Link protection (many-to-one or facility backup) allows a router immediately upstream from a link failure to use an alternate interface to forward traffic to its downstream

neighbor. This is accomplished by preestablishing a bypass path that is shared by all protected LSPs traversing the failed link. A single bypass path can safeguard a set of protected LSPs. When an outage occurs, the router immediately upstream from the link outage switches protected traffic to the bypass link, then signals the link failure to the ingress router.

Like fast reroute, link protection provides local repair and restores connectivity faster than the ingress router switching traffic to a standby secondary path. However, unlike fast reroute, link protection does not provide protection against the failure of the downstream neighbor.

Link protection is appropriate in the following situations:

- The number of LSPs to be protected is large.
- Satisfying path selection criteria (priority, bandwidth, and link coloring) for bypass paths is less critical.
- Control at the granularity of individual LSPs is not required.

---

## Verify One-to-One Backup

**Purpose** You can verify that one-to-one backup is established by examining the ingress router and the other routers in the network.

**Action** To verify one-to-one backup, enter the following Junos OS CLI operational mode commands:

```
user@host> show mpls lsp ingress extensive
user@host> show rsvp session
```

## Sample Output

The following sample output is from the ingress router **R1**:

```
user@R1> show mpls lsp ingress extensive
Ingress LSP: 1 sessions

192.168.5.1
  From: 192.168.1.1, State: Up, ActiveRoute: 0, LSPname: r1-to-r5
  ActivePath: via-r2 (primary)
  FastReroute desired

    4 May 11 14:50:52 Record Route: 10.0.12.14 10.0.24.2 10.0.45.2
    3 May 11 14:50:52 Up
```

```
2 May 11 14:50:52 Originate Call
1 May 11 14:50:52 CSPF: computation result accepted
Created: Thu May 11 14:50:52 2006
Total 1 displayed, Up 1, Down 0
```

**Meaning** The sample output from **R1** shows that the **FastReroute desired** object was included in the Path messages for the LSP, allowing **R1** to select the active path for the LSP and establish a detour path to avoid **R2**.

In line 8, **Fast-reroute Detour Up** shows that the detour is operational. Lines 6 and 7 indicate that transit routers **R2** and **R4** have established their detour paths.

**R2, 10.0.12.14**, includes (**flag=9**), indicating that node protection is available for the downstream node and link. **R4, 10.0.24.2**, includes (**flag=1**), indicating that link protection is available for the next downstream link. In this case, **R4** can protect only the downstream link because the node is the egress router **R5**, which cannot be protected. For more information about flags, see the *Junos Feature Guide*.

The output for the **show mpls lsp extensive** command does not show the actual path of the detour. To see the actual links used by the detour paths, you must use the **show rsvp session ingress detail** command.

**Sample Output** The following sample output is from the ingress router **R1** in the network shown in [Figure 111 on page 1115](#).

```
user@R1> show rsvp session ingress detail
Ingress RSVP: 1 sessions

```

**Meaning** The sample output from R2 shows the detour is established (**Detour is Up**) and avoids R4, and the link connecting R4 and R5 (10.0.45.2). The detour path is through R7 (10.0.27.2) and R9 (10.0.79.2) to R5 (10.0.59.1), which is different from the explicit route for the detour from R1. R1 has the detour passing through the 10.0.17.14 link on R7, while R1 is using the 10.0.27.2 link. Both detours merge at R9 through the 10.0.79.2 link to R5 (10.0.59.1).

**Sample Output** The following sample output is from the second transit router R4 in the network shown in [Figure 111 on page 1115](#):

```
user@R4> show rsvp session transit detail

    Label in: 100752, Label out: 100368
Total 1 displayed, Up 1, Down 0
```

**Meaning** The sample output from **R7** shows the same information as for a regular transit router used in the primary path of the LSP: the ingress address (**192.168.1.1**), the egress address (**192.168.5.1**), and the name of the LSP (**r1-to-r5**). Two detour paths are displayed; the first to avoid **R4** (**192.168.4.1**) and the second to avoid **R2** (**192.168.2.1**). Because **R7** is used as a transit router by **R2** and **R4**, **R7** can merge the detour paths together as indicated by the identical **Label out** value (**100368**) for both detour paths. Whether **R7** receives traffic from **R4** with a label value of **100736** or from **R2** with a label value of **100752**, **R7** forwards the packet to **R5** with a label value of **100368**.

**Sample Output** The following sample output is from R9, which is a router used in the detour path in the network shown in [Figure 111 on page 1115](#):

```

user@R9> show rsvp session transit detail
Transit RSVP: 1 sessions, 1 detours

Total 1 displayed, Up 1, Down 0

```

**Meaning** The sample output from R9 shows that R9 is the penultimate router for the detour path, the explicit route includes only the egress link address (10.0.59.1), and the Label out value (3) indicates that R9 has performed penultimate-hop label popping. Also, the detour branch from 10.0.27.1 does not include path information because R7 has merged the detour paths from R2 and R4. Notice that the Label out value in the detour branch from 10.0.17.13 is 100368, the same value as the Label out value on R7.

**Sample Output** The following sample output is from the egress router R5 in the network shown in [Figure 111 on page 1115](#):

```

**Meaning** The sample output from R5 shows the main LSP in the **Record route** field and the detours through the network.

## Verify That the Primary Path Is Operational

**Purpose** Primary paths must always be used in the network if they are available, therefore an LSP always moves back to the primary path after a failure, unless the configuration is adjusted. For more information on adjusting the configuration to prevent a failed primary path from reestablishing, see [“Preventing Use of a Path That Previously Failed” on page 918](#).

**Action** To verify that the primary path is operational, enter the following Junos OS command-line interface (CLI) operational mode commands:

```
user@host> show mpls lsp extensive ingress
user@host> show rsvp interface
```

## Sample Output 1

```

user@R1> show mpls lsp extensive ingress
Ingress LSP: 1 sessions

192.168.5.1
  From: 192.168.1.1, State: Up, ActiveRoute: 0, LSPname: r1-to-r5
  ActivePath: via-r2 (primary)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4
  *Primary via-r2          State: Up
    Priorities: 6 6
    Bandwidth: 35Mbps
    SmartOptimizeTimer: 180
    Computed ERO (S [L] denotes strict [loose] hops): (CSPF metric: 11)
  10.0.12.14 S 10.0.24.2 S
    Received RRO (ProtectionFlag 1=Available 2=InUse 4=B/W 8=Node
  10=SoftPreempt):
      10.0.12.14 10.0.24.2
    5 Apr 29 14:40:43 Selected as active path
    4 Apr 29 14:40:43 Record Route: 10.0.12.14 10.0.24.2
    3 Apr 29 14:40:43 Up
    2 Apr 29 14:40:43 Originate Call

  Standby via-r7          State: Dn
    SmartOptimizeTimer: 180
    No computed ERO.
  Created: Sat Apr 29 14:40:43 2006
Total 1 displayed, Up 1, Down 0

```

## Sample Output 2

```

user@R1> show rsvp interface
RSVP interface: 3 active

```

Interface	State	Active resv	Subscr- ption	Static BW	Available BW	Reserved BW	Highwater mark
fe-0/1/0.0	Up	2	100%	100Mbps	100Mbps	0bps	0bps
fe-0/1/1.0	Up	1	100%	100Mbps	100Mbps	0bps	0bps
so-0/0/3.0	Up	1	100%	155.52Mbps	155.52Mbps	0bps	0bps

**Meaning** Sample output 1 shows that the LSP is operational and is using the primary path (**via-r2**) with **R2 (10.0.12.14)** and **R4 (10.0.24.2)** as transit routers. The priority values are the same for setup and hold, **6 6**. Priority 0 is the highest (best) priority and 7 is the lowest (worst) priority. The Junos OS default for setup and hold priority is 7:0. Unless some LSPs are more important than others, preserving the default is a good practice. Configuring a setup priority that is better than the hold priority is not allowed, resulting in a failed commit in order to avoid preemption loops.

## Preventing Use of a Path That Previously Failed

If you configure an alternate path through the network in case the active path fails, you may not want traffic to revert back to the failed path, even if it is no longer failing. When

you configure a primary path, the traffic switches over to the secondary path during a failure, and reverts back to the primary path when it returns.

At times, switching traffic back to a primary path that has previously failed may not be a particularly sound idea. In this case, only configure secondary paths, resulting in the next configured secondary path establishing when the first secondary path fails. Later, if the first secondary path becomes operational, the Junos OS will not revert to it, but will continue using the second secondary path.

## Verify That the Secondary Path Is Established

**Purpose** When the secondary path is configured with the **standby** statement, the secondary path should be *up* but *not active*; it will become active if the primary path fails. A secondary path configured without the **standby** statement will not come up unless the primary path fails. To test that the secondary path is correctly configured and would come up if the primary path were to fail, you must deactivate a link or node critical to the primary path, then issue the **show mpls lsp *lsp-path-name* extensive** command.

**Action** To verify that the secondary path is established, enter the following Junos OS CLI operational mode command:

### Sample Output

```
user@R1> show mpls lsp extensive
```

### Sample Output

The following sample output shows a correctly configured secondary path before and after it comes up. In the example, interface **fe-0/1/0** on **R2** is deactivated, which brings down the primary path **via-r2**. The ingress router **R1** switches traffic to the secondary path **via-r7**.

**Meaning** The sample output from egress router R1 shows a correctly configured standby secondary path in a down state because the primary path is still up. Upon deactivation of an interface (interface fe-0/1/0 on R2) critical to the primary path, the primary path via-r2 goes down

and the standby secondary path **via-r7** comes up, allowing **R1** to switch traffic to the standby secondary path.

## Checklist for Checking the MPLS Layer

**Problem** **Description:** This checklist provides the steps and commands for checking the Multiprotocol Label Switching (MPLS) layer of the layered MPLS model. The checklist provides links to an overview of the MPLS layer and more detailed information about the commands used to investigate the problem.

[Table 21 on page 921](#) provides commands for checking the MPLS layer.

**Table 21: Checklist for Checking the MPLS Layer**

Tasks	Command or Action
<b>“Checking the MPLS Layer” on page 921</b>	
1. <a href="#">Verify the LSP on page 923</a>	<pre>show mpls lsp show mpls lsp extensive show mpls lsp name <i>name</i> show mpls lsp name <i>name</i> extensive</pre>
2. <a href="#">Verify the LSP Route on the Transit Router on page 926</a>	<pre>show route table mpls.0</pre>
3. <a href="#">Verify the LSP Route on the Ingress Router on page 927</a>	<pre>show route <i>destination</i></pre>

8. <a href="#">Verify the LSP Again on page 934</a>	<pre>show mpls lsp extensive</pre>

## Checking the MPLS Layer

**Purpose** After you have configured the label-switched path (LSP), issued the **show mpls lsp** command, and determined that there is an error, you might find that the error is not in

the physical, data link, Internet Protocol (IP), interior gateway protocol (IGP), or Resource Reservation Protocol (RSVP) layers. Continue investigating the problem at the MPLS layer of the network.

Figure 93 on page 922 illustrates the MPLS layer of the layered MPLS model.

**Figure 93: Checking the MPLS Layer**

<b>Data Link Layer</b>		<b>Physical Layer</b>													
<b>Physical Layer</b>															

With the MPLS layer, you check whether the LSP is up and functioning correctly. If the network is not functioning at this layer, the LSP does not work as configured.

Figure 94 on page 923 illustrates the MPLS network used in this topic.

Figure 94: MPLS Network Broken at the MPLS Layer

The network shown in [Figure 94 on page 923](#) is a fully meshed configuration where every directly connected interface can receive and send packets to every other similar interface. The LSP in this network is configured to run from ingress router **R1**, through transit router **R3**, to egress router **R6**. In addition, a reverse LSP is configured to run from **R6** through **R3** to **R1**, creating bidirectional traffic.

However, in this example, the reverse LSP is down without a path from **R6** to **R1**.

The cross shown in [Figure 94 on page 923](#) indicates where the LSP is broken. Some possible reasons the LSP is broken might include an incorrectly configured MPLS protocol, or interfaces that are incorrectly configured for MPLS.

In the network shown in [Figure 94 on page 923](#), a configuration error on egress router **R6** prevents the LSP from traversing the network as expected.

To check the MPLS layer, follow these steps:

1. [Verify the LSP on page 923](#)
2. [Verify the LSP Route on the Transit Router on page 926](#)
3. [Verify the LSP Route on the Ingress Router on page 927](#)
4. [Verify MPLS Labels with the traceroute Command on page 929](#)
5. [Verify MPLS Labels with the ping Command on page 930](#)
6. [Verify the MPLS Configuration on page 931](#)
7. [Take Appropriate Action on page 933](#)
8. [Verify the LSP Again on page 934](#)

## Verify the LSP

**Purpose** Typically, you use the `show mpls lsp extensive` command to verify the LSP. However for quick verification of the LSP state, use the `show mpls lsp` command. If the LSP is down, use the `extensive` option (`show mpls lsp extensive`) as a follow-up. If your network has

numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

**Action** To verify that the LSP is up, enter some or all of the following commands from the ingress router:

```
user@host> show mpls lsp
user@host> show mpls lsp extensive
user@host> show mpls lsp name name
user@host> show mpls lsp name name extensive
```

### Sample Output 1

```

**Meaning** Sample Output 1 shows a brief description of the state of the LSP for the ingress, transit, and egress routers. Output from ingress router **R1** and egress router **R6** shows that both LSPs are down, **R1-to-R6** and **R6-to-R1**. With the configured LSPs on **R1** and **R6**, we would expect egress LSP sessions on both **R1** and **R6**. In addition, transit router **R3** has no transit sessions.

Sample Output 2 shows all information about the LSPs, including all past state history and the reason why an LSP failed. Output from **R1** and **R6** indicates that there is no route to the destination because the Constrained Shortest Path First (CSPF) algorithm failed.

Sample Outputs 3 and 4 show examples of the output for the **show mpls lsp name** command with the **extensive** option. In this instance, the output is very similar to the **show mpls lsp** command because only one LSP is configured in the example network in [Figure 94 on page 923](#). However, in a large network with many LSPs configured, the results would be quite different between the two commands.

## Verify the LSP Route on the Transit Router

**Purpose** If the LSP is up, the LSP route should appear in the **mpls.0** routing table. MPLS maintains an MPLS path routing table (**mpls.0**), which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP. If routes are not present in the output for the transit router, check the MPLS protocol configuration on the ingress and egress routers.

**Action** To verify the LSP route on the transit router, enter the following command from the transit router:

```
user@host> show route table mpls.0
```

## Sample Output 1

```

user@R3> show route table mpls.0
mpls.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0          *[MPLS/0] 16w2d 21:52:40, metric 1
            Receive
1          *[MPLS/0] 16w2d 21:52:40, metric 1
            Receive

```

```
2          *[MPLS/0] 16w2d 21:52:40, metric 1
          Receive
```

## Sample Output 2

```
user@R3> show route table mpls.0
mpls.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0          *[MPLS/0] 16w2d 22:26:08, metric 1
          Receive
1          *[MPLS/0] 16w2d 22:26:08, metric 1
          Receive
2          *[MPLS/0] 16w2d 22:26:08, metric 1
          Receive
100864     *[RSVP/7] 00:07:23, metric 1
          > via so-0/0/2.0, label-switched-path R6-to-R1
100864(S=0) *[RSVP/7] 00:07:23, metric 1
          > via so-0/0/2.0, label-switched-path R6-to-R1
100880     *[RSVP/7] 00:07:01, metric 1
          > via so-0/0/3.0, label-switched-path R1-to-R6
100880(S=0) *[RSVP/7] 00:07:01, metric 1
          > via so-0/0/3.0, label-switched-path R1-to-R6
```

**Meaning** Sample Output 1 from transit router **R3** shows three route entries in the form of MPLS label entries. These MPLS labels are reserved MPLS labels defined in RFC 3032, and are always present in the **mpls.0** routing table, regardless of the state of the LSP. The incoming labels assigned by RSVP to the upstream neighbor are missing from the output, indicating that the LSP is down. For more information on MPLS label entries, see [“Checklist for Verifying LSP Use” on page 1058](#).

In contrast, Sample Output 2 shows the MPLS labels and routes for a correctly configured LSP. The three reserved MPLS labels are present, and the four other entries represent the incoming labels assigned by RSVP to the upstream neighbor. These four entries represent two routes. There are two entries per route because the stack values in the MPLS header may be different. For each route, the second entry **100864 (S=0)** and **100880 (S=0)** indicates that the stack depth is not 1, and additional label values are included in the packet. In contrast, the first entry, **100864** and **100880** has an inferred S=1 value which indicates a stack depth of 1 and makes each label the last label in that particular packet. The dual entries indicate that this is the penultimate router. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding*.

## Verify the LSP Route on the Ingress Router

**Purpose** Check whether the LSP route is included in the active entries in the **inet.3** routing table for the specified address.

**Action** To verify the LSP route, enter the following command from the ingress router:

```
user@host> show route destination
```

## Sample Output 1

```
user@R1> show route 10.0.0.6
inet.0 : 27 destinations, 27 routes (27 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```

10.0.0.6/32      *[IS-IS/18] 6d 01:41:37, metric 20
                  to 10.1.12.2 via so-0/0/0.0
                  > to 10.1.15.2 via so-0/0/1.0
                  to 10.1.13.2 via so-0/0/2.0

user@R6> show route 10.0.0.1

inet.0 : 28 destinations, 28 routes (28 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
10.0.0.1/32      *[IS-IS/18] 5d 01:01:38, metric 20
                  to 10.1.56.1 via so-0/0/0.0
                  > to 10.1.26.1 via so-0/0/2.0
                  to 10.1.36.1 via so-0/0/3.0

```

## Sample Output 2

```

user@R1> show route 10.0.0.6
inet.0: 28 destinations, 28 routes (27 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32      *[IS-IS/18] 6d 02:13:42, metric 20
                  to 10.1.12.2 via so-0/0/0.0
                  > to 10.1.15.2 via so-0/0/1.0
                  to 10.1.13.2 via so-0/0/2.0

inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32      *[RSVP/7] 00:08:07, metric 20
                  > via so-0/0/2.0, label-switched-path R1-to-R6

user@R6> show route 10.0.0.1

inet.0: 29 destinations, 29 routes (28 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.1/32      *[IS-IS/18] 5d 01:34:03, metric 20
                  to 10.1.56.1 via so-0/0/0.0
                  > to 10.1.26.1 via so-0/0/2.0
                  to 10.1.36.1 via so-0/0/3.0

inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.1/32      *[RSVP/7] 00:10:39, metric 20
                  > via so-0/0/3.0, label-switched-path R6-to-R1

```

**Meaning** Sample Output 1 shows entries in the **inet.0** routing table only. The **inet.3** routing table is missing from the output because the LSP is not working. The **inet.0** routing table is used by interior gateway protocols (IGPs) and Border Gateway Protocol (BGP) to store routing information. In this case, the IGP is Intermediate System-to-Intermediate System (IS-IS). For more information on the **inet.0** routing table, see the *Junos MPLS Applications Configuration Guide*.

If the LSP was working, we would expect to see entries that include the LSP in the **inet.3** routing table. The **inet.3** routing table is used on ingress routers to route BGP packets to the destination egress router. BGP uses the **inet.3** routing table on the ingress router to

help resolve next-hop addresses. BGP is configured in the example network shown in [Figure 94 on page 923](#).

Sample Output 2 shows output you should receive when the LSP is up. The output shows both the **inet.0** and **inet.3** routing tables, indicating that LSPs **R1-to-R6** and **R6-to-R1** are available.

## Verify MPLS Labels with the traceroute Command

**Purpose** Display the route packets take to a BGP destination where the BGP next hop for that route is the LSP egress address. By default, BGP uses the **inet.0** and the **inet.3** routing tables to resolve the next-hop address. When the next-hop address of the BGP route is not the router ID of the egress router, traffic is mapped to IGP routes, not to the LSP. Use the **traceroute** command as a debugging tool to determine whether the LSP is being used to forward traffic.

**Action** To verify MPLS labels, enter the following command from the ingress router:

```
user@host> traceroute hostname
```

### Sample Output 1

```
user@R1> traceroute 100.100.6.1
traceroute to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.12.2 (10.1.12.2)  0.627 ms  0.561 ms  0.520 ms
 2  10.1.26.2 (10.1.26.2)  0.570 ms !N  0.558 ms !N  4.879 ms !N

user@R6> traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
 1  10.1.26.1 (10.1.26.1)  0.630 ms  0.545 ms  0.488 ms
 2  10.1.12.1 (10.1.12.1)  0.551 ms !N  0.557 ms !N  0.526 ms !N
```

### Sample Output 2

```
user@R1> traceroute 100.100.6.1
to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.13.2 (10.1.13.2)  0.866 ms  0.746 ms  0.724 ms
    MPLS Label=100912 CoS=0 TTL=1 S=1
 2  10.1.36.2 (10.1.36.2)  0.577 ms !N  0.597 ms !N  0.546 ms !N

user@R6> traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
 1  10.1.36.1 (10.1.36.1)  0.802 ms  0.716 ms  0.688 ms
    MPLS Label=100896 CoS=0 TTL=1 S=1
 2  10.1.13.1 (10.1.13.1)  0.570 ms !N  0.568 ms !N  0.546 ms !N
```

**Meaning** Sample Output 1 shows that BGP traffic is not using the LSP, consequently MPLS labels do not appear in the output. Instead of using the LSP, BGP traffic is using the IGP (IS-IS, in the example network in [Figure 94 on page 923](#)) to reach the BGP next-hop LSP egress address. The Junos OS default behavior uses LSPs for BGP traffic when the BGP next hop equals the LSP egress address.

Sample Output 2 is an example of output for a correctly configured LSP. The output shows MPLS labels, indicating that BGP traffic is using the LSP to reach the BGP next hop.

## Verify MPLS Labels with the ping Command

**Purpose** When you ping a specific LSP, you check that echo requests are sent over the LSP as MPLS packets.

**Action** To verify MPLS labels, enter the following command from the ingress router to ping the egress router:

```
user@host> ping mpls rsvp lsp-name detail
```

For example:

```
user@R1> ping mpls rsvp R1-to-R6 detail
```

### Sample Output 1

```
user@R1> ping mpls rsvp R1-to-R6 detail
LSP R1-to-R6 - LSP has no active path, exiting.
```

```
user@R6> ping mpls rsvp R6-to-R1 detail
LSP R6-to-R1 - LSP has no active path, exiting.
```

### Sample Output 2

```
user@R1> traceroute 10.0.0.6
traceroute to 10.0.0.6 (10.0.0.6), 30 hops max, 40 byte packets
 1 10.1.15.2 (10.1.15.2) 0.708 ms 0.613 ms 0.576 ms
 2 10.0.0.6 (10.0.0.6) 0.763 ms 0.708 ms 0.700 ms
```

```
user@R1> ping mpls rsvp R1-to-R6 detail
Request for seq 1, to interface 69, label 100880
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 69, label 100880
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 69, label 100880
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 69, label 100880
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 69, label 100880
Reply for seq 5, return code: Egress-ok
```

```
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

```
user@R6> ping mpls rsvp R6-to-R1 detail
Request for seq 1, to interface 70, label 100864
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 70, label 100864
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 70, label 100864
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 70, label 100864
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 70, label 100864
Reply for seq 5, return code: Egress-ok
```

```
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

**Meaning** Sample Output 1 shows that the LSP does not have an active path to forward echo requests, indicating that the LSP is down.

Sample Output 2 is an example of output you should receive when the LSP is up and forwarding packets.

## Verify the MPLS Configuration

**Purpose** After you have checked the transit and ingress routers, use the **traceroute** command to verify the BGP next hop, and used the **ping** command to verify the active path, you can check for problems with the MPLS configuration at the **[edit protocols mpls]** and **[edit interfaces]** hierarchy levels.

**Action** To verify the MPLS configuration, enter the following commands from the ingress, transit, and egress routers:

```
user@host> show configuration protocols mpls
user@host> show configuration interfaces
```

## Sample Output 1

```
user@R1> show configuration protocols mpls
label-switched-path R1-to-R6 {
    to 10.0.0.6;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface fxp0.0 {
    disable;
}

user@R3> show configuration protocols mpls
interface fxp0.0 {
    disable;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
interface so-0/0/2.0;
interface so-0/0/3.0;

user@R6> show configuration protocols mpls
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured
```

## Sample Output 2

```
user@R6> show configuration interfaces
so-0/0/0 {
    unit 0 {
        family inet {
            address 10.1.56.2/30;
```

```

    }
    family iso;
    family mpls;
  }
}
so-0/0/1 {
  unit 0 {
    family inet {
      address 10.1.46.2/30;
    }
    family iso;
    family mpls;
  }
}
so-0/0/2 {
  unit 0 {
    family inet {
      address 10.1.26.2/30;
    }
    family iso;
    family mpls;
  }
}
so-0/0/3 {
  unit 0 {
    family inet {
      address 10.1.36.2/30;
    }
    family iso;
    family mpls;
  }
}
fxp0 {
  unit 0 {
    family inet {
      address 192.168.70.148/21;
    }
  }
}
lo0 {
  unit 0 {
    family inet {
      address 10.0.0.6/32;
      address 127.0.0.1/32;
    }
    family iso {
      address 49.0003.1000.0000.0006.00;
    }
  }
}
}

```

**Meaning** Sample Output 1 from the ingress, transit, and egress routers shows that the configuration of interfaces on egress router **R6** is incorrect. Interface **so-0/0/3.0** is included as inactive at the **[edit protocols mpls]** hierarchy level, when it should be active because it is the interface through which the LSP travels.

Sample Output 2 shows that interfaces are correctly configured for MPLS on egress router **R6**. The interfaces are also correctly configured on the ingress and transit routers (not shown).

## Take Appropriate Action

**Problem**    **Description:** Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, an interface is incorrectly configured at the `[edit protocols mpls]` hierarchy level on egress router **R6**.

**Solution**    To correct the error in this example, follow these steps:

1. Activate the interface in the MPLS protocol configuration on egress router **R6**:

```
user@R6> edit
user@R6# edit protocols mpls
[edit protocols mpls]
user@R6# show
user@R6# activate interface so-0/0/3.0
```

2. Verify and commit the configuration:

```
[edit protocols mpls]
user@R6# show
user@R6# commit
```

**Sample Output**

```
user@R6> edit
Entering configuration mode

[edit]
user@R6# edit protocols mpls

[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured interface

[edit protocols mpls]
user@R6# activate interface so-0/0/3

[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
interface so-0/0/3.0; <<< Correctly configured interface

[edit protocols mpls]
user@R6# commit
commit complete
```

**Meaning** The sample output shows that the incorrectly configured interface **so-0/0/3.0** on egress router **R6** is now activated at the **[edit protocols mpls]** hierarchy level. The LSP can now come up.

## Verify the LSP Again

**Purpose** After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the BGP layer has been resolved.

**Action** To verify the LSP again, enter the following command from the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

## Sample Output

```
user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

Transit LSP: 0 sessions

Total 0 displayed, Up 0, Down 0

**Meaning** Sample Output 1 from ingress router **R1** shows that LSP **R1-to-R6** has an active route to **R6** and the state is up.

Sample Output 2 from transit router **R3** shows that there are two transit LSP sessions, one from **R1** to **R6** and the other from **R6** to **R1**. Both LSPs are up.

Sample Output 3 from egress router **R6** shows that the LSP is up and the active route is the primary route. The LSP is now traversing the network along the expected path, from **R1** through **R3** to **R6**, and the reverse LSP, from **R6** through **R3** to **R1**.

## Verify the LSP

**Purpose** Typically, you use the **show mpls lsp extensive** command to verify the LSP. However for quick verification of the LSP state, use the **show mpls lsp** command. If the LSP is down, use the **extensive** option (**show mpls lsp extensive**) as a follow-up. If your network has numerous LSPs, you might consider specifying the name of the LSP, using the **name** option (**show mpls lsp name *name*** or **show mpls lsp name *name* extensive**).

**Action** To verify that the LSP is up, enter some or all of the following commands from the ingress router:

```
user@host> show mpls lsp
user@host> show mpls lsp extensive
user@host> show mpls lsp name name
user@host> show mpls lsp name name extensive
```

## Sample Output 1

```
user@R1> show mpls lsp

Egress LSP: 0 sessions
Total 0 displayed, Up 0, Down 0

Transit LSP: 0 sessions
Total 0 displayed, Up 0, Down 0
```

**Meaning** Sample Output 1 shows a brief description of the state of the LSP for the ingress, transit, and egress routers. Output from ingress router **R1** and egress router **R6** shows that both LSPs are down, **R1-to-R6** and **R6-to-R1**. With the configured LSPs on **R1** and **R6**, we would expect egress LSP sessions on both **R1** and **R6**. In addition, transit router **R3** has no transit sessions.

Sample Output 2 shows all information about the LSPs, including all past state history and the reason why an LSP failed. Output from **R1** and **R6** indicates that there is no route to the destination because the Constrained Shortest Path First (CSPF) algorithm failed.

Sample Outputs 3 and 4 show examples of the output for the **show mpls lsp name** command with the **extensive** option. In this instance, the output is very similar to the **show mpls lsp** command because only one LSP is configured in the example network in [Figure 94 on page 923](#). However, in a large network with many LSPs configured, the results would be quite different between the two commands.

## Verify the LSP Route on the Transit Router

**Purpose** If the LSP is up, the LSP route should appear in the **mpls.0** routing table. MPLS maintains an MPLS path routing table (**mpls.0**), which contains a list of the next label-switched router in each LSP. This routing table is used on transit routers to route packets to the next router along an LSP. If routes are not present in the output for the transit router, check the MPLS protocol configuration on the ingress and egress routers.

**Action** To verify the LSP route on the transit router, enter the following command from the transit router:

```
user@host> show route table mpls.0
```

### Sample Output 1

```
user@R3> show route table mpls.0
mpls.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0          *[MPLS/0] 16w2d 21:52:40, metric 1
            Receive
1          *[MPLS/0] 16w2d 21:52:40, metric 1
            Receive
2          *[MPLS/0] 16w2d 21:52:40, metric 1
            Receive
```

### Sample Output 2

```
user@R3> show route table mpls.0
mpls.0: 7 destinations, 7 routes (7 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
0          *[MPLS/0] 16w2d 22:26:08, metric 1
            Receive
1          *[MPLS/0] 16w2d 22:26:08, metric 1
            Receive
2          *[MPLS/0] 16w2d 22:26:08, metric 1
            Receive
100864     *[RSVP/7] 00:07:23, metric 1
            > via so-0/0/2.0, label-switched-path R6-to-R1
100864(S=0) *[RSVP/7] 00:07:23, metric 1
            > via so-0/0/2.0, label-switched-path R6-to-R1
100880     *[RSVP/7] 00:07:01, metric 1
            > via so-0/0/3.0, label-switched-path R1-to-R6
100880(S=0) *[RSVP/7] 00:07:01, metric 1
            > via so-0/0/3.0, label-switched-path R1-to-R6
```

**Meaning** Sample Output 1 from transit router **R3** shows three route entries in the form of MPLS label entries. These MPLS labels are reserved MPLS labels defined in RFC 3032, and are always present in the **mpls.0** routing table, regardless of the state of the LSP. The incoming labels assigned by RSVP to the upstream neighbor are missing from the output, indicating that the LSP is down. For more information on MPLS label entries, see [“Checklist for Verifying LSP Use” on page 1058](#).

In contrast, Sample Output 2 shows the MPLS labels and routes for a correctly configured LSP. The three reserved MPLS labels are present, and the four other entries represent the incoming labels assigned by RSVP to the upstream neighbor. These four entries

represent two routes. There are two entries per route because the stack values in the MPLS header may be different. For each route, the second entry **100864 (S=0)** and **100880 (S=0)** indicates that the stack depth is not 1, and additional label values are included in the packet. In contrast, the first entry, **100864** and **100880** has an inferred S=1 value which indicates a stack depth of 1 and makes each label the last label in that particular packet. The dual entries indicate that this is the penultimate router. For more information on MPLS label stacking, see RFC 3032, *MPLS Label Stack Encoding*.

## Verify the LSP Route on the Ingress Router

**Purpose** Check whether the LSP route is included in the active entries in the **inet.3** routing table for the specified address.

**Action** To verify the LSP route, enter the following command from the ingress router:

```
user@host> show route destination
```

### Sample Output 1

```
user@R1> show route 10.0.0.6
inet.0 : 27 destinations, 27 routes (27 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
10.0.0.6/32      *[IS-IS/18] 6d 01:41:37, metric 20
                  to 10.1.12.2 via so-0/0/0.0
                  > to 10.1.15.2 via so-0/0/1.0
                  to 10.1.13.2 via so-0/0/2.0

user@R6> show route 10.0.0.1

inet.0 : 28 destinations, 28 routes (28 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
10.0.0.1/32      *[IS-IS/18] 5d 01:01:38, metric 20
                  to 10.1.56.1 via so-0/0/0.0
                  > to 10.1.26.1 via so-0/0/2.0
                  to 10.1.36.1 via so-0/0/3.0
```

### Sample Output 2

```
user@R1> show route 10.0.0.6
inet.0: 28 destinations, 28 routes (27 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32      *[IS-IS/18] 6d 02:13:42, metric 20
                  to 10.1.12.2 via so-0/0/0.0
                  > to 10.1.15.2 via so-0/0/1.0
                  to 10.1.13.2 via so-0/0/2.0

inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.6/32      *[RSVP/7] 00:08:07, metric 20
                  > via so-0/0/2.0, label-switched-path R1-to-R6

user@R6> show route 10.0.0.1

inet.0: 29 destinations, 29 routes (28 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both
```

```

10.0.0.1/32      *[IS-IS/18] 5d 01:34:03, metric 20
                  to 10.1.56.1 via so-0/0/0.0
                  > to 10.1.26.1 via so-0/0/2.0
                  to 10.1.36.1 via so-0/0/3.0

inet.3 : 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.1/32      *[RSVP/7] 00:10:39, metric 20
                  > via so-0/0/3.0, label-switched-path R6-to-R1

```

**Meaning** Sample Output 1 shows entries in the **inet.0** routing table only. The **inet.3** routing table is missing from the output because the LSP is not working. The **inet.0** routing table is used by interior gateway protocols (IGPs) and Border Gateway Protocol (BGP) to store routing information. In this case, the IGP is Intermediate System-to-Intermediate System (IS-IS). For more information on the **inet.0** routing table, see the *Junos MPLS Applications Configuration Guide*.

If the LSP was working, we would expect to see entries that include the LSP in the **inet.3** routing table. The **inet.3** routing table is used on ingress routers to route BGP packets to the destination egress router. BGP uses the **inet.3** routing table on the ingress router to help resolve next-hop addresses. BGP is configured in the example network shown in [Figure 94 on page 923](#).

Sample Output 2 shows output you should receive when the LSP is up. The output shows both the **inet.0** and **inet.3** routing tables, indicating that LSPs **R1-to-R6** and **R6-to-R1** are available.

## Verify MPLS Labels with the traceroute Command

**Purpose** Display the route packets take to a BGP destination where the BGP next hop for that route is the LSP egress address. By default, BGP uses the **inet.0** and the **inet.3** routing tables to resolve the next-hop address. When the next-hop address of the BGP route is not the router ID of the egress router, traffic is mapped to IGP routes, not to the LSP. Use the **traceroute** command as a debugging tool to determine whether the LSP is being used to forward traffic.

**Action** To verify MPLS labels, enter the following command from the ingress router:

```
user@host> traceroute hostname
```

### Sample Output 1

```

user@R1> traceroute 100.100.6.1
traceroute to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1  10.1.12.2 (10.1.12.2)  0.627 ms  0.561 ms  0.520 ms
 2  10.1.26.2 (10.1.26.2)  0.570 ms !N  0.558 ms !N  4.879 ms !N

user@R6> traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
 1  10.1.26.1 (10.1.26.1)  0.630 ms  0.545 ms  0.488 ms
 2  10.1.12.1 (10.1.12.1)  0.551 ms !N  0.557 ms !N  0.526 ms !N

```

## Sample Output 2

```

user@R1> traceroute 100.100.6.1
to 100.100.6.1 (100.100.6.1), 30 hops max, 40 byte packets
 1 10.1.13.2 (10.1.13.2) 0.866 ms 0.746 ms 0.724 ms
    MPLS Label=100912 CoS=0 TTL=1 S=1
 2 10.1.36.2 (10.1.36.2) 0.577 ms !N 0.597 ms !N 0.546 ms !N

user@R6> traceroute 100.100.1.1
traceroute to 100.100.1.1 (100.100.1.1), 30 hops max, 40 byte packets
 1 10.1.36.1 (10.1.36.1) 0.802 ms 0.716 ms 0.688 ms
    MPLS Label=100896 CoS=0 TTL=1 S=1
 2 10.1.13.1 (10.1.13.1) 0.570 ms !N 0.568 ms !N 0.546 ms !N

```

**Meaning** Sample Output 1 shows that BGP traffic is not using the LSP, consequently MPLS labels do not appear in the output. Instead of using the LSP, BGP traffic is using the IGP (IS-IS, in the example network in [Figure 94 on page 923](#)) to reach the BGP next-hop LSP egress address. The Junos OS default behavior uses LSPs for BGP traffic when the BGP next hop equals the LSP egress address.

Sample Output 2 is an example of output for a correctly configured LSP. The output shows MPLS labels, indicating that BGP traffic is using the LSP to reach the BGP next hop.

## Verify MPLS Labels with the ping Command

**Purpose** When you ping a specific LSP, you check that echo requests are sent over the LSP as MPLS packets.

**Action** To verify MPLS labels, enter the following command from the ingress router to ping the egress router:

```
user@host> ping mpls rsvp lsp-name detail
```

For example:

```
user@R1> ping mpls rsvp R1-to-R6 detail
```

## Sample Output 1

```

user@R1> ping mpls rsvp R1-to-R6 detail
LSP R1-to-R6 - LSP has no active path, exiting.

user@R6> ping mpls rsvp R6-to-R1 detail
LSP R6-to-R1 - LSP has no active path, exiting.

```

## Sample Output 2

```

user@R1> traceroute 10.0.0.6
traceroute to 10.0.0.6 (10.0.0.6), 30 hops max, 40 byte packets
 1 10.1.15.2 (10.1.15.2) 0.708 ms 0.613 ms 0.576 ms
 2 10.0.0.6 (10.0.0.6) 0.763 ms 0.708 ms 0.700 ms

user@R1> ping mpls rsvp R1-to-R6 detail
Request for seq 1, to interface 69, label 100880
Reply for seq 1, return code: Egress-ok

```

```
Request for seq 2, to interface 69, label 100880
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 69, label 100880
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 69, label 100880
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 69, label 100880
Reply for seq 5, return code: Egress-ok

--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss

user@R6> ping mpls rsvp R6-to-R1 detail
Request for seq 1, to interface 70, label 100864
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 70, label 100864
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 70, label 100864
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 70, label 100864
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 70, label 100864
Reply for seq 5, return code: Egress-ok

--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

**Meaning** Sample Output 1 shows that the LSP does not have an active path to forward echo requests, indicating that the LSP is down.

Sample Output 2 is an example of output you should receive when the LSP is up and forwarding packets.

---

## Take Appropriate Action

**Problem** **Description:** Depending on the error you encountered in your investigation, you must take the appropriate action to correct the problem. In this example, an interface is incorrectly configured at the `[edit protocols mpls]` hierarchy level on egress router **R6**.

**Solution** To correct the error in this example, follow these steps:

1. Activate the interface in the MPLS protocol configuration on egress router **R6**:

```
user@R6> edit
user@R6# edit protocols mpls
[edit protocols mpls]
user@R6# show
user@R6# activate interface so-0/0/3.0
```

2. Verify and commit the configuration:

```
[edit protocols mpls]
user@R6# show
user@R6# commit
```

**Sample Output**

```

user@R6> edit
Entering configuration mode

[edit]
user@R6# edit protocols mpls

[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
inactive: interface so-0/0/3.0; <<< Incorrectly configured interface

[edit protocols mpls]
user@R6# activate interface so-0/0/3

[edit protocols mpls]
user@R6# show
label-switched-path R6-to-R1 {
    to 10.0.0.1;
}
inactive: interface so-0/0/0.0;
inactive: interface so-0/0/1.0;
inactive: interface so-0/0/2.0;
interface so-0/0/3.0; <<< Correctly configured interface

[edit protocols mpls]
user@R6# commit
commit complete

```

**Meaning** The sample output shows that the incorrectly configured interface **so-0/0/3.0** on egress router **R6** is now activated at the **[edit protocols mpls]** hierarchy level. The LSP can now come up.

## Verify the LSP Again

**Purpose** After taking the appropriate action to correct the error, the LSP needs to be checked again to confirm that the problem in the BGP layer has been resolved.

**Action** To verify the LSP again, enter the following command from the ingress, transit, and egress routers:

```
user@host> show mpls lsp extensive
```

## Sample Output

```

user@R1> show mpls lsp extensive
Ingress LSP: 1 sessions

10.0.0.6
  From: 10.0.0.1, State: Up, ActiveRoute: 1, LSPname: R1-to-R6
  ActivePath: (primary)
  LoadBalance: Random
  Encoding type: Packet, Switching type: Packet, GPID: IPv4

```

```

*Primary                               State: Up
