### Configuring an Inter-AS MS-PW

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

T-PE1 set interfaces ge-3/1/0 unit 0 family inet address 192.0.2.1/24
 set interfaces ge-3/1/0 unit 0 family mpls
 set interfaces ge-3/1/2 encapsulation ethernet-ccc
 set interfaces ge-3/1/2 unit 0
 set interfaces lo0 unit 0 family inet address 10.255.10.1/32 primary
 set routing-options autonomous-system 1
 set protocols mpls interface all
 set protocols mpls interface fxp0.0 disable
 set protocols bgp family l2vpn auto-discovery-mspw
 set protocols bgp group mspw type internal
 set protocols bgp group mspw local-address 10.255.10.1
 set protocols bgp group mspw neighbor 10.255.2.1
 set protocols ospf area 0.0.0.0 interface lo0.0
 set protocols ospf area 0.0.0.0 interface all
 set protocols ospf area 0.0.0.0 interface fxp0.0 disable
 set protocols ldp interface all
 set protocols ldp interface fxp0.0 disable
 set protocols ldp interface lo0.0

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the T-PE1 router in the inter-AS scenario:

**NOTE:** Repeat this procedure for the T-PE2 device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the T-PE1 interfaces.  

```
[edit interfaces]
user@T-PE1# set ge-3/1/0 unit 0 family inet address 192.0.2.1/24
user@T-PE1# set ge-3/1/0 unit 0 family mpls

user@T-PE1# set ge-3/1/2 encapsulation ethernet-ccc
user@T-PE1# set ge-3/1/2 unit 0

user@T-PE1# set lo0 unit 0 family inet address 10.255.10.1/32 primary
```
2. Set the autonomous system number.  

```
[edit routing-options]
user@T-PE1# set autonomous-system 1
```
3. Enable MPLS on all the interfaces of T-PE1, excluding the management interface.  

```
[edit protocols]
user@T-PE1# set mpls interface all
user@T-PE1# set mpls interface fxp0.0 disable
```
4. Enable autodiscovery of intermediate S-PEs that make up the MS-PW using BGP.  

```
[edit protocols]
user@T-PE1# set bgp family l2vpn auto-discovery-mspw
```
5. Configure the BGP group for T-PE1.  

```
[edit protocols]
user@T-PE1# set bgp group mspw type internal
```
6. Assign local and neighbor addresses to the mspw group for T-PE1 to peer with S-PE1.  

```
[edit protocols]
user@T-PE1# set bgp group mspw local-address 10.255.10.1
user@T-PE1# set bgp group mspw neighbor 10.255.2.1
```
7. Configure OSPF on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ospf area 0.0.0.0 interface lo0.0
user@T-PE1# set ospf area 0.0.0.0 interface all
user@T-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

8. Configure LDP on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@T-PE1# set ldp interface all
user@T-PE1# set ldp interface fxp0.0 disable
user@T-PE1# set ldp interface lo0.0
```

9. Configure the Layer 2 VPN routing instance on T-PE1.

```
[edit routing-instances]
user@T-PE1# set ms-pw instance-type l2vpn
```

10. Assign the interface name for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw interface ge-3/1/2.0
```

11. Configure the route distinguisher for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw route-distinguisher 10.10.10.15
```

12. Configure the Layer 2 VPN ID community for FEC 129 MS-PW.

```
[edit routing-instances]
user@T-PE1# set ms-pw l2vpn-id l2vpn-id:100:15
```

13. Configure a VPN routing and forwarding (VRF) target for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw vrf-target target:100:115
```

14. Configure the source attachment identifier (SAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 source-attachment-identifier
800:800:800
```

15. Assign the interface name that connects the CE1 site to the VPN, and configure the target attachment identifier (TAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 interface ge-3/1/2.0
target-attachment-identifier 700:700:700
```

16. (Optional) Configure T-PE1 to send MS-PW status TLVs.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn pseudowire-status-tlv
```

17. (Optional) Configure OAM capabilities for the VPN.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn oam bfd-liveness-detection
minimum-interval 300
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure S-PE1 (ASBR 1) in the inter-AS scenario:

**NOTE:** Repeat this procedure for the S-PE2 (ASBR 2) device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure S-PE1 (ASBR 1) interfaces.

```
[edit interfaces]
user@S-PE1# set ge-1/3/1 unit 0 family inet address 192.0.2.9/24
user@S-PE1# set ge-1/3/1 unit 0 family mpls

user@S-PE1# set ge-1/3/2 unit 0 family inet address 192.0.2.22/24
user@S-PE1# set ge-1/3/2 unit 0 family mpls

user@S-PE1# set lo0 unit 0 family inet address 10.255.2.1/32 primary
```

2. Set the autonomous system number.

```
[edit routing-options]
user@S-PE1# set autonomous-system 1
```

3. Enable MPLS on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set mpls interface all
user@S-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of S-PE using BGP.

```
[edit protocols]
user@S-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the IBGP group for S-PE1 (ASBR 1) to peer with T-PE1.

```
[edit protocols]
user@S-PE1# set bgp group to_T-PE1 type internal
```

6. Configure the IBGP group parameters.

```
[edit protocols]
user@S-PE1# set bgp group to_T-PE1 local-address 10.255.2.1
user@S-PE1# set bgp group to_T-PE1 export next-hop-self
user@S-PE1# set bgp group to_T-PE1 neighbor 10.255.10.1
```

7. Configure the EBGP group for S-PE1 (ASBR 1) to peer with S-PE2 (ASBR 2).

```
[edit protocols]
user@S-PE1# set bgp group to_S-PE2 type external
```

8. Configure the EBGP group parameters.

```
[edit protocols]
user@S-PE1# set bgp group to_S-PE2 local-address 10.255.2.1
user@S-PE1# set bgp group to_S-PE2 peer-as 2
user@S-PE1# set bgp group to_S-PE2 neighbor 10.255.3.1 multihop ttl 1
```

9. Configure OSPF on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set ospf area 0.0.0.0 interface all
user@S-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@S-PE1# set ospf area 0.0.0.0 interface lo0.0 passive
```

10. Configure LDP on all the interfaces of S-PE1 (ASBR 1), excluding the management interface.

```
[edit protocols]
user@S-PE1# set ldp interface all
user@S-PE1# set ldp interface fxp0.0 disable
user@S-PE1# set ldp interface lo0.0
```

11. Define the policy for enabling next-hop-self on S-PE1 (ASBR 1).

```
[edit policy-options]
user@S-PE1# set policy-statement next-hop-self then next-hop self
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, **show routing-options**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
T-PE1 user@T-PE1# show interfaces

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the Routes on page 1074](#)
- [Verifying the LDP Database on page 1077](#)
- [Checking the MS-PW Connections on T-PE1 on page 1078](#)
- [Checking the MS-PW Connections on S-PE1 on page 1081](#)
- [Checking the MS-PW Connections on S-PE2 on page 1084](#)
- [Checking the MS-PW Connections on T-PE2 on page 1087](#)

### Verifying the Routes

**Purpose** Verify that the expected routes are learned.

**Action** From operational mode, run the **show route** command for the **bgp.l2vpn.1**, **ldp.l2vpn.1**, **mpls.0**, and **ms-pw.l2vpn.1** routing tables.

From operational mode, run the **show route table bgp.l2vpn.1** command.

```
user@T-PE1> show route table bgp.l2vpn.1
bgp.l2vpn.1: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.10.10.10:15:700:0.0.2.188:700/160 AD2
 * [BGP/170] 16:13:11, localpref 100, from 10.255.2.1
 AS path: 2 I, validation-state: unverified
 > to 203.0.113.2 via ge-3/1/0.0, Push 300016
```

From operational mode, run the **show route table ldp.l2vpn.1** command.

```
user@T-PE1> show route table ldp.l2vpn.1
ldp.l2vpn.1: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.255.2.1:CtrlWord:5:100:15:700:0.0.2.188:700:800:0.0.3.32:800/304 PW2
 * [LDP/9] 16:21:27
 Discard
```

From operational mode, run the **show route table mpls.0** command.

```
user@T-PE1> show route table mpls.0
mpls.0: 12 destinations, 12 routes (12 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0 * [MPLS/0] 1w6d 00:28:26, metric 1
 Receive
1 * [MPLS/0] 1w6d 00:28:26, metric 1
 Receive
2 * [MPLS/0] 1w6d 00:28:26, metric 1
 Receive
13 * [MPLS/0] 1w6d 00:28:26, metric 1
```

```

 Receive

 *[L2VPN/7] 16:23:27, metric2 1
 > to 203.0.113.2 via ge-3/1/0.0, Push 300016

```

**Meaning** The output shows all the learned routes, including the autodiscovery (AD) routes.

The AD2 prefix format is **RD:SAII-type2**, where:

- **RD** is the route distinguisher value.
- **SAII-type2** is the type 2 source attachment identifier value.

The PW2 prefix format is **Neighbor\_Addr:C:PWtype:l2vpn-id:SAII-type2:TAII-type2**, where:

- **Neighbor\_Addr** is the loopback address of neighboring S-PE device.
- **C** indicates if Control Word (CW) is enabled or not.
  - **C** is **CtrlWord** if CW is set.
  - **C** is **NoCtrlWord** if CW is not set.

- **PWtype** indicates the type of the pseudowire.
  - **PWtype** is **4** if it is in Ethernet tagged mode.
  - **PWtype** is **5** if it is Ethernet only.
- **l2vpn-id** is the Layer 2 VPN ID for the MS-PW routing instance.
- **SAll-type2** is the type 2 source attachment identifier value.
- **TAll-type2** is the type 2 target attachment identifier value.

## Verifying the LDP Database

**Purpose** Verify the MS-PW labels received by T-PE1 from S-PE1 and sent from T-PE1 to S-PE1.

**Action** From operational mode, run the **show ldp database** command.

```
user@T-PE1> show ldp database
Input label database, 10.255.10.1:0--10.255.2.1:0
 Label Prefix
 3 10.255.2.1/32
 300112 10.255.3.1/32
 300128 10.255.4.1/32
 299968 10.255.10.1/32
 299904 10.255.13.1/32
 300144 10.255.14.1/32
 300176 FEC129 CtrlWord ETHERNET 000a0064:0000000f 000002bc:000002bc:000002bc
00000320:00000320:00000320

Output label database, 10.255.10.1:0--10.255.2.1:0
 Label Prefix
 299936 10.255.2.1/32
 300096 10.255.3.1/32
 300112 10.255.4.1/32
 3 10.255.10.1/32

 3 10.255.10.1/32
 299920 10.255.13.1/32
 300128 10.255.14.1/32
```

**Meaning** The labels with **FEC129** prefix are related to the MS-PW.

### Checking the MS-PW Connections on T-PE1

---

**Purpose** Make sure that all of the FEC 129 MS-PW connections come up correctly.

**Action** From operational mode, run the **show l2vpn connections extensive** command.

```

user@T-PE1> show l2vpn connections extensive
Layer-2 VPN connections:

```

Check the following fields in the output to verify that MS-PW is established between the T-PE devices:

- **Target-attachment-id**—Check if the TAI value is the SAI value of T-PE2.
- **Remote PE**—Check if the T-PE2 loopback address is listed.

- **Negotiated PW status TLV**—Ensure that the value is **Yes**.
- **Pseudowire Switching Points**—Check if the switching points are listed from S-PE1 to S-PE2 and from S-PE2 to T-PE2.

**Meaning** MS-PW is established between T-PE1 and T-PE2 in the forwarding direction.

### Checking the MS-PW Connections on S-PE1

---

**Purpose** Make sure that all of the FEC 129 MS-PW connections come up correctly for the mspw routing instance.

**Action** From operational mode, run the **show l2vpn connections instance \_\_MSPW\_\_ extensive** command.

```
user@S-PE1> show l2vpn connections instance __MSPW__ extensive
Layer-2 VPN connections:
```

Check the following fields in the output to verify that MS-PW is established between the T-PE devices:

- **Target-attachment-id**—Check if the TAI value is the SAI value of T-PE1.
- **Remote PE**—Check if the T-PE1 loopback address is listed.

- **Negotiated PW status TLV**—Ensure that the value is **Yes**.
- **Pseudowire Switching Points**—Check if the switching points are listed from S-PE2 to S-PE1 and from S-PE1 to T-PE1.

**Meaning** MS-PW is established between T-PE1 and T-PE2 in the reverse direction.

## Troubleshooting

To troubleshoot the MS-PW connection, see:

- [Ping on page 1089](#)
- [Bidirectional Forwarding Detection on page 1089](#)
- [Traceroute on page 1090](#)

### Ping

**Problem** How to check the connectivity between the T-PE devices and between a T-PE device and an intermediary device.

**Solution** Verify that T-PE1 can ping T-PE2. The **ping mpls l2vpn fec129** command accepts SAls and TAls as integers or IP addresses and also allows you to use the CE-facing interface instead of the other parameters (**instance**, **local-id**, **remote-id**, **remote-pe-address**).

#### Checking Connectivity Between T-PE1 and T-PE2

```
user@T-PE1> ping mpls l2vpn fec129 instance FEC129-VPWS local-id 800:800:800
remote-pe-address 10.255.14.1 remote-id 700:700:700
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss

user@T-PE1> ping mpls l2vpn fec129 interface ge-3/1/2
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

#### Checking Connectivity Between T-PE1 and S-PE2

```
user@T-PE1> ping mpls l2vpn fec129 interface ge-3/1/2 bottom-label-ttl 2
!!!!

## Configuring the FAT Flow Label for FEC 128 VPWS Pseudowires for Load-Balancing MPLS Traffic

This topic shows how to configure flow-aware transport of pseudowires (FAT) flow labels for forwarding equivalence class (FEC) 128 virtual private wire service (VPWS) pseudowires for load-balancing MPLS traffic.

FAT flow labels enable load-balancing of MPLS packets across equal-cost multipath (ECMP) paths or link aggregation groups (LAGs) without the need for deep packet inspection of the payload. FAT flow labels can be used for LDP-signaled FEC 128 and FEC 129 pseudowires for virtual private LAN service (VPLS) and VPWS networks.

You can configure FAT flow labels to be signaled by LDP on FEC 128 VPWS pseudowires by including the **flow-label-transmit** and **flow-label-receive** configuration statements at the `[edit protocols l2circuit neighbor neighbor-id interface interface-name]` hierarchy level. This configuration sets the T bit and R bit advertisement to 1 (the default being 0) in the Sub-TLV field, which is one of the interface parameters of the FEC for the LDP label-mapping message header. These statements signal the pushing and popping of the load-balancing label to the routing peers in the control plane.

Alternatively, you can configure the following statements at the `[edit protocols l2circuit neighbor neighbor-id interface interface-name]` hierarchy level:

- **flow-label-transmit-static** to statically push the flow label on the pseudowire packets sent to the remote provider edge (PE) router.
- **flow-label-receive-static** to statically pop the flow label on the pseudowire packets received from the remote PE router.

Before you begin:

1. Configure the device interfaces and enable MPLS on all the interfaces.
2. Configure MPLS and an LSP to the remote PE router.
3. Configure OSPF and IS-IS.
4. Configure LDP on the loopback interface and the PE interface connecting to the P (transit) router.

To configure the FAT flow label for an FEC 128-signaled VPLS pseudowire, on the ingress PE router:

1. Configure the neighbors for the Layer 2 circuit.

```
[edit protocols l2circuit]
user@PE1# set neighbor neighbor-id
```

All the Layer 2 circuits using a particular remote PE router designated for remote CE routers are listed under the **neighbor** statement. Each neighbor is identified by its IP address and is usually the end-point destination for the label-switched path (LSP) tunnel transporting the Layer 2 circuit.

2. Configure the interface for the Layer 2 circuit neighbor and a unique identifier for the Layer 2 circuit.

```
[edit protocols l2circuit neighbor neighbor-id]
user@PE1# set interface interface-name virtual-circuit-id unique-l2ckt-identifier
```

- 3.

**NOTE:** You can only configure one of the following pairs of statements:

- **flow-label-transmit** and **flow-label-receive** or,
- **flow-label-transmit-static** and **flow-label-receive-static**

Configure the router to signal the capability to push the flow label in the transmit direction to the remote PE router.

```
[edit protocols l2circuit neighbor neighbor-id interface interface-name]
user@PE1# set flow-label-transmit
```

4. Alternatively, configure the **flow-label-transmit-static** statement to statically push the flow label on the pseudowire packets sent to the remote PE router.

```
[edit protocols l2circuit neighbor neighbor-id interface interface-name]
user@PE1# set flow-label-transmit-static
```

If the incoming pseudowire packet is not marked with the flow label, the packet is dropped by the egress PE router.

5. Configure the router to signal the capability to pop the flow label in the receive direction to the remote egress PE router.

```
[edit protocols l2circuit neighbor neighbor-id interface interface-name]
user@PE1# set flow-label-receive
```

6. Alternatively, configure the **flow-label-receive-static** statement to pop the flow label on the pseudowire packets received from the remote PE router.

```
[edit protocols l2circuit neighbor neighbor-id interface interface-name]
user@PE1# set flow-label-receive-static
```

The ingress PE router inserts the flow label in the pseudowire packet, irrespective of the information exchanged in the signaling plane. If the egress PE router cannot handle the pseudowire packet marked with the flow label, the packet is dropped.

7. Verify and commit the configuration.

For example:

```
[edit protocols l2circuit]
user@PE1# show
neighbor 10.255.104.135 {
 interface ge-1/0/8.0 {
 virtual-circuit-id 1;
 flow-label-transmit;
```

```
 flow-label-receive;
 }
}

OR:

[edit protocols l2circuit]
user@PE1# show
neighbor 10.255.104.135 {
 interface ge-1/0/8.0 {
 virtual-circuit-id 1;
 flow-label-transmit-static;
 flow-label-receive-static;
 }
}
```

8. Repeat the configuration on the remote egress PE router.

## Configuring the FAT Flow Label for FEC 129 VPWS Pseudowires for Load-Balancing MPLS Traffic

This topic shows how to configure flow-aware transport of pseudowires (FAT) flow labels for forwarding equivalence class (FEC) 129 virtual private wire service (VPWS) pseudowires.

FAT flow labels enable load-balancing of MPLS packets across equal-cost multipath (ECMP) paths or link aggregation groups (LAGs) without the need for deep packet inspection of the payload. FAT flow labels can be used for LDP-signaled FEC 128 and FEC 129 pseudowires for virtual private LAN service (VPLS) and VPWS networks.

You can configure FAT flow labels to be signaled by LDP on FEC 129 VPWS pseudowires (Layer 2 circuits) by including the **flow-label-transmit** and **flow-label-receive** configuration statements at the **[edit routing-instances *instance-name* protocols l2vpn site *name*]** or the **[edit routing-instances *instance-name* protocols l2vpn site *name* interface *interface-name*]** hierarchy level. This configuration sets the T bit and R bit advertisement to 1 (the default being 0) in the Sub-TLV field, which is one of the interface parameters of the FEC for the LDP label-mapping message header. These statements signal the pushing and popping of the load-balancing label to the routing peers in the control plane.

Before you begin:

1. Configure the device interfaces and enable MPLS on all core-facing interfaces.
2. Configure CCC encapsulation and the CCC address family for interfaces configured as members of the FEC 129 VPWS instance.
3. Configure MPLS and an LSP to the remote provider edge (PE) router.
4. Configure the BGP sessions on the PE devices with the BGP autodiscovery-only address family to allow exchange of the autodiscovery routes.
5. Configure an IGP such as IS-IS or OSPF.
6. Configure LDP on the loopback interface and the core-facing interface.
7. Configure the autonomous system (AS) number.

To configure the FAT flow label for an FEC 129 VPWS pseudowire, on the ingress PE router:

1. Configure the VPWS routing instance.

LDP listens for routes from instance.l2vpn.0 for any instance configured for FEC 129 VPWS. These routes are identified by the **instance-type l2vpn** statement in the routing instance and the presence of the **l2vpn-id** statement.

```
[edit]
user@PE1# set routing-instances instance-name instance-type l2vpn
user@PE1# set routing-instances instance-name interface interface-name
user@PE1# set routing-instances instance-name route-distinguisher (as-number:x:y
| ip-address:id)
user@PE1# set routing-instances instance-name l2vpn-id (as-number:x:y | ip-address:id)
```

```

user@PE1# set routing-instances instance-name vrf-target community
user@PE1# set routing-instances instance-name protocols l2vpn site site-name
 source-attachment-identifier identifier
user@PE1# set routing-instances instance-name protocols l2vpn site site-name
 interface interface-name target-attachment-identifier identifier

```

Because VPWS is a point-to-point service, FEC 129 VPWS routing instances are configured as **instance-type l2vpn**. As with FEC 129 VPLS, FEC 129 VPWS uses the **l2vpn-id** statement to define the Layer 2 VPN of which the routing instance is a member. The presence of the **l2vpn-id** statement designates that FEC 129 LDP-signaling is used for the routing instance.

2. Configure the device to signal the capability to push the flow label in the transmit direction to the remote PE router.

```

[edit routing-instances instance-name protocols l2vpn site name interface
interface-name]
user@PE1# set flow-label-transmit

```

3. Configure the device to signal the capability to pop the flow label in the receive direction to the remote PE router.

```

[edit routing-instances instance-name protocols l2vpn site name interface
interface-name]
user@PE1# set flow-label-receive

```

4. Alternatively, configure the **flow-label-transmit** and **flow-label-receive** statements directly within the site. When configured within the site, the defined parameters affect any pseudowire originating from that site. When configured under an interface within the site, the defined parameters affect that single specific pseudowire. This enables you to manipulate the parameters across all pseudowires associated with a particular local site in one place in the configuration.

```

[edit routing-instances instance-name protocols l2vpn site name]
user@PE1# set flow-label-receive
user@PE1# set flow-label-transmit

```

5. Verify and commit the configuration.

For example:

```

[edit routing-instances FEC129-VPWS]
user@PE1# show
instance-type l2vpn;
interface ge-0/0/1.600;
route-distinguisher 10.255.255.1:100;
l2vpn-id l2vpn-id:100:100;
vrf-target target:100:100;
protocols {
 l2vpn {
 site ONE {
 source-attachment-identifier 1;
 interface ge-0/0/1.600 {
 target-attachment-identifier 2;

```

```
 flow-label-transmit; <<< Applicable only to the pseudowire specific to the
 interface >>>
 flow-label-receive;
 }
}
site TWO {
 source-attachment-identifier 3;
 flow-label-transmit; <<< Applicable to all pseudowires within the site >>>
 flow-label-receive;
 interface ge-0/0/2.600 {
 target-attachment-identifier 1;
 }
 interface ge-0/0/2.601 {
 target-attachment-identifier 4;
 }
}
}
```

6. Repeat the configuration on the remote egress PE router.

# Configuring VPWS Service with EVPN Mechanisms

- [Overview of VPWS with EVPN Signaling Mechanisms on page 1098](#)
- [Configuring VPWS with EVPN Signaling Mechanisms on page 1101](#)
- [Example: Configuring VPWS with EVPN Signaling Mechanisms on page 1103](#)

## Overview of VPWS with EVPN Signaling Mechanisms

An Ethernet VPN (EVPN) enables you to connect dispersed customer sites using a Layer 2 virtual bridge. As compared with other types of Layer 2 VPNs, an EVPN consists of customer edge (CE) devices (host, router, or switch) connected to provider edge (PE) routers. The PE routers can include an MPLS edge switch (MES) that acts at the edge of the MPLS infrastructure. Either an MX Series 3D Universal Edge Router or a standalone switch can be configured to act as an MES. You can deploy multiple EVPNs within a service provider network, each providing network connectivity to a customer while ensuring that the traffic sharing on that network remains private.

Virtual private wire service (VPWS) Layer 2 VPNs employ Layer 2 services over MPLS to build a topology of point-to-point connections that connect end customer sites in a VPN. The service provisioned with these Layer 2 VPNs is known as VPWS. You can configure a VPWS instance on each associated edge device for each VPWS Layer 2 VPN.

An EVPN-VPWS network provides a framework for delivering VPWS with EVPN signaling mechanisms. The advantages of VPWS with EVPN mechanisms are single-active or all-active multihoming capabilities and support for Inter-autonomous system (AS) options associated with BGP-signaled VPNs. Metro Ethernet Forum (MEF) describes the following two service models for VPWS:

- Ethernet private line (EPL)— EPL provides a point-to-point Ethernet virtual connection (EVC) between a pair of dedicated user–network interfaces (UNIs) that is between a pair of Ethernet segment identifiers (ESIs) with a high degree of transparency.
- Ethernet virtual private line (EVPL)— EVPL provides point-to-point EVC between {ESI, VLAN} pairs. EVPL allows service multiplexing; that is multiple EVCs or Ethernet services per UNI.

An EVPN-VPWS network is supported on an EVPN-MPLS network.

Figure 113 on page 1098 illustrates an EVPN-VPWS network. Device CE1 is multihomed to Routers PE1 and PE2 and Device CE2 is multihomed to Routers PE3 and PE4. Device CE2 has two potential paths to reach CE1, and depending on the multihoming mode of redundancy, only one path or all paths can be active at any one time. When a CE device is multihomed to two or more PE routers, the set of Ethernet links constitutes an Ethernet segment. An Ethernet segment appears as a link aggregation group (LAG) to the CE device. The links from PE1 and PE2 to CE1 and PE3 and PE4 to CE2 form an Ethernet segment.

Figure 113: VPWS in EVPN

An Ethernet segment must have a unique nonzero identifier, called the *Ethernet segment identifier (ESI)*. The ESI is encoded as a 10-octet integer. When manually configuring an ESI value, the most significant octet, known as the *type byte*, must be 00. When a single-homed CE device is attached to an Ethernet segment, the entire ESI value is zero. The Ethernet segment of the multihomed Device CE1 has an ESI value of 00:11:11:11:11:11:11:11 and the Ethernet segment of the multihomed Device CE2 has an ESI value of 00:22:22:22:22:22:22:22.

An EVPN instance (EVI) is an EVPN routing and forwarding instance spanning across all the PE routers participating in that VPN. An EVI is configured on the PE routers on a per-customer basis. Each EVI has a unique route distinguisher and one or more route targets. An EVI is configured on PE1, PE2, PE3, and PE4. An Ethernet tag identifies a particular broadcast domain, such as a VLAN. An EVI consists of one or more broadcast domains. Ethernet tags are assigned to the broadcast domains of a given EVI by the provider of that EVPN. Each PE router in that EVI performs a mapping between broadcast domain identifiers understood by each of its attached CE devices and the corresponding Ethernet tag. Depending on the multihoming mode of redundancy, only one path or all paths can be active at any one time.

The multihoming mode of operation along with VPWS service identifiers determine which PE router or routers forward and receive traffic in the EVPN-VPWS network. The VPWS service identifier identifies the endpoints of the EVPN-VPWS network. These endpoints are autodiscovered by BGP and are used to exchange the service labels (learned from the respective PE routers) that are used by autodiscovered routes per EVI route type. The service identifier is of two types:

- Local— Unique local VPWS service identifier. This is a logical identifier mapped to a physical interface of a PE router connected to the customer site that is forwarding the traffic to a remote VPWS service identifier.
- Remote—Unique remote VPWS service identifier. This is a logical identifier mapped to a physical interface of a PE router connected to the customer site that is receiving the traffic forwarded from the local VPWS service identifier.

The PE router forwarding traffic to the CE device uses MPLS LSP to forward traffic. If a failure occurs over this path, a new designated forwarder is elected to forward the traffic to the CE device.

The EVPN-VPWS network uses only an autodiscovered route per ESI and an autodiscovered router per EVI route types. In autodiscovered routes per EVI, the 24-bit values of the Ethernet tag are encoded with the VPWS service identifier. The autodiscovered route per ESI is encoded with the route targets of all the EVPN-VPWS instances connected to the ESI on the advertising PE router. When the PE router loses its connectivity to the ESI, it withdraws the autodiscovered route per ESI, resulting in faster convergence. The receiving PE router updates the forwarding next hop of the VPWS service identifier impacted by the failure. Depending on the mode of operation, these two endpoints of the EVPN-VPWS network can be colocated on the same PE router or on different PE routers. The different modes of operation in an EVPN-VPWS network are as follows:

- **Local switching**—In this mode, the VPWS endpoints (that is, local and remote service identifiers) are connected through the local interfaces configured on the same PE router. Traffic from one CE router is forwarded to another CE router through the same PE router.
- **Single-homing**—When a PE router is connected to a single-homed customer site, this mode is in operation.
- **Active-standby multihoming**—In this mode, only a single PE router among a group of PE routers with the same VPWS service identifier attached to an Ethernet segment is allowed to forward traffic to and from that Ethernet segment. The process of electing one among many PE routers with the same VPWS service identifier is known as the *designated forwarder (DF) election*. Each PE router connected to the Ethernet segment with the same VPWS service identifier participates in the DF election and informs the network of its status. The status can be as follows:
  - **Designated forwarder(DF)**—This is the designated forwarder for forwarding the current traffic.
  - **Backup designated forwarder(BDF)**—This becomes the DF in case the current DF encounters a failure.
  - **Non-designated forwarder(non-DF)**—This is neither the DF nor the BDF. When more than two PE routers are part of an ESI redundancy group, then this PE router becomes a non-DF.

To configure the active-standby mode, include the ESI value and the **single-active** statement under the [edit interfaces] hierarchy level. Configure the **local** and the **remote** VPWS service identifier under the [edit routing-instances *vpws-routing-instance* protocols *evpn* interface *interface-name* *vpws-service-id*] for each PE router connected to the Ethernet segment.

In [Figure 113 on page 1098](#), for the PE routers connected to Device CE1, Router PE1 is assumed to be the DF and PE2 is assumed to be the BDF for VPWS service identifier 100. For the PE routers connected to CE2, PE3 is assumed to be the DF and Router PE4 is assumed to be the BDF for VPWS service identifier 200. PE2 and PE4 indicate their BDF status to CE1 and CE2 by setting their circuit cross-connect (CCC)-Down flag on their respective interfaces.

- **Active-active multi-homing**—In active-active multi homing, the CE device is connected to the PE routers with the same local VPWS identifier through the LAG interface so that the traffic is load-balanced among the set of multihomed PE routers with the same remote VPWS service identifiers. Here, election of DF is not required, because all the PE routers connected to the LAG interface participate in forwarding the traffic. In [Figure 113 on page 1098](#), Device CE1 forwards traffic to PE1 and PE2 with VPWS service identifier 100 and CE2 forwards traffic to PE3 and PE4 with VPWS service identifier 200. PE1 forwards the traffic to PE3 and PE4 with remote VPWS service identifier 200. PE2 forwards the traffic to PE3 and PE4. Similarly, traffic from CE2 to PE3 and PE4 with VPWS service identifier is load-balanced across PE routers with VPWS service identifier 100 connected to CE1.

## NSR and Unified ISSU Support on VPWS with EVPN

Nonstop active routing (NSR) and graceful Routing Engine switchover (GRES) minimize traffic loss when there is a Routing Engine switchover. When a Routing Engine fails, NSR and GRES enable a routing platform with redundant Routing Engines to switch over from a primary Routing Engine to a backup Routing Engine and continue forwarding packets. Unified in-service software upgrade (ISSU) allows you to upgrade your Junos OS software on your MX Series router with no disruption on the control plane and with minimal disruption of traffic. Both GRES and NSR must be enabled to use unified ISSU.

To enable GRES, include the **graceful-switchover** statement at the **[edit chassis redundancy]** hierarchy level.

To enable NSR, include the **nonstop-routing** statement at the **[edit routing-options]** hierarchy level and the **commit synchronize** statement at the **[edit system]** hierarchy level.

## Configuring VPWS with EVPN Signaling Mechanisms

The virtual private wire service (VPWS) with Ethernet VPN (EVPN) provides single-active or all-active multihoming capabilities along with support for Inter-AS options associated with BGP-signaled VPNs. The VPWS service identifiers identify the endpoints of the EVPN-VPWS network. Each provider edge (PE) router in EVPN-VPWS network is configured with local and remote VPWS service identifiers.

Before you configure VPWS service with EVPN mechanisms, you must do the following:

1. Configure the router interfaces.
2. Configure the router ID and autonomous system number for the device.
3. Configure OSPF.
4. Configure a BGP internal group.
5. Configure ISIS.
6. Include the EVPN signaling network layer reachability information (NLRI) to the internal BGP group.
7. Configure LDP.
8. Configure MPLS.
9. Configure MPLS LSP or GRE tunnels.
10. Configure EVPN all-active multihoming and EVPN single-active multihoming.

To configure a PE device with a VPWS service identifier in an EVPN-VPWS network, do the following:

1. Configure the EVPN-VPWS routing instance.

```
[edit routing-instances]
user@PE# set evpn-vpws-instance instance-type instance-type-value
```

For example, configure routing instance `vpws1004` with instance type `evpn-vpws`.

```
[edit routing-instances]
user@PE# set vpws1004 instance-type evpn-vpws
```

2. Configure the interface names for the EVPN-VPWS routing instance.

```
[edit routing-instances]
user@PE# set evpn-vpws-instance interface interface-name
```

For example, configure interface `ge-0/0/1.1004` for the EVPN-VPWS instance `vpws1004`.

```
[edit routing-instances]
user@PE# set vpws1004 interface ge-0/0/1.1004
```

3. Configure the route distinguisher for the EVPN-VPWS routing instance.

```
[edit routing-instances]
user@PE# set evpn-vpws-instance route-distinguisher route-distinguisher-value
```

For example, configure route distinguisher `10.255.0.1:100` for EVPN-VPWS routing instance `vpws1004`.

```
[edit routing-instances]
user@PE# set vpws1004 route-distinguisher 10.255.0.1:100
```

4. Configure the VPN routing and forwarding (VRF) target community for the EVPN-VPWS routing instance.

```
[edit routing-instances]
user@PE# set evpn-vpws-instance vrf-target vrf-target
```

For example, configure VRF target `target:100:1004` for EVPN-VPWS routing instance `vpws1004`.

```
[edit routing-instances]
user@PE# set vpws1004 vrf-target target:100:1004
```

5. Configure the interface of a routing instance with local and remote service identifiers. These identifiers identify the PE routers that forward and receive the traffic in the EVPN-VPWS network. The local service identifier is used to identify the PE router that is forwarding the traffic, and the remote service identifier is used to identify the PE router that is receiving the traffic in the network.

```
[edit routing-instances evpn-vpws-instance protocols evpn interface interface-name]
user@PE# set vpws-service-id local local-service-id
user@PE# set vpws-service-id remote remote-service-id
```

For example, configure the interface `ge-0/0/1.1004` with the local and remote service identifiers 1004 and 2004 for EVPN-VPWS routing instance `vpws1004`.

```
[edit routing-instances vpws1004 protocols evpn interface ge-0/0/1.1004]
user@PE# set vpws-service-id local 1004
user@PE# set vpws-service-id remote 2004
```

## Example: Configuring VPWS with EVPN Signaling Mechanisms

This example shows how to implement Virtual Private Wire Service (VPWS) with Ethernet Virtual Private Network (EVPN) signaling. The use of EVPN signaling provides single-active or all-active multihoming capabilities for BGP-signaled VPNs.

- [Requirements on page 1103](#)
- [Overview and Topology on page 1103](#)
- [Configuration on page 1104](#)
- [Verification on page 1114](#)

### Requirements

This example uses the following hardware and software components:

- Four MX Series routers acting as provider edge (PE) devices, running Junos OS Release 17.1 or later
- Two customer edge (CE) devices (MX Series routers are used in this example)

### Overview and Topology

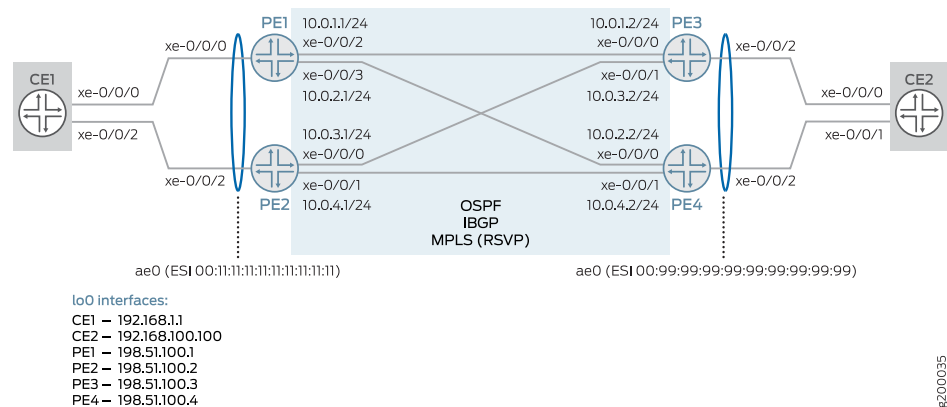

VPWS employs Layer 2 VPN services over MPLS to build a topology of point-to-point connections that connect end customer sites. EVPN enables you to connect dispersed customer sites using a Layer 2 virtual bridge. Starting with Junos OS Release 17.1, these two elements can be combined to provide an EVPN-signaled VPWS.

The **vpws-service-id** statement identifies the endpoints of the EVPN-VPWS based on **local** and **remote** service identifiers configured on the PE routers in the network. These endpoints are autodiscovered using BGP-based EVPN signaling to exchange the service identifier labels.

#### Topology

This example uses the topology shown in [Figure 114 on page 1104](#), consisting of four PE routers and two CE routers. Router CE1 is multihomed to Routers PE1 and PE2; Router CE2 is multihomed to Routers PE3 and PE4.

Figure 114: VPWS with EVPN Signaling

E200035

The following configuration elements are used in this scenario:

- CE devices:
  - Aggregated Ethernet (AE) interface towards related PE devices
- PE devices:
  - AE interface, with EVPN segment identifier (ESI), towards related CE device
  - OSPF and IBGP in the core
  - MPLS LSPs using RSVP in the core
  - Per-packet load balancing
  - Routing instance using instance type **evpn-vpws**, and the **vpws-service-id** statement to define the local and remote endpoints.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

CE1 set interfaces xe-0/0/0 gigether-options 802.3ad ae0
 set interfaces xe-0/0/2 gigether-options 802.3ad ae0
 set chassis aggregated-devices ethernet device-count 1
 set interfaces ae0 description "to PE1/2"
 set interfaces ae0 flexible-vlan-tagging
 set interfaces ae0 encapsulation flexible-ethernet-services
 set interfaces ae0 aggregated-ether-options lacp active
 set interfaces ae0 unit 100 encapsulation vlan-bridge
 set interfaces ae0 unit 100 vlan-id 1000
 set interfaces lo0 unit 0 family inet address 192.168.1.1/32
 set policy-options policy-statement LB then load-balance per-packet
 set routing-options forwarding-table export LB
 set bridge-domains bd100 domain-type bridge
 set bridge-domains bd100 vlan-id 1000

```

```
set bridge-domains bd100 interface ae0.100
```

```
CE2 set interfaces xe-0/0/0 gigether-options 802.3ad ae0
 set interfaces xe-0/0/1 gigether-options 802.3ad ae0

```

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

**NOTE:** Only Router PE1 is shown here. Repeat this procedure for all other PE devices, using the appropriate interface names, addresses, and other parameters for each device.

The step-by-step procedure for CE devices is not shown.

To configure Router PE1:

1. Configure the CE-facing interface to be part of the ae0 bundle.

The second interface for the AE bundle will be configured on the other local PE device.

```
[edit interfaces]
user@PE1# set xe-0/0/0 description "to CE1"
user@PE1# set xe-0/0/0 gigether-options 802.3ad ae0
```

2. Configure the core-facing interfaces toward Routers PE3 and PE4.

Be sure to include the MPLS protocol family.

```
[edit interfaces]
user@PE1# set xe-0/0/2 unit 0 description "to PE3"
user@PE1# set xe-0/0/2 unit 0 family inet address 10.0.1.1/24
user@PE1# set xe-0/0/2 unit 0 family mpls
user@PE1# set xe-0/0/3 unit 0 description "to PE4"
user@PE1# set xe-0/0/3 unit 0 family inet address 10.0.2.1/24
user@PE1# set xe-0/0/3 unit 0 family mpls
```

3. Configure the loopback interface.

```
[edit interfaces]
user@PE1# set lo0 unit 0 family inet address 198.51.100.1/32
```

4. Define the number of aggregated Ethernet interfaces to be supported on the device.

```
[edit chassis]
user@PE1# set aggregated-devices ethernet device-count 1
```

5. Configure the ae0 interface.

Alternate VLAN tagging and encapsulation options can be used, depending on your needs.

```
[edit interfaces]
user@PE1# set ae0 description "to CE1"
user@PE1# set ae0 flexible-vlan-tagging
user@PE1# set ae0 encapsulation flexible-ethernet-services
```

```
user@PE1# set ae0 unit 100 encapsulation vlan-ccc
user@PE1# set ae0 unit 100 vlan-id 1000
```

6. Assign an Ethernet segment identifier (ESI) value to the ae0 interface and enable EVPN active-active multihoming.

```
[edit interfaces]
user@PE1# set ae0 esi 00:11:11:11:11:11:11:11
user@PE1# set ae0 esi all-active
```

7. Configure link aggregation control protocol (LACP) for the ae0 interface.

The system ID used here must be the same on both local PE devices.

```
[edit interfaces]
user@PE1# set ae0 aggregated-ether-options lacp active
user@PE1# set ae0 aggregated-ether-options lacp system-id 00:00:00:00:00:01
```

8. Enable OSPF on the core-facing (and loopback) interfaces.

```
[edit protocols]
user@PE1# set ospf area 0.0.0.0 interface xe-0/0/2.0
user@PE1# set ospf area 0.0.0.0 interface xe-0/0/3.0
user@PE1# set ospf area 0.0.0.0 interface lo0.0
```

9. Configure an IBGP mesh with the other PE devices, using EVPN for signaling.

```
[edit routing-options]
user@PE1# set autonomous-system 65000
[edit protocols]
user@PE1# set bgp group IBGP type internal
user@PE1# set bgp group IBGP local-address 198.51.100.1
user@PE1# set bgp group IBGP family evpn signaling
user@PE1# set bgp group IBGP neighbor 198.51.100.2
user@PE1# set bgp group IBGP neighbor 198.51.100.3
user@PE1# set bgp group IBGP neighbor 198.51.100.4
```

10. Enable RSVP on the core-facing interfaces.

```
[edit protocols]
user@PE1# set rsvp interface xe-0/0/2.0
user@PE1# set rsvp interface xe-0/0/3.0
```

11. Enable MPLS on the core-facing interfaces, and configure LSPs to the remote PE devices.

For this example, be sure to disable CSPF.

```
[edit protocols]
user@PE1# set mpls interface xe-0/0/2.0
user@PE1# set mpls interface xe-0/0/3.0
user@PE1# set mpls no-cspf
user@PE1# set mpls label-switched-path PE1toPE3 to 198.51.100.3
user@PE1# set mpls label-switched-path PE1toPE4 to 198.51.100.4
```

12. Configure load balancing.

```
[edit policy-options]
user@PE1# set policy-statement LB then load-balance per-packet
[edit routing-options]
user@PE1# set forwarding-table export LB
```

13. Configure a routing instance using the **evpn-vpws** instance type. Add the AE (CE-facing) interface configured earlier, as well as a route distinguisher and VRF target.

In EVPN terms, this is an EVPN instance (EVI).

```
[edit routing-instances]
user@PE1# set EVPN-VPWS instance-type evpn-vpws
user@PE1# set EVPN-VPWS interface ae0.100
user@PE1# set EVPN-VPWS route-distinguisher 198.51.100.1:11
user@PE1# set EVPN-VPWS vrf-target target:100:11
```

14. In the routing instance, enable EVPN and add the AE interface. Then associate local and remote VPWS identifiers to the interface.

```
[edit routing-instances]
user@PE1# set EVPN-VPWS protocols evpn interface ae0.100 vpws-service-id local
1111
user@PE1# set EVPN-VPWS protocols evpn interface ae0.100 vpws-service-id
remote 9999
```

## Results

From configuration mode, confirm your configuration. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

- [Verifying Local EVPN Table Route Information on page 1119](#)

### Verifying Agregated Ethernet Interfaces and LACP

**Purpose** Verify that the AE interfaces are up and properly.

**Action** Verify that the AE interfaces are up, and LACP connections are established between the PE devices and their related CE device..

```
user@CE1> show lacp interfaces extensive
```

```

1

```

**Meaning** The AE interface on each device is up, and there are active LACP connections between the CE device and its local PE devices. Note also that the system ID configured on the PE devices, **00:00:00:00:00:01** (and shown on the PE device outputs as the **Actor**), matches the **Partner** system ID value on the CE device.

### Verifying OSPF

**Purpose** Verify that OSPF is working properly.

**Action** Verify that OSPF has adjacencies established with its remote neighbors.

```
user@PE1> show ospf neighbor
```

```

Address Interface State ID Pri Dead
10.0.1.2 #PE3# xe-0/0/2.0 Full 198.51.100.3 128 37
10.0.2.2 #PE4# xe-0/0/3.0 Full 198.51.100.4 128 33

```

```
user@PE3> show ospf neighbor
```

```

Address Interface State ID Pri Dead

10.0.3.1 #PE2# xe-0/0/1.0 Full 198.51.100.2 128 34

```

**Meaning** Adjacencies have been established with remote neighbors.

### Verifying BGP

**Purpose** Verify that BGP is working properly.

**Action** Verify that IBGP has peerings established with its neighbors using EVPN signaling.

```

```

**Meaning** The outputs show the ESI routes being shared across the VPWS to the remote PE devices.

The routes beginning with **1:198.51.100.x:0::** are the per-Ethernet-segment autodiscovery Type 1 EVPN routes originating from the remote PE devices. The route distinguishers (RDs) are derived at the global level of the devices.

The routes beginning with **1:198.51.100.x:11::** are the per-EVI autodiscovery Type 1 EVPN routes from the remote PE devices. The RDs are taken from the remote PE devices' routing instances.

## Verifying Local EVPN Table Route Information

**Purpose** Verify that the local EVPN routing tables are being populated.

|               |                                                                                                |
|---------------|------------------------------------------------------------------------------------------------|
| <b>Action</b> | Verify that both local and remote reachability information is being added into the EVPN table. |
|---------------|------------------------------------------------------------------------------------------------|

```

 Indirect

```

**Meaning** In addition to the remote ESI routes being shared across the VPWS, as explained in the previous section, the EVPN table on each PE device also includes a local ESI route. This Type 1 route represents the locally configured Ethernet segment, and is derived from the locally configured RD and ESI values.

- [Supported Platforms and PICs on page 1126](#)

## Introduction to VPLS

---

VPLS is an Ethernet-based point-to-multipoint Layer 2 VPN. It allows you to connect geographically dispersed Ethernet local area networks (LAN) sites to each other across an MPLS backbone. For customers who implement VPLS, all sites appear to be in the same Ethernet LAN even though traffic travels across the service provider's network.

**NOTE:** In ACX Series routers, VPLS configuration is supported only on ACX5048 and ACX5096 routers.

VPLS, in its implementation and configuration, has much in common with a Layer 2 VPN. In VPLS, a packet originating within a service provider customer's network is sent first to a customer edge (CE) device (for example, a router or Ethernet switch). It is then sent to a provider edge (PE) router within the service provider's network. The packet traverses the service provider's network over a MPLS label-switched path (LSP). It arrives at the egress PE router, which then forwards the traffic to the CE device at the destination customer site.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The difference is that for VPLS, packets can traverse the service provider's network in point-to-multipoint fashion, meaning that a packet originating from a CE device can be broadcast to all the PE routers participating in a VPLS routing instance. In contrast, a Layer 2 VPN forwards packets in point-to-point fashion only.

The paths carrying VPLS traffic between each PE router participating in a routing instance are called pseudowires. The pseudowires are signaled using either BGP or LDP.

## Supported VPLS Standards

---

Junos OS substantially supports the following Internet RFCs and draft, which define standards for virtual private LAN service (VPLS).

- RFC 4761, *Virtual Private LAN Service (VPLS) Using BGP for Auto-Discovery and Signaling*
- RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*

FEC 128, FEC 129, control bit 0, the Ethernet pseudowire type 0x0005, and the Ethernet tagged mode pseudowire type 0x0004 are supported.

- RFC 6391, *Flow-Aware Transport of Pseudowires over an MPLS Packet Switched Network*
- RFC 6790, *The Use of Entropy Labels in MPLS Forwarding*
- Internet draft draft-kompella-l2vpn-vpls-multihoming, *Multi-homing in BGP-based Virtual Private LAN Service*

## Supported Platforms and PICs

---

Virtual private LAN service (VPLS) is supported on all M Series routers except the M160.

VPLS is supported on all MX Series and T Series routers.

VPLS is supported on the following SRX Services Gateways for the branch:

- SRX100
- SRX210
- SRX240
- SRX650

VPLS is supported on the following PICs:

- All ATM2 IQ PICs
- 4-port Fast Ethernet PIC with 10/100 Base-TX interfaces PIC
- 1-port, 2-port, and 10-port Gigabit Ethernet PICs

- 1-port, 2-port, and 4-port Gigabit Ethernet PICs with SFP
- 1-port 10-Gigabit Ethernet PIC
- 1-port and 2-port Gigabit Ethernet Intelligent Queuing (IQ) PICs
- 4-port and 8-port Gigabit Ethernet IQ2 PICs with SFP
- 1-port 10-Gigabit Ethernet IQ2 PIC with XFP
- 4-port, quad-wide Gigabit Ethernet PIC
- 10-port 10-Gigabit OSE PIC

# VPLS Configuration Overview

- [Introduction to Configuring VPLS on page 1129](#)
- [Configuring an Ethernet Switch as the CE Device for VPLS on page 1130](#)

## Introduction to Configuring VPLS

---

Virtual private LAN service (VPLS) allows you to provide a point-to-multipoint LAN between a set of sites in a virtual private network (VPN).

**NOTE:** In ACX Series routers, VPLS configuration is supported only on ACX5048 and ACX5096 routers.

To configure VPLS functionality, you must enable VPLS support on the provider edge (PE) router. You must also configure PE routers to distribute routing information to the other PE routers in the VPLS and configure the circuits between the PE routers and the customer edge (CE) routers.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Each VPLS is configured under a routing instance of type **vpls**. A **vpls** routing instance can transparently carry Ethernet traffic across the service provider's network. As with other routing instances, all logical interfaces belonging to a VPLS routing instance are listed under that instance.

In addition to VPLS routing instance configuration, you must configure MPLS label-switched paths (LSPs) between the PE routers, IBGP sessions between the PE routers, and an interior gateway protocol (IGP) on the PE and provider (P) routers.

By default, VPLS is disabled.

Many configuration procedures for VPLS are identical to the procedures for Layer 2 VPNs and Layer 3 VPNs.

## Configuring an Ethernet Switch as the CE Device for VPLS

---

For VPLS configurations, the CE device does not necessarily need to be a router. You can link the PE routers directly to Ethernet switches. However, there are a few configuration issues to be aware of:

- When you configure VPLS routing instances and establish two or more connections between a CE Ethernet switch and a PE router, you must enable the Spanning Tree Protocol (STP) on the switch to prevent loops.
- The Junos OS allows standard Bridge Protocol Data Unit (BPDU) frames to pass through emulated Layer 2 connections, such as those configured with Layer 2 VPNs, Layer 2 circuits, and VPLS instances. However, CE Ethernet switches that generate proprietary BPDU frames might not be able to run STP across Juniper Networks routing platforms configured for these emulated Layer 2 connections.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

## VPLS Routing and Virtual Ports

---

Because VPLS carries Ethernet traffic across a service provider network, it must mimic an Ethernet network in some ways. When a PE router configured with a VPLS routing instance receives a packet from a CE device, it first determines whether it has the destination of the VPLS packet in the appropriate routing table. If it does, it forwards the packet to the appropriate PE router or CE device. If it does not, it broadcasts the packet to all other PE routers and CE devices that are members of that VPLS routing instance. In both cases, the CE device receiving the packet must be different from the one sending the packet.

**NOTE:** In the VPLS documentation, the term *router* is used to refer to any device that provides routing functions.

When a PE router receives a packet from another PE router, it first determines whether it has the destination of the VPLS packet in the appropriate routing table. If it does, the PE router either forwards the packet or drops it depending on whether the destination is a local or remote CE device:

- If the destination is a local CE device, the PE router forwards the packet to it.
- If the destination is a remote CE device (connected to another PE router), the PE router discards the packet.

If the PE router cannot determine the destination of the VPLS packet, it floods the packet to all attached CE devices.

This process is illustrated in [Figure 115 on page 1132](#).

**Figure 115: Flooding a Packet with an Unknown Destination to All PE Routers in the VPLS Instance**

VPLS can be directly connected to an Ethernet switch. Layer 2 information gathered by an Ethernet switch (for example, media access control [MAC] addresses and interface ports) is included in the VPLS routing instance table. However, instead of all VPLS interfaces being physical switch ports, the router allows remote traffic for a VPLS instance to be delivered across an MPLS LSP and arrive on a virtual port. The virtual port emulates a local, physical port. Traffic can be learned, forwarded, or flooded to the virtual port in almost the same way as traffic is sent to a local port.

The VPLS routing table learns MAC address and interface information for both physical and virtual ports. The main difference between a physical port and a virtual port is that the router captures additional information from the virtual port, an outgoing MPLS label used to reach the remote site and an incoming MPLS label for VPLS traffic received from the remote site. The virtual port is generated dynamically on a Tunnel Services Physical Interface Card (PIC) when you configure VPLS on the router.

You can also configure VPLS without a Tunnel Services PIC. To do so, you use a label-switched interface (LSI) to provide VPLS functionality. An LSI MPLS label is used as the inner label for VPLS. This label maps to a VPLS routing instance. On the PE router, the LSI label is stripped and then mapped to a logical LSI interface. The Layer 2 Ethernet frame is then forwarded using the LSI interface to the correct VPLS routing instance.

One restriction on flooding behavior in VPLS is that traffic received from remote PE routers is never forwarded to other PE routers. This restriction helps prevent loops in the core network. However, if a CE Ethernet switch has two or more connections to the same PE router, you must enable the Spanning Tree Protocol (STP) on the CE switch to prevent loops. STP is supported on MX Series routers and EX Series switches only.

The Junos OS allows standard Bridge Protocol Data Unit (BPDU) frames to pass through emulated Layer 2 connections, such as those configured with Layer 2 VPNs, Layer 2 circuits, and VPLS routing instances. However, CE Ethernet switches that generate proprietary BPDU frames might not be able to run STP across Juniper Networks routing platforms configured for these emulated Layer 2 connections.

**NOTE:** Under certain circumstances, VPLS provider routers might duplicate an Internet Control Message Protocol (ICMP) reply from a CE router when a PE router has to flood an ICMP request because the destination MAC address has not yet been learned. The duplicate ICMP reply can be triggered when a CE router with promiscuous mode enabled is connected to a PE router. The PE router automatically floods the promiscuous mode-enabled CE router, which then returns the ICMP request to the VPLS provider routers. The VPLS provider routers consider the ICMP request to be new and flood the request again, creating a duplicate ping reply.

## BGP Signaling for VPLS PE Routers Overview

BGP can autonomously signal pseudowires between the PE routers participating in the same virtual private LAN service (VPLS) network. As PE routers are added to and removed from the VPLS network, BGP can signal pseudowires to new PE routers and tear down old pseudowires to old PE routers. Each PE router only needs to be configured with the identity of the VPLS routing instance. Each PE router does not need to be configured with the identities of all of the PE routers that are or might become a part of the VPLS network.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

When you configure BGP for signaling in a VPLS network, customer sites can be either single-homed to a single PE router or multihomed to two or more PE routers. Multihoming provides redundancy for the connection between the customer site and the service provider's network.

You can either configure all of the PE routers in the VPLS network as a full mesh or you can use BGP route reflectors. For full mesh configurations, each PE router needs to be able to create a bidirectional pseudowire to each of the other PE routers participating in the VPLS network.

## Control Word for BGP VPLS Overview

---

In a BGP VPLS network, transit routers must determine the payload for hash calculations for load balancing. While parsing an MPLS encapsulated packet for hashing, a transit router can incorrectly calculate an Ethernet payload as an IPv4 or IPv6 payload if the first nibble of the destination address MAC is 0x4 or 0x6, respectively. This false positive can cause out-of-order packet delivery over a pseudowire. This issue can be avoided by configuring a BGP VPLS edge (VE) router to request that other BGP VE routers insert a control word between the label stack and the MPLS payload.

By inserting a control word between the label stack and the Layer 2 header of a packet traversing a VPLS, the first nibble of the destination address MAC can be ensured to be 0, thus preventing the packet from being identified as an IPv4 or IPv6 packet. All VE routers should want incoming packets to contain control words.

BGP is used to negotiate the support for control words between VE routers. You configure a VE router with the [control-word \(BGP VPLS\)](#) parameter to indicate the preference to receive packets with the control word. By setting the control word, the VE router expects that all frames marked with a label from the VPLS contain the control word. When remote VE routers advertise their NLRI, if the control word is set on them as well, both ends of the pseudowire have control-word support and the control word is expected in packets arriving at the VE routers in both directions.

If a VE router doesn't have the control word set, a VE router that does have a control word set will act as if the VE router without the control word can neither send nor accept BGP VPLS packets with a control word included.

  - [control-word \(BGP VPLS\) on page 1757](#)

## Configuring a Control Word for BGP VPLS

In a BGP VPLS network, transit routers must determine the payload for hash calculations for load balancing. While parsing an MPLS encapsulated packet for hashing, a transit router can incorrectly calculate an Ethernet payload as an IPv4 or IPv6 payload if the first nibble of the destination address MAC is 0x4 or 0x6, respectively. This false positive can cause out-of-order packet delivery over a pseudowire. This issue can be avoided by configuring a BGP VPLS PE router to request that other BGP VPLS edge (VE) routers insert a control word between the label stack and the MPLS payload.

**WARNING:** If you attempt to set a control word in a VPLS network that contains a VE router that does not support a control word, the pseudowire will not come up. To ensure that the pseudowire comes up, be sure that all VE routers in the VPLS network support the presence of a control word.

Before configuring support for a control word in a BGP VPLS network, ensure that the router meets the following requirements:

- MX Series router running Junos OS Release 14.1 or later and containing one of the following Flexible PIC Concentrators: ADPC, NPC, or I-Chip
- OR
- M320 router running Junos OS Release 14.1 or later and containing either the I-Chip or the Trio

To configure a VE router to expect a control word between the label stack and the MPLS payload:

1. At the **[edit routing-instances]** hierarchy level in configuration mode, set **control-word** for the VPLS protocol for the specified routing instance.

```
[edit routing-instances]
user@host# set routing-instance-name protocols vpls control-word
```

For example:

```
[edit routing-instances]
user@host# set vpls1 protocols vpls control-word
```

2. If you are setting **control-word** on a Trio-based MPC on an MX Series router, set **no-ether-pseudowire** to omit the IP payload over the Ethernet pseudowire from the hash key.

```
[edit forwarding-options]
user@host# set enhanced-hash-key family mpls no-ether-pseudowire
```

3. Verify the configuration.

```
[edit routing-instances]
user@host# show
```

```

vpls1 {
 protocols {
 vpls {
 control-word;
 }
 }
}

[edit forwarding-options]
user@host# show
enhanced-hash-key {
 family mpls {
 no-ether-pseudowire;
 }
}

```

4. Repeat the configuration on each VE router in the BGP VPLS network.
5. Run **show vpls connections instance *routing-instance-name* extensive** to verify the presence of a control word for the pseudowire.

For example:

```

user@host# show vpls connections instance vpls1 extensive
Layer-2 VPN connections:

Legend for connection status (St)
EI -- encapsulation invalid NC -- interface encapsulation not CCC/TCC/VPLS
...
PF -- Profile parse failure PB -- Profile busy

Legend for interface status
Up -- operational
Dn -- down

Instance: vpls1
...

```

| connection-site | Type | St | Time last up         | # Up trans |
|-----------------|------|----|----------------------|------------|
| 1               | rmt  | Up | May 21 10:08:34 2013 | 2          |

```

Remote PE: 192.0.2.0, Negotiated control-word: Yes

```

  - [no-control-word \(BGP VPLS\) on page 1853](#)

## BGP Route Reflectors for VPLS

In large networks, it might be necessary to configure BGP route reflectors to reduce the control plane workload for the routers participating in the VPLS network. BGP route reflectors can help to reduce the workload of the network control plane in the following ways.

- Making it unnecessary to configure all of the VPLS PE routers in a full mesh.

- Limiting the total volume of BGP VPLS messages exchanged within the network by transmitting messages to interested routers only (instead of all of the BGP routers in the network)
- Reducing the network signaling load whenever another BGP router is added to or removed from the network

The basic solution to these problems is to deploy a small group of BGP route reflectors that are in a full mesh with one another. Each of the VPLS PE routers is configured to have a BGP session with one or more of the route reflectors, making it unnecessary to maintain a full mesh of BGP sessions between all of the PE routers.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

This type of configuration only affects the control plane of the VPLS network (how routers signal and tear down pseudowires to one another in the network). The actual data plane state and forwarding paths for the VPLS traffic are not modified by the route reflectors. Effectively, the VPLS pseudowires should take the same paths across the network whether or not you have configured route reflectors. For a description of how VPLS selects the best path to a PE router, see “[VPLS Path Selection Process for PE Routers](#)” on page 180.

The MAC addresses themselves are not exchanged or processed in any way by BGP. Each VPLS PE router performs all MAC address learning and aging individually. BGP's only function relative to VPLS is to exchange messages related to automatic discovery of PE routers being added to and removed from the VPLS network and the MPLS label exchange needed to signal a pseudowire from one PE router to another.

## Interoperability Between BGP Signaling and LDP Signaling in VPLS

---

You can configure a VPLS routing instance where some of the PE routers use BGP for signaling and some use LDP for signaling.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The following concepts form the basis of the configuration needed to include both BGP-signaled and LDP-signaled PE routers in a VPLS routing instance:

- **PE router mesh group**—Consists of a set of routers participating in a VPLS routing instance that share the same signaling protocol, either BGP or LDP, and are also fully meshed. Each VPLS routing instance can have just one BGP mesh group. However, you can configure multiple LDP mesh groups for each routing instance.
- **Border router**—A PE router that must be reachable by all of the other PE routers participating in a VPLS routing instance, whether they are LDP-signaled or BGP-signaled. Bidirectional pseudowires are created between the border router and all of these PE routers. The border router is aware of the composition of each PE mesh group configured as a part of the VPLS routing instance. It can also have direct connections to local CE routers, allowing it to act as a typical PE router in a VPLS routing instance.

The following sections describe how the LDP-signaled and BGP-signaled PE routers function when configured to interoperate within a VPLS routing instance:

- [LDP-Signaled and BGP-Signaled PE Router Topology on page 1138](#)
- [Flooding Unknown Packets Across Mesh Groups on page 1140](#)
- [Unicast Packet Forwarding on page 1140](#)

### LDP-Signaled and BGP-Signaled PE Router Topology

[Figure 116 on page 1139](#) illustrates a topology for a VPLS routing instance configured to support both BGP and LDP signaling. Router B is the border router. Routers PE1 and PE2 are in the LDP-signaled mesh group LDP-1. Routers PE3, PE4, and PE5 are in the LDP-signaled mesh group LDP-2. Routers PE6, PE7, PE8, and router B (the border router) are in the BGP-signaled mesh group. The border router also acts as a standard VPLS PE router (having local connections to CE routers). All of the PE routers shown are within the same VPLS routing instance.

Figure 116: BGP and LDP Signaling for a VPLS Routing Instance

Two-way pseudowires are established between the PE routers in each mesh group and between each PE router in the VPLS routing instance and the border router. In [Figure 116 on page 1139](#), two-way pseudowires are established between routers PE1 and PE2 in mesh group LDP-1, routers PE3, PE4, and PE5 in mesh group LDP-2, and routers PE6, PE7, and PE8 in the BGP mesh group. Routers PE1 through PE8 also all have two-way pseudowires to the Border router. Based on this topology, the LDP-signaled routers are able to interoperate with the BGP-signaled routers. Both the LDP-signaled and BGP-signaled PE routers can logically function within a single VPLS routing instance.

**NOTE:** The following features are not supported for VPLS routing instances configured with both BGP and LDP signaling:

- Point-to-multipoint LSPs
- Integrated routing and bridging
- IGMP snooping

## Flooding Unknown Packets Across Mesh Groups

Broadcast, multicast, and unicast packets of unknown origin received from a PE router are flooded to all local CE routers. They are also flooded to all of the PE routers in the VPLS routing instance except the PE routers that are a part of the originating PE router mesh group.

For example, if a multicast packet is received by the border router in [Figure 116 on page 1139](#), it is flooded to the two local CE routers. It is also flooded to routers PE1 and PE2 in the LDP-1 mesh group and to routers PE3, PE4, and PE5 in the LDP-2 mesh group. However, the packet is not flooded to routers PE6, PE7, and PE8 in the BGP mesh group.

## Unicast Packet Forwarding

The PE border router is made aware of the composition of each PE router mesh group. From the data plane, each PE router mesh group is viewed as a virtual pseudowire LAN. The border router is configured to interconnect all of the PE router mesh groups belonging to a single VPLS routing instance. To interconnect the mesh groups, a common MAC table is created on the border router.

Unicast packets originating within a mesh group are dropped if the destination is another PE router within the same mesh group. However, if the destination MAC address of the unicast packet is a PE router located in a different mesh group, the packet is forwarded to that PE router.

## Configuring Interoperability Between BGP Signaling and LDP Signaling in VPLS

---

A single VPLS routing instance can encompass one set of PE routers that use BGP for signaling and another set of PE routers that use LDP for signaling. Within each set, all of the PE routers are fully meshed in both the control and data planes and have a bidirectional pseudowire to each of the other routers in the set. However, the BGP-signaled routers cannot be directly connected to the LDP-signaled routers. To be able to manage the two separate sets of PE routers in a single VPLS routing instance, a border PE router must be configured to interconnect the two sets of routers.

The VPLS RFCs and Internet drafts require that all of the PE routers participating in a single VPLS routing instance must be fully meshed in the data plane. In the control plane, each fully meshed set of PE routers in a VPLS routing instance is called a PE router mesh group. The border PE router must be reachable by and have bidirectional pseudowires to all of the PE routers that are a part of the VPLS routing instance, both the LDP-signaled and BGP-signaled routers.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

---

For LDP BGP interworking to function, LDP-signaled routers can be configured with forwarding equivalence class (FEC) 128 or FEC 129.

The following sections describe how to configure BGP LDP interworking for VPLS:

- [LDP BGP Interworking Platform Support on page 1141](#)
- [Configuring FEC 128 VPLS Mesh Groups for LDP BGP Interworking on page 1141](#)
- [Configuring FEC 129 VPLS Mesh Groups for LDP BGP Interworking on page 1142](#)
- [Configuring Switching Between Pseudowires Using VPLS Mesh Groups on page 1142](#)
- [Configuring Integrated Routing and Bridging Support for LDP BGP Interworking with VPLS on page 1143](#)
- [Configuring Inter-AS VPLS with MAC Processing at the ASBR on page 1143](#)

## LDP BGP Interworking Platform Support

LDP BGP interworking is supported on the following Juniper Networks routers and routing platforms:

- ACX5048
- ACX5096
- M7i
- M10i
- M40e
- M120
- M320
- MX Series routers
- T Series routers
- TX Matrix routers
- EX Series switches

## Configuring FEC 128 VPLS Mesh Groups for LDP BGP Interworking

To configure FEC 128 LDP BGP interworking for VPLS, include the **mesh-group** statement in the VPLS routing instance configuration of the PE border router:

```
mesh-group mesh-group-name {
 local-switching;
 mac-flush [explicit-mac-flush-message-options];
 neighbor address;
 peer-as all;
 vpls-id number;
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

Using the **neighbor** statement, configure each PE router that is a part of the mesh group. You must separate the LDP-signaled routers and the BGP-signaled routers into their own respective mesh groups. The LDP-signaled routers can be divided into multiple mesh groups. The BGP-signaled routers must be configured within a single mesh group for each routing instance.

## Configuring FEC 129 VPLS Mesh Groups for LDP BGP Interworking

Configuration for a mesh group for FEC 129 is very similar to the configuration for FEC 128.

Note the following differences for FEC 129:

- Each user-defined mesh group must have a unique route distinguisher. Do not use the route distinguisher that is defined for the default mesh group at the **[edit routing-instances]** hierarchy level.
- Each user-defined mesh group must have its own import and export route target.
- Each user-defined mesh group can have a unique Layer 2 VPN ID. By default, all the mesh groups that are configured for the a VPLS routing-instance use the same Layer 2 VPN ID, the one that you configure at the **[edit routing-instances]** hierarchy level.

## Configuring Switching Between Pseudowires Using VPLS Mesh Groups

To configure switching between Layer 2 circuit pseudowires using VPLS mesh groups, you can do either of the following:

- Configure a mesh group for each Layer 2 circuit pseudowire terminating at a VPLS routing instance. The Junos OS can support up to 16 mesh groups on MX Series routers and up to 128 on M Series and T Series routers. However, two mesh groups are created by default, one for the CE routers and one for the PE routers. Therefore, the maximum number of user-defined mesh groups is 14 for MX Series routers and 126 for M Series and T Series routers.
- Configure a single mesh group, terminate all the Layer 2 circuit pseudowires into it, and enable local switching between the pseudowires by including the **local-switching** statement at the **[edit routing-instances routing-instance-name protocols vpls mesh-group mesh-group-name]** hierarchy level. By default, you cannot configure local switching for mesh groups (except for the CE mesh group) because all of the VPLS PE routers must be configured in a full mesh. However, local switching is useful if you are terminating Layer 2 circuit pseudowires in a mesh group configured for an LDP signaled VPLS routing instance.

**NOTE:** Do not include the **local-switching** statement on PE routers configured in a full mesh VPLS network.

---

To terminate multiple pseudowires at a single VPLS mesh group, include the **local-switching** statement:

**local-switching;**

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*]

## Configuring Integrated Routing and Bridging Support for LDP BGP Interworking with VPLS

Beginning with Junos OS Release 9.4, you can configure an integrated routing and bridging (IRB) interface on a router that functions as an autonomous system border router (ASBR) in an inter-AS VPLS environment between BGP-signaled VPLS and LDP-signaled VPLS. Previously, IRB interfaces were supported only on Provider Edge (PE) routers.

**NOTE:** ACX Series routers do not support configuring IRB for LDP BGP Interworking with VPLS.

To configure a IRB support for LDP BGP Interworking with VPLS, include the **routing-interface** *interface-name* statement.

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name*]
- [edit logical-routers *logical-router-name* routing-instances *routing-instance-name*]

## Configuring Inter-AS VPLS with MAC Processing at the ASBR

Inter-AS VPLS with MAC processing at the ASBR enables you to interconnect customer sites that are located in different ASs. In addition, you can configure the ASs with different signaling protocols. You can configure one of the ASs with BGP-signaled VPLS and the other with LDP-signaled VPLS. For more information about how to configure LDP-signaled and BGP signaled VPLS, see [“Configuring Interoperability Between BGP Signaling and LDP Signaling in VPLS” on page 1140](#).

For inter-AS VPLS to function properly, you need to configure IBGP peering between the PE routers, including the ASBRs in each AS, just as you do for a typical VPLS configuration. You also need to configure EBGP peering between the ASBRs in the separate ASs. The EBGP peering is needed between the ASBRs only. The link between the ASBR routers does not have to be Ethernet. You can also connect a CE router directly to one of the ASBRs, meaning you do not have to have a PE router between the ASBR and the CE router.

The configuration for the connection between the ASBRs makes inter-AS VPLS with MAC operations unique. The other elements of the configuration are described in other sections of this manual.

The following sections describe how to configure inter-AS VPLS with MAC operations:

- [Inter-AS VPLS with MAC Operations Configuration Summary on page 1144](#)
- [Configuring the ASBRs for Inter-AS VPLS on page 1144](#)

### [Inter-AS VPLS with MAC Operations Configuration Summary](#)

---

This section provides a summary of all of the elements which must be configured to enable inter-AS VPLS with MAC operations. These procedures are described in detail later in this chapter and in other parts of the *Junos OS VPNs Library for Routing Devices*.

The following lists all of major elements of an inter-AS VPLS with MAC operations configuration:

- Configure IBGP between all of the routers within each AS, including the ASBRs.
- Configure EBGP between the ASBRs in the separated ASs. The EBGP configuration includes the configuration that interconnects the ASs.
- Configure a full mesh of LSPs between the ASBRs.
- Configure a VPLS routing instance encompassing the ASBR routers. The ASBRs are VPLS peers and are linked by a single pseudowire. Multihoming between ASs is not supported. A full mesh of pseudowires is needed between the ASBR routers in all of the interconnected ASs.
- Configure the VPLS routing instances using either BGP signaling or LDP signaling. LDP BGP interworking is supported for inter-AS VPLS with MAC operations, so it is possible to interconnect the BGP-signaled VPLS routing instances with the LDP-signaled VPLS routing instances.
- Configure a single VPLS mesh group for all of the ASBRs interconnected using inter-AS VPLS.

### [Configuring the ASBRs for Inter-AS VPLS](#)

---

This section describes the configuration on the ASBRs needed to enable inter-AS VPLS with MAC operations.

On each ASBR, you need to configure a VPLS mesh group within the VPLS routing instance which needs to include all of the PE routers within the AS, in addition to the ASBR. You need to configure the same mesh group for each of the ASs you want to interconnect using inter-AS VPLS. The mesh group name should be identical on each AS. You also must include the **peer-as all** statement. This statement enables the router to establish a single pseudowire to each of the other ASBRs.

To configure the mesh group on each ASBR, include the **mesh-group** and **peer-as all** statements:

```
mesh-group mesh-group-name {
 peer-as all;
}
```

You can include these statements at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name* protocols vpls]**

- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

Related Documentation

- [Example: Configuring BGP Autodiscovery for LDP VPLS on page 1350](#)
- [Example: Configuring BGP Autodiscovery for LDP VPLS with User-Defined Mesh Groups on page 1367](#)

Example: VPLS Configuration (BGP Signaling)

In [Figure 117 on page 1145](#), a simple VPLS topology is enabled between routers PE1 and PE2. CE routers CE1 and CE2 use Ethernet-based interfaces to connect VLAN 600 to their local PE router. The PE routers PE1 and PE2 are connected to one another by LSPs enabled across a service provider backbone running MPLS, BGP, RSVP, and OSPF.

In a VPLS routing instance named **green**, PE1 has a local interface **fe-0/1/0** and a virtual port of **vt-0/3/0.32770** (the virtual port is created dynamically on the Tunnel Services PIC when VPLS is configured). PE2 has a local interface **fe-0/1/0** and a virtual port of **vt-0/3/0.32771** in the same **green** instance. As a result, routers CE1 and CE2 send Ethernet traffic to one another as if they were physically connected to each other on a LAN.

On Router CE1, the only item you need to configure is the Fast Ethernet interface that connects to PE1. Be sure to write down the VLAN identifier and IP address, so you can match them later on CE2.

```
Router CE1 [edit]
interfaces {
 fe-0/1/0 {
 vlan-tagging; # Configure VLAN tagging for VLAN VPLS or extended VLAN VPLS.
 unit 0 {
 vlan-id 600; # The Ethernet interface on CE2 must use the same VLAN ID.
 family inet {
 address 10.11.3.1/24; # The interface on CE2 must use the same prefix.
 }
 }
 }
}
```

```
}
```

If Router PE1 is an MX Series device, you need to configure a tunnel service interface.

To create tunnel interfaces on an MX Series router, include the **tunnel-services** statement at the **[edit chassis fpc slot-number pic number]** hierarchy level. To configure the bandwidth for a tunnel interface, include the **bandwidth** statement at the **[edit chassis fpc slot-number pic number tunnel services]** hierarchy level.

The following example shows a tunnel interface with 1 Gbps of bandwidth configured on PFE 3 of the DPC installed in slot 0 of an MX Series router:

```
[edit chassis]
fpc 0 {
 pic 3 {
 tunnel services {
 bandwidth 1g;
 }
 }
}
```

On Router PE1, prepare the router for VPLS by configuring BGP, MPLS, OSPF, and RSVP. (These protocols are the basis for most Layer 2 VPN-related applications, including VPLS.) Include the **signaling** statement at the **[edit protocols bgp group group-name family l2vpn]** hierarchy level, because VPLS uses the same infrastructure for internal BGP as Layer 2 VPNs.

**NOTE:** In Junos OS Release 7.3 and later, the **signaling** statement replaces the **unicast** statement at the **[edit protocols bgp group group-name family l2vpn]** hierarchy level. You must use the **signaling** statement if you wish to configure VPLS domains and Layer 2 VPNs simultaneously.

Next, configure VLAN tagging on the Fast Ethernet interface connected to Router CE1. Include VLAN VPLS encapsulation at both the physical and logical interface levels. Be sure to use the same VLAN ID for all Ethernet interfaces that are part of a single VPLS instance. Finally, add the Fast Ethernet interface into a VPLS routing instance and specify the site range, site ID number, and site name.

```
Router PE1 [edit]
interfaces {
 fe-0/1/0 {
 vlan-tagging;# Configure VLAN tagging for VLAN VPLS or extended VLAN VPLS.
 encapsulation vlan-vpls; # Configure VPLS encapsulation on both the
 unit 0 { # physical interface and the logical interface.
 encapsulation vlan-vpls;
 vlan-id 600;# The VLAN ID is the same one used by the CE routers.
 }
 }

 }
 }
}

```

If Router PE2 is an MX Series device, you need to configure a tunnel service interfaces.

To create tunnel interfaces on an MX Series router, include the **tunnel-services** statement at the `[edit chassis fpc slot-number pic number]` hierarchy level. To configure the bandwidth for a tunnel interface, include the **bandwidth** statement at the `[edit chassis fpc slot-number pic number]` hierarchy level.

The following example shows a tunnel interface with 1 Gbps of bandwidth configured on PFE 3 of the DPC installed in slot 0 of an MX Series router:

```

[edit chassis]
fpc 0 {
 pic 3 {
 tunnel-services {
 bandwidth 1g;
 }
 }
}

```

On Router PE2, configure BGP, MPLS, OSPF, and RSVP to complement the configuration on PE1. Next, configure VLAN tagging on the Fast Ethernet interface connected to Router CE2. Include VLAN VPLS encapsulation at both the physical and logical interface levels. Be sure to use the same VLAN ID for all Ethernet interfaces that are part of a single VPLS instance. Finally, add the Fast Ethernet interface into a VPLS routing instance and specify the site range, site ID number, and site name.

```
Router PE2 [edit]
interfaces {
 fe-0/1/0 {
 vlan-tagging; # Configure VLAN tagging for VLAN VPLS or extended VLAN VPLS.
 encapsulation vlan-vpls; # Configure VPLS encapsulation on both the
 unit 0 { # physical interface and logical interface.
 encapsulation vlan-vpls;
 vlan-id 600;# The VLAN ID is the same one used by the CE routers.
 }
 }
 so-0/0/0 {

 }
 }
}
}

```

On Router CE2, complete your VPLS network by configuring the Fast Ethernet interface that connects to PE2. Use the same VLAN identifier and IP address prefix used on Router CE1.

**Router CE2**    [\[edit\]](#)  
 interfaces {

```

fe-0/1/0 {
 vlan-tagging; # Configure VLAN tagging for VLAN VPLS or extended VLAN VPLS.
 unit 0 {
 vlan-id 600; # The Ethernet interface on CE1 must use the same VLAN ID.
 family inet {
 address 10.11.3.2/24; # The interface on CE1 must use the same prefix.
 }
 }
}

```

## Verifying Your Work

To verify proper operation of VPLS, use the following commands:

- `clear vpls mac-address instance instance-name`
- `show interfaces terse`
- `show route forwarding-table family mpls`
- `show route forwarding-table family vpls (destination | extensive | matching | table)`
- `show route instance (detail)`
- `show system statistics vpls`
- `show vpls connections`
- `show vpls statistics`

The following section shows the output of these commands on Router PE1 as a result of the configuration example:

```

user@PE1> show interfaces terse

```

To display VPLS source and destination MAC address accounting information, use the **destination**, **extensive**, **matching**, or **table** option with the **show route forwarding-table family vpls** command. When you analyze the display output, keep in mind the following:

- VPLS MAC address accounting is handled on a per-MAC address basis for each VPLS instance. All information is retrieved from MAC address entries in the MAC address table. VPLS MAC address accounting is performed only on local CE routers.
- The VPLS counters for source and destination MAC addresses increment continuously until the oldest MAC address entries are removed from the memory buffer, either when the entries time out or if the VPLS instance is restarted.

To clear all MAC address entries for a VPLS instance from the VPLS table, issue the **clear vpls mac-address instance *instance-name*** command. Add the **logical-system *logical-system-name*** option to clear entries in a VPLS instance within a logical system. Use the **mac-address** option to remove individual MAC addresses.

## Example: VPLS Configuration (BGP and LDP Interworking)

Figure 118: Topology for VPLS Configuration Example

Figure 118 on page 1156, shows two VPLS mesh groups: LDP-1 and the default BGP mesh group. The VPLS instance is named **v1** in the configuration. Table 25 on page 1157 shows the addresses for the router interfaces in the example topology.

Table 25: Router Interface Addresses for VPLS Configuration Example

| Router | Interface                     | Address        |
|--------|-------------------------------|----------------|
| CE1    | fe-0/0/3 (link to Router PE1) | 10.12.31.1     |
|        | loopback                      | 10.12.53.1     |
| CE2    | fe-0/0/1 (link to Router PE2) | 10.12.31.2     |
|        | loopback                      | 10.12.53.2     |
| PE1    | t1-1/1/1 (link to Router PE2) | 10.12.100.17   |
|        | t1-0/1/0 (link to Router B)   | 10.12.100.2    |
|        | loopback                      | 10.255.170.106 |
| PE2    | t1-0/1/1 (link to Router PE1) | 10.12.100.18   |
|        | t1-0/1/3 (link to Router B)   | 10.12.100.6    |
|        | loopback                      | 10.255.170.104 |
| B      | t1-0/1/2 (link to Router PE1) | 10.12.100.1    |
|        | t1-0/1/3 (link to Router PE2) | 10.12.100.5    |
|        | so-0/2/2 (link to Router PE3) | 10.12.100.9    |
|        | fe-0/0/3 (link to Router PE4) | 10.12.100.13   |
|        | loopback                      | 10.255.170.98  |
| PE3    | s0-0/2/1 (link to Router B)   | 10.12.100.10   |
|        | so-0/2/2 (link to Router P0)  | 10.12.100.21   |
|        | loopback                      | 10.255.170.96  |
| P0     | so-0/2/1 (link to Router PE3) | 10.12.100.22   |
|        | t1-0/1/3 (link to Router PE4) | 10.12.100.25   |
|        | loopback                      | 10.255.170.100 |
| PE4    | fe-0/0/3 (link to Router B)   | 10.12.100.14   |
|        | t1-0/1/3 (link to Router P0)  | 10.12.100.26   |
|        | loopback                      | 10.255.170.102 |

**Table 25: Router Interface Addresses for VPLS Configuration Example (*continued*)**

| Router | Interface              | Address    |
|--------|------------------------|------------|
| CE3    | ge-1/2/1 (link to PE3) | 10.12.31.3 |
|        | loopback               | 10.12.53.3 |
| CE4    | fe-0/0/2 (link to PE4) | 10.12.31.4 |
|        | loopback               | 10.12.53.4 |

On Router CE3, the only item you need to configure is the Gigabit Ethernet interface that connects to PE3.

```
Router CE3 [edit]
 interfaces {
 ge-1/2/1 {
 unit 0 {
 family inet {
 address 10.12.31.1/24;
 }
 }
 }
 }
```

On Router PE3, prepare the router for VPLS by configuring BGP, MPLS, OSPF, and LDP. (These protocols are the basis for most Layer 2 VPN-related applications, including VPLS.) Include the **signaling** statement at the **[edit protocols bgp group *group-name* family l2vpn]** hierarchy level, because VPLS uses the same infrastructure for internal BGP as Layer 2 VPNs.

**NOTE:** In Junos OS Release 7.3 and later, the **signaling** statement replaces the **unicast** statement at the **[edit protocols bgp group *group-name* family l2vpn]** hierarchy level. You must use the **signaling** statement if you wish to configure VPLS domains and Layer 2 VPNs simultaneously.

Next, configure VLAN tagging on the Gigabit Ethernet interface connected to Router CE3. Finally, add the Gigabit Ethernet interface into a VPLS routing instance and specify the site range, site ID number, and site name.

```
Router PE3 [edit]
 interfaces {
 so-0/2/1 {
 unit 0 {
 family inet {
 address 10.12.100.10/30;
 }
 family mpls;
 }
 }
 }
```

```

so-0/2/2 {
 unit 0 {
 family inet {
 address 10.12.100.21/30;
 }
 family mpls;
 }
}
ge-1/3/1 {
 encapsulation ethernet-vpls;
 unit 0 {
 family vpls;
 }
}
}

 passive;
 }
 }
 }
}
ldp {
 interface t1-0/1/3.0;
 interface so-0/2/1.0;
}
}
```

On Router PE4, configure BGP, MPLS, OSPF, and LDP to complement the configuration on PE3. Next, configure VLAN tagging on the Fast Ethernet interface connected to Router CE4. Include VLAN VPLS encapsulation at both the physical and logical interface levels. Finally, add the Fast Ethernet interface into a VPLS routing instance and specify the site range, site ID number, and site name.

```
Router PE4 [edit]
interfaces {
 fe-0/0/2 {
 encapsulation ethernet-vpls;
```

```

 unit 0 {
 family vpls;
 }
 fe-0/0/3 {
 unit 0 {
 family inet {
 address 10.12.100.14/30;
 }
 family mpls;
 }

 }
 }
 }
 ldp {
 interface fe-0/0/3.0;
 interface t1-0/1/3.0;
 interface lo0.0;
 }
}

```

On Router CE4, configure the Fast Ethernet interface that connects to PE4.

**Router CE4**    [\[edit\]](#)

```

interfaces {
 fe-0/0/2 {
 unit 0 {
 family inet {
 address 10.12.31.4/24;
 }
 }
 }
}

```

On Router B, the area border router, configure the interfaces. Next, configure BGP, MPLS, OSPF, and LDP. Be sure to include the loopback interface in the LDP configuration by including the **interface lo0.0** statement at the **[edit protocols ldp]** hierarchy level. For BGP, include the **signaling** statement at the **[edit bgp group group-name family l2vpn]** hierarchy level. Last, configure the VPLS instance with both BGP and LDP signaling. Configure the LDP-1 mesh group by including the **mesh-group ldp1** statement at the **[edit routing-instances v1 protocols vpls]** hierarchy level.

```

Router B [edit]
interfaces {
 fe-0/0/3 {
 unit 0 {

 }
 }
 }
}
}

```

Finally, configure the LDP PE routers. On Router PE1, prepare the router for VPLS by configuring LDP, MPLS, and OSPF. Next, configure VPLS encapsulation on the Fast

Ethernet interface connected to CE1. Finally, add the Fast Ethernet interface to the routing instance, specifying the VPLS ID and the neighboring routers' loopback addresses.

```
Router PE1 [edit]
interfaces {
 fe-0/0/3 {
 encapsulation ethernet-vpls;
 unit 0 {
 family vpls;
 }
 }
 t1-0/1/0 {
 unit 0 {
 family inet {
 address 10.12.100.2/30;
 }
 family mpls;
 }
 }
 t1-1/1/1 {
 unit 0 {
 family inet {
 address 10.12.100.17/30;
 }
 family mpls;
 }
 }
}
protocols {
 mpls {
 interface all;
 }

 }
 }
 }
 ldp {
 interface t1-0/1/0.0;
 interface t1-1/1/1.0;
 interface lo0.0;
 }
}
routing-instances {
 v1 {
 instance-type vpls;
 interface fe-0/0/3.0;
 protocols {
 vpls {
 vpls-id 101;
 neighbor 10.255.170.98;
 }
 }
 }
}
```

```

 neighbor 10.255.170.104;
 }
}
}

```

Next, configure the Fast Ethernet interface on Router CE1 that connects to Router PE1.

```

Router CE1 [edit]
interfaces {
 fe-0/0/3 {
 unit 0 {
 family inet {
 address 10.12.31.1/24;
 }
 }
 }
}

```

On Router PE2, prepare the router for VPLS by configuring LDP, MPLS, and OSPF. Next, configure VPLS encapsulation on the Fast Ethernet interface connected to Router CE1. Finally, add the Fast Ethernet interface to the routing instance, specifying the VPLS ID and the neighboring routers' loopback addresses.

```

Router PE2 [edit]
interfaces {
 t1-0/1/1 {
 unit 0 {
 family inet {
 address 10.12.100.18/30;
 }
 family mpls;
 }
 }
 t1-0/1/3 {
 unit 0 {
 family inet {
 address 10.12.100.6/30;
 }
 family mpls;
 }
 }
 fe-1/0/2 {
 encapsulation ethernet-vpls;

 neighbor 10.255.170.98;
 neighbor 10.255.170.106;
 }
 }
 }
}
}
```

Finally, on Router CE2 configure the Fast Ethernet interface connected to PE2:

```
Router CE2 [edit]
interfaces {
 fe-0/0/1 {
 unit 0 {
 family inet {
 address 10.12.31.2/24;
 }
 }
 }
}
```

## Verifying Your Work

To verify proper operation of VPLS, use the following commands:

- `show bgp summary`
- `show ldp neighbor`
- `show vpls connections`
- `show route forwarding-table family vpls (destination | extensive | matching | table)`
- `show interfaces vt* terse`
- `show vpls flood extensive`
- `show vpls statistics`

The following section shows the output of some of these commands on Router B as a result of the configuration example.

Use the **show bgp summary** command to verify BGP signaling for VPLS is up.

```
user@B> show bgp summary
Groups: 1 Peers: 2 Down peers: 0
Table Tot Paths Act Paths Suppressed History Damp State Pending
bgp.l2vpn.0 2 2 0 0 0 0
Peer AS InPkt OutPkt OutQ Flaps Last Up/Dwn
State|#Active/Received/Damped...
10.255.170.96 65000 124 125 0 0 54:26 Establ
 bgp.l2vpn.0: 1/1/0
 v1.l2vpn.0: 1/1/0
10.255.170.102 65000 122 124 0 0 54:18 Establ
 bgp.l2vpn.0: 1/1/0
 v1.l2vpn.0: 1/1/0
```

Use the **show ldp neighbors** command to verify that LDP signaling for VPLS is up.

```
user@B> show ldp neighbors
Address Interface Label space ID Hold time
10.255.170.104 lo0.0 10.255.170.104:0 41
10.255.170.106 lo0.0 10.255.170.106:0 38
10.12.100.14 fe-0/0/3.0 10.255.170.102:0 12
10.12.100.10 so-0/2/2.0 10.255.170.96:0 14
10.12.100.2 t1-0/1/2.0 10.255.170.106:0 14
10.12.100.6 t1-0/1/3.0 10.255.170.104:0 13
```

To verify that the VPLS connections are up, use the **show vpls connections** command.

```
user@B> show vpls connections
Layer-2 VPN connections:

Legend for connection status (St)
EI -- encapsulation invalid NC -- interface encapsulation not CCC/TCC/VPLS

so-0/2/2.0

```

To display VPLS source and destination MAC address accounting information, use the **destination**, **extensive**, **matching**, or **table** option with the **show route forwarding-table family vpls** command. When you analyze the display output, keep in mind the following:

- VPLS MAC address accounting is handled on a per-MAC address basis for each VPLS instance. All information is retrieved from MAC address entries in the MAC address table. VPLS MAC address accounting is performed only on local CE routers.

- The VPLS counters for source and destination MAC addresses increment continuously until the oldest MAC address entries are removed from the memory buffer, either when the entries time out or if the VPLS instance is restarted.

To display status information about Virtual Loopback Tunnel interfaces in the VPLS instance, use the **show interfaces vt\* terse** command.

```
user@B> show interfaces vt* terse
Interface Admin Link Proto Local Remote
vt-0/3/0 up up
vt-0/3/0.1048832 up up vpls
vt-0/3/0.1048833 up up vpls
vt-0/3/0.1048834 up up vpls
vt-0/3/0.1048835 up up vpls
```

To display VPLS route information related to the flood process, use the **show vpls flood extensive** command.

```
user@B> show vpls flood extensive
Name: v1
CEs: 0
VEs: 4
Flood route prefix: 0x4a/32
Flood route type: IFF_FLOOD

## Configuring VPLS Routing Instances

---

To configure a VPLS routing instance, include the **vpls** statement:

```
vpls {
 active-interface {
 any;
 primary interface-name;
 }
 connectivity-type (ce | irb | permanent);
 control-word;
 encapsulation-type encapsulation-type;
 interface-mac-limit limit;
 import-labeled-routes [routing-instance-name];
 label-block-size size;
 mac-table-aging-time time;
 mac-table-size size;
 neighbor neighbor-id;
 no-control-word;
```

```

no-tunnel-services;
site site-name {
 active-interface {
 any;
 primary interface-name;
 }
 interface interface-name {
 interface-mac-limit limit;
 }
 mesh-group mesh-group-name;
 multi-homing;
 site-identifier identifier;
 site-preference preference-value {
 backup;
 primary;
 }
}
site-range number;
traceoptions {
 file filename <files number> <size size> <world-readable | no-world-readable>;
 flag flag <flag-modifier> <disable>;
}
tunnel-services {
 devices device-names;
 primary primary-device-name;
}
vpls-id vpls-id;
}

```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols]

**NOTE:** ACX Series routers do not support the [edit logical-systems] hierarchy.

**NOTE:** You cannot configure a routing protocol (OSPF, RIP, IS-IS or BGP) inside a VPLS routing instance (instance-type vpls). The Junos CLI disallows this configuration.

**NOTE:** Starting in Junos OS Release 16.1, you can use the import-labeled-routes statement to specify one or more nondefault routing instances where you want MPLS pseudowire labeled routes to be leaked from the mpls.0 path routing table in the master routing instance.

The configuration for the VPLS routing instance statements is explained in the following sections:

- [Configuring BGP Signaling for VPLS on page 1175](#)
- [Configuring LDP Signaling for VPLS on page 1180](#)
- [Configuring VPLS Routing Instance and VPLS Interface Connectivity on page 1183](#)

## Configuring BGP Signaling for VPLS

You can configure BGP signaling for the VPLS routing instance. BGP is used to signal the pseudowires linking each of the PE routers participating in the VPLS routing instance. The pseudowires carry VPLS traffic across the service provider's network between the VPLS sites.

**NOTE:** You cannot configure both BGP signaling and LDP signaling for the same VPLS routing instance. If you attempt to configure the statements that enable BGP signaling for the VPLS routing instance (the `site`, `site-identifier`, and `site-range` statements) and the statements that enable LDP signaling for the same instance (the `neighbor` and `vpls-id` statements), the commit operation fails.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Configure BGP signaling for the VPLS routing instance by completing the steps in the following sections:

- [Configuring the VPLS Site Name and Site Identifier on page 1175](#)
- [Configuring Automatic Site Identifiers for VPLS on page 1176](#)
- [Configuring the Site Range on page 1177](#)
- [Configuring the VPLS Site Interfaces on page 1179](#)
- [Configuring the VPLS Site Preference on page 1179](#)

### Configuring the VPLS Site Name and Site Identifier

When you configure BGP signaling for the VPLS routing instance, on each PE router you must configure each VPLS site that has a connection to the PE router. All the Layer 2

circuits provisioned for a VPLS site are listed as the set of logical interfaces (using the **interface** statement) within the **site** statement.

You must configure a site name and site identifier for each VPLS site.

To configure the site name and the site identifier, include the **site** and the **site-identifier** statements:

```
site site-name {
 interface interface-name {
 interface-mac-limit limit;
 }
 site-identifier identifier;
}
```

The numerical identifier can be any number from 1 through 65,534 that uniquely identifies the local VPLS site.

You can include these statements at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

---

### Configuring Automatic Site Identifiers for VPLS

When you enable automatic site identifiers, the Junos OS automatically assigns site identifiers to VPLS sites. To configure automatic site identifiers for a VPLS routing instance, include the **automatic-site-id** statement:

```
automatic-site-id {
 collision-detect-time seconds;
 new-site-wait-time seconds;
 reclaim-wait-time minimum seconds maximum seconds;
 startup-wait-time seconds;
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls site *site-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls site *site-name*]

**NOTE:** ACX Series routers do not support the [edit logical-systems] hierarchy.

---

The **automatic-site-id** statement includes a number of options that control different delays in network layer reachability information (NLRI) advertisements. All of these options are configured with default values. See the statement summary for the **automatic-site-id** statement for more information.

The **automatic-site-id** statement includes the following options:

- **collision-detect-time**—The time in seconds to wait after a claim advertisement is sent to the other routers in a VPLS instance before a PE router can begin using a site identifier. If the PE router receives a competing claim advertisement for the same site identifier during this time period, it initiates the collision resolution procedure for site identifiers.
- **new-site-wait-time**—The time in seconds to wait to receive VPLS information for a newly configured routing instance or a new site. This time interval is also applied whenever the automatic site identifier feature is activated on a VPLS routing instance other than at startup. Effectively, this timer indicates how long to wait before an attempt is made to allocate a site identifier. This timer is also triggered whenever a VPLS routing instance is enabled.
- **reclaim-wait-time**—The time to wait before attempting to claim a site identifier after a collision. A collision occurs whenever an attempt is made to claim a site identifier by two separate VPLS sites.
- **startup-wait-time**—The time in seconds to wait at startup to receive all the VPLS information for the route targets configured on the other PE routers included in the VPLS routing instance.

### Configuring the Site Range

When you enable BGP signaling for each VPLS routing instance, you can optionally configure the site range. The site range specifies an upper limit on the maximum site identifier that can be accepted to allow a pseudowire to be brought up. You must specify a value from 1 through 65,534. The default value is 65,534. We recommend using the default. Pseudowires cannot be established to sites with site identifiers greater than the configured site range. If you issue the **show vpls connections** command, such sites are displayed as OR (out of range).

To configure the site range, include the **site-range** statement:

```
site-range number;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

**NOTE:** ACX Series routers do not support the [edit logical-systems] hierarchy.

There are networks that require that the site range be configured using a value smaller than the local site identifier, for example, a hub-and-spoke VPLS with multihomed sites.

For this type of network, you need to allow pseudowires to be established between the spoke routers and the hub router. However, you also need to prevent pseudowires from being established between spoke routers directly. Due to the multihoming requirement of spoke sites, Layer 2 VPN NRLIs need to be accepted from other spoke routers (at least from spokes with the same site identifier as the locally configured sites) to determine the status of local spoke routers (active or not active) based on the local preference included in the NRLIs received from the other spoke routers.

This type of VPLS network can be implemented by, for example, numbering hub sites with identifiers 1 through 8 and spoke sites with identifiers 9 and larger. You can then configure a site range of 8 on each of the spoke sites. Although the spoke sites accept NRLIs and install them in the Layer 2 VPN routing tables (allowing the multihomed sites to determine the status of the local site), the spoke sites cannot establish pseudowires directly to the other spoke sites due to the configured site range.

The following configurations illustrate this concept. The configurations are for the VPLS routing instances on three routers, two spoke routers and one hub router:

Router 1—spoke:

```
routing-instance hub-and-spoke {
 no-local-switching;
 protocols {
 vpls {
 site-range 8;
 no-tunnel-services;
 site spoke-9 {
 site-identifier 9 {
 multi-homing;
 site-preference primary;
 }
 }
 site spoke-10 {
 site-identifier 10 {
 multi-homing;
 site-preference backup;
 }
 }
 }
 }
}
```

Router 2—spoke:

```
routing-instance hub-and-spoke {
 no-local-switching;
 protocols {
 vpls {
 site-range 8;
 no-tunnel-services;
 site spoke-9 {
 site-identifier 9 {
 multi-homing;
 site-preference backup;
 }
 }
 }
 }
}
```

```

 }
 site spoke-10 {
 site-identifier 10 {
 multi-homing;
 site-preference primary;
 }
 }
}
}
}
}

```

Hub—router 3:

```

routing-instance hub-and-spoke {
 no-local-switching;
 protocols {
 vpls {
 no-tunnel-services;
 site hub {
 site-identifier 1;
 }
 }
 }
}
}

```

### Configuring the VPLS Site Interfaces

You must configure an interface for each of the pseudowires you specify for the VPLS site.

To configure an interface for the VPLS site, include the **interface** statement:

```

interface interface-name {
 interface-mac-limit limit;
}

```

You can include these statements at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls site *site-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

You can also configure a limit on the number of MAC addresses that can be learned from the specified interface. For more information, see [“Limiting the Number of MAC Addresses Learned from an Interface” on page 1186](#).

### Configuring the VPLS Site Preference

You can specify the local preference value advertised for a particular VPLS site. The site preference value is specified using the **site-preference** statement configured at the [edit routing-instances *routing-instance-name* protocols vpls site *site-name*] hierarchy level. By configuring the **site-preference** statement, a value configured for the **local-preference** statement at the [edit protocols **bgp**] hierarchy level is ignored by the VPLS routing instance. However, you can change the site preference value for VPLS routes exported to other routers by configuring an export policy. When a PE router receives multiple

advertisements with the same VPLS edge (VE) device identifier, the advertisement with the highest local preference value is preferred.

To configure the VPLS site preference, include the **site-preference** statement:

```
site-preference preference-value {
 backup;
 primary;
}
```

You can also specify either the **backup** option or the **primary** option for the **site-preference** statement. The **backup** option specifies the preference value as 1, the lowest possible value, ensuring that the VPLS site is the least likely to be selected. The **primary** option specifies the preference value as 65,535, the highest possible value, ensuring that the VPLS site is the most likely to be selected.

For a list of hierarchy levels at which you can include the **site-preference** statement, see the statement summary section for this statement.

## Configuring LDP Signaling for VPLS

You can configure LDP as the signaling protocol for a VPLS routing instance. This functionality is described in RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*.

The Junos OS software does not support all of RFC 4762. When enabling LDP signaling for a VPLS routing instance, network engineers should be aware that only the following values are supported:

- FEC—128 or 129
- Control bit—0
- Ethernet pseudowire type—0x0005
- Ethernet tagged mode pseudowire type—0x0004

LDP signaled VPLS supports the Virtual Circuit Connectivity Verification (VCCV) Type Length Value (TLV) for pseudowire label mapping, label database display, and LDP trace. When you enable LDP signaling for a pseudowire, LDP advertises the VCCV capabilities to the neighboring routers. VCCV provides a control channel for a pseudowire and includes both operations and management functions (for example, connectivity verification). This control channel is established between the pseudowire's ingress and egress devices. Once established, connectivity verification messages can be sent over the VCCV control channel.

The Junos OS software supports the following VCCV capabilities for LDP signaled VPLS (defined in RFC 5085 Section 8.1):

- VCCV connectivity check types:
  - Router Alert Label
  - MPLS pseudowire label with TTL=1

- VCCV connectivity verification type:
  - LSP ping

If the peer device also advertises VCCV parameters during pseudowire setup, the Junos OS software selects the set of common advertised parameters to use as the method for performing VCCV OAM on the pseudowire.

The locally advertised and peer advertised VCCV parameters can be viewed using the **show ldp database** command as show here:

```
user@host> show ldp database l2circuit extensive
Input label database, 10.255.245.198:0--10.255.245.194:0
 Label Prefix
 299872 L2CKT CtrlWord PPP VC 100
 MTU: 4470
 VCCV Control Channel types:
 MPLS router alert label
 MPLS PW label with TTL=1
 VCCV Control Verification types:
 LSP ping
 Label Prefix
 State: Active
 Age: 19:23:08
```

Be aware of the following behavior with regard to TLVs when configuring LDP-signaled VPLS in a network with equipment from other vendors:

- When a Juniper Network's device receives a TLV with an empty address, LDP accepts the TLV.
- When a MAC address is withdrawn, LDP specifies a zero address (0.0.0.0) for the AddressList.

To enable LDP signaling for the set of PE routers participating in the same VPLS routing instance, you need to use the **vpls-id** statement configured at the **[edit routing-instances routing-instance-name protocols vpls]** hierarchy level to configure the same VPLS identifier on each of the PE routers. The VPLS identifier must be globally unique. When each VPLS routing instance (domain) has a unique VPLS identifier, it is possible to configure multiple VPLS routing instances between a given pair of PE routers.

LDP signaling requires that you configure a full-mesh LDP session between the PE routers in the same VPLS routing instance. Neighboring PE routers are statically configured. Tunnels are created between the neighboring PE routers to aggregate traffic from one PE router to another. Pseudowires are then signaled to demultiplex traffic between VPLS routing instances. These PE routers exchange the pseudowire label, the MPLS label that acts as the VPLS pseudowire demultiplexer field, by using LDP forwarding equivalence classes (FECs). Tunnels based on both MPLS and generic routing encapsulation (GRE) are supported.

**NOTE:** You cannot configure both BGP signaling and LDP signaling for the same VPLS routing instance. If you attempt to configure the statements that enable BGP signaling for the VPLS routing instance (the `site`, `site-identifier`, and `site-range` statements), and the statements that enable LDP signaling for the same instance, `neighbor` and `vpls-id`, the commit operation fails.

To enable LDP signaling for the VPLS routing instance, complete the steps in the following sections:

- [Configuring LDP Signaling for the VPLS Routing Instance on page 1182](#)
- [Configuring LDP Signaling on the Router on page 1183](#)

---

### Configuring LDP Signaling for the VPLS Routing Instance

---

To configure the VPLS routing instance to use LDP signaling, you must configure the same VPLS identifier on each PE router participating in the instance. Specify the VPLS identifier with the `vpls-id` statement:

`vpls-id vpls-id;`

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

**NOTE:** ACX Series routers do not support the [edit logical-systems] hierarchy.

To configure the VPLS routing instance to use LDP signaling, you also must include the `neighbor` statement to specify each of the neighboring PE routers that are a part of this VPLS domain:

`neighbor neighbor-id;`

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

**NOTE:** ACX Series routers do not support the [edit logical-systems] hierarchy.

### Configuring LDP Signaling on the Router

To enable LDP signaling, you need to configure LDP on each PE router participating in the VPLS routing instance. A minimal configuration is to enable LDP on the loopback interface, which includes the router identifier (**router-id**), on the PE router using the **interface** statement:

```
interface interface-name;
```

You can include this statement at the following hierarchy levels:

- [edit protocols ldp]
- [edit logical-systems *logical-system-name* protocols ldp]

**NOTE:** ACX Series routers do not support the [edit logical-systems] hierarchy.

You can enable LDP on all the interfaces on the router using the **all** option for the **interfaces** statement. For more information about how to configure LDP, see the *MPLS Applications Feature Guide*.

### Configuring VPLS Routing Instance and VPLS Interface Connectivity

You can configure the VPLS routing instance to take down or maintain its VPLS connections depending on the status of the interfaces configured for the VPLS routing instance. By default, the VPLS connection is taken down whenever a customer-facing interface configured for the VPLS routing instance fails. This behavior can be explicitly configured by specifying the **ce** option for the **connectivity-type** statement:

```
connectivity-type ce;
```

You can alternatively specify that the VPLS connection remain up so long as an Integrated Routing and Bridging (IRB) interface is configured for the VPLS routing instance by specifying the **irb** option for the **connectivity-type** statement:

```
connectivity-type irb;
```

To ensure that the VPLS connection remain up until explicitly taken down, specify the **permanent** option for the **connectivity-type** statement:

```
connectivity-type permanent;
```

This option is reserved for use in configuring Layer 2 Wholesale subscriber networks. See the *Broadband Subscriber Management Solutions Guide* for details about configuring a Layer 2 Wholesale network.

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

NOTE: ACX Series routers do not support the `[edit logical-systems]` hierarchy.

ACX Series routers do not support `irb` interface in VPLS instance, therefore `connectivity-type irb` for VPLS is not supported.

---

## Configuring the VPLS Encapsulation Type

You can specify a VPLS encapsulation type for the pseudowires established between VPLS neighbors. The encapsulation type is carried in the LDP-signaling messages exchanged between VPLS neighbors when pseudowires are created. You might need to alter the encapsulation type depending on what other vendors' equipment is deployed within your network.

VPLS effectively provides a bridge between Ethernet networks. As a consequence, only two encapsulation types are available:

- **ethernet**—Ethernet
- **ethernet-vlan**—Ethernet virtual LAN (VLAN)

If you do not specify an encapsulation type for the VPLS routing instance or the VPLS neighbor, **ethernet** is used.

To specify an encapsulation type for the VPLS routing instance, include the **encapsulation-type** statement:

```
encapsulation-type (ethernet | ethernet-vlan);
```

You can include this statement at the following hierarchy levels:

- `[edit routing-instances routing-instance-name protocols vpls]`
- `[edit logical-systems logical-system-name routing-instances routing-instance-name protocols vpls]`

You can also specify an encapsulation type for a specific VPLS neighbor by including the **encapsulation-type** statement at the following hierarchy levels:

- `[edit routing-instances routing-instance-name protocols vpls neighbor address]`
- `[edit logical-systems logical-system-name routing-instances routing-instance-name protocols vpls neighbor address]`

## Configuring the MPLS Routing Table to Leak Routes a Nondefault Routing Instance

Starting in Junos OS Release 16.1, you can specify one or more nondefault routing instances where you want MPLS routes to be leaked from the `mpls.0` path routing table in the master routing instance. This capability is useful in an L2VPN/VPLS configuration when the remote PE router is learned from the IGP in a nondefault routing instance, because L2VPN/VPLS installs ingress-labeled routes only in the master `mpls.0` table.

By default, routes in the `mpls.0` routing table in the master routing instance are not leaked to the corresponding routing tables in nondefault routing instances. When L2VPN/VPLS traffic is received on the core-facing interface in a nondefault routing instance, the router performs a lookup in the table that corresponds to that interface, `routing-instance-name.mpls.0`. Because the routes are not leaked by default, then no routes are found in the `routing-instance-name.mpls.0` routing table and all the incoming traffic is dropped.

To leak MPLS routes to a nondefault routing instance, include the **import-labeled-routes** statement and specify one or more routing instances where the routes need to be leaked:

```
import-labeled-routes [routing-instance-name];
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

## Configuring the VPLS MAC Table Timeout Interval

You can modify the timeout interval for the VPLS table. We recommend you that configure longer values for small, stable VPLS networks and shorter values for large, dynamic VPLS networks. If the VPLS table does not receive any updates during the timeout interval, the router waits one additional interval before automatically clearing the MAC address entries from the VPLS table.

To modify the timeout interval for the VPLS table, include the **mac-table-aging-time** statement:

```
mac-table-aging-time seconds;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

**NOTE:** The `mac-table-aging-time` statement is not available on ACX Series and MX Series routers.

**NOTE:** ACX Series routers do not support the [edit logical-systems] hierarchy.

## Configuring the Size of the VPLS MAC Address Table

You can modify the size of the VPLS media access control (MAC) address table. The default table size is 512 MAC addresses, the minimum is 16 addresses, and the maximum is 65,536 addresses.

**NOTE:** T4000 routers with Type 5 FPCs support up to 262,143 MAC addresses per VPLS routing instance. To enable the improved VPLS MAC address learning limit (that is, 262,143 MAC addresses), you must include the **enhanced-mode** statement at the **[edit chassis network-services]** hierarchy level, reboot the router, and then modify the size of the VPLS MAC address table.

If the MAC table limit is reached, new MAC addresses can no longer be added to the table. Eventually the oldest MAC addresses are removed from the MAC address table automatically. This frees space in the table, allowing new entries to be added. However, as long as the table is full, new MAC addresses are dropped.

To change the VPLS MAC table size for each VPLS or VPN routing instance, include the **mac-table-size** statement:

**mac-table-size** *size*;

You can include this statement at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name* protocols vpls]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]**

**NOTE:** ACX Series routers do not support the **[edit logical-systems]** hierarchy.

When you include the **mac-table-size** statement, the affected interfaces include all interfaces within the VPLS routing instance, including the local interfaces, the LSI interfaces, and the VT interfaces.

**NOTE:** ACX Series routers do not support **mac-table-size** statement for VPLS.

---

## Limiting the Number of MAC Addresses Learned from an Interface

You can configure a limit on the number of MAC addresses learned by a VPLS routing instance using the **mac-table-size** statement. If the MAC table limit is reached, new MAC addresses can no longer be added to the table. Eventually the oldest MAC addresses are removed from the MAC address table automatically. This frees space in the table, allowing new entries to be added. However, as long as the table is full, new MAC addresses are dropped.

Because this limit applies to each VPLS routing instance, the MAC addresses of a single interface can consume all the available space in the table, preventing the routing instance from acquiring addresses from other interfaces.

You can limit the number of MAC addresses learned from each interface configured for a VPLS routing instance. To do so, include the **interface-mac-limit** statement:

`interface-mac-limit limit;`

**NOTE:** ACX Series routers do not support `interface-mac-limit limit` for VPLS.

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

The `interface-mac-limit` statement affects the local interfaces only (the interfaces facing CE devices).

Configuring the `interface-mac-limit` statement at the [edit routing-instances *routing-instance-name* protocols vpls] hierarchy level causes the same limit to be applied to all of the interfaces configured for that specific routing instance.

**NOTE:** Starting in Junos OS Release 12.3R4, if you do not configure the parameter to limit the number of MAC addresses to be learned by a VPLS instance, the default value is not effective. Instead, if you do not include the `interface-mac-limit` option at the [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls site *site-name* interfaces *interface-name*], hierarchy level, this setting is not present in the configuration with the default value of 1024 addresses. If you upgrade a router running a Junos OS release earlier than Release 12.3R4 to Release 12.3R4 or later, you must configure the `interface-mac-limit` option with a valid value for it to be saved in the configuration.

You can also limit the number of MAC addresses learned by a specific interface configured for a VPLS routing instance. This gives you the ability to limit particular interfaces that you expect might generate a lot of MAC addresses.

To limit the number of MAC addresses learned by a specific interface, include the `interface-mac-limit` statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls site *site-name* interfaces *interface-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls site *site-name* interfaces *interface-name*]

**NOTE:** ACX Series routers do not support the [edit logical-systems] hierarchy.

The MAC limit configured for an individual interface at this hierarchy level overrides any value configured at the [edit routing-instances *routing-instance-name* protocols vpls]

hierarchy level. Also, the MAC limit configured using the **mac-table-size** statement can override the limit configured using the **interface-mac-limit** statement.

The MAC address limit applies to customer-facing interfaces only.

## Removing Addresses from the MAC Address Database

You can enable MAC flush processing for the VPLS routing instance or for the mesh group under a VPLS routing instance. MAC flush processing removes MAC addresses from the MAC address database that have been learned dynamically. With the dynamically learned MAC addresses removed, MAC address convergence requires less time to complete.

You can clear dynamically learned MAC addresses from the MAC address database by including the **mac-flush** statement:

**mac-flush** [*explicit-mac-flush-message-options*];

To clear dynamically learned MAC addresses globally across all devices participating in the routing instance, you can include the statement at the following hierarchy levels:

- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]
- [edit routing-instances *routing-instance-name* protocols vpls]

To clear the MAC addresses on the routers in a specific mesh group, you can include the statement at the following hierarchy levels:

- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*]
- [edit routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*]

**NOTE:** On ACX Series routers, the mesh-group statement is supported only on ACX5000 line of routers. ACX5000 line of routers can support up to 8 user-defined mesh groups per VPLS routing instance.

---

**NOTE:** ACX Series routers do not support the [edit logical-systems] hierarchy.

---

For certain cases where MAC flush processing is not initiated by default, you can also specify **explicit-mac-flush-message-options** to additionally configure the router to send explicit MAC flush messages under specific conditions. For a list of the explicit MAC flush message options you can include with this statement, see the summary section for this statement.

## Release History Table

| Release | Description                                                                                                                                                                                            |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16.1    | Starting in Junos OS Release 16.1, you can specify one or more nondefault routing instances where you want MPLS routes to be leaked from the mpls.0 path routing table in the master routing instance. |
| 12.3R4  | Starting in Junos OS Release 12.3R4, if you do not configure the parameter to limit the number of MAC addresses to be learned by a VPLS instance, the default value is not effective.                  |

## Configuring a VPLS Routing Instance

Use the **vpls** routing instance type for point-to-multipoint LAN implementations between a set of sites in a VPN.

To create a routing instance for VPLS, include at least the following statements in the configuration:

```
routing-instances {
 routing-instance-name {
 instance-type vpls;
 interface interface-name;
 route-distinguisher (as-number:number | ip-address:number);
 vrf-import [policy-names];
 vrf-export [policy-names];
 protocols {
 vpls {
 ... vpls configuration ...
 }
 }
 }
}
```

You can include these statements at the following hierarchy levels:

- **[edit]**
- **[edit logical-systems *logical-system-name*]**

For more information about configuring VPLS, see the *Junos OS VPNs Library for Routing Devices*.

## Support of Inner VLAN List and Inner VLAN Range for Qualified BUM Pruning on a Dual-Tagged Interface for a VPLS Routing Instance Overview

---

Junos OS provides the **qualified-bum-pruning-mode** statement, which supports constraining of broadcast, multicast, and unknown (BUM) traffic in a VPLS instance to a specific subscriber VLAN stack. This cuts down unnecessary consumption of bandwidth and thereby, improves network performance.

All subscriber VLANs that need to be backhauled to their respective retail-ISPs are also created in the same VPLS instance as the retail-ISP. Each retail-ISP is allocated a VPLS instance. Any traffic on subscriber VLANs is hauled over the VPLS tunnel to the retail-ISP. Similarly, any traffic from a retail-ISP on a VPLS tunnel is forwarded to all the subscriber VLANs in that VPLS instance. For multicast traffic (which includes broadcast, unknown DMAC, and layer 2 and layer 3 multicast), the standard Layer-2 VPLS instance-forwarding creates a BUM packet, which comes from a retail-ISP over a VPLS tunnel, to be flooded to all subscriber VLANs in the VPLS instance. This causes the individual subscribers who might have subscribed to specific multicast traffic channels to receive all the traffic instead of the multicast traffic that the subscriber has signed up for.

To overcome this, BUM traffic needs to be forwarded only to subscribers who are the intended recipients, by mapping the VLAN-tags present in the BUM packet to these subscribers. A subscriber is assigned a stacked VLAN-tag and BUM packets are sent only to a subscriber whose stacked VLAN-tags match the VLAN-tags present in the BUM packet. This ensures that subscribers receive only the BUM traffic that is specifically intended for them, which prevents the normal flooding of BUM traffic. This is called *BUM-pruning*. Hitherto, Junos OS supported only single VLAN tagged and dual VLAN tagged subscriber interfaces. This implies that for each subscriber, a different interface must be configured. Such a BUM-pruning solution does not scale well. To address this issue, Junos OS now supports configuring VLAN ranges on the subscriber interfaces. This enables better management of subscriber services.

BUM-pruning on Junos OS allows subscriber interfaces to be configured with inner-vlan-lists. Each inner VLAN list includes all the subscriber VLANs that must be grouped on a particular subscriber interface mapped to a VPLS instance. You can configure BUM-pruning on each VPLS instance allocated to a retail-ISP by using the **set routing-instances routing-instance-name qualified-bum-pruning-mode** command.

For normal VPLS flooding, BUM traffic is received over the VPLS tunnel and flooded to all the subscriber interfaces mapped to the vpls-instance. These interfaces might be or might not be mapped to the same subscriber VLAN as the packet received over the VPLS tunnel. By enabling the qualified BUM pruning mode in a VPLS instance, VPLS flooding is restricted to a combination of service-provider VLAN and subscriber VLAN. The **qualified-bum-pruning** statement implements BUM-pruning on the Packet Forwarding Engine in the egress list of each subscriber interface mapped to the VPLS instance. On the Packet Forwarding Engine, BUM-pruning is implemented as a vlan-check nexthop installed in the egress list of the subscriber interface. The vlan-check nexthop checks whether the BUM packet exiting the ifl has the same combination of service-provider VLAN and subscriber VLAN as that configured on the interface. If the VLAN check matches, the packet is forwarded or else it is discarded. This ensures that only the subscriber that is the intended recipient of the BUM traffic receives the packet. This feature is supported for both single-tagged and dual-tagged subscriber interfaces as well as for subscriber interfaces configured with vlan-map operations. If vlan-map operations are configured

on the interfaces, then the normalized VLAN on the interface is considered for the vlan-check nexthop. This feature is supported for both default and logical systems.

Currently, dual-tagged subscriber interfaces can support a single pair of service-provider VLAN and subscriber VLAN. With the support for BUM-pruning of VPLS traffic on dual-tagged interfaces, you can configure a single service provider VLAN(S) on the subscriber interface and map it to multiple customer VLANs using a single inner VLAN list or inner VLAN range. The inner VLAN list on a subscriber interface can have multiple elements. Each element of the inner VLAN list can be as follows:

- A single VLAN tag
- A range of VLANs

The BUM traffic flow through dual-tagged interfaces is supported on both aggregated and non-aggregated subscriber interfaces. When BUM traffic exits a subscriber interface configured with inner VLAN list or inner VLAN range, the service provider VLAN (S) and the subscriber VLAN (C) in the packet are checked against all combinations of (S,C) of the S and C VLANs possible on the interface. If the packet matches any of the combination, it is forwarded on the subscriber interface. If the packet does not match any combination, it is discarded. If the subscriber has vlan-map configured, then the S and C VLANs to be checked are modified based on the VLAN normalization on the interface.

## Configuring Qualified BUM Pruning for a Dual-Tagged Interface with Inner VLAN list and InnerVLAN range for a VPLS Routing Instance

---

Currently, dual-tagged subscriber interfaces can support a single pair of service-provider VLAN and subscriber VLAN. With the support for broadcast, unknown unicast, multicast (BUM) pruning of VPLS traffic on dual-tagged interfaces, you can configure a single service provider VLAN—referred to as VLAN(S) in this topic—on the subscriber interface and map it to multiple customer VLANs by using a single inner VLAN list or inner VLAN range. The inner VLAN list on a subscriber interface can have multiple elements. Each element of the inner VLAN list can be a single VLAN tag or a range of VLANs. The BUM traffic flow through dual-tagged interfaces is supported on both aggregated and nonaggregated subscriber interfaces. When BUM traffic exits a subscriber interface that has an inner VLAN list or range configured, the VLAN(S) and the subscriber VLAN—referred to as VLAN(C)—in the packet are checked against all combinations of VLAN(S) and VLAN(C) possible on the interface. If the packet contents match any of the combinations, then the packet is forwarded on the subscriber interface. If the contents do not match any combination, then the packet is discarded. If the subscriber has a VLAN map configured, then the VLAN(S) and VLAN(C) to be checked are modified based on the VLAN normalization on the interface.

Before you configure qualified BUM pruning for a dual-tagged interface including inner VLAN list and inner VLAN range for a VPLS routing instance, you must do the following:

1. Configure the device interfaces.
2. Configure the VPLS routing instance.

To configure qualified-bum-pruning for dual tagged interface including inner VLAN list and inner VLAN range for a VPLS routing instance:

1. Configure a member interface with a service provider VLAN for the VPLS routing instance. You can configure service provider VLAN with an inner VLAN list or inner VLAN range for the VPLS routing instance.

```
[edit interfaces interface-name unit unit-number vlan-tags]
user@host# set outer vlan-id
```

For example, to configure member interface with the service provider VLAN ID 200 for a VPLS routing instance:

```
[edit interfaces ae0 unit 100 vlan-tags]
user@host# set outer 200
```

2. Configure the **inner-list** of the member interface with a single customer VLAN ID or a range of customer VLAN IDs or both for a VPLS routing instance.

```
[edit interfaces interface-name unit unit-number vlan-tags]
user@host# set inner-list [vlan-id]
```

For example, to configure the member interface with a single customer VLAN ID and a range of customer VLAN IDs for a VPLS routing instance:

```
[edit interfaces ae0 unit 100 vlan-tags]
user@host# set inner-list [210 -215 216]
```

3. Configure the member interface with inner VLAN ID range.

```
[edit interfaces interface-name unit unit-number vlan-tags]
user@host# set inner-range vlan-range
```

For example, to configure the member interface with an inner range of 300-310 for VPLS routing instance:

```
[edit interfaces ae6 unit 500 vlan-tags]
user@host# set inner-range 300-310
```

4. Configure BUM pruning for VPLS traffic on dual-tagged interfaces to forward the BUM traffic only to the intended member interfaces.

```
[edit routing-instance VPLS routing-instance]
user@host# set qualified-bum-pruning-mode
```

For example, to configure qualified BUM pruning for routing instance r1:

```
[edit routing-instance r1]
user@host# set qualified-bum-pruning-mode
```

## Configuring a Layer 2 Control Protocol Routing Instance

On MX Series routers only, use the **layer2-control** routing instance type for Rapid Spanning-Tree Protocol (RSTP) or Multiple Spanning-Tree Protocol (MSTP) in customer edge interfaces of a VPLS routing instance. Layer 2 control protocols enable features such as Layer 2 protocol tunneling or nonstop bridging. This instance type cannot be used if the customer edge interface is multihomed to two provider edge interfaces. If the customer edge interface is multihomed to two provider edge interfaces, use the default bridge protocol data unit (BPDU) tunneling.

To create a routing instance for Layer 2 control protocols, include at least the following statements in the configuration:

```
routing-instances {
 routing-instance-name {
 instance-type layer2-control;
 interface interface-name;
 route-distinguisher (as-number:number | ip-address:number);
 vrf-import [policy-names];
 vrf-export [policy-names];
 protocols {
 mstp {
```

```
... interface options ...
msti msti-id {
 ... MSTP MSTI configuration ...
}
}
}
}
```

You can include these statements at the following hierarchy levels:

- **[edit]**
- **[edit logical-systems *logical-system-name*]**

## PE Router Mesh Groups for VPLS Routing Instances

---

A PE router mesh group consists of a set of routers participating in a VPLS routing instance that share the same signaling protocol, either BGP or LDP. Each VPLS routing instance can have just one BGP mesh group. However, you can configure multiple LDP mesh groups for each routing instance.

The Junos OS can support up to 16 mesh groups on MX Series routers and up to 128 on M Series and T Series routers. However, two mesh groups are created by default, one for the CE routers and one for the PE routers. Therefore, the maximum number of user-defined mesh groups is 14 for MX Series routers and 126 for M Series and T Series routers.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The Junos OS supports both forwarding equivalency class (FEC) 128 and FEC 129. FEC 129 uses VPLS autodiscovery to convey endpoint information. FEC 128 requires manually configured pseudowires.

The following describes the behavior of mesh groups in regards to BGP-signaled PE routers and LDP-signaled PE routers:

- **BGP-signaled PE routers**—Automatically discovered PE routers that use BGP for signaling are associated with the default VE mesh group. You cannot configure the Junos OS to associate these routers with a user-defined VE mesh group.
- **LDP-signaled PE routers (FEC 128)**—PE routers statically configured using FEC-128 LDP signaling are placed in a default mesh group. However, you can configure a VE

mesh group and associate each LDP FEC-128 neighbor with it. Each configured VE mesh group contains a set of VEs that are in the same interior gateway protocol (IGP) routing instance and are fully meshed with each other in the control and data planes.

- LDP-signaled PE routers (FEC 129)—Configuration for a mesh group for FEC 129 is very similar to the configuration for FEC 128.

Note the following differences for FEC 129:

- Each user-defined mesh group must have a unique route distinguisher. Do not use the route distinguisher that is defined for the default mesh group at the **[edit routing-instances]** hierarchy level.
- Each user-defined mesh group must have its own import and export route target.
- Each user-defined mesh group can have a unique Layer 2 VPN ID. By default, all the mesh groups that are configured for the a VPLS routing-instance use the same Layer 2 VPN ID, the one that you configure at the **[edit routing-instances]** hierarchy level.

---

## Configuring VPLS Fast Reroute Priority

---

When a path is rerouted after a link failure by using the MPLS fast reroute feature, the router repairs the affected next hops by switching them from the active label switched path (LSP) to the standby LSP. To specify the order in which the router repairs next hops and restores traffic convergence for VPLS routing instances after a fast reroute event, you can use the **fast-reroute-priority** statement to configure **high**, **medium**, or **low** fast reroute priority for a VPLS routing instance. By default, the fast reroute priority for a VPLS routing instance is **low**.

The router repairs next hops and restores known unicast, unknown unicast, broadcast, and multicast traffic for VPLS routing instances in the following order, based on the fast reroute priority configuration:

1. The router repairs next hops for high-priority VPLS routing instances.
2. The router repairs next hops for medium-priority VPLS routing instances.
3. The router repairs next hops for low-priority VPLS routing instances.

Because the router repairs next hops for VPLS routing instances configured with **high** fast reroute priority first, the traffic traversing high-priority VPLS instances is restored faster than the traffic for VPLS instances configured with **medium** or **low** fast reroute priority. The ability to prioritize specific VPLS routing instances for faster convergence and traffic restoration enables service providers to offer differentiated service levels to their customers.

Within a particular fast reroute priority level (**high**, **medium**, or **low**), the router follows no particular order for traffic restoration of VPLS routing instances.

**NOTE:** VPLS fast reroute priority is not supported on EX Series switches.

To configure **high**, **medium**, or **low** fast reroute priority for a VPLS routing instance, include the **fast-reroute-priority** statement:

**fast-reroute-priority** (high | medium | low);

You can include this statement at the following hierarchy levels:

- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* forwarding-options]
- [edit routing-instances *routing-instance-name* forwarding-options]

You can configure fast reroute priority only for routing instances with the **instance-type** set to **vpls**. If you attempt to configure fast reroute priority for a routing instance with an **instance-type** other than **vpls**, the router displays a warning message and the configuration fails.

The following example snippet shows configuration of **high** fast reroute priority for a VPLS routing instance named **test-vpls**:

```
test-vpls {
 instance-type vpls;
 forwarding-options {
 fast-reroute-priority high;
 }
}
```

To display the fast reroute priority setting configured for a VPLS routing instance, use the **show route instance detail** operational command. For information about using this command, see the [CLI Explorer](#).

---

## Specifying the VT Interfaces Used by VPLS Routing Instances

By default, the Junos OS automatically selects one of the virtual tunnel (VT) interfaces available to the router for de-encapsulating traffic from a remote site. The Junos OS cycles through the currently available VT interfaces, regularly updating the list of available VT interfaces as new remote sites are discovered and new connections are brought up. However, you can also explicitly configure which VT interfaces will receive the VPLS traffic.

By including the **tunnel-services** statement at the [edit routing-instances *routing-instance-name* protocols vpls] hierarchy level, you can specify that traffic for particular VPLS routing instances be forwarded to specific VT interfaces. Doing so allows you to load-balance VPLS traffic among all the available VT interfaces on the router.

The **tunnel-services** statement includes the following options:

- **devices**—Specifies the VT interfaces acceptable for use by the VPLS routing instance. If you do not configure this option, all VT interfaces available to the router can be used for de-encapsulating traffic for this instance.

- **primary**—Specifies the primary VT interface to be used by the VPLS routing instance. The VT interface specified is used to de-encapsulate all VPLS traffic from the MPLS core network for this routing instance. If the VT interface specified is unavailable, then one of the other acceptable VT interfaces (specified in the `devices` option) is used for handling the VPLS traffic. If you do not configure this option, any acceptable VT interface can be used to de-encapsulate VPLS traffic from the core.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

To specify that traffic for a particular VPLS routing instance be forwarded to specific VT interfaces, include the **tunnel-services** statement:

```
tunnel-services {
 devices device-names;
 primary primary-device-name;
}
```

These statements can be configured at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols vpls]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]

## Understanding PIM Snooping for VPLS

There are two ways to direct PIM control packets:

- By the use of PIM snooping
- By the use of PIM proxying

PIM snooping configures a device to examine and operate only on PIM hello and join/prune packets. A PIM snooping device snoops PIM hello and join/prune packets on each interface to find interested multicast receivers and populates the multicast forwarding tree with this information. PIM snooping differs from PIM proxying in that both PIM hello and join/prune packets are transparently flooded in the VPLS as opposed to the flooding of only hello packets in the case of PIM proxying. PIM snooping is configured on PE routers connected through pseudowires. PIM snooping ensures that no new PIM packets are generated in the VPLS, with the exception of PIM messages sent through LDP on pseudowires.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

A device that supports PIM snooping snoops hello packets received on attachment circuits. It does not introduce latency in the VPLS core when it forwards PIM join/prune packets.

To configure PIM snooping on a PE router, use the **pim-snooping** statement at the **[edit routing-instances *instance-name* protocols]** hierarchy level:

```
routing-instances {
 customer {
 instance-type vpls;
 ...
 protocols {
 pim-snooping {
 traceoptions {
 file pim.log size 10m;
 flag all;
 flag timer disable;
 }
 }
 }
 }
}
```

“[Example: Configuring PIM Snooping for VPLS](#)” on page 1200 explains the PIM snooping method. The use of the PIM proxying method is not discussed here and is outside the scope of this document. For more information about PIM proxying, see [PIM Snooping over VPLS](#).

---

## Example: Configuring PIM Snooping for VPLS

This example shows how to configure PIM snooping in a virtual private LAN service (VPLS) to restrict multicast traffic to interested devices.

- [Requirements on page 1200](#)
- [Overview on page 1200](#)
- [Configuration on page 1201](#)
- [Verification on page 1208](#)

### Requirements

This example uses the following hardware and software components:

- M Series Multiservice Edge Routers (M7i and M10i with Enhanced CFEB, M120, and M320 with E3 FPCs) or MX Series 3D Universal Edge Routers (MX80, MX240, MX480, and MX960)
- Junos OS Release 13.2 or later

### Overview

The following example shows how to configure PIM snooping to restrict multicast traffic to interested devices in a VPLS.

**NOTE:** This example demonstrates PIM snooping by the use of a PIM snooping device to restrict multicast traffic. The use of the PIM proxying method to achieve PIM snooping is out of the scope of this document and is yet to be implemented in Junos OS.

## Topology

In this example, two PE routers are connected to each other through a pseudowire connection. Router PE1 is connected to Routers CE1 and CE2. A multicast receiver is attached to Router CE2. Router PE2 is connected to Routers CE3 and CE4. A multicast source is connected to Router CE3, and a second multicast receiver is attached to Router CE4.

PIM snooping is configured on Routers PE1 and PE2. Hence, data sent from the multicast source is received only by members of the multicast group.

Figure 119 on page 1201 shows the topology used in this example.

**Figure 119: PIM Snooping for VPLS**

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the [edit] hierarchy level.

#### Router PE1

```
set multicast-snooping-options traceoptions file snoop.log size 10m
set interfaces ge-2/0/0 encapsulation ethernet-vpls
```

```

set interfaces ge-2/0/0 unit 0 description toCE1

## Configuring PIM Snooping for VPLS

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

**NOTE:** This section includes a step-by-step configuration procedure for one or more routers in the topology. For comprehensive configurations for all routers, see “CLI Quick Configuration” on page 1201.

To configure PIM snooping for VPLS:

1. Configure the router interfaces forming the links between the routers.

### Router PE2

```
[edit interfaces]
user@PE2# set ge-2/0/0 encapsulation ethernet-vpls
user@PE2# set ge-2/0/0 unit 0 description toCE3
user@PE2# set ge-2/0/1 encapsulation ethernet-vpls
user@PE2# set ge-2/0/1 unit 0 description toCE4
user@PE2# set ge-2/0/2 unit 0 description toPE1
user@PE2# set ge-2/0/2 unit 0 family mpls
user@PE2# set ge-2/0/2 unit 0 family inet address 10.0.0.2/30
user@PE2# set lo0 unit 0 family inet address 10.255.7.7/32
```

**NOTE:** ge-2/0/0.0 and ge-2/0/1.0 are configured as VPLS interfaces and connect to Routers CE3 and CE4. See *Virtual Private LAN Service Feature Guide* for more details.

### Router CE3

```
[edit interfaces]
user@CE3# set ge-2/0/0 unit 0 description toPE2
user@CE3# set ge-2/0/0 unit 0 family inet address 10.0.0.18/30
user@CE3# set ge-2/0/1 unit 0 description toSource
user@CE3# set ge-2/0/1 unit 0 family inet address 10.0.0.29/30
user@CE3# set lo0 unit 0 family inet address 10.255.3.3/32
```

**NOTE:** The ge-2/0/1.0 interface on Router CE3 connects to the multicast source.

### Router CE4

```
[edit interfaces]
user@CE4# set ge-2/0/0 unit 0 description toPE2
user@CE4# set ge-2/0/0 unit 0 family inet address 10.0.0.22/30
user@CE4# set ge-2/0/1 unit 0 description toReceiver2
user@CE4# set ge-2/0/1 unit 0 family inet address 10.0.0.25/30
```

```
user@CE4# set lo0 unit 0 family inet address 10.255.4.4/32
```

**NOTE:** The ge-2/0/1.0 interface on Router CE4 connects to a multicast receiver.

Similarly, configure Routers PE1, CE1, and CE2.

2. Configure the router IDs of all routers.

```
Router PE2
[edit routing-options]
user@PE2# set router-id 10.255.7.7
```

Similarly, configure other routers.

3. Configure an IGP on interfaces of all routers.

```
Router PE2
[edit protocols ospf area 0.0.0.0]
user@PE2# set interface ge-2/0/2.0
user@PE2# set interface lo0.0
```

Similarly, configure other routers.

4. Configure the LDP, MPLS, and BGP protocols on the PE routers.

```
Router PE2
[edit protocols]
user@PE2# set ldp interface lo0.0
user@PE2# set mpls interface ge-2/0/2.0
user@PE2# set bgp group toPE1 type internal
user@PE2# set bgp group toPE1 local-address 10.255.7.7
user@PE2# set bgp group toPE1 family l2vpn signaling
user@PE2# set bgp group toPE1 neighbor 10.255.1.1
user@PE2# set ldp interface ge-2/0/2.0
```

The BGP group is required for interfacing with the other PE router. Similarly, configure Router PE1.

5. Configure PIM on all CE routers.

Ensure that Router CE3 is configured as the rendezvous point (RP) and that the RP address is configured on other CE routers.

```
Router CE3
[edit protocols pim]
user@CE3# set rp local address 10.255.3.3
user@CE3# set interface all

Router CE4
[edit protocols pim]
user@CE4# set rp static address 10.255.3.3
user@CE4# set interface all
```

Similarly, configure Routers CE1 and CE2.

6. Configure multicast snooping options on the PE routers.

```
Router PE2
[edit multicast-snooping-options traceoptions]
user@PE2# set file snoop.log size 10m
```

Similarly, configure Router PE1.

7. Create a routing instance (**titanium**), and configure the VPLS on the PE routers.

```
Router PE2
[edit routing-instances titanium]
user@PE2# set instance-type vpls
user@PE2# set vlan-id none
user@PE2# set interface ge-2/0/0.0
user@PE2# set interface ge-2/0/1.0
user@PE2# set route-distinguisher 101:101
user@PE2# set vrf-target target:201:201
user@PE2# set protocols vpls vpls-id 15
user@PE2# set protocols vpls site pe2 site-identifier 2
```

Similarly, configure Router PE1.

8. Configure PIM snooping on the PE routers.

```
Router PE2
[edit routing-instances titanium]
user@PE2# set protocols pim-snooping
```

Similarly, configure Router PE1.

---

## Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, **show multicast-snooping-options**, and **show routing-instances** commands.

If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
ge-2/0/2 {
 unit 0 {
 description toPE1
 family inet {
 address 10.0.0.2/30;
 }
 family mpls;
 }
}
ge-2/0/0 {
 encapsulation ethernet-vpls;
 unit 0 {
```

```

 description toCE3;
 }
}
ge-2/0/1 {
 encapsulation ethernet-vpls;
 unit 0 {
 description toCE4;
 }
}
lo0 {
 unit 0 {
 family inet {
 address 10.255.7.7/32;
 }
 }
}

```

```

user@PE2# show routing-options
router-id 10.255.7.7;

```

```

user@PE2# show protocols
mpls {
 interface ge-2/0/2.0;
}
ospf {
 area 0.0.0.0 {
 interface ge-2/0/2.0;
 interface lo0.0;
 }
}
ldp {
 interface ge-2/0/2.0;
 interface lo0.0;
}
bgp {
 group toPE1 {
 type internal;
 local-address 10.255.7.7;
 family l2vpn {
 signaling;
 }
 neighbor 10.255.1.1;
 }
}

```

```

user@PE2# show multicast-snooping-options
traceoptions {
 file snoop.log size 10m;
}

```

```

user@PE2# show routing-instances
titanium {
 instance-type vpls;
 vlan-id none;
 interface ge-2/0/0.0;
 interface ge-2/0/1.0;
 route-distinguisher 101:101;
 vrf-target target:201:201;
 protocols {

```

```
 vpls {
 site pe2 {
 site-identifier 2;
 }
 vpls-id 15;
 }
 pim-snooping;
}
```

Similarly, confirm the configuration on all other routers. If you are done configuring the routers, enter **commit** from configuration mode.

**NOTE:** Use the **show protocols** command on the CE routers to verify the configuration for the PIM RP .

## Verification

Confirm that the configuration is working properly.

- [Verifying PIM Snooping for VPLS on page 1208](#)

### Verifying PIM Snooping for VPLS

**Purpose** Verify that PIM Snooping is operational in the network.

**Action** To verify that PIM snooping is working as desired, use the following commands:

- **show pim snooping interfaces**
- **show pim snooping neighbors detail**
- **show pim snooping statistics**
- **show pim snooping join**
- **show pim snooping join extensive**
- **show multicast snooping route extensive instance <instance-name> group <group-name>**

1. From operational mode on Router PE2, run the **show pim snooping interfaces** command.

```
user@PE2> show pim snooping interfaces
Instance: titanium
```

```
Learning-Domain: default
```

| Name       | State | IP | NbrCnt |
|------------|-------|----|--------|
| ge-2/0/0.0 | Up    | 4  | 1      |
| ge-2/0/1.0 | Up    | 4  | 1      |

```
DR address: 10.0.0.22
DR flooding is ON
```

The output verifies that PIM snooping is configured on the two interfaces connecting Router PE2 to Routers CE3 and CE4.

Similarly, check the PIM snooping interfaces on Router PE1.

2. From operational mode on Router PE2, run the **show pim snooping neighbors detail** command.

```
user@PE2> show pim snooping neighbors detail
Instance: titanium
Learning-Domain: default
```

```
Interface: ge-2/0/0.0
```

```
Address: 10.0.0.18
Uptime: 00:17:06
Hello Option Holdtime: 105 seconds 99 remaining
Hello Option DR Priority: 1
Hello Option Generation ID: 552495559
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
Tracking is supported
```

```
Interface: ge-2/0/1.0
```

```
Address: 10.0.0.22
Uptime: 00:15:16
Hello Option Holdtime: 105 seconds 103 remaining
Hello Option DR Priority: 1
Hello Option Generation ID: 1131703485
Hello Option LAN Prune Delay: delay 500 ms override 2000 ms
Tracking is supported
```

The output verifies that Router PE2 can detect the IP addresses of its PIM snooping neighbors (10.0.0.18 on CE3 and 10.0.0.22 on CE4).

Similarly, check the PIM snooping neighbors on Router PE1.

3. From operational mode on Router PE2, run the **show pim snooping statistics** command.

```
user@PE2> show pim snooping statistics
```

```
Instance: titanium

Learning-Domain: default

Tx J/P messages 0
Rx J/P messages 246
Rx J/P messages -- seen 0
Rx J/P messages -- received 246
Rx Hello messages 1036
Rx Version Unknown 0
Rx Neighbor Unknown 0
Rx Upstream Neighbor Unknown 0
Rx J/P Busy Drop 0
Rx J/P Group Aggregate 0
Rx Malformed Packet 0

Rx No PIM Interface 0
Rx Bad Length 0
Rx Unknown Hello Option 0
Rx Unknown Packet Type 0
Rx Bad TTL 0
Rx Bad Destination Address 0
Rx Bad Checksum 0
Rx Unknown Version 0
```

The output shows the number of hello and join/prune messages received by Router PE2. This verifies that PIM sparse mode is operational in the network.

4. Send multicast traffic from the source terminal attached to Router CE3, for the multicast group 203.0.113.1.
5. From operational mode on Router PE2, run the **show pim snooping join**, **show pim snooping join extensive**, and **show multicast snooping route extensive instance <instance-name> group <group-name>** commands to verify PIM snooping.

```
user@PE2> show pim snooping join
Instance: titanium
Learning-Domain: default

Group: 203.0.113.1
Source: *
Flags: sparse,rptree,wildcard
Upstream neighbor: 10.0.0.18, Port: ge-2/0/0.0

Group: 203.0.113.1
Source: 10.0.0.30
Flags: sparse
Upstream neighbor: 10.0.0.18, Port: ge-2/0/0.0

user@PE2> show pim snooping join extensive
Instance: titanium
Learning-Domain: default

Group: 203.0.113.1
Source: *
Flags: sparse,rptree,wildcard
Upstream neighbor: 10.0.0.18, Port: ge-2/0/0.0
```

```

Downstream port: ge-2/0/1.0
Downstream neighbors:
 10.0.0.22 State: Join Flags: SRW Timeout: 180

```

```

Group: 203.0.113.1
Source: 10.0.0.30
Flags: sparse
Upstream neighbor: 10.0.0.18, Port: ge-2/0/0.0
Downstream port: ge-2/0/1.0
Downstream neighbors:
 10.0.0.22 State: Join Flags: S Timeout: 180

```

The outputs show that multicast traffic sent for the group 203.0.113.1 is sent to Receiver 2 through Router CE4 and also display the upstream and downstream neighbor details.

```

user@PE2> show multicast snooping route extensive instance titanium group 203.0.113.1
Next-hop Bulking: OFF

```

```

Family: INET

```

```

Group: 203.0.113.1/24
Bridge-domain: titanium
Mesh-group: __all_ces__
Downstream interface list:
 ge-2/0/1.0 -(1072)
Statistics: 0 kbps, 0 pps, 0 packets
Next-hop ID: 1048577
Route state: Active
Forwarding state: Forwarding

```

```

Group: 203.0.113.1/24
Source: 10.0.0.8
Bridge-domain: titanium
Mesh-group: __all_ces__
Downstream interface list:
 ge-2/0/1.0 -(1072)
Statistics: 0 kbps, 0 pps, 0 packets
Next-hop ID: 1048577
Route state: Active
Forwarding state: Forwarding

```

**Meaning** PIM snooping is operational in the network.

## VPLS Label Blocks Operation

A virtual private LAN service (VPLS) is a Layer 2 (L2) service that emulates a local area network (LAN) across a wide area network (WAN). VPLS labels are defined and exchanged in the Border Gateway Protocol (BGP) control plane. In the Junos OS implementation, label blocks are allocated and used in the VPLS control plane for two primary functions: autodiscovery and signaling.

- **Autodiscovery**—A method for automatically recognizing each provider edge (PE) router in a particular VPLS domain, using BGP update messages.
- **Signaling**—Each pair of PE routers in a VPLS domain sends and withdraws VPN labels to each other. The labels are used to establish and dismantle pseudowires between the routers. Signaling is also used to transmit certain characteristics of a pseudowire.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The PE router uses BGP extended communities to identify the members of its VPLS. Once the PE router discovers its members, it is able to establish and tear down pseudowires between members by exchanging and withdrawing labels and transmitting certain characteristics of the pseudowires.

The PE router sends common update messages to all remote PE routers, using a distinct BGP update message, thereby reducing the control plane load. This is achieved by using VPLS label blocks.

## Elements of Network Layer Reachability Information

VPLS BGP network layer reachability information (NLRI) is used to exchange VPLS membership and parameters. The elements of a VPLS BGP NLRI are defined in [Table 26 on page 1212](#).

**Table 26: NLRI Elements**

| Element             | Acronym | Description                                                                                                        | Default Size (Octets) |
|---------------------|---------|--------------------------------------------------------------------------------------------------------------------|-----------------------|
| Length              |         | Total length of the NLRI size represented in bytes.                                                                | 2                     |
| Route Distinguisher | RD      | Unique identifier for each routing instance configured on a PE.                                                    | 8                     |
| VPLS Edge ID        | VE ID   | Unique number to identify the edge site.                                                                           | 2                     |
| VE Block Offset     | VBO     | Value used to identify a label block from which a label value is selected to set up pseudowires for a remote site. | 2                     |

Table 26: NLRI Elements (*continued*)

| Element       | Acronym | Description                                                                | Default Size (Octets) |
|---------------|---------|----------------------------------------------------------------------------|-----------------------|
| VE Block Size | VBS     | Indicates the number of pseudowires that peers can have in a single block. | 2                     |
| Label Base    | LB      | Starting value of the label in the advertised label block.                 | 3                     |

## Requirements for NLRI Elements

Junos OS requires a unique route distinguisher (RD) for each routing instance configured on a PE router. A PE router might use the same RD across a VPLS (or VPN) domain or it might use different RDs. Using different RDs helps identify the originator of the VPLS NLRI.

The VPLS edge (VE) ID can be a unique VE ID, site ID, or customer edge (CE) ID. The VE ID is used by a VPLS PE router to index into label blocks used to derive the transmit and receive VPN labels needed for transport of VPLS traffic. The VE ID identifies a particular site, so it needs to be unique within the VPLS domain, except for some scenarios such as multihoming.

All PE routers have full mesh connectivity with each other to exchange labels and set up pseudowires. The VE block size (VBS) is a configurable value that represents the number of label blocks required to cover all the pseudowires for the remote peer.

A single label block contains 8 labels (1 octet) by default. The default VBS in Junos OS is 2 blocks (2 octets) for a total of 16 labels.

## How Labels are Used in Label Blocks

Each PE router creates a mapping of the labels in the label block to the sites in a VPLS domain. A PE router advertising a label block with a block offset indicates which sites can use the labels to reach it. When a PE router is ready to advertise its membership to a VPLS domain, it allocates a label block and advertises the VPLS NLRI. In this way, other PE routers in the same VPLS domain can learn of the existence of the VPLS and set up pseudowires to it if needed. The VPLS NLRI advertised for this purpose is referred to as the *default VPLS NLRI*. The label block in the default VPLS NLRI is referred to as the *default label block*.

## Label Block Composition

A label block (set of labels) is used to reach a given site ID. A single label block contains 8 labels (1 octet) by default. The VBS is 2 octets by default in Junos OS.

The label block advertised is defined as a label base (LB) and a VE block size (VBS). It is a contiguous set of labels (LB, LB+1,...LB+VBS-1). For example, when Router PE-A sends a VPLS update, it sends the same label block information to all other PE routers. Each PE router that receives the LB advertisement infers the label intended for Router PE-A by adding its own site ID to the label base.

In this manner, each receiving PE gets a unique label for PE-A for that VPLS. This simple method is enhanced by using a VE block offset (VBO).

A label block is defined as: <Label Base (LB), VE block offset (VBO), VE block size (VBS)> is the set  $\{LB+VBO, LB+VBO+1, \dots, LB+VBO+VBS-1\}$ .

## Label Blocks in Junos OS

Instead of a single large label block to cover all VE IDs in a VPLS, the Junos OS implementation contains several label blocks, each with a different label base. This makes label block management easier, and also allows Router PE-A to seamlessly integrate a PE router joining a VPLS with a site ID not covered by the set of label blocks that Router PE-A has already advertised.

## VPLS Label Block Structure

This section illustrates how a label block is uniquely identified.

A VPLS BGP NLRI with site ID V, VE block offset VBO, VE block size VBS, and label base LB communicates the following to its peers:

- Label block for V: Labels from LB to  $(LB + VBS - 1)$ .
- Remote VE set for V: from VBO to  $(VBO + VBS - 1)$ .

The label block advertised is a set of labels used to reach a given site ID. If there are several label blocks, the remote VE set helps to identify which label block to use. The example in [Figure 120 on page 1214](#) illustrates label blocks. There are two blocks and each block has eight labels. In this example, the label values are 64 to 71 and 80 to 87.

**Figure 120: VPLS Label Block Structure**

To create a one-to-one mapping of these 16 labels to 16 sites, assume the site IDs are the numbers 1 to 16, as shown in the illustration. The site block indicates which site ID can use which label in the label block. So, in the first block, site ID 1 uses 64, site ID 2 uses 65, and so forth. Finally, site ID 8 uses 71. The 9th site ID will use the second block instead of the first block.

The labels are calculated by comparing the values of  $VBO \leq \text{Local site ID} < (VBO + VBS)$ . Consequently, site ID 9 uses 80, site ID 10 uses 81, and so on.

To advertise the default VPLS NLRI, a PE router picks a starting block offset that fits its own site ID and is such that the end block offset is a multiple of a single label block. In Junos OS a single label block is eight labels by default.

The VPLS NLRI shown in [Figure 121 on page 1215](#) is for site ID 18. The label base contains value 262145. The block offset contains value 17. The illustration shows which site IDs correspond to which labels.

VPLS NLRI for Site ID 18

## Configuring the Label Block Size for VPLS

---

VPLS MPLS packets have a two-label stack. The outer label is used for normal MPLS forwarding in the service provider's network. If BGP is used to establish VPLS, the inner label is allocated by a PE router as part of a label block. One inner label is needed for each remote VPLS site. Four sizes are supported. We recommend using the default size of 8, unless the network design requires a different size for optimal label usage, to allow the router to support a larger number of VPLS instances.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

If you allocate a large number of small label blocks to increase efficiency, you also increase the number of routes in the VPLS domain. This has an impact on the control plane overhead.

Changing the configured label block size causes all existing pseudowires to be deleted. For example, if you configure the label block size to be 4 and then change the size to 8, all existing label blocks of size 4 are deleted, which means that all existing pseudowires are deleted. The new label block of size 8 is created, and new pseudowires are established.

Four label block sizes are supported: 2, 4, 8, and 16. Consider the following scenarios:

- 2—Allocate the label blocks in increments of 2. For a VPLS domain that has only two sites with no future expansion plans.
- 4—Allocate the label blocks in increments of 4.
- 8 (default)—Allocate the label blocks in increments of 8.
- 16—Allocate the label blocks in increments of 16. A label block size of 16 enables you to minimize the number of routes in the VPLS domain. Use this setting only if the number of routes is the most important concern.

Configure the label block size:

```
[edit routing-instances instance-name protocols vpls]
user@router# set label-block-size 2
```

### Related Documentation

- [Configuring VPLS Routing Instances on page 1173](#)

## Example: Building a VPLS From Router 1 to Router 3 to Validate Label Blocks

This example illustrates how VPLS label blocks are allocated for a specific configuration. It is organized in the following sections:

- [Requirements on page 1217](#)
- [Overview and Topology on page 1217](#)
- [Configuration on page 1218](#)

### Requirements

This configuration example requires three Juniper Networks routers.

### Overview and Topology

In the network shown in [Figure 122 on page 1217](#) Router 1 is establishing a pseudowire to Router 3

**Figure 122: Router 1 to Router 3 Topology**

Each PE filters the VPLS NLRI contained in the BGP update messages based on route target communities. Those VPLS NLRI instances that match the route target (in this case 8717:2000:2:1) are imported for further processing. The NLRI for Router 1 and Router 3 is shown in [Table 27 on page 1217](#).

**Table 27: NLRI Exchange Between for Router 1 and Router 3**

| Router 1 NLRI Advertisement to Router 3 | Router 3 NLRI Advertisement to Router 1 |
|-----------------------------------------|-----------------------------------------|
| RD - 8717:1000                          | RD - 8717:1000                          |
| VE ID - 1                               | VE ID - 2                               |
| VE Block Offset - 1                     | VE Block Offset - 1                     |
| VE Block Size - 8                       | VE Block Size - 8                       |
| Label Base - 262161                     | Label Base - 262153                     |

To set up a pseudowire to Router 3, Router 1 must select a label to use to send traffic to Router 3 and also select a label that it expects Router 3 to use to send traffic to itself. The site ID contained in the VPLS NLRI from Router 3 is 2.

Router 1 learns of the existence of site ID 2 in the same VPLS domain. Using the equation  $VBO \leq \text{Local Site ID} < (VBO + VBS)$ , Router 1 checks if the route advertised by site ID 2 fits in the label block and block offset that it previously advertised to Router 3. In this example it does fit, so the site ID 2 is mapped by the VPLS NLRI advertised by Router 1, and Router 1 is ready to set up a pseudowire to Router 3.

To select the label to reach Router 3, Router 1 looks at the label block advertised by Router 3 and performs a calculation. The calculation a PE router uses to check if its site ID is mapped in the label block from the remote peer is  $VBO \leq \text{Local Site ID} < (VBO + VBS)$ . So, Router 1 selects label  $(262153 + (1 - 1)) = 262153$  to send traffic to Router 3. Using the same equation, Router 1 looks at its own label block that it advertised and selects label  $(262161 + (2 - 1)) = 262162$  to receive traffic from Router 3. Router 1 programs its forwarding state such that any traffic destined to Router 3 carries the pseudowire label 262153 and any traffic coming from Router 3 is expected to have the pseudowire label 262162. This completes the operations on the VPLS NLRI received from Router 3. Router 1 now has a pseudowire set up to Router 3.

Router 3 operation is very similar to the Router 1 operation. Since the Router 3 site ID of 2 fits in the label block and block offset advertised by Router 1, Router 3 selects label  $(262161 + (2 - 1)) = 262162$  to send traffic to Router 1. Router 3 looks at its own label block that it advertised and selects label  $(262153 + (1 - 1)) = 262153$  to receive traffic from Router 1. This completes the creation of a pseudowire to Router 1.

By default, for VPLS operation Junos OS uses a virtual tunnel (VT) loopback interface to represent a pseudowire. This example uses a label-switched interface (LSI) instead of a VT interface because there is no change in the VPLS control plane operation. Thus, for an MX platform, if there is a tunnel physical interface card (PIC) configured, it is mandatory to include the **no-tunnel-services** statement at the **[edit routing-instances routing-instance-name protocols vpls]** hierarchy level.

## Configuration

The following sections present the steps to configure and verify the example in [Figure 122 on page 1217](#).

- [Configuring Router 1 on page 1218](#)
- [Configuring Router 3 on page 1219](#)
- [Verifying the VPLS Label Allocations on page 1220](#)

### Configuring Router 1

#### Step-by-Step Procedure

1. Configure Router 1. Create the **edut** routing instance. Specify the **vpls** instance type. Configure the route distinguisher and specify the value **8717:1000**. Configure the route target and specify the value **8717:100**. Configure the VPLS protocol. Specify **10** as the site range. Specify **1** as the site ID. Include the **no-tunnel-services** statement.
 

```
[edit routing-instances]
edut {
 instance-type vpls;
 interface ge-5/0/2.0;
 route-distinguisher 8717:1000;
```

```

vrf-target target:8717:100;
protocols {
 vpls {
 site-range 10;
 no-tunnel-services;
 site router-1 {
 site-identifier 1;
 }
 }
}

```

### Configuring Router 3

- Step-by-Step Procedure**
1. Configure Router 3. Create the **edut** routing instance. Specify the **vpls** instance type. Configure the route distinguisher and specify the value **8717:2000**. Configure the route target and specify the value **8717:200**. Configure the VPLS protocol. Specify **10** as the site range. Specify **2** as the site ID. Include the **no-tunnel-services** statement.

```

[edit routing-instances]
edut {
 instance-type vpls;
 interface ge-4/0/2.0;
 route-distinguisher 8717:2000;
 vrf-target target:8717:100;
 protocols {
 vpls {
 site-range 10;
 no-tunnel-services;
 site router-3 {
 site-identifier 2;
 }
 }
 }
}

```

## Verifying the VPLS Label Allocations

### Step-by-Step Procedure

1. As shown in the figure and the configuration, Site A is attached to Router 1. Site A is assigned a site ID of 1. Before Router 1 can announce its membership to VPLS **edut** using a BGP update message, Router 1 needs to allocate a default label block. In this example, the label base of the label block allocated by Router 1 is 262161. Since Router 1's site ID is 1, Router 1 associates the assigned label block with block offset of 1. The following messages are sent from Router 1 to Router 3 and displayed using the **monitor traffic interface *interface-name*** command:

```
user@Router1> monitor traffic interface ge-5/3/2
Jun 14 12:26:31.280818 BGP SEND 10.10.10.1+179 -> 10.10.10.3+53950
Jun 14 12:26:31.280824 BGP SEND message type 2 (Update) length 88
Jun 14 12:26:31.280828 BGP SEND flags 0x40 code Origin(1): IGP
Jun 14 12:26:31.280833 BGP SEND flags 0x40 code ASPath(2) length 0: <null>
Jun 14 12:26:31.280837 BGP SEND flags 0x40 code LocalPref(5): 100
Jun 14 12:26:31.280844 BGP SEND flags 0xc0 code Extended Communities(16): 2:8717:100 800a:19:0:0
Jun 14 12:26:31.280848 BGP SEND flags 0x90 code MP_reach(14): AFI/SAFI 25/65
Jun 14 12:26:31.280853 BGP SEND nhop 10.10.10.1 len 4
Jun 14 12:26:31.280862 BGP SEND 8717:1000:1:1 (label base : 262161 range : 8, ce id: 1, offset: 1)
Jun 14 12:26:31.405067 BGP RECV 10.10.10.3+53950 -> 10.10.10.1+179
Jun 14 12:26:31.405074 BGP RECV message type 2 (Update) length 88
Jun 14 12:26:31.405080 BGP RECV flags 0x40 code Origin(1): IGP
Jun 14 12:26:31.405085 BGP RECV flags 0x40 code ASPath(2) length 0: <null>
Jun 14 12:26:31.405089 BGP RECV flags 0x40 code LocalPref(5): 100
Jun 14 12:26:31.405096 BGP RECV flags 0xc0 code Extended Communities(16): 2:8717:100 800a:19:0:0
Jun 14 12:26:31.405101 BGP RECV flags 0x90 code MP_reach(14): AFI/SAFI 25/65
Jun 14 12:26:31.405106 BGP RECV nhop 10.10.10.3 len 4
Jun 14 12:26:31.405116 BGP RECV 8717:2000:2:1 (label base : 262153 range : 8, ce id: 2, offset: 1)
1)
```

2. As shown in the figure and the configuration, Site B is attached to Router 3. Site B is assigned a site ID of 2. Before Router 3 can announce its membership to VPLS **edut** using a BGP update message, Router 3 assigns a default label block with the label base of 262153. The block offset for this label block is 1 because its own site ID of 2 fits in the block being advertised. The following messages are sent from Router 3 to Router 1 and displayed using the **monitor traffic interface *interface-name*** command:

```
user@Router3> monitor traffic interface ge-2/0/1
Jun 14 12:26:31.282008 BGP SEND 10.10.10.3+53950 -> 10.10.10.1+179
Jun 14 12:26:31.282018 BGP SEND message type 2 (Update) length 88
Jun 14 12:26:31.282026 BGP SEND flags 0x40 code Origin(1): IGP
Jun 14 12:26:31.282034 BGP SEND flags 0x40 code ASPath(2) length 0: <null>
Jun 14 12:26:31.282041 BGP SEND flags 0x40 code LocalPref(5): 100
Jun 14 12:26:31.282052 BGP SEND flags 0xc0 code Extended Communities(16): 2:8717:100 800a:19:0:0
Jun 14 12:26:31.282078 BGP SEND flags 0x90 code MP_reach(14): AFI/SAFI 25/65
Jun 14 12:26:31.282088 BGP SEND nhop 10.10.10.3 len 4
Jun 14 12:26:31.282102 BGP SEND 8717:2000:2:1 (label base : 262153 range : 8, ce id: 2, offset: 1)

Jun 14 12:26:31.283395 BGP RECV 10.10.10.1+179 -> 10.10.10.3+53950
Jun 14 12:26:31.283405 BGP RECV message type 2 (Update) length 88
Jun 14 12:26:31.283412 BGP RECV flags 0x40 code Origin(1): IGP
Jun 14 12:26:31.283419 BGP RECV flags 0x40 code ASPath(2) length 0: <null>
Jun 14 12:26:31.283426 BGP RECV flags 0x40 code LocalPref(5): 100
Jun 14 12:26:31.283435 BGP RECV flags 0xc0 code Extended Communities(16): 2:8717:100 800a:19:0:0
```

```

Jun 14 12:26:31.283443 BGP RECV flags 0x90 code MP_reach(14): AFI/SAFI 25/65
Jun 14 12:26:31.283471 BGP RECV nhop 10.10.10.1 len 4
Jun 14 12:26:31.283486 BGP RECV 8717:1000:1:1 (label base : 262161 range : 8, ce id: 1, offset:
1)

```

3. Verify the connection status messages for Router 1 using the **show vpls connections** command. Notice the base label is **262161**, the incoming label from Router 3 is **262162**, and the outgoing label to Router 3 is **262153**.

# Associating Interfaces with VPLS

- [Configuring Interfaces for VPLS Routing on page 1223](#)
- [VPLS and Aggregated Ethernet Interfaces on page 1230](#)
- [Enabling VLAN Tagging on page 1231](#)
- [Configuring VPLS Without a Tunnel Services PIC on page 1231](#)

## Configuring Interfaces for VPLS Routing

---

On each PE router and for each VPLS routing instance, specify which interfaces are intended for the VPLS traffic traveling between PE and CE routers. To specify the interface for VPLS traffic, include the **interface** statement in the routing instance configuration:

```
interface interface-name;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]

You must also define each interface by including the following statements:

```
vlan-tagging vlan-tagging;
encapsulation encapsulation-type;
unit logical-unit-number {
 family vpls;
 vlan-id vlan-id-number;
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name*]
- [edit logical-systems *logical-system-name* interfaces *interface-name*]

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The following sections provide enough information to enable you to configure interfaces for VPLS routing.

- [Configuring the VPLS Interface Name on page 1224](#)
- [Configuring VPLS Interface Encapsulation on page 1224](#)
- [Enabling VLAN Tagging on page 1227](#)
- [Configuring VLAN IDs for Logical Interfaces on page 1227](#)
- [Enabling VLANs for Hub and Spoke VPLS Networks on page 1228](#)
- [Configuring Aggregated Ethernet Interfaces for VPLS on page 1228](#)

## Configuring the VPLS Interface Name

Specify both the physical and logical portions of the interface name, in the following format:

*physical.logical*

For example, in **ge-1/2/1.2**, **ge-1/2/1** is the physical portion of the interface name and **2** is the logical portion. If you do not specify the logical portion of the interface name, **0** is set by default.

A logical interface can be associated with only one routing instance.

If you enable a routing protocol on all instances by specifying **interfaces all** when configuring the master instance of the protocol at the **[edit protocols]** hierarchy level, and you configure a specific interface for VPLS routing at the **[edit routing-instances routing-instance-name]** hierarchy level, the latter interface statement takes precedence and the interface is used exclusively for VPLS.

If you explicitly configure the same interface name at both the **[edit protocols]** and **[edit routing-instances routing-instance-name]** hierarchy levels and then attempt to commit the configuration, the commit operation fails.

## Configuring VPLS Interface Encapsulation

You need to specify an encapsulation type for each PE-router-to-CE-router interface configured for VPLS. This section describes the **encapsulation** statement configuration options available for VPLS.

To configure the encapsulation type on the physical interface, include the **encapsulation** statement:

**encapsulation** (ethernet-vpls | ether-vpls-over-atm-llc | extended-vlan-vpls | vlan-vpls);

**NOTE:** ACX Series routers do not support the *ether-vpls-over-atm-llc* and *extended-vlan-vpls* options for encapsulation.

---

You can include the **encapsulation** statement for physical interfaces at the following hierarchy levels:

- [edit interfaces *interface-name*]
- [edit logical-systems *logical-system-name* interfaces *interface-name*]

**NOTE:** ACX Series routers do not support the [edit logical-systems] hierarchy.

You can configure the following physical interface encapsulations for VPLS routing instances:

- **ethernet-vpls**—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled. The PE router expects to receive Ethernet frames with VLAN tags that are not service-delimiting. The Ethernet frames are not meaningful to the PE router and cannot be used by the service provider to separate customer traffic.

On M Series routers (except the M320 router), the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

- **ether-vpls-over-atm-llc**—For ATM intelligent queuing (IQ) interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.
- **extended-vlan-vpls**—Use extended virtual LAN (VLAN) VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled and that must accept packets carrying TPIDs 0x8100, 0x9100, and 0x9901. On M Series routers (except the M320 router), the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

**NOTE:** The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.

- **vlan-vpls**—Use VLAN VPLS encapsulation on Ethernet interfaces with VLAN 802.1Q tagging and VPLS enabled. The PE router expects to receive Ethernet frames with VLAN tags that are service-delimiting. These VLAN tags can be used by the service provider to separate customer traffic. For example, LAN traffic from different customers can flow through the same service provider switch, which can then apply VLAN tags to distinguish one customer's traffic from the others. The traffic can then be forwarded to the PE router.

Interfaces with VLAN VPLS encapsulation accept packets carrying standard TPID values only. On M Series routers (except the M320 router), the 4-port Fast Ethernet

TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

To configure the encapsulation type for logical interfaces, include the **encapsulation** statement:

**encapsulation** (ether-vpls-over-atm-llc | vlan-vpls);

You can include the **encapsulation** statement for logical interfaces at the following hierarchy levels:

- [edit interfaces *interface-name* unit *number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *number*]

You can configure the following logical interface encapsulations for VPLS routing instances:

- **ether-vpls-over-atm-llc**—Use Ethernet VPLS over Asynchronous Transfer Mode (ATM) logical link control (LLC) encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3-encapsulated Ethernet frames with the frame check sequence (FCS) field removed. This encapsulation type is supported on ATM intelligent queuing (IQ) interfaces only.
- **vlan-vpls**—Use VLAN VPLS encapsulation on Ethernet interfaces with VLAN 802.1Q tagging and VPLS enabled. The PE router expects to receive Ethernet frames with VLAN tags that are service-delimiting. These VLAN tags can be used by the service provider to separate customer traffic. For example, LAN traffic from different customers can flow through the same service provider switch, which can then apply VLAN tags to distinguish one customer's traffic from the others. The traffic can then be forwarded to the PE router.

Interfaces with VLAN VPLS encapsulation accept packets carrying standard TPID values only. On M Series routers (except the M320 router), the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

**NOTE:** Label-switched interfaces (LSIs) do not support VLAN VPLS encapsulation. Therefore, you can only use VLAN VPLS encapsulation on a PE-router-to-CE-router interface and not a core-facing interface.

---

When you configure the physical interface encapsulation as **vlan-vpls**, you also need to configure the same interface encapsulation for the logical interface. You need to configure the **vlan-vpls** encapsulation on the logical interface because the **vlan-vpls** encapsulation allows you to configure a mixed mode, where some of the logical interfaces use regular Ethernet encapsulation (the default for logical interfaces) and some use **vlan-vpls**.

**NOTE:** Starting with Junos OS release 13.3, a commit error occurs when you configure `vlan-vpls` encapsulation on a physical interface and configure `family inet` on one of the logical units. Previously, it was possible to commit this invalid configuration.

## Enabling VLAN Tagging

Junos OS supports receiving and forwarding routed Ethernet frames with 802.1Q virtual local area network (VLAN) tags and running the Virtual Router Redundancy Protocol (VRRP) over 802.1Q-tagged interfaces. For VPLS to function properly, configure the router to receive and forward frames with 802.1Q VLAN tags by including the `vlan-tagging` statement at the `[edit interfaces interface-name]` hierarchy level:

```
[edit interfaces interface-name]
vlan-tagging;
```

Gigabit Ethernet interfaces can be partitioned. You can assign up to 4095 different logical interfaces, one for each VLAN, but you are limited to a maximum of 1024 VLANs on any single Gigabit Ethernet or 10-Gigabit Ethernet port. Fast Ethernet interfaces can also be partitioned, with a maximum of:

- 1024 logical interfaces for the 4-port FE PIC
- 1024 logical interfaces for the 2-port Fixed Interface Card (FIC) on an M7i router
- 16 logical interfaces for the M40e router

Table 28 on page 1227 lists VLAN ID ranges by interface type.

**Table 28: VLAN ID Range by Interface Type**

| Interface Type   | VLAN ID Range    |
|------------------|------------------|
| Fast Ethernet    | 512 through 1023 |
| Gigabit Ethernet | 512 through 4094 |

## Configuring VLAN IDs for Logical Interfaces

You can bind a VLAN identifier to a logical interface by including the `vlan-id` statement:

```
vlan-id number;
```

You can include this statement at the following hierarchy levels:

- `[edit interfaces interface-name unit logical-unit-number]`
- `[edit logical-systems logical-system-name interfaces interface-name unit logical-unit-number]`

You can also configure a logical interface to forward packets and learn MAC addresses within each VPLS routing instance configured with a VLAN ID that matches a VLAN ID specified in a list using the **vlan-id-list** statement. VLAN IDs can be entered individually using a space to separate each ID, entered as an inclusive list separating the starting VLAN ID and ending VLAN ID with a hyphen, or a combination of both.

For example, to configure the VLAN IDs 20 and 45 and the range of VLAN IDs between 30 and 40, issue the following command from the CLI:

```
set interfaces ge-1/0/1 unit 1 vlan-id-list [20 30-40 45];
```

To configure a list of VLAN IDs for a logical interface, include the **vlan-id-list** statement:

```
vlan-id-list list-of-vlan-ids;
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

**NOTE:** ACX Series routers do not support the [edit logical-systems] hierarchy.

---

For more information about how to configure VLANs, see the *Junos OS Network Interfaces Library for Routing Devices*. For detailed information about how VLAN identifiers in a VPLS routing instance are processed and translated, see the *MX Series Layer 2 Configuration Guide*.

## Enabling VLANs for Hub and Spoke VPLS Networks

For hub and spoke VPLS networks, you need to configure the **swap** option for the **output-vlan-map** statement on the hub facing interface of each spoke PE router. The **output-vlan-map** statement ensures that the vlan ID of the spoke PE router matches the VLAN ID of the hub PE router in the VPLS network. The following configuration example illustrates an interface configuration with the output-vlan-map statement included:

```
[edit interfaces xe-4/0/0]
vlan-tagging;
encapsulation flexible-ethernet-services;
unit 610 {
 encapsulation vlan-ccc;
 vlan-id 610;
 output-vlan-map swap;
}
```

## Configuring Aggregated Ethernet Interfaces for VPLS

You can configure aggregated Ethernet interfaces between CE devices and PE routers for VPLS routing instances. Traffic is load-balanced across all of the links in the aggregated interface. If one or more links in the aggregated interface fails, the traffic is switched to the remaining links.

For more information about how aggregated Ethernet interfaces function in the context of VPLS, see [“VPLS and Aggregated Ethernet Interfaces” on page 1230](#).

To configure aggregated Ethernet interfaces for VPLS, configure the interface for the VPLS routing instance as follows:

```
interfaces aex {
 vlan-tagging;
 encapsulation encapsulation-type;
 unit logical-unit-number {
 vlan-id number;
 }
}
```

You can configure the following physical link-layer encapsulation types for the VPLS aggregated Ethernet interface:

- **ethernet-vpls**
- **extended-vlan-vpls**
- **flexible-ethernet-services**
- **vlan-vpls**

**NOTE:** ACX Series routers do not support the **extended-vlan-vpls** and **vlan-vpls** encapsulation types.

For the **interface** configuration statement, in **aex**, the **x** represents the interface instance number to complete the link association; **x** can be from 0 through 127, for a total of 128 aggregated interfaces.

For more information about how to configure aggregated Ethernet interfaces, see the *Ethernet Interfaces Feature Guide for Routing Devices*.

The aggregated Ethernet interface must also be configured for the VPLS routing instance as shown in the following example:

```
[edit]
routing-instances {
 green {
 instance-type vpls;
 interface ae0.0;
 route-distinguisher 10.255.234.34:1;
 vrf-target target:11111:1;
 protocols {
 vpls {
 site-range 10;
 site green3 {
 site-identifier 3;
 }
 }
 }
 }
}
```

}

Interface **ae0.0** represents the aggregated Ethernet interface in the routing instance configuration. The VPLS routing instance configuration is otherwise standard.

## VPLS and Aggregated Ethernet Interfaces

---

You can configure aggregated Ethernet interfaces between CE devices and PE routers for VPLS routing instances. Traffic is load-balanced across all of the links in the aggregated interface. If one or more links in the aggregated interface fails, the traffic is switched to the remaining links.

Forwarding is based on a lookup of the DA MAC address. For the remote site, if a packet needs to be forwarded over an LSP, the packet is encapsulated and forwarded through the LSP. If the packet destination is a local site, it is forwarded over appropriate local site interface. For an aggregated Ethernet interface on the local site, packets are sent out of the load-balanced child interface. The Packet Forwarding Engine acquires the child link to transmit the data.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

When a received packet does not have a match to a MAC address in the forwarding database, the packet is forwarded over a set of interfaces determined from a lookup in the flooding database based on the incoming interface. This is denoted by a flood next hop. The flood next hop can include the aggregated Ethernet interface as the set of interfaces to flood the packet.

Each VPLS routing instance configured on a PE router has its own forwarding database entries that associate all of the MAC addresses the VPLS routing instance acquires with each corresponding port. A route is added to the kernel with a MAC address as the prefix and the next hop used to reach the destination. The route is an interface if the destination is local. For a remote destination, the route is a next hop for the remote site.

For local aggregated Ethernet interfaces on M Series and T Series routers, learning is based on the parent aggregated Ethernet logical interface. To age out MAC addresses for aggregated Ethernet interfaces, each Packet Forwarding Engine is queried to determine where the individual child interfaces are located. MAC addresses are aged out based on the age of the original interface.

For MX Series routers and EX Series switches, when a Dense Port Concentrator (DPC) learns a MAC address it causes the Routing Engine to age out the entry. This behavior applies to all logical interfaces. For an aggregated Ethernet logical interface, once all the member DPCs have aged out the entry, the entry is deleted from the Routing Engine.

## Enabling VLAN Tagging

Junos OS supports receiving and forwarding routed Ethernet frames with 802.1Q virtual local area network (VLAN) tags and running the Virtual Router Redundancy Protocol (VRRP) over 802.1Q-tagged interfaces. For VPLS to function properly, configure the router to receive and forward frames with 802.1Q VLAN tags by including the **vlan-tagging** statement at the **[edit interfaces *interface-name*]** hierarchy level:

```
[edit interfaces interface-name]
vlan-tagging;
```

Gigabit Ethernet interfaces can be partitioned. You can assign up to 4095 different logical interfaces, one for each VLAN, but you are limited to a maximum of 1024 VLANs on any single Gigabit Ethernet or 10-Gigabit Ethernet port. Fast Ethernet interfaces can also be partitioned, with a maximum of:

- 1024 logical interfaces for the 4-port FE PIC
- 1024 logical interfaces for the 2-port Fixed Interface Card (FIC) on an M7i router
- 16 logical interfaces for the M40e router

Table 28 on page 1227 lists VLAN ID ranges by interface type.

**Table 29: VLAN ID Range by Interface Type**

| Interface Type   | VLAN ID Range    |
|------------------|------------------|
| Fast Ethernet    | 512 through 1023 |
| Gigabit Ethernet | 512 through 4094 |

## Configuring VPLS Without a Tunnel Services PIC

VPLS normally uses a dynamic virtual tunnel logical interface on a Tunnel Services PIC to model traffic from a remote site (a site on a remote PE router that is in a VPLS domain). All traffic coming from a remote site is treated as coming in over the virtual port representing this remote site, for the purposes of Ethernet flooding, forwarding, and learning. An MPLS lookup based on the inner VPN label is done on a PE router. The label is stripped and the Layer 2 Ethernet frame contained within is forwarded to a Tunnel Services PIC. The PIC loops back the packet and then a lookup based on Ethernet MAC addresses is completed. This approach requires that the router have a Tunnel Services PIC and that the PE router complete two protocol lookups.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

You can configure VPLS without a Tunnel Services PIC by configuring the **no-tunnel-services** statement. This statement creates a label-switched interface (LSI)

to provide VPLS functionality. An LSI MPLS label is used as the inner label for VPLS. This label maps to a VPLS routing instance. On the PE router, the LSI label is stripped and then mapped to a logical LSI interface. The Layer 2 Ethernet frame is then forwarded using the LSI interface to the correct VPLS routing instance.

By default, VPLS requires a Tunnel Services PIC. To configure VPLS on a router without a Tunnel Services PIC and create an LSI, include the **no-tunnel-services** statement:

**no-tunnel-services;**

For a list of the hierarchy levels at which you can include this statement, see the summary section for this statement.

To configure a VPLS routing instance on a router without a tunnel services PIC, include the **no-tunnel-services** statement at the **[edit routing-instances *routing-instance-name* protocols vpls]** hierarchy level. To configure static VPLS on a router without a tunnel services PIC, include the **no-tunnel-services** statement at the **[edit protocols vpls static-vpls]** hierarchy level.

When you configure VPLS without a Tunnel Services PIC by including the **no-tunnel-services** statement, the following limitations apply:

- An Enhanced FPC is required.
- ATM1 interfaces are not supported.
- Aggregated SONET/SDH interfaces are not supported as core-facing interfaces.
- Channelized interfaces are not supported as core-facing interfaces.
- GRE-encapsulated interfaces are not supported as core-facing interfaces.

## Configuring Static Pseudowires for VPLS

---

You can configure a VPLS domain using static pseudowires. A VPLS domain consists of a set of PE routers that act as a single virtual Ethernet bridge for the customer sites connected to these routers. By configuring static pseudowires for the VPLS domain, you do not need to configure the LDP or BGP protocols that would normally be used for signaling. However, if you configure static pseudowires, any changes to the VPLS network topology have to be managed manually.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Static pseudowires require that you configure a set of in and out labels for each pseudowire configured for the VPLS domain. You still need to configure a VPLS identifier and neighbor identifiers for a static VPLS domain. You can configure both static and dynamic neighbors within the same VPLS routing instance.

To configure a static pseudowire for a VPLS neighbor, include the **static** statement:

```
static (Protocols VPLS) {
 incoming-label label;
 outgoing-label label;
}
```

You must configure an incoming and outgoing label for the static pseudowire using the **incoming-label** and **outgoing-label** statements. These statements identify the static pseudowire's incoming traffic and destination.

To configure a static pseudowire for a VPLS neighbor, include the **static** statement at the **[edit routing-instances routing-instance-name protocols vpls neighbor address]** hierarchy level.

You can also configure the **static** statement for a backup neighbor (if you configure the neighbor as static the backup must also be static) by including it at the **[edit routing-instances routing-instance-name protocols vpls neighbor address backup-neighbor address]** hierarchy level and for a mesh group by including it at the **[edit routing-instances routing-instance-name protocols vpls mesh-group mesh-group-name neighbor address]** hierarchy level.

For a list of hierarchy levels at which you can include the **static** statement, see the statement summary section for this statement.

To enable static VPLS on a router, you need to either configure a virtual tunnel interface (requires the router to have a tunnel services PIC) or you can configure a label switching interface (LSI). To configure an LSI, include the **no-tunnel-services** statement at the **[edit protocols vpls static-vpls]** hierarchy level. For more information, see ["Configuring VPLS Without a Tunnel Services PIC" on page 1231](#).

**NOTE:** Static pseudowires for VPLS using an LSI is supported on MX series routers and EX Series switches only. For M series and T series routers, a tunnel services PIC is required.

If you issue a **show vpls connections** command, static neighbors are displayed with **"SN"** next to their addresses in the command output.

## VPLS Path Selection Process for PE Routers

The VPLS path selection process is used to select the best path between a remote PE router and a local PE router in a VPLS network. This path selection process is applied to routes received from both single-homed and multi-homed PE routers.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

When the VPLS path selection process is complete, a PE router is made the designated VPLS edge (VE) device. The designated VE device effectively acts as the endpoint for the VPLS pseudowire that is signaled from the remote PE router. Once a PE router is made the designated VE device, a pseudowire can be signaled between the remote PE router and the local PE router and then VPLS packets can begin to flow between the PE routers.

Routes from multihomed PE routers connected to the same customer site share the same site ID, but can have different route distinguishers and block offsets. You can alter the configurations of the route distinguishers and block offsets to make a router more likely or less likely to be selected as the designated VE device.

On each PE router in the VPLS network, the best path to the CE device is determined by completing the following VPLS path selection process on each route advertisement received:

1. If the advertisement has the down bit set to 0, the advertisement is discarded.
2. Select the path with a higher preference. The preference attribute is obtained from the site-preference configured using the **site-preference** statement at the **[edit routing-instances routing-instance-name protocols vpls site site-name]** hierarchy level. If the site preference is 0, the preference attribute is obtained from the local preference.
3. If the preference values are the same, select the path with the lower router ID.
4. If the router IDs are the same, the routes are from the same PE router and the advertisement is considered to be an update. The router ID corresponds to the value of the originator ID for the BGP attribute (if present). Otherwise, the IP address for the remote BGP peer is used.
5. If the block offset values are the same, the advertisement is considered to be an update.

Once the VPLS path selection process has been completed and the designated VE device has been selected, a pseudowire is signaled between the remote PE router and the local PE router.

**NOTE:** The VPLS path selection process works the same whether or not the route has been received from another PE router, a route reflector, or an autonomous system border router (ASBR).

When the remote PE router establishes or refreshes a pseudowire to the local PE router, it verifies that the prefix is in the range required for the site ID based on the block offset and label range advertised by the designated VE device. If the prefix is out of range, the pseudowire status is set to out of range.

The following cases outline the potential decisions that could be made when a PE router completes the VPLS path selection process for a Layer 2 advertisement in the VPLS network:

- The PE router originated one of the advertisements and selected its own advertisement as the best path.

This PE router has been selected as the designated VE device. Selection as the designated VE device triggers the creation of pseudowires to and from the other PE routers in the VPLS network. If the remote customer site is multihomed, the designated VE device triggers the creation of pseudowires to and from only the designated VE device for the remote site.

- The PE router originated one of the advertisements but did not select its own advertisement as the best path.

This PE router is a redundant PE router for a multihomed site, but it was not selected as the designated VE device. However, if this PE router has just transitioned from being the designated VE device (meaning it was receiving traffic from the remote PE routers addressed to the multihomed customer site), the PE router tears down all the pseudowires that it had to and from the other PE routers in the VPLS network.

- The PE router received the route advertisements and selected a best path. It did not originate any of these advertisements because it was not connected to the customer site.

If the best path to the customer site (the designated VE device) has not changed, nothing happens. If the best path has changed, this PE router brings up pseudowires to and from the newly designated VE device and tears down the pseudowires to and from the previously designated VE device.

If this PE router does not select a best path after running the VPLS path selection process, then the local PE router does not consider the remote site to exist.

When a VE device receives an advertisement for a Layer 2 NLRI that matches its own site ID but the site is not multihomed, the pseudowire between the VE device and the transmitting PE router transitions to a site collision state and is not considered to be up.

**Related  
Documentation**

- [BGP Route Reflectors for VPLS on page 1136](#)

## BGP and VPLS Path Selection for Multihomed PE Routers

The BGP and VPLS path selection procedures are used to select the best path between the remote PE router and one of the multihomed PE routers. As part of these path selection procedures, one of the multihomed PE routers is made the designated VE device. The designated VE device effectively acts as the endpoint for the VPLS pseudowire from the remote PE router. Once a multihomed PE router is made the designated VE device, a pseudowire can be created between the remote PE router and the multihomed PE router.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Routes from multihomed PE routers connected to the same customer site share the same site ID, but can have different route distinguishers and block offsets. On each PE router in the VPLS network, the best path to the multihomed PE router is determined by completing the following VE device-selection procedures on each route advertisement received from a multihomed PE router:

1. BGP designated VE device-selection procedure—Runs before the VPLS designated VE device-selection procedure. However, the BGP designated VE device-selection procedure is used only when the route distinguishers for the multihomed PE routers are identical. If the route distinguishers are unique, only the VPLS designated VE device-selection procedure is run.
2. VPLS designated VE device-selection procedure—Runs after the BGP designated VE device-selection procedure. However, if the route distinguishers for each multihomed PE router are unique, the advertisements are not considered relevant to the BGP designated VE device-selection procedure. As a consequence, only the VPLS designated VE device-selection procedure is used.

The BGP designated VE device-selection procedure is as follows:

1. If the advertisement has the down bit set to 0, the advertisement is discarded.
2. Select the path with a higher preference. The preference attribute is obtained from the site-preference configured using the **site-preference** statement at the [edit routing-instances *routing-instance-name* protocols vpls site *site-name*] hierarchy level. If the site-preference is 0, the preference attribute is obtained from the local-preference.
3. If the preference values are the same, select the path with the lower router-id.
4. If the router-ids are the same, the routes are from the same PE router and the advertisement is considered to be an update.

Once the BGP designated VE device-selection procedure is complete, the VPLS designated VE device-selection procedure begins. This procedure is carried out regardless of the outcome of the BGP designated VE device-selection procedure:

1. If the advertisement has the down bit set to 0, the advertisement is discarded.
2. Select the path with a higher preference. The preference attribute is obtained from the site-preference configured using the **site-preference** statement at the [edit routing-instances *routing-instance-name* protocols vpls site *site-name*] hierarchy level. If the site-preference is 0, the preference attribute is obtained from the local-preference.
3. If the preference values are the same, select the path with the lower router-id.
4. If the router-ids are the same, select the path with a lower route distinguisher.
5. If the route distinguishers are the same, select the path with the lower block offset value.
6. If the block offset values are the same, the advertisement is considered to be an update.

Once the BGP and VPLS path selection procedures have been completed and the designated VE devices have been selected, a pseudowire can be created between the remote PE router and the multihomed PE router.

When the remote PE router establishes or refreshes a pseudowire to the local PE router, it verifies that the prefix is in the range required for the site ID based on the block offset and label range advertised by the designated VE device. If the prefix is out of range, the pseudowire status is set to out of range.

The following cases outline the potential decisions that could be made when a PE router completes the BGP and VPLS path selection procedures for a Layer 2 advertisement in the VPLS network:

- The PE router originated one of the multihomed advertisements and selected its own advertisement as the best path.

This PE router has been selected as the designated VE device. Selection as the designated VE device triggers the creation of pseudowires to and from the other PE routers in the VPLS network. When the remote customer site is also multihomed, the designated VE device triggers the creation of pseudowires to and from only the designated VE device for the remote site.

- The PE router originated one of the multihomed advertisements but did not select its own advertisement as the best path.

This PE router is one of the redundant PE routers for the multihomed site; it was not selected as the designated VE device. However, if this PE router has just transitioned

from being the designated VE device (meaning it was receiving traffic from the remote PE routers addressed to the multihomed customer site), the PE router tears down all the pseudowires that it had to and from the other PE routers in the VPLS network.

- The PE router receives the multihomed advertisements and selects a best path; it does not originate any of these advertisements because it is not connected to the multihomed customer site.

If the preferred path to the customer site (the designated VE device) has not changed, nothing happens. If the preferred path has changed, this PE router brings up pseudowires to and from the newly designated VE device and tears down the pseudowires to and from the previously designated VE device.

If this PE router does not select a best path after running the BGP and VPLS path selection process, the local PE router does not consider the remote site to exist.

When a VE device receives an advertisement for a Layer 2 NLRI which matches its own site ID but the site is not multihomed, the pseudowire between it and the transmitting PE router transitions to a site collision state and is not considered to be up.

---

## Dynamic Profiles for VPLS Pseudowires

A router often has two types of interfaces:

- Static interfaces, which are configured before the router is booted
- Dynamic interfaces, which are created after the router is booted and while it is running

A virtual private LAN service (VPLS) pseudowire interface (such as `lsi.1048576`) is dynamically created by the system. Therefore, the logical interface unit number for the VPLS pseudowire is not available in advance to configure characteristics such as virtual local area network (VLAN) identifiers and other parameters. As a result, certain VLAN manipulation features that are easily applied to static interfaces (such as `xe-`, `ge-`, and so on) are either not supported on dynamic interfaces or supported in a nonstandard method.

However, on MX Series routers, there is another configuration method that dynamic interfaces can use to determine their VLAN parameters when they are created by a running router: *dynamic profiles*. A dynamic profile is a conceptual container that includes parameters associated with a dynamic entity, parameters whose values are not known at the time the entity is configured.

A dynamic profile acts as a kind of template that enables you to create, update, or remove a configuration that includes client access (for example, interface or protocol) or service (for example, CoS) attributes. Using these profiles you can consolidate all of the common attributes of a client (and eventually a group of clients) and apply the attributes simultaneously. The router contains several predefined variables that enable dynamic association of interfaces and logical units to incoming subscriber requests. While configuring a dynamic profile, use the `$junos-interface-ifd-name` variable for a dynamic physical interface and the `$junos-underlying-unit-number` variable for a dynamic logical interface (unit). When a client accesses the router, the dynamic profile configuration

replaces the predefined variable with the actual interface name or unit value for the interface the client is accessing.

Dynamic profiles for VPLS are supported only on MX Series routers. For more information about dynamic profiles, see *Junos OS Broadband Subscriber Management and Services Library*.

---

## Use Cases for Dynamic Profiles for VPLS Pseudowires

---

A dynamic profile is a set of characteristics, defined in a type of template, that you can use to provide dynamic subscriber access and services for broadband applications. These services are assigned dynamically to interfaces. You can use dynamic profiles to configure the VLAN parameters of the dynamic interfaces on MX Series routers.

Two use cases for configuring VPLS pseudowires with dynamic profiles are:

- **Configuring an extra VLAN tag onto pseudowire traffic** — This is a common scenario where all the traffic received from a customer edge (CE) interface needs an additional VLAN tag toward the core. In such cases, you can use dynamic profiles at ingress and egress to control the pseudowire behavior. You can apply dynamic profiles to receive the desired frames, set the additional VLAN tag for these frames, and send these tagged frames with the desired VLAN identifier.
- **Configuring a VPLS pseudowire as a trunk interface** — This is another common scenario where the requirement is to accept traffic from a particular source and to route the traffic based on specific criteria. Dynamic profiles can be used to create multiple pseudowire trunk interfaces to accept the traffic based on specific VLAN identifiers, and to route the accepted traffic to the desired destination.

**Related  
Documentation**

- *Dynamic Profiles Overview*
- [Dynamic Profiles for VPLS Pseudowires on page 1239](#)

## Example: Configuring VPLS Pseudowires with Dynamic Profiles—Basic Solutions

The following limitations apply to dynamic profiles for VPLS on MX Series routers:

- The **native-vlan-id** statement is not supported.
- The **native-inner-vlan-id** statement is not supported.
- The **interface-mode access** statement option is not supported.
- The **vlan-id-range** statement is not supported.

In many cases, a configuration using dynamic profiles is more efficient than a static configuration, as shown by the examples in this topic.

- [VPLS Pseudowire Interfaces Without Dynamic Profiles on page 1241](#)
- [VPLS Pseudowire Interfaces and Dynamic Profiles on page 1242](#)
- [CE Routers Without Dynamic Profiles on page 1243](#)
- [CE Routers and Dynamic Profiles on page 1244](#)

### VPLS Pseudowire Interfaces Without Dynamic Profiles

Consider the following configuration, which does not use dynamic profiles to manipulate VLAN identifiers:

```
[edit routing-instances]
green {
 instance-type vpls;
 interface ge-0/0/1.1;
 interface ge-0/0/2.1;
 interface ge-0/0/3.1;
 vlan-tags outer 200 inner 100;
 protocols vpls {
 vpls-id 10;
 neighbor 10.1.1.20;
 }
 {...more...}
}

[edit interfaces]
ge-0/0/1 {
 unit 0 {
 vlan-id 10;
 }
}
ge-0/0/2 {
 unit 0 {
 vlan-id 20;
 }
}
ge-0/0/3 {
 unit 0 {
 vlan-id 30;
 }
}
```

```
}
.....
```

**NOTE:** This is not a complete router configuration.

.....

With this configuration, broadcast packets inside frames arriving with VLAN identifier 10 on **ge-0/0/1** are normalized to a dual-tagged frame with an outer VLAN value of 200 and an inner VLAN value of 100. The broadcast packet and frames exiting **ge-0/0/2** or **ge-0/0/3** have the outer VLAN value stripped and the inner VLAN value swapped to 20 and 30 respectively, according to the interface configuration. However, this stripping of the outer VLAN tag and the swapping is extra work, because the frames will still egress the VPLS pseudowire in routing instance **green** with an outer VLAN tag value of 200 and an inner VLAN tag value of 100, also according to the configuration.

The same configuration can be accomplished more effectively using dynamic profiles.

## VPLS Pseudowire Interfaces and Dynamic Profiles

Consider the following configuration, which uses dynamic profiles to manipulate VLAN identifiers:

```
[edit routing-instances]
green {
 instance-type vpls;
 interface ge-0/0/1.1;
 interface ge-0/0/2.1;
 interface ge-0/0/3.1;
 vlan-id 100; # Desired inner VLAN tag on the VPLS pseudowire
 protocols vpls {
 vpls-id 10;
 neighbor 10.1.1.20 {
 associate-profile green_vpls_pw_1; # The profile
 }
 }
 {...more...}
}

[edit interfaces]
ge-0/0/1 {
 unit 0 {
 vlan-id 10;
 }
}
ge-0/0/2 {
 unit 0 {
 vlan-id 20;
 }
}
ge-0/0/3 {
 unit 0 {
 vlan-id 30;
 }
}
```

```
[edit dynamic-profiles]
green_vpls_pw_1 interfaces $junos-interface-ifd-name {
 unit $junos-underlying-unit-number {
 vlan-tags outer 200 inner 100;
 }
}
```

**NOTE:** This is not a complete router configuration.

With this configuration, broadcast packets inside frames arriving with VLAN identifier 10 on **ge-0/0/1** normalized to a frame with VLAN identifier 100. The broadcast packet and frames exiting **ge-0/0/2** or **ge-0/0/3** have this VLAN value swapped to 20 and 30 respectively, according to the interface configuration. Frames egress the VPLS pseudowire in routing instance **green** with an outer VLAN tag value of 200 pushed on top of the normalized value.

## CE Routers Without Dynamic Profiles

You can apply a dynamic profile to an entire VPLS configuration, not just a neighbor.

Consider the following configuration, which does not use dynamic profiles to manipulate VLAN identifiers on a customer edge (CE) router with VLAN identifier 100:

```
[edit routing-instances]
green {
 instance-type vpls;
 interface ge-0/0/1.1;
 interface ge-0/0/2.1;
 interface ge-0/0/3.1;
 vlan-tags outer 200 inner 100;
 protocols vpls {
 vpls-id 10;
 neighbor 10.1.1.20;
 }
 {...more...}
}

[edit interfaces]
ge-0/0/1 {
 unit 0 {
 vlan-id 100;
 }
}
ge-0/0/2 {
 unit 0 {
 vlan-id 100;
 }
}
ge-0/0/3 {
 unit 0 {
 vlan-id 100;
 }
}
```

**NOTE:** This is not a complete router configuration.

With this configuration, broadcast packets inside frames arriving on **ge-0/0/1** are normalized to a dual-tagged frame with an outer VLAN value of 200 and an inner VLAN value of 100. The same configuration can be accomplished using dynamic profiles.

## CE Routers and Dynamic Profiles

Consider the following configuration, which uses dynamic profiles at the **protocols** level:

```
[edit routing-instances]
green {
 instance-type vpls;
 interface ge-0/0/1.1;
 interface ge-0/0/2.1;
 interface ge-0/0/3.1;
 vlan-id 100; # Desired inner VLAN tag on the VPLS pseudowire
 protocols vpls {
 associate-profile green_vpls_pw_2; # The profile
 vpls-id 10;
 neighbor 10.1.1.20;
 }
 {...more...}
}

[edit interfaces]
ge-0/0/1 {
 unit 0 {
 vlan-id 100;
 }
}
ge-0/0/2 {
 unit 0 {
 vlan-id 100;
 }
}
ge-0/0/3 {
 unit 0 {
 vlan-id 100;
 }
}

[edit dynamic-profiles]
green_vpls_pw_2 interfaces $junos-interface-ifd-name {
 unit $junos-underlying-unit-number {
 vlan-tags outer 200 inner 100;
 }
}
```

**NOTE:** This is not a complete router configuration.

With this configuration, broadcast packets inside frames arriving with VLAN identifier 100 on **ge-0/0/1** are normalized to a frame with VLAN identifier 100 (in this case, they are unchanged). The broadcast packet and frames exiting **ge-0/0/2** or **ge-0/0/3** are unchanged as well, according to the interface configuration. Frames egress the VPLS pseudowire in routing instance **green** with an outer VLAN tag value of 200 pushed on top of the normalized value.

## Example: Configuring VPLS Pseudowires with Dynamic Profiles—Complex Solutions

Dynamic profiles for VPLS pseudowires can be helpful in a variety of VLAN configurations. This section explores some of these situations through examples.

**NOTE:** These examples are not complete router configurations.

All of the examples in this section address the same basic topology. A routing instance **blue** uses a trunk bridge to connect different departments in an organization, each with their own VLANs, at two different sites. The organization uses a BGP-based VPLS with a virtual switch to accomplish this.

### Configuration of Routing Instance and Interfaces Without Dynamic Profiles

The basic configuration of routing instance and interfaces without dynamic profiles follows:

```
[edit routing-instance blue]
instance-type virtual-switch;
route-distinguisher 10.1.1.10:1;
vrf-target target:1000:1;
interface ge-3/0/0; # The trunk interface
bridge-domains {
 sales {
 vlan-id 10;
 interface ge-0/0/0.1;
 ... # Other interfaces and statements for Sales
 }
 engineering {
 vlan-id 20;
 interface ge-1/0/2.0;
 ... # Other interfaces and statements for Engineering
 }
 accounting {
```

```
 vlan-id 30;
 interface ge-2/0/3.0;
 ... # Other interfaces and statements for Accounting
 }
 others {
 vlan-id-list [40 50]; # Other departments
 }
}
protocols vpls {
 site-range 10;
 site sample-site-1 {
 site-identifier 1;
 }
}
... # Other statements for instance Blue

[edit interfaces]
ge-0/0/1 {
 unit 0 {
 vlan-id 100;
 }
}
ge-3/0/0 {
 unit 0 {
 family bridge {
 interface-mode trunk; # This is the trunk
 vlan-id-list [10 20 30 40 50];
 }
 }
}
... # More interface statements
```

This configuration switches the departmental VLAN traffic (sales, engineering, etc.) bridge domains over the VPLS pseudowire trunk connecting to the other site.

## Configuration of Routing Instance and Interfaces Using Dynamic Profiles

Here is how dynamic profiles can be applied to this basic configuration.

First, consider the requirement to push an outer VLAN tag value of 200 onto the VPLS pseudowire frames on egress. Dynamic profiles easily satisfy this requirement.

```
[edit routing-instance green]
instance-type virtual-switch;
... # Other routing instance statements
protocols vpls {
 site-range 10;
 site sample-site-1 {
 site-identifier 1;
 }
 associate-profile green_vpls_pw_1; # Apply profile here
}
... # Other routing instance statements

[edit dynamic-profiles]
green_vpls_pw_1 interfaces $junos-interface-ifd-name {
```

```

unit $junos-underlying-unit-number {
 vlan-id 200; # This is the outer tag
 family bridge {
 interface-mode trunk;
 inner-vlan-id-list [10 20 30 40 50];
 }
}

```

**NOTE:** This is not a complete router configuration.

With the dynamic profile, a packet in a frame arriving on an interface is classified as belonging to one of the bridge domains (VLANs 10–50). At the egress of the trunk VPLS pseudowire, the outer VLAN tag 200 is pushed onto the frame. At the ingress of the pseudowire at the remote location, the outer VLAN tag 200 is removed and the frame is delivered to the appropriate bridge domain.

But what if the packets associated with the Accounting VLAN are not to be forwarding to the remote site? Dynamic profiles are useful here as well.

This configuration keeps the Accounting frames from reaching the remote site.

```

[edit routing-instances green]
instance-type virtual-switch;
... # Other routing instance statements
protocols vpls {
 site-range 10;
 site sample-site-1 {
 site-identifier 1;
 }
 associate-profile green_vpls_pw_2; # Apply profile here
}
... # Other routing instance statements

[edit dynamic-profiles]
green_vpls_pw_2 interfaces $junos-interface-ifd-name {
 unit $junos-underlying-unit-number {
 family bridge {
 interface-mode trunk;
 inner-vlan-id-list [10 20 40 50]; # Removed Accounting VLAN 30
 }
 }
}

```

**NOTE:** This is not a complete router configuration.

In this case, frames arriving on the interfaces are classified according to their bridge domains and switched, if necessary, to the VPLS pseudowire trunk, except for Engineering frames. Engineering frames (VLAN 30) are only switched within the interfaces listed within bridge domain **accounting** and any statically configured trunk interfaces and are

prevented from crossing the VPLS pseudowire due to the absence of VLAN 30 on the trunk.

We can combine the two examples and use dynamic profiles to forward the frames (other than **accounting** frames) to the remote site with an out tag of 200.

This configuration keeps the Accounting frames from reaching the remote site and pushes an outer tag of 200 on VPLS pseudowire traffic.

```
[edit routing-instances green]
instance-type virtual-switch;
... # Other routing instance statements
protocols vpls {
 site-range 10;
 site sample-site-1 {
 site-identifier 1;
 }
 associate-profile green_vpls_pw_3; # Apply profile here
}
... # Other routing instance statements

[edit dynamic-profiles]
green_vpls_pw_3 interfaces $junos-interface-ifd-name {
 unit $junos-underlying-unit-number {
 vlan-id 200; # This is the outer tag
 family bridge {
 interface-mode trunk;
 inner-vlan-id-list [10 20 40 50]; # Removed Accounting VLAN 30
 }
 }
}
```

**NOTE:** This is not a complete router configuration.

In this case, frames arriving on the interfaces are classified according to their bridge domains and switched, if necessary, to the VPLS pseudowire trunk with an outer VLAN tag of 200, except for Engineering frames. Engineering frames (VLAN 30) are only switched within the interfaces listed within bridge domain **accounting** and any statically configured trunk interfaces and are prevented from crossing the VPLS pseudowire due to the absence of VLAN 30 on the trunk.

## Configuration of Tag Translation Using Dynamic Profiles

Consider a final case where the bridge domain VLANs need translation at the VPLS pseudowire trunk interface. In this case, **sales** (VLAN 10) is mapped to VLAN 110 and **engineering** (VLAN 20) is mapped to VLAN 120.

This configuration adds tag translation to the VPLS pseudowire traffic.

```
[edit routing-instances green]
instance-type virtual-switch;
... # Other routing instance statements
protocols vpls {
```

```

site-range 10;
site sample-site-1 {
 site-identifier 1;
}
associate-profile green_vpls_pw_4; # Apply profile here
}
... # Other routing instance statements

[edit dynamic-profiles]
green_vpls_pw_4 interfaces $junos-interface-ifd-name {
 unit $junos-underlying-unit-number {
 family bridge {
 interface-mode trunk;
 vlan-id-list [10 20 30 40 50]; # All VLANs
 vlan-rewrite translate 110 10; # Sales VLAN
 vlan-rewrite translate 120 20; # Engineering VLAN
 }
 }
}
}

```

**NOTE:** This is not a complete router configuration.

This translates the **sales** and **engineering** VLAN tags exiting the VPLS pseudowire accordingly. At the ingress of the VPLS pseudowire, VLANs 110 and 120 are translated back to 10 and 20, respectively.

## Configuring the FAT Flow Label for FEC 128 VPLS Pseudowires for Load-Balancing MPLS Traffic

---

This topic shows how to configure flow-aware transport of pseudowires (FAT) flow labels for forwarding equivalence class (FEC) 128 virtual private LAN service (VPLS) pseudowires for load-balancing MPLS traffic.

FAT flow labels enable load-balancing of MPLS packets across equal-cost multipath (ECMP) paths or link aggregation groups (LAGs) without the need for deep packet inspection of the payload. FAT flow labels can be used for LDP-signaled FEC 128 and FEC 129 pseudowires for VPLS and virtual private wire service (VPWS) networks.

You can configure FAT flow labels to be signaled by LDP on FEC 128 VPLS pseudowires by including the **flow-label-transmit** and **flow-label-receive** configuration statements at the **[edit routing-instances *instance-name* protocols vpls]** hierarchy level. This configuration sets the T bit and R bit advertisement to 1 (the default being 0) in the Sub-TLV field, which is one of the interface parameters of the FEC for the LDP label-mapping message header. This configuration is applicable for all the pseudowires providing full mesh connectivity from the VPLS routing instance to all its neighbors.

Before you begin:

1. Configure the device interfaces and enable MPLS on all the interfaces on the provider edge (PE) router.
2. Configure MPLS and an LSP from the ingress PE router to the remote egress PE router.
3. Configure an interior gateway protocol (IGP) on the PE router and provider (P) routers.
4. Configure the circuits between the PE routers and the customer edge (CE) routers.
5. Configure LDP on all the interfaces.

To configure the FAT flow label for an FEC 128 VPLS pseudowire, on the ingress PE router:

1. Configure the FEC 128 VPLS routing instance.

```
[edit]
user@PE1# set routing-instances instance-name instance-type vpls
user@PE1# set routing-instances instance-name interface interface-name
user@PE1# set routing-instances instance-name protocols vpls vpls-id vpls-id
user@PE1# set routing-instances instance-name protocols vpls neighbor neighbor-id
user@PE1# set routing-instances instance-name protocols vpls neighbor neighbor-id
```

2. Configure the routing instance to signal the capability to push the flow label in the transmit direction to the remote PE router.

```
[edit routing-instances instance-name protocols vpls]
user@PE1# set flow-label-transmit
```

3. Configure the routing instance to signal the capability to pop the flow label in the receive direction to the remote PE router.

```
[edit routing-instances instance-name protocols vpls]
```

```
user@PE1# set flow-label-receive
```

4. Verify and commit the configuration.

For example:

```
[edit routing-instances]
user@PE1# show
ldp-fec128-signaled-vpls {
 instance-type vpls;
 interface ge-0/0/1.0;
 protocols {
 vpls {
 vpls-id 100;
 flow-label-transmit;
 flow-label-receive;
 }
 }
}
```

5. Repeat the configuration on the remote egress PE router.

## Configuring the FAT Flow Label for FEC 129 VPLS Pseudowires for Load-Balancing MPLS Traffic

This topic shows how to configure flow-aware transport of pseudowires (FAT) flow labels for forwarding equivalence class (FEC) 129 virtual private LAN service (VPLS) pseudowires for load-balancing MPLS traffic.

FAT flow labels enable load-balancing of MPLS packets across equal-cost multipath (ECMP) paths or link aggregation groups (LAGs) without the need for deep packet inspection of the payload. FAT flow labels can be used for LDP-signaled FEC 128 and FEC 129 pseudowires for VPLS and virtual private wire service (VPWS) networks.

You can configure FAT flow labels to be signaled by LDP on FEC 129 VPLS pseudowires by including the **flow-label-transmit** and **flow-label-receive** configuration statements at the **[edit routing-instances *instance-name* protocols vpls]** hierarchy level. This configuration sets the T bit and R bit advertisement to 1 (the default being 0) in the Sub-TLV field, which is part one of the interface parameters of the FEC for the LDP label-mapping message header. This configuration is applicable for all the pseudowires providing full mesh connectivity from the VPLS routing instance to all its neighbors.

Before you begin:

1. Configure the device interfaces and enable MPLS on all the interfaces.
2. Configure MPLS and an LSP from the ingress provider edge (PE) router to the remote PE router.
3. Configure IBGP sessions between the PE routers.
4. Configure an interior gateway protocol (IGP) on the PE router and provider (P) routers.
5. Configure the circuits between the PE routers and the customer edge (CE) routers.
6. Configure LDP on all the interfaces.

To configure the FAT flow label for an FEC 129 VPLS pseudowire, on the ingress PE router:

1. Configure the FEC 129 VPLS routing instance.

```
[edit]
user@PE1# set routing-instances instance-name instance-type vpls
user@PE1# set routing-instances instance-name interface interface-name
user@PE1# set routing-instances instance-name route-distinguisher (as-number:id |
ip-address:id)
user@PE1# set routing-instances instance-name l2vpn-id (as-number:x:y | ip-address:id)
user@PE1# set routing-instances instance-name vrf-target target:x:y
```

2. Configure the routing instance to signal the capability to push the flow label in the transmit direction to the remote PE router.

```
[edit routing-instances instance-name protocols vpls]
user@PE1# set flow-label-transmit
```

3. Configure the routing instance to signal the capability to pop the flow label in the receive direction to the remote PE router.

```
[edit routing-instances instance-name protocols vpls]
user@PE1# set flow-label-receive
```

4. Verify and commit the configuration.

For example:

```
[edit routing-instances]
user@PE1# show
ldp-fec129-signaled-vpls {
 instance-type vpls;
 interface fe-0/0/0.0;
 route-distinguisher 10.255.245.45:100;
 l2vpn-id l2vpn-id:100:100;
 vrf-target target:100:100;
 protocols {
 vpls {
 flow-label-transmit;
 flow-label-receive;
 }
 }
}
```

5. Repeat the configuration on the remote egress PE router.

## Example: Configuring H-VPLS BGP-Based and LDP-Based VPLS Interoperation

This example shows how to configure the hierarchical virtual private LAN service (H-VPLS) in a scenario that uses both LDP-based VPLS and BGP-based VPLS interoperating in a multihoming deployment. This scenario is useful when a customer deployment has the two different types of VPLS in use, and you need to integrate them. Another example is when ISP-A is running BGP-based VPLS and ISP-B is running the LDP-based VPLS, and the two ISPs are merging their networks.

### Requirements

No special configuration beyond device initialization is required before configuring this example.

## Overview

In this example, Device PE2 and Device PE3 are acting as internetworking provider edge (PE) routers with BGP-based as well as LDP-based VPLS termination.

The devices in this example have the following roles:

- BGP VPLS only PE—Device PE1
- LDP VPLS only PE—Device PE4
- BGP-LDP VPLS PE—Device PE2 and Device PE3

Figure 123 on page 1254 shows the topology used in this example.

**Figure 123: H-VPLS with LDP-Based and BGP-Based VPLS Interoperation**

From Device PE4, the pseudowire to Device PE3 is the primary or working path. The pseudowire Device PE2 is the backup path.

“CLI Quick Configuration” on page 1254 shows the configuration for all of the devices in Figure 123 on page 1254. The section “Step-by-Step Procedure” on page 1258 describes the steps on Device PE1, Device PE2, and Device PE4.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

set protocols ospf area 0.0.0.0 interface ge-2/0/9.0

```

Device CE4

```

set interfaces ge-2/1/6 unit 0 description to_PE4
set interfaces ge-2/1/6 unit 0 family inet address 172.16.0.4/24
set interfaces lo0 unit 0 family inet address 10.255.14.219/32
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ospf area 0.0.0.0 interface ge-2/1/6.0

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the BGP-based VPLS PE device:

1. Configure the interfaces.

On the device interface that connects to the customer edge, enable VPLS encapsulation and the VPLS address family.

On the core-facing interfaces, enable MPLS labels.

```
[edit interfaces]
user@PE1# set ge-2/0/5 encapsulation ethernet-vpls
user@PE1# set ge-2/0/5 unit 0 description to_CE1
user@PE1# set ge-2/0/5 unit 0 family vpls

user@PE1# set fe-2/0/10 unit 0 description to_PE3
user@PE1# set fe-2/0/10 unit 0 family inet address 10.10.1.1/30
user@PE1# set fe-2/0/10 unit 0 family mpls

user@PE1# set fe-2/0/9 unit 0 description to_PE2
user@PE1# set fe-2/0/9 unit 0 family inet address 10.10.3.1/30
user@PE1# set fe-2/0/9 unit 0 family mpls

user@PE1# set lo0 unit 0 family inet address 192.0.2.1/24
```

2. Enable MPLS and LDP on the interfaces.

On the MTU device interfaces that connect to other PE devices, configure MPLS and LDP.

```
[edit protocols mpls]
user@PE1# set interface fe-2/0/10.0
user@PE1# set interface fe-2/0/9.0

[edit protocols ldp]
user@PE1# set interface fe-2/0/10.0
user@PE1# set interface fe-2/0/9.0
user@PE1# set interface lo0.0
```

3. Enable routing on the interfaces.

On the MTU device interfaces that connect to other PE devices, configure an interior gateway protocol (IGP), such as OSPF or IS-IS.

```
[edit protocols ospf area 0.0.0.0]
user@PE1# set interface lo0.0 passive
user@PE1# set interface fe-2/0/10.0
user@PE1# set interface fe-2/0/9.0
```

4. Configure BGP with Layer 2 VPN signaling.

The **l2vpn signaling** statement enables support for both VPLS and Layer 2 VPN advertisement under the same network layer reachability information (NLRI).

The internal IBGP (IBGP) full mesh includes Device PE1, Device PE2, and Device PE3. Device PE4 is not included.

```
[edit protocols bgp group internal-peers]
user@PE1# set type internal
user@PE1# set local-address 192.0.2.1
user@PE1# set family l2vpn signaling
user@PE1# set neighbor 192.0.2.2
user@PE1# set neighbor 192.0.2.3
```

5. Configure the VPLS routing instance.

Because this is BGP-based VPLS, include a route distinguisher, a VRF target, and a site name and ID.

```
[edit routing-instances h-vpls-PE1]
user@PE1# set instance-type vpls
user@PE1# set interface ge-2/0/5.0
user@PE1# set route-distinguisher 1:1
user@PE1# set vrf-target target:1:1

[edit routing-instances h-vpls-PE1 protocols vpls]
user@PE1# set interface ge-2/0/5.0
user@PE1# set site PE1-vpls site-identifier 2
```

6. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@PE1# set autonomous-system 64510
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure the BGP-LDP-based VPLS PE device:

1. Configure the interfaces.

On the PE-r device interface that connects to the customer edge, configure one of the VPLS encapsulation types and the VPLS address family. This enables VPLS.

On the core-facing interfaces, enable MPLS labels.

```
[edit interfaces]
user@PE2# set ge-2/0/6 encapsulation ethernet-vpls
user@PE2# set ge-2/0/6 unit 0 description to_CE2
user@PE2# set ge-2/0/6 unit 0 family vpls

user@PE2# set fe-2/0/10 unit 0 description to_PE1
user@PE2# set fe-2/0/10 unit 0 family inet address 10.10.3.2/30
user@PE2# set fe-2/0/10 unit 0 family mpls
```

```
user@PE2# set fe-2/0/9 unit 0 description to_PE4
user@PE2# set fe-2/0/9 unit 0 family inet address 10.10.5.1/30
user@PE2# set fe-2/0/9 unit 0 family mpls
```

```
user@PE2# set fe-2/0/8 unit 0 description to_PE3
user@PE2# set fe-2/0/8 unit 0 family inet address 10.10.4.2/30
user@PE2# set fe-2/0/8 unit 0 family mpls
```

```
user@PE2# set lo0 unit 0 family inet address 192.0.2.2/24
```

2. Enable MPLS and LDP on the interfaces.

On the MTU device interfaces that connect to other PE devices, configure MPLS and LDP.

```
[edit protocols mpls]
user@PE2# set interface fe-2/0/10.0
user@PE2# set interface fe-2/0/9.0
user@PE2# set interface fe-2/0/8.0
```

```
[edit protocols ldp]
user@PE2# set interface fe-2/0/10.0
user@PE2# set interface fe-2/0/9.0
user@PE2# set interface fe-2/0/8.0
user@PE2# set interface lo0.0
```

3. Enable routing on the interfaces.

On the MTU device interfaces that connect to other PE devices, configure an interior gateway protocol (IGP), such as OSPF or IS-IS.

```
[edit protocols ospf area 0.0.0.0]
user@PE2# set interface lo0.0 passive
user@PE2# set interface fe-2/0/10.0
user@PE2# set interface fe-2/0/9.0
user@PE2# set interface fe-2/0/8.0
```

4. 

```
[edit protocols bgp group ibgp]
user@PE2# set type internal
user@PE2# set local-address 192.0.2.2
user@PE2# set family l2vpn signaling
user@PE2# set neighbor 192.0.2.3
user@PE2# set neighbor 192.0.2.1
```

5. Configure VPLS.

The **vpls-id** statement enables LDP signaling for the VPLS instance.

```
[edit routing-instances h-vpls-PE2]
user@PE2# set instance-type vpls
user@PE2# set interface ge-2/0/6.0
user@PE2# set route-distinguisher 1:2
user@PE2# set vrf-target target:1:1
```

```
[edit routing-instances h-vpls-PE2 protocols vpls]
user@PE2# set interface ge-2/0/6.0
user@PE2# set site PE2-vpls site-identifier 1
user@PE2# set site PE2-vpls multi-homing
user@PE2# set site PE2-vpls mesh-group h-vpls-PE2
user@PE2# set vpls-id 100
user@PE2# set mesh-group h-vpls-PE2 vpls-id 100
user@PE2# set mesh-group h-vpls-PE2 local-switching
user@PE2# set mesh-group h-vpls-PE2 neighbor 192.0.2.4
```

6. [edit routing-options]  
user@PE2# set autonomous-system 64510

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure LDP-based VPLS PE device:

1. Configure the interfaces.

On the PE-r device interface that connects to the customer edge, configure one of the VPLS encapsulation types and the VPLS address family. This enables VPLS.

On the core-facing interfaces, enable MPLS labels.

```
[edit interfaces]
user@PE4# set fe-2/0/10 unit 0 description to_PE2
user@PE4# set fe-2/0/10 unit 0 family inet address 10.10.5.2/30
user@PE4# set fe-2/0/10 unit 0 family mpls

user@PE4# set fe-2/0/9 unit 0 description to_PE3
user@PE4# set fe-2/0/9 unit 0 family inet address 10.10.6.2/30
user@PE4# set fe-2/0/9 unit 0 family mpls

user@PE4# set ge-2/1/7 encapsulation ethernet-vpls
user@PE4# set ge-2/1/7 unit 0 description to_CE4
user@PE4# set ge-2/1/7 unit 0 family vpls

user@PE4# set lo0 unit 0 family inet address 192.0.2.4/24
```

2. Enable MPLS and LDP on the interfaces.

On the MTU device interfaces that connect to other PE devices, configure MPLS and LDP.

```
[edit protocols mpls]
user@PE4# set interface fe-2/0/10.0
user@PE4# set interface fe-2/0/9.0

[edit protocols ldp]
user@PE4# set interface fe-2/0/10.0
```

```
user@PE4# set interface fe-2/0/9.0
user@PE4# set interface lo0.0
```

3. Enable routing on the interfaces.

On the MTU device interfaces that connect to other PE devices, configure an interior gateway protocol (IGP), such as OSPF or IS-IS.

```
[edit protocols ospf area 0.0.0.0]
user@PE4# set interface lo0.0 passive
user@PE4# set interface fe-2/0/10.0
user@PE4# set interface fe-2/0/9.0
```

4. Configure VPLS.

The **vpls-id** statement enables LDP signaling for the VPLS instance.

```
[edit routing-instances ldp-vpls]
user@PE4# set instance-type vpls
user@PE4# set interface ge-2/1/7.0
user@PE4# set protocols vpls vpls-id 100
```

```
[edit routing-instances ldp-vpls protocols vpls]
user@PE4# set neighbor 192.0.2.3
user@PE4# set neighbor 192.0.2.2
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

If you are done configuring the devices, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly. In a multihoming scenario with BGP-LDP VPLS, the LDP pseudowires are in the down state for the backup PE (Device PE2). Whereas on the LDP-only VPLS PE (Device PE4), the pseudowires to the primary and backup BGP-LDP PE devices are in the up state.

- [Verifying the VPLS Connections on page 1267](#)
- [Manually Triggering a Switch from the Active Pseudowire to the Backup Pseudowire on page 1270](#)
- [Checking Connectivity on page 1273](#)
- [Checking the BGP Layer 2 VPN Routing Tables on page 1274](#)
- [Checking the Layer 2 Circuit Routing Tables on page 1274](#)

### Verifying the VPLS Connections

**Purpose** Verify that the VPLS connections are working as expected.

**Action** From operational mode, enter the **show vpls connections** command.

```

user@PE1> show vpls connections
Layer-2 VPN connections:

```

**Meaning** On Device PE1, the BGP-VPLS connection to Device PE2 is up. In a steady-state condition, Device PE2 is the primary router and has all pseudowires terminating on it. Traffic flows from CE1 to PE1 to PE2 to PE4 to CE4.

On Device PE2, the BGP-VPLS connection to Device PE1 is up. The connection to Device PE3 is in the RN state. The LDP-VPLS connection to Device PE4 is up.

On Device PE3, all VPLS connections are in the LN state. This is expected because Device PE3 is the backup.

On Device PE4, the LDP-only VPLS router, the primary pseudowire to Device PE2 and the backup pseudowire to Device PE3 are in the up state.

### Manually Triggering a Switch from the Active Pseudowire to the Backup Pseudowire

**Purpose** Verify that when Device PE2 becomes unavailable, the traffic flow shifts to Device PE3.

**Action** 1. On Device PE2, deactivate the interfaces.

```
user@PE2# deactivate interfaces
user@PE2# commit
```

2. Rerun the **show vpls connections** command on all of the PE devices.

```
user@PE1> show vpls connections

Instance: ldp-vpls

VPLS-id: 100

| Neighbor               | Type | St        | Time last up         | # Up trans |
|------------------------|------|-----------|----------------------|------------|
| 192.0.2.2(vpls-id 100) | rmt  | <b>OL</b> |                      |            |
| 192.0.2.3(vpls-id 100) | rmt  | <b>Up</b> | Oct 16 17:12:20 2012 | 1          |

Remote PE: 192.0.2.3, Negotiated control-word: No

Incoming label: 800000, Outgoing label: 800000

Negotiated PW status TLV: No

Local interface: vt-2/0/10.17825792, Status: Up, Encapsulation: ETHERNET

Description: Intf - vpls ldp-vpls neighbor 192.0.2.3 vpls-id 100

**Meaning** On Device PE1, the BGP-VPLS connection to Device PE3 is up. Traffic flows from CE1 to PE1 to PE3 to PE4 to CE4.

On Device PE2, the BGP-VPLS connection to Device PE1 is in the OL state.

On Device PE3, all VPLS connections are up.

On Device PE4, the VPLS connection to Device PE2 is in the OL state. The VPLS connection to Device PE3 is up.

If you reactivate the interfaces on Device PE2, the connections revert to their previous state and traffic flow.

### Checking Connectivity

**Purpose** Verify that Device CE1 can ping Device CE4.

**Action** user@CE1> ping 10.255.14.219

```
PING 10.255.14.219 (10.255.14.219): 56 data bytes
64 bytes from 10.255.14.219: icmp_seq=0 ttl=64 time=1.149 ms
64 bytes from 10.255.14.219: icmp_seq=1 ttl=64 time=0.779 ms
^C
--- 10.255.14.219 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.779/0.964/1.149/0.185 ms
```

**Meaning** The output shows that VPLS is operational.

---

### Checking the BGP Layer 2 VPN Routing Tables

**Purpose** Verify that the VPLS routes are learned from BGP.

**Action** user@PE1> show route table bgp.l2vpn.0

```
bgp.l2vpn.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
1:3:1:1/96
```

```
*[BGP/170] 20:00:11, localpref 100, from 192.0.2.3
 AS path: I, validation-state: unverified
 > to 10.10.1.2 via fe-2/0/10.0
```

user@PE3> show route table bgp.l2vpn.0

```
bgp.l2vpn.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
1:1:2:1/96
```

```
*[BGP/170] 20:00:11, localpref 100, from 192.0.2.1
 AS path: I, validation-state: unverified
 > to 10.10.1.1 via fe-2/0/10.0
```

---

### Checking the Layer 2 Circuit Routing Tables

**Purpose** Verify that the VPLS routes are learned from LDP.

```

Action user@PE3> show route table l2circuit.0
l2circuit.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.0.2.4:NoCtrlWord:5:100:Local/96
 *[VPLS/7] 01:30:11, metric2 1
 > to 10.10.6.2 via fe-2/0/9.0
192.0.2.4:NoCtrlWord:5:100:Remote/96
 *[LDP/9] 20:41:57
 Discard

user@PE4> show route table bgp.l2vpn.0
l2circuit.0: 3 destinations, 3 routes (2 active, 0 holddown, 1 hidden)
+ = Active Route, - = Last Active, * = Both

192.0.2.3:NoCtrlWord:5:100:Local/96
 *[VPLS/7] 20:42:51, metric2 1
 > to 10.10.6.1 via fe-2/0/9.0

## Example: Configuring BGP-Based H-VPLS Using Different Mesh Groups for Each Spoke Router

This example shows how to configure the hierarchical virtual private LAN service (H-VPLS) using different mesh groups to provide H-VPLS functionality and provides steps for verifying the configuration. This is one type of H-VPLS configuration possible in the Juniper Networks implementation. For information about the alternate type of configuration see [“Example: Configuring LDP-Based H-VPLS Using a Single Mesh Group to Terminate the Layer 2 Circuits” on page 1297](#).

Using mesh groups improves LDP-based VPLS control plane scalability and avoids the requirement for a full mesh of LDP sessions. This example uses BGP-based VPLS.

This example is organized into the following sections:

- [Requirements on page 1276](#)
- [Overview and Topology on page 1276](#)
- [Configuration on page 1277](#)

## Requirements

This example uses the following hardware components:

- Four MX Series 3D Universal Edge Routers for Router PE1, Router PE2, Router PE3, and Router PE4
- One M Series Multiservice Edge Router for Router CE4
- Two EX Series Ethernet Switches for Device CE1 and Device CE2
- One J Series Services Router for Router CE3

## Overview and Topology

Figure 124 on page 1276 shows the physical topology used in this example.

Figure 124: Physical Topology of H-VPLS

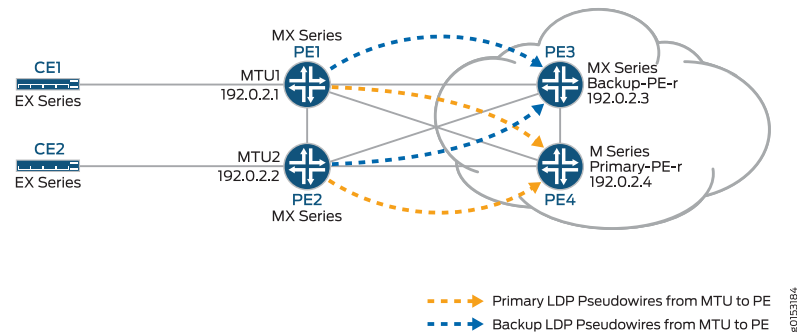

The following describes the base configuration used in this example:

- Router PE1 and Router PE2 are configured as MTU devices.
- Router PE3 and Router PE4 are configured as PE-r routers, each using an LDP-based VPLS routing instance.
- The LDP and OSPF protocols are configured on all of the MTU devices and PE-r routers.
- Core-facing interfaces are enabled with the MPLS address family.
- Optionally, the VPLS routing instances can be configured on PE-r routers with the **no-tunnel-interface** statement. This allows the routers to use a label-switched interface (LSI), which is useful if your routers do not have Tunnel Services PICs or built-in support for tunnel services.

- All of the routers are configured with loopback IP addresses.
- BGP is configured on the PE-r routers. Optionally, you can configure route reflection. This is useful for scaling internal BGP (IBGP). The BGP configuration includes the **signaling** statement at the `[edit protocols bgp group group-name family l2vpn]` hierarchy level to support Layer 2 VPN signaling using BGP.

Figure 125 on page 1277 shows the logical topology used in this example.

Figure 125: Logical Topology of H-VPLS

In Figure 125 on page 1277:

- The MTU devices (Router PE1 and Router PE2) have Layer 2 circuit connections to the PE-r routers (Router PE3 and Router PE4). For redundancy, a backup neighbor is configured for the Layer 2 circuit connections to the PE-r routers.
- The **l2circuit** statement in the `[edit protocols]` hierarchy is included on the MTU devices.
- A VPLS routing instance is configured on the PE-r routers.
- In the VPLS routing instance on the PE-r routers, mesh groups are created to terminate the Layer 2 circuit pseudowires that originate at the MTU devices.
- Each MTU device is configured with a different virtual circuit ID.
- Each PE-r router's mesh groups configuration includes VPLS ID values that match the virtual circuit IDs used on the MTU devices.

## Configuration

To configure H-VPLS with different mesh groups for each spoke PE-r router using BGP-based VPLS, perform the following tasks:

- [Configuring the Spoke MTU PE Routers on page 1277](#)
- [Configuring the Hub PE \(PE-r\) on page 1279](#)
- [Verifying the H-VPLS Operation on page 1282](#)

### Configuring the Spoke MTU PE Routers

- |                               |                                                                                                                                                                                                                                   |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step-by-Step Procedure</b> | <ol style="list-style-type: none"> <li>1. On Router PE1, configure the Gigabit Ethernet interface connected to Router CE1. Include the <b>encapsulation</b> statement and specify the <b>ethernet-ccc</b> option. Also</li> </ol> |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

configure the logical interface by including the **family** statement and specifying the **ccc** option.

```
[edit interfaces]
ge-2/0/5 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
}
```

2. On Router PE1, configure the Layer 2 circuit by including the **neighbor** statement and specifying the IP address of Router PE3 as the neighbor. Configure the Gigabit Ethernet logical interface by including the **virtual-circuit-id** statement and specifying **100** as the ID. Also configure a backup neighbor for the Layer 2 circuit by including the **backup-neighbor** statement, specifying the loopback interface IP address of Router PE4 as the backup neighbor, and including the **standby** statement.

```
[edit protocols]
l2circuit {
 neighbor 192.0.2.3 {
 interface ge-2/0/5.0 {
 virtual-circuit-id 100;
 backup-neighbor 192.0.2.4 { # Backup H-VPLS PE router
 standby;
 }
 }
 }
}
```

3. On Router PE2, configure the Gigabit Ethernet interface connected to Router CE2. Include the **encapsulation** statement and specify the **ethernet-ccc** option. Also configure the logical interface by including the **family** statement and specifying the **ccc** option.

```
[edit interfaces]
ge-2/0/6 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
}
```

4. On Router PE2, configure the Layer 2 circuit by including the **neighbor** statement and specifying the IP address of Router PE3 as the neighbor. Configure the Gigabit Ethernet logical interface by including the **virtual-circuit-id** statement and specifying **200** as the ID. Configure the encapsulation by including the **encapsulation-type** statement and specifying the **ethernet** option. Also configure a backup neighbor for the Layer 2 circuit by including the **backup-neighbor** statement, specifying the loopback interface IP address of Router PE4 as the backup neighbor, and including the **standby** statement.

```
[edit protocols]
l2circuit {
```

```

neighbor 192.0.2.3 {
 interface ge-1/0/2.0 {
 virtual-circuit-id 200; # different VC-ID
 encapsulation-type ethernet; # default encapsulation
 backup-neighbor 192.0.2.4 {
 standby;
 }
 }
}

```

### Configuring the Hub PE (PE-r)

- Step-by-Step Procedure**
1. On Router PE3 (the primary hub), configure the Gigabit Ethernet interface connected to Router CE3. Include the **encapsulation** statement and specify the **ethernet-vpls** option. Also configure the logical interface by including the **family vpls** statement.

```

[edit interfaces]
ge-2/0/0 {
 encapsulation ethernet-vpls;
 unit 0 {
 family vpls;
 }
}
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.3/24;
 }
 }
}

```

2. On Router PE4 (the backup hub), configure the Gigabit Ethernet interface connected to Router CE4. Include the **encapsulation** statement and specify the **ethernet-vpls** option. Also configure the logical interface by including the **family vpls** statement.

```

[edit interfaces]
ge-2/1/7 {
 encapsulation ethernet-vpls;
 unit 0 {
 description to_CE4;
 family vpls;
 }
}
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.4/24;
 }
 }
}

```

3. On PE-r Router PE3, configure the BGP-based VPLS routing instance by including the **instance-type** statement at the **[edit routing-instances H-VPLS]** hierarchy level and specifying the **vpls** option. Include the **interface** statement and specify the Gigabit Ethernet interface connected to Router CE3. Configure a route distinguisher to ensure that the route advertisement is unique by including the **route-distinguisher** statement and specifying **192.0.2.3:33** as the value. Also configure the VPN routing and forwarding (VRF) route target to be included in the route advertisements to the other routers participating in the VPLS. To configure the VRF route target, include the **vrf-target** statement and specify **target:64510:2** as the value. Optionally, include the **no-tunnel-services** statement to enable the use of LSI interfaces, which is useful if the device does not have tunnel services. The **no-tunnel-services** statement is omitted in this example. Optionally, you can include the **site-range** statement to specify an upper limit on the maximum site identifier that can be accepted to allow a pseudowire to be brought up. The **site-range** statement is omitted in this example. We recommend using the default of 65,534.

Configure the VPLS protocol and the mesh groups for each MTU PE device.

To configure the VPLS protocol, include the **vpls** statement at the **[edit routing-instances H-VPLS protocols]** hierarchy level. Include the **site** statement and specify a name for the site. Include the **interface** statement and specify the Gigabit Ethernet interface connected to Device CE3.

Configuring mesh groups under the VPLS instance terminates the Layer 2 circuit into the VPLS instance. To configure each mesh group, include the **mesh-group** statement and specify the mesh group name. In this example, the mesh group name is the name of the MTU device associated with each mesh group. Include the **vpls-id** statement and specify the ID that matches the virtual circuit ID configured in [“Configuring the Spoke MTU PE Routers” on page 1277](#). Also include the **neighbor** statement and specify the IP address of the spoke PE router associated with each mesh group. Optionally, include the **local-switching** statement if you are not using a full mesh of VPLS connections. The **local-switching** statement is useful if you are configuring a single mesh group and terminating multiple Layer 2 circuit pseudowires into it. The **local-switching** statement is omitted in this example.

```
routing-instances {
 H-VPLS {
 instance-type vpls;
 interface ge-2/1/3.0;
 route-distinguisher 192.0.2.3:33;
 vrf-target target:64510:2;
 protocols {
 vpls {
 site pe3 {
 site-identifier 3;
 interface ge-2/1/3.0;
 }
 mesh-group pe1 {
 vpls-id 100;
 neighbor 192.0.2.1;
 }
 mesh-group pe2 {
 vpls-id 200;
 }
 }
 }
 }
}
```

```

 neighbor 192.0.2.2;
 }
 }
 }
}

```

4. On PE-r Router PE4, configure a routing instance like the one on Router PE3.

```

routing-instances {
 H-VPLS {
 instance-type vpls;
 interface ge-2/1/7.0;
 route-distinguisher 192.0.2.4:44;
 vrf-target target:64510:2;
 protocols {
 vpls {
 site pe4 {
 site-identifier 4;
 interface ge-2/1/7.0;
 }
 mesh-group pe1 {
 vpls-id 100;
 neighbor 192.0.2.1;
 }
 mesh-group pe2 {
 vpls-id 200;
 neighbor 192.0.2.2;
 }
 }
 }
 }
}

```

### Verifying the H-VPLS Operation

---

**Step-by-Step Procedure** This section describes the operational commands that you can use to validate that the H-VPLS is working as expected.

1. On Router PE1 and Router PE2, use the **show l2circuit connections** command to verify that the Layer 2 circuit to Router PE3 is **Up** and the Layer 2 circuit to Router PE4 is in **standby** mode.

The output also shows the assigned label, virtual circuit ID, and the **ETHERNET** encapsulation type.

```
user@PE1> show l2circuit connections
Layer-2 Circuit Connections:
```

Incoming label: 800003, Outgoing label: 299888
Negotiated PW status TLV: No
Local interface: vt-2/0/10.17826049, Status: Up, Encapsulation: ETHERNET
Description: Intf - vpls H-VPLS neighbor 192.0.2.2 vpls-id 200

```

4. On Router PE3 and Router PE4, use the **show vpls flood** command to verify that the H-VPLS PE router created a flood group for each spoke PE site.

```

user@PE3> show vpls flood
Name: H-VPLS
CEs: 1
VEs: 3
Flood Routes:
 Prefix Type Owner NhType NhIndex
 0x300cc/51 FLOOD_GRP_COMP_NH __ves__ comp 1376
 0x300cf/51 FLOOD_GRP_COMP_NH __all_ces__ comp 744
 0x300d5/51 FLOOD_GRP_COMP_NH pe1 comp 1702
 0x300d3/51 FLOOD_GRP_COMP_NH pe2 comp 1544
 0x30001/51 FLOOD_GRP_COMP_NH __re_flood__ comp 740

```

```

user@PE4> show vpls flood
Name: H-VPLS
CEs: 1
VEs: 3
Flood Routes:
 Prefix Type Owner NhType NhIndex
 0x300d1/51 FLOOD_GRP_COMP_NH __ves__ comp 1534
 0x300d0/51 FLOOD_GRP_COMP_NH __all_ces__ comp 753
 0x300d6/51 FLOOD_GRP_COMP_NH pe1 comp 1378
 0x300d4/51 FLOOD_GRP_COMP_NH pe2 comp 1695
 0x30002/51 FLOOD_GRP_COMP_NH __re_flood__ comp 750

```

5. On Router PE3 and Router PE4, use the **show vpls mac-table** command to verify that MAC addresses of the CE devices have been learned.

```

user@PE3> show vpls mac-table
MAC flags (S -static MAC, D -dynamic MAC, L -locally learned, C -Control MAC
 SE -Statistics enabled, NM -Non configured MAC, R -Remote PE MAC)

Routing instance : H-VPLS
Bridging domain : __H-VPLS__, VLAN : NA
 MAC MAC Logical NH RTR
 address flags interface Index ID

```

```

00:21:59:0f:35:32 D vt-2/0/8.135266560
00:21:59:0f:35:33 D ge-2/1/3.0
00:21:59:0f:35:d4 D vt-2/0/9.135266561
00:21:59:0f:35:d5 D vt-2/0/10.135266562

```

```
user@PE4> show vpls mac-table
```

MAC flags (S -static MAC, D -dynamic MAC, L -locally learned, C -Control MAC  
SE -Statistics enabled, NM -Non configured MAC, R -Remote PE MAC)

```

Logical system : PE4
Routing instance : H-VPLS
Bridging domain : __H-VPLS__, VLAN : NA
MAC MAC Logical NH RTR
address flags interface Index ID
00:21:59:0f:35:32 D vt-2/0/8.17826050
00:21:59:0f:35:33 D vt-2/0/9.17826050
00:21:59:0f:35:d4 D vt-2/0/10.17826050
00:21:59:0f:35:d5 D ge-2/1/7.0

```

6. Make sure that the CE devices can ping each other.

```

user@CE1> ping 10.255.14.219 # ping sent from CE1 CE4
PING 10.255.14.219 (10.255.14.219): 56 data bytes
64 bytes from 10.255.14.219: icmp_seq=0 ttl=64 time=10.617 ms
64 bytes from 10.255.14.219: icmp_seq=1 ttl=64 time=9.224 ms
^C
--- 10.255.14.219 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max/stddev = 9.224/9.921/10.617/0.697 ms

```

```

user@CE2> ping 10.255.14.218 # ping sent from CE2 to CE3

PING 10.255.14.218 (10.255.14.218): 56 data bytes
64 bytes from 10.255.14.218: icmp_seq=0 ttl=64 time=1.151 ms
64 bytes from 10.255.14.218: icmp_seq=1 ttl=64 time=0.674 ms
^C
--- 10.255.14.218 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max/stddev = 0.674/0.913/1.151/0.238 ms

```

7. Check the relevant routing tables.

```

user@PE1> show route table l2circuit.0
l2circuit.0: 4 destinations, 4 routes (4 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

## Example: Configuring LDP-Based H-VPLS Using a Single Mesh Group to Terminate the Layer 2 Circuits

This example shows how to configure a single mesh group to terminate the Layer 2 circuits into an LDP-based VPLS. This is one type of hierarchical virtual private LAN service (H-VPLS) configuration possible in the Juniper Networks implementation. For information about the alternate type of configuration see [“Example: Configuring BGP-Based H-VPLS Using Different Mesh Groups for Each Spoke Router” on page 1275](#).

This example provides step-by-step configuration instructions and also provides steps for verifying and troubleshooting the configuration.

This example is organized into the following sections:

- [Requirements on page 1298](#)
- [Overview and Topology on page 1298](#)
- [Configuration on page 1299](#)

## Requirements

This example uses the following hardware components:

- Four MX Series 3D Universal Edge Routers for Routers PE1, PE2, PE3, and PE4
- Two M Series Multiservice Edge Routers for Routers CE4 and PE5
- Two EX Series Ethernet Switches for Devices CE1 and CE2
- Two T Series Core Routers for Routers P1 and the route reflector

## Overview and Topology

[Figure 126 on page 1298](#) shows the physical topology used in this example.

**Figure 126: Physical Topology of H-VPLS using a Single Mesh Group**

In [Figure 126 on page 1298](#):

- Local switching is used to switch traffic between Layer 2 circuit pseudowires from the different spoke PE routers.
- The spoke PE routers are configured with the same virtual circuit ID and VPLS ID pair in a mesh group.
- The spoke PE routers are configured in an LDP-signaled VPLS routing instance.
- The layer 2 circuits are terminated into the LDP-based VPLS.

## Configuration

To configure a single mesh group to terminate the Layer 2 circuits into an LDP-based VPLS, perform the following tasks:

- [Configuring the Spoke PE Routers on page 1299](#)
- [Configuring the Hub PE Router on page 1301](#)
- [Verification on page 1302](#)

### Configuring the Spoke PE Routers

**Step-by-Step Procedure** Configure a single mesh group to terminate all the Layer 2 circuit pseudowires and enable local switching between the pseudowires.

1. On Router PE1, configure the Layer 2 circuit by including the **l2circuit** statement at the **[edit protocols]** hierarchy level. Include the **neighbor** statement and specify the IPv4 address of the hub PE router. Also configure the logical interface by including the **interface** statement and specify the interface connected to Router CE1.

Configure the virtual circuit ID by including the **virtual-circuit-id** statement and specifying **100** as the ID value at the **[edit protocols l2circuit neighbor 192.0.2.5 interface ge-1/0/0.0]** hierarchy level.

Configure the backup neighbor by including the **backup-neighbor** statement and specifying the IPv4 address of the backup hub PE router. Router PE3 is the backup neighbor in this example. Also include the **standby** statement at the **[edit protocols l2circuit neighbor 192.0.2.5 interface ge-1/0/0.0 backup-neighbor 192.0.2.3]** hierarchy level.

```
[edit protocols]
l2circuit {
 neighbor 192.0.2.5 {
 interface ge-1/0/0.0 {
 virtual-circuit-id 100;
 backup-neighbor 192.0.2.3 {
 standby;
 }
 }
 }
}
```

2. On Router PE2, configure the Layer 2 circuit by including the **l2circuit** statement at the **[edit protocols]** hierarchy level. Include the **neighbor** statement and specify the IPv4 address of the hub PE router. Configure the logical interface by including the **interface** statement and specifying the interface connected to Router CE2.

Configure the virtual circuit ID by including the **virtual-circuit-id** statement and specifying **100** as the ID value at the **[edit protocols l2circuit neighbor 192.0.2.5 interface ge-1/0/2.0]** hierarchy level. Include the **encapsulation** statement and specify **ethernet** as the type.

Configure the backup neighbor by including the **backup-neighbor** statement and specifying the IPv4 address of the backup hub PE router. Router PE3 is the backup neighbor in this example. Also include the **standby** statement at the **[edit protocols l2circuit neighbor 192.0.2.5 interface ge-1/0/0.0 backup-neighbor 192.0.2.3]** hierarchy level.

```
[edit protocols]
l2circuit {
 neighbor 192.0.2.5 {
 interface ge-1/0/2.0 {
 virtual-circuit-id 100;
 encapsulation-type ethernet;
 backup-neighbor 192.0.2.3 {
 standby;
 }
 }
 }
}
```

3. On Router PE4, configure the Layer 2 circuit by including the **l2circuit** statement at the **[edit protocols]** hierarchy level. Include the **neighbor** statement and specify the IPv4 address of the hub PE router. Configure the logical interface by including the **interface** statement and specify the interface connected to Router CE4.

Configure the virtual circuit ID by including the **virtual-circuit-id** statement and specifying **100** as the ID value at the **[edit protocols l2circuit neighbor 192.0.2.5 interface ge-1/2/0.0]** hierarchy level.

Configure the backup neighbor by including the **backup-neighbor** statement and specifying the IPv4 address of the backup hub PE router. Router PE3 is the backup neighbor in this example. Also include the **standby** statement at the **[edit protocols l2circuit neighbor 192.0.2.5 interface ge-1/2/0.0 backup-neighbor 192.0.2.3]** hierarchy level.

```
[edit protocols]
l2circuit {
 neighbor 192.0.2.5 {
 interface ge-1/2/0.0 {
 virtual-circuit-id 100;
 backup-neighbor 192.0.2.3 {
 standby;
 }
 }
 }
}
```

### Configuring the Hub PE Router

**Step-by-Step Procedure** Configure a single mesh group to terminate all the Layer 2 circuit pseudowires and enable local switching between the pseudowires.

1. On Router PE3, configure the Gigabit Ethernet interface connected to Router CE3 by including the **encapsulation** statement and specifying the **ethernet-vpls** option. Also configure the logical interface by including the **family** statement and specifying the **vpls** option.

```
[edit interfaces]
ge-1/0/1 {
 encapsulation ethernet-vpls;
 unit 0 {
 family vpls;
 }
}
```

2. On Router PE3, configure the logical loopback interface by including the **family** statement and specifying the **inet** option. Include the **address** statement and specify the IPv4 address for the interface.

```
[edit interfaces]
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.3/24;
 }
 }
}
```

3. On Router PE3, configure the LDP-based VPLS routing instance by including the **instance-type** statement at the **[edit routing-instances H-VPLS]** hierarchy level and specifying the **vpls** option. Include the **interface** statement and specify the Gigabit Ethernet interface connected to Router CE3.

Configure the VPLS protocol by including the **vpls** statement at the **[edit routing-instances H-VPLS protocols]** hierarchy level. Include the **no-tunnel-services** statement to enable the router to use an LSI interface.

```
[edit routing-instances]
H-VPLS {
 instance-type vpls;
 interface ge-1/0/1.0;
 protocols {
 vpls {
 no-tunnel-services;
 }
 }
}
```

- On Router PE3, configure the mesh group by including the **mesh-group** statement at the **[edit routing-instances H-VPLS protocols vpls]** hierarchy level and specifying **L2-Circuits** as the name of the group. Include the **vpls-id** statement and specify **100** as the ID value. Include the **local-switching** statement to enable the router to switch traffic between the pseudowires.

For each neighbor in the mesh group, include the **neighbor** statement and specify the IPv4 address of the spoke PE router.

```
[edit routing-instances H-VPLS protocols vpls]
mesh-group L2-Circuits {
 vpls-id 100; <<< Same VPLS ID on all MTUs
 local-switching; << Local-switching enabled
 neighbor 192.0.2.1; <<MTU IP addresses
 neighbor 192.0.2.2;
 neighbor 192.0.2.4;
}
```

## Verification

- Step-by-Step Procedure**
- On Router PE5, use the **show ldp neighbor** command to verify that LDP sessions have been created to each of the spoke PE routers.

```
user@PE5# show ldp neighbor
```

| Address   | Interface | Label space ID | Hold time |
|-----------|-----------|----------------|-----------|
| 192.0.2.1 | lo0.0     | 192.0.2.1:0    | 33        |
| 192.0.2.2 | lo0.0     | 192.0.2.2:0    | 37        |
| 192.0.2.4 | lo0.0     | 192.0.2.4:0    | 39        |

- On Router PE5, use the **show vpls connections extensive** command to verify that the mesh group neighbor session is **Up**, that inbound and outbound labels have been assigned, that the VPLS ID is correct, and that the virtual tunnel interface is being used.

```
user@PE5# show vpls connections extensive

## Example: Configuring H-VPLS With VLANs

This example shows how to configure the hierarchical virtual private LAN service (H-VPLS). VLANs are configured in this example.

- [Requirements on page 1303](#)
- [Overview on page 1304](#)
- [Configuration on page 1305](#)
- [Verification on page 1313](#)

## Requirements

No special configuration beyond device initialization is required before configuring this example.

## Overview

H-VPLS uses LDP-based VPLS to signal and establish pseudowires. LDP-based VPLS is defined in RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*. RFC 4762 also defines a hierarchical mode of operation for LDP VPLS called H-VPLS.

VPLS and H-VPLS are different with respect to scaling. VPLS requires a full mesh of tunnel label-switched paths (LSPs) among all of the provider edge (PE) routers that participate in the VPLS service. For each VPLS service,  $n*(n-1)/2$  pseudowires must be set up between the PE routers. In contrast, H-VPLS partitions the network into several edge domains that are interconnected using an MPLS core. Each edge device only needs to learn of one local PE device and therefore needs less routing table support. This has the potential to allow service providers to use relatively less costly devices (such as EX Series switches) at the customer edge.

**NOTE:** As alternatives to H-VPLS, Juniper Networks offers other ways to address VPLS scalability. For more information, see [Application Note: Demystifying H-VPLS](#).

H-VPLS defines two roles or functionalities:

- PE-r—PE device that runs VPLS with other PE-r devices, but which also has pseudowires (it can be based on QinQ access) with another device called a multi-tenant unit (MTU), which provides the access layer.
- MTU—PE device that represents the access layer on the H-VPLS architecture and establishes pseudowires to one or more PE-r devices through which VPLS traffic is forwarded.

Figure 127 on page 1304 shows the topology used in this example.

**Figure 127: Basic H-VPLS With One MTU and Two PE-r Devices**

The example shows one MTU (Device PE1) connected to two PE-r devices (Device PE2 and Device PE3).

The pseudowire between Device PE1 and Device PE3 is the primary or working path. The pseudowire between Device PE1 and Device PE2 is the backup path.

To support VLANs with H-VPLS, you must include the **output-vlan-map swap** statement in the configuration of the MTU device as a workaround to prevent a VLAN ID mismatch. Otherwise, the PE-r devices report a VLAN ID mismatch, as shown here:

```
user@PE2> show vpls connections
Layer-2 VPN connections:
```

“CLI Quick Configuration” on page 1305 shows the configuration for all of the devices in Figure 127 on page 1304. The section “Step-by-Step Procedure” on page 1307 describes the steps on Device PE1 and Device PE2.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

**Device PE1**

```
set interfaces ge-2/0/5 vlan-tagging
set interfaces ge-2/0/5 encapsulation vlan-ccc
set interfaces ge-2/0/5 unit 601 encapsulation vlan-ccc
set interfaces ge-2/0/5 unit 601 vlan-id 601
set interfaces ge-2/0/5 unit 601 output-vlan-map swap
set interfaces ge-2/0/5 unit 601 family ccc
```

```
set interfaces ge-2/0/10 unit 0 family inet address 192.0.2.2/24
set interfaces ge-2/0/10 unit 0 family iso

set interfaces lo0 unit 0 family inet address 10.255.14.218/32
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ospf area 0.0.0.0 interface ge-2/0/9.601

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure H-VPLS on the MTU device:

1. Configure the interfaces.

On the MTU device interface that connects to the customer edge, configure one of the circuit cross-connect (CCC) encapsulation types and the CCC address family. This enables Layer 2 circuits.

On the core-facing interfaces, enable MPLS labels. The ISO address is needed as well on the core-facing interfaces because IS-IS is used in the core.

[edit interfaces]

```
user@PE1# set ge-2/0/5 vlan-tagging
user@PE1# set ge-2/0/5 encapsulation vlan-ccc
user@PE1# set ge-2/0/5 unit 601 family ccc
user@PE1# set ge-2/0/5 unit 601 encapsulation vlan-ccc
user@PE1# set ge-2/0/5 unit 601 vlan-id 601
user@PE1# set ge-2/0/5 unit 601 output-vlan-map swap

user@PE1# set ge-2/0/10 unit 0 family inet address 192.0.2.2/24
user@PE1# set ge-2/0/10 unit 0 family iso
user@PE1# set ge-2/0/10 unit 0 family mpls

user@PE1# set ge-2/0/11 unit 0 family inet address 192.0.2.3/24
user@PE1# set ge-2/0/11 unit 0 family iso
user@PE1# set ge-2/0/11 unit 0 family mpls

user@PE1# set lo0 unit 0 family inet address 10.255.14.217/32
user@PE1# set lo0 unit 0 family iso address 49.0001.0102.5501.4217.00
```

2. Enable MPLS and LDP on the interfaces.

On the MTU device interfaces that connect to other PE devices, configure MPLS and LDP.

```
[edit protocols mpls]
user@PE1# set interface ge-2/0/10.0
user@PE1# set interface ge-2/0/11.0
```

```
[edit protocols ldp]
user@PE1# set interface ge-2/0/10.0
user@PE1# set interface ge-2/0/11.0
user@PE1# set interface lo0.0
```

3. Enable routing on the interfaces.

On the MTU device interfaces that connect to other PE devices, configure an interior gateway protocol (IGP), such as OSPF or IS-IS.

```
[edit protocols isis]
user@PE1# set level 1 disable
user@PE1# set interface ge-2/0/10.0
user@PE1# set interface ge-2/0/11.0
user@PE1# set interface lo0.0
```

4. Configure the Layer 2 circuit.

The neighbor 10.255.14.225 is Device PE3's loopback interface address. This sets up the working path.

The neighbor 10.255.14.216 is Device PE2's loopback interface address. This sets up the backup path.

The virtual circuit ID must match the VPLS ID that is configured on Device PE2 and Device PE3.

```
[edit protocols l2circuit neighbor 10.255.14.225 interface ge-2/0/5.601]
user@PE1# set virtual-circuit-id 601
user@PE1# set encapsulation-type ethernet-vlan
user@PE1# set backup-neighbor 10.255.14.216 standby
```

5. Configure the router ID.

```
[edit routing-options]
user@PE1# set router-id 10.255.14.217
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure H-VPLS on the MTU device:

1. Configure the interfaces.

On the PE-r device interface that connects to the customer edge, configure one of the VPLS encapsulation types and the VPLS address family. This enables VPLS.

On the core-facing interfaces, enable MPLS labels. The ISO address is needed as well on the core-facing interfaces because IS-IS is used in the core.

```
[edit interfaces]
user@PE2# set ge-2/0/6 vlan-tagging
user@PE2# set ge-2/0/6 encapsulation vlan-vpls
user@PE2# set ge-2/0/6 unit 601 encapsulation vlan-vpls
user@PE2# set ge-2/0/6 unit 601 vlan-id 601
user@PE2# set ge-2/0/6 unit 601 family vpls

user@PE2# set ge-2/0/10 unit 0 family inet address 192.0.2.4/24
user@PE2# set ge-2/0/10 unit 0 family iso
user@PE2# set ge-2/0/10 unit 0 family mpls

user@PE2# set lo0 unit 0 family inet address 10.255.14.216/32
user@PE2# set lo0 unit 0 family iso address 49.0001.0102.5501.4216.00
```

2. Enable MPLS and LDP on the interfaces.

On the MTU device interfaces that connect to other PE devices, configure MPLS and LDP.

```
[edit protocols mpls]
user@PE2# set interface ge-2/0/10.0

[edit protocols ldp]
user@PE2# set interface ge-2/0/10.0
user@PE2# set interface lo0.0
```

3. Enable routing on the interfaces.

On the MTU device interfaces that connect to other PE devices, configure an interior gateway protocol (IGP), such as OSPF or IS-IS.

```
[edit protocols isis]
user@PE2# set level 1 disable
user@PE2# set interface ge-2/0/10.0
user@PE2# set interface lo0.0
```

4. Configure VPLS.

The **neighbor 10.255.14.217** statement points to Device PE1's loopback interface address.

The VPLS ID must match the virtual circuit ID that is configured on the MTU (Device PE1).

```
[edit routing-instances customer]
user@PE2# set instance-type vpls
user@PE2# set interface ge-2/0/6.601
user@PE2# set protocols vpls vpls-id 601
user@PE2# set protocols vpls neighbor 10.255.14.217 encapsulation-type
 ethernet-vlan
```

5. Configure the router ID.

```
[edit routing-options]
user@PE2# set router-id 10.255.14.216
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
Device PE1 user@PE1# show interfaces

If you are done configuring the devices, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the Layer 2 Circuit on page 1313](#)
- [Checking the VPLS Connections on page 1313](#)
- [Checking Connectivity on page 1315](#)
- [Manually Triggering a Switch from the Active Pseudowire to the Redundant Pseudowire on page 1315](#)

### Verifying the Layer 2 Circuit

**Purpose** Verify that Layer 2 circuit is operational on the MTU device.

**Action** From operational mode, enter the **show l2circuit connections** command.

```
user@PE1> show l2circuit connections
Layer-2 Circuit Connections:
```

```

**Meaning** As expected, the VPLS connections are operational on both PE-r devices.

### Checking Connectivity

**Purpose** Verify that Device CE1 can ping Device CE3.

**Action** user@CE1> ping 10.255.14.218  
PING 10.255.14.218 (10.255.14.218): 56 data bytes  
64 bytes from 10.255.14.218: icmp\_seq=0 ttl=64 time=0.858 ms  
64 bytes from 10.255.14.218: icmp\_seq=1 ttl=64 time=0.527 ms  
64 bytes from 10.255.14.218: icmp\_seq=2 ttl=64 time=0.670 ms  
^C  
--- 10.255.14.218 ping statistics ---  
3 packets transmitted, 3 packets received, 0% packet loss  
round-trip min/avg/max/stddev = 0.527/0.685/0.858/0.136 ms

**Meaning** The output shows that H-VPLS is operational.

### Manually Triggering a Switch from the Active Pseudowire to the Redundant Pseudowire

**Purpose** Make sure that the pseudowire between Device PE1 and Device PE2 becomes operational.

**Action**    user@CE1> [request l2circuit-switchover](#) virtual-circuit-id 601 neighbor 10.255.14.225  
user@CE1> ping 10.255.14.215  
PING 10.255.14.215 (10.255.14.215): 56 data bytes  
64 bytes from 10.255.14.215: icmp\_seq=0 ttl=64 time=0.738 ms  
64 bytes from 10.255.14.215: icmp\_seq=1 ttl=64 time=0.627 ms  
64 bytes from 10.255.14.215: icmp\_seq=2 ttl=64 time=0.629 ms  
^C  
--- 10.255.14.215 ping statistics ---  
3 packets transmitted, 3 packets received, 0% packet loss  
round-trip min/avg/max/stddev = 0.627/0.665/0.738/0.052 ms

**Meaning**    The successful ping from Device CE1 to Device CE2 shows that the pseudowire between Device PE1 and PE2 is operational. Now, if you ping Device CE3 from Device CE1, the ping should fail.

## Example: Configuring H-VPLS Without VLANs

---

This example shows how to configure the hierarchical virtual private LAN service (H-VPLS). No VLANs are configured in this example.

- [Requirements on page 1316](#)
- [Overview on page 1316](#)
- [Configuration on page 1317](#)
- [Verification on page 1324](#)

### Requirements

No special configuration beyond device initialization is required before configuring this example.

### Overview

H-VPLS uses LDP-based VPLS to signal and establish pseudowires. LDP-based VPLS is defined in RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*. RFC 4762 also defines a hierarchical mode of operation for LDP VPLS called H-VPLS.

VPLS and H-VPLS are different with respect to scaling. VPLS requires a full mesh of tunnel label-switched paths (LSPs) among all of the provider edge (PE) routers that participate in the VPLS service. For each VPLS service,  $n*(n-1)/2$  pseudowires must be set up between the PE routers. In contrast, H-VPLS partitions the network into several edge domains that are interconnected using an MPLS core. Each edge device only needs

to learn of one local PE device and therefore needs less routing table support. This has the potential to allow service providers to use relatively less costly devices (such as EX Series switches) at the customer edge.

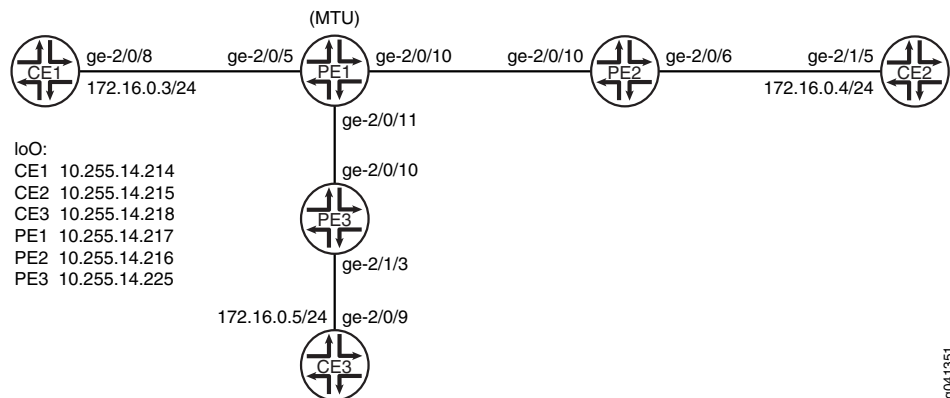

**NOTE:** As alternatives to H-VPLS, Juniper Networks offers other ways to address VPLS scalability. For more information, see [Application Note: Demystifying H-VPLS](#).

H-VPLS defines two roles or functionalities:

- PE-r—PE device that runs VPLS with other PE-r devices, but which also has pseudowires (it can be based on QinQ access) with another device called a multi-tenant unit (MTU), which provides the access layer.
- MTU—PE device that represents the access layer on the H-VPLS architecture and establishes pseudowires to one or more PE-r devices through which VPLS traffic is forwarded.

[Figure 128 on page 1317](#) shows the topology used in this example.

**Figure 128: Basic H-VPLS With One MTU and Two PE-r Devices**

The example shows one MTU (Device PE1) connected to two PE-r devices (Device PE2 and Device PE3).

The pseudowire between Device PE1 and Device PE3 is the primary or working path. The pseudowire between Device PE1 and Device PE2 is the backup path.

[“CLI Quick Configuration” on page 1317](#) shows the configuration for all of the devices in [Figure 128 on page 1317](#). The section [“Step-by-Step Procedure” on page 1319](#) describes the steps on Device PE1 and Device PE2.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network

configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

`set protocols ospf area 0.0.0.0 interface ge-2/0/9.0`

**Step-by-Step Procedure**      The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure H-VPLS on the MTU device:

1. Configure the interfaces.

On the MTU device interface that connects to the customer edge, configure one of the circuit cross-connect (CCC) encapsulation types and the CCC address family. This enables Layer 2 circuits.

On the core-facing interfaces, enable MPLS labels. The ISO address is needed as well on the core-facing interfaces because IS-IS is used in the core.

```

[edit interfaces]
user@PE1# set ge-2/0/5 encapsulation ethernet-ccc
user@PE1# set ge-2/0/5 unit 0 family ccc

user@PE1# set ge-2/0/10 unit 0 family inet address 192.0.2.2/24
user@PE1# set ge-2/0/10 unit 0 family iso
user@PE1# set ge-2/0/10 unit 0 family mpls

user@PE1# set ge-2/0/11 unit 0 family inet address 192.0.2.3/24
user@PE1# set ge-2/0/11 unit 0 family iso
user@PE1# set ge-2/0/11 unit 0 family mpls

```

```
user@PE1# set lo0 unit 0 family inet address 10.255.14.217/32
user@PE1# set lo0 unit 0 family iso address 49.0001.0102.5501.4217.00
```

2. Enable MPLS and LDP on the interfaces.

On the MTU device interfaces that connect to other PE devices, configure MPLS and LDP.

```
[edit protocols mpls]
user@PE1# set interface ge-2/0/10.0
user@PE1# set interface ge-2/0/11.0
```

```
[edit protocols ldp]
user@PE1# set interface ge-2/0/10.0
user@PE1# set interface ge-2/0/11.0
user@PE1# set interface lo0.0
```

3. Enable routing on the interfaces.

On the MTU device interfaces that connect to other PE devices, configure an interior gateway protocol (IGP), such as OSPF or IS-IS.

```
[edit protocols isis]
user@PE1# set level 1 disable
user@PE1# set interface ge-2/0/10.0
user@PE1# set interface ge-2/0/11.0
user@PE1# set interface lo0.0
```

4. Configure the Layer 2 circuit.

The neighbor 10.255.14.225 is Device PE3's loopback interface address. This sets up the working path.

The neighbor 10.255.14.216 is Device PE2's loopback interface address. This sets up the backup path.

The virtual circuit ID must match the VPLS ID that is configured on Device PE2 and Device PE3.

```
[edit protocols l2circuit neighbor 10.255.14.225 interface ge-2/0/5.0]
user@PE1# set virtual-circuit-id 601
user@PE1# set backup-neighbor 10.255.14.216 standby
```

5. Configure the router ID.

```
[edit routing-options]
user@PE1# set router-id 10.255.14.217
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure H-VPLS on the MTU device:

1. Configure the interfaces.

On the PE-r device interface that connects to the customer edge, configure one of the VPLS encapsulation types and the VPLS address family. This enables VPLS.

On the core-facing interfaces, enable MPLS labels. The ISO address is needed as well on the core-facing interfaces because IS-IS is used in the core.

```
[edit interfaces]
user@PE2# set ge-2/0/6 encapsulation ethernet-vpls
user@PE2# set ge-2/0/6 unit 0 family vpls

user@PE2# set ge-2/0/10 unit 0 family inet address 192.0.2.4/24
user@PE2# set ge-2/0/10 unit 0 family iso
user@PE2# set ge-2/0/10 unit 0 family mpls

user@PE2# set lo0 unit 0 family inet address 10.255.14.216/32
user@PE2# set lo0 unit 0 family iso address 49.0001.0102.5501.4216.00
```

2. Enable MPLS and LDP on the interfaces.

On the MTU device interfaces that connect to other PE devices, configure MPLS and LDP.

```
[edit protocols mpls]
user@PE2# set interface ge-2/0/10.0

[edit protocols ldp]
user@PE2# set interface ge-2/0/10.0
user@PE2# set interface lo0.0
```

3. Enable routing on the interfaces.

On the MTU device interfaces that connect to other PE devices, configure an interior gateway protocol (IGP), such as OSPF or IS-IS.

```
[edit protocols isis]
user@PE2# set level 1 disable
user@PE2# set interface ge-2/0/10.0
user@PE2# set interface lo0.0
```

4. Configure VPLS.

The **neighbor 10.255.14.217** statement points to Device PE1's loopback interface address.

The VPLS ID must match the virtual circuit ID that is configured on the MTU (Device PE1).

```
[edit routing-instances customer]
user@PE2# set instance-type vpls
user@PE2# set interface ge-2/0/6.0
user@PE2# set protocols vpls vpls-id 601
user@PE2# set protocols vpls neighbor 10.255.14.217
```

5. Configure the router ID.

```
[edit routing-options]
user@PE2# set router-id 10.255.14.216
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
Device PE1 user@PE1# show interfaces
ge-2/0/5 {
 encapsulation ethernet-ccc;

```

If you are done configuring the devices, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying the Layer 2 Circuit on page 1324](#)
- [Checking the VPLS Connections on page 1325](#)
- [Checking Connectivity on page 1326](#)
- [Manually Triggering a Switch from the Active Pseudowire to the Redundant Pseudowire on page 1327](#)

---

### Verifying the Layer 2 Circuit

**Purpose** Verify that the Layer 2 circuit is operational on the MTU device.

**Action** From operational mode, enter the **show l2circuit connections** command.

```
user@PE1> show l2circuit connections
Layer-2 Circuit Connections:
```

Legend for connection status (St)

|                              |                                 |
|------------------------------|---------------------------------|
| EI -- encapsulation invalid  | NP -- interface h/w not present |
| MM -- mtu mismatch           | Dn -- down                      |
| EM -- encapsulation mismatch | VC-Dn -- Virtual circuit Down   |

```

CM -- control-word mismatch Up -- operational
VM -- vlan id mismatch CF -- Call admission control failure
OL -- no outgoing label IB -- TDM incompatible bitrate
NC -- intf encaps not CCC/TCC TM -- TDM misconfiguration
BK -- Backup Connection ST -- Standby Connection
CB -- rcvd cell-bundle size bad SP -- Static Pseudowire
LD -- local site signaled down RS -- remote site standby
RD -- remote site signaled down XX -- unknown

```

#### Legend for interface status

Up -- operational

Dn -- down

Neighbor: **10.255.14.216**

| Interface          | Type | St        | Time last up | # Up trans |
|--------------------|------|-----------|--------------|------------|
| ge-2/0/5.0(vc 601) | rmt  | <b>ST</b> |              |            |

Neighbor: **10.255.14.225**

| Interface          | Type | St        | Time last up        | # Up trans |
|--------------------|------|-----------|---------------------|------------|
| ge-2/0/5.0(vc 601) | rmt  | <b>Up</b> | Oct 5 19:38:15 2012 | 1          |

Remote PE: 10.255.14.225, Negotiated control-word: No

Incoming label: 299872, Outgoing label: 800001

Negotiated PW status TLV: No

Local interface: ge-2/0/5.0, Status: Up, Encapsulation: ETHERNET

**Meaning** As expected, the Layer 2 circuit connection to Device PE3 is operational, and the connection to Device PE2 is in standby mode.

### Checking the VPLS Connections

**Purpose** Verify that the VPLS connections are operational on the PE-r devices.

**Action** From operational mode, enter the **show vpls connections** command.

```
user@PE2> show vpls connections
```

Layer-2 VPN connections:

#### Legend for connection status (St)

```

EI -- encapsulation invalid NC -- interface encapsulation not CCC/TCC/VPLS
EM -- encapsulation mismatch WE -- interface and instance encaps not same
VC-Dn -- Virtual circuit down NP -- interface hardware not present
CM -- control-word mismatch -> -- only outbound connection is up
CN -- circuit not provisioned <- -- only inbound connection is up
OR -- out of range Up -- operational
OL -- no outgoing label Dn -- down
LD -- local site signaled down CF -- call admission control failure
RD -- remote site signaled down SC -- local and remote site ID collision
LN -- local site not designated LM -- local site ID not minimum designated
RN -- remote site not designated RM -- remote site ID not minimum designated

| VM -- VLAN ID mismatch           |                                                |

## Legend for interface status

Up -- operational  
Dn -- down

Instance: customer

VPLS-id: 601

| Neighbor                   | Type | St | Time last up        | # Up trans |
|----------------------------|------|----|---------------------|------------|
| 10.255.14.217(vpls-id 601) | rmt  | Up | Oct 8 14:46:54 2012 | 1          |

Remote PE: 10.255.14.217, Negotiated control-word: No  
Incoming label: 800001, Outgoing label: 299872  
Negotiated PW status TLV: No  
Local interface: vt-2/0/10.68157697, Status: Up, Encapsulation: ETHERNET  
Description: Intf - vpls customer neighbor 10.255.14.217 vpls-id 601

**Meaning** As expected, the VPLS connections are operational on both PE-r devices.

### Checking Connectivity

**Purpose** Verify that Device CE1 can ping Device CE3.

**Action**    user@CE1> ping 10.255.14.218  
PING 10.255.14.218 (10.255.14.218): 56 data bytes  
64 bytes from 10.255.14.218: icmp\_seq=0 ttl=64 time=0.858 ms  
64 bytes from 10.255.14.218: icmp\_seq=1 ttl=64 time=0.527 ms  
64 bytes from 10.255.14.218: icmp\_seq=2 ttl=64 time=0.670 ms  
^C  
--- 10.255.14.218 ping statistics ---  
3 packets transmitted, 3 packets received, 0% packet loss  
round-trip min/avg/max/stddev = 0.527/0.685/0.858/0.136 ms

**Meaning**    The output shows that H-VPLS is operational.

### Manually Triggering a Switch from the Active Pseudowire to the Redundant Pseudowire

---

**Purpose**    Make sure that the pseudowire between Device PE1 and Device PE2 becomes operational.

**Action**    user@CE1> [request l2circuit-switchover virtual-circuit-id 601 neighbor 10.255.14.225](#)  
user@CE1> ping 10.255.14.215  
PING 10.255.14.215 (10.255.14.215): 56 data bytes  
64 bytes from 10.255.14.215: icmp\_seq=0 ttl=64 time=0.738 ms  
64 bytes from 10.255.14.215: icmp\_seq=1 ttl=64 time=0.627 ms  
64 bytes from 10.255.14.215: icmp\_seq=2 ttl=64 time=0.629 ms  
^C  
--- 10.255.14.215 ping statistics ---  
3 packets transmitted, 3 packets received, 0% packet loss  
round-trip min/avg/max/stddev = 0.627/0.665/0.738/0.052 ms

**Meaning**    The successful ping from Device CE1 to Device CE2 shows that the pseudowire between Device PE1 and PE2 is operational. Now, if you ping Device CE3 from Device CE1, the ping should fail.

## VPLS Multihoming Overview

---

Virtual private LAN service (VPLS) multihoming enables you to connect a customer site to two or more PE routers to provide redundant connectivity. A redundant PE router can provide network service to the customer site as soon as a failure is detected. VPLS multihoming helps to maintain VPLS service and traffic forwarding to and from the multihomed site in the event of the following types of network failures:

- PE router to CE device link failure
- PE router failure
- MPLS-reachability failure between the local PE router and a remote PE router

Figure 129: CE Device Multihomed to Two PE Routers

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Figure 34 on page 337 illustrates how a CE device could be multihomed to two PE routers. Device CE1 is multihomed to Routers PE1 and PE2. Device CE2 has two potential paths to reach Device CE1, but only one path is active at any one time. If Router PE1 were the designated VPLS edge (VE) device (also called a designated forwarder), BGP would signal a pseudowire from Router PE3 to Router PE1. If a failure occurred over this path, Router PE2 would be made the designated VE device, and BGP would re-signal the pseudowire from Router PE3 to Router PE2.

Multihomed PE routers advertise network layer reachability information (NLRI) for the multihomed site to the other PE routers in the VPLS network. The NLRI includes the site ID for the multihomed PE routers. For all of the PE routers multihomed to the same CE device, you need to configure the same site ID. The remote VPLS PE routers use the site ID to determine where to forward traffic addressed to the customer site. To avoid route collisions, the site ID shared by the multihomed PE routers must be different than the site IDs configured on the remote PE routers in the VPLS network.

Although you configure the same site ID for each of the PE routers multihomed to the same CE device, you can configure unique values for other parameters, such as the route distinguisher. These values help to determine which multihomed PE router is selected as the designated VE device to be used to reach the customer site.

**BEST PRACTICE:** We recommend that you configure unique route distinguishers for each multihomed PE router. Configuring unique route distinguishers helps with faster convergence when the connection to a primary multihomed PE router goes down. If you configure unique route distinguishers, the other PE routers in the VPLS network must maintain additional state for the multihomed PE routers.

Remote PE routers in the VPLS network need to determine which of the multihomed PE routers should forward traffic to reach the CE device. To make this determination, remote PE routers use the VPLS path-selection process to select one of the multihomed PE

routers based on its NLRI advertisement. Because remote PE routers pick only one of the NLRI advertisements, it establishes a pseudowire to only one of the multihomed PE routers, the PE router that originated the winning advertisement. This prevents multiple paths from being created between sites in the network, preventing the formation of Layer 2 loops. If the selected PE router fails, all PE routers in the network automatically switch to the backup PE router and establish new pseudowires to it.

**BEST PRACTICE:** To prevent the formation of Layer 2 loops between the CE devices and the multihomed PE routers, we recommend that you employ the Spanning Tree Protocol (STP) on your CE devices. Layer 2 loops can form due to incorrect configuration. Temporary Layer 2 loops can also form during convergence after a change in the network topology.

The PE routers run the BGP path selection procedure on locally originated and received Layer 2 route advertisements to establish that the routes are suitable for advertisement to other peers, such as BGP route reflectors. If a PE router in a VPLS network is also a route reflector, the path selection process for the multihomed site has no effect on the path selection process performed by this PE router for the purpose of reflecting Layer 2 routes. Layer 2 prefixes that have different route distinguishers are considered to have different NLRIs for route reflection. The VPLS path selection process enables the route reflector to reflect all routes that have different route distinguishers to the route reflector clients, even though only one of these routes is used to create the VPLS pseudowire to the multihomed site.

Junos OS supports VPLS multihoming for both FEC 128 and FEC 129. Support for FEC 129 is added in Junos OS Release 12.3.

## Advantages of Using Autodiscovery for VPLS Multihoming

---

Virtual private LAN service (VPLS) provides a multipoint-to-multipoint Ethernet service that can span one or more metropolitan areas and provides connectivity between multiple sites as if these sites were attached to the same Ethernet LAN.

VPLS uses an IP and MPLS service provider infrastructure. From a service provider's point of view, use of IP and MPLS routing protocols and procedures instead of the Spanning Tree Protocol (STP), and MPLS labels instead of VLAN IDs, significantly improves the scalability of the VPLS service.

It is frequently a requirement for a service provider to supply its customers with redundant connectivity to one or more sites. This capability is called multihoming.

VPLS multihoming enables you to connect a customer site to two or more PE routers to provide redundant connectivity. A redundant PE router can provide network service to the customer site as soon as a failure is detected. VPLS multihoming helps to maintain VPLS service and traffic forwarding to and from the multihomed site in the event of the following types of network failures:

- PE router to CE device link failure
- PE router failure
- MPLS-reachability failure between the local PE router and a remote PE router

The Junos<sup>®</sup> operating system (Junos OS) supports both forwarding equivalency class (FEC) 128 and FEC 129. FEC 128 requires manually configured pseudowires. FEC 129 uses VPLS autodiscovery to convey endpoint information. After PE routers are autodiscovered, pseudowires are created automatically.

VPLS multihoming with support for FEC 129 enables you to interoperate with other vendor's auto-discovery for LDP-signaled VPLS. This interoperability allows you to select the vendor that offers the best value.

## Example: Configuring FEC 129 BGP Autodiscovery for VPWS

---

- [Understanding VPWS on page 1332](#)
- [Understanding FEC 129 BGP Autodiscovery for VPWS on page 1335](#)
- [Example: Configuring FEC 129 BGP Autodiscovery for VPWS on page 1337](#)

### Understanding VPWS

Virtual private wire service (VPWS) Layer 2 VPNs employ Layer 2 services over MPLS to build a topology of point-to-point connections that connect end customer sites in a VPN.

These Layer 2 VPNs provide an alternative to private networks that have been provisioned by means of dedicated leased lines or by means of Layer 2 virtual circuits that employ ATM or Frame Relay. The service provisioned with these Layer 2 VPNs is known as VPWS. You configure a VPWS *instance* on each associated edge device for each VPWS Layer 2 VPN.

Traditional VPNs over Layer 2 circuits require the provisioning and maintenance of separate networks for IP and for VPN services. In contrast, VPWS enables the sharing of a provider's core network infrastructure between IP and Layer 2 VPN services, reducing the cost of providing those services.

Junos OS supports two types of VPWS Layer 2 VPNs:

- Kompella Layer 2 VPNs, which use BGP for autodiscovery and signaling.
- FEC 129 BGP autodiscovery for VPWS, which uses BGP for autodiscovery and LDP as the signaling protocol.

FEC 129 BGP autodiscovery for VPWS requires the **l2vpn-id**, **source-attachment-identifier**, and **target-attachment-identifier** statements. Kompella Layer 2 VPNs require the **site-identifier** and **remote-site-id** statements.

**NOTE:** VPWS creates pseudowires that emulate Layer 2 circuits. A virtual private LAN service (VPLS) network is similar to VPWS, but provides point-to-multipoint traffic forwarding in contrast to the VPWS Layer 2 VPN's point-to-point traffic forwarding. If you need point-to-multipoint service instead of point-to-point service, consider using VPLS instead of VPWS.

A VPWS Layer 2 VPN can have either a full-mesh or a hub-and-spoke topology. The tunneling mechanism in the core network typically is MPLS. However, VPWS can also use other tunneling protocols, such as GRE. VPWS is similar to Martini Layer 2 services over MPLS, and employs a similar encapsulation scheme for forwarding traffic.

[Figure 104 on page 1000](#) illustrates an example of a simple VPWS Layer 2 VPN topology.

Figure 130: VPWS Sample Topology

In this example, the service provider offers VPWS services to Customer A and Customer B. Customer A wants to create a full mesh of point-to-point links between Westford and Bangalore. Customer B needs only a single point-to-point link between Westford and Sunnyvale. The service provider uses BGP and MPLS signaling in the core, and creates a set of unidirectional pseudowires at each provider edge (PE) device to separately cross-connect each customer's Layer 2 circuits.

In order to provision this service, the provider configures two VPWS Layer 2 VPNs, Layer 2 VPN A and Layer 2 VPN B. The circuit cross-connect (CCC) encapsulation type (**ethernet-ccc** or **vlan-ccc**) is configured for each VPWS Layer 2 VPN. All interfaces in a given VPWS Layer 2 VPN must be configured with the VPWS Layer 2 VPN's encapsulation type.

Local and remote site information for the interfaces identifies the cross-connect. Local cross-connects are supported when the interfaces that are connected belong to two different sites configured in the same VPWS instance and on the same PE device.

BGP advertises reachability for the VPNs. The BGP configuration is similar to that used for other VPN services, such as Layer 3 VPNs and VPLS. MPLS is configured to set up base LSPs to the remote PE devices similarly to the other VPN services.

Junos OS provides VPWS support the following configuration methods:

- Pseudowires are manually configured using Forwarding Equivalence Class (FEC) 128.
- Pseudowires are signaled by LDP using FEC 129. This arrangement reduces the configuration burden that is associated with statically configured Layer 2 circuits while still using LDP as the underlying signaling protocol.

### Supported and Unsupported Features

---

Junos OS supports the following features with VPWS :

- Intra-AS VPWS functionality using BGP for autodiscovery and FEC 129 LDP for pseudowire signaling.
- Graceful Routing Engine switchover.
- Operation, administration, and maintenance (OAM) mechanisms, including Bidirectional Forwarding Detection and MPLS ping.
- FEC 128 LDP signaling with static configuration (in Junos OS this is configured within **protocols l2circuit**). With this option, there is no BGP autodiscovery.

Junos OS does not support the following VPWS functionality:

- Multihoming of customer sites to multiple PE devices using the BGP site model of multihoming.
- Terminating FEC 129 VPWS into a mesh group of an FEC 129 VPLS instance.
- Intra-AS VPWS functionality using BGP for autodiscovery and FEC 128 LDP for pseudowire signaling.
- FEC 129 VPWS without BGP autodiscovery.
- Static configuration of VPWS with FEC 129 signaling.
- Nonstop active routing.
- Multi-segment pseudowires.
- Interworking of FEC 128 and FEC 129 VPWS.
- Statically configured Layer 2 circuit-style pseudowire redundancy.
- Inter-AS deployments.

### Understanding FEC 129 BGP Autodiscovery for VPWS

The major functional components in a VPWS with FEC 129 are BGP, LDP, and the Layer 2 VPN module of Junos OS. BGP is responsible for distributing the local autodiscovery routes created on each PE device to all other PE devices. LDP is responsible for using the autodiscovery information provided by BGP to set up targeted LDP sessions over which to signal the pseudowires. The Layer 2 VPN is the glue that binds the BGP and LDP functionalities together.

### Supported Standards in FEC 129 BGP Autodiscovery for VPWS

---

The relevant RFCs for this feature are as follows:

- RFC 4447, *Pseudowire Setup and Maintenance Using the Label Distribution Protocol (LDP)*
- RFC 6074, *Provisioning, Auto-Discovery, and Signaling in Layer 2 Virtual Private Networks (L2VPNs)*

### Routes and Routing Table Interaction in FEC 129 BGP Autodiscovery for VPWS

BGP, LDP, and Layer 2 VPNs interact through different types of routes installed in the *instance.l2vpn.0* table. The routes that are present in the table are autodiscovery routes and pseudowire routes.

- Autodiscovery routes are used by BGP to allow autodiscovery of remote source access individual identifiers (SAIs) (the sources of the point-to-point pseudowires) and PE device addresses. Autodiscovery routes are advertised when you configure the **l2vpn auto-discovery-only** address family.

The format of the autodiscovery routes is a combination of the route distinguisher and the SAI. For example: 10.255.0.1:100:0.0.0.1/96 AD.

[Table 23 on page 1012](#) lists the route elements and the number of associated bytes allocated to each element.

**Table 30: Autodiscovery Route Format**

| Route Element | Bytes   |
|---------------|---------|
| RD            | 8 bytes |
| SAI           | 4 bytes |

The **l2vpn-id** of the FEC 129 VPWS instance is attached to the route in a BGP extended community. One autodiscovery route is advertised for each source attachment identifier (SAI) in the instance.

- Pseudowire routes are installed by the Layer 2 VPN (local) and LDP (remote) to represent the bidirectional components of the pseudowire. For example: NoCtrlWord:5:100:200:2:0.0.0.1/176. The format of the routes is described in [Table 24 on page 1012](#).

**Table 31: Pseudowire Route Format**

| Field Name                                                                                  | Field Description |
|---------------------------------------------------------------------------------------------|-------------------|
| Pseudowire type + control word bit                                                          | 2 bytes           |
| Remote PE address                                                                           | 4 bytes           |
| Attachment group identifier (AGI)                                                           | 8 bytes           |
| The AGI field of the pseudowire route is always set to the <b>l2vpn-id</b> of the instance. |                   |
| SAI                                                                                         | 4 bytes           |
| Target attachment individual identifier (TAII)                                              | 4 bytes           |

### Layer 2 VPN Behavior in FEC 129 BGP Autodiscovery for VPWS

A Layer 2 VPN installs a locally generated autodiscovery route into the instance.l2vpn.0 table for every SAll configured in an FEC 129 VPWS instance. The extended community containing the **l2vpn-id** is attached when the route is added to the instance.l2vpn.0 table.

For each autodiscovered SAll from a remote neighbor where the **l2vpn-id** matches the local **l2vpn-id** and the received SAll matches a locally configured TAll, the Layer 2 VPN obtains an MPLS label and generates a pseudowire route and adds it to the instance.l2vpn.0 table. The remote PE address is copied from the BGP protocol next hop for the autodiscovery route.

The Layer 2 VPN module of Junos OS is responsible for installing the forwarding routes into the mpls.0 table as usual.

### BGP Autodiscovery Behavior in FEC 129 BGP Autodiscovery for VPWS

Local autodiscovery routes installed by the Layer 2 VPN in the instance.l2vpn.0 table are advertised by BGP to remote PE devices **sl2vpn auto-discovery-only** address family according to the instance and BGP export policies.

On the receiving side, BGP accepts autodiscovery routes from remote peers and installs them in the local bgp.l2vpn.0 table, if they are allowed by inbound policy. The route is installed, and a secondary route is imported into the instance.l2vpn.0 table when an import route target match between the route and instance is found.

### LDP Signaling Behavior in VPWS in FEC 129 BGP Autodiscovery for VPWS

LDP listens for routes from instance.l2vpn.0 for any instance configured for FEC 129 VPWS. These routes are identified by the **instance-type l2vpn** statement in the routing instance and the presence of the **l2vpn-id** statement.

When a BGP autodiscovery route is installed, LDP sets up a targeted session with the remote peer, where the peer address is identified as the protocol next hop of the BGP autodiscovery route.

When a pseudowire route is installed in the instance.l2vpn.0 table, LDP uses the parameters associated with the route to signal the creation of the pseudowire using FEC 129. Upon receiving an FEC 129 label mapping message from a remote peer, LDP installs the pseudowire route in the ldp.l2vpn.0 table.

Upon a successful **l2vpn-id** match with a configured FEC 129 VPWS instance, a secondary pseudowire route is imported to the instance.l2vpn.0 table. If an outgoing pseudowire has not already been set up when the incoming pseudowire signaling is received, LDP initiates the outgoing pseudowire creation as well.

### Example: Configuring FEC 129 BGP Autodiscovery for VPWS

This example shows how to configure the virtual private wire service (VPWS), where remote provider edge (PE) devices are automatically discovered dynamically by BGP, and pseudowires are signaled by LDP using FEC 129. This arrangement reduces the

configuration burden that is associated with statically configured Layer 2 circuits while still using LDP as the underlying signaling protocol.

- [Requirements on page 1338](#)
- [Overview on page 1338](#)
- [Configuration on page 1342](#)
- [Verification on page 1346](#)

## Requirements

This example requires Junos OS Release 13.2 or later on the PE devices.

## Overview

Because VPWS is a point-to-point service, FEC 129 VPWS routing instances are configured as **instance-type l2vpn**. As with FEC 129 VPLS, FEC 129 VPWS uses the **l2vpn-id** statement to define the Layer 2 VPN of which the routing instance is a member. The presence of the **l2vpn-id** statement designates that FEC 129 LDP signaling is used for the routing instance. The absence of **l2vpn-id** indicates that BGP signaling is used instead.

The point-to-point nature of VPWS requires that you specify the source access individual identifier (SAIL) and the target access individual identifier (TAIL). This SAIL-TAIL pair defines a unique pseudowire between two PE devices.

The SAIL is specified with the **source-attachment-identifier** statement within the FEC 129 VPWS routing instance. You configure the source attachment identifier and the interfaces to associate with that source attachment identifier. Under each interface, you can configure the TAIL with the **target-attachment-identifier** statement. If the configured target identifier matches a source identifier advertised by a remote PE device by way of a BGP autodiscovery message, the pseudowire between that source-target pair is signaled. If there is no match between an advertised source identifier and the configured target identifier, the pseudowire is not established.

### Sample: VPWS Configuration with Multiple Interfaces and Sites

```
routing-instances {
 FEC129-VPWS {
 instance-type l2vpn;
 interface ge-0/0/1.0;
 interface ge-0/0/2.0;
 interface ge-0/0/3.0;
 route-distinguisher 10.255.0.1:200;
 l2vpn-id l2vpn-id:100:200;
 vrf-target target:100:200;
 protocols l2vpn {
 site CUSTOMER-1 {
 source-attachment-identifier 1;
 interface ge-0/0/1.0 {
 target-attachment-identifier 2;
 }
 interface ge-0/0/2.0 {
 target-attachment-identifier 3;
 }
 }
 }
 }
}
```

```

 }
 }

```

You can configure multiple interfaces within a site, because each SAII-TAII pair defines a unique pseudowire, as shown with pseudowires 1-2 and 1-3 in the sample configuration. Both the source and target access identifiers are 4-byte numbers and can only be configured in FEC 129 VPWS instances where the **instance-type** is **l2vpn** and the **l2vpn-id** configuration statement is present.

You can specify the source and target identifiers as plain unsigned integers in the range 1 through 4,292,967,295.

The Layer 2 circuit and Layer 2 VPN services allow many optional parameters to be included on a per-pseudowire basis. FEC 129 VPWS allows such parameters as MTU settings, community tagging, and inclusion of a control word, as shown in this sample configuration:

**Sample: VPWS  
Configuration with  
Optional Configuration  
Parameters**

```

routing-instances {
 FEC129-VPWS {

 encapsulation-type ethernet;
 ignore-encapsulation-mismatch;
 ignore-mtu-mismatch;
 mtu 1500;
 no-control-word;
 interface ge-0/0/1.0 {
 target-attachment-identifier 2;
 }
 interface ge-0/0/2.0 {
 target-attachment-identifier 3;
 community COMM;
 control-word;
 encapsulation-type ethernet;
 ignore-encapsulation-mismatch;
 ignore-mtu-mismatch;
 mtu 1500;
 no-control-word;
 }
 }
 }
 }
}

```

When configured within the site, the defined parameters affect any pseudowire originating from that site. When configured under an interface, the defined parameters affect that single specific pseudowire. This allows you to manipulate the parameters across all pseudowires associated with a particular local site in one place in the configuration.

Like other point-to-point services, the interfaces configured as members of the FEC 129 VPWS instance must be configured for CCC encapsulation and the CCC address family, as shown here:

```
interfaces {
 ge-0/0/1 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
 }
 ge-0/0/2 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
 }
 ge-0/0/3 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
 }
}
```

You can use **vlan-ccc** instead of **ethernet-ccc**.

To support the basic FEC 129 VPWS functionality, the BGP sessions on the PE devices also need to be configured with the BGP **auto-discovery-only** address family to allow exchange of the autodiscovery routes. If traditional BGP VPLS or Layer 2 VPN service is also provisioned on the PE devices, the address family **l2vpn signaling** is also required, as shown here:

```
bgp {
 group pe {
 type internal;
 local-address 10.255.0.1;
 family l2vpn {
 auto-discovery-only;
 signaling;
 }
 neighbor 10.255.0.2;
 neighbor 10.255.0.3;
 }
}
```

The following configuration sample shows an FEC 129 VPWS routing instance with the operation, administration, and maintenance (OAM) (ping and BFD) configuration options:

**Sample: VPWS  
Configuration with  
OAM**

```

routing-instances {
 FEC129-VPWS {
 instance-type l2vpn;
 interface ge-0/0/1.0;
 route-distinguisher 10.255.0.1:200;
 l2vpn-id l2vpn-id:100:200;
 vrf-target target:100:200;
 protocols l2vpn {
 oam {
 ping-interval 600;
 bfd-liveness-detection {
 minimum-interval 200;
 }
 }
 }
 site CUSTOMER {
 source-attachment-identifier 1;
 oam {
 ping-interval 600;
 bfd-liveness-detection {
 minimum-interval 200;
 }
 }
 }
 interface ge-0/0/1.0 {
 oam {
 ping-interval 600;
 bfd-liveness-detection {
 minimum-interval 200;
 }
 }
 }
 target-attachment-identifier 2;
 }
}
}

```

OAM options configured under **protocols l2vpn** apply to all sites and pseudowires in the routing instance. OAM options configured under a particular site apply to the pseudowires configured under that site. OAM options configured under a particular interface apply to the pseudowire configured under that interface.

***Topology Diagram***

Figure 107 on page 1017 shows the topology used in this example.

This example uses a simple topology with two PE devices and two customer edge (CE) devices.

Figure 131: Simple VPWS Topology

“CLI Quick Configuration” on page 1018 shows the configuration for all of the devices in Figure 107 on page 1017. The section “Step-by-Step Procedure” on page 1019 describes the steps on Device PE1.

### Configuration

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

```

**Step-by-Step** To configure a FEC 129 VPWS:

**Procedure**

1. Configure the interfaces.

```
[edit interfaces]
```

```

user@PE1# set ge-2/0/5 encapsulation ethernet-ccc
user@PE1# set ge-2/0/5 unit 0 description PE1_to_CE1
user@PE1# set ge-2/0/5 unit 0 family ccc

```

```

user@PE1# set fe-2/0/10 unit 0 description to_PE2
user@PE1# set fe-2/0/10 unit 0 family inet address 10.0.0.1/30
user@PE1# set fe-2/0/10 unit 0 family mpls

```

```

user@PE1# set lo0 unit 0 family inet address 192.0.2.1/24

```

2. Configure MPLS on the core-facing interface.

```
[edit protocols mpls]
user@PE1# set interface fe-2/0/10.0
```

3. Configure BGP.

```
[edit protocols bgp]
user@PE1# set local-address 192.0.2.1
user@PE1# set group pe-pe type internal
user@PE1# set group pe-pe family l2vpn auto-discovery-only
user@PE1# set group pe-pe family l2vpn signaling
user@PE1# set group pe-pe neighbor 192.0.2.2
```

4. Configure an interior gateway protocol, such as IS-IS or OSPF.

If you use OSPF, enable traffic engineering. Traffic engineering is supported by IS-IS by default.

```
[edit protocols ospf]
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface lo0.0 passive
user@PE1# set area 0.0.0.0 interface fe-2/0/10.0
```

5. Configure LDP on the core-facing interface and on the loopback interface.

```
[edit protocols ldp]
user@PE1# set interface fe-2/0/10.0
user@PE1# set interface lo0.0
```

6. Configure the VPWS routing instance.

LDP listens for routes from instance.l2vpn.0 for any instance configured for FEC 129 VPWS. These routes are identified by the **instance-type l2vpn** statement in the routing instance and the presence of the **l2vpn-id** statement.

Make sure that the **target-attachment-identifier** matches the **source-attachment-identifier** in the remote PE device's corresponding site. In this example, the pseudowire is established between Device PE1 and Device PE2. Device PE1 uses SAI 1 and TAI 2, while Device PE2 uses the opposite, SAI 2 and TAI 1.

```
[edit routing-instances FEC129-VPWS]
user@PE1# set instance-type l2vpn
user@PE1# set interface ge-2/0/5.0
user@PE1# set route-distinguisher 192.0.2.1:100
user@PE1# set l2vpn-id l2vpn-id:100:100
user@PE1# set vrf-target target:100:100
user@PE1# set protocols l2vpn site ONE source-attachment-identifier 1
user@PE1# set protocols l2vpn site ONE interface ge-2/0/5.0
 target-attachment-identifier 2
```

7. Configure the autonomous system (AS) number.

```
[edit routing-options]
```

```
user@PE1# set autonomous-system 64510
```

8. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE1# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, and **show routing-options** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-2/0/5 {
 encapsulation ethernet-ccc;
 unit 0 {
 description PE1_to_CE1;
 family ccc;
 }
}
fe-2/0/10 {

```

---

### Verification

Confirm that the configuration is working properly.

- [Verifying the Routes on page 1346](#)
- [Checking Connectivity Between the CE Devices on page 1348](#)
- [Checking the VPWS Connections on page 1348](#)
- [Checking Connectivity Between the PE Devices on page 1349](#)

#### *Verifying the Routes*

**Purpose** Verify that the expected routes are learned.

**Action** From operational mode, enter the **show route** command.

```
user@PE1> show route
inet.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.0.2.1/24 *[Direct/0] 6d 21:16:32
> via lo0.0
```

```

192.0.2.2/24 *[OSPF/10] 6d 21:15:31, metric 1
 > to 10.0.0.2 via fe-2/0/10.0
10.0.0.0/30 *[Direct/0] 6d 21:16:31
 > via fe-2/0/10.0
10.0.0.1/32 *[Local/0] 6d 21:16:32
 Local via fe-2/0/10.0
203.0.113.0/24 *[OSPF/10] 6d 21:16:34, metric 1
 MultiRecv

inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.0.2.2/24 *[LDP/9] 5d 22:25:19, metric 1
 > to 10.0.0.2 via fe-2/0/10.0

mpls.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0 *[MPLS/0] 6d 21:16:33, metric 1
 Receive
1 *[MPLS/0] 6d 21:16:33, metric 1
 Receive
2 *[MPLS/0] 6d 21:16:33, metric 1

Remote PE: 192.0.2.2, Negotiated control-word: No  
 Incoming label: 299792, Outgoing label: 299792  
 Local interface: ge-2/0/5.0, Status: Up, Encapsulation: ETHERNET

**Meaning** As expected, the connection is up. The output includes the source attachment ID and the target attachment ID.

### *Checking Connectivity Between the PE Devices*

**Purpose** Verify that Device PE1 can ping Device PE2. The `ping mpls l2vpn fec129` command accepts SAs and TAs as integers or IP addresses and also allows you to use the CE-facing interface instead of the other parameters (`instance`, `local-id`, `remote-id`, `remote-pe-address`).

**Action**    user@PE1> ping mpls l2vpn fec129 instance FEC129-VPWS remote-id 2 remote-pe-address 192.0.2.2 local-id 1  
!!!!!  
--- lsping statistics ---  
5 packets transmitted, 5 packets received, 0% packet loss

user@PE1> ping mpls l2vpn fec129 interface ge-2/0/5.0  
!!!!!  
--- lsping statistics ---  
5 packets transmitted, 5 packets received, 0% packet loss

**Meaning**    The output shows that the VPWS is operational.

## Example: Configuring BGP Autodiscovery for LDP VPLS

This example describes how to configure BGP autodiscovery for LDP VPLS, as specified in forwarding equivalency class (FEC) 129. FEC 129 uses BGP autodiscovery to convey endpoint information, so you do not need to manually configure pseudowires.

- [Requirements on page 1350](#)
- [Overview on page 1351](#)
- [Configuration on page 1353](#)
- [Verification on page 1367](#)

### Requirements

This example uses the following hardware and software components:

- Four MX Series 3D Universal Edge Routers
- Junos OS Release 10.4R2 or later

If you are using M Series or T Series routers, the PE routers must have either virtual loopback tunnel (**vt**) interfaces or label-switched interfaces (LSIs). On M Series and T Series routers, VPLS uses tunnel-based PICs to create virtual ports on **vt** interfaces. If you do not have a tunnel-based PIC installed on your M Series or T Series router, you can still configure VPLS by using LSIs to support the virtual ports. Use of LSIs requires Ethernet-based PICs installed in an Enhanced Flexible PIC Concentrator (FPC).

You do not need to use routers for the CE devices. For example, the CE devices can be EX Series Ethernet Switches.

## Overview

All PE routers in a VPLS network operate like a large, distributed Ethernet switch to provide Layer 2 services to attached devices. This example shows a minimum configuration for PE routers and CE devices to create an autodiscovered VPLS network. The topology consists of five routers: two PE routers, two CE routers, and an optional route reflector (RR). The PE routers use BGP to autodiscover two different VPLS instances that are configured on both PE routers. Then the PE routers use LDP to automatically signal two pseudowires between the discovered end points. Finally, the PE routers bring up both VPLS instances for forwarding traffic. Each CE device is configured with two VLANs, with each VLAN belonging to different VPLS instances in the PE routers.

This example includes the following settings:

- **auto-discovery-only**—Allows the router to process only the autodiscovery network layer reachability information (NLRI) update messages for LDP-based Layer 2 VPN and VPLS update messages (BGP\_L2VPN\_AD\_NLRI) (FEC 129). Specifically, the **auto-discovery-only** statement notifies the routing process (rpd) to expect autodiscovery-related NLRI messages so that information can be deciphered and used by LDP and VPLS. You can configure this statement at the global, group, and neighbor levels for BGP. The **auto-discovery-only** statement must be configured on all PE routers in the VPLS. If you configure route reflection, the **auto-discovery-only** statement is also required on P routers that act as the route reflector in supporting FEC 129-related updates.

The **signaling** statement is not included in this example but is discussed here for completeness. The **signaling** statement allows the router to process only the BGP\_L2VPN\_NLRIs used for BGP-based Layer 2 VPNs (FEC 128).

For interoperation scenarios in which a PE router must support both types of NLRI (FEC 128 and FEC 129), you can configure both the **signaling** statement and the **auto-discovery-only** statement. For example, a single PE router might need to process a combination of BGP-signaled virtual private wire service (VPWS) and LDP-signaled VPLS assisted by BGP autodiscovery. Configuring both the **signaling** statement and the **auto-discovery-only** statement together allows both types of signaling to run independently. The **signaling** statement is supported at the same hierarchy levels as the **auto-discovery-only** statement.

- **cluster**—Configuring a route reflector is optional for FEC 129 autodiscovered PE routers. In this example, the **cluster** statement configures Router RR to be a route reflector in the IBGP group. For inbound updates, BGP autodiscovery NLRI messages are accepted if the router is configured to be a route reflector or if the **keep all** statement is configured in the IBGP group.
- **l2vpn-id**—Specifies a globally unique Layer 2 VPN community identifier for the instance. This statement is configurable for routing instances of type **vpls**.

You can configure the following formats for the community identifier:

- Autonomous system (AS) number format—***l2vpn-id:as-number:2-byte-number***. For example: ***l2vpn-id:100:200***. The AS number can be in the range from 1 through 65,535.
- IPv4 format—***l2vpn-id:ip-address:2-byte-number***. For example: ***l2vpn-id:10.1.1.1:2***.
- **vrf-target**—Defines the import and export route targets for the NLRI. You must either configure the **vrf-target** statement or the **vrf-import** and **vrf-export** statements to define the instance import and export policy or the import and export route targets for the NLRI. This example uses the **vrf-target** statement.
- **route-distinguisher**—Forms part of the BGP autodiscovery NLRI and distinguishes to which VPN or VPLS routing instance each route belongs. Each route distinguisher is a 6-byte value. You must configure a unique route distinguisher for each routing instance.

You can configure the following formats for the route distinguisher:

- AS number format—***as-number:2-byte-number***
- IPv4 format—***ip-address:2-byte-number***

Two notable statements are included in this example. These statements are important for interoperability with other vendors' equipment. The interoperability statements are not necessary for the topology that is used in this example, but they are included for completeness.

The interoperability statements are as follows:

- **input-vlan-map pop**—Removes an outer VLAN tag from the top of the VLAN tag stack.
- **output-vlan-map push**—Adds an outer VLAN tag in front of the existing VLAN tag.

### Topology Diagram

Figure 132 on page 1352 shows the topology used in this example.

Figure 132: BGP Autodiscovery for LDP VPLS

## Configuration

**CLI Quick Configuration** To quickly configure BGP autodiscovery for LDP VPLS, copy the following commands, remove any line breaks, and then paste the commands into the CLI of each device.

On Router PE1:

## Router PE1

### Step-by-Step Procedure

To configure Router PE1:

1. Configure the interfaces, the interface encapsulation, and the protocol families.

```
[edit]
user@PE1# edit interfaces
[edit interfaces]
user@PE1# set ge-0/1/0 encapsulation flexible-ethernet-services
user@PE1# set ge-0/1/0 unit 100 encapsulation vlan-vpls
user@PE1# set ge-0/1/0 unit 100 family vpls
user@PE1# set ge-0/1/0 unit 200 encapsulation vlan-vpls
user@PE1# set ge-0/1/0 unit 200 family vpls
user@PE1# set ge-0/1/1 unit 0 description "PE1 to PE2"
user@PE1# set ge-0/1/1 unit 0 family inet address 192.0.2.4/24
user@PE1# set ge-0/1/1 unit 0 family iso
user@PE1# set ge-0/1/1 unit 0 family mpls
user@PE1# set ge-0/3/0 unit 0 description "PE1 to RR"
```

```
user@PE1# set ge-0/3/0 unit 0 family inet address 192.0.2.7/24
user@PE1# set ge-0/3/0 unit 0 family iso
user@PE1# set ge-0/3/0 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 192.0.2.8/24
```

2. Configure the VLANs.

```
[edit interfaces]
user@PE1# set ge-0/1/0 vlan-tagging
user@PE1# set ge-0/1/0 unit 100 vlan-id 100
user@PE1# set ge-0/1/0 unit 100 input-vlan-map pop
user@PE1# set ge-0/1/0 unit 100 output-vlan-map push
user@PE1# set ge-0/1/0 unit 200 vlan-id 200
user@PE1# exit
```

3. Configure the protocol-independent properties.

We recommend that the router ID be the same as the local address. (See the **local-address** statement in Step 4.)

```
[edit]
user@PE1# edit routing-options
[edit routing-options]
user@PE1# set router-id 192.0.2.8
user@PE1# set autonomous-system 100
user@PE1# exit
```

4. Configure IBGP, including the **auto-discovery-only** statement.

```
[edit]
user@PE1# edit protocols
[edit protocols]
user@PE1# set bgp group int type internal
user@PE1# set bgp group int local-address 192.0.2.8
user@PE1# set bgp group int family l2vpn auto-discovery-only
user@PE1# set bgp group int neighbor 192.0.2.9
```

5. Configure MPLS, LDP, and an IGP.

```
[edit protocols]
user@PE1# set mpls interface lo0.0
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
user@PE1# set isis level 1 disable
user@PE1# set isis interface all
user@PE1# set isis interface fxp0.0 disable
user@PE1# set isis interface lo0.0
user@PE1# set ldp interface all
user@PE1# set ldp interface fxp0.0 disable
user@PE1# set ldp interface lo0.0
user@PE1# exit
```

6. Configure the routing instances.

The **no-tunnel-services** statement is required if you are using LSI interfaces for VPLS instead of **vt** interfaces.

```
[edit]
user@PE1# edit routing-instances
[edit routing-instances]
user@PE1# set vpls100 instance-type vpls
user@PE1# set vpls100 interface ge-0/1/0.100
user@PE1# set vpls100 route-distinguisher 192.0.2.8:100
user@PE1# set vpls100 l2vpn-id l2vpn-id:100:100
user@PE1# set vpls100 vrf-target target:100:100
user@PE1# set vpls100 protocols vpls no-tunnel-services
user@PE1# set vpls200 instance-type vpls
user@PE1# set vpls200 interface ge-0/1/0.200
user@PE1# set vpls200 route-distinguisher 192.0.2.8:200
user@PE1# set vpls200 l2vpn-id l2vpn-id:100:200
user@PE1# set vpls200 vrf-target target:100:208
user@PE1# set vpls200 protocols vpls no-tunnel-services
```

7. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE1# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

### Device CE1

#### Step-by-Step Procedure

To configure Device CE1:

1. Configure interface addresses and the interface maximum transmission unit (MTU).

```

[edit]
user@CE1# edit interfaces
[edit interfaces]
user@CE1# set ge-1/2/1 mtu 1400
user@CE1# set ge-1/2/1 unit 100 family inet address 203.0.113.3/24
user@CE1# set ge-1/2/1 unit 200 family inet address 203.0.113.2/24

```

2. Configure VLANs.

```

[edit interfaces]
user@CE1# set ge-1/2/1 vlan-tagging
user@CE1# set ge-1/2/1 unit 100 vlan-id 100
user@CE1# set ge-1/2/1 unit 200 vlan-id 200
user@CE1# exit

```

3. Configure an IGP.

```

user@CE1# edit protocols
[edit protocols]
user@CE1# set ospf area 0.0.0.0 interface ge-1/2/1.100
user@CE1# set ospf area 0.0.0.0 interface ge-1/2/1.200
user@CE1# exit

```

4. If you are done configuring the device, commit the configuration.

```

[edit]

```

```
user@CE1# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE1# show interfaces
ge-1/2/1 {
 vlan-tagging;
 mtu 1400;
 unit 100 {
 vlan-id 100;
 family inet {
 address 203.0.113.3/24;
 }
 }
 unit 200 {
 vlan-id 200;
 family inet {
 address 203.0.113.2/24;
 }
 }
}

user@CE1# show protocols
ospf {
 area 0.0.0.0 {
 interface ge-1/2/1.100;
 interface ge-1/2/1.200;
 }
}
```

---

### Router PE2

**Step-by-Step Procedure** To configure Router PE2:

1. Configure the interfaces, the interface encapsulation, and the protocol families.

```
[edit]
user@PE2# edit interfaces
[edit interfaces]
user@PE2# set ge-1/1/0 encapsulation flexible-ethernet-services
user@PE2# set ge-1/1/0 unit 100 encapsulation vlan-vpls
user@PE2# set ge-1/1/0 unit 100 family vpls
user@PE2# set ge-1/1/0 unit 200 encapsulation vlan-vpls
user@PE2# set ge-1/1/0 unit 200 family vpls
user@PE2# set ge-1/2/1 unit 0 description "PE2 to PE1"
user@PE2# set ge-1/2/1 unit 0 family inet address 192.0.2.14/24
user@PE2# set ge-1/2/1 unit 0 family iso
user@PE2# set ge-1/2/1 unit 0 family mpls
user@PE2# set lo0 unit 0 family inet address 192.0.2.10/24
```

2. Configure the VLANs.

```
[edit interfaces]
user@PE2# set ge-1/1/0 vlan-tagging
user@PE2# set ge-1/1/0 unit 100 vlan-id 100
user@PE2# set ge-1/1/0 unit 100 input-vlan-map pop
user@PE2# set ge-1/1/0 unit 100 output-vlan-map push
user@PE2# set ge-1/1/0 unit 200 vlan-id 200
user@PE2# exit
```

3. Configure the protocols-independent properties.

We recommend that the router ID be the same as the local address. (See the **local-address** statement in Step 4.)

```
[edit]
user@PE2# edit routing-options
[edit routing-options]
user@PE2# set router-id 192.0.2.10
user@PE2# set autonomous-system 100
```

4. Configure IBGP, including the **auto-discovery-only** statement.

```
[edit]
user@PE2# edit protocols
[edit protocols]
user@PE2# set bgp group int type internal
user@PE2# set bgp group int local-address 192.0.2.10
user@PE2# set bgp group int family l2vpn auto-discovery-only
user@PE2# set bgp group int neighbor 192.0.2.9
```

5. Configure MPLS, LDP, and an IGP.

```
[edit protocols]
user@PE2# set mpls interface lo0.0
user@PE2# set mpls interface all
user@PE2# set mpls interface fxp0.0 disable
user@PE2# set isis level 1 disable
user@PE2# set isis interface ge-1/2/1.0
user@PE2# set isis interface lo0.0
user@PE2# set ldp interface all
user@PE2# set ldp interface fxp0.0 disable
user@PE2# set ldp interface lo0.0
user@PE2# exit
```

6. Configure the routing instances.

The **no-tunnel-services** statement is required if you are using LSI interfaces for VPLS instead of **vt** interfaces.

```
[edit]
user@PE2# edit routing-instances
[edit routing-instances]
user@PE2# set vpls100 instance-type vpls
user@PE2# set vpls100 interface ge-1/1/0.100
```

```
user@PE2# set vpls100 route-distinguisher 192.0.2.10:100
user@PE2# set vpls100 l2vpn-id l2vpn-id:100:100
user@PE2# set vpls100 vrf-target target:100:100
user@PE2# set vpls100 protocols vpls no-tunnel-services
user@PE2# set vpls200 instance-type vpls
user@PE2# set vpls200 interface ge-1/1/0.200
user@PE2# set vpls200 route-distinguisher 192.0.2.10:200
user@PE2# set vpls200 l2vpn-id l2vpn-id:100:200
user@PE2# set vpls200 vrf-target target:100:208
user@PE2# set vpls200 protocols vpls no-tunnel-services
```

7. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE2# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces
ge-1/1/0 {
 vlan-tagging;
 encapsulation flexible-ethernet-services;
 unit 100 {
 encapsulation vlan-vpls;

 }
 }
}

```

```
}
}
```

### Device CE2

---

#### Step-by-Step Procedure

To configure Device CE2:

1. Configure VLAN interfaces.

```
[edit]
user@CE2# edit interfaces ge-1/1/0
[edit interfaces ge-1/1/0]
user@CE2# set vlan-tagging
user@CE2# set mtu 1400
user@CE2# set unit 100 vlan-id 100
user@CE2# set unit 100 family inet address 203.0.113.15/24
user@CE2# set unit 200 vlan-id 200
user@CE2# set unit 200 family inet address 203.0.113.16/24
user@CE2# exit
```

2. Configure OSPF on the interfaces.

```
[edit]
user@CE2# edit protocols ospf area 0.0.0.0
[edit protocols ospf area 0.0.0.0]
user@CE2# set interface ge-1/1/0.100
user@CE2# set interface ge-1/1/0.200
user@CE2# exit
```

3. If you are done configuring the device, commit the configuration.

```
[edit]
user@CE2# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces** and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE2# show interfaces
ge-1/1/0 {
 vlan-tagging;
 mtu 1400;
 unit 100 {
 vlan-id 100;
 family inet {
 address 203.0.113.15/24;
 }
 }
 unit 200 {
 vlan-id 200;
 family inet {
 address 203.0.113.16/24;
 }
 }
}
```

```

 }
 }
user@CE2# show protocols
ospf {
 area 0.0.0.0 {
 interface ge-1/1/0.100;
 interface ge-1/1/0.200;
 }
}

```

### Router RR

#### Step-by-Step Procedure

To configure Router RR:

1. Configure interface addresses and the protocol families.

```

[edit]
user@RR# edit interfaces
[edit interfaces]
user@RR# set ge-1/3/2 unit 0 description "RR to PE1"
user@RR# set ge-1/3/2 unit 0 family inet address 192.0.2.17/24
user@RR# set ge-1/3/2 unit 0 family iso
user@RR# set ge-1/3/2 unit 0 family mpls
user@RR# set lo0 unit 0 family inet address 192.0.2.9/24
user@RR# exit

```

2. Configure the autonomous systems and the router ID.

```

[edit]
user@RR# edit routing-options
[edit routing-options]
user@RR# set autonomous-system 100
user@RR# set router-id 192.0.2.9
user@RR# exit

```

3. Configure BGP and set this router to be the route reflector. Route reflection is optional for FEC 129.

```

[edit]
user@RR# edit protocols bgp group int
[edit protocols bgp group int]
user@RR# set type internal
user@RR# set local-address 192.0.2.9
user@RR# set family l2vpn auto-discovery-only
user@RR# set cluster 198.51.100.0
user@RR# set neighbor 192.0.2.8
user@RR# set neighbor 192.0.2.10
user@RR# exit

```

4. Configure IS-IS for the IGP.

```

[edit]
user@RR# edit protocols isis

```

```
[edit protocols isis]
user@RR# set level 1 disable
user@RR# set interface all
user@RR# set interface fxp0.0 disable
user@RR# set interface lo0.0
user@RR# exit
```

5. Configure LDP for the MPLS signaling protocol.

```
[edit]
user@RR# edit protocols ldp
[edit protocols ldp]
user@RR# set interface all
user@RR# set interface fxp0.0 disable
user@RR# set interface lo0.0
user@RR# exit
```

6. If you are done configuring the device, commit the configuration.

```
[edit]
user@RR# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@RR# show interfaces
ge-1/3/2 {
 unit 0 {
 description "RR to PE1";
 family inet {
 address 192.0.2.17/24;
 }
 family iso;
 family mpls;
 }
}
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.9/24;;
 }
 }
}

user@RR# show protocols
bgp {
 group int {
 type internal;
 local-address 192.0.2.9;
 family l2vpn {
 auto-discovery-only;
 }
 }
}
```

```

 cluster 198.51.100.0;
 neighbor 192.0.2.8;
 neighbor 192.0.2.10;
 }
}
isis {
 level 1 disable;
 interface lo0.0;
 interface all;
 interface fxp0 disable;
}
ldp {
 interface lo0.0;
 interface all;
 interface fxp0 disable;
}

user@RR# show routing-options
router-id 192.0.2.9;
autonomous-system 100;

```

## Verification

To verify the operation, use the following commands:

- `show route extensive`
- `show route advertising-protocol bgp neighbor`
- `show route receive-protocol bgp neighbor`
- `show route table bgp.l2vpn.0`
- `show route table vpls100.l2vpn.0`
- `show route table vpls200.l2vpn.0`
- `show vpls connections extensive`
- `show vpls mac-table detail`
- `show vpls statistics`

AD in the routing table output indicates autodiscovery NLRI.

### Related Documentation

- [Configuring Interoperability Between BGP Signaling and LDP Signaling in VPLS on page 1140](#)

## Example: Configuring BGP Autodiscovery for LDP VPLS with User-Defined Mesh Groups

This example describes how to configure user-defined mesh groups for BGP autodiscovery for LDP VPLS, as specified in forwarding equivalency class (FEC) 129. FEC 129 uses BGP autodiscovery to convey endpoint information, so you do not need to manually configure

pseudowires. You configure mesh groups on the border router to group the sets of PE routers that are automatically fully meshed and that share the same signaling protocol, either BGP or LDP. You can configure multiple mesh groups to map each fully meshed LDP-signaled or BGP-signaled VPLS domain to a mesh group.

- [Requirements on page 1368](#)
- [Overview on page 1368](#)
- [Configuration on page 1369](#)
- [Verification on page 1374](#)

## Requirements

Before you begin, configure BGP autodiscovery for LDP VPLS. See “[Example: Configuring BGP Autodiscovery for LDP VPLS](#)” on page 1350.

The hardware and software requirements for this example are the same as the requirements for the *Example: Configuring BGP Autodiscovery for LDP VPLS*. You will need to adapt the example configuration to the topology used in this example.

## Overview

Configuration for a mesh group for FEC 129 is very similar to the mesh-group configuration for FEC 128.

Note the following differences for FEC 129:

- Each user-defined mesh group must have a unique route distinguisher. Do not use the route distinguisher that is defined for the default mesh group at the **[edit routing-instances]** hierarchy level.
- Each user-defined mesh group must have its own import and export route target.
- Each user-defined mesh group can have a unique Layer 2 VPN ID. By default, all the mesh groups that are configured for a VPLS routing instance use the same Layer 2 VPN ID as the one that you configure at the **[edit routing-instances]** hierarchy level.

---

### Topology Diagram

[Figure 133 on page 1369](#) shows a topology that includes a user-defined mesh group.

Figure 133: BGP Autodiscovery for LDP VPLS with a User-Defined Mesh Group

"CLI Quick Configuration" on page 1369 shows the configuration for all of the devices in Figure 133 on page 1369. The section "Step-by-Step Procedure" on page 1371 describes the steps on Device R2.

## Configuration

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

```

**Step-by-Step Procedure** To configure a mesh group:

1. Configure the interfaces.

```

[edit interfaces]
user@R2# set ge-2/0/5 encapsulation ethernet-vpls
user@R2# set ge-2/0/5 unit 0 description to_CE1
user@R2# set ge-2/0/5 unit 0 family vpls

user@R2# set ge-2/0/10 unit 0 description to_R3
user@R2# set ge-2/0/10 unit 0 family inet address 10.10.4.2/30
user@R2# set ge-2/0/10 unit 0 family mpls

user@R2# set ge-2/0/11 unit 0 description to_R4
user@R2# set ge-2/0/11 unit 0 family inet address 10.10.5.1/30
user@R2# set ge-2/0/11 unit 0 family mpls

user@R2# set lo0 unit 0 family inet address 192.0.2.2/24

```

2. Configure MPLS on the interfaces.

```

[edit protocols mpls]
user@R2# set interface ge-2/0/10.0
user@R2# set interface ge-2/0/11.0

```

3. Configure BGP.

```
[edit protocols bgp]
user@R2# set local-address 192.0.2.2

[edit protocols bgp group pe-pe]
user@R2# set type internal
user@R2# set connect-retry-interval 1
user@R2# set family l2vpn auto-discovery-only
user@R2# set family l2vpn signaling
user@R2# set neighbor 192.0.2.3
user@R2# set neighbor 192.0.2.4
```

4. Set the import and export route target for the default mesh group.

```
[edit protocols ospf]
user@R2# set traffic-engineering
user@R2# set area 0.0.0.0 interface lo0.0 passive
user@R2# set area 0.0.0.0 interface ge-2/0/10.0
user@R2# set area 0.0.0.0 interface ge-2/0/11.0
```

5. Configure LDP on the core-facing interfaces and on the loopback interface.

```
[edit protocols ldp]
user@R2# set interface ge-2/0/10.0
user@R2# set interface ge-2/0/11.0
user@R2# set interface lo0.0
```

6. Configure the VPLS routing instance.

Make sure that the route distinguisher in the mesh group is unique.

```
[edit routing-instances inst512]
user@R2# set instance-type vpls
user@R2# set interface ge-2/0/5.0
user@R2# set route-distinguisher 100:100
user@R2# set l2vpn-id l2vpn-id:1:2
user@R2# set vrf-target target:1:1
user@R2# set protocols vpls mesh-group metro1 vrf-target target:2:1
user@R2# set protocols vpls mesh-group metro1 route-distinguisher 100:200
```

7. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@R2# set autonomous-system 64510
```

8. If you are done configuring the device, commit the configuration.

```
[edit]
user@R2# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show routing-instances** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@R2# show interfaces
ge-2/0/5 {
 encapsulation ethernet-vpls;
 unit 0 {
 description PE1_to_CE1;
 family vpls;
 }
}
ge-2/0/10 {

```

## Verification

Confirm that the configuration is working properly.

- [Verifying the Routes on page 1374](#)
- [Checking Connectivity on page 1376](#)
- [Checking the VPLS Connections on page 1377](#)
- [Display Learned VPLS MAC Address Information on page 1377](#)

---

### Verifying the Routes

**Purpose** Verify that the expected routes are learned.

**Action** From operational mode, enter the **show route** command.

```
user@R2> show route
inet.0: 9 destinations, 9 routes (9 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```

```

**Meaning** The output shows all the learned routes, including the autodiscovered (AD) routes.

### Checking Connectivity

**Purpose** Verify that Device CE1 can ping Device CE3 and Device CE4.

**Action** user@CE1> ping 10.255.14.218  
 PING 10.255.14.218 (10.255.14.218): 56 data bytes  
 64 bytes from 10.255.14.218: icmp\_seq=0 ttl=64 time=0.787 ms  
 64 bytes from 10.255.14.218: icmp\_seq=1 ttl=64 time=0.651 ms  
 ^C  
 --- 10.255.14.218 ping statistics ---  
 2 packets transmitted, 2 packets received, 0% packet loss  
 round-trip min/avg/max/stddev = 0.651/0.719/0.787/0.068 ms

user@CE1> ping 10.255.14.219  
 PING 10.255.14.219 (10.255.14.219): 56 data bytes  
 64 bytes from 10.255.14.219: icmp\_seq=0 ttl=64 time=1.054 ms  
 64 bytes from 10.255.14.219: icmp\_seq=1 ttl=64 time=0.669 ms  
 ^C  
 --- 10.255.14.219 ping statistics ---  
 2 packets transmitted, 2 packets received, 0% packet loss  
 round-trip min/avg/max/stddev = 0.669/0.862/1.054/0.193 ms

**Meaning** The output shows that VPLS is operational.

### Checking the VPLS Connections

**Purpose** Make sure that all of the FEC 129 VPLS connections come up correctly.

**Action** user@R2> show vpls connections  
 Instance: inst512

## VPLS Multihoming Reactions to Network Failures

VPLS multihoming is designed to protect customer sites from a loss of network connectivity in the event of the following types of network failures:

- Link failure between the CE device and the PE router—BGP on the PE router is notified when the link goes down. BGP sets the circuit status vector bit in the MP\_REACH\_NLRI to indicate that the circuit is down.

If all of the VPLS local attachment circuits are down, then BGP modifies the down bit in the VPLS advertisement Layer2-Extended-Community to indicate that the customer site is down. When the bit is modified, BGP advertises the route to all of the remote PE routers to notify them that the circuit (and site) is down. Each of the remote PE routers run the BGP and VPLS path selection procedures again and reroute the VPLS pseudowires as needed.

- MPLS connectivity failure to the remote PE router—On the multihomed PE router, BGP discovers that MPLS cannot connect to the BGP next hop in the service provider's network. BGP modifies the circuit status vector bit in the MP\_REACH\_NLRI to indicate that the LSP is down. Once the bit is modified, BGP readvertises the route to all of the remote PE routers to notify them that connectivity from the local site to the remote site is down.

The remote PE routers each run the BGP and VPLS path selection procedures again. With the LSP to the original multihomed PE router down, the remote PE routers designate the backup multihomed PE router as the VE device for the multihomed customer site. The pseudowires to and from the remote PE routers are then rerouted to the backup multihomed PE router.

- PE router failure—When either the multihomed PE router or the BGP process running on it fails, the remote PE routers detect the expiration of the holdtimer, bring down their peering sessions, and delete the Layer 2 advertisements from that multihomed

PE router. The remote PE routers each run the BGP and VPLS path selection procedures again and reroute their pseudowires to the backup multihomed PE router.

Alternatively, the remote PE routers could discover that the BGP next hop, represented by the failed multihomed PE router, is unreachable. For this case, the remote PE routers mark the Layer 2 routes advertised by the multihomed PE router as unreachable. The remote PE routers each run the BGP and VPLS path selection procedures again and reroute their pseudowires to the backup multihomed PE router.

The remote PE routers behave in the same manner if you reconfigure the local preference attribute of the primary multihomed PE router (effectively performing an administrative failover to the backup multihomed PE router). On the primary multihomed PE router, BGP advertises a Layer 2 update with the new local preference attribute to all of the remote PE routers. The remote PE routers each run the BGP and VPLS path selection procedures again and reroute their pseudowires to the backup multihomed PE router.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

## Configuring VPLS Multihoming (FEC 128)

VPLS multihoming allows you to connect a customer site to multiple PE routers to provide redundant connectivity while preventing the formation of Layer 2 loops in the service provider's network. A VPLS site multihomed to two or more PE routers provides redundant connectivity in the event of a PE router-to-CE device link failure or the failure of a PE router. For more information about VPLS multihoming, see "[VPLS Multihoming Overview](#)" on page 1329.

**NOTE:** If you want to enable multihoming for a VPLS routing instance, you cannot also enable LDP signaling. You can only enable BGP signaling.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The following sections describe how to configure VPLS multihoming. Some information is also provided on single-homed site configuration versus multihomed site configuration.

- [VPLS Multihomed Site Configuration on page 1380](#)
- [VPLS Single-Homed Site Configuration on page 1382](#)

## VPLS Multihomed Site Configuration

The following describes the requirements for a VPLS multihomed site configuration:

- Assign the same site ID on all PE routers connected to the same CE devices.

When two PE routers use the same site ID, VPLS assumes multihoming behavior by default. The site preference value is used to signal the primary and backup PE router. In such cases, when multihoming is explicitly configured using the **multi-homing** statement, it is only used for tracking the BGP peer status, such as to prevent isolation of the PE router from the core or split brain. There are scenarios, however that require preventing of BGP peer tracking, such as in a two-PE-router topology. In such cases, multihoming should not be explicitly configured as it can break node redundancy.

When identical site IDs are used without configuring multihoming, a collision log message is generated at each signaling: **RPD\_L2VPN\_SITE\_COLLISION: Same site ID 2 configured on remote PE (RD 8.8.8.1:1013:) and local PE in VPN 1013 (non-multihomed site 2)**. This is expected behavior.

- Assign unique route distinguishers for each multihomed PE router.
- Reference all interfaces assigned to the multihomed VPLS site on each PE router. Only one of these interfaces is used to send and receive traffic for this site at a time.
- Either designate a primary interface or allow the router to select the interface to be used as the primary interface.

If the router selects the interface, the interface used to connect the PE router to the site depends on the order in which interfaces are listed in the PE router's configuration. The first operational interface in the set of configured interfaces is chosen to be the designated interface. If this interface fails, the next interface in the list is selected to send and receive traffic for the site.

The following configuration shows the statements you need to configure to enable VPLS multihoming:

```
[edit routing-instances routing-instance-name]
instance-type vpls;
interface interface-name;
interface interface-name;
protocols vpls {
 site site-name {
 active-interface {
 any;
 primary interface-name;
 }
 interface interface-name;
 interface interface-name;
 multi-homing;
 site-identifier number;
 }
}
route-distinguisher (as-number:id | ip-address:id);
```

**NOTE:** If you add a direct connection between CE devices that are multihomed to the same VPLS site on different PE routers, the traffic can loop and a loss of connectivity might occur. We do not recommend this topology.

Most of these statements are explained in more detail in the rest of this chapter. The following sections explain how to configure the statements that are specific to VPLS multihoming:

- [Specifying an Interface as the Active Interface on page 1381](#)
- [Configuring Multihoming on the PE Router on page 1381](#)

### Specifying an Interface as the Active Interface

You need to specify one of the interfaces for the multihomed site as the primary interface. If there are multiple interfaces, the remaining interfaces are activated only when the primary interface goes down. If no active interfaces are configured at the site level, all traffic for a VPLS site travels through a single, non-multihomed PE router.

You must configure one of the following options for the **active-interface** statement:

- **any**—One configured interface is randomly designated as the active interface for the VPLS site.
- **primary**—Specify the name of the multihomed interface to be used as the primary interface by the VPLS site.

To specify a multihomed interface as the primary interface for the VPLS site, include the **active-interface** statement:

```
active-interface {
 any;
 primary interface-name;
}
```

You can include this statement at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name* protocols vpls site *site-name*]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls site *site-name*]**

### Configuring Multihoming on the PE Router

When a CE device is connected to the same VPLS site on more than one PE router, including the **multi-homing** statement on all associated PE routers results in tracking of BGP peers. If no BGP peer is available, VPLS deactivates all active interfaces for a site. When two PE routers use the same site ID, VPLS assumes multihoming behavior by default. The site preference value is used to signal the primary and backup PE router. In such cases, when multihoming is explicitly configured using the **multi-homing** statement, it is only used for tracking the BGP peer status, such as to prevent isolation of the PE router from the core or split brain.

**NOTE:** When identical site IDs are used without configuring multihoming, a collision log message is generated at each signaling:  
**RPD\_L2VPN\_SITE\_COLLISION:** Same site ID 2 configured on remote PE (RD 8.8.8.1:1013:) and local PE in VPN1013 (non-multihomed site 2). This is expected behavior.

---

## VPLS Single-Homed Site Configuration

All VPLS single-homed sites are connected to the same default VE device. All interfaces in a VPLS routing instance that are not configured as part of a multihomed site are assumed to be single-homed to the default VE device.

---

## Example: VPLS Multihoming, Improved Convergence Time

This example shows how to configure a virtual private LAN service (VPLS) employing multihoming to a customer site. This particular VPLS multihoming example shows how to configure a feature that improves the network convergence time in the event a multihomed site needs to switch traffic to its alternate PE router.

- [Requirements on page 1382](#)
- [Overview on page 1383](#)
- [Configuration on page 1384](#)

## Requirements

This example uses the following hardware and software components:

- Three M Series, MX Series, or T Series routers
- Junos OS Release 12.2 or later

If you are using M Series or T Series routers, the PE routers must have either virtual loopback tunnel (**vt**) interfaces or label-switched interfaces (LSIs). On M Series and T Series routers, VPLS uses tunnel-based PICs to create virtual ports on vt interfaces. If you do not have a tunnel-based PIC installed on your M Series or T Series router, you can still configure VPLS by using LSIs to support the virtual ports. Use of LSIs requires Ethernet-based PICs installed in an Enhanced Flexible PIC Concentrator (FPC).

You do not need to use routers for the CE devices. For example, the CE devices can be EX Series Ethernet Switches.

## Overview

All PE routers in a VPLS network operate like a large, distributed Ethernet switch to provide Layer 2 services to attached devices. This example illustrates a network of PE routers and CE devices configured to use VPLS multihoming. The topology consists of six routers: four PE routers and two CE devices. Device CE1 is multihomed to Routers PE1 and PE2. The PE routers are configured with the **best-site** and **mac-flush** statements to improve the convergence time in the event the connection between Device CE1 and one of its multihomed PE routers fails.

This example includes the following settings:

- **best-site**—Uses the B-bit of the control flags bit vector (the third bit counting from the most significant bit) within the Layer 2 information extended community to indicate that the site is preferred. Each VPLS site configured with the **best-site** statement signals to the other PE routers that it is the preferred site. The Layer 2 information extended community includes the following information:
  - Extended community type (2 octets)
  - Encapsulation type (1 octet)
  - Control flags (1 octet)
  - Layer 2 MTU (2 octets)
  - Reserved (2 octets)

When a neighboring PE router within the VPLS routing instance receives the label block advertisement, it knows that the corresponding PE router is the most preferable router of those remote PE routers multihomed to that site. If a neighboring PE router does not support the best site feature, the standard local site selection process is used. For example, if Router PE1 does not receive a B-bit from any of the label blocks advertisements received from Router PE3, Router PE1 proceeds to assume that Router PE3 does not support the best site feature. It creates a virtual circuit based on its minimum-designated site. For the other PE routers that do support the best site feature, Router PE1 builds virtual circuits using the locally tagged best site.

- **mac-flush**—Enables media access control (MAC) flush processing for the VPLS routing instance or for the mesh group under a VPLS routing instance. MAC flush processing removes MAC addresses from the MAC address database that have been learned dynamically. With the dynamically learned MAC addresses removed, MAC address convergence requires less time to complete.

## Topology

Figure 134 on page 1384 shows the topology used in this example. Router PE2 is configured with the **best-site** statement and acts as the preferred gateway for traffic from Device CE1.

Figure 134: VPLS Multihoming Topology with Router PE2 Configured as the Best Site

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Router PE1:

```
set interfaces fe-0/1/0 encapsulation ethernet-vpls
set interfaces fe-0/1/0 unit 0 family vpls
set interfaces fe-0/1/2 unit 0 family inet address 10.0.59.14/32

```

---

### Router PE1

#### Step-by-Step Procedure

To configure Router PE1:

1. Configure the interfaces, interface encapsulation, and the protocol families.  

```
[edit interfaces]
user@PE1# set fe-0/1/0 encapsulation ethernet-vpls
user@PE1# set fe-0/1/0 unit 0 family vpls
user@PE1# set fe-0/1/2 unit 0 family inet address 10.0.59.14/32
user@PE1# set fe-0/1/2 unit 0 family iso
user@PE1# set fe-0/1/2 unit 0 family mpls
user@PE1# set fe-0/1/3 unit 0 family inet address 10.0.89.14/30
user@PE1# set fe-0/1/3 unit 0 family iso set interfaces fe-0/1/3 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 192.168.9.1/32
user@PE1# set lo0 unit 0 family iso address
47.0005.8083.0000.1921.6800.5003.00
```
2. Configure the protocol-independent properties.  

```
[edit routing-options]
user@PE1# set router-id 192.168.9.1
```
3. Configure MPLS on the router's interfaces.  

```
[edit protocols mpls]
user@PE1# set interface all
```
4. Configure BGP.  

```
[edit protocols bgp]
user@PE1# set group int type internal
user@PE1# set group int local-address 192.0.2.1
user@PE1# set group int family l2vpn signaling
```
5. Configure IS-IS as the IGP between the PE routers.  

```
[edit protocols isis]
user@PE1# set level 1 disable
user@PE1# set interface fe-0/1/3.0
user@PE1# set interface lo0.0
```
6. Configure LDP as the signaling protocol for MPLS.  

```
[edit protocols ldp]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
user@PE1# set interface lo0.0
```

## 7. Configure the VPLS routing instance.

Include the **mac-flush** statement to ensure that stale routes are removed from Router PE1 promptly.

```
[edit routing-instances vpls_1]
user@PE1# set instance-type vpls
user@PE1# set interface fe-0/1/0.0
user@PE1# set route-distinguisher 10.255.107.74:1
user@PE1# set vrf-target target:65056:1
user@PE1# set protocols vpls no-tunnel-services
user@PE1# set protocols vpls site site_3 site-identifier 3
user@PE1# set protocols vpls site site_3 multi-homing
user@PE1# set protocols vpls site site_3 site-preference primary
user@PE1# set protocols vpls site site_3 interface fe-0/1/0.0
user@PE1# set protocols vpls site site_994 site-identifier 994
user@PE1# set protocols vpls mac-flush
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
fe-0/1/0 {
 encapsulation ethernet-vpls;
 unit 0 {
 family vpls;
 }
}
fe-0/1/2 {

## Router PE2

### Step-by-Step Procedure

To configure Router PE2:

1. Configure the interfaces, interface encapsulation, and the protocol families.

```
[edit interfaces]
user@PE2# set fe-0/1/1 encapsulation ethernet-vpls
user@PE2# set fe-0/1/1 unit 0 family vpls
user@PE2# set fe-0/1/2 unit 0 family inet address 10.0.59.13/32
user@PE2# set fe-0/1/2 unit 0 family iso
user@PE2# set fe-0/1/2 unit 0 family mpls
user@PE2# set lo0 unit 0 family inet address 192.168.5.1/32
user@PE2# set lo0 unit 0 family iso address
47.0005.8083.0000.1921.6800.5005.00
```

2. Configure the protocol-independent properties.

```
[edit routing-options]
user@PE2# set router-id 192.168.5.1
```

3. Configure MPLS on the Router PE2 interfaces.

```
[edit protocols]
user@PE2# set mpls interface all
```

4. Configure the LDP as the signaling protocol for MPLS on the PE router facing interface.

```
[edit protocols ldp]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
user@PE2# set interface lo0.0
```

5. Configure IS-IS as the IGP between the PE routers.

```
[edit protocols isis]
user@PE2# set level 1 disable
user@PE2# set interface fe-0/1/2.0
user@PE2# set interface lo0.0
```

6. Configure the VPLS routing instance vpls\_1.

Include the **best-site** statement to ensure that Router PE2 acts as the preferred path for the CE router. Include the **mac-flush** statement to ensure that stale routes are removed from Router PE2 promptly.

```
[edit routing-instances vpls_1]
user@PE2# set instance-type vpls
user@PE2# set interface fe-0/1/1.0
user@PE2# set route-distinguisher 10.255.107.76:1
user@PE2# set vrf-target target:65056:1
user@PE2# set protocols vpls no-tunnel-services
user@PE2# set protocols vpls site site_3 site-identifier 3
```

```
user@PE2# set protocols vpls site site_3 multi-homing
user@PE2# set protocols vpls site site_3 site-preference backup
user@PE2# set protocols vpls site site_3 interface fe-0/1/1.0
user@PE2# set protocols vpls site site_995 site-identifier 995
user@PE2# set protocols vpls site site_995 best-site
user@PE2# set protocols vpls mac-flush
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces

```

### Router PE3

#### Step-by-Step Procedure

To configure Router PE3:

1. Configure the interfaces, interface encapsulation, and the protocol families.

```

[edit interfaces]
user@PE3# set fe-1/3/0 unit 0 description "PE3 to PE1"
user@PE3# set fe-1/3/0 unit 0 family inet address 10.0.89.13/30
user@PE3# set fe-1/3/0 unit 0 family iso
user@PE3# set fe-1/3/0 unit 0 family mpls
user@PE3# set fe-1/3/1 encapsulation ethernet-vpls
user@PE3# set fe-1/3/1 unit 0 family vpls
user@PE3# set lo0 unit 0 family inet address 192.168.8.1/32
user@PE3# set lo0 unit 0 family iso address
47.0005.8083.0000.1921.6800.5002.00

```

2. Configure the protocol-independent properties.

```

[edit routing-options]
user@PE3# set router-id 192.168.8.1

```

3. Configure IS-IS as the IGP between the PE routers.

```

[edit protocols isis]
user@PE3# set level 1 disable
user@PE3# set interface fe-0/1/3.0

```

```
user@PE3# set interface lo0.0
```

4. Configure LDP as the signaling protocol for MPLS.

```
[edit protocols ldp]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
user@PE3# set interface lo0.0
```

5. Configure the VPLS routing instance.

Include the **mac-flush** statement here to ensure that stale routes are removed from Router PE1 promptly.

```
[edit routing-instances vpls_1]
user@PE3# set instance-type vpls
user@PE3# set interface fe-1/3/1.0
user@PE3# set route-distinguisher 10.255.107.72:1
user@PE3# set vrf-target target:65056:1
user@PE3# set protocols vpls no-tunnel-services
user@PE3# set protocols vpls site site_2 site-identifier 2
user@PE3# set protocols vpls site site_2 interface fe-0/1/0.100
user@PE3# set protocols vpls site site_993 site-identifier 993
user@PE3# set protocols vpls mac-flush
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols show routing-instances**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE3# show interfaces

### VPLS Multihoming Overview

Virtual private LAN service (VPLS) multihoming enables you to connect a customer site to two or more PE routers to provide redundant connectivity. A redundant PE router can provide network service to the customer site as soon as a failure is detected. VPLS multihoming helps to maintain VPLS service and traffic forwarding to and from the multihomed site in the event of the following types of network failures:

- PE router to CE device link failure
- PE router failure
- MPLS-reachability failure between the local PE router and a remote PE router

Figure 135: CE Device Multihomed to Two PE Routers

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Figure 34 on page 337 illustrates how a CE device could be multihomed to two PE routers. Device CE1 is multihomed to Routers PE1 and PE2. Device CE2 has two potential paths to reach Device CE1, but only one path is active at any one time. If Router PE1 were the designated VPLS edge (VE) device (also called a designated forwarder), BGP would signal a pseudowire from Router PE3 to Router PE1. If a failure occurred over this path,

Router PE2 would be made the designated VE device, and BGP would re-signal the pseudowire from Router PE3 to Router PE2.

Multihomed PE routers advertise network layer reachability information (NLRI) for the multihomed site to the other PE routers in the VPLS network. The NLRI includes the site ID for the multihomed PE routers. For all of the PE routers multihomed to the same CE device, you need to configure the same site ID. The remote VPLS PE routers use the site ID to determine where to forward traffic addressed to the customer site. To avoid route collisions, the site ID shared by the multihomed PE routers must be different than the site IDs configured on the remote PE routers in the VPLS network.

Although you configure the same site ID for each of the PE routers multihomed to the same CE device, you can configure unique values for other parameters, such as the route distinguisher. These values help to determine which multihomed PE router is selected as the designated VE device to be used to reach the customer site.

**BEST PRACTICE:** We recommend that you configure unique route distinguishers for each multihomed PE router. Configuring unique route distinguishers helps with faster convergence when the connection to a primary multihomed PE router goes down. If you configure unique route distinguishers, the other PE routers in the VPLS network must maintain additional state for the multihomed PE routers.

Remote PE routers in the VPLS network need to determine which of the multihomed PE routers should forward traffic to reach the CE device. To make this determination, remote PE routers use the VPLS path-selection process to select one of the multihomed PE routers based on its NLRI advertisement. Because remote PE routers pick only one of the NLRI advertisements, it establishes a pseudowire to only one of the multihomed PE routers, the PE router that originated the winning advertisement. This prevents multiple paths from being created between sites in the network, preventing the formation of Layer 2 loops. If the selected PE router fails, all PE routers in the network automatically switch to the backup PE router and establish new pseudowires to it.

**BEST PRACTICE:** To prevent the formation of Layer 2 loops between the CE devices and the multihomed PE routers, we recommend that you employ the Spanning Tree Protocol (STP) on your CE devices. Layer 2 loops can form due to incorrect configuration. Temporary Layer 2 loops can also form during convergence after a change in the network topology.

The PE routers run the BGP path selection procedure on locally originated and received Layer 2 route advertisements to establish that the routes are suitable for advertisement to other peers, such as BGP route reflectors. If a PE router in a VPLS network is also a route reflector, the path selection process for the multihomed site has no effect on the path selection process performed by this PE router for the purpose of reflecting Layer 2 routes. Layer 2 prefixes that have different route distinguishers are considered to have different NLRIs for route reflection. The VPLS path selection process enables the route reflector to reflect all routes that have different route distinguishers to the route reflector.

clients, even though only one of these routes is used to create the VPLS pseudowire to the multihomed site.

Junos OS supports VPLS multihoming for both FEC 128 and FEC 129. Support for FEC 129 is added in Junos OS Release 12.3.

### Example: Configuring VPLS Multihoming (FEC 129)

This example shows how to configure virtual private LAN service (VPLS) multihoming. Multihoming allows a customer site to connect to multiple provider edge (PE) routers. A VPLS site multihomed to two or more PE routers provides redundant connectivity in the event of a PE router-to-CE device link failure or the failure of a PE router. The example demonstrates BGP-based multihoming support for FEC 129 VPLS (also known as LDP VPLS with BGP-based autodiscovery).

- [Requirements on page 1396](#)
- [Overview on page 1396](#)
- [Configuration on page 1398](#)
- [Verification on page 1405](#)

---

#### Requirements

This example has the following hardware and software requirements:

- One or more CE devices to represent a VPLS site.
- Two or more PE devices.
- Junos OS Release 12.3 or later running on the PE devices that are connected to the multihomed VPLS site.

---

#### Overview

BGP-based VPLS autodiscovery (FEC 129) enables each VPLS PE router to discover the other PE routers that are in the same VPLS domain. VPLS autodiscovery also automatically detects when PE routers are added or removed from the VPLS domain. You do not need to manually configure the VPLS and maintain the configuration when a PE router is added or deleted. VPLS autodiscovery uses BGP to discover the VPLS members and to set up and tear down pseudowires in the VPLS.

BGP multihoming enables you to connect a customer site to two or more PE routers to provide redundant connectivity while preventing the formation of Layer 2 loops in the service provider's network. The redundant connectivity maintains the VPLS service and traffic forwarding to and from the multihomed site in the event of a PE router-to-CE device link failure, the failure of a PE router, or an MPLS reachability failure between the local PE router and a remote PE router. A redundant PE router can begin providing service to the customer site as soon as the failure is detected.

When a CE device connects to multiple PE routers, each of these routers advertises reachability for the multihomed site—routes that have the same site ID in the Layer 2 network layer reachability information (NLRI). The other PE routers in the network use a BGP path selection process to select only one of the advertising routers to which they

send traffic destined for the CE device. This path selection process eliminates Layer 2 loops in the VPLS network.

Autodiscovery is not specifically related to multihoming. Autodiscovery is not required for multihoming to work. They are two separate features. That said, the meaning of FEC 129 is that VPLS does autodiscovery. So when you configure multihoming for FEC 129, you must also, by definition, configure autodiscovery (with the **auto-discovery-only** statement).

There are two places in the configuration where you can configure VPLS multihoming. One is for FEC 128, and the other is for FEC 129:

- For FEC 128—`routing-instances instance-name protocols vpls site site-name multi-homing`
- For FEC 129—`routing-instances instance-name protocols vpls multi-homing`

The following statements are used for configuring multihoming for FEC 129:

```
[edit routing-instances instance-name protocols vpls]
multi-homing {
 peer-active;
 site site-name {
 active-interface interface-name {
 any;
 primary interface-name;
 }
 identifier identifier;
 interface interface-name {
 preference preference-value;
 }
 peer-active;
 preference (preference-value | backup | primary);
 }
}
```

This example shows Device CE1 multihomed to Router PE1 and Router PE2. In addition, Device CE2 is single-homed to Router PE1. Device PE3 is the remote PE router, connected to Device CE3. Multihoming is not enabled on Device PE3. “CLI Quick Configuration” on [page 1398](#) shows the configuration for all of the devices in [Figure 136 on page 1398](#). The section “Configuring Device PE1” on [page 1401](#) has step-by-step instructions for configuring Device PE1.

Figure 136: Topology for FEC 129 Multihoming

### Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

**Device PE1**

```

### Configuring Device PE1

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the interfaces.

Configure **family mpls** on the provider-facing interfaces. Configure **family vpls** on the customer-facing interfaces.

[edit interfaces]

```

user@PE1# set ge-0/3/3 encapsulation ethernet-vpls
user@PE1# set ge-0/3/3 unit 0 description PE1-to-CE2
user@PE1# set ge-0/3/3 unit 0 family vpls

```

```

user@PE1# set ge-0/3/1 encapsulation ethernet-vpls
user@PE1# set ge-0/3/1 unit 0 description PE1-to-CE1
user@PE1# set ge-0/3/1 unit 0 family vpls

```

```

user@PE1# set ge-1/2/0 unit 1 description PE1-to-P
user@PE1# set ge-1/2/0 unit 1 family inet address 10.1.1.30
user@PE1# set ge-1/2/0 unit 1 family mpls

```

```

user@PE1# set ge-1/2/1 unit 5 description PE1-to-PE2
user@PE1# set ge-1/2/1 unit 5 family inet address 10.1.1.5/30
user@PE1# set ge-1/2/1 unit 5 family mpls

```

```

user@PE1# set lo0 unit 2 family inet address 192.0.2.2/24

```

2. Configure the interior gateway protocol (IGP) and signaling protocols on the provider-facing interfaces.

The **traffic-engineering** statement enables OSPF to advertise the label-switched path (LSP) metric in summary link-state advertisements (LSAs).

```
[edit protocols]
user@PE1# set ldp interface ge-1/2/0.1
user@PE1# set ldp interface ge-1/2/1.5
user@PE1# set ldp interface lo0.2

user@PE1# set mpls interface ge-1/2/0.1
user@PE1# set mpls interface ge-1/2/1.5

user@PE1# set ospf traffic-engineering
user@PE1# set ospf area 0.0.0.0 interface ge-1/2/0.1
user@PE1# set ospf area 0.0.0.0 interface ge-1/2/1.5
user@PE1# set ospf area 0.0.0.0 interface lo0.2 passive
```

3. Configure BGP.

The **auto-discovery-only** statement notifies the routing process (rpd) to expect autodiscovery-related NLRI messages so that information can be deciphered and used by LDP and VPLS. The **auto-discovery-only** statement must be configured on all PE routers in a VPLS. If you configure route reflection, the **auto-discovery-only** statement is also required on provider (P) routers that act as the route reflector in supporting FEC 129-related updates.

For interoperation scenarios in which a PE router must support both types of NLRI (FEC 128 and FEC 129), this example also includes the **signaling** statement.

```
[edit protocols bgp]
user@PE1# set local-address 192.0.2.2
user@PE1# set group pe-pe type internal
user@PE1# set group pe-pe family l2vpn auto-discovery-only
user@PE1# set group pe-pe family l2vpn signaling
user@PE1# set group pe-pe neighbor 192.0.2.3
user@PE1# set group pe-pe neighbor 192.0.2.4
user@PE1# set group pe-pe neighbor 192.0.2.5
```

4. Configure the routing instance.

Both CE-facing interfaces are included in the routing instance. Only the multihomed interface is included in the multihoming site.

As a convention, the route distinguisher is composed of Device PE1's loopback interface address and the multihoming site identifier.

```
[edit routing-instances green]
user@PE1# set instance-type vpls
user@PE1# set interface ge-0/3/1.0
user@PE1# set interface ge-0/3/3.0
user@PE1# set route-distinguisher 192.0.2.2:1
user@PE1# set l2vpn-id l2vpn-id:100:100
user@PE1# set vrf-target target:100:100
```

```

user@PE1# set protocols vpls no-tunnel-services
user@PE1# set protocols vpls multi-homing site test identifier 1
user@PE1# set protocols vpls multi-homing site test interface ge-0/3/1.0

```

5. (Optional) Configure bidirectional forwarding detection (BFD) for FEC 129 VPLS.

```

[edit routing-instances green]
user@PE1# set protocols vpls oam ping-interval 600
user@PE1# set protocols vpls oam bfd-liveness-detection minimum-interval 200

```

6. Configure the autonomous system (AS) number and router ID.

```

[edit routing-options]
user@PE1# set router-id 192.0.2.2
user@PE1# set autonomous-system 100

```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@PE1# show interfaces

 Discard

```

**Meaning** MH in the output indicates a multihoming route. AD indicates autodiscovery.

### Checking the BFD Sessions

**Purpose** Verify that the BFD session status is operational.

**Action** From operational mode, enter the **show bfd session** command.

```

user@PE1> show bfd session

Address State Interface Detect Transmit
198.51.100.1 Up ge-1/2/1.5 0.600 0.200 3
198.51.100.1 Up ge-1/2/0.1 0.600 0.200 3

2 sessions, 2 clients
Cumulative transmit rate 10.0 pps, cumulative receive rate 10.0 pps

```

**Meaning** Up in the State field indicates that BFD is working.

### Pinging the Remote PE Router in the VPLS Domain

**Purpose** Check the operability of the MPLS Layer 2 virtual private network (VPN) connection.

**Action** From operational mode, enter the `ping mpls l2vpn` command with the `fec129` option.

```
user@PE1> ping mpls l2vpn fec129 instance green remote-id 192.0.2.5 remote-pe-address 192.0.2.5
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
```

**Meaning** The output shows that the ping operation is successful, meaning that the LSP for a FEC 129 Layer 2 VPN connection is reachable.

## Next-Generation VPLS for Multicast with Multihoming Overview

VPLS emulates the broadcast domain of a LAN across an MPLS network cloud. Traditional MPLS implementations of VPLS require that all participating ingress PE routers make separate copies of each broadcast or multicast packet to send to all other PE routers that are part of the VPLS site for the same extended LAN. In a large virtual private network (VPN), replication overhead can be significant for each ingress router and its attached core-facing links.

Junos OS offers the following VPLS enhancements which provide redundancy for VPLS between PE and CE routers:

- Redundancy using BGP for multihomed links between PE and CE devices— Juniper Networks integrates the local preference and path selection capability of BGP with VPLS to allow a CE Ethernet switch to have a backup path across the network.
- Redundancy using the Spanning Tree Protocol (STP) for multihomed links between PE and CE devices— Various versions of STP can be used in the CE network to avoid loops in a multihoming environment. The provider does not have any control over this customer network configuration. The provider can also implement BGP-based loop avoidance as an additional measure to avoid loops.

The following standardized VPLS implementations are supported by the Internet Engineering Task Force (IETF):

- RFC 4761, *Virtual Private LAN Service (VPLS) Using BGP for Auto-Discovery and Signaling*
- RFC 4762, *Virtual Private LAN Service (VPLS) Using LDP Signaling*

For more information about the basic configuration of next-generation VPLS, see the *Technology Overview Next-Generation VPLS Using Point-to-Multipoint LSPs for Unicast and Multicast Forwarding*.

For a detailed technology overview of VPLS, you can refer to *LDP-BGP VPLS Interworking* at the following location:

<http://www.juniper.net/us/en/local/pdf/whitepapers/2000282-en.pdf>.

### Redundancy Using BGP for Multihomed Links between PE and CE Routers

Juniper Networks implements a BGP-based multihoming solution to provide redundancy for VPLS between PE and CE routers.

In this implementation:

- VPLS-enabled PE routers (also called VPLS PE routers) collectively elect one of the VPLS PE routers, to which a site is multihomed, as the designated forwarder of traffic between this site and all other sites.
- All the other VPLS PE routers, to which the same site is connected, do not forward traffic to or from the site.
- Essentially all VPLS PE routers behave as if the site is singlehomed to the VPLS PE router that is the designated forwarder.
- Service providers are able to prevent well-known Layer 2 loops without relying on the customer's STP configuration.
- Customers can still run STP as a fallback strategy to prevent loops that are formed without the service provider's knowledge.

The benefits of multihoming include:

- Redundancy of the link connecting the PE router and the CE device.
- Redundancy of the directly connected PE routers.
- Faster convergence when there is a link failure between a PE router and CE device.
- The same BGP attributes are used to configure primary and backup links.

## Operation of Next-Generation VPLS for Multicast with Multihoming Using BGP

VPLS provides a multipoint-to-multipoint Ethernet service that can span one or more metro areas and multiple sites. VPLS provides connectivity as if these sites are attached to the same Ethernet LAN.

VPLS uses an IP and MPLS service provider infrastructure. From the service provider's point of view, using IP and MPLS routing protocols and procedures instead of STP, and using MPLS labels instead of VLAN identifiers (IDs), significantly improves the scalability of the VPLS service.

### Single CE Site Connected to Multiple VPLS PE Routers

This section describes the process used to elect a single designated forwarder for a multihomed site.

For a multihomed site, all the PE routers in the VPLS instance elect the same designated forwarder PE router using the BGP VPLS multihoming procedure. Only elected designated

forwarders forward traffic to and receive traffic from the multihomed site. All other PE routers where this multihomed site is present do not participate in forwarding for that site.

All remote PE routers are aware of the designated forwarder PE router for each multihomed site and do not create a pseudowire to the PE routers that are not the designated forwarder for the multihomed site.

In [Figure 137 on page 1411](#):

- The same site ID (sometimes known as a VPLS edge identifier or VE ID) is configured on all VPLS PE routers to which a site is multihomed.
- All PE routers are aware of which sites are multihomed since they see multiple advertisements with the same site ID.
- One of the VPLS PE routers is selected as the designated forwarder for this site by all PE routers based on a deterministic algorithm.
- The algorithm selects the VPLS PE router that originates the best advertisement with a particular site ID as the designated forwarder. There are two possible selection methods:
  - BGP path selection on the route reflector and the PE routers
  - VPLS site selection on the PE router only
- If multiple network layer reachability information (NLRI) advertisements have the same route distinguisher and site ID, the router uses BGP path selection rules to select the best path. The BGP rules are:
  - Always prefer advertisements that do not have the down bit set over ones that do have this bit set.
  - Prefer the advertisement with the higher local preference.
  - Use the configurable per-site site preference to set the BGP local preference in the advertisement and influence the choice of the designated forwarder.
  - Ignore the interior gateway protocol (IGP) metric while doing path selection because the choice of designated forwarder must be the same on all PE routers.
- Among advertisements with the same route distinguisher, apply VPLS site selection rules (a subset of BGP path selection rules) to pick the select advertisement.

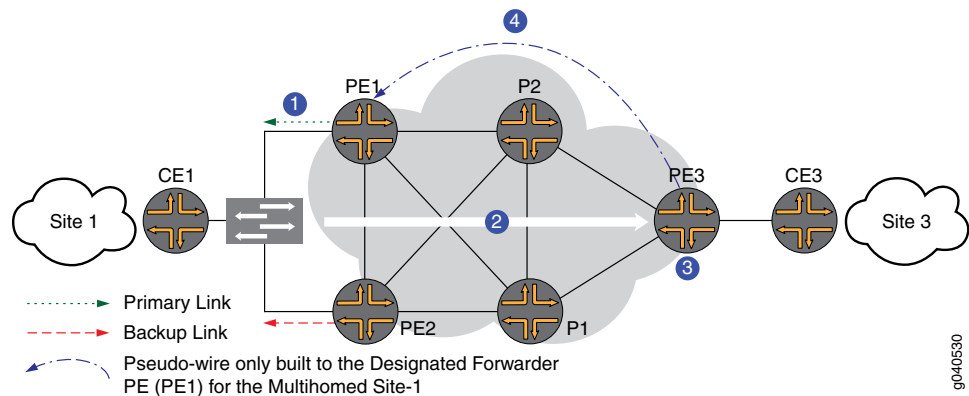

[Figure 137 on page 1411](#) illustrates the following four-step process to select the designated forwarder and create the pseudowire:

1. Router PE1 and Router PE2 both have the same site ID (Site 1) for Router CE1.  
Router PE1 has a better local preference of 65535 and is configured as the primary router.
2. Router PE3 receives the BGP NLRI advertisement from Router PE1 and Router PE2 with the local preferences of 65535 and 1, respectively.

3. Router PE3 runs the BGP path selection algorithm and selects Router PE1 as the designated forwarder VPLS edge PE router for Site 1.
4. Router PE3 creates the pseudowire only to Router PE1, which helps to save bandwidth in the network core.

**Figure 137: Single CE Site Multihomed with Two PE Routers**

The resulting VPLS PE router roles for Site 1 are:

- Router PE1 is the designated forwarder VPLS edge PE router.
- Router PE2 is the non-designated forwarder VPLS edge PE router.
- Router PE3 is the remote VPLS edge PE router.

All the interfaces linking the CE and PE devices that are connected to the designated forwarder VPLS PE router, are marked **Up** and **forwarding** in **show** command output.

All the interfaces linking the CE and PE devices on the non-designated forwarder VPLS PE router, are marked **vc-down** in **show** command output. The router does not send traffic or forward received traffic on these interfaces.

Remote VPLS PE routers establish pseudowires only to the designated PE router, and tear down any pseudowires to the non-designated PE router.

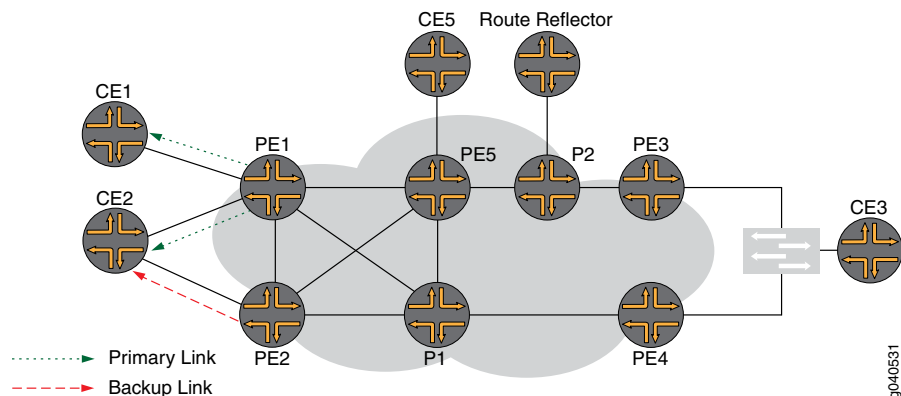

### Multiple CE Sites Connected to a Single VPLS PE Router for Link Redundancy

This section describe some of the operational details of multiple CE sites connected to a single VPLS PE router.

In [Figure 138 on page 1412](#):

- Router CE2 is multihomed to Router PE1 and Router PE2.
- Router CE1 is singlehomed to Router PE1.

**Figure 138: Two CE Sites Multihomed to a Single PE Router on Different Line Cards**

The scenario shown in Figure 2 is common. Your network might have a single PE router in a remote area, but you would like to multihome a Layer 2 network to different Flexible PIC Concentrators (FPCs) on the same PE router. This configuration provides link redundancy on the CE devices and link redundancy on the links between the CE and PE devices, but limited link redundancy on PE devices. In this case, you need the ability to configure a site to use a single active interface for forwarding.

In this scenario:

- Path selection is done per site to determine if a PE router is the designated forwarder for that site or not.
- Only a single pseudowire is established between any two PE routers, even if one or both of them have multiple designated PE routers.

**NOTE:** A pseudowire between two PE routers is always established between the designated sites with the minimum site IDs on the two PE routers.

- Establishing a single pseudowire avoids the need to maintain multiple flooding and media access control (MAC) address tables per instance (one per site) on each PE router.
- The local interfaces are marked **vc-down** in the **show** command output where a site is connected to the non-designated forwarder router.
- When a designated site on a PE router fails, all MAC addresses from this remote PE router have to be learned again, since the router does not know the exact site where the MAC addresses were originally learned from.

## Implementation of Redundancy Using VPLS Multihomed Links Between PE and CE Devices

You might need to multihome a CE device to multiple PE routers without causing a Layer 2 forwarding loop. This is not a problem if the CE device is a router, since no Layer 2 loops

can form when using a router. However, if the CE device is a Layer 2 device, like a hub or switch, multihoming it to two PE routers can cause a Layer 2 loop.

You can use one of the following methods to prevent the Layer 2 loop:

- BGP-based primary and backup link selection.
- Spanning tree protocol (STP) to prune links to the CE router. However, this method requires the service provider to trust its customer to not cause any Layer 2 loops by misconfiguration.
- Active and standby up link functionality, such as the redundant trunk groups that are supported on Juniper Networks EX Series Ethernet Switches.

The limitations of using STP on the CE site are:

- Backbone and access network bandwidth is not used efficiently.
- PE routers using STP to prevent loops with dual-homed sites receive broadcast traffic unnecessarily because the pseudowire to the standby PE router still exists.
- When the direct link between the CE and PE router fails, multihoming works fine. When a link connected downstream from the CE router fails, multihoming does not work.

The benefits and properties of the BGP-based solution are:

- BGP path selection does not have the limitations of STP.
- A CE device that is multihomed to multiple PE routers is given the same site ID on all the PE routers it is multihomed to.
- The BGP path selection algorithm selects the router that originates the best advertisement as the VPLS PE designated forwarder.
- If desired, you can set the local preference on the PE routers to control BGP path selection.
- BGP path selection occurs on the route reflector and the PE router.
- An IGP metric is not part of the selection process.
- If the route distinguisher is the same on both PE routers, the route reflector selects one PE router as the designated forwarder. If the route distinguishers are different on the PE routers, the route reflector forwards both copies of the route to the remote PE routers.

## Example: Next-Generation VPLS for Multicast with Multihoming

This example shows how to configure next-generation VPLS for multicast with multihoming. It is organized in the following sections:

- [Requirements on page 1414](#)
- [Overview and Topology on page 1414](#)
- [Configuration on page 1417](#)

### Requirements

The following table lists the hardware and software requirements for this configuration.

**Table 32: Hardware and Software Used**

| Equipment                                                    | Components                                                   | Software                      |
|--------------------------------------------------------------|--------------------------------------------------------------|-------------------------------|
| Four MX Series 3D Universal Edge Routers                     | DPC40X-1GE -X, DPC 4X-10GE-X,<br>DPC40x-1GE-R, DPC 4X-10GE-R | Junos OS Release 9.3 or later |
| Two M320 Multiservice Edge Routers and T Series Core Routers | FPC 3, 10GE Xenpak                                           | Junos OS Release 9.3 or later |
| Five EX Series Ethernet Switches                             | EX4200, EX3200                                               | Junos OS Release 9.4 or later |

### Overview and Topology

[Figure 139 on page 1415](#) shows the physical topology used in this next-generation VPLS multihoming example.

**Figure 139: Physical Topology of Next-Generation VPLS for Multicast with Multihoming**

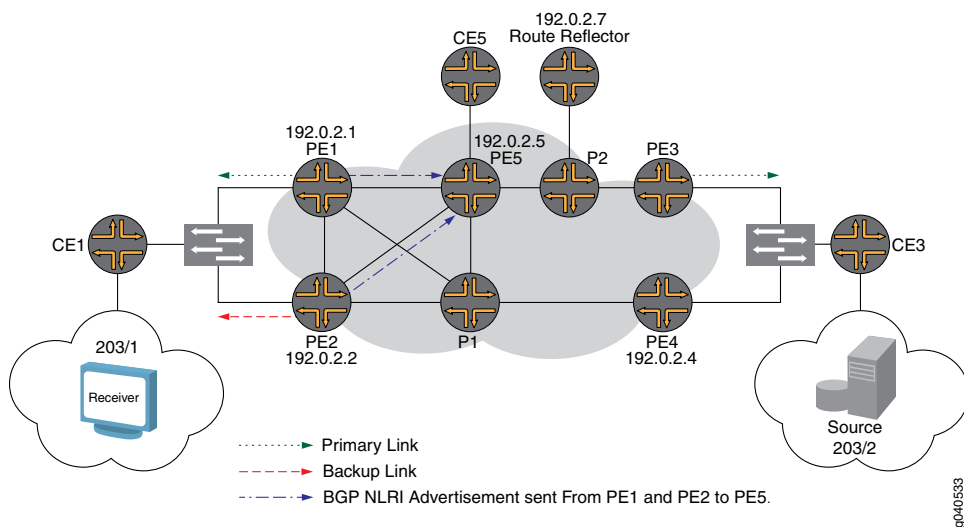

Figure 140 on page 1415 show the logical topology of the next-generation VPLS multihoming example.

**Figure 140: Logical Topology of Next-Generation VPLS for Multicast with Multihoming**

The network state and configuration before the implementation is as follows:

- Five PE routers participating in the next-generation VPLS domain named GOLD.
- OSPF, BGP, and RSVP are configured on the MPLS core interfaces.
- The **no-tunnel-services** statement is included in the VPLS routing instance. This statement supports the use of label-switched interface (LSI) tunnel interfaces for VPLS.
- Router PE1 and Router PE2 are configured with a dynamic point-to-multipoint LSP using the **vpls-GOLD-p2mp-template** template.
- Router PE3 and Router PE4 are configured to use static point-to-multipoint LSPs.

**NOTE:** Single-hop point-to-multipoint LSPs are not supported, so single-hop point-to-multipoint LSPs are down.

- Router CE1 is multihomed to Router PE1 and Router PE2 through an EX4200 Layer 2 switch.
- Router CE3 is multihomed to Router PE3 and Router PE4 through an EX4200 Layer 2 switch.
- Router CE5 is singlehomed to Router PE5.
- The off-path route reflector is configured for BGP. The **family l2vpn** statement is included in the route reflector configuration.
- Router CE3 is connected to test equipment through port 203/2. The test equipment generates multicast traffic to groups 203.0.113.1 through 203.0.113.10 at the rate of 10,000 pps.
- Router CE1 and Router CE5 are configured with static Internet Group Management Protocol (IGMP) joins so they can receive the multicast traffic from Router CE3.
- The Layer 2 switches are configured with trunk ports to the PE routers and access ports to the test equipment.

Here is a summary of the steps necessary to complete the configuration successfully:

1. Configure a unique route distinguisher for the VPLS routing instance named GOLD on Router PE1, Router PE2, Router PE3, and Router PE4.
2. Configure the same site ID for the multihomed PE routers. Configure both Router PE1 and Router PE2 with a site ID value of 1. Configure both Router PE3 and Router PE4 with a site ID value of 3.
3. Configure multihoming under the CE1 site configuration.
4. Configure the site-preference **Primary** on Router PE1 and configure the site-preference **Backup** on Router PE2. In this case, Router PE1 has the primary link to Router CE1 and Router PE2 has the backup link to Router CE1.
5. Configure the site preference on Router PE3 and Router PE4. Configure Router PE3 as the primary and Router PE4 as the backup.

## Configuration

This section provides a step-by-step procedure to configure next-generation VPLS for multicast with multihoming.

**NOTE:** In any configuration session, it is good practice to verify periodically that the configuration can be committed using the `commit check` command.

This example is organized in the following sections:

- [Configuring Next-Generation VPLS Multihoming on page 1417](#)
- [Validating the VPLS Control Plane on page 1419](#)
- [Verifying the VPLS Data Plane on page 1425](#)
- [Results on page 1429](#)

### Configuring Next-Generation VPLS Multihoming

#### Step-by-Step Procedure

1. In BGP-based VPLS multihoming, it is recommended that you configure distinct route distinguishers for each multihomed router. Configuring distinct route distinguishers helps with faster convergence when the connection to a primary router goes down. It also requires the other backup PE routers to maintain additional state information for faster convergence.

There are two levels of path selection:

- The first is BGP: BGP uses a combination of route distinguisher, site ID, and VE block offset for BGP path selection.
- The second is in VPLS: VPLS uses the site ID for VPLS path selection.

By configuring unique route distinguishers, the prefixes for BGP path selection are all unique. Therefore, BGP path selection is skipped and VPLS path selection is used, which only looks at the site ID.

On Router PE1, Router PE2, Router PE3, and Router PE4 configure a unique router distinguisher for the **GOLD** routing instance.

```
user@PE1# set routing-instance GOLD route-distinguisher 192.0.2.1:1
```

```
user@PE2# set routing-instance GOLD route-distinguisher 192.0.2.2:10
```

```
user@PE3# set routing-instance GOLD route-distinguisher 192.0.2.3:1
```

```
user@PE4# set routing-instance GOLD route-distinguisher 192.0.2.4:10
```

2. Configure site ID 1 on Routers PE1 and PE2 for Router CE1. Configure site ID 3 on Routers PE3 and PE4 for Router CE3.

```
user@PE1# set routing-instance GOLD protocols vpls site CE1 site-identifier 1
```

```
user@PE2# set routing-instance GOLD protocols vpls site CE1 site-identifier 1
```

```
user@PE3# set routing-instance GOLD protocols vpls site CE3 site-identifier 3
```

```
user@PE4# set routing-instance GOLD protocols vpls site CE3 site-identifier 3
```

3. Enable multihoming by including the **multi-homing** statement under the multihomed site configuration on Router PE1, Router PE2, Router PE3, and Router PE4.

```
user@PE1# set routing-instance GOLD protocols vpls site CE1 multi-homing
```

```
user@PE2# set routing-instance GOLD protocols vpls site CE1 multi-homing
```

```
user@PE3# set routing-instance GOLD protocols vpls site CE3 multi-homing
```

```
user@PE4# set routing-instance GOLD protocols vpls site CE3 multi-homing
```

4. Include the **site-preference primary** statement on Router PE1 and Router PE3, and include the **site-preference backup** statement on Router PE2 and Router PE4. The **site-preference primary** statement sets the local preference to the highest value (65535) and the **site-preference backup** statement sets the BGP local preference to 1. Since the site ID is the same, the routers select the highest local preference value as the designated forwarder.

```
user@PE1# set routing-instance GOLD protocols vpls site CE1 site-preference primary
```

```
user@PE2# set routing-instance GOLD protocols vpls site CE1 site-preference backup
```

```
user@PE3# set routing-instance GOLD protocols vpls site CE3 site-preference
primary
```

```
user@PE4# set routing-instance GOLD protocols vpls site CE3 site-preference
backup
```

### Validating the VPLS Control Plane

---

**Step-by-Step Procedure** This section presents show commands that you can use to verify the operation of the example configuration.

In this example the traffic patterns are:

- The source is connected to Router CE3 and sends 10,000 pps for the groups 203.0.113.1 to 203.0.113.10. Router CE3 is configured as a rendezvous point.
- Multicast receivers are connected to both Router CE1 and Router CE5. Protocol Independent Multicast (PIM) join messages are generated by the test equipment.
- The link between Router PE3 and Router CE3 and the link between Router PE1 and Router CE1 are configured as primaries for VPLS multihoming.
- All PE routers have a BGP session with the route reflector.
- All PE routers have a label-switched path (LSP) that is created to the route reflector so that the PE routers have a route to the route reflector in the **inet.3** table for route resolution.

1. On Router PE1, use the **show vpls connections** command to verify that the VPLS connections are **Up** between Router PE1 and Router PE3 and between Router PE1 and PE5. Router PE1 is the primary link selected by the VPLS multihoming configuration.

```
user@PE1# show vpls connections
Layer-2 VPN connections:
```

Legend for connection status (St)

|                                  |                                                |
|----------------------------------|------------------------------------------------|
| EI -- encapsulation invalid      | NC -- interface encapsulation not CCC/TCC/VPLS |
| EM -- encapsulation mismatch     | WE -- interface and instance encaps not same   |
| VC-Dn -- Virtual circuit down    | NP -- interface hardware not present           |
| CM -- control-word mismatch      | -> -- only outbound connection is up           |
| CN -- circuit not provisioned    | <- -- only inbound connection is up            |
| OR -- out of range               | Up -- operational                              |
| OL -- no outgoing label          | Dn -- down                                     |
| LD -- local site signaled down   | CF -- call admission control failure           |
| RD -- remote site signaled down  | SC -- local and remote site ID collision       |
| LN -- local site not designated  | LM -- local site ID not minimum designated     |
| RN -- remote site not designated | RM -- remote site ID not minimum designated    |
| XX -- unknown connection status  | IL -- no incoming label                        |
| MM -- MTU mismatch               | MI -- Mesh-Group ID not available              |
| BK -- Backup connection          | ST -- Standby connection                       |

Legend for interface status

Up -- operational  
Dn -- down

Instance: GOLD

| Description: Intf - vpls GOLD local site 3 remote site 1      |      |    |                      |            |
| 3                                                             | rmt  | RN |                      |            |
| 5                                                             | rmt  | Up | Nov 16 11:22:56 2009 | 1          |
| Remote PE: 192.0.2.5, Negotiated control-word: No             |      |    |                      |            |
| Incoming label: 262149, Outgoing label: 262163                |      |    |                      |            |
| Local interface: lsi.1048834, Status: Up, Encapsulation: VPLS |      |    |                      |            |
| Description: Intf - vpls GOLD local site 3 remote site 5      |      |    |                      |            |

- On Router PE4, use the **show vpls connections** command to verify that the VPLS connections are in the **LN** state, meaning the local site is not designated. Router PE4 is configured to be the backup link for Router CE3.

```
user@PE4# show vpls connections
...
```

Instance: GOLD

Local site: CE3 (3)

| connection-site | Type | St | Time last up | # Up trans |
|-----------------|------|----|--------------|------------|
| 1               | rmt  | LN |              |            |
| 3               | rmt  | SC |              |            |
| 5               | rmt  | LN |              |            |

- On Router PE1, use the **show route advertising-protocol** command to verify that Router PE1 (the multihoming primary router) is sending the BGP Layer 2 VPN route advertisement to the route reflector with the local preference value of **65535**. The local preference is used by Router PE3 to select Router PE1 as the designated forwarder, rather than selecting Router PE2 that has a local preference of 1.

```
user@PE1# show route advertising-protocol bgp 192.0.2.7 extensive
```

GOLD.l2vpn.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)

\* 192.0.2.1:1:1:1/96 (1 entry, 1 announced)

BGP group to-RR type Internal

Route Distinguisher: 192.0.2.1:1

Label-base: 262145, range: 8

Nexthop: Self

Flags: Nexthop Change

Localpref: 65535

AS path: [65000] I

Communities: target:65000:1 Layer2-info: encaps:VPLS, control flags:, mtu: 0, site preference: 65535

PMSI: Flags 0:RSVP-TE:label[0:0:0]:Session\_13[192.0.2.1:0:9519:192.0.2.1]

6. On Router PE2, use the **show route advertising-protocol** command to verify that Router PE2 is configured as the multihoming backup with a local preference of 1.

```

user@PE2# show route advertising-protocol bgp 192.0.2.7 extensive
GOLD.l2vpn.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)
* 192.0.2.2:10:1:1/96 (1 entry, 1 announced)

 Route Distinguisher: 192.0.2.2:10
 Label-base: 262145, range: 8
 Nexthop: Self
 Flags: Nexthop Change
 Localpref: 1
 AS path: [65000] I
 Communities: target:65000:1 Layer2-info: encaps:VPLS, control flags:, mtu: 0, site preference: 1

```

7. On Router PE3, use the **show route receive-protocol** command to verify that Router PE3 receives the Layer 2 VPN route from the route reflector for Router PE1 and Router PE2 with different local preference values.

BGP route selection is based on the received **l2vpn** routes for the VPLS site connected to multihomed PE routers. Since the route distinguishers are different on Router PE1 and Router PE2, Router PE3 and Router PE4 consider the received routes from Router PE1 and Router PE2 as different routes. Router PE3 and Router PE4 run the BGP path selection algorithm and select Router PE1, the router advertising the route with the higher local preference value, as the designated forwarder.

```

user@PE3# show route receive-protocol bgp 192.0.2.7
bgp.l2vpn.0: 4 destinations, 4 routes (4 active, 0 holddown, 0 hidden)
 Prefix Nexthop MED Lc1pref AS path
 192.0.2.1:1:1:1/96

* 192.0.2.5 192.0.2.5 100 I

```

8. On Router PE3, use the **show route table** command to verify that Router PE3 has selected the static point-to-multipoint LSP from Router PE3 to Router PE1 for forwarding.

Notice that Router PE2 does not have any provider multicast service interface (PMSI) flags because PMSI attributes are not attached.

```

user@PE3# show route table GOLD.l2vpn.0 extensive

9. On Router PE3, use the **show vpls connections** command to verify that the VPLS connection is in the **Up** state.

Notice the display also shows the local interface and the incoming and outgoing label values used.

## Verifying the VPLS Data Plane

**Step-by-Step Procedure** After the control plane is verified using the previous steps, you can verify the data plane. The data plane operation in the VPLS multihoming scenario is the same as the regular next-generation VPLS operation. This section describes the **show** command outputs that you can use to validate the data plane.

1. On Router PE3, use the **show mpls lsp** command to verify the state of the static LSPs and sub-LSPs.

Router PE2 is configured with static point-to-multipoint LSPs and sub-LSPs with link protection. Point to multipoint LSPs are not supported for single-hop LSPs. In the following output notice that the single-hop point-to-multipoint LSP from Router PE3 to Router PE4 is **down**.

```
user@PE3# show mpls lsp p2mp ingress
Ingress LSP: 1 sessions
P2MP name: vpls-GOLD, P2MP branch count: 4
To From State Rt P ActivePath LSPname
192.0.2.5 192.0.2.3 Up 0 * to-pe5
192.0.2.1 192.0.2.3 Up 0 * to-pe1
192.0.2.4 192.0.2.3 Dn 0 * to-pe4
192.0.2.2 192.0.2.3 Up 0 * to-pe2
Total 4 displayed, Up 3, Down 1
```

2. On Router PE1, use the **show mpls lsp** command to verify the state of the dynamic LSPs.

Router PE1 is using a dynamic point-to-multipoint LSP template configured with link protection. Notice that the LSP state is **Up** and that link protection is **desired**.

```
user@PE1# show mpls lsp p2mp ingress extensive
Ingress LSP: 1 sessions
P2MP name: 192.0.2.1:1:vpls-GOLD, P2MP branch count: 1

192.0.2.3
 From: 192.0.2.1, State: Up, ActiveRoute: 0, LSPname: 192.0.2.3:192.0.2.1:1:vpls-GOLD
 ActivePath: (primary)
 P2MP name: 192.0.2.1:1:vpls-GOLD
 Link protection desired
 LoadBalance: Random
 Encoding type: Packet, Switching type: Packet, GPID: IPv4

```

3. On Router PE3, use the **monitor interface traffic** command to verify the multicast replication behavior for the point-to-multipoint LSP on the designated forwarder Router PE3.

The output shows that 10,000 pps are received on interface **ge-1/0/0** from Router CE3. The traffic has been forwarded to the provider (P) Router P2 and Router PE4 through **xe-0/0/0** and **xe-0/1/0**, respectively. Based on the output, you can determine that a single copy of the packet is being sent to Router P2 and Router PE4.

```
user@PE3> monitor interface traffic
```

```
PE3 Seconds: 8 Time: 11:58:40
```

| Interface | Link | Input packets | (pps)  | Output packets | (pps)   |
|-----------|------|---------------|--------|----------------|---------|
| lc-0/0/0  | Up   | 0             |        | 0              |         |
| xe-0/0/0  | Up   | 13570505      | (0)    | 4507338866     | (10000) |
| lc-0/1/0  | Up   | 0             |        | 0              |         |
| xe-0/1/0  | Up   | 292843        | (1)    | 628972219      | (10000) |
| lc-0/2/0  | Up   | 0             |        | 0              |         |
| xe-0/2/0  | Up   | 343292        | (0)    | 206808         | (1)     |
| lc-0/3/0  | Up   | 0             |        | 0              |         |
| xe-0/3/0  | Down | 0             | (0)    | 0              | (0)     |
| ge-1/0/0  | Up   | 2703709733    | (9999) | 13203544       | (1)     |
| lc-1/0/0  | Up   | 0             |        | 0              |         |
| ge-1/0/1  | Down | 50380341937   | (0)    | 60024542111    | (0)     |
| ge-1/0/2  | Down | 60652323068   | (0)    | 84480825838    | (0)     |
| ge-1/0/3  | Down | 81219536264   | (0)    | 84614255165    | (0)     |
| ge-1/0/4  | Down | 54379241112   | (0)    | 83656815208    | (0)     |

4. On Router P2, use the **monitor interface traffic** command to verify that the multicast packet replication happens close to the PE routers connected to the receivers.

Router PE1 and Router PE5 are connected to receivers that have joined this multicast group. Notice that incoming multicast packets from Router PE3 on the **ge-0/1/0** interface are replicated twice and sent out on the **ge-1/1/0** interface.

```
user@P2> monitor interface traffic
```

```
P2 Seconds: 6 Time: 12:07:58
```

| Interface | Link | Input packets | (pps)   | Output packets | (pps)   |
|-----------|------|---------------|---------|----------------|---------|
| ge-0/1/0  | Up   | 661459806     | (10000) | 116236         | (0)     |
| ge-1/1/0  | Up   | 115956        | (0)     | 1322690473     | (20000) |
| gr-2/1/0  | Up   | 0             | (0)     | 0              | (0)     |
| ip-2/1/0  | Up   | 0             | (0)     | 0              | (0)     |

- On Router PE3, use the **show vpls flood** command to verify information about the flood next-hop route.

Junos OS Release 9.0 and later identifies the flood next-hop route as a composite next hop. Notice that the interface is **ge-1/0/0.1**, the next-hop type is **composite**, and that the flood composition is **flood-to-all**. This means the traffic is flooded to all the PE routers.

```
user@PE3# show vpls flood extensive
```

```
Name: GOLD
```

```
CEs: 1
```

```

6. On Router PE3, use the **show vpls mac-table** command to verify that the MAC address of the PE router at the remote end of the VPLS has been learned and added to the MAC address table.

Notice that the MAC address is learned on the **ge-1/0/0.1** interface.

```

user@PE3# show vpls mac-table
MAC flags (S -static MAC, D -dynamic MAC,
 SE -Statistics enabled, NM -Non configured MAC)

```

```

Routing instance : GOLD
Bridging domain : __GOLD__, VLAN : NA
MAC MAC Logical
address flags interface
00:14:f6:75:78:00 D ge-1/0/0.1

```

7. On Router PE3, use the **show route forwarding-table** command to verify that the forwarding table has the required entries with two labels: one for the VPLS service and the other for the next-hop interface.

```

user@PE3> show route forwarding-table family vpls vpn GOLD
Routing table: GOLD.vpls
VPLS:

## Next-Generation VPLS Point-to-Multipoint Forwarding Overview

---

VPLS is a Layer 2 solution for efficiently sending multicast traffic over a multiprotocol label switching (MPLS) core.

VPLS emulates the broadcast domain of a LAN across an MPLS network cloud. Traditional MPLS implementations of VPLS require that all participating ingress provider edge (PE) routers make separate copies of each broadcast or multicast packet to send to all other PE routers that are part of the VPLS site for the same extended LAN. In a large virtual private network (VPN), replication overhead can be significant for each ingress router and its attached core-facing links.

Juniper Networks has several important VPLS enhancements that provide a solution for the replication overhead issue:

- Point-to-multipoint LSP support provides efficient distribution of multicast traffic such as IP-based television (IPTV).
- Multihoming support integrates the path selection capability of BGP with VPLS to allow a customer edge (CE) Ethernet switch to have a backup path across the network.

This document explains the use of point-to-multipoint LSPs in the MPLS core as an alternative to ingress replication. Point-to-multipoint LSPs enable ingress routers to send only one copy of each packet into the MPLS cloud. Each PE router maintains a point-to-multipoint tree so traffic can be efficiently sent to all VPN sites. This process requires the fewest possible replications of the packets and does the replication at the most optimal points in the network.

The benefits of this approach are:

- Conservation of bandwidth
- Increased PE router efficiency
- Improved traffic engineering for flows of flooded traffic
- Manual control or several levels of automatic operation
- Simplified multicast optimization, which is ideal for IPTV or network access wholesale

The Internet Engineering Task Force (IETF) supports two standardized VPLS implementations: *RFC 4761: Virtual Private LAN Service (VPLS) Using BGP for Auto-Discovery and Signaling* and *RFC 4762: Virtual Private LAN Service (VPLS) Using LDP Signaling*.

Juniper Networks has implemented VPLS solutions based on both RFCs. BGP-based VPLS is the superior solution, but LDP-based VPLS is supported for those service providers that have already deployed this alternative.

For a detailed technology overview of LDP-BGP VPLS interworking see *LDP-BGP VPLS Interworking* at <http://www.juniper.net/us/en/local/pdf/whitepapers/2000282-en.pdf>.

## Next-Generation VPLS Point-to-Multipoint Forwarding Applications

VPLS provides a multipoint-to-multipoint Ethernet service that can span one or more metro areas and provides connectivity between multiple sites as if these sites were attached to the same Ethernet LAN.

VPLS uses an IP and MPLS service provider infrastructure. From a service provider's point of view, use of IP and MPLS routing protocols and procedures instead of the Spanning Tree Protocol (STP), and MPLS labels instead of VLAN IDs, significantly improves the scalability of the VPLS service.

### VPLS Protocol Operation

VPLS carries Ethernet traffic across a service provider network, so it must mimic an Ethernet network in some ways. When a PE router configured with a VPLS routing instance receives a packet from a CE device, it first determines whether it knows the destination of the VPLS packet. If it does, it forwards the packet to the appropriate PE router or CE device. If it does not, it broadcasts the packet to all the other PE routers and CE devices that are members of that VPLS routing instance. In both cases, the CE device receiving the packet must be different from the one sending the packet.

When a PE router receives a packet from another PE router, it first determines whether it knows the destination of the VPLS packet. If the destination is known, the PE router either forwards the packet or drops it, depending on whether the destination is a local or remote CE device. The PE router has three options (scenarios):

- If the destination is a local CE device, the PE router forwards the packet to it.
- If the destination is a remote CE device (connected to another PE router), it discards the packet.

- If it cannot determine the destination of the VPLS packet, the PE router floods it to its attached CE devices.

A VPLS can be directly connected to an Ethernet switch. Layer 2 information gathered by an Ethernet switch, such as media access control (MAC) addresses and interface ports, is included in the VPLS routing instance table. However, instead of all VPLS interfaces being physical switch ports, the router allows remote traffic for a VPLS instance to be delivered across an MPLS LSP and arrive on a virtual port. The virtual port emulates a local, physical port. Traffic can be learned, forwarded, or flooded to the virtual port in almost the same way as traffic sent to a local port.

The VPLS routing table is populated with MAC addresses and interface information for both physical and virtual ports. One difference between a physical port and a virtual port is that on a virtual port, the router captures the outgoing MPLS label used to reach the remote site and an incoming MPLS label for VPLS traffic received from the remote site. The virtual port is generated dynamically on a Tunnel Services PIC when you configure VPLS on a Juniper Networks M Series Multiservice Edge Router or T Series Core Router. A Tunnel Services PIC is required on each M Series or T Series VPLS router.

If your router has an Enhanced FPC installed, you can configure VPLS without a Tunnel Services PIC. To do so, you use a label-switched interface (LSI) to provide VPLS functionality. An LSI MPLS label is used as the inner label for VPLS. This label maps to a VPLS routing instance. On the PE router, the LSI label is stripped and then mapped to a logical LSI interface. The Layer 2 Ethernet frame is then forwarded using the LSI interface to the correct VPLS routing instance. To configure VPLS on a router without a Tunnel Services PIC, include the **no-tunnel-services** statement.

One restriction on flooding behavior in VPLS is that traffic received from remote PE routers is never forwarded to other PE routers. This restriction helps prevent loops in the core network. This also means that the core network of PE routers must be fully meshed. Additionally, if a CE Ethernet switch has two or more connections to the same PE router, you must enable the Spanning Tree Protocol (STP) on the CE switch to prevent loops.

### Point-to-Multipoint Implementation

In next-generation VPLS, point-to-multipoint LSPs are used to flood broadcast, multicast, and unknown unicast traffic across a VPLS core network to all the PE routers. This is more efficient in terms of bandwidth utilization between the PE router and provider (P) router.

If point-to-multipoint LSPs are not being used, the PE router needs to forward multiple copies of broadcast, multicast, and unknown unicast packets to all PE routers. If point-to-multipoint LSPs are used, the PE router floods one copy of each packet to the P router, where it is replicated close to the egress router.

**NOTE:** For next-generation VPLS, both point-to-point LSPs and point-to-multipoint LSPs are needed between the PE routers.

In VPLS, point-to-multipoint LSPs are only used to transport broadcast frames, multicast frames, and unicast frames with an unknown destination MAC address. All other frames are still transported using point-to-point LSPs. This structure is much more efficient for bandwidth use, particularly near the source of the broadcast, multicast, and unknown frames. However, it also results in more state in the network because each PE router is the ingress of one point-to-multipoint LSP that touches all other PE routers and one point-to-point LSP going to each of the other PE routers.

Enabling point-to-multipoint LSPs for any VPLS instance starts the flooding of unknown-unicast, broadcast, and multicast traffic using point-to-multipoint LSPs.

For each VPLS instance, a PE router creates a dedicated point-to-multipoint LSP. Whenever VPLS discovers a new neighbor through BGP, a source-to-leaf sub-LSP is added for this neighbor in the point-to-multipoint LSP instance.

If there are  $n$  PE routers in the VPLS instance, then the discovery of a new neighbor through BGP creates  $n$  point-to-multipoint LSPs in the network, where each PE router is the root of the tree and the rest of the  $n-1$  PE routers are leaf nodes (or source-to-leaf sub-LSPs).

Each point-to-multipoint LSP created by PE routers can be identified using an RSVP-traffic engineering point-to-multipoint session object, which is passed as a provider multicast service interface (PMSI) tunnel attribute by BGP while advertising VPLS routes. Using this tunnel attribute, incoming source-to-leaf sub-LSP add request messages (RSVP-path message) can be associated with the right VPLS instance and originator PE router. As a result, label allocation is done in such a way that when traffic arrives on the LSP, it is not only terminated on the right VPLS instance, but the originator PE router is also identified so that source MAC addresses can be learned.

Point-to-multipoint LSPs can be enabled incrementally on any PE router that is part of a specific VPLS instance. This means a PE router that has this feature uses point-to-multipoint LSPs to flood traffic, whereas other PE routers in the same VPLS instance can use ingress replication to flood the traffic. However, when point-to-multipoint LSPs are enabled on any PE router, make sure that all the PE routers that are part of the same VPLS instance also support this feature.

**NOTE:** Penultimate-hop popping (PHP) is disabled for point-to-multipoint LSPs terminating in a VPLS instance.

---

### Limitations of Point-to-Multipoint LSPs

When implementing point-to-multipoint LSPs remember the following limitations:

- There is no mechanism to allow only multicast traffic to go over the point-to-multipoint LSP.
- Point-to-multipoint LSPs do not support inter-AS traffic. Only intra-AS traffic is supported.
- Point-to-multipoint LSPs do not support graceful restart for ingress LSPs. This also affects VPLS when flooding is done using point-to-multipoint LSPs.

- The same point-to-multipoint LSP cannot be shared across multiple VPLS instances.
- When this feature is enabled, ingress PE routers use only point-to-multipoint LSPs for flooding. The router initiates the creation of source-to-leaf sub-LSPs for each PE router that is part of the same VPLS instance. Any PE router for which this source-to-leaf sub-LSP fails to come up does not receive any flooded traffic from the ingress PE router.
- It is possible that flooding of unknown unicast traffic over point-to-multipoint LSPs may lead to packet reordering, because as soon as learning is done, unicast traffic is sent out using point-to-point pseudowire LSPs.
- Static LSPs and LSPs configured using the **label-switched-path-template** statement cannot be configured at the same time.
- When an LSP is configured using the **static-lsp** statement, a point-to-multipoint LSP is created statically to include all neighbors in the VPLS instance.

Before enabling the point-to-multipoint LSP feature on any PE router, make sure that all the other PE routers that are part of the same VPLS instance are upgraded to a Junos OS Release that supports it. If a router in the VPLS instance does not support point-to-multipoint LSPs, it may lose all the traffic sent on the point-to-multipoint LSP. Therefore, do not enable this feature if there is a single router in a VPLS instance that is not capable of supporting this feature, either because it is not running the appropriate Junos OS Release or because it is a router from a vendor that does not support this feature.

### Simultaneous Transit and Egress Router Operation

A PE router that plays the role of both an MPLS transit router and an MPLS egress router can do so by receiving either one or two copies of a packet to fulfill each of its roles.

To fulfill both roles while using only a single copy of a packet, Juniper Networks M Series and T Series routers require a Tunnel Services PIC configured with virtual tunnel (vt) interfaces and ultimate-hop popping must be enabled. With a virtual tunnel interface and ultimate-hop popping, a single copy of the received packet is forwarded beyond the PE router to fulfill the transit router role and is also consumed internally by the virtual tunnel interface to fulfill the egress router role.

If a label-switched interface (LSI) logical interface is used, then two copies of each packet must be received on the point-to-multipoint LSP, one to fulfill the transit router role and one to fulfill the egress router role.

## Implementation

Some implementations of VPLS use ingress replication. Ingress replication is simple but inefficient. It sends multiple copies of the same packet on a link, especially the PE-P link. This causes wasted bandwidth when there is a heavy broadcast and multicast traffic.

As shown in the sample network in [Figure 141 on page 1440](#) the ingress PE router makes three copies of every broadcast, multicast, and flooded packet for each VPLS instance.

Figure 141: Ingress Replication

Figure 142 on page 1440 shows how a point-to-multipoint LSP works for multicast.

In a VPLS using point-to-multipoint LSPs, the ingress PE router sends a single copy of the multicast packet to Router P1. Router P1 makes two copies for this point-to-multipoint LSP. Each of the other P routers also makes multiple copies of the packet. This moves replication closer to the endpoints and results in significant improvements in the network bandwidth utilization.

Figure 142: Point-to-Multipoint Replication

### Requirements

[Table 33 on page 1441](#) lists the hardware that is used and the software that is required for this example:

**Table 33: Hardware and Software Used**

| Equipment                               | Components                  | Software                        |
|-----------------------------------------|-----------------------------|---------------------------------|
| Six MX Series 3D Universal Edge Routers | DPC-4 10GE-X, DPC-40 1GE-X  | Junos OS Release 9.3R4 or later |
| One T Series Core Router                | FPC3, 10GE-Xenpak           | Junos OS Release 9.3R4 or later |
| Eight EX4200 Ethernet Switches          | EX4200 virtual switches     | Junos OS Release 9.3R4 or later |
| One M7i Multiservice Edge Router        | Gigabit Ethernet interfaces | Junos OS Release 9.3R4 or later |

### Overview and Topology

The logical topology of the NG-VPLS example is shown in [Figure 143 on page 1442](#).

Figure 143: Logical Topology of NG-VPLS Using Point-to-Multipoint LSPs

The routers in this example are preconfigured with the following:

- OSPF area 0 is configured on all the PE routers and P routers with traffic engineering enabled.
- All of the core-facing interfaces are configured with the **mpls** protocol address family.
- The RSVP and MPLS protocols are enabled for all the core-facing interfaces.
- All the MX Series routers have their network services mode set to Ethernet. The network services mode is configured by including the **network-services** statement and specifying the **ethernet** option.
- All the PE routers are configured for autonomous system **65000**.

The physical topology of the NG-VPLS example is shown in [Figure 144 on page 1443](#). The topology consists of six MX Series routers connected with redundant links in the core. Four MX Series routers are acting as PE routers and two are core routers.

Figure 144: Physical Topology of NG-VPLS Using Point-to-Multipoint LSPs

Note the following topology details:

- A route reflector is configured in the topology to reflect the family **l2-vpn** routes to all the PE routers for BPG-VPLS.
- The GOLD VPLS routing instance is configured with two sites in each of the PE routers.
- One GOLD site is connected to the CE router and the other one is directly connected to the test equipment on each PE router.
- The **no-tunnel-services** statement is included in the GOLD VPLS instance to enable the use of LSI interfaces for VPLS tunnel services.
- Router CE1 and Router CE2 are EX Series Virtual Chassis switches acting as CE routers.
- Router CE3 is an M7i router acting as a CE router.
- Two multicast sources are configured. One is connected to Router CE1 (Site 1) and the other to Router PE2 (Site 4) to simulate different scenarios.
- Router CE1 is configured as the rendezvous point (RP).
- Unicast traffic is enabled on all the test equipment ports and is sent to all the sites in the GOLD VPLS instance.

## Configuration

This example shows how to configure next-generation VPLS using point-to-multipoint LSPs. It is organized in the following sections:

---

### Configuring the PE Router Interfaces

#### Step-by-Step Procedure

On the customer-facing PE interfaces, enable VLAN tagging, configure the encapsulation type, and enable the VPLS address family. There are four possible interface encapsulations for VPLS routing instances that you can choose depending on your needs.

1. If your network requires that each logical interface on the PE router-to-CE router link be configured to only accept packets with VLAN ID 1000, include the **vlan-tagging** statement, include the **encapsulation** statement, and specify **vlan-vpls** as the encapsulation type. Also include the **vlan-id** statement and specify **1000** as the VLAN ID.

```
[edit interfaces]
ge-1/1/0 {
 vlan-tagging;
 encapsulation vlan-vpls;
 unit 1 {
 encapsulation vlan-vpls;
 vlan-id 1000;
 family vpls;
 }
}
```

With this configuration, you can configure multiple logical interfaces with different VLAN IDs and associate each logical interface with a different routing instance.

2. If your network requires each physical interface on the PE router to CE router link to be configured to use the entire Ethernet port as part of a single VPLS instance, include the **encapsulation** statement, and specify **ethernet-vpls** as the encapsulation type.

```
[edit interfaces]
ge-1/2/0 {
 encapsulation ethernet-vpls;
 unit 0 {
 family vpls;
 }
}
```

With this encapsulation mode, you cannot create multiple logical units (VLANs).

3. If your network requires that each logical interface of the single physical interface on the PE router to CE router link be configured to use a mix of different encapsulations, include the **encapsulation** statement, and specify **flexible-ethernet-services** as the encapsulation type at the **[edit interfaces interface-name]** hierarchy level. Also include the **encapsulation** statement, and specify **vlan-vpls** or **vlan-ccc** as the encapsulation type at the **[edit interfaces interface-name unit logical-unit-number]** hierarchy level.

```
[edit interfaces]
ge-1/2/0 {
 vlan-tagging;
 encapsulation flexible-ethernet-services;
 unit 1 {
 encapsulation vlan-vpls;
 }
 unit 2 {
 encapsulation vlan-ccc;
 }
}
```

4. If your network requires support for using a mix of single and dual tagged VLANs configured in different logical interfaces on a single physical interface, include the **encapsulation** statement, and specify **flexible-vlan-tagging** as the encapsulation type.
5. Configure the core-facing CE router interfaces. The CE router and PE router logical interface configuration must match encapsulation types and VLAN IDs. Typically the IP address is configured on the core-facing CE router interfaces if the CE device is a router and terminates the Layer 2 domain into the Layer 3 network. In this example, the interface is configured for single tagging with a VLAN ID of **1000**.

```
[edit interfaces]
ge-1/1/0 {
 vlan-tagging;
 unit 1 {
 vlan-id 1000;
 family inet {
 address 198.51.100.4/24;
 }
 }
}
```

## Configuring a Route Reflector for all PE Routers for BGP-Based VPLS

### Step-by-Step Procedure

Configuring a route reflector is the preferred method to enable any BGP-based service offerings. Configuring a route reflector avoids the requirement for a full mesh of BGP peer sessions, and it scales well. BGP redundancy can be achieved using multiple route reflectors in a single cluster.

1. To enable BGP to carry Layer 2 VPN and VPLS NLRI messages, create a peer group, include the **family** statement, specify the **l2vpn** option, and include the **signaling** statement. To configure the route reflector cluster and complete the BGP peer sessions, include the **cluster** statement and specify the IP address for the cluster ID. Then include the **neighbor** statement and specify the IP address of the PE routers that are BGP client peers in the cluster.

```
[edit protocols]
bgp {
 group RR {
 type internal;
 local-address 192.0.2.7;
 family l2vpn {
 signaling;
 }
 cluster 192.0.2.7;
 neighbor 192.0.2.1; # To PE1
 neighbor 192.0.2.2; # To PE2
 neighbor 192.0.2.3; # To PE3
 neighbor 192.0.2.4; # To PE4
 }
}
```

2. Configure OSPF and enable traffic engineering on the route reflector to create the Constrained Shortest Path First (CSPF) database for the egress LSPs terminating from the PE routers.

```
[edit protocols]
ospf {
 traffic-engineering;
 area 0.0.0.0 {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
}
```

3. Enable the MPLS and RSVP protocols on all interfaces connected to the MPLS core. This terminates the RSVP egress LSPs from the PE routers.

```
[edit protocols]
rsvp {
 interface all;
 interface fxp0.0 {
 disable;
 }
}
```

```

 }
 }
 mpls {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
}

```

### Establishing BGP-Based VPLS with a Route Reflector

#### Step-by-Step Procedure

For BGP-based VPLS, all PE routers need to have a full mesh of BGP peer sessions with each other or have a single peer with the route reflector. The route reflector reflects the routes received from the other PE routers. In this example, the PE router is configured to establish a peer relationship with the route reflector.

1. To have all the PE routers establish a BGP client peer session with the route reflector, create an internal peer group, include the **local-address** statement, and specify the IP address of the PE router. Also include the **neighbor** statement, and specify the IP address of the route reflector. To enable BGP to carry Layer 2 VPN and VPLS NLRI messages, include the **family** statement, specify the **l2vpn** option, and include the **signaling** statement.

```

[edit protocols]
bgp {
 group to-RR {
 type internal;
 local-address 192.0.2.1;
 family l2vpn {
 signaling;
 }
 neighbor 192.0.2.7; # To the route reflector
 }
}

```

2. Configure a point-to-point RSVP LSP from the PE routers to the route reflector. To create the LSP, include the **label-switched-path** statement, give the LSP a meaningful name, include the **to** statement and specify the IP address of the route reflector as the LSP end point. This LSP is needed to resolve the BGP next hops in the **inet.3** routing table for the routes received from the route-reflector.

```

[edit protocols]
mpls {
 label-switched-path to-RR {
 to 192.0.2.7;
 }
 interface all;
 interface fxp0.0 {
 disable;
 }
}

```

### Configuring Point-to-Point LSPs Between PE Routers

---

#### Step-by-Step Procedure

In next-generation VPLS, point-to-multipoint LSPs are only used to transport broadcast, multicast, and unknown unicast frames. All other frames are still transported using point-to-point RSVP LSPs. This is a more efficient use of bandwidth, particularly near the source of the unknown, broadcast, and multicast frames. The trade-off is more state in the network, because each PE router is the ingress of one point-to-multipoint LSP that touches all other PE routers, and  $n$  point-to-point LSPs are needed, one going to each of the other PE routers.

1. To create a point-to-point LSP, include the **label-switched-path** statement, give the LSP a meaningful name, include the **to** statement, and specify the IP address of the other PE router as the LSP endpoint. The example shows the configuration of LSPs from Router PE1 to Routers PE2, PE3, and PE4.

```
[edit protocols]
mpls {
 label-switched-path to-PE2 {
 to 192.0.2.2;
 }
 label-switched-path to-PE3 {
 to 192.0.2.3;
 }
 label-switched-path to-PE4 {
 to 192.0.2.4;
 }
}
```

### Configuring Dynamic and Static Point-to-Multipoint LSPs Between PE Routers

---

#### Step-by-Step Procedure

This procedure describes how to enable the creation of dynamic point-to-multipoint LSPs and how to configure static point-to-multipoint LSPs. On a router configured with static point-to-multipoint LSPs, the LSPs come up immediately. On a router configured with dynamic point-to-multipoint LSPs, the LSP comes up only after receiving BGP neighbor information from the route reflector or from the other PE routers participating in the VPLS domain.

For each VPLS instance, a PE router with dynamic point-to-multipoint LSPs enabled creates a dedicated point-to-multipoint LSP based on the point-to-multipoint template. Whenever VPLS discovers a new neighbor through BGP, a sub-LSP for this neighbor is added to the point-to-multipoint LSP.

If there are  $n$  PE routers in the VPLS instance then the router creates  $n$  point-to-multipoint LSPs in the network where each PE router is the root of the tree and includes the rest of the  $n-1$  PE routers as leaf nodes connected through a source-to-leaf sub-LSP.

1. In this step, you configure Router PE1 and Router PE2 to use a dynamic point-to-multipoint LSP template for LSP creation. When these routers receive a new BGP route advertised from the route reflector for a new neighbor, they create a point-to-multipoint sub-LSP to that neighbor. To create the dynamic

point-to-multipoint LSP template, include the **label-switched-path** statement, give the LSP template a meaningful name, include the **template** statement and include the **p2mp** statement. Also enable link protection and configure the optimize timer to periodically reoptimize the LSP path.

```
[edit protocols]
mpls {
 label-switched-path vpls-GOLD-p2mp-template {
 template; # identify as a template
 optimize-timer 50;
 link-protection; # link protection is enabled on point-to-multipoint LSPs
 p2mp;
 }
}
```

2. In this step, you configure static point-to-multipoint LSPs. Creating static point-to-multipoint LSPs is similar to creating point-to-point LSPs, except you can also configure other RSVP parameters under each point-to-multipoint LSP.

To create static point-to-multipoint LSPs, include the **label-switched-path** statement, give the LSP a meaningful name, include the **to** statement, and specify the IP address of the PE router that is the endpoint of the LSP. Also include the **p2mp** statement and specify a pathname.

```
[edit protocols]
mpls {
 label-switched-path to-pe2 {
 to 192.0.2.2;
 p2mp vpls-GOLD;
 }
 label-switched-path to-pe3 {
 to 192.0.2.3;
 p2mp vpls-GOLD;
 }
 label-switched-path to-pe1 {
 to 192.0.2.1;
 p2mp vpls-GOLD;
 }
}
```

### Configuring Point-to-Multipoint Link Protection

#### Step-by-Step Procedure

Point-to-multipoint LSPs only support RSVP link protection for traffic engineering. Node protection is not supported. Link protection is optional, but it is the recommended configuration for most networks.

1. To enable link protection on the core-facing interfaces, include the **link-protection** statement at the **[edit protocols rsvp interface *interface-name*]** hierarchy level.

```
[edit protocols]
rsvp {
 interface all;
 interface fxp0.0 {
```

```
 disable;
 }
 interface xe-0/3/0.0 {
 link-protection;
 }
 interface xe-0/2/0.0 {
 link-protection;
 }
 interface xe-0/1/0.0 {
 link-protection;
 }
}
```

2. Enable the point-to-multipoint LSP to use the RSVP link protection feature. Link-protection can be configured for both static point-to-multipoint and dynamic point-to-multipoint LSPs that use a template.

For static point-to-multipoint LSPs, configure each branch sub-LSP. To enable link protection, include the **link-protection** statement at the **[edit protocols mpls label-switched-path *label-switched-path-name*]** hierarchy level.

```
[edit protocols mpls label-switched-path]
label-switched-path to-pe2 {
 to 192.0.2.2;
 link-protection;
 p2mp vpls-GOLD;
}
label-switched-path to-pe3 {
 to 192.0.2.3;
 link-protection;
 p2mp vpls-GOLD;
}
label-switched-path to-pe1 {
 to 192.0.2.1;
 link-protection;
 p2mp vpls-GOLD;
}
```

3. For dynamic point-to-multipoint LSPs using a template, only the template needs to have link protection configured. All the point-to-multipoint branch LSPs that use the template inherit this configuration.

To enable link protection for dynamic point-to-multipoint LSPs, include the **link-protection** statement at the **[edit protocols mpls label-switched-path *label-switched-path-name*]** hierarchy level.

```
[edit protocols mpls label-switched-path]
label-switched-path vpls-GOLD-p2mp-template {
 template;
 optimize-timer 50;
 link-protection;
 p2mp;
}
```

### Configuring a BGP-Based VPLS Routing Instance for NG-VPLS

#### Step-by-Step Procedure

For NG-VPLS, the routing-instance configuration is similar to that for a regular VPLS routing instance. The routing instance defines the VPLS site and creates the VPLS connection. The following parameters are configured.

- Instance Type – VPLS.
  - Interface – The interface connecting to the CE router.
  - Route Distinguisher – Each routing instance you configure on a PE router must have a unique route distinguisher. The route distinguisher is used by BGP to distinguish between potentially identical network reachability information (NLRI) messages received from different VPNs. If you use a unique route distinguisher for each routing instance on each PE, you can determine which PE originated the route.
  - VRF Target – Configuring a VRF target community using the **vrf-target** statement causes default VRF import and export policies to be generated that accept imported routes and tag exported routes with the specified target community.
  - Protocols – Configure the VPLS protocol as described in the following procedure.
1. To configure the NG-VPLS routing instance, include the **routing-instances** statement and specify the instance name. Also include the **instance-type** statement and specify **vpls** as the type. Include the **route-distinguisher** statement and specify a route distinguisher that is unique throughout all VPNs configured on the router. Configure a VRF route target by including the **vrf-target** statement and specify the route target. The route target exported by one router must match the route target imported by another router for the same VPLS.

```
[edit]
routing-instances {
 GOLD {
 instance-type vpls;
 interface ge-1/0/0.1;
 interface ge-1/1/0.1;
 route-distinguisher 192.0.2.1:1;
 vrf-target target:65000:1;
 }
}
```

2. To use a point-to-multipoint LSP for VPLS flooding, configure an LSP under the VPLS routing instance.

To configure the point-to-multipoint LSP for VPLS flooding, include the **label-switched-path-template** statement and specify the name of the LSP template at the **[edit routing-instances routing-instances-name provider-tunnel rsvp-te]** hierarchy level.

```
[edit]
routing-instances {
 GOLD {
 instance-type vpls;
 interface ge-1/0/0.1;
```

```

interface ge-1/1/0.1;
route-distinguisher 192.0.2.1:1;
provider-tunnel {
 rsvp-te {
 label-switched-path-template {
 vpls-GOLD-p2mp-template;
 }
 }
}
vrf-target target:65000:1;
}

```

3. Configuring the VPLS protocol enables the VPLS between different sites in the VPLS domain. Multiple sites can be configured under a single VPLS routing instance, but note that the lowest site ID is used to build the VPLS pseudowire to the other PE routers, and the label block associated with the lowest site ID is advertised. The following parameters are configured for the VPLS protocol:
  - Site – Name of the VPLS site.
  - Site Range – Maximum site ID allowed in the VPLS. The site range specifies the highest-value site ID allowed within the VPLS, not the number of sites in the VPLS.
  - Site Identifier – Any number between 1 and 65,534 that uniquely identifies the VPLS site. This is also referred as the VE-ID in the relevant RFC.
  - PE-CE Interface – The interface participating in this site.
  - Tunnel services for VPLS – If you do not configure any tunnel interface at the **[edit protocol vpls tunnel-services]** hierarchy, the router uses any tunnel interface available on the router for VPLS.
  - No-tunnel-services – If you include the **no-tunnel-services** statement, the router uses a label-switched interface (LSI) for the tunnel services for that VPLS instance.
  - Mac Table Size – The size of the VPLS media access control (MAC) address table. The default is 512 addresses and the maximum is 65,536. When the table is full, new MAC addresses are no longer added to the table.

To configure the VPLS protocol, include the **vpls** statement at the **[edit routing-instances routing-instance-name protocols]** hierarchy level. To configure the site range, include the **site-range** statement and specify the highest-value site ID allowed within the VPLS. To cause the router to use an LSI interface, include the **no-tunnel-services** statement. To create a VPLS site, include the **site** statement and specify a site name. Also include the **site-identifier** statement and specify the site ID. Then include the **interface** statement and specify the interface name for the interface connected to the CE device.

```

[edit]
routing-instances {
 GOLD {
 instance-type vpls;
 interface ge-1/0/0.1;
 interface ge-1/1/0.1;
 }
}

```

```
route-distinguisher 192.0.2.1:1;
provider-tunnel {
 rsvp-te {
 label-switched-path-template {
 vpls-GOLD-p2mp-template;
 }
 }
}
vrf-target target:65000:1;
protocols {
 vpls {
 site-range 8;
 no-tunnel-services;
 site CE1 {
 site-identifier 1;
 interface ge-1/0/0.1;
 }
 site Direct {
 site-identifier 2;
 interface ge-1/1/0.1;
 }
 }
}
}
```

## Configuring Tunnel Services for VPLS

### Step-by-Step Procedure

A tunnel interface is needed for VPLS configuration to encapsulate the originating traffic, and to de-encapsulate the traffic coming from a remote site. If the tunnel interface is not configured, the router selects one of the available tunnel interfaces on the router by default. There are three methods available in Junos OS to configure this tunnel interface.

- To specify a virtual tunnel interface to be used as the primary device for tunneling, include the **primary** statement, and specify the virtual tunnel interface to be used at the **[edit routing-instances *routing-instance-name* protocols vpls tunnel-services]** hierarchy level.

```
[edit routing-instances routing-instance-name]
protocols {
 vpls {
 site-range 8;
 tunnel-services {
 primary vt-1/2/10;
 }
 }
}
```

- To configure the router to use an LSI interface for tunnel services rather than a virtual tunnel interface, include the **no-tunnel-services** statement at the **[edit routing-instances *routing-instance-name* protocols vpls]** hierarchy level.

```
[edit routing-instances routing-instance-name]
protocols {
 vpls {
 site-range 8;
 no-tunnel-services;
 }
}
```

- In an MX Series router you must create the tunnel services interface to be used for tunnel services. To create the tunnel service interface, include the **bandwidth** statement and specify the amount of bandwidth to reserve for tunnel services in gigabits per second at the **[edit chassis fpc *slot-number* pic *slot-number* tunnel-services]** hierarchy level.

```
[edit chassis]
fpc 1 {
 pic 3 {
 tunnel-services {
 bandwidth 1g;
 }
 }
}
```

### Verifying the Control Plane

---

- Step-by-Step Procedure** This section describes **show** command outputs you can use to validate the control plane. It also provides methodologies for troubleshooting. Note the following:
- In this example there are six sites. Router PE1 and Router PE2 have two sites each. Router PE3 and Router PE4 have one site each. All sites are in the GOLD VPLS instance.
  - In VPLS if you have multiple sites configured under a single VPLS routing instance, the label block from the site with the lowest site ID is used to establish pseudowires between remote PEs. Note that the data traffic is still sent to those PE router interfaces connected to CE devices that are in one of the following states:
    - LM – Local site ID is not the minimum designated. The local site ID is not the lowest. Therefore the local site ID is not being used to establish pseudowires or distribute VPLS label blocks.
    - RM – Remote site ID is not the minimum designated. The remote site ID is not the lowest. Therefore, the remote site ID is not being used to establish pseudowires or distribute VPLS label blocks.
  - For more information about how VPLS label blocks are allocated and used, see *Understanding VPLS Label Blocks Operation*.

1. After the entire configuration is done, you can verify the VPLS connections state.

In the following output, the VPLS connections show the **Up** state for certain sites, and the remaining sites show either the **RM** or **LM** state. This is the expected state in a VPLS implementation on multihoming sites.

In this example, Router PE1 has site **CE1** configured with site ID 1 and site **Direct** configured with site ID 2. The label block for site **CE1** is advertised to the remote PE routers and used for receiving the data packets from the remote PE routers. In the **show** command output, notice the following:

- Router PE1 uses its lowest site ID, which is site ID 1. Site ID 1 is used for Device **CE1**.
- Router PE2 uses its lowest site ID, which is site ID 3. Site ID 3 is used for Device **CE2**.
- Router PE3 and Router PE4 each have a single site configured.

For site **CE1**, connection site 3 is in the **Up** state and connection site 4 is in the **RM** state.

- For site **Direct**, all the connections are in the **LM** state.
- Site **Direct** has a higher site ID than site 1 on this router.

On Router PE1, use the **show vpls connections** command to verify the VPLS connections state.

```
user@PE1> show vpls connections
```

Layer-2 VPN connections:

Legend for connection status (St)

|                                  |                                             |

3 rmt LM
4 rmt LM
5 rmt LM
6 rmt LM

```

2. On Router PE4, use the **show vpls connections** command to verify the VPLS connections state.

Verify that site 2 and site 4 are in the **RM** state. This state tells you that the sites are configured with the highest site ID on Router PE1 and Router PE2. Because Router PE4 has only one site configured, it does not have any sites in the **LM** states.

```

user@PE4> show vpls connections
...
Instance: GOLD
Local site: Direct (6)
connection-site Type St Time last up # Up trans
1 rmt Up Oct 6 16:28:35 2009 1

Incoming label: 800004, Outgoing label: 262150
Local interface: vt-1/2/10.1048578, Status: Up, Encapsulation: VPLS
Description: Intf - vpls GOLD local site 6 remote site 5

```

3. On each PE router, use the **show bgp summary** command to verify that the IBGP sessions between the PE routers or between the PE router and the route reflector have been established. The sessions must be operational before the PE routers can exchange any Layer 2 VPN routes. In the example below, also notice that the output from Router PE1 shows that the **bgp.l2vpn.0** and **GOLD.l2vpn.0** routing tables have been created.

```

user@PE1> show bgp summary

```

```

Groups: 1 Peers: 1 Down peers: 0
Table Tot Paths Act Paths Suppressed History Damp State Pending
bgp.l2vpn.0 4 4 0 0 0 0 0
Peer AS InPkt OutPkt OutQ Flaps Last Up/Dwn State
192.0.2.7 65000 40 39 0 1 15:45 Estab1

```

```

bgp.l2vpn.0: 4/4/4/0
GOLD.l2vpn.0: 4/4/4/0

```

```

admin@PE2# run show bgp summary
Groups: 1 Peers: 1 Down peers: 0
Table Tot Paths Act Paths Suppressed History Damp State Pending
bgp.l2vpn.0 4 4 0 0 0 0 0
inet6.0 0 0 0 0 0 0 0
inet.0 0 0 0 0 0 0 0
Peer AS InPkt OutPkt OutQ Flaps Last Up/Dwn State
192.0.2.7 65000 43 42 0 0 17:25 Estab1

```

```

bgp.l2vpn.0: 4/4/4/0
GOLD.l2vpn.0: 4/4/4/0

```

4. On Router PE4, use the **show route table** command to verify that there is one Layer 2 VPN route to each of the other PE routers. Router PE3 should have a similar **show** command output.

```

user@PE4> show route table bgp.l2vpn.0
bgp.l2vpn.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.0.2.1:1:1/96
 * [BGP/170] 00:23:18, localpref 100, from 192.0.2.7
 AS path: I
 > to 10.10.9.1 via xe-0/0/0.0, label-switched-path to-PE1
192.0.2.1:1:2:1/96
 * [BGP/170] 00:23:18, localpref 100, from 192.0.2.7
 AS path: I
 > to 10.10.9.1 via xe-0/0/0.0, label-switched-path to-PE1
192.0.2.2:10:3:1/96
 * [BGP/170] 00:23:18, localpref 100, from 192.0.2.7
 AS path: I
 > to 10.10.9.1 via xe-0/0/0.0, label-switched-path to-PE2
192.0.2.2:10:4:1/96
 * [BGP/170] 00:23:18, localpref 100, from 192.0.2.7
 AS path: I
 > to 10.10.9.1 via xe-0/0/0.0, label-switched-path to-PE2
192.0.2.3:10:5:1/96
 * [BGP/170] 00:23:18, localpref 100, from 192.0.2.7
 AS path: I
 > to 10.10.8.1 via xe-0/1/0.0, label-switched-path to-PE3

```

5. On the route reflector, use the **show bgp summary** command to verify that the router has an IBGP peer session with each of the PE routers.

```

user@RR> show bgp summary
Groups: 2 Peers: 5 Down peers: 1
Table Tot Paths Act Paths Suppressed History Damp State Pending
bgp.l2vpn.0 6 6 0 0 0 0 0
inet.0 0 0 0 0 0 0 0
Peer AS InPkt OutPkt OutQ Flaps Last Up/Dwn State

```

```

192.0.2.1 65000 44 46 0 0 18:27 Establ
 bgp.12vpn.0: 2/2/2/0
192.0.2.2 65000 43 45 0 0 18:22 Establ
 bgp.12vpn.0: 2/2/2/0
192.0.2.3 65000 42 45 0 0 18:19 Establ
 bgp.12vpn.0: 1/1/1/0
192.0.2.4 65000 43 45 0 0 18:15 Establ
 bgp.12vpn.0: 1/1/1/0

```

6. In NG-VPLS, point-to-multipoint LSPs carry only unknown unicast, broadcast, and multicast packets. A full mesh of point-to-point LSPs is needed between the PE routers for NG-VPLS. The point-to-point LSPs create routes in the **inet.3** routing table. These entries are used to resolve the Layer 2 VPN routes received from the BGP peers. All other data traffic is sent over point-to-point LSPs.

A point-to-point LSP is also created for the route reflector. This LSP creates a route in the **inet.3** routing table for BGP next-hop resolution.

On Router PE1, use the **show mpls lsp** command to verify that the **to-PE2**, **to-PE3**, **to-PE4**, and **to-RR** LSPs are in the **Up** state.

```

user@PE1> show mpls lsp ingress unidirectional
Ingress LSP: 7 sessions
To From State Rt P ActivePath LSPName
192.0.2.2 192.0.2.1 Up 0 * to-PE2
192.0.2.3 192.0.2.1 Up 0 * to-PE3
192.0.2.4 192.0.2.1 Up 0 * to-PE4

Ingress LSP: 7 sessions
To From State Rt P ActivePath LSPName
192.0.2.1 192.0.2.4 Up 0 * to-PE1
192.0.2.2 192.0.2.4 Up 0 * to-PE2
192.0.2.3 192.0.2.4 Up 0 * to-PE3
192.0.2.7 192.0.2.4 Up 0 * to-RR
Total 4 displayed, Up 4, Down 0

```

7. For each VPLS instance, a PE router creates a dedicated point-to-multipoint LSP. In this example, Router PE1 and Router PE2 are configured to use a point-to-multipoint dynamic template.

For dynamic point-to-multipoint LSPs, whenever VPLS discovers a new Layer 2 VPN neighbor through BGP, a source-to-leaf sub-LSP is added in the VPLS instance for this neighbor PE router.

On Router PE1, use the **show mpls lsp** command to verify that three source-to-leaf sub-LSPs are created.

```
user@PE1> show mpls lsp ingress p2mp
Ingress LSP: 1 sessions
P2MP name: 192.0.2.1:1:vp1s:GOLD, P2MP branch count: 3
To From State Rt P ActivePath LSPname
192.0.2.4 192.0.2.1 Up 0 *
192.0.2.4:192.0.2.1:1:vp1s:GOLD
192.0.2.3 192.0.2.1 Up 0 *
192.0.2.3:192.0.2.1:1:vp1s:GOLD
192.0.2.2 192.0.2.1 Up 0 *
192.0.2.2:192.0.2.1:1:vp1s:GOLD
Total 3 displayed, Up 3, Down 0
```

8. On Router PE2, use the **show mpls lsp** command to verify that three source-to-leaf sub-LSPs are created.

```
user@PE2> show mpls lsp p2mp ingress
Ingress LSP: 1 sessions
P2MP name: 192.0.2.2:10:vp1s:GOLD, P2MP branch count: 3
To From State Rt P ActivePath LSPname
192.0.2.4 192.0.2.2 Up 0 *
192.0.2.4:192.0.2.2:10:vp1s:GOLD
192.0.2.3 192.0.2.2 Up 0 *

```

9. In this step, Router PE3 and Router PE4 are using static point-to-multipoint LSPs. For static point-to-multipoint LSPs, the source-to-leaf sub-LSPs to all the PE routers are manually configured.

On Router PE3, use the **show mpls lsp** command to verify that three source-to-leaf sub-LSPs have been configured.

```
user@PE3> show mpls lsp p2mp ingress
Ingress LSP: 1 sessions
P2MP name: vp1s-GOLD, P2MP branch count: 3
To From State Rt P ActivePath LSPname
192.0.2.1 192.0.2.3 Up 0 * to-pe1
192.0.2.4 192.0.2.3 Up 0 * to-pe4
192.0.2.2 192.0.2.3 Up 0 * to-pe2
Total 3 displayed, Up 3, Down 0
```

10. On Router PE4, use the **show mpls lsp** command to verify that three source-to-leaf sub-LSPs are configured.

```

user@PE4> show mpls lsp ingress p2mp
Ingress LSP: 1 sessions
P2MP name: vpls-GOLD, P2MP branch count: 3
To From State Rt P ActivePath LSPname
192.0.2.1 192.0.2.4 Up 0 * to-pe1
192.0.2.3 192.0.2.4 Up 0 * to-pe3
192.0.2.2 192.0.2.4 Up 0 * to-pe2
Total 3 displayed, Up 3, Down 0

```

11. Each point-to-multipoint LSP created by the PE router can be identified using an RSVP-TE point-to-multipoint session object. The session object is passed as a PMSI tunnel attribute by BGP when it advertises VPLS routes. Using this tunnel attribute, an incoming source-to-leaf sub LSP add request (RSVP-Path message) supports label allocation in such a way that when traffic arrives on this source-to-leaf sub-LSP the router terminates the message in the right VPLS instance and also identifies the originating PE. This supports source MAC address learning.

On Router PE1, use the **show rsvp session** command to verify that the RSVP session for the dynamic point-to-multipoint LSP is **Up** and that link protection is configured as **desired**. Notice that the point-to-multipoint session object to be sent in BGP is **54337**.

```

user@PE1> show rsvp session detail p2mp ingress
Ingress RSVP: 7 sessions
P2MP name: 192.0.2.1:1:vpls:GOLD, P2MP branch count: 3

192.0.2.2

```

12. Router PE4 is configured for static point-to-multipoint LSPs. Link protection is not configured for these LSPs. Use the **show rsvp session** command to verify that the point-to-multipoint session object to be sent in BGP is **42873**.

```

user@PE4> show rsvp session detail p2mp ingress
Ingress RSVP: 7 sessions

### Verifying the Data Plane

**Step-by-Step Procedure** After the control plane is verified using the previous steps, you can verify the data plane. This section describes **show** command outputs you can use to validate the data plane.

1. On Router PE1, use the **show vpls connections extensive | match Flood** command to verify the point-to-multipoint LSP name and status of all the sites. Notice the flood next-hop identifier of **600** for the **192.0.2.1:1:vp1s:GOLD** LSP.

```

user@PE1> show vpls connections extensive | match Flood
Ingress RSVP-TE P2MP LSP: 192.0.2.1:1:vp1s:GOLD, Flood next-hop ID: 600

```

2. On Router PE1, use the **show vpls connections extensive** command to verify the point-to-multipoint LSP name and status of all the sites.

```

user@PE1> show vpls connections extensive

Next-hop interface: ge-1/1/0.1

```

5. On Router PE1, use the **show vpls mac-table instance GOLD** command to verify the learned MAC addresses of CE routers connected to the VPLS domain.

```

user@PE1> show vpls mac-table instance GOLD
MAC flags (S -static MAC, D -dynamic MAC,
 SE -Statistics enabled, NM -Non configured MAC)

```

```

Routing instance : GOLD
Bridging domain : __GOLD__, VLAN : NA
 MAC MAC Logical
address flags interface
00:00:28:28:28:02 D ge-1/1/0.1
00:00:28:28:28:04 D lsi.1049353
00:14:f6:75:78:00 D lsi.1049354
00:19:e2:51:7f:c0 D lsi.1049353
00:19:e2:57:e7:c0 D ge-1/0/0.1

```

6. On Router PE1, use the **show vpls statistics** command to verify the broadcast, multicast, and unicast traffic flow using the packet statistics for the VPLS instance.

```

user@PE1> show vpls statistics
VPLS statistics:

## Flooding Unknown Traffic Using Point-to-Multipoint LSPs in VPLS

For a VPLS routing instance, you can flood unknown unicast, broadcast, and multicast traffic using point-to-multipoint (also called *P2MP*) LSPs. By default, VPLS relies upon ingress replication to flood unknown traffic to the members of a VPLS routing instance. This can cause replication of data at routing nodes shared by multiple VPLS members, as shown in [Figure 145 on page 1474](#). The flood data is tripled between PE router PE1 and provider router P1 and doubled between provider routers P1 and P2. By configuring point-to-multipoint LSPs to handle flood traffic, the VPLS routing instance can avoid this type of traffic replication in the network, as shown in [Figure 146 on page 1474](#).

**Figure 145: Flooding Unknown VPLS Traffic Using Ingress Replication**

**Figure 146: Flooding Unknown VPLS Traffic Using a Point-to-Multipoint LSP**

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The point-to-multipoint LSP used for VPLS flooding can be either static or dynamic. In either case, for each VPLS routing instance, the PE router creates a dedicated point-to-multipoint LSP. All of the neighbors of the VPLS routing instance are added to the point-to-multipoint LSP when the feature is enabled. If there are  $n$  PE routers in the VPLS routing instance,  $n$  point-to-multipoint LSPs are created in the network where each PE router is the root of the point-to-multipoint tree and includes the rest of the  $n - 1$  PE routers as leaf nodes. If you configured static point-to-multipoint LSPs for flooding, any additional VPLS neighbors added to the routing instance later are not automatically added to the point-to-multipoint LSP. You will need to manually add the new VPLS

neighbors to the static point-to-multipoint flooding LSP. If you configure dynamic point-to-multipoint LSPs, whenever VPLS discovers a new neighbor through BGP, a sub-LSP for this neighbor is added to the point-to-multipoint LSP for the routing instance.

This feature can be enabled incrementally on any PE router that is part of a specific VPLS routing instance. The PE routers can then use point-to-multipoint LSPs to flood traffic, whereas other PE routers in the same VPLS routing instance can still use ingress replication to flood traffic. However, when this feature is enabled on any PE router, you must ensure that all PE routers in the VPLS routing instance that participate in the flooding of traffic over point-to-multipoint LSPs are upgraded to Junos OS Release 8.3 or later to support this feature.

To flood unknown unicast, broadcast, and multicast traffic using point-to-multipoint LSPs, configure the **rsvp-te** statement as follows:

```
rsvp-te {
 label-switched-path-template (Multicast) {
 (default-template | lsp-template-name);
 }
 static-lsp lsp-name;
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instance *routing-instance-name* provider-tunnel]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel]

You can configure either a static point-to-multipoint LSP for VPLS flooding or a dynamic point-to-multipoint LSP.

**NOTE:** You cannot specify both the **static** and **label-switched-path-template** statements at the same time.

The following sections describe how to configure static and dynamic point-to-multipoint LSPs for flooding unknown traffic in a VPLS routing instance:

- [Configuring Static Point-to-Multipoint Flooding LSPs on page 1475](#)
- [Configuring Dynamic Point-to-Multipoint Flooding LSPs on page 1476](#)

## Configuring Static Point-to-Multipoint Flooding LSPs

The **static-lsp** option creates a static flooding point-to-multipoint LSP that includes all of the neighbors in the VPLS routing instance. Flood traffic is sent to all of the VPLS neighbors using the generated point-to-multipoint LSP. VPLS neighbors added to the routing instance later are not automatically added to the point-to-multipoint LSP. You will need to manually add the new VPLS neighbors to the static point-to-multipoint flooding LSP. By configuring static point-to-multipoint LSPs for flooding, you have more control over which path each sub-LSP follows.

To configure a static flooding point-to-multipoint LSP, specify the name of the static flooding point-to-multipoint LSP by including the **static-lsp** statement:

```
static-lsp lsp-name;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* provider-tunnel rsvp-te]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel rsvp-te]

## Configuring Dynamic Point-to-Multipoint Flooding LSPs

To configure a dynamic point-to-multipoint flooding LSP, include the **label-switched-path-template** statement option at the [edit routing-instances *routing-instance-name* provider-tunnel rsvp-te] hierarchy level:

```
[edit routing-instances routing-instance-name provider-tunnel rsvp-te]
label-switched-path-template (Multicast) {
 (default-template | lsp-template-name);
}
```

You can automatically generate the point-to-multipoint LSP to be used for flooding unknown traffic or you can manually configure the point-to-multipoint LSP:

- [Configuring Dynamic Point-to-Multipoint Flooding LSPs with the Default Template on page 1476](#)
- [Configuring Dynamic Point-to-Multipoint Flooding LSPs with a Preconfigured Template on page 1477](#)

### Configuring Dynamic Point-to-Multipoint Flooding LSPs with the Default Template

The **default-template** option, specified at the [edit routing-instances *routing-instance-name* provider-tunnel rsvp-te label-switched-path-template] hierarchy level, causes the point-to-multipoint LSPs to be created with default parameters. The default parameters are for a minimally configured point-to-multipoint LSP. The name of this point-to-multipoint LSP is also generated automatically and is based on the following model:

***id:vp1s:router-id:routing-instance-name***

The following **show** command output for **show mpls lsp p2mp ingress** illustrates how a point-to-multipoint flood LSP name could appear if you configure the **label-switched-path-template** statement with the **default-template** option:

```
user@host> show mpls lsp p2mp ingress
Ingress LSP: 2 sessions P2MP name: static, P2MP branch count: 3
To From State Rt ActivePath P LSPname
10.255.14.181 10.255.14.172 Up 0
10.255.14.177 10.255.14.172 Up 0 path2 * vpn02-vpn11
10.255.14.174 10.255.14.172 Up 0 path3 * vpn02-vpn07
10.255.14.174 10.255.14.172 Up 0 path3 * vpn02-vpn04
P2MP name: 9:vp1s:10.255.14.172:green, P2MP branch count: 2
To From State Rt ActivePath P LSPname
10.255.14.177 10.255.14.172 Up 0 * LSPname
```

```

11:vp1s:10.255.14.172:green
10.255.14.174 10.255.14.172 Up 0 *
10:vp1s:10.255.14.172:green
Total 5 displayed, Up 5, Down 0

```

The dynamically generated point-to-multipoint LSP name is **9:vp1s:10.255.14.172:green**.

### Configuring Dynamic Point-to-Multipoint Flooding LSPs with a Preconfigured Template

You can configure a point-to-multipoint flooding LSP template for the VPLS routing instance. The template allows you to specify the properties of the dynamic point-to-multipoint LSPs that are used to flood traffic for the VPLS routing instance. You can specify all of the standard options available for a point-to-multipoint LSP within this template. These properties are inherited by the dynamic point-to-multipoint flood LSPs.

To configure a point-to-multipoint LSP template for flooding VPLS traffic, specify all of the properties you want to include in a point-to-multipoint LSP configuration. To specify this LSP as a point-to-multipoint flooding template, include the **p2mp** and **template** statements:

```

p2mp;
template;

```

You can include these statements at the following hierarchy levels:

- [edit protocols mpls label-switched-path *p2mp-lsp-template-name*]
- [edit logical-systems *logical-system-name* protocols mpls label-switched-path *p2mp-lsp-template-name*]

For more information about how to configure the **p2mp** statement and point-to-multipoint LSPs, see the *MPLS Applications Feature Guide*.

Once you have configured the point-to-multipoint LSP template, specify the name of the point-to-multipoint LSP template with the **label-switched-path-template** statement:

```

label-switched-path-template (Multicast) p2mp-lsp-template-name;

```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* provider-tunnel rsvp-te]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* provider-tunnel rsvp-te]

### Example: Configuring Ingress Replication for IP Multicast Using MBGP MVPNs

- [Requirements on page 1478](#)
- [Overview on page 1478](#)
- [Configuration on page 1479](#)
- [Verification on page 1484](#)

## Requirements

The routers used in this example are Juniper Networks M Series Multiservice Edge Routers, T Series Core Routers, or MX Series 3D Universal Edge Routers. When using ingress replication for IP multicast, each participating router must be configured with BGP for control plane procedures and with ingress replication for the data provider tunnel, which forms a full mesh of MPLS point-to-point LSPs. The ingress replication tunnel can be selective or inclusive, depending on the configuration of the provider tunnel in the routing instance.

## Overview

The **ingress-replication** provider tunnel type uses unicast tunnels between routers to create a multicast distribution tree.

The **mpls-internet-multicast** routing instance type uses ingress replication provider tunnels to carry IP multicast data between routers through an MPLS cloud, using MBGP (or Next Gen) MVPN. Ingress replication can also be configured when using MVPN to carry multicast data between PE routers.

The **mpls-internet-multicast** routing instance is a non-forwarding instance used only for control plane procedures. It does not support any interface configurations. Only one **mpls-internet-multicast** routing instance can be defined for a logical system. All multicast and unicast routes used for IP multicast are associated only with the default routing instance (**inet.0**), not with a configured routing instance. The **mpls-internet-multicast** routing instance type is configured for the default master instance on each router, and is also included at the **[edit protocols pim]** hierarchy level in the default instance.

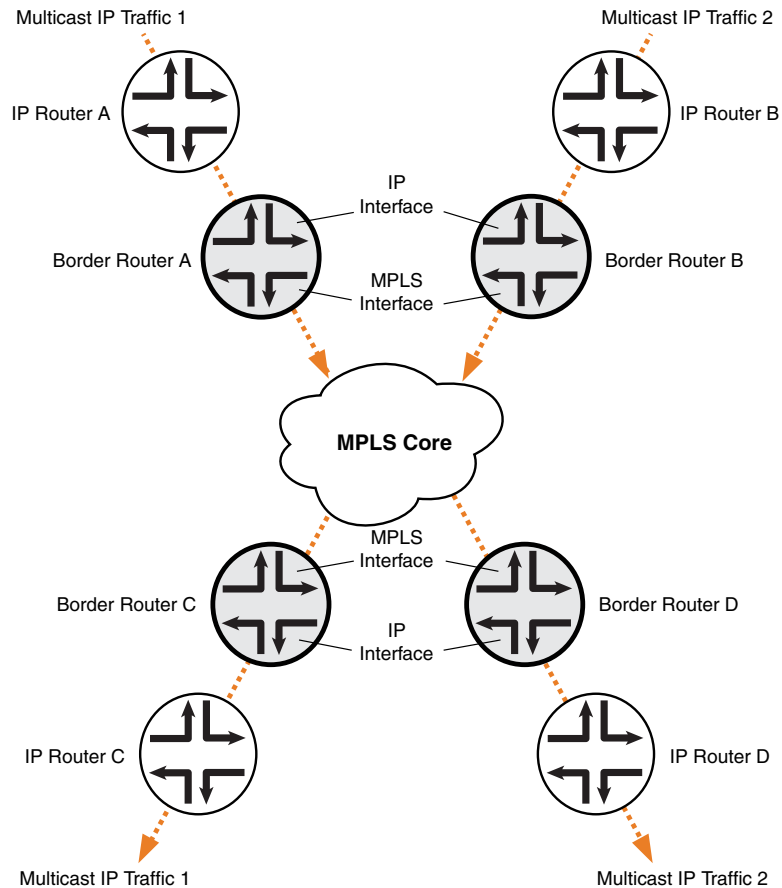

For each **mpls-internet-multicast** routing instance, the **ingress-replication** statement is required under the **provider-tunnel** statement and also under the **[edit routing-instances routing-instance-name provider-tunnel selective group source]** hierarchy level.

When a new destination needs to be added to the ingress replication provider tunnel, the resulting behavior differs depending on how the ingress replication provider tunnel is configured:

- **create-new-ucast-tunnel**—When this statement is configured, a new unicast tunnel to the destination is created, and is deleted when the destination is no longer needed. Use this mode for RSVP LSPs using ingress replication.
- **label-switched-path-template (Multicast)**—When this statement is configured, an LSP template is used for the point-to-multipoint LSP for ingress replication.

The IP topology consists of routers on the edge of the IP multicast domain. Each router has a set of IP interfaces configured toward the MPLS cloud and a set of interfaces configured toward the IP routers. See [Figure 147 on page 1479](#). Internet multicast traffic is carried between the IP routers, through the MPLS cloud, using ingress replication tunnels for the data plane and a full-mesh IBGP session for the control plane.

Figure 147: Internet Multicast Topology

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

#### Border Router C

```
set protocols mpls ipv6-tunneling
set protocols mpls interface all
set protocols bgp group ibgp type internal
set protocols bgp group ibgp local-address 10.255.10.61
set protocols bgp group ibgp family inet unicast
set protocols bgp group ibgp family inet-vpn any
set protocols bgp group ibgp family inet6 unicast
set protocols bgp group ibgp family inet6-vpn any
set protocols bgp group ibgp family inet-mvpn signaling
set protocols bgp group ibgp family inet6-mvpn signaling
set protocols bgp group ibgp export to-bgp
set protocols bgp group ibgp neighbor 10.255.10.97
set protocols bgp group ibgp neighbor 10.255.10.55
```

```
set protocols bgp group ibgp neighbor 10.255.10.57
set protocols bgp group ibgp neighbor 10.255.10.59
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface fxp0.0 disable
set protocols ospf area 0.0.0.0 interface lo0.0
set protocols ospf area 0.0.0.0 interface so-1/3/1.0
set protocols ospf area 0.0.0.0 interface so-0/3/0.0
set protocols ospf3 area 0.0.0.0 interface lo0.0
set protocols ospf3 area 0.0.0.0 interface so-1/3/1.0
set protocols ospf3 area 0.0.0.0 interface so-0/3/0.0
set protocols ldp interface all
set protocols pim rp static address 192.0.2.2
set protocols pim rp static address 2::192.0.2.2
set protocols pim interface fe-0/1/0.0
set protocols pim mpls-internet-multicast
set routing-instances test instance-type mpls-internet-multicast
set routing-instances test provider-tunnel ingress-replication label-switched-path
set routing-instances test protocols mvpn
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

The following example shows how to configure ingress replication on an IP multicast instance with the routing instance type **mpls-internet-multicast**. Additionally, this example shows how to configure a selective provider tunnel that selects a new unicast tunnel each time a new destination needs to be added to the multicast distribution tree.

This example shows the configuration of the link between Border Router C and edge IP Router C, from which Border Router C receives PIM join messages.

1. Enable MPLS.

```
[edit protocols mpls]
user@Border_Router_C# set ipv6-tunneling
user@Border_Router_C# set interface all
```

2. Configure a signaling protocol, such as RSVP or LDP.

```
[edit protocols ldp]
user@Border_Router_C# set interface all
```

3. Configure a full-mesh of IBGP peering sessions.

```
[edit protocols bgp group ibgp]
user@Border_Router_C# set type internal
user@Border_Router_C# set local-address 10.255.10.61
user@Border_Router_C# set neighbor 10.255.10.97
user@Border_Router_C# set neighbor 10.255.10.55
user@Border_Router_C# set neighbor 10.255.10.57
user@Border_Router_C# set neighbor 10.255.10.59
user@Border_Router_C# set export to-bgp
```

4. Configure the multiprotocol BGP-related settings so that the BGP sessions carry the necessary NLRI.

```
[edit protocols bgp group ibgp]
user@Border_Router_C# set family inet unicast
user@Border_Router_C# set family inet-vpn any
user@Border_Router_C# set family inet6 unicast
user@Border_Router_C# set family inet6-vpn any
user@Border_Router_C# set family inet-mvpn signaling
user@Border_Router_C# set family inet6-mvpn signaling
```

5. Configure an interior gateway protocol (IGP).

This example shows a dual stacking configuration with OSPF and OSPF version 3 configured on the interfaces.

```
[edit protocols ospf3]
user@Border_Router_C# set area 0.0.0.0 interface lo0.0
user@Border_Router_C# set area 0.0.0.0 interface so-1/3/1.0
user@Border_Router_C# set area 0.0.0.0 interface so-0/3/0.0
```

```
[edit protocols ospf]
user@Border_Router_C# set traffic-engineering
user@Border_Router_C# set area 0.0.0.0 interface fxp0.0 disable
user@Border_Router_C# set area 0.0.0.0 interface lo0.0
user@Border_Router_C# set area 0.0.0.0 interface so-1/3/1.0
user@Border_Router_C# set area 0.0.0.0 interface so-0/3/0.0
```

6. Configure a global PIM instance on the interface facing the edge device.

PIM is not configured in the core.

```
[edit protocols pim]
user@Border_Router_C# set rp static address 192.0.2.2
user@Border_Router_C# set rp static address 2::192.0.2.2
user@Border_Router_C# set interface fe-0/1/0.0
user@Border_Router_C# set mpls-internet-multicast
```

7. Configure the ingress replication provider tunnel to create a new unicast tunnel each time a destination needs to be added to the multicast distribution tree.

```
[edit routing-instances test]
user@Border_Router_C# set instance-type mpls-internet-multicast
user@Border_Router_C# set provider-tunnel ingress-replication label-switched-path
user@Border_Router_C# set protocols mvpn
```

**NOTE:** Alternatively, use the `label-switched-path-template` statement to configure a point-to-point LSP for the ingress tunnel.

Configure the point-to-point LSP to use the default template settings (this is needed only when using RSVP tunnels). For example:

```
[edit routing-instances test provider-tunnel]
user@Border_Router_C# set ingress-replication label-switched-path
label-switched-path-template default-template
user@Border_Router_C# set selective group 203.0.113.0/24 source
192.168.195.145/32 ingress-replication label-switched-path
```

8. Commit the configuration.

```
user@Border_Router_C# commit
```

**Results** From configuration mode, confirm your configuration by issuing the **show protocols** and **show routing-instances** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@Border_Router_C# show protocols
mpls {

### Checking the Ingress Replication Status on Border Router C

**Purpose** Use the `show ingress-replication mvpn` command to check the ingress replication status.

**Action** `user@Border_Router_C> show ingress-replication mvpn`

```
Ingress Tunnel: mvpn:1
Application: MVPN
Unicast tunnels
 Leaf Address Tunnel-type Mode State
 10.255.10.61 P2P LSP Existing Up
```

**Meaning** The ingress replication is using a point-to-point LSP, and is in the Up state.

---

### Checking the Routing Table for the MVPN Routing Instance on Border Router C

**Purpose** Use the `show route table` command to check the route status.

**Action** user@Border\_Router\_C> show route table test.mvpn

```
test.mvpn.0: 5 destinations, 7 routes (5 active, 1 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

1:0:0:10.255.10.61/240
 *[BGP/170] 00:45:55, localpref 100, from 10.255.10.61
 AS path: I, validation-state: unverified
 > via so-2/0/1.0
1:0:0:10.255.10.97/240
 *[MVPN/70] 00:47:19, metric2 1

## Mapping VPLS Traffic to Specific LSPs

---

You can map VPLS traffic to specific LSPs by configuring forwarding table policies. This procedure is optional but can be useful. The following example illustrates how you can map lower priority VPLS routing instances to slower LSPs while mapping other higher priority VPLS routing instances to faster LSPs. In this example configuration, **a-to-b1** and **a-to-c1** are high-priority LSPs between the PE routers, while **a-to-b2** and **a-to-c2** are low-priority LSPs between the PE routers.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

To map VPLS traffic, include the **policy-statement vpls-priority** statement:

```
policy-statement vpls-priority {
 term a {
 from {
 rib mpls.0;
 community company-1;
 }
 then {
 install-nexthop lsp [a-to-b1 a-to-c1];
 accept;
 }
 }
 term b {
 from {
 rib mpls.0;
 community company-2;
 }
 then {
 install-nexthop lsp-regex ["^a-to-b2$" "^a-to-c2$"];
 accept;
 }
 }
}
community company-1 members target:11111:1;
community company-2 members target:11111:2;
```

You can include the **policy-statement vpls-priority** statement at the following hierarchy levels:

- **[edit policy-options]**
- **[edit logical-systems *logical-system-name* policy-options]**

Include the **export** statement to apply the **vpls-priority** policy to the forwarding table:

```
export vpls-priority;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-options forwarding-table]**
- **[edit logical-systems *logical-system-name* routing-options forwarding-table]**

For more information about how to configure routing policies, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

# Configuring Inter-AS VPLS and IRB VPLS

- [Example: Configuring Inter-AS VPLS with MAC Processing at the ASBR on page 1495](#)
- [Configuring VPLS and Integrated Routing and Bridging on page 1521](#)
- [Configuring Integrated Routing and Bridging in a VPLS Instance \(MX Series Routers Only\) on page 1523](#)

## Example: Configuring Inter-AS VPLS with MAC Processing at the ASBR

---

This example describes how to configure inter-AS Virtual Private LAN Service (VPLS) with MAC processing between BGP-signaled VPLS and LDP-signaled VPLS. This feature is described in RFC 4761 as multi-AS VPLS option E or method E.

This example is organized in the following sections:

- [Requirements on page 1495](#)
- [Overview and Topology on page 1495](#)
- [Configuration on page 1497](#)

### Requirements

To support inter-AS VPLS between BGP-signaled VPLS and LDP-signaled VPLS, your network must meet the following hardware and software requirements:

- MX Series or M320 routers for the ASBRs.
- Junos OS Release 9.3 or higher.
- Gigabit Ethernet or 10-Gigabit Ethernet interfaces.

### Overview and Topology

VPLS is a key enabler for delivering multipoint Ethernet service. Major service providers have implemented IP and MPLS backbones and offer VPLS services to large enterprises. Growing demand requires the VPLS network to scale to support many VPLS customers with multiple sites spread across geographically dispersed regions. BGP-signaled VPLS signaling offers scaling advantages over LDP-signaled VPLS. In some environments there is a need for BGP-signaled VPLS to interoperate with existing LDP-signaled VPLS.

This example shows one way to configure BGP-signaled VPLS interworking with an existing LDP-signaled VPLS network.

The advantages of the configuration are:

- You can interconnect customer sites that are spread across different autonomous systems (ASs).
- LDP-signaled VPLS and BGP-signaled VPLS interworking is supported.
- Because the ASBR supports MAC operations, customer sites can be connected directly to the ASBR.
- The inter-AS link is not restricted to Ethernet interfaces.
- Additional configuration for multihoming is relatively straightforward.

Traffic from the interworking virtual private LAN services is switched at the ASBR. The ASBR does all the data plane operations: flooding, MAC learning, aging, and MAC forwarding for each AS to switch traffic among any customer facing interfaces and between the fully meshed pseudowires in the AS. A single pseudowire is created between the ASBRs across the inter-AS link and the ASBRs forward traffic from the pseudowires in each AS to the peer ASBR.

Each ASBR performs VPLS operations within its own AS and performs VPLS operations with the ASBR in the other AS. The ASBR treats the other AS as a BGP-signaled VPLS site. To establish VPLS pseudowires, VPLS NLRI messages are exchanged across the EBGP sessions on the inter-AS links between the ASBRs.

The sample metro network is configured for LDP-signaled VPLS. The core network is configured for BGP-signaled VPLS.

The first part of the example shows the basic configuration steps to configure the logical interfaces, OSPF, internal BGP, LDP, and MPLS. This part of the configuration is the same as other VPLS configurations for LDP-signaled VPLS and BGP-signaled VPLS.

The unique part of the example is configured in the VPLS routing instances, external BGP, and the policy that populates the BGP route table with routes learned from direct routes and OSPF routes. Additional details about the configuration statements are included in the step-by-step procedure.

[Figure 148 on page 1497](#) shows the topology used in this example.

Figure 148: Inter-AS VPLS with MAC Operations Example Topology

## Configuration

To configure inter-AS VPLS between BGP-signaled VPLS and LDP-signaled VPLS, perform these tasks.

**NOTE:** In any configuration session it is a good practice to periodically use the `commit check` command to verify that the configuration can be committed.

- [Configuring OSPF on page 1499](#)
- [Configuring the Internal BGP Peer Group on page 1500](#)
- [Configuring LDP on page 1502](#)
- [Configuring MPLS on page 1503](#)
- [Configuring the External BGP Peer Group Between the Loopback Interfaces on page 1503](#)
- [Configuring the External BGP Peer Group Between the Inter-AS Link Interfaces on page 1504](#)
- [Configuring the VPLS Routing Instances on page 1508](#)
- [Results on page 1512](#)

### Configuring Interfaces

#### Step-by-Step Procedure

To configure interfaces:

1. On each router, configure an IP address on the loopback logical interface 0 (lo0.0):
 

```
user@CE1# set interfaces lo0 unit 0 family inet address 192.168.1.1/32 primary
```

```
user@PE1# set interfaces lo0 unit 0 family inet address 192.168.2.1/32 primary
```

```
user@ASBR1# set interfaces lo0 unit 0 family inet address 192.168.3.1/32 primary
```

```
user@ASBR2# set interfaces lo0 unit 0 family inet address 192.168.10.1/32 primary
```

```
user@PE2# set interfaces lo0 unit 0 family inet address 192.168.11.1/32 primary
```

```
user@CE2# set interfaces lo0 unit 0 family inet address 192.168.12.1/32 primary
```

2. On each router, commit the configuration:

```
user@host> commit check
```

```
configuration check succeeds
```

```
user@host> commit
```

```
commit complete
```

3. On each router, display the interface information for **lo0** and verify that the correct IP address is configured:

```
user@host> show interfaces lo0
```

```
Physical interface: lo0, Enabled, Physical link is Up
```

```
Interface index: 6, SNMP ifIndex: 6
```

```
Type: Loopback, MTU: Unlimited
```

```
Device flags : Present Running Loopback
```

```
Interface flags: SNMP-Traps
```

```
Link flags : None
```

```
Last flapped : Never
```

```
Input packets : 0
```

```
Output packets: 0
```

```
Logical interface lo0.0 (Index 75) (SNMP ifIndex 16)
```

```
Flags: SNMP-Traps Encapsulation: Unspecified
```

```
Input packets : 0
```

```
Output packets: 0
```

```
Protocol inet, MTU: Unlimited
```

```
Flags: None
```

```
Addresses
```

```
Local: 127.0.0.1
```

```
Addresses, Flags: Primary Is-Default Is-Primary
```

```
Local: 192.168.3.1
```

```
Logical interface lo0.16384 (Index 64) (SNMP ifIndex 21)
```

```
Flags: SNMP-Traps Encapsulation: Unspecified
```

```
Input packets : 0
```

```
Output packets: 0
```

```
Protocol inet, MTU: Unlimited
```

```
Flags: None
```

```
Addresses
```

```
Local: 127.0.0.1
```

```
Logical interface lo0.16385 (Index 65) (SNMP ifIndex 22)
```

```
Flags: SNMP-Traps Encapsulation: Unspecified
```

```
Input packets : 0
```

```
Output packets: 0
```

```
Protocol inet, MTU: Unlimited
```

```
Flags: None
```

In the example above notice that the primary **lo0** local address for the **inet** protocol family on Router ASBR1 is **192:168:3:1**.

4. On each router, configure an IP address and protocol family on the Gigabit Ethernet interfaces. Specify the **inet** protocol family.

```
user@CE1# set interfaces ge-0/3/0 unit 0 family inet address 10.10.11.1/24
```

```
user@PE1# set interfaces ge-1/3/1 unit 0 family inet address 10.0.23.9/30
```

```
user@ASBR1# set interfaces ge-0/3/1 unit 0 family inet address 10.0.23.10/30
```

```
user@ASBR1# set interfaces ge-0/3/0 unit 0 family inet address 10.0.78.1/30
```

```
user@ASBR2# set interfaces ge-3/1/0 unit 0 family inet address 10.0.78.2/30
```

```
user@ASBR2# set interfaces ge-3/1/1 unit 0 family inet address 10.0.90.13/30
```

```
user@PE2# set interfaces ge-0/1/0 unit 0 family inet address 10.0.90.14/30
```

```
user@CE2# set interfaces ge-0/1/1 unit 0 family inet address 10.10.11.2/24
```

5. On each router, commit the configuration:

```
user@host> commit check
```

```
configuration check succeeds
```

```
user@host> commit
```

```
commit complete
```

6. Display information for Gigabit Ethernet interfaces and verify that the IP address and protocol family are configured correctly.

```
user@ASBR2> show interfaces ge-* terse
```

| Interface  | Admin | Link | Proto | Local         | Remote |
|------------|-------|------|-------|---------------|--------|
| ge-3/1/0   | up    | up   |       |               |        |

| ge-3/1/1.0 | up    | up   | inet  | 10.0.90.13/30 |        |
|            |       |      |       | multiservice  |        |
| ge-3/1/2   | up    | down |       |               |        |
| ge-3/1/3   | up    | down |       |               |        |

## Configuring OSPF

### Step-by-Step Procedure

To configure OSPF:

1. On the PE and ASBR routers, configure the provider instance of OSPF. Configure OSPF traffic engineering support. Specify area 0.0.0.1 in the LDP-signaled VPLS network and area 0.0.0.0 in the BGP-signaled network. Specify the Gigabit Ethernet

logical interfaces between the PE and ASBR routers. Specify **lo0.0** as a passive interface.

```
user@PE1# set protocols ospf traffic-engineering
user@PE1# set protocols ospf area 0.0.0.1 interface ge-1/3/1.0
user@PE1# set protocols ospf area 0.0.0.1 interface lo0.0 passive
```

```
user@ASBR1# set protocols ospf traffic-engineering
user@ASBR1# set protocols ospf area 0.0.0.1 interface ge-0/3/1.0
user@ASBR1# set protocols ospf area 0.0.0.1 interface lo0.0 passive
```

```
user@ASBR2# set protocols ospf traffic-engineering
user@ASBR2# set protocols ospf area 0.0.0.0 interface ge-3/1/1.0
user@ASBR2# set protocols ospf area 0.0.0.0 interface lo0.0 passive
```

```
user@PE2# set protocols ospf traffic-engineering
user@PE2# set protocols ospf area 0.0.0.0 interface ge-0/1/0.0
user@PE2# set protocols ospf area 0.0.0.0 interface lo0.0 passive
```

2. On each router, commit the configuration:

```
user@host> commit check

configuration check succeeds

user@host> commit

commit complete
```

3. Display OSPF neighbor information and verify that the PE routers form adjacencies with the ASBR router in the same area. Verify that the neighbor state is **Full**.

```
user@host> show ospf neighbor
```

| Address    | Interface  | State | ID          | Pri | Dead |
|------------|------------|-------|-------------|-----|------|
| 10.0.23.10 | ge-1/3/1.0 | Full  | 192.168.3.1 | 128 | 31   |

### Configuring the Internal BGP Peer Group

#### Step-by-Step Procedure

The purpose of configuring an internal BGP peer group is to create a full mesh of BGP LSPs among the PE routers in the BGP-signaled AS, including the ASBR routers.

To configure the internal BGP peer group:

1. The purpose of this step is to create a full mesh of IBGP peers between the PE routers, including the ASBR routers, within the BGP-signaled AS.

On Router ASBR2, configure internal BGP. Specify the BGP type as **internal**. Specify the local address as the local **lo0** IP address.

Specify the **inet** protocol family. Specify the **labeled-unicast** statement and the **resolve-vpn** option. The **labeled-unicast** statement causes the router to advertise labeled routes out of the IPv4 inet.0 route table and places labeled routes into the inet.0 route table. The **resolve-vpn** option puts labeled routes in the MPLS inet.3

route table The inet.3 route table is used to resolve routes for the PE router located in the other AS.

Specify the **l2vpn** family to indicate to the router that this is a VPLS. Specify the **signaling** option to configure BGP as the signaling protocol. This enables BGP to carry Layer 2 VPLS NLRI messages for this peer group.

Specify the **lo0** interface IP address of the PE as the neighbor. Configure an autonomous system identifier.

```
user@ASBR2# set protocols bgp group core-ibgp type internal
user@ASBR2# set protocols bgp group core-ibgp local-address 192.168.10.1
user@ASBR2# set protocols bgp group core-ibgp family inet labeled-unicast
resolve-vpn
user@ASBR2# set protocols bgp group core-ibgp family l2vpn signaling
user@ASBR2# set protocols bgp group core-ibgp neighbor 192.168.11.1
user@ASBR2# set routing-options autonomous-system 0.65020
```

2. On Router PE2, configure internal BGP. Specify the BGP type as **internal**. Specify the local address as the local **lo0** IP address.

Specify the **l2vpn** family to indicate this is a VPLS. Specify the **signaling** option to configure BGP as the signaling protocol. This enables BGP to carry Layer 2 VPLS NLRI messages.

Specify the **lo0** interface IP address of Router ASBR2 as the neighbor. Configure an autonomous system identifier.

```
user@PE2# set protocols bgp group core-ibgp type internal
user@PE2# set protocols bgp group core-ibgp local-address 192.168.11.1
user@PE2# set protocols bgp group core-ibgp family l2vpn signaling
user@PE2# set protocols bgp group core-ibgp neighbor 192.168.10.1
user@PE2# set routing-options autonomous-system 0.65020
```

3. On each router, commit the configuration:

```
user@host> commit check

configuration check succeeds

user@host> commit

commit complete
```

4. On Router PE2 and Router ASBR2, display BGP neighbor information and verify that the peer connection state is **Established**.

```
user@ASBR2> show bgp neighbor
Peer: 192.168.11.1+49443 AS 65020 Local: 192.168.10.1+179 AS 65020
Type: Internal State: Established Flags: ImportEval Sync
Last State: OpenConfirm Last Event: RecvKeepAlive
Last Error: None
Options: Preference LocalAddress AddressFamily Rib-group Refresh
Address families configured: l2vpn-signaling inet-labeled-unicast
Local Address: 192.168.10.1 Holdtime: 90 Preference: 170
Number of flaps: 0
```

```

Peer ID: 192.168.11.1 Local ID: 192.168.10.1 Active Holdtime: 90
Keepalive Interval: 30 Peer index: 0

```

...

## Configuring LDP

### Step-by-Step Procedure

To configure LDP:

1. On the PE and ASBR routers, configure LDP with the Gigabit Ethernet interfaces between the PE and ASBR routers, and between the two ASBR routers. To support LDP-signaled VPLS, additionally configure LDP with the **lo0.0** interface on Router PE1 and Router ASBR1:

```

user@PE1# set protocols ldp interface ge-1/3/1.0
user@PE1# set protocols ldp interface lo0.0

```

```

user@ASBR1# set protocols ldp interface ge-0/3/1.0
user@ASBR1# set protocols ldp interface ge-0/3/0.0
user@ASBR1# set protocols ldp interface lo0.0

```

```

user@ASBR2# set protocols ldp interface ge-3/1/0.0
user@ASBR2# set protocols ldp interface ge-3/1/1.0

```

```

user@PE2# set protocols ldp interface ge-0/1/0.0

```

**NOTE:** The configuration of LDP signaling between the ASBR routers is not required for Inter-AS VPLS. It is included here for reference only and might be used in LDP environments.

2. On each router, commit the configuration:

```

user@host> commit check

configuration check succeeds

user@host> commit

commit complete

```

3. Display LDP configuration information and verify that the correct interfaces are configured. LDP operation can be verified after MPLS is configured.

```

user@ASBR1> show configuration protocols ldp
interface ge-0/3/0.0;
interface ge-0/3/1.0;
interface lo0.0;

```

The preceding example is from ASBR1.

## Configuring MPLS

### Step-by-Step Procedure

To configure MPLS:

1. On the PE and ASBR routers, configure MPLS. Enable MPLS on the logical interfaces. Add the Gigabit Ethernet interfaces to the MPLS protocol. This adds entries to the MPLS forwarding table.

```
user@PE1# set protocols mpls interface ge-1/3/1.0
user@PE1# set interfaces ge-1/3/1 unit 0 family mpls
```

```
user@ASBR1# set protocols mpls interface ge-0/3/1.0
user@ASBR1# set protocols mpls interface ge-0/3/0.0
user@ASBR1# set interfaces ge-0/3/1 unit 0 family mpls
user@ASBR1# set interfaces ge-0/3/0 unit 0 family mpls
```

```
user@ASBR2# set protocols mpls interface ge-3/1/0.0
user@ASBR2# set protocols mpls interface ge-3/1/1.0
user@ASBR2# set interfaces ge-3/1/0 unit 0 family mpls
user@ASBR2# set interfaces ge-3/1/1 unit 0 family mpls
```

```
user@PE2# set protocols mpls interface ge-0/1/0.0
user@PE2# set interfaces ge-0/1/0 unit 0 family mpls
```

2. On each router, commit the configuration:

```
user@host> commit check

configuration check succeeds

user@host> commit

commit complete
```

3. On the PE and ASBR routers, display LDP neighbor information and verify that the directly connected LDP neighbors are listed:

```
user@ASBR1> show ldp neighbor
```

| Address     | Interface  | Label space ID | Hold time |
|-------------|------------|----------------|-----------|
| 192.168.2.1 | lo0.0      | 192.168.2.1:0  | 44        |
| 10.0.78.2   | ge-0/3/0.0 | 192.168.10.1:0 | 13        |
| 10.0.23.9   | ge-0/3/1.0 | 192.168.2.1:0  | 11        |

The preceding example is from ASBR1.

## Configuring the External BGP Peer Group Between the Loopback Interfaces

### Step-by-Step Procedure

To configure the external BGP (EBGP) peer group between the loopback interfaces:

1. On Router ASBR1 and Router PE1, configure an autonomous system identifier:

```
user@PE1# set routing-options autonomous-system 0.65010
```

```
user@ASBR1# set routing-options autonomous-system 0.65010
```

2. On Router ASBR1, configure an external BGP peer group for the loopback interfaces. Specify the **external** BGP group type. Include the **multihop** statement. Specify the local address as the local **lo0** IP address. Configure the **l2vpn** family for BGP signaling. Configure the peer AS as the core AS number. Specify the **lo0** IP address of Router ASBR2 as the neighbor.

```
user@ASBR1# set protocols bgp group vpls-core type external
user@ASBR1# set protocols bgp group vpls-core multihop
user@ASBR1# set protocols bgp group vpls-core local-address 192.168.3.1
user@ASBR1# set protocols bgp group vpls-core family l2vpn signaling
user@ASBR1# set protocols bgp group vpls-core peer-as 65020
user@ASBR1# set protocols bgp group vpls-core neighbor 192.168.10.1
```

3. On Router ASBR2, configure an external BGP peer group for the loopback interfaces. Specify the **external** BGP group type. Include the **multihop** statement. The **multihop** statement is needed because the EBGP neighbors are in different ASs. Specify the local address as the local **lo0** IP address. Configure the **l2vpn** family for BGP signaling. Configure the peer AS as the metro AS number. Specify the **lo0** IP address of Router ASBR1 as the neighbor.

```
user@ASBR2# set protocols bgp group vpls-metro type external
user@ASBR2# set protocols bgp group vpls-metro multihop
user@ASBR2# set protocols bgp group vpls-metro local-address 192.168.10.1
user@ASBR2# set protocols bgp group vpls-metro family l2vpn signaling
user@ASBR2# set protocols bgp group vpls-metro peer-as 65010
user@ASBR2# set protocols bgp group vpls-metro neighbor 192.168.3.1
```

4. On each router, commit the configuration:

```
user@host> commit
```

### Configuring the External BGP Peer Group Between the Inter-AS Link Interfaces

#### Step-by-Step Procedure

The purpose of configuring external BGP peer groups between the inter-AS link interfaces is to create a full mesh of BGP LSPs among the ASBR routers. To configure the external BGP peer group between the inter-AS link interfaces:

1. On Router ASBR1, configure a policy to export OSPF and direct routes, including the **lo0** address of the PE routers, into BGP for the establishment of label-switched paths (LSPs):

```
user@ASBR1# set policy-options policy-statement loopback term term1 from
protocol ospf
user@ASBR1# set policy-options policy-statement loopback term term1 from
protocol direct
user@ASBR1# set policy-options policy-statement loopback term term1 from
route-filter 192.168.0.0/16 longer
user@ASBR1# set policy-options policy-statement loopback term term1 then accept
```

2. On Router ASBR1, configure an external BGP peer group for the inter-AS link. Specify the **external** BGP group type. Specify the local inter-AS link IP address as the local address. Configure the **inet** family and include the **labeled-unicast** and **resolve-vpn** statements. The **labeled-unicast** statement advertises labeled routes out of the IPv4 inet.0 route table and places labeled routes into the inet.0 route table. The **resolve-vpn** option stores labeled routes in the MPLS **inet.3** route table.

Include the **export** statement and specify the policy you created. Configure the peer AS as the core AS number. Specify the inter-AS link IP address of Router ASBR2 as the neighbor.

```
user@ASBR1# set protocols bgp group metro-core type external
user@ASBR1# set protocols bgp group metro-core local-address 10.0.78.1
user@ASBR1# set protocols bgp group metro-core family inet labeled-unicast
resolve-vpn
user@ASBR1# set protocols bgp group metro-core export loopback
user@ASBR1# set protocols bgp group metro-core peer-as 65020
user@ASBR1# set protocols bgp group metro-core neighbor 10.0.78.2
```

3. On Router ASBR2, configure a policy to export OSPF and direct routes, including the **lo0** address, into BGP for the establishment of LSPs:

```
user@ASBR2# set policy-options policy-statement loopback term term1 from
protocol ospf
user@ASBR2# set policy-options policy-statement loopback term term1 from
protocol direct
user@ASBR2# set policy-options policy-statement loopback term term1 from
route-filter 192.168.0.0/16 longer
user@ASBR2# set policy-options policy-statement loopback term term1 then accept
```

4. On Router ASBR2, configure an external BGP peer group for the inter-AS link. Specify the **external** BGP group type. Specify the local inter-AS link IP address as the local address. Configure the **inet** family and include the **labeled-unicast** and **resolve-vpn** statements. Include the **export** statement and specify the policy you created. Configure the peer AS as the core AS number. Specify the inter-AS link IP address of Router ASBR1 as the neighbor.

```
user@ASBR2# set protocols bgp group core-metro type external
user@ASBR2# set protocols bgp group core-metro local-address 10.0.78.2
user@ASBR2# set protocols bgp group core-metro family inet labeled-unicast
resolve-vpn
user@ASBR2# set protocols bgp group core-metro export loopback
user@ASBR2# set protocols bgp group core-metro peer-as 65010
user@ASBR2# set protocols bgp group core-metro neighbor 10.0.78.1
```

5. On each router, commit the configuration:

```
user@host> commit check

configuration check succeeds

user@host> commit

commit complete
```

6. On Router ASBR1, display the BGP neighbors. Verify that the first peer is the IP address of the Gigabit Ethernet interface of Router ASBR2. Verify that the second peer is the IP address of the **lo0** interface of Router ASBR2. Also verify that the state of each peer is **Established**. Notice that on Router ASBR1 the NLRI advertised by Router ASBR2 the inter-AS link peer is **inet-labeled-unicast** and the NLRI advertised by Router ASBR2 the loopback interface peer is **l2vpn-signaling**.

user@ASBR1> show bgp neighbor

```

### Configuring the VPLS Routing Instances

#### Step-by-Step Procedure

To configure the VPLS routing instances:

1. On Router PE1, configure the VPLS routing instance. To enable a VPLS instance, specify the **vpls** instance type. Configure VPLS on the CE-facing Gigabit Ethernet interface. Configure the CE-facing interface to use **ethernet-vpls** encapsulation.
 

```
user@PE1# set routing-instances metro instance-type vpls
user@PE1# set routing-instances metro interface ge-1/3/0.0
```
2. On Router PE1, configure the VPLS protocol within the routing instance. To uniquely identify the virtual circuit, configure the VPLS identifier. The VPLS identifier uniquely identifies each VPLS in the router. Configure the same VPLS ID on all the routers for a given VPLS.

Specify the IP address of the **lo0** interface on Router ASBR2 as the neighbor.

Configure the CE-facing interface to use **ethernet-vpls** encapsulation and the **vpls** protocol family.

```
user@PE1# set routing-instances metro protocols vpls vpls-id 101
user@PE1# set routing-instances metro protocols vpls neighbor 192.168.3.1
user@PE1# set interfaces ge-1/3/0 encapsulation ethernet-vpls
user@PE1# set interfaces ge-1/3/0 unit 0 family vpls
```

3. On Router ASBR1, configure the VPLS routing instance. To enable a VPLS instance, specify the **vpls** instance type. Configure a route distinguisher and a VRF target. The **vrf-target** statement causes default VRF import and export policies to be generated that accept and tag routes with the specified target community.

**NOTE:** A route distinguisher allows the router to distinguish between two identical IP prefixes used as VPN routes. Configure a different route distinguisher on each ASBR router.

**NOTE:** You must configure the same VRF target on both ASBR routers.

```
user@ASBR1# set routing-instances inter-as instance-type vpls
user@ASBR1# set routing-instances inter-as route-distinguisher 65010:1
user@ASBR1# set routing-instances inter-as vrf-target target:2:1
```

4. On Router ASBR1, configure the VPLS protocol within the routing instance.

Configure the VPLS identifier. Specify the IP address of the **lo0** interface on Router PE1 as the neighbor.

```
user@ASBR1# set routing-instances inter-as protocols vpls vpls-id 101
user@ASBR1# set routing-instances inter-as protocols vpls neighbor 192.168.2.1
```

**NOTE:** The VPLS identifier uniquely identifies each LDP-signaled VPLS in the router. Configure the same VPLS ID on Router PE1 and Router ASBR1.

5. On Router ASBR1, configure the VPLS site within the routing instance. Configure the site identifier as required by the protocol to establish the EBGp pseudowire. As a best practice for more complex topologies involving multihoming, configure a site preference.

```
user@ASBR1# set routing-instances inter-as protocols vpls site ASBR-metro
site-identifier 1
user@ASBR1# set routing-instances inter-as protocols vpls site ASBR-metro
site-preference 10000
```

6. On Router ASBR1, configure the VPLS mesh group **peer-as** statement within the routing instance to specify which ASs belong to this AS mesh group. Configure the peer AS for the mesh group as **all**.

This statement enables the router to establish a single pseudowire between the ASBR routers. VPLS NLRI messages are exchanged across the EBGp sessions on the inter-AS links between the ASBR routers. All autonomous systems are in one mesh group.

```
user@ASBR1# set routing-instances inter-as protocols vpls mesh-group metro
peer-as all
```

7. On ASBR2, configure the VPLS routing instance. To enable a VPLS instance, specify the **vpls** instance type. Configure a route distinguisher and a VRF target. The **vrf-target** statement causes default VRF import and export policies to be generated that accept and tag routes with the specified target community.

**NOTE:** A route distinguisher allows the router to distinguish between two identical IP prefixes used as VPN routes. Configure a different route distinguisher on each ASBR router.

**NOTE:** You must configure the same VRF target community on both ASBR routers.

```
user@ASBR2# set routing-instances inter-as instance-type vpls
user@ASBR2# set routing-instances inter-as route-distinguisher 65020:1
user@ASBR2# set routing-instances inter-as vrf-target target:2:1
```

8. On Router ASBR2, configure the VPLS site within the routing instance. Configure the site identifier as required by the protocol.

```
user@ASBR2# set routing-instances inter-as protocols vpls site ASBR-core
site-identifier 2
```

9. On Router ASBR2, configure the VPLS mesh group within the routing instance to specify which VPLS PEs belong to this AS mesh group. Configure the peer AS for the mesh group as **all**.

This statement enables the router to establish a single pseudowire between the ASBR routers. VPLS NLRI messages are exchanged across the EBGp sessions on the inter-AS links between the ASBR routers. All autonomous systems are in one mesh group.

```
user@ASBR1# set routing-instances inter-as protocols vpls mesh-group core peer-as
all
```

10. On Router PE2, configure the VPLS routing instance. To enable a VPLS instance, specify the **vpls** instance type. Configure VPLS on the CE-facing Gigabit Ethernet interface. Configure a route distinguisher and a VRF target.

```
user@PE2# set routing-instances inter-as instance-type vpls
user@PE2# set routing-instances inter-as interface ge-0/1/1.0
user@PE2# set routing-instances inter-as route-distinguisher 65020:1
user@PE2# set routing-instances inter-as vrf-target target:2:1
```

11. On Router PE2, configure the VPLS site within the routing instance. Configure the site identifier as required by the protocol.

Configure the CE-facing interface to use **ethernet-vpls** encapsulation and the **vpls** protocol family.

```
user@PE2# set routing-instances inter-as protocols vpls site PE2 site-identifier 3
user@PE2# set interfaces ge-0/1/1 encapsulation ethernet-vpls
user@PE2# set interfaces ge-0/1/1 unit 0 family vpls
```

12. On each router, commit the configuration:

```
user@host> commit check

configuration check succeeds

user@host> commit

commit complete
```

13. On the PE routers, display the CE-facing Gigabit Ethernet interface information and verify that the encapsulation is configured correctly:

```
user@host> show interfaces ge-1/3/0
```

| Address    | Interface  | Label space ID | Hold time |
|------------|------------|----------------|-----------|
| 10.0.23.10 | ge-1/3/1.0 | 192.168.3.1:0  | 11        |

Physical interface: ge-1/3/0, Enabled, Physical link is Up

```
Interface index: 147, SNMP ifIndex: 145
Link-level type: Ethernet, MTU: 1514, Speed: 1000mbps, MAC-REWRITE Error: None,

```

## Results

This section describes commands you can use to test the operation of the VPLS.

1. To verify the VPLS connections have been established, enter the **show vpls connections** command on Router PE1.

```
user@PE1> show vpls connections
Layer-2 VPN connections:
```

Legend for connection status (St)

|                                  |                                                |
|----------------------------------|------------------------------------------------|
| EI -- encapsulation invalid      | NC -- interface encapsulation not CCC/TCC/VPLS |
| EM -- encapsulation mismatch     | WE -- interface and instance encaps not same   |
| VC-Dn -- Virtual circuit down    | NP -- interface hardware not present           |
| CM -- control-word mismatch      | -> -- only outbound connection is up           |
| CN -- circuit not provisioned    | <- -- only inbound connection is up            |
| OR -- out of range               | Up -- operational                              |
| OL -- no outgoing label          | Dn -- down                                     |
| LD -- local site signaled down   | CF -- call admission control failure           |
| RD -- remote site signaled down  | SC -- local and remote site ID collision       |
| LN -- local site not designated  | LM -- local site ID not minimum designated     |
| RN -- remote site not designated | RM -- remote site ID not minimum designated    |
| XX -- unknown connection status  | IL -- no incoming label                        |
| MM -- MTU mismatch               | MI -- Mesh-Group ID not available              |
| BK -- Backup connection          | ST -- Standby connection                       |

Legend for interface status

Up -- operational  
Dn -- down

Remote PE: 192.168.2.1, Negotiated control-word: No
Incoming label: 800000, Outgoing label: 800001
Local interface: vt-0/1/0.1049089, Status: Up, Encapsulation: ETHERNET
Description: Intf - vpls inter-as neighbor 192.168.2.1 vpls-id 101

```

In the display from Router ASBR1, verify that the neighbor is the **lo0** address of Router PE1 and that the status is **Up**.

3. To verify the VPLS connections have been established, enter the **show vpls connections** command on Router ASBR2.

```

user@ASBR2> show vpls connections
...
Instance: inter-as
BGP-VPLS State
Mesh-group connections: __ves__
Neighbor Local-site Remote-site St Time last up
192.168.11.1 2 3 Up Sep 11 15:18:23 2008
Incoming label: 800002, Outgoing label: 800001
Local interface: vt-4/0/0.1048839, Status: Up, Encapsulation: VPLS
Mesh-group connections: core
Neighbor Local-site Remote-site St Time last up

Local interface: vt-4/0/0.1048834, Status: Up, Encapsulation: VPLS

```

In the display from Router ASBR2, verify that the neighbor is the **lo0** address of Router PE2 and that the status is **Up**.

4. To verify the VPLS connections have been established, enter the **show vpls connections** command on Router PE2.

```

user@PE2> show vpls connections
...
Instance: inter-as
Local site: PE2 (3)
connection-site Type St Time last up # Up trans
2 rmt Up Sep 8 20:16:28 2008 1
Remote PE: 192.168.10.1, Negotiated control-word: No
Incoming label: 800001, Outgoing label: 800002
Local interface: vt-0/3/0.1048832, Status: Up, Encapsulation: VPLS
Description: Intf - vpls inter-as local site 3 remote site 2

```

In the display from Router PE2, verify that the remote PE is the **lo0** address of Router ASBR2 and that the status is **Up**.

5. To verify that the CE routers can send and receive traffic across the VPLS, use the **ping** command.

```

user@CE1> ping 10.10.11.2
PING 10.10.11.2 (10.10.11.2): 56 data bytes
64 bytes from 10.10.11.2: icmp_seq=0 ttl=64 time=1.369 ms
64 bytes from 10.10.11.2: icmp_seq=1 ttl=64 time=1.360 ms

```

```
64 bytes from 10.10.11.2: icmp_seq=2 ttl=64 time=1.333 ms
^C
```

```
user@CE2> ping 10.10.11.1
PING 10.10.11.1 (10.10.11.1): 56 data bytes
64 bytes from 10.10.11.1: icmp_seq=0 ttl=64 time=6.209 ms
64 bytes from 10.10.11.1: icmp_seq=1 ttl=64 time=1.347 ms
64 bytes from 10.10.11.1: icmp_seq=2 ttl=64 time=1.324 ms
^C
```

If Router CE1 can send traffic to and receive traffic from Router CE2 and Router CE2 can send traffic to and receive traffic from Router CE1, the VPLS is performing correctly.

6. To display the configuration for Router CE1, use the **show configuration** command.

For your reference, the relevant sample configuration for Router CE1 follows.

```
interfaces {
 lo0 {
 unit 0 {
 family inet {
 address 192.168.1.1/32 {
 primary;
 }
 address 127.0.0.1/32;
 }
 }
 }
 ge-0/3/0 {

## Configuring VPLS and Integrated Routing and Bridging

Traditional Layer 2 switching environments consist of Layer 2 devices (such as switches) that partition data into broadcast domains. The broadcast domains can be created through physical topologies or logically through virtual local area networks (VLANs). For MX Series routers, you can logically configure broadcast domains within virtual switch

routing instances, VPLS routing instances, or bridging domains. The individual routing instances or bridging domains are differentiated through VLAN identifiers and these instances or domains function much like traditional VLANs.

To configure a VLAN with IRB support, include the following statements:

```
[edit]
routing-instances {
 instance-name {
 instance-type vpls;
 vlan-id (VLAN) id;
 route-distinguisher distinguisher;
 vrf-target target;
 interface interface-name;
 interface interface-name;
 routing-interface interface-name;
 }
}
```

In multihomed VPLS configurations, you can configure VPLS to keep a VPLS connection up if only an IRB interface is available by configuring the **irb** option for the **connectivity-type** statement at the **[edit routing-instances routing-instance-name protocols vpls]** hierarchy level. The **connectivity-type** statement has the **ce** and **irb** options. The **ce** option is the default and specifies that a CE interface is required to maintain the VPLS connection. By default, if only an IRB interface is available, the VPLS connection is brought down.

**NOTE:** A maximum of 4096 active logical interfaces are supported for a VLAN or on each mesh group in a VPLS routing instance configured for Layer 2 bridging.

For detailed information and configuration instructions on bridging domains and spanning tree protocol, see *Junos OS Network Interfaces Library for Routing Devices* and *Junos OS Routing Protocols Library*.

The following sections provide configuration information specific to VPLS in regards to integrated routing and bridging:

- [Configuring MAC Address Flooding and Learning for VPLS on page 1522](#)
- [Configuring MSTP for VPLS on page 1523](#)

## Configuring MAC Address Flooding and Learning for VPLS

In a VPLS routing instance or bridge domain, when a frame is received from a CE interface, it is flooded to the other CE interfaces and all of the VE interfaces if the destination MAC address is not learned or if the frame is either broadcast or multicast. If the destination MAC address is learned on another CE device, such a frame is unicasted to the CE interface on which the MAC address is learned. This might not be desirable if the service provider does not want CE devices to communicate with each other directly.

To prevent CE devices from communicating directly include the **no-local-switching** statement at the **[edit bridge-domains bridge-domain-name]** hierarchy level:

```
[edit bridge-domains bridge-domain-name]
no-local-switching;
```

The **no-local-switching** statement is available only on MX Series routers. If you include it, frames arriving on a CE interface are sent to VE or core-facing interfaces only.

**NOTE:** (MX80, MX104, and the 16x10GE MPC, MPC1, or MPC2 on MX240, MX480, MX960, MX2010, and MX2020 only) If you configure the **no-local-switching** command at the [edit bridge-domains *bridge-domain-name*] hierarchy level, it might not prevent multicast traffic from being forwarded between the CE-facing interfaces of the bridge domain. Broadcast, unknown unicast, and known multicast traffic does not exhibit this behavior.

## Configuring MSTP for VPLS

When you configure integrated routing and bridging, you might also need to configure the Multiple Spanning Tree Protocol (MSTP). When you configure MSTP on a provider edge (PE) router running VPLS, you must also configure **ethernet-vpls** encapsulation on the customer-facing interfaces. VLAN-based VPLS interface encapsulations are not supported with MSTP.

## Configuring Integrated Routing and Bridging in a VPLS Instance (MX Series Routers Only)

Integrated routing and bridging (IRB) over VPLS cannot be used in conjunction with the **vlan-id all** statement. One or more Layer 2 logical interfaces must be configured inside the instance in order for IRB to function properly.

To configure IRB within a VPLS instance, include the **routing-interface *irb-interface-name*** statement at the [edit routing-instances *routing-instance-name* instance-type vpls] hierarchy level:

```
[edit]
routing-instances {
 marketing {
 instance-type vpls;
 vlan-id 123;
 route-distinguisher 11.11.11.11:10;
 vrf-target target:100:100;
 interface ae0.100;
```

```
 interface ae0.200;
 routing-interface irb.1234;
 }
 }
```

## Configuring VPLS Load Balancing

---

By default, when there are multiple equal-cost paths to the same destination for the active route, the Junos OS uses a hash algorithm to select one of the next-hop addresses to install in the forwarding table. Whenever the set of next hops for a destination changes, the next-hop address is reselected using the hash algorithm.

You can configure the Junos OS so that, for the active route, all next-hop addresses for a destination are installed in the forwarding table. This feature is called per-packet load balancing. You can use load balancing to spread traffic across multiple paths between routers. You can also configure per-packet load balancing to optimize VPLS traffic flows across multiple paths.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

You can load-balance VPLS traffic based on Layer 2 media access control (MAC) information, IP information and MPLS labels, or MPLS labels only.

**NOTE:** For platform support information, see [family multiservice](#).

To optimize VPLS traffic flows across multiple paths, include the **family multiservice** statement at the **[edit forwarding-options hash-key]** hierarchy level:

```
family multiservice {
 destination-mac;
 label-1;
 label-2;
 payload {
 ip {
 layer-3 {
 (destination-ip-only | source-ip-only);
 }
 layer-3-only;
 layer-4;
 }
 }
}
```

```

 }
 }
 source-mac;
 symmetric-hash {
 complement;
 }
}

```

You can configure one or more of the following options to load-balance using the specified packet information:

- **destination-mac**—Include the destination-address MAC information in the hash key for Layer 2 load balancing.
- **source-mac**—Include the source-address MAC information in the hash key.
- **label-1**—Include the first MPLS label in the hash key. Used for including a one-label packet for per-flow load balancing of IPv4 VPLS traffic based on IP information and MPLS labels.
- **label-2**—Include the second MPLS label in the hash key. If both **label-1** and **label-2** are specified, the entire first label and the first 16 bits of the second label are hashed.
- **payload**—Include the packet's IP payload in the hash key.
- **ip**—Include the IP address of the IPv4 or IPv6 payload in the hash key.
- **layer-3-only**—Include only the Layer 3 information from the packet's IP payload in the hash key.
- **layer-3**—Include Layer 3 information from the packet's IP payload in the hash key.
- **destination-address-only**—Include only the destination IP address in the payload in the hash key.

**NOTE:** You can include either the **source-address-only** or the **destination-address-only** statement, not both. They are mutually exclusive.

- **source-address-only**—Include only the source IP address in the payload in the hash key.

**NOTE:** You can include either the **source-address-only** or the **destination-address-only** statement, not both. They are mutually exclusive.

- **layer-4**—Include Layer 4 information from the packet's IP payload in the hash key.
- **symmetric-hash**—Configure the symmetric hash or symmetric hash complement for configuring symmetrical load balancing on an 802.3ad Link Aggregation Group.
- **complement**—Include the complement of the symmetric hash in the hash key.

For more information about how to configure per-packet load balancing, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

- Related Documentation**
- [Configuring VPLS Load Balancing Based on IP and MPLS Information on page 1528](#)
  - [Configuring VPLS Load Balancing on MX Series 3D Universal Edge Routers on page 1529](#)

## Configuring VPLS Load Balancing Based on IP and MPLS Information

In Junos OS Release 9.4 and later, you can configure load balancing for VPLS traffic to have the hash key include IP information and MPLS labels on the M120 and M320 routers only. In earlier Junos OS Releases, you can configure load balancing based only on Layer 2 information. In Junos OS Release 9.5 and later, you can configure load balancing for VPLS traffic based on Layer 3 IP and Layer 4 information on MX Series routers only. For more information, see [“Configuring VPLS Load Balancing on MX Series 3D Universal Edge Routers” on page 1529](#).

For IPv4 traffic, only the IP source and destination addresses are included in the hash key. For MPLS and IPv4 traffic, one or two MPLS labels and IPv4 source and destination addresses are included. For MPLS Ethernet pseudowires, only one or two MPLS labels are included in the hash key.

**NOTE:** VPLS load balancing based on MPLS labels and IP information is supported only on the M120 and M320 routers. In Junos OS Release 9.5 and later, on MX Series routers only, you can configure VPLS load balancing based on IP and Layer 4 information.

To optimize VPLS flows across multiple paths based on IP and MPLS information, include the **family multiservice** statement at the **[edit forwarding-options hash-key]** hierarchy level:

```
[edit forwarding-options hash-key]
family multiservice {
 label-1;
 label-2;
 payload {
 ip {
 layer-3-only;
 }
 }
}
```

To use the first MPLS label in the hash key, include the **label-1** statement:

```
[edit forwarding-options hash-key family multiservice]
label-1;
```

To use the second MPLS label, include both the **label-1** and **label-2** statements:

```
[edit forwarding-options hash-key family multiservice]
label-1;
label-2;
```

To use the packet's IPv4 payload in the hash key, include the **payload** and **ip** statements:

```
[edit forwarding-options hash-key family multiservice]
payload {
 ip;
}
```

**NOTE:** Only IPv4 is supported.

To include only Layer 3 information from the IPv4 payload, specify the **layer-3-only** option to the **payload ip** statement:

```
[edit forwarding-options hash-key family multiservice]
payload {
 ip {
 layer-3-only;
 }
}
```

To use the first and second MPLS labels and the packet's IP payload in the hash key, include the **label-1**, **label-2**, and **payload ip** statements:

```
[edit forwarding-options hash-key family multiservice]
label-1;
label-2;
payload {
 ip;
}
```

## Configuring VPLS Load Balancing on MX Series 3D Universal Edge Routers

In Junos OS Release 9.5 and later, on MX Series routers, you can configure the load balancing hash key for Layer 2 traffic to use fields in the Layer 3 and Layer 4 headers inside the frame payload. You can also configure VPLS load balancing based on IP and MPLS information on M120 and M320 routers only. For more information, see [“Configuring VPLS Load Balancing Based on IP and MPLS Information” on page 1528](#).

You can configure load balancing on MX Series routers based on Layer 3 or Layer 4 information or both.

To configure VPLS load balancing on the MX Series router to include either Layer 3 IP information or Layer 4 headers or both:

1. Include the **payload** statement at the **[edit forwarding-options hash-key family multiservice]** hierarchy level.
2. Include the **ip** statement at the **[edit forwarding-options hash-key family multiservice payload]** hierarchy level.

To configure VPLS load balancing to include the Layer 3 information:

1. Include the **layer-3** statement at the **[edit forwarding-options hash-key family multiservice payload ip]** hierarchy level.

2. Include the **source-ip-only** statement at the **[edit forwarding-options hash-key family multiservice payload ip layer-3]** hierarchy level to include information about the IP source address only in the hash key.
3. Include **destination-ip-only** statement at the **[edit forwarding-options hash-key family multiservice payload ip layer-3]** hierarchy level to include information about the IP destination address only in the hash key.

**NOTE:** You can configure either the **source-ip-only** or the **destination-ip-only** statements at a time, not both. They are mutually exclusive.

To configure VPLS load balancing to include Layer 4 information:

- Include the **layer-4** statement at the **[edit forwarding-options hash-key family multiservice payload ip]** hierarchy level.

The following example shows load balancing configured to use the source Layer 3 IP address option and Layer 4 header fields as well as the source and destination MAC addresses:

```
[edit forwarding-options hash-key]
family multiservice {
 source-mac;
 destination-mac;
 payload {
 ip {
 layer-3 {
 source-ip-only;
 }
 layer-4;
 }
 }
}
```

## MAC Moves Loop Prevention in VPLS Network Overview

Starting in Junos OS 14.2, you can configure the router to prevent a loop in a VPLS network. In a virtual private LAN service (VPLS) deployment, when a previously learned media access control (MAC) address appears on a different physical interface, for example, local interfaces (Gigabit Ethernet interfaces) or label switched Interfaces (LSIs), or within a different unit of the same physical interface and if this behavior occurs frequently, then it is considered a MAC move.

You can configure the router to report a MAC address move based on the following parameters:

- Number of times a MAC address move occurs
- Specified period of time over which the MAC address move occurs

Configuration errors at the network can force traffic into never ending circular paths or loops. These loops in the VPLS network cause frequent MAC moves between different interfaces which can be used to rectify the problem by disabling such an interface in the network. The following two approaches can be used to disable the interface causing the loop:

- Base learning interface (base IFL) approach algorithm– This is the primary approach used to disable the looped interface. Base interface information is maintained for every MAC in the routing instance. If the MAC stays at the interface it was first learned for 300 seconds, then the interface-MAC association is considered to be stable and this interface is considered as the base interface of the MAC. If the MAC move happens frequently between the local interface and the LSI interface while the base interface of the MAC is an LSI, then the local interface is considered to be looped and has to be disabled.
- Statistical approach algorithm– This is the secondary approach used to disable the looped interface. If the MAC has not been learned for over 300 seconds at an interface, then it does not have a base interface and hence the statistical approach is used.

If the MAC that has no base interface information( Base Learning interface is null) starts moving, then the statistics of such MAC moves between different interfaces is learned. If the statistics show MAC moves from LSI to local interface or from local interface to local interface, then the local interface is considered to be looped and is disabled.

There are certain MACs that can move between different interfaces, for example, mastership change in the Virtual Router Redundancy Protocol (VRRP). The base interface of such MAC moves cannot be maintained as this leads to the assumption of a loop creation. Hence, such MACs should be configured as virtual MACs. Example of virtual MACs are 00:00:5e:00:01:xx for VRRP, 00:00:0c:07:ac:xx for hot standby router protocol (HSRP) , 00:07:b4:00:01:xx for global server load balancing (GSLB), and 02:bf:xx:xx:xx:xx for VMotion.

The following timers help in monitoring the disabled interfaces:

- Cooloff time — The cooloff time starts when the interface gets disabled. During this time any MAC move happening in the routing instance is ignored. This ensures that only one interface is blocked at a given time on a routing instance, and blocking of another interface happens only after the expiration of the cooloff timer provided the given MAC moves are still observed. By default, the cooloff time is 30 seconds.
- Interface recovery time — When an interface gets disabled , it is disabled permanently. Configuring the interface recovery time ensures that the interface gets enabled on completion of the interface recovery time duration.
- Statistical approach wait time — The time when the statistics are collected after MAC moves are observed to determine the existence of a loop when there is no base IFL for the MAC address. . By default, the statistical approach wait timer is 30 seconds.

## Release History Table

| Release | Description                                                                                  |
|---------|----------------------------------------------------------------------------------------------|
| 14.2    | Starting in Junos OS 14.2, you can configure the router to prevent a loop in a VPLS network. |

## Related Documentation

## Configuring VPLS Loop Prevention Due to MAC Moves

In a virtual private LAN service (VPLS) deployment, when a previously learned media access control (MAC) address appears on a different physical interface, for example, local interfaces (Gigabit Ethernet interfaces) or label switched Interfaces (LSIs), or within a different unit of the same physical interface and if this behavior occurs frequently, then it is considered a MAC move. The router reports a MAC address move based on the number of times a MAC address move occurs and the specified period of time over which the MAC address move occurs. Configuration errors at the VPLS network can lead to loops that cause frequent MAC moves between different interfaces. These moves can be used to rectify the problem by disabling such interface in the network. The following two approaches can be used to disable the interface:

- Base learning interface (base IFL) approach algorithm — This is the primary approach used to disable the looped local interface.
- Statistical approach algorithm — This is the secondary approach used to disable the looped local interface.

Some virtual MACs can genuinely move between different interfaces and such MACs can be configured to ignore the moves. The cooloff time and the statistical approach wait time are used internally to find out the looped interface. The interface recovery time can be configured to auto-enable the interface that gets disabled due to a loop in the network.

Before you begin to configure loop prevention in a VPLS network:

1. Configure the VPLS topology.
2. Configure the VPLS routing instances.
3. Enable VPLS MAC move action on a VPLS instance.
4. Configure the routing and signaling protocols.

To configure loop prevention in a VPLS network:

1. Configure the threshold time and the threshold count to detect MAC moves.

```
[edit protocols l2-learning global-mac-move]
user@host# set threshold-time seconds
```

```
user@host# set threshold-count seconds
```

For example, configure the threshold time as 30 and the threshold count as 4 to detect MAC moves.

```
[edit protocols l2-learning global-mac-move]
user@host# set threshold-time 30
user@host# set threshold-count 4
```

**NOTE:** If the threshold time and threshold count are not configured, then the default values are used. The default value of threshold time is 1 second, and default value of threshold count is 50.

2. (Optional) Configure a cooloff time to ensure that no other interface gets disabled once an interface, for a routing instance, is disabled during this time period.

```
[edit protocols l2-learning vpls-mac-move]
user@host# set cooloff-time seconds
```

3. (Optional) Configure the statistical approach wait time to determine the existence of a loop based on the statistics collected after MAC moves are observed when there is no base IFL for the MAC address.

```
[edit protocols l2-learning vpls-mac-move]
user@host# set statistical-approach-wait-time seconds
```

4. (Optional) Configure the interface recovery time to ensure that the disabled interface gets enabled on completion of the interface recovery time duration.

```
[edit protocols l2-learning vpls-mac-move]
user@host# set interface-recovery-time seconds
```

5. (Optional) Configure the virtual MAC address to ignore the MAC moves as this leads to the assumption of loop creation.

```
[edit protocols l2-learning vpls-mac-move]
user@host# set virtual-mac mac-address
```

6. Configure the VPLS routing instance of an interface.

```
[edit routing-instances instance-name]
user@host# set instance-type vpls
user@host# set interface interface
```

7. Enable MAC move action on the interface for the VPLS instance, and configure the VPLS neighbor.

```
[edit routing-instances instance-name]
user@host# set protocols vpls enable-mac-move-action
user@host# set protocols vpls no-tunnel-services
user@host# set protocols vpls vpls-id vpls-id
user@host# set protocols vpls neighbor IP-address
```

### MAC Moves Loop Prevention in VPLS Network Overview

Starting in Junos OS 14.2, you can configure the router to prevent a loop in a VPLS network. In a virtual private LAN service (VPLS) deployment, when a previously learned media access control (MAC) address appears on a different physical interface, for example, local interfaces (Gigabit Ethernet interfaces) or label switched Interfaces (LSIs), or within a different unit of the same physical interface and if this behavior occurs frequently, then it is considered a MAC move.

You can configure the router to report a MAC address move based on the following parameters:

- Number of times a MAC address move occurs
- Specified period of time over which the MAC address move occurs

Configuration errors at the network can force traffic into never ending circular paths or loops. These loops in the VPLS network cause frequent MAC moves between different interfaces which can be used to rectify the problem by disabling such an interface in the network. The following two approaches can be used to disable the interface causing the loop:

- Base learning interface (base IFL) approach algorithm- This is the primary approach used to disable the looped interface. Base interface information is maintained for every MAC in the routing instance. If the MAC stays at the interface it was first learned for 300 seconds, then the interface-MAC association is considered to be stable and this interface is considered as the base interface of the MAC. If the MAC move happens frequently between the local interface and the LSI interface while the base interface of the MAC is an LSI, then the local interface is considered to be looped and has to be disabled.
- Statistical approach algorithm- This is the secondary approach used to disable the looped interface. If the MAC has not been learned for over 300 seconds at an interface, then it does not have a base interface and hence the statistical approach is used.

If the MAC that has no base interface information( Base Learning interface is null) starts moving, then the statistics of such MAC moves between different interfaces is learned. If the statistics show MAC moves from LSI to local interface or from local interface to local interface, then the local interface is considered to be looped and is disabled.

There are certain MACs that can move between different interfaces, for example, mastership change in the Virtual Router Redundancy Protocol (VRRP). The base interface of such MAC moves cannot be maintained as this leads to the assumption of a loop creation. Hence, such MACs should be configured as virtual MACs. Example of virtual MACs are 00:00:5e:00:01:xx for VRRP, 00:00:0c:07:ac:xx for hot standby router protocol (HSRP), 00:07:b4:00:01:xx for global server load balancing (GSLB), and 02:bf:xx:xx:xx:xx for VMotion.

The following timers help in monitoring the disabled interfaces:

- **Cooloff time** — The cooloff time starts when the interface gets disabled. During this time any MAC move happening in the routing instance is ignored. This ensures that only one interface is blocked at a given time on a routing instance, and blocking of another interface happens only after the expiration of the cooloff timer provided the given MAC moves are still observed. By default, the cooloff time is 30 seconds.
- **Interface recovery time** — When an interface gets disabled, it is disabled permanently. Configuring the interface recovery time ensures that the interface gets enabled on completion of the interface recovery time duration.
- **Statistical approach wait time** — The time when the statistics are collected after MAC moves are observed to determine the existence of a loop when there is no base IFL for the MAC address. By default, the statistical approach wait timer is 30 seconds.

### Example: Configuring Loop Prevention in VPLS Network Due to MAC Moves

This example shows how to prevent a loop in the VPLS network due to MAC moves between different physical interfaces.

When a MAC move is detected in the VPLS network, Junos OS allows the prevention of the loop in the network by disabling the interface using a base IFL or statistical approach algorithm.

- [Requirements on page 1535](#)
- [Overview on page 1536](#)
- [Configuration on page 1537](#)
- [Verification on page 1545](#)

#### Requirements

This example uses the following hardware and software components:

- Four MX Series 3D Universal Edge Routers
- Junos OS Release 14.2 or later running on all devices

Before you begin:

1. Configure the VPLS topology.
2. Configure the VPLS routing instances.

3. Enable VPLS MAC move action on a VPLS instance.
4. Configure the routing and signaling protocols.

### Overview

---

Starting with Junos OS Release 14.2, the loop creation in the VPLS network due to frequent MAC moves between different physical interfaces can be prevented by identifying and disabling such interfaces using the base IFL approach or statistical approach algorithm.

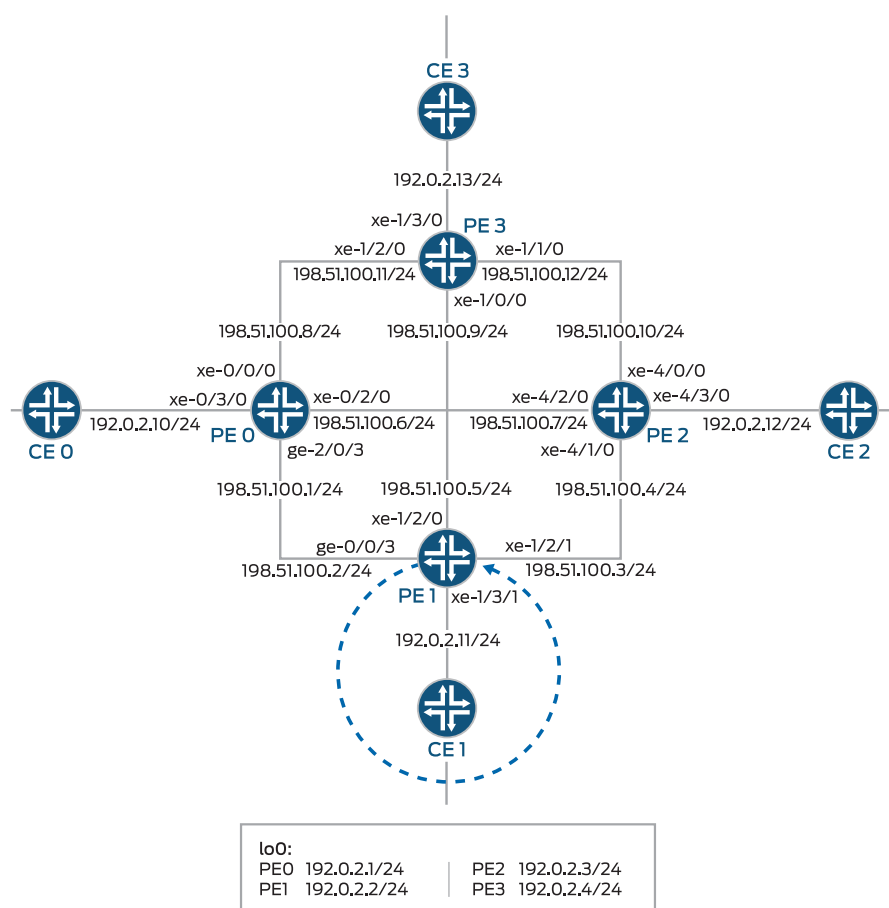

The *base IFL approach* algorithm is the primary approach. Base interface information is maintained for every MAC in the routing instance. If the MAC stays at the interface it was first learned for 300 seconds, then the interface-MAC association is considered to be stable, and this interface is considered as the base interface of the MAC. If the MAC move happens frequently between the local interface and the LSI interface while the base interface of the MAC is an LSI, then the local interface is considered to be looped and has to be disabled.

The *statistical approach* algorithm is the secondary approach used to disable the looped interface. If the MAC has not been learned for over 300 seconds at an interface, then it does not have a base interface and hence the statistical approach is used. If the MAC that has no base interface information (Base Learning interface is null) starts moving then the statistics of such MAC moves between different interfaces is learned. If the statistics show MAC moves from LSI to local interface or from local interface to local interface then the local interface is considered to be looped and is disabled.

### Topology

In the topology shown in [Figure 149 on page 1537](#), a loop was detected on Device PE1 in the VPLS network.

Figure 149: Example Loop Prevention Due to MAC Move in VPLS Network

### Configuring Device PE1

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

**NOTE:** Repeat this procedure for Routers PE0, PE2, and PE3 after modifying the appropriate interface names, addresses, and any other parameters for the router.

1. Configure the interfaces.

```
[edit interfaces]
```

```
user@PE1# set ge-0/0/3 unit 0 family inet address 198.51.100.2/24
user@PE1# set ge-0/0/3 unit 0 family mpls
```

```
user@PE1# set xe-1/2/0 unit 0 family inet address 198.51.100.5/24
user@PE1# set xe-1/2/0 unit 0 family mpls
```

```
user@PE1# set xe-1/2/1 unit 0 family inet address 198.51.100.3/24
user@PE1# set xe-1/2/1 unit 0 family mpls
```

```
user@PE1# set xe-1/3/1 vlan-tagging
user@PE1# set xe-1/3/1 encapsulation vlan-vpls
user@PE1# set xe-1/3/1 unit 600 encapsulation vlan-vpls
user@PE1# set xe-1/3/1 unit 600 vlan-id 600
```

```
user@PE1# set lo0 unit 0 family inet address 192.0.2.2/24
```

2. Configure the routing options.

```
[edit routing-options]
```

```
user@PE1# set router-id 192.0.2.2
user@PE1# set autonomous-system 701
```

3. Configure the MPLS protocol on the interface.

```
[edit protocols mpls]
```

```
user@PE1# set interface fxp0.0 disable
user@PE1# set interface ge-0/0/3.0
user@PE1# set interface xe-1/2/1.0
user@PE1# set interface xe-1/2/0.0
```

4. Configure the OSPF protocol.

```
[edit protocols ospf]
user@PE1# set area 0.0.0.0 interface lo0.0 passive
user@PE1# set area 0.0.0.0 interface fxp0.0 disable
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0 interface-type p2p
user@PE1# set area 0.0.0.0 interface ge-0/0/3.0 metric 10
user@PE1# set area 0.0.0.0 interface xe-1/2/1.0 interface-type p2p
user@PE1# set area 0.0.0.0 interface xe-1/2/1.0 metric 10
user@PE1# set area 0.0.0.0 interface xe-1/2/0.0 interface-type p2p
user@PE1# set area 0.0.0.0 interface xe-1/2/0.0 metric 10
```

5. Configure the LDP protocols on the interfaces.

```
[edit protocols ldp]
user@PE1# set interface ge-0/0/3.0
user@PE1# set interface xe-1/2/0.0
user@PE1# set interface xe-1/2/1.0
user@PE1# set interface fxp0.0 disable
user@PE1# set interface lo0.0
```

6. Configure the threshold time and the threshold count to detect MAC moves.

```
[edit protocols l2-learning global-mac-move]
user@PE1# set threshold-time 30
user@PE1# set threshold-count 4
```

7. Configure VPLS MAC move parameters like cooloff time, statistical approach wait time, interface recovery time, and virtual MAC.

```
[edit protocols l2-learning vpls-mac-move]
user@PE1# set cooloff-time 10
user@PE1# set statistical-approach-wait-time 10
user@PE1# set interface-recovery-time 10
user@PE1# set virtual-mac 00:00:5e:00:01:00/40
```

8. Enable MAC move action on the interface for the VPLS instance vpls\_1.

```
[edit routing-instances vpls_1]
user@PE1# set instance-type vpls
user@PE1# set interface xe-1/3/1.600
user@PE1# set protocols vpls enable-mac-move-action
user@PE1# set protocols vpls no-tunnel-services
user@PE1# set protocols vpls vpls-id 100
user@PE1# set protocols vpls neighbor 192.0.2.1
```

## Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/3 {
```

```
unit 0 {
 family inet {
 address 198.51.100.2/24;
 }
 family mpls;
}
xe-1/2/0 {
 unit 0 {
 family inet {
 address 198.51.100.5/24;
 }
 family mpls;
 }
}
xe-1/2/1 {
 unit 0 {
 family inet {
 address 198.51.100.3/24;
 }
 family mpls;
 }
}
xe-1/3/1 {
 vlan-tagging;
 encapsulation vlan-vpls;
 unit 600 {
 encapsulation vlan-vpls;
 vlan-id 600;
 }
}
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.2/24;
 }
 }
}

user@PE1# show protocols
mpls {
 interface fxp0.0 {
 disable;
 }
 interface ge-0/0/3.0;
 interface xe-1/2/1.0;
 interface xe-1/2/0.0;
}
ospf {
 area 0.0.0.0 {
 interface lo0.0 {
 passive;
 }
 interface fxp0.0 {
 disable;
 }
 }
}
```

```

 interface ge-0/0/3.0 {
 interface-type p2p;
 metric 10;
 }
 interface xe-1/2/1.0 {
 interface-type p2p;
 metric 10;
 }
 interface xe-1/2/0.0 {
 interface-type p2p;
 metric 10;
 }
 }
}
ldp {
 interface ge-0/0/3.0;
 interface xe-1/2/0.0;
 interface xe-1/2/1.0;
 interface fxp0.0 {
 disable;
 }
 interface lo0.0;
}
l2-learning {
 global-mac-move {
 threshold-time 30;
 threshold-count 4;
 }
 vpls-mac-move {

 statistical-approach-wait-time 10;
 interface-recovery-time 10;
 virtual-mac 00:00:5e:00:01:00/40;
 }
}
}

user@PE1# show routing-instances
vpls_1 {
 instance-type vpls;
 interface xe-1/3/1.600;
 protocols {
 vpls {
 enable-mac-move-action;
 no-tunnel-services;
 vpls-id 100;
 neighbor 192.0.2.1;
 }
 }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Verify that the configuration is working properly.

- [Verifying the MAC Move in a VPLS Network on page 1545](#)
- [Verifying the MAC Move in a VPLS Instance on page 1545](#)
- [Verifying the MAC Move Buffer in a VPLS Network on page 1546](#)
- [Verifying the VPLS MAC Table for the Base IFL Approach Algorithm on page 1546](#)
- [Verifying That the Interface Is Disabled on page 1547](#)
- [Verifying the VPLS MAC Table for the Statistical Approach Algorithm on page 1548](#)

### *Verifying the MAC Move in a VPLS Network*

**Purpose** Verify that the MAC move is observed in a VPLS network.

**Action** From operational mode, run the **show vpls mac-move-action** command for Device PE1.

```
user@PE1> show vpls mac-move-action
Instance: vpls_1
 Local interface: xe-1/3/1.600, Index: 341
 Algorithm used : Base IFL
 Time rec : 02:30:35
 Recovery timer : Yes
```

**Meaning** The output shows Instance name, Local interface and Algorithm used indicating that VPLS MAC Move is observed in a VPLS network.

### *Verifying the MAC Move in a VPLS Instance*

**Purpose** Verify that the MAC move is observed in a VPLS instance.

**Action** From operational mode, run the **show vpls mac-move-action instance *instance-name*** command for Device PE1.

```
user@PE1> show vpls mac-move-action instance vpls_1

Instance: vpls_1
 Local interface: xe-1/3/1.600, Index: 341
 Algorithm used : Base IFL
 Time rec : 02:29:35
 Recovery timer : Yes
```

**Meaning** The output shows Local interface, and Algorithm used indicating that VPLS MAC move has been observed in a VPLS instance.

***Verifying the MAC Move Buffer in a VPLS Network***

**Purpose** Verify the MAC move buffer to monitor the MAC moves that are occurring in the VPLS network.

**Action** From operational mode, run the **show l2-learning mac-move-buffer** command for Device PE1.

```
user@PE1> show l2-learning mac-move-buffer
```

| MAC<br>Address    | Time<br>Rec. | Bridge<br>Domain |

| 00:10:00:01:00:01 | 03:26:01     | __vpls_1__       |
| 00:10:00:01:00:09 | 03:26:01     | __vpls_1__       |

***Verifying the VPLS MAC Table for the Base IFL Approach Algorithm***

**Purpose** Verify the base learning interfaces for the MAC addresses. .

**Action** From operational mode, run the **show vpls mac-table extensive** command to obtain extensive information of VPLS MAC table.

```
user@PE1> show vpls mac-table extensive
```

```
MAC address: 00:10:00:01:00:00
 Routing instance: vpls_1
 Bridging domain: __vpls_1__, VLAN : NA
 Learning interface: lsi.1049165
 Base learning interface: lsi.1049165
 Layer 2 flags: in_hash,in_ifd,in_ifl,in_vlan,in_rtt,kernel,in_ifbd
 Epoch: 0 Sequence number: 1
 Learning mask: 0x00000001

MAC address: 00:10:00:01:00:01
 Routing instance: vpls_1
 Bridging domain: __vpls_1__, VLAN : NA
 Learning interface: lsi.1049165
 Base learning interface: lsi.1049165
 Layer 2 flags: in_hash,in_ifd,in_ifl,in_vlan,in_rtt,kernel,in_ifbd
 Epoch: 0 Sequence number: 1
 Learning mask: 0x00000001

MAC address: 00:10:00:01:00:02
 Routing instance: vpls_1
 Bridging domain: __vpls_1__, VLAN : NA
 Learning interface: lsi.1049165
 Base learning interface: lsi.1049165
 Layer 2 flags: in_hash,in_ifd,in_ifl,in_vlan,in_rtt,kernel,in_ifbd
 Epoch: 0 Sequence number: 1
 Learning mask: 0x00000001

MAC address: 00:10:00:01:00:03
 Routing instance: vpls_1
 Bridging domain: __vpls_1__, VLAN : NA
 Learning interface: lsi.1049165
 Base learning interface: lsi.1049165
 Layer 2 flags: in_hash,in_ifd,in_ifl,in_vlan,in_rtt,kernel,in_ifbd
 Epoch: 0 Sequence number: 1
 Learning mask: 0x00000001
```

**Meaning** The output of the command **show vpls mac-table extensive** shows the base learning interface of the MAC address.

#### *Verifying That the Interface Is Disabled*

**Purpose** Verify that the base learning interface of the MAC address is disabled.

**Action** From operational mode, run the **show interfaces *interface-name*** command for Device PE1.

```
user@PE1> show interfaces xe-1/3/1.600
```

```
Logical interface xe-1/3/1.600 (Index 341) (SNMP ifIndex 2864)
 Flags: Up Link-Layer-Down SNMP-Traps 0x4000 VLAN-Tag [0x8100.600]
Encapsulation: VLAN-VPLS
Input packets : 2234018970
Output packets: 2234728895
Protocol vpls, MTU: 1518
Flags: Is-Primary
```

**Meaning** The flag **link-layer-down** in the output indicates that the interface is disabled.

#### *Verifying the VPLS MAC Table for the Statistical Approach Algorithm*

**Purpose** Verify the VPLS MAC table for the statistical approach algorithm.

**Action** From operational mode, run the **show vpls mac-table extensive** command for Device PE1.

```
user@PE1> show vpls mac-table extensive
```

```
MAC address: 00:10:00:01:00:00

Layer 2 flags: in\_hash,in\_ifd,in\_ifl,in\_vlan,in\_rtt,kernel,in\_ifbd  
 Epoch: 3 Sequence number: 442  
 Learning mask: 0x00000002

**Meaning** The **Base learning interface** is null which indicates that the statistical approach is in use.

#### Release History Table

| Release | Description                                                                                  |
|---------|----------------------------------------------------------------------------------------------|
| 14.2    | Starting in Junos OS 14.2, you can configure the router to prevent a loop in a VPLS network. |

## Understanding MAC Pinning

Starting in Junos OS Release 16.1, Junos OS supports MAC pinning to prevent loops on the MX series routers. A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops in Layer 2 bridges and in virtual private LAN service (VPLS) networks. To avoid loops, you can enable the MAC pinning feature on an interface. The MAC pinning feature is applicable only when dynamic learning of MAC addresses over interfaces is enabled.

When you enable MAC pinning on an interface in a bridge domain or VPLS domain, MAC addresses learned over that interface cannot be relearned on any other interface in the same bridge domain or VPLS domain until the MAC address either ages out on the first interface or is cleared from the MAC table. If a packet with the same MAC address arrives at any other interface in the same bridge domain, it is discarded. This, effectively, controls MAC address moves and prevents the creation of loops in Layer 2 bridges and VPLS domains.

**NOTE:** If the timeout interval for the MAC addresses is not specified by setting the `mac-table-aging-time` statement, the MAC addresses learned over the MAC pinning interface are pinned to the interface until the default timeout period.

You can configure MAC pinning in a bridging environment and in VPLS routing instances. In a bridging environment, you can enable MAC pinning on an access interface and a trunk interface. You can also enable MAC pinning on an access interface or trunk interface of a virtual switch. To avoid loops in the bridging environment, you can use any of the configurations mentioned previously in this topic. To avoid MAC moves and loops, you can use any one of the 16 different MAC pinning configurations.

Starting in Junos OS Release 17.2, the MAC pinning feature is enabled on provider backbone bridging (PBB) and Ethernet VPN (EVPN) integration, including customer edge (CE) interfaces and EVPN over PBB core in both all-active or single-active mode.

To configure MAC pinning for PBB-EVPN, include the **mac-pinning** statement at the **[edit routing-instances *pbbn* protocols evpn]**, where **pbbn** is the PBB routing instance over backbone port (B-component). With this configuration, the dynamically learned MAC addresses in the PBB I-component (customer routing instance) bridge domain over CE interfaces, as well as PBB-MPLS core interfaces are pinned. This prevents MAC move on duplicate MAC detection, avoiding loop creation in a network.

## Configuring MAC Pinning on Access Interfaces for Bridge Domains

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. To avoid loops across interfaces in bridge domains, you can configure MAC pinning.

This topic describes how to configure MAC pinning on an access interface in a bridge domain. A logical interface configured to accept untagged packets is called an *access interface* or *access port*. When an access interface receives a tagged or an untagged packet, the interface's VLAN ID is added to the packet. The packet is then forwarded within the bridge domain that is configured with the matching VLAN ID.

To configure MAC pinning on access interfaces in bridge domains:

1. Configure the interface as an access interface and specify the VLAN ID at the **[edit interfaces]** hierarchy level.

```
[edit interfaces]
user@host# set interfacetype-fpc/pic/port encapsulation ethernet-bridge
user@host# set interfacetype-fpc/pic/port unit logical-unit-number family bridge
 interface-mode access
user@host# set interfacetype-fpc/pic/port unit logical-unit-number family bridge
 vlan-id vlan-id
```

2. Configure MAC pinning on the interface by including the **mac-pinning** statement at the **[edit bridge-domains]** hierarchy level.

```
[edit bridge-domains]
user@host# set bridge-domain-name bridge-options interface
 interfacetype-fpc/pic/port mac-pinning
```

3. In configuration mode, verify the configuration.

```
user@host# show interfaces
interfaces {
 interfacetype-fpc/pic/port {
 encapsulation ethernet-bridge;
 unit logical-unit-number {
 family bridge {
 interfaces-mode access;
 vlan-id vlan-id;
 }
 }
 }
}
user@host# show bridge-domains
bridge-domains {
 bridge-domain-name {
 bridge-options {
 interfacetype-fpc/pic/port {
 mac-pinning;
 }
 }
 }
}
```

```
}
}
```

## Configuring MAC Pinning on Trunk Interfaces for Bridge Domains

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. To avoid MAC moves across interfaces in bridge domains, you can configure MAC pinning.

In this topic, we are configuring MAC pinning on a trunk interface in a bridge domain. A logical interface configured to accept any packet tagged with a VLAN ID that matches a VLAN ID specified in the domain is called a *trunk interface* or *trunk port*. When a trunk interface receives a packet tagged with a VLAN ID that matches the list of VLAN IDs specified within the bridge domain, the packet is then forwarded within the bridge domain that is configured with the matching VLAN ID.

To configure MAC pinning on trunk interfaces in bridge domains:

1. Configure the interface as a trunk interface and specify the list of VLAN IDs.

```
[edit interfaces]
user@host# set interfacetype-fpc/pic/port flexible-vlan-tagging
user@host# set interfacetype-fpc/pic/port encapsulation flexible-ethernet-services
user@host# set interfacetype-fpc/pic/port unit logical-unit-number family bridge
 interface-mode trunk
user@host# set interfacetype-fpc/pic/port unit logical-unit-number family bridge
 vlan-id-list vlan-id-numbers
```

2. Configure the bridge domain by specifying the name of the bridge and the VLAN ID.

```
[edit bridge-domains]
user@host# set bridge-domain-name vlan-id all
```

3. Configure MAC pinning on the interface by including the **mac-pinning** statement at the **[edit switch-options]** hierarchy level.

```
[edit switch-options]
user@host# set interface interfacetype-fpc/pic/port mac-pinning
```

4. In configuration mode, verify the configuration.

```
user@host# show interfaces
interfaces {
 interfacetype-fpc/pic/port {
```

```

flexible-vlan-tagging;
encapsulation flexible-ethernet-services;
unit logical-unit-number {
 family bridge {
 interfaces-mode trunk ;
 vlan-id-list vlan-id-numbers;
 }
}
}
}
user@host# show bridge-domains
bridge-domains {
 bridge-domain-name {
 vlan-id all;
 }
}
user@host# show switch-options
switch-options {
 interface interfacetype-fpc/pic/port {
 mac-pinning;
 }
}

```

## Configuring MAC Pinning on Access Interfaces for Bridge Domains in a Virtual Switch

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. To avoid loops across interfaces in virtual switches, you can configure MAC pinning.

This topic describes how to configure MAC pinning on an access interface for a bridge domain in a virtual switch. A virtual switch represents a Layer 2 network as it filters and forwards traffic only at the data link layer. Each bridge domain in a virtual switch participates in Layer 2 Learning and Forwarding. When an access interface for a bridge domain receives a tagged or untagged packet, the interface's VLAN ID is added to the packet. The packet is then forwarded within the bridge domain that is configured with the matching VLAN ID.

To configure MAC pinning on access interfaces for bridge domains in a virtual switch:

1. Configure the interface as an access interface and specify the VLAN ID.

```

[edit interfaces]
user@host# set interfacetype-fpc/pic/port encapsulation ethernet-bridge
user@host# set interfacetype-fpc/pic/port unit logical-unit-number family bridge
interface-mode access

```

```
user@host# set interfacetype-fpc/pic/port unit logical-unit-number family bridge
vlan-id vlan-id
```

2. Configure the routing instance as a virtual switch and specify the access interface.

```
[edit routing-instances]
user@host# set routing-instance-name instance-type virtual-switch
user@host# set routing-instance-name interface interfacetype-fpc/pic/port
```

3. Configure the bridge domain and specify the list of VLAN IDs.

```
[edit routing-instances]
user@host# set routing-instance-name bridge-domains bridge-domain-name vlan-id-list
vlan-id-numbers
```

4. Configure MAC pinning on the interface.

```
[edit routing-instances]
user@host# set routing-instance-name bridge-domains bridge-domain-name
bridge-options interface interfacetype-fpc/pic/port mac-pinning
```

5. In configuration mode, verify the configuration.

```
user@host# show interfaces
interfaces {
 interfacetype-fpc/pic/port {
 encapsulation ethernet-bridge;
 unit logical-unit-number {
 family bridge {
 interface-mode access;
 vlan-id vlan-id;
 }
 }
 }
}
user@host# show routing-instances
routing-instances{
 routing-instance-name {
 instance-type virtual-switch;
 interface interfacetype-fpc/pic/port;
 }
}
user@host# show bridge-domains
bridge-domains {
 bridge-domain-name {
 vlan-id -list vlan-id-numbers;
 bridge-options {
 interface interfacetype-fpc/pic/port {
 mac-pinning;
 }
 }
 }
}
```

## Configuring MAC Pinning on Trunk Interfaces for Bridge Domains in a Virtual Switch

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. To avoid loops across interfaces in virtual switches, you can configure MAC pinning.

This topic describes how to configure MAC pinning on a trunk interface for a bridge domain in a virtual switch. A virtual switch represents a Layer 2 network as it filters and forwards traffic only at the data link layer. Each bridge domain in a virtual switch participates in Layer 2 Learning and Forwarding. When a trunk interface for a bridge domain receives a packet tagged with a VLAN ID that matches the list of VLAN IDs specified with the bridge domain, the packet is then forwarded within the bridge domain that is configured with the matching VLAN ID.

To configure MAC pinning on trunk interfaces for bridge domains in a virtual switch:

1. Configure the interface as a trunk interface and specify the list of VLAN IDs.

```
[edit interfaces]
user@host# set interfacetype-fpc/pic/port flexible-vlan-tagging
user@host# set interfacetype-fpc/pic/port encapsulation flexible-ethernet-services
user@host# set interfacetype-fpc/pic/port unit logical-unit-number family bridge
 interface-mode trunk
user@host# set interfacetype-fpc/pic/port unit logical-unit-number family bridge
 vlan-id-list vlan-id-numbers
```

2. Configure the routing instance as virtual switch and specify the trunk interface.

```
[edit routing-instances]
user@host# set routing-instance-name instance-type virtual-switch;
user@host# set routing-instance-name interface interfacetype-fpc/pic/port
```

3. Configure the bridge domain and specify the list of VLAN IDs.

```
[edit routing-instances]
user@host# set routing-instance-name bridge-domains bridge-domain-name vlan-id-list
 vlan-id-numbers
```

4. Configure MAC pinning on the interface by including the **mac-pinning** statement at the **[edit switch-options]** hierarchy level.

```
[edit switch-options]
user@host# set interface interfacetype-fpc/pic/port mac-pinning
```

5. In configuration mode, verify the configuration.

```
user@host# show interfaces
interfaces {
 interfacetype-fpc/pic/port {
 flexible-vlan-tagging;
 encapsulation flexible-ethernet-services;
 unit logical-unit-number {
 family bridge {
 interface-mode trunk ;
 vlan-id-list vlan-id-numbers;
 }
 }
 }
}
user@host# show routing-instances
routing-instances{
 routing-instance-name{
 instance-type virtual-switch;
 interface interfacetype-fpc/pic/port;
 }
}
user@host# show bridge-domains
bridge-domains {
 bridge-domain-name{
 vlan-id -list vlan-id-numbers;
 }
}
}
user@host# show switch-options
switch-options {
 interface interfacetype-fpc/pic/port {
 mac-pinning;
 }
}
```

## Configuring MAC Pinning for All Pseudowires of the VPLS Routing Instance (LDP and BGP)

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. To avoid loops across interfaces in virtual private LAN services (VPLS), you can configure MAC pinning.

This topic describes how to configure MAC pinning on a trunk interface for all pseudowires of the VPLS routing instance.

To configure MAC pinning for the VPLS routing instance:

1. Configure the interface as a trunk interface and specify the list of VLAN IDs.

```
[edit interfaces]
user@host# set interfacetype-fpc/pic/port flexible-vlan-tagging
user@host# set interfacetype-fpc/pic/port encapsulation flexible-ethernet-services
user@host# set interfacetype-fpc/pic/port unit logical-unit-number encapsulation
 vlan-vpls;
user@host# set interfacetype-fpc/pic/port unit logical-unit-number family bridge
 interface-mode trunk
user@host# set interfacetype-fpc/pic/port unit logical-unit-number family bridge
 vlan-id-list vlan-id-numbers
```

2. Configure the routing instance as VPLS and specify the trunk interface.

```
[edit routing-instances]
user@host# set routing-instance-name instance-type vpls;
user@host# set routing-instance-name interface interfacetype-fpc/pic/port
```

3. Configure MAC pinning after specifying the routing protocol configuration.

```
[edit routing-instances]
user@host# set routing-instance-name protocols vpls mac-pinning
```

4. In configuration mode, verify the configuration.

```
user@host# show interfaces
interfaces {
 interfacetype-fpc/pic/port {
 flexible-vlan-tagging;
 encapsulation flexible-ethernet-services;
 unit logical-unit-number {
 encapsulation vlan-vpls;
 }
 family bridge {
 interface-mode trunk ;
 vlan-id-list vlan-id-numbers;
 }
 }
}
user@host# show routing-instances
```

```
routing-instances{
 routing-instance-name {
 instance-type vpls;
 interface interfacetype-fpc/pic/port;
 protocols{
 vpls {
 mac-pinning;
 }
 }
}
```

## Configuring MAC Pinning on VPLS CE Interface

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. To avoid loops across interfaces in virtual private LAN services (VPLS), you can configure MAC pinning.

This topic describes how to configure MAC pinning on a VPLS customer edge (CE) trunk interface.

To configure MAC pinning on a VPLS CE interface:

1. Configure the trunk interface and specify the list of VLAN IDs.

```
[edit interfaces]
user@host# set interfacetype-fpc/pic/port flexible-vlan-tagging
user@host# set interfacetype-fpc/pic/port encapsulation flexible-ethernet-services
user@host# set interfacetype-fpc/pic/port unit logical-unit-number encapsulation
vlan-vpls;
user@host# set interfacetype-fpc/pic/port unit logical-unit-number family bridge
interface-mode trunk
user@host# set interfacetype-fpc/pic/port unit logical-unit-number family bridge
vlan-id-list vlan-id-numbers
```

2. Configure the VPLS routing instance and specify the CE interface.

```
[edit routing-instances]
user@host# set routing-instance-name instance-type vpls;
user@host# set routing-instance-name interface interfacetype-fpc/pic/port
```

3. Configure MAC pinning on the VPLS CE interface.

```
[edit routing-instances]
```

```
user@host# set routing-instance-name protocols vpls interfacetype-fpc/pic/port
mac-pinning
```

4. In configuration mode, verify the configuration.

```
user@host# show interfaces
interfaces {
 interfacetype-fpc/pic/port {
 flexible-vlan-tagging;
 encapsulation flexible-ethernet-services;
 unit logical-unit-number {
 encapsulation vlan-vpls;
 }
 family bridge {
 interface-mode trunk;
 vlan-id-list vlan-id-numbers;
 }
 }
}
user@host# show routing-instances
routing-instances{
 routing-instance-name{
 instance-type vpls;
 interface interfacetype-fpc/pic/port;
 protocols{
 vpls {
 interface interfacetype-fpc/pic/port {
 mac-pinning;
 }
 }
 }
 }
}
```

## Configuring MAC Pinning on All Pseudowires of a Specific Neighbor of LDP-Based VPLS Routing Instance

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. To avoid loops across interfaces in virtual private LAN services (VPLS), you can configure MAC pinning.

This topic describes how to configure MAC pinning on all pseudowires of a specific neighbor of an LDP-based VPLS routing instance.

To configure MAC pinning on all pseudowires of a specific neighbor in a VPLS routing instance with LDP signaling:

1. Configure the interfaces as trunk interfaces and specify the list of VLAN IDs.

```

[edit interfaces]
user@host# set interfacetype-fpc/pic/port flexible-vlan-tagging
user@host# set interfacetype-fpc/pic/port encapsulation flexible-ethernet-services
user@host# set interfacetype-fpc/pic/port unit logical-unit-number encapsulation
 vlan-vpls;
user@host# set interfacetype-fpc/pic/port unit logical-unit-number family bridge
 interface-mode trunk
user@host# set interfacetype-fpc/pic/port unit logical-unit-number family bridge
 vlan-id-list vlan-id-numbers

```

2. Configure the VPLS routing instance and specify the trunk interface.

```
[edit routing-instances]
user@host# set routing-instance-name instance-type vpls;
user@host# set routing-instance-name interface interfacetype-fpc/pic/port;
```

3. Configure the routing protocol and specify the trunk interface and the VPLS identifier.

```
[edit routing-instances]
user@host# set routing-instance-name protocols vpls interface
interfacetype-fpc/pic/port
user@host# set routing-instance-name protocols vpls vpls-id vpls-id
```

4. Configure MAC pinning after specifying the neighbor ID.

```
user@host# set routing-instance-name protocols vpls neighbor neighbor-id mac-pinning
```

5. In configuration mode, verify the configuration.

```
user@host# show interfaces
interfaces {
 interfacetype-fpc/pic/port {
 flexible-vlan-tagging;
 encapsulation flexible-ethernet-services;
 unit logical-unit-number {
 encapsulation vlan-vpls;
 family bridge {
 interface-mode trunk ;
 vlan-id-list vlan-id-numbers;
 }
 }
 }
}
user@host# show routing-instances
routing-instances{
 routing-instance-name {
 instance-type vpls;
 interface interfacetype-fpc/pic/port;
 protocols{
 vpls {
 interface interfacetype-fpc/pic/port;
 vpls-id vpls-id;
 neighbor neighbor-id {
 mac-pinning;
 }
 }
 }
 }
}
```

## Configuring MAC Pinning on Access Interfaces for Logical Systems

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. To avoid loops across interfaces in logical systems, you can configure MAC pinning. A set of logical systems within a single router can handle the functions previously handled by several small routers.

This topic describes how to configure MAC pinning on access interfaces of a logical system.

To configure MAC pinning on access interfaces in logical systems:

1. Configure the access interface.

[edit interfaces]

```
user@host# set interfacetype-fpc/pic/port encapsulation ethernet-vpls
```

2. Create the logical system by specifying the name of the logical system, and specify the access interface and list of VLAN IDs associated with the interface.

[edit]

```
user@host# set logical-systems logical-system-name interfaces
interfacetype-fpc/pic/port unit logical-unit-number family bridge interface-mode
access vlan-id vlan-id
```

3. Configure MAC pinning on the access interface by including the [mac-pinning] statement in the [edit bridge-domains] hierarchy.

[edit bridge-domains]

```
user@host# set bridge-domain-name bridge-options interface
interfacetype-fpc/pic/port mac-pinning
```

4. In configuration mode, verify the configuration.

```
user@host# show interfaces
```

```
interfaces {
 interfacetype-fpc/pic/port {
 encapsulation ethernet-vpls;
 }
}
```

```
user@host# show logical-systems
```

```

logical-systems {
 logical-system-name {
 interfaces {
 interfacetype-fpc/pic/port {
 unit logical-unit-number {
 family bridge {
 interface-mode access;

## Configuring MAC Pinning on Trunk Interfaces for Logical Systems

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. To avoid loops across interfaces in logical systems, you can configure MAC pinning. A set of logical systems within a single router can handle the functions previously handled by several small routers.

This topic describes how to configure MAC pinning on trunk interfaces of a logical system.

To configure MAC pinning on trunk interfaces in logical systems:

1. Configure the interface and specify the encapsulation.

[edit interfaces]

```
user@host# set interfacetype-fpc/pic/port flexible-vlan-tagging
```

```
user@host# set interfacetype-fpc/pic/port encapsulation flexible-ethernet-services
```

2. Create the logical system by specifying the name of the logical system, and specify the trunk interface and list of VLAN IDs associated with the interface.

```
[edit]
user@host# set logical-systems logical-system-name interfaces
interfacetype-fpc/pic/port unit logical-unit-number encapsulation vlan-vpls family
bridge interface-mode trunk vlan-id-list vlan-id-numbers
```

3. Configure the bridge domain by specifying the VLAN ID parameter.

```
[edit bridge-domains]
user@host# set bridge-domain-name vlan-id all
```

4. Configure MAC pinning on the trunk interface by including the `[mac-pinning]` statement at the `[edit switch-options]` hierarchy level.

```
[edit switch-options]
user@host# set interface interfacetype-fpc/pic/port mac-pinning
```

5. In configuration mode, verify the configuration.

```
user@host# show interfaces
interfaces {
 interfacetype-fpc/pic/port {
 flexible-vlan-tagging;
 encapsulation flexible-ethernet-services;
 }
}

user@host# show logical-systems
logical-systems {
 logical-system-name {
 interfaces {
 interfacetype-fpc/pic/port
 {
 unit 0 {
 encapsulation vlan-vpls;
 family bridge {
 interface-mode trunk;
 vlan-id-list vlan-id-numbers;
 }
 }
 }
 }
}

user@host# show bridge-domains
bridge-domains {
 bridge-domain-name {
 vlan-id all;
 }
}

user@host# show switch-options
switch-options {
 interface interfacetype-fpc/pic/port {
 mac-pinning;
 }
}
}
```

## Configuring MAC Pinning on Access Interfaces in Virtual Switches for Logical Systems

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. To avoid loops across interfaces in virtual switches in logical systems, you can configure MAC pinning. A set of logical systems within a single router can handle the functions previously handled by several small routers.

This topic describes how to configure MAC pinning on access interfaces in virtual switch routing instance of a logical system.

To configure MAC pinning on access interfaces in virtual switches for logical systems:

1. Configure the interface and specify the encapsulation.

[edit interfaces]

```
user@host# set interfacetype-fpc/pic/port encapsulation ethernet-vpls
```

2. Create the logical system by specifying the name of the logical system, and specify the access interface.

[edit ]

```
user@host# set logical-systems logical-system-name interfaces
 interfacetype-fpc/pic/port unit logical-unit-number family bridge interface-mode
 access vlan-id vlan-id
```

3. Configure the routing instance as virtual switch and specify the access interface.

[edit routing-instances]

```
user@host# set routing-instance-name instance-type virtual-switch;
user@host# set routing-instance-name interface interfacetype-fpc/pic/port
```

4. Configure the bridge domain and specify the list of VLAN IDs.

[edit routing-instances]

```
user@host# set routing-instance-name bridge-domains bridge-domain-name vlan-id-list
 vlan-id-numbers
user@host# set routing-instance-name bridge-domains bridge-domain-name
 bridge-options interface interfacetype-fpc/pic/port mac-pinning
```

5. In configuration mode, verify the configuration.

```
user@host# show interfaces
```

```

 interfaces {
 interfacetype-fpc/pic/port {
 encapsulation ethernet-vpls;
 }
 }

user@host# show logical-systems

## Configuring MAC Pinning on VPLS CE Interface for Logical Systems

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. To avoid loops across interfaces in virtual private LAN services (VPLS), you can configure MAC pinning.

This topic describes how to configure MAC pinning on a VPLS customer edge (CE) trunk interface in a logical system.

To configure MAC pinning for VPLS customer edge interface for logical systems:

1. Configure the interfaces by specifying the encapsulation.

```

[edit interfaces]
user@host# set interfacetype-fpc/pic/port flexible-vlan-tagging
user@host# set interfacetype-fpc/pic/port encapsulation flexible-ethernet-services

```

2. Create the logical system by specifying the name and the trunk interface on the logical unit.

```

[edit]
user@host# set logical-systems logical-system-name interfaces
 interfacetype-fpc/pic/port unit logical-unit-number encapsulation vpls family
 bridge interface-mode trunk vlan-id-list vlan-id-numbers

```

3. Configure the VPLS CE interface and VPLS routing instance.

```
[edit routing-instances]
user@host# set routing-instance-name instance-type vpls;
user@host# set routing-instance-name interface interfacetype-fpc/pic/port
```

4. Configure MAC pinning on the VPLS CE interface.

```
[edit routing-instances]
user@host# set routing-instance-name protocols vpls interfacetype-fpc/pic/port
mac-pinning
```

5. In configuration mode, verify the configuration.

```
user@host# show interfaces
interfaces {
 interfacetype-fpc/pic/port {
 flexible-vlan-tagging;
 encapsulation flexible-ethernet-services;
 }
}

user@host# show logical-systems
logical-systems {
 logical-system-name {
 interfaces {
 interfacetype-fpc/pic/port {
 unit logical-unit-number {
 encapsulation vlan-vpls;
 family bridge {
 interface-mode trunk;
 vlan-id-list vlan-id-numbers;
 }
 }
 }
 }
 }
}

user@host# show routing-instances
routing-instances{
 routing-instance-name {
 instance-type vpls;
 interface interfacetype-fpc/pic/port;
 }
 protocols{
 vpls {
 interface interfacetype-fpc/pic/port {
 mac-pinning;
 }
 }
 }
}
```

## Configuring MAC Pinning for All Pseudowires of the VPLS Site in a BGP-Based VPLS Routing Instance for Logical Systems

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. To avoid loops across interfaces in virtual private LAN services (VPLS), you can configure MAC pinning.

This topic describes how to configure MAC pinning for all pseudowires of the VPLS site in a BGP-based VPLS routing instance for a logical system.

To configure MAC pinning for all pseudowires in a BGP-based VPLS Routing instance for a logical system:

1. Configure the interface by specifying the encapsulation.

```
[edit interfaces]
user@host# set interfacetype-fpc/pic/port flexible-vlan-tagging
user@host# set interfacetype-fpc/pic/port encapsulation flexible-ethernet-services
```

2. Create the logical system and specify the trunk interface and list of VLAN IDs on the logical unit.

```
[edit]
user@host# set logical-systems logical-system-name interfaces
 interfacetype-fpc/pic/port unit logical-unit-number encapsulation vlan-vpls family
 bridge interface-mode trunk vlan-id-list vlan-id-numbers
```

3. Configure the VPLS routing instance and specify the trunk interface.

```
[edit routing-instances]
user@host# set routing-instance-name instance-type vpls;
user@host# set routing-instance-name interface interfacetype-fpc/pic/port
```

4. Configure MAC pinning after specifying the routing protocol and the trunk interface.

```
[edit routing-instances]
user@host# set routing-instance-name protocols vpls interface
 interfacetype-fpc/pic/port
user@host# set routing-instance-name protocols vpls site site-name mac-pinning
```

5. In configuration mode, verify the configuration.

```
user@host# show interfaces
 interfaces {
 interfacetype-fpc/pic/port {
 flexible-vlan-tagging;
 encapsulation flexible-ethernet-services;
 }
 }

user@host# show logical-systems
 logical-systems {
 logical-system-name {
```

```

 interfaces {
 interfacetype-fpc/pic/port {
 unit logical-unit-number {
 encapsulation vlan-vpls;
 family bridge {
 interface-mode trunk;
 vlan-id-list vlan-id-numbers;
 }
 }
 }
 }

 routing-instances{
 routing-instance-name {
 instance-type vpls;
 interface interfacetype-fpc/pic/port;
 protocols{
 vpls {
 interface interfacetype-fpc/pic/port;
 site site-name {
 mac-pinning;
 }
 }
 }
 }
}

```

## Configuring MAC Pinning on All Pseudowires of a Specific Neighbor of LDP-Based VPLS Routing Instance for Logical Systems

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. To avoid loops across interfaces in virtual private LAN services (VPLS), you can configure MAC pinning.

This topic describes how to configure MAC pinning on all pseudowires of a specific neighbor of an LDP-based VPLS routing instance for logical systems.

To configure MAC pinning on all pseudowires of a specific neighbor in a VPLS routing instance with LDP signaling for logical systems:

1. Configure the interfaces by specifying the encapsulation.

[edit interfaces]

user@host# **set interfacetype-fpc/pic/port flexible-vlan-tagging**

user@host# **set interfacetype-fpc/pic/port encapsulation flexible-ethernet-services**

2. Create the logical system interface by specifying the name of the logical system and specifying the trunk interface on the logical unit.

```
[edit]
user@host# set logical-systems logical-system-name interfaces
interfacetype-fpc/pic/port unit logical-unit-number encapsulation vlan-vpls family
bridge interface-mode trunk vlan-id-list vlan-id-numbers
```

3. Configure the VPLS routing instance and specify the interface.

```
[edit routing-instances]
user@host# set routing-instance-name instance-type vpls
user@host# set routing-instance-name interface interfacetype-fpc/pic/port
```

4. Configure the routing protocol and specify the trunk interface and the VPLS identifier.

```
[edit routing-instances]
user@host# set routing-instance-name protocols vpls interface
interfacetype-fpc/pic/port
user@host# set routing-instance-name protocols vpls vpls-id vpls-id
```

5. Configure MAC pinning after specifying the neighbor ID.

```
user@host# set routing-instance-name protocols vpls neighbor neighbor-id mac-pinning
```

6. In configuration mode, verify the configuration.

```
user@host# show interfaces
interfaces {
 interfacetype-fpc/pic/port {
 flexible-vlan-tagging;
 encapsulation flexible-ethernet-services;
 }
}

user@host# show logical-systems
logical-systems {
 logical-system-name {
 interfaces {
 interfacetype-fpc/pic/port {
 unit logical-unit-number {
 encapsulation vlan-vpls;
 family bridge {
 interface-mode trunk;
 vlan-id-list vlan-id-numbers;
 }
 }
 }
 }
 }
}

user@host# show routing-instance
routing-instances{
 routing-instance-name {
 instance-type vpls;
 interface interfacetype-fpc/pic/port;
 }
 protocols{
 vpls {
 interface interfacetype-fpc/pic/port;
```

```
vpls-id vpls-id;
 neighbor neighbor-id {
 mac-pinning;
 }
}
```

## Example: Prevention of Loops in Bridge Domains by Enabling the MAC Pinning Feature on Access Interfaces

---

This example shows how to avoid loops in bridge domains by enabling the MAC pinning feature on access interfaces.

- [Requirements on page 1576](#)
- [Overview on page 1576](#)
- [Configuration on page 1577](#)
- [Verification on page 1579](#)

### Requirements

This example uses the following hardware and software components:

- MX Series 3D Universal Edge Routers
- Junos OS Release 16.1 running on the routers

### Overview

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. Loops can occur in Layer 2 bridges and in VPLS networks. To avoid loops, you can enable the MAC pinning feature on the interfaces. The MAC pinning feature is applicable only when dynamic learning of MAC addresses over interfaces is enabled.

This example shows how to enable MAC pinning on two access interfaces in a bridge domain.

#### Topology

---

In this example, you configure the interfaces **ge-4/0/6** and **xe-4/2/0** on the MX Series router as access interfaces. Access interfaces accept both untagged and tagged packets and forward the packets within a specified bridge domain, **bd1**. Specify **1** as the VLAN ID for the interfaces and the bridge domain. When an untagged or a tagged packet is received

on any of the access interfaces, the packet is accepted, the VLAN ID is added to the packet, and the packet is forwarded within the bridge domain that is configured with the matching ID.

In the bridge domain, after specifying the VLAN ID, specify **131071** as the maximum number of MAC addresses that can be learned on the access interfaces and specify **1048575** as the size of the MAC address table for the bridge domain or VLAN.

In this topology, frequent MAC moves can occur, which can result in loops. To prevent these loops, you can configure MAC pinning. When you configure MAC pinning on an interface, the MAC address learned on the interface cannot be learned on another interface in the same bridge domain. For example, configure MAC pinning on the access interface **ge-4/0/6**. When a packet is received on this interface, the packet is accepted, the VLAN ID is added and the packet is forwarded within the bridge domain with the matching ID. However, if a packet with the same MAC address is received on any other access interface, say **xe-4/2/0**, the packet is discarded or dropped as that MAC address is pinned to the access interface **ge-4/0/6**. This behavior is common to all access interfaces configured on the router, regardless of whether access pinning is enabled on the access interface or not.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set interfaces ge-4/0/6 encapsulation ethernet-bridge
set interfaces ge-4/0/6 unit 0 family bridge interface-mode access
set interfaces ge-4/0/6 unit 0 family bridge vlan-id 1
set interfaces xe-4/2/0 encapsulation ethernet-bridge
set interfaces xe-4/2/0 unit 0 family bridge interface-mode access
set interfaces xe-4/2/0 unit 0 family bridge vlan-id 1
set bridge-domains bd1 vlan-id 1
set bridge-domains bd1 bridge-options mac-table-size 1048575
set bridge-domains bd1 bridge-options interface ge-4/0/6.0 interface-mac-limit 131071
set bridge-domains bd1 bridge-options interface ge-4/0/6.0 mac-pinning
set bridge-domains bd1 bridge-options interface xe-4/2/0.0 interface-mac-limit 131071
set bridge-domains bd1 bridge-options interface xe-4/2/0.0 mac-pinning
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure MAC pinning on access interfaces in bridge domains:

1. Configure both the interfaces as access interfaces and specify the VLAN ID.

```
[edit interfaces]
user@host# set interfaces ge-4/0/6 encapsulation ethernet-bridge
user@host# set interfaces ge-4/0/6 unit 0 family bridge interface-mode access
user@host# set interfaces ge-4/0/6 unit 0 family bridge vlan-id 1
user@host# set interfaces xe-4/2/0 encapsulation ethernet-bridge
```

```
user@host# set interfaces xe-4/2/0 unit 0 family bridge interface-mode access
user@host# set interfaces xe-4/2/0 unit 0 family bridge vlan-id 1
```

2. Specify the name of the bridge domain.

```
[edit bridge-domains]
user@host# set bridge-domains bd1 vlan-id 1
```

3. Specify the size of the MAC address table for the bridge domain.

```
[edit bridge-domains]
user@host# set bridge-domains bd1 bridge-options mac-table-size 1048575
```

4. Specify the maximum number of MAC addresses that can be learned on both the access interfaces.

```
[edit bridge-domains]
user@host# set bridge-domains bd1 bridge-options interface ge-4/0/6.0
interface-mac-limit 131071
user@host# set bridge-domains bd1 bridge-options interface xe-4/2/0.0
interface-mac-limit 131071
```

5. Configure MAC pinning on both the access interfaces.

```
[edit bridge-domains]
user@host# set bridge-domains bd1 bridge-options interface ge-4/0/6.0
mac-pinning
user@host# set bridge-domains bd1 bridge-options interface xe-4/2/0.0
mac-pinning
```

---

## Results

From configuration mode, confirm your configuration by entering **show interfaces** and **show bridge-domains** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show interfaces
ge-4/0/6 {
 encapsulation ethernet-bridge;
 unit 0 {
 family bridge {
 interface-mode access;
 vlan-id 1;
 }
 }
}
xe-4/2/0 {
 encapsulation ethernet-bridge;
 unit 0 {
 family bridge {
 interface-mode access;
 vlan-id 1;
 }
 }
}
```

```
 }
 }
user@host# show bridge-domains
bridge-domains {
 bd1 {
 vlan-id 1;
 bridge-options {
 mac-table-size {
 1048575;
 }
 interface ge-4/0/6.0 {
 interface-mac-limit {
 131071;
 }
 mac-pinning;
 }
 interface xe-4/2/0.0 {
 interface-mac-limit {
 131071;
 }
 mac-pinning;
 }
 }
 }
}
```

If you have completed configuring the device, enter **commit** from the configuration mode.

## Verification

### Verifying That MAC Pinning Is Configured Correctly

**Purpose** Ensure that MAC pinning has been enabled on the access interfaces.

**Action** From operational mode, enter the **show l2-learning interface** command.

```

user@host> show l2-learning interface
Routing Instance Name : default-switch
Logical Interface flags (DL -disable learning, AD -packet action drop,
 LH - MAC limit hit, DN - Interface Down, MP - MAC Pinning)
Logical BD MAC STP Logical
Interface Name Limit State Interface flags
xe-4/0/6.0 MP
 BD_Tr.. 131000 Forwarding
 BD_Tr.. 131000 Forwarding
 BD_Tr.. 131000 Forwarding
 BD_Tr.. 131000 Forwarding
 BD_Tr.. 131000 Forwarding
Routing Instance Name : default-switch
Logical Interface flags (DL -disable learning, AD -packet action drop,
 LH - MAC limit hit, DN - Interface Down, MP - MAC Pinning)
Logical BD MAC STP Logical
Interface Name Limit State Interface flags
xe-4/2/0.0 MP
 BD_Tr.. 131000 Forwarding
 BD_Tr.. 131000 Forwarding
 BD_Tr.. 131000 Forwarding
 BD_Tr.. 131000 Forwarding
 BD_Tr.. 131000 Forwarding

```

**Meaning** The **Interface flags** field indicates the interfaces that have MAC pinning enabled.

## Example: Prevention of Loops in Bridge Domains by Enabling the MAC Pinning Feature on Trunk Interfaces

This example shows how to avoid loops in bridge domains by enabling the MAC pinning feature on trunk interfaces.

- [Requirements on page 1581](#)
- [Overview on page 1581](#)
- [Configuration on page 1581](#)
- [Verification on page 1586](#)

## Requirements

This example uses the following hardware and software components:

- MX Series 3D Universal Edge Routers
- Junos OS Release 16.1 running on the routers

## Overview

A MAC move occurs when a MAC address frequently appears on a different physical interface than the one it was learned on. Frequent MAC moves indicate the presence of loops. Loops can occur in Layer 2 bridges and in VPLS networks. To avoid loops, you can enable the MAC pinning feature on the interfaces. The MAC pinning feature is applicable only when dynamic learning of MAC addresses over interfaces is enabled.

This example shows how to enable MAC pinning on three aggregated trunk interfaces in a bridge domain.

### Topology

In this example, you configure the interfaces **xe-0/1/1** and **xe-0/3/1** on the MX Series router as an aggregated Ethernet interface, **ae1**. You can configure the other four interfaces, **ge-4/0/6**, **ge-4/1/6**, **xe-4/2/0**, and **xe-4/3/0**, as aggregated Ethernet interfaces, **ae2** and **ae3**. Each of these aggregated Ethernet interfaces are configured as trunk interfaces. Trunk interfaces accept only tagged packets and forward the packets within a specified bridge domain, **BD\_Trunk\_all**. Specify the list of VLAN IDs for the interfaces and the bridge domain. When a tagged packet is received on any of the aggregated trunk interfaces, the packet is accepted, and the packet is forwarded within the bridge domain that is configured with the matching ID.

In the bridge domain, after specifying the VLAN ID, specify **131000** as the maximum number of MAC addresses that can be learned on each of the aggregated Ethernet trunk interfaces and specify **1048575** as the size of the MAC address table for the bridge domain or VLAN.

In this topology, frequent MAC moves can occur, which can result in loops. To prevent these loops, you can configure MAC pinning. When you configure MAC pinning on an interface, the MAC address learned on the interface cannot be learned on another interface in the same bridge domain. For example, configure MAC pinning on the aggregated Ethernet interface **ae1**. When a packet is received on this interface, the packet is accepted, and the packet is forwarded within the bridge domain with the matching ID. However, if a packet with the same MAC address is received on any other trunk interface, say **ae2**, the packet is discarded or dropped as that MAC address is pinned to the trunk interface **ae1**. This behavior is common to all trunk interfaces configured on the router, regardless of whether access pinning is enabled on the trunk interface or not.

## Configuration

|                                |                                                                                                                                                                         |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

set switch-options interface ae3.0 mac-pinning

```

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure MAC pinning on trunk interfaces in bridge domains:

1. Configure the interfaces as member aggregated Ethernet interfaces.

```
[edit interfaces]
```

```

user@host# set interfaces xe-0/1/1 gigether-options 802.3ad ae1
user@host# set interfaces xe-0/3/1 gigether-options 802.3ad ae1
user@host# set interfaces ge-4/0/6 gigether-options 802.3ad ae3
user@host# set interfaces ge-4/1/6 gigether-options 802.3ad ae3
user@host# set interfaces xe-4/2/0 gigether-options 802.3ad ae2
user@host# set interfaces xe-4/3/0 gigether-options 802.3ad ae2

```

2. Configure the aggregated Ethernet interfaces as trunk interfaces and specify the list of VLAN IDs.

```

user@host# set interfaces ae1 flexible-vlan-tagging
user@host# set interfaces ae1 encapsulation flexible-ethernet-services
user@host# set interfaces ae1 unit 0 family bridge interface-mode trunk
user@host# set interfaces ae1 unit 0 family bridge vlan-id-list 1-5
user@host# set interfaces ae2 flexible-vlan-tagging
user@host# set interfaces ae2 encapsulation flexible-ethernet-services
user@host# set interfaces ae2 unit 0 family bridge interface-mode trunk
user@host# set interfaces ae2 unit 0 family bridge vlan-id-list 1-5
user@host# set interfaces ae3 flexible-vlan-tagging
user@host# set interfaces ae3 encapsulation flexible-ethernet-services
user@host# set interfaces ae3 unit 0 family bridge interface-mode trunk
user@host# set interfaces ae3 unit 0 family bridge vlan-id-list 1-5

```

3. Specify the name of the bridge domain.

```

[edit bridge-domains]
user@host# set bridge-domains BD_Trunk_all vlan-id-list 1-5

```

4. Specify the size of the MAC address table for the bridge domain.

```

user@host# set bridge-domains BD_Trunk_all bridge-options mac-table-size
1048575

```

5. Specify the maximum number of MAC addresses that can be learned on all three trunk interfaces.

```

user@host# set bridge-domains BD_Trunk_all bridge-options interface ae1.0
interface-mac-limit 131000
user@host# set bridge-domains BD_Trunk_all bridge-options interface ae2.0
interface-mac-limit 131000
user@host# set bridge-domains BD_Trunk_all bridge-options interface ae3.0
interface-mac-limit 131000

```

6. Configure MAC pinning on each of the aggregated Ethernet interfaces at the **[edit switch-options]** hierarchy level.

```

[edit switch-options]
user@host# set switch-options interface ae1.0 interface-mac-limit 131000
user@host# set switch-options interface ae1.0 mac-pinning
user@host# set switch-options interface ae2.0 interface-mac-limit 131000
user@host# set switch-options interface ae2.0 mac-pinning
user@host# set switch-options interface ae3.0 interface-mac-limit 131000
user@host# set switch-options interface ae3.0 mac-pinning

```

## Results

From configuration mode, confirm your configuration by entering **show interfaces** and **show bridge-domains** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@host# show interfaces
interfaces {
 xe-0/0/0 {

```

```
flexible-vlan-tagging;
encapsulation flexible-ethernet-services;
unit 0 {
 family bridge {
 interface-mode trunk;
 vlan-id-list 1-5;
 }
}
xe-0/1/1 {
 gigether-options {
 802.3ad ae1;
 }
}
xe-0/3/1 {
 gigether-options {
 802.3ad ae1;
 }
}
ge-4/0/6 {
 gigether-options {
 802.3ad ae3;
 }
}
ge-4/1/6 {
 gigether-options {
 802.3ad ae3;
 }
}
xe-4/2/0 {
 gigether-options {
 802.3ad ae2;
 }
}
xe-4/3/0 {
 gigether-options {
 802.3ad ae2;
 }
}
ae1 {
 flexible-vlan-tagging;
 encapsulation flexible-ethernet-services;
 unit 0 {
 family bridge {
 interface-mode trunk;
 vlan-id-list 1-5;
 }
 }
}
ae2 {
 flexible-vlan-tagging;
 encapsulation flexible-ethernet-services;
 unit 0 {
 family bridge {
 interface-mode trunk;
 vlan-id-list 1-5;
 }
 }
}
ae3 {
 flexible-vlan-tagging;
```

```

 encapsulation flexible-ethernet-services;
 unit 0 {
 family bridge {
 interface-mode trunk;
 vlan-id-list 1-5;
 }
 }
 }
}

```

user@host# show bridge-domains

```

bridge-domains {
 BD_Trunk_all {
 vlan-id-list 1-5;
 bridge-options {
 mac-table-size {
 1048575;
 }
 interface ae1.0 {
 interface-mac-limit {
 131000;
 }
 }
 interface ae2.0 {
 interface-mac-limit {
 131000;
 }
 }
 interface ae3.0 {
 interface-mac-limit {
 131000;
 }
 }
 }
 }
}

```

user@host# show switch-options

```

switch-options {
 interface ae1.0 {
 interface-mac-limit {
 131000;
 }
 mac-pinning;
 }
 interface ae2.0 {
 interface-mac-limit {
 131000;
 }
 mac-pinning;
 }
 interface ae3.0 {
 interface-mac-limit {
 131000;
 }
 mac-pinning;
 }
}

```

If you have completed configuring the device, enter **commit** from the configuration mode.

## Verification

### Verifying that MAC Pinning Is Configured Correctly

**Purpose** Ensure that MAC pinning is enabled on the trunk interfaces.

**Action** From operational mode, enter the **show l2-learning interface** command.

```
user@host> show l2-learning interface
Routing Instance Name : default-switch
Logical Interface flags (DL -disable learning, AD -packet action drop,
 LH - MAC limit hit, DN - Interface Down, MP - MAC Pinning)

## Configuring Improved VPLS MAC Address Learning on T4000 Routers with Type 5 FPCs

Junos OS Release 12.3 enables improved virtual private LAN service (VPLS) MAC address learning on T4000 routers with Type 5 FPCs by supporting up to 262,143 MAC addresses per VPLS routing instance. In Junos OS releases before Release 12.3, T4000 routers with Type 5 FPCs support only 65,535 MAC addresses per VPLS routing instance.

Before you begin, configure VPLS. See [“Configuring VPLS Routing Instances” on page 1173](#).

To enable improved VPLS MAC address learning on T4000 routers with Type 5 FPCs:

1. Enable the network services mode by including the **enhanced-mode** statement at the **[edit chassis network-services]** hierarchy level.

```
[edit chassis network-services]
user@host# set enhanced-mode
```

**NOTE:** After you configure the **enhanced-mode** statement and commit your configuration, a warning message prompts you to reboot the router.

2. Perform a system reboot in operational mode.

```
user@host> request system-reboot
```

After the router reboots, only the T4000 Type 5 FPCs are online while the remaining FPCs are offline. You can verify the status of the FPCs by using the **show chassis fpc operational mode** command.

3. Modify the size of the VPLS MAC address table at the **[edit routing-instance instance-name protocols vpls]** hierarchy level.

```
[edit routing-instance instance-name protocols vpls]
user@host# set mac-table-size size
```

For example, to set the MAC address learning limit to 262,143 addresses for each **vpls** routing instance:

```
[edit routing-instance vpls protocols vpls]
user@host# set mac-table-size 262143
```

**NOTE:** The `enhanced-mode` statement supports up to 262,143 MAC addresses per VPLS routing instance. However, the MAC address learning limit for each interface remains the same (that is, 65,535 MAC addresses).

4. In configuration mode, verify the configuration.

```
user@host# show routing-instances instance-name
vpls {
 instance-type vpls;
 protocols {
 vpls {
 mac-table-size {
 262143;
 }
 }
 }
}
```

To disable the improved VPLS MAC address learning feature on T4000 routers with Type 5 FPCs, include the `delete chassis network-services enhanced-mode` statement at the `[edit]` hierarchy level.

**NOTE:** After you disable network services mode and commit your configuration, a warning message prompts you to reboot the router. You must reboot the router. Continuing without a reboot might result in unexpected system behavior.

# Configuring Class of Service and Firewall Filters in VPLS

- [Configuring EXP-Based Traffic Classification for VPLS on page 1589](#)
- [Configuring Firewall Filters and Policers for VPLS on page 1589](#)
- [Firewall Filter Match Conditions for VPLS Traffic on page 1594](#)

## Configuring EXP-Based Traffic Classification for VPLS

---

You can enable EXP classification on traffic entering core facing VPLS LSI interfaces on a VPLS routing instance by configuring either a logical tunnel interface (**lt-**) or the **no-tunnel-services** statement. By configuring either of these, a default EXP classifier is enabled on every core facing interface that includes **family mpls** in its configuration. This feature works on MX Series routers and EX Series switches only. You can configure an EXP classifier explicitly at the **[edit class-of-service]** hierarchy level. For more information about EXP classifiers, see the *Class of Service Feature Guide for Routing Devices*.

To enable EXP classification on traffic entering core facing VPLS LSI interfaces on a VPLS routing instance, include the **no-tunnel-services** statement:

```
no-tunnel-services;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name* protocols vpls]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]**

- [Configuring Firewall Filters and Policers for VPLS on page 1589](#)
- [Firewall Filter Match Conditions for VPLS Traffic on page 1594](#)

## Configuring Firewall Filters and Policers for VPLS

---

You can configure both firewall filters and policers for VPLS. Firewall filters allow you to filter packets based on their components and to perform an action on packets that match

the filter. Policers allow you to limit the amount of traffic that passes into or out of an interface.

VPLS filters and policers act on a Layer 2 frame that includes the media access control (MAC) header (after any VLAN rewrite or other rules are applied), but does not include the cyclical redundancy check (CRC) field.

You can apply VPLS filters and policers on the PE router to customer-facing interfaces only.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

**NOTE:** The behavior of firewall filters processing with MAC addresses differs between DPCs and MPCs. On MPCs, interface filters are always applied before MAC learning occurs. The input forwarding table filter is applied after MAC learning is completed. However, on DPCs, MAC learning occurs independently of the application of filters. If the CE-facing interface of the PE where the firewall filter is applied is an MPC, then the MAC entry times out and is never learned again. However, if the CE-facing interface of the PE where the firewall filter is applied is an DP, then the MAC entry is not timed out and if the MAC address entry is manually cleared, it is relearned.

The following sections explain how to configure filters and policers for VPLS:

- [Configuring a VPLS Filter on page 1590](#)
- [Configuring a VPLS Policer on page 1593](#)

## Configuring a VPLS Filter

To configure a filter for VPLS, include the **filter** statement at the **[edit firewall family vpls]** hierarchy level:

```
[edit firewall family vpls]
filter filter-name {
 interface-specific;
 term term-name {
 from {
 match-conditions;
 }
 then {
 actions;
 }
 }
}
```

For more information about how to configure firewall filters, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*. For information on how to configure a

VPLS filter match condition, see “Firewall Filter Match Conditions for VPLS Traffic” on page 1594.

To configure a filter for VPLS traffic, complete the following tasks:

- [Configuring an Interface-Specific Counter for VPLS on page 1591](#)
- [Configuring an Action for the VPLS Filter on page 1591](#)
- [Configuring VPLS FTFs on page 1591](#)
- [Changing Precedence for Spanning-Tree BPDU Packets on page 1592](#)
- [Applying a VPLS Filter to an Interface on page 1592](#)
- [Applying a VPLS Filter to a VPLS Routing Instance on page 1592](#)
- [Configuring a Filter for Flooded Traffic on page 1593](#)

### Configuring an Interface-Specific Counter for VPLS

When you configure a firewall filter for VPLS and apply it to multiple interfaces, you can specify individual counters specific to each interface. This allows you to collect separate statistics on the traffic transiting each interface.

To generate an interface-specific counter for VPLS, you configure the **interface-specific** statement. A separate instantiation of the filter is generated. This filter instance has a different name (based on the interface name) and collects statistics on the interface specified only.

To configure interface-specific counters, include the **interface-specific** statement at the **[edit firewall family vpls filter *filter-name*]** hierarchy level:

```
[edit firewall family vpls filter filter-name]
interface-specific;
```

**NOTE:** The counter name is restricted to 24 bytes. If the renamed counter exceeds this maximum length, it might be rejected.

### Configuring an Action for the VPLS Filter

You can configure the following actions for a VPLS filter at the **[edit firewall family vpls filter *filter-name* term *term-name* then]** hierarchy level: **accept**, **count**, **discard**, **forwarding-class**, **loss-priority**, **next**, **policer**.

### Configuring VPLS FTFs

Forwarding table filters (FTFs) are filters configured for forwarding tables. For VPLS, they are attached to the destination MAC (DMAC) forwarding table of the VPLS routing instance. You define VPLS FTFs in the same manner as any other type of FTF. You can only apply a VPLS FTF as an input filter.

To specify a VPLS FTF, include the **filter input** statement at the **[edit routing-instance *routing-instance-name* forwarding-options family vpls]** hierarchy level:

```
[edit routing-instance routing-instance-name forwarding-options family vpls]
```

filter input *filter-name*;

### Changing Precedence for Spanning-Tree BPDU Packets

Spanning tree BPDU packets are automatically set to a high precedence. The queue number on these packets is set to 3. On M Series routers (except the M320 router) by default, a queue value of 3 indicates high precedence. To enable this higher precedence on BPDU packets, an instance-specific BPDU precedence filter named **default\_bpdu\_filter** is automatically attached to the VPLS DMAC table. This filter places a high precedence on all packets sent to **01:80:c2:00:00:00/24**.

You can overwrite this filter by configuring a VPLS FTF filter and applying it to the VPLS routing instance. For more information, see [“Configuring VPLS FTFs” on page 1591](#) and [“Applying a VPLS Filter to a VPLS Routing Instance” on page 1592](#).

### Applying a VPLS Filter to an Interface

To apply a VPLS filter to an interface, include the **filter** statement:

```
filter {
 group index;
 input input-filter-name;
 output output-filter-name;
}
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *number* family vpls]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *number* family vpls]

**NOTE:** ACX Series routers do not support the [edit logical-systems] hierarchy.

In the **input** statement, list the name of the VPLS filter to be evaluated when packets are received on the interface. In the **output** statement, list the name of the VPLS filter to be evaluated when packets are transmitted on the interface.

**NOTE:** For output interface filters, MAC addresses are learned after the filter action is completed. When an output interface filter's action is **discard**, the packet is dropped before the MAC address is learned. However, an input interface filter learns the MAC address before discarding the packet.

### Applying a VPLS Filter to a VPLS Routing Instance

You can apply a VPLS filter to a VPLS routing instance. The filter checks traffic passing through the specified routing instance.

Input routing instance filters learn the MAC address before the filter action is completed, so if the filter action is **discard**, the MAC address is learned before the packet is dropped.

To apply a VPLS filter to packets arriving at a VPLS routing instance and specify the filter, include the **filter input** statement at the **[edit routing-instances *routing-instance-name* forwarding-options family vpls]** hierarchy level:

```
[edit routing-instances routing-instance-name forwarding-options family vpls]
filter input input-filter-name;
```

### Configuring a Filter for Flooded Traffic

---

You can configure a VPLS filter to filter flooded packets. CE routers typically flood the following types of packets to PE routers in VPLS routing instances:

- Layer 2 broadcast packets
- Layer 2 multicast packets
- Layer 2 unicast packets with an unknown destination MAC address
- Layer 2 packets with a MAC entry in the DMAC routing table

You can configure filters to manage how these flooded packets are distributed to the other PE routers in the VPLS routing instance.

To apply a flooding filter to packets arriving at the PE router in the VPLS routing instance, and specify the filter, include the **flood input** statement:

```
flood input filter-name;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name* forwarding-options family vpls]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* forwarding-options family vpls]**

**NOTE:** ACX Series routers do not support the **[edit logical-systems]** hierarchy.

---

### Configuring a VPLS Policer

You can configure a policer for VPLS traffic. The VPLS policer configuration is similar to the configuration of any other type of policer.

VPLS policers have the following characteristics:

- You cannot police the default VPLS routes stored in the flood table from PE router-sourced flood traffic.
- When specifying policing bandwidth, the VPLS policer considers all Layer 2 bytes in a packet to determine the packet length.

To configure a VPLS policer, include the **policer** statement at the **[edit firewall]** hierarchy level:

```
[edit firewall]
```

```
policer policer-name {
 bandwidth-limit limit;
 burst-size-limit limit;
 then action;
}
```

To apply a VPLS policer to an interface, include the **policer** statement:

```
policer {
 input input-policer-name;
 output output-policer-name;
}
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *number* family vpls]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *number* family vpls]

**NOTE:** ACX Series routers do not support the [edit logical-systems] hierarchy.

---

In the **input** statement, list the name of the VPLS policer to be evaluated when packets are received on the interface. In the **output** statement, list the name of the VPLS policer to be evaluated when packets are transmitted on the interface. This type of VPLS policer can only apply to unicast packets. For information about how to filter flood packets, see [“Configuring a Filter for Flooded Traffic” on page 1593](#).

---

## Firewall Filter Match Conditions for VPLS Traffic

---

In the **from** statement in the VPLS filter term, you specify conditions that the packet must match for the action in the **then** statement to be taken. All conditions in the **from** statement must match for the action to be taken. The order in which you specify match conditions is not important, because a packet must match all the conditions in a term for a match to occur.

If you specify no match conditions in a term, that term matches all packets.

An individual condition in a **from** statement can contain a list of values. For example, you can specify numeric ranges. You can also specify multiple source addresses or destination addresses. When a condition defines a list of values, a match occurs if one of the values in the list matches the packet.

Individual conditions in a **from** statement can be negated. When you negate a condition, you are defining an explicit mismatch. For example, the negated match condition for **forwarding-class** is **forwarding-class-except**. If a packet matches a negated condition, it

is immediately considered not to match the **from** statement, and the next term in the filter is evaluated, if there is one. If there are no more terms, the packet is discarded.

You can configure a firewall filter with match conditions for Virtual Private LAN Service (VPLS) traffic (**family vpls**). Table 34 on page 1595 describes the **match-conditions** you can configure at the `[edit firewall family vpls filter filter-name term term-name from]` hierarchy level.

**NOTE:** Not all match conditions for VPLS traffic are supported on all routing platforms or switching platforms. A number of match conditions for VPLS traffic are supported only on MX Series 3D Universal Edge Routers.

In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

**Table 34: Firewall Filter Match Conditions for VPLS Traffic**

| Match Condition                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>destination-mac-address address</b>     | Match the destination media access control (MAC) address of a VPLS packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>destination-port number</b>             | <p>(MX Series routers and EX Series switches only) Match the UDP or TCP destination port field.</p> <p>You cannot specify both the <b>port</b> and <b>destination-port</b> match conditions in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the port numbers are also listed): <b>afs</b> (1483), <b>bgp</b> (179), <b>biff</b> (512), <b>bootpc</b> (68), <b>bootps</b> (67), <b>cmd</b> (514), <b>cvspserver</b> (2401), <b>dhcp</b> (67), <b>domain</b> (53), <b>eklogin</b> (2105), <b>ekshell</b> (2106), <b>exec</b> (512), <b>finger</b> (79), <b>ftp</b> (21), <b>ftp-data</b> (20), <b>http</b> (80), <b>https</b> (443), <b>ident</b> (113), <b>imap</b> (143), <b>kerberos-sec</b> (88), <b>klogin</b> (543), <b>kpasswd</b> (761), <b>krb-prop</b> (754), <b>krbupdate</b> (760), <b>kshell</b> (544), <b>ldap</b> (389), <b>ldp</b> (646), <b>login</b> (513), <b>mobileip-agent</b> (434), <b>mobileip-mn</b> (435), <b>msdp</b> (639), <b>netbios-dgm</b> (138), <b>netbios-ns</b> (137), <b>netbios-ssn</b> (139), <b>nfsd</b> (2049), <b>nntp</b> (119), <b>ntalk</b> (518), <b>ntp</b> (123), <b>pop3</b> (110), <b>pptp</b> (1723), <b>printer</b> (515), <b>radacct</b> (1813), <b>radius</b> (1812), <b>rip</b> (520), <b>rkinit</b> (2108), <b>smtp</b> (25), <b>snmp</b> (161), <b>snmptrap</b> (162), <b>snpp</b> (444), <b>socks</b> (1080), <b>ssh</b> (22), <b>sunrpc</b> (111), <b>syslog</b> (514), <b>tacacs</b> (49), <b>tacacs-ds</b> (65), <b>talk</b> (517), <b>telnet</b> (23), <b>tftp</b> (69), <b>timed</b> (525), <b>who</b> (513), or <b>xdmcp</b> (177).</p> |
| <b>destination-port-except number</b>      | <p>(MX Series routers and EX Series switches only) Do not match on the TCP or UDP destination port field. You cannot specify both the <b>port</b> and <b>destination-port</b> match conditions in the same term.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>destination-prefix-list name</b>        | <p>(ACX Series routers, MX Series routers, and EX Series switches only) Match destination prefixes in the specified list. Specify the name of a prefix list defined at the <code>[edit policy-options prefix-list prefix-list-name]</code> hierarchy level.</p> <p><b>NOTE:</b> VPLS prefix lists support only IPv4 addresses. IPv6 addresses included in a VPLS prefix list will be discarded.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>destination-prefix-list name except</b> | <p>(MX Series routers and EX Series switches only) Do not match destination prefixes in the specified list. For more information, see the <b>destination-prefix-list</b> match condition.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Table 34: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

| Match Condition                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dscp number</b>              | <p>(MX Series routers and EX Series switches only) Match the Differentiated Services code point (DSCP). The DiffServ protocol uses the type-of-service (ToS) byte in the IP header. The most significant 6 bits of this byte form the DSCP. For more information, see the <i>Understanding How Behavior Aggregate Classifiers Prioritize Trusted Traffic</i>.</p> <p>You can specify a numeric value from <b>0</b> through <b>63</b>. To specify the value in hexadecimal form, include <b>0x</b> as a prefix. To specify the value in binary form, include <b>b</b> as a prefix.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed):</p> <ul style="list-style-type: none"> <li>• RFC 3246, <i>An Expedited Forwarding PHB (Per-Hop Behavior)</i>, defines one code point: <b>ef</b> (46).</li> <li>• RFC 2597, <i>Assured Forwarding PHB Group</i>, defines 4 classes, with 3 drop precedences in each class, for a total of 12 code points:</li> </ul> <p><b>af11</b> (10), <b>af12</b> (12), <b>af13</b> (14),</p> <p><b>af21</b> (18), <b>af22</b> (20), <b>af23</b> (22),</p> <p><b>af31</b> (26), <b>af32</b> (28), <b>af33</b> (30),</p> <p><b>af41</b> (34), <b>af42</b> (36), <b>af43</b> (38)</p> |
| <b>dscp-except number</b>       | <p>(MX Series routers and EX Series switches only) Do not match on the DSCP. For details, see the <b>dscp</b> match condition.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>ether-type values</b>        | <p>Match the 2-octet IEEE 802.3 Length/EtherType field to the specified value or list of values.</p> <p>You can specify decimal or hexadecimal values from 0 through 65535 (0xFFFF). A value from 0 through 1500 (0x05DC) specifies the length of an Ethernet Version 1 frame. A value from 1536 (0x0600) through 65535 specifies the EtherType (nature of the MAC client protocol) of an Ethernet Version 2 frame.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the hexadecimal values are also listed): <b>aarp</b> (0x80F3), <b>appletalk</b> (0x809B), <b>arp</b> (0x0806), <b>ipv4</b> (0x0800), <b>ipv6</b> (0x86DD), <b>mpls-multicast</b> (0x8848), <b>mpls-unicast</b> (0x8847), <b>oam</b> (0x8902), <b>ppp</b> (0x880B), <b>pppoe-discovery</b> (0x8863), <b>pppoe-session</b> (0x8864), or <b>sna</b> (0x80D5).</p>                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>ether-type-except values</b> | <p>Do not match the 2-octet Length/EtherType field to the specified value or list of values.</p> <p>For details about specifying the <b>values</b>, see the <b>ether-type</b> match condition.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>icmp-code message-code</b>        | <p>Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the <b>next-header icmp</b> or <b>next-header icmp6</b> match condition in the same term.</p> <p>If you configure this match condition, you must also configure the <b>icmp-type message-type</b> match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> <li>parameter-problem: <b>ip6-header-bad</b> (0), <b>unrecognized-next-header</b> (1), <b>unrecognized-option</b> (2)</li> <li>time-exceeded: <b>ttl-eq-zero-during-reassembly</b> (1), <b>ttl-eq-zero-during-transit</b> (0)</li> <li>destination-unreachable: <b>address-unreachable</b> (3), <b>administratively-prohibited</b> (1), <b>no-route-to-destination</b> (0), <b>port-unreachable</b> (4)</li> </ul>                                                 |
| <b>icmp-code-except message-code</b> | Do not match the ICMP message code field. For details, see the <b>icmp-code</b> match condition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>icmp-code number</b>              | <p>(MX Series routers and EX Series switches only) Match the ICMP message code field.</p> <p>If you configure this match condition, we recommend that you also configure the <b>ip-protocol icmp</b> or <b>ip-protocol icmp6</b> match condition in the same term.</p> <p>If you configure this match condition, you must also configure the <b>icmp-type message-type</b> match condition in the same term. An ICMP message code provides more specific information than an ICMP message type, but the meaning of an ICMP message code is dependent on the associated ICMP message type.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed). The keywords are grouped by the ICMP type with which they are associated:</p> <ul style="list-style-type: none"> <li>parameter-problem: <b>ip6-header-bad</b> (0), <b>unrecognized-next-header</b> (1), <b>unrecognized-option</b> (2)</li> <li>time-exceeded: <b>ttl-eq-zero-during-reassembly</b> (1), <b>ttl-eq-zero-during-transit</b> (0)</li> <li>destination-unreachable: <b>address-unreachable</b> (3), <b>administratively-prohibited</b> (1), <b>no-route-to-destination</b> (0), <b>port-unreachable</b> (4)</li> </ul> |
| <b>icmp-code-except number</b>       | (MX Series routers and EX Series switches only) Do not match on the ICMP code field. For details, see the <b>icmp-code</b> match condition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>icmp-type number</b>              | <p>(MX Series routers and EX Series switches only) Match the ICMP message type field.</p> <p>If you configure this match condition, we recommend that you also configure the <b>ip-protocol icmp</b>, <b>ip-protocol icmp6</b>, or <b>ip-protocol icmpv6</b> match condition in the same term.</p> <p>In place of the numeric value, you can specify one of the following text synonyms (the field values are also listed): <b>destination-unreachable</b> (1), <b>echo-reply</b> (129), <b>echo-request</b> (128), <b>membership-query</b> (130), <b>membership-report</b> (131), <b>membership-termination</b> (132), <b>neighbor-advertisement</b> (136), <b>neighbor-solicit</b> (135), <b>node-information-reply</b> (140), <b>node-information-request</b> (139), <b>packet-too-big</b> (2), <b>parameter-problem</b> (4), <b>redirect</b> (137), <b>router-advertisement</b> (134), <b>router-renumbering</b> (138), <b>router-solicit</b> (133), or <b>time-exceeded</b> (3).</p>                                                                                                                                                                                                                                                                  |

Table 34: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

| Match Condition                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>icmp-type-except</b> <i>number</i>                     | (MX Series routers and EX Series switches only) Do not match the ICMP message type field. For details, see the <b>icmp-type</b> match condition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>interface</b> <i>interface-name</i>                    | Interface on which the packet was received. You can configure a match condition that matches packets based on the interface on which they were received.<br><br><b>NOTE:</b> If you configure this match condition with an interface that does not exist, the term does not match any packet.                                                                                                                                                                                                                                                                                                                                     |
| <b>interface-group</b><br><i>group-number</i>             | Match the logical interface on which the packet was received to the specified interface group or set of interface groups. For <i>group-number</i> , specify a single value or a range of values from 0 through 255.<br><br>To assign a logical interface to an interface group <i>group-number</i> , specify the <i>group-number</i> at the <b>[interfaces interface-name unit number family family filter group]</b> hierarchy level.<br><br>For more information, see <i>Filtering Packets Received on a Set of Interface Groups Overview</i> .<br><br><b>NOTE:</b> This match condition is not supported on T4000 Type 5 FPCs. |
| <b>interface-group-except</b><br><i>group-name</i>        | Do not match the logical interface on which the packet was received to the specified interface group or set of interface groups. For details, see the <b>interface-group</b> match condition.<br><br><b>NOTE:</b> This match condition is not supported on T4000 Type 5 FPCs.                                                                                                                                                                                                                                                                                                                                                     |
| <b>interface-set</b><br><i>interface-set-name</i>         | Match the interface on which the packet was received to the specified interface set.<br><br>To define an interface set, include the <b>interface-set</b> statement at the <b>[edit firewall]</b> hierarchy level. For more information, see <i>Filtering Packets Received on an Interface Set Overview</i> .                                                                                                                                                                                                                                                                                                                      |
| <b>ip-address</b> <i>address</i>                          | (MX Series routers and EX Series switches only) 32-bit address that supports the standard syntax for IPv4 addresses.<br><br>Note that when using this term, the match condition ether-type IPv4 must be defined on the same term.                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>ip-destination-address</b><br><i>address</i>           | (MX Series routers and EX Series switches only) 32-bit address that is the final destination node address for the packet.<br><br>Note that when using this term, the match condition ether-type IPv4 must be defined on the same term.                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ip-precedence</b><br><i>ip-precedence-field</i>        | (MX Series routers and EX Series switches only) IP precedence field. In place of the numeric field value, you can specify one of the following text synonyms (the field values are also listed): <b>critical-ecp</b> (0xa0), <b>flash</b> (0x60), <b>flash-override</b> (0x80), <b>immediate</b> (0x40), <b>internet-control</b> (0xc0), <b>net-control</b> (0xe0), <b>priority</b> (0x20), or <b>routine</b> (0x00).                                                                                                                                                                                                             |
| <b>ip-precedence-except</b><br><i>ip-precedence-field</i> | (MX Series routers and EX Series switches only) Do not match on the IP precedence field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>ip-protocol</b> <i>number</i>                          | (MX Series routers and EX Series switches only) IP protocol field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ip-protocol-except</b> <i>number</i>                   | (MX Series routers and EX Series switches only) Do not match on the IP protocol field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>learn-vlan-id</b> <i>number</i>                 | (MX Series routers and EX Series switches only) VLAN identifier used for MAC learning.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>learn-vlan-id-except</b> <i>number</i>          | (MX Series routers and EX Series switches only) Do not match on the VLAN identifier used for MAC learning.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

Table 34: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

| Match Condition                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>loss-priority <i>level</i></b>        | <p>Packet loss priority (PLP) level. Specify a single level or multiple levels: <b>low</b>, <b>medium-low</b>, <b>medium-high</b>, or <b>high</b>.</p> <p>Supported on M120 and M320 routers; M7i and M10i routers with the Enhanced CFEB (CFEB-E); and MX Series routers.</p> <p>For IP traffic on M320, MX Series, and T Series routers with Enhanced II Flexible PIC Concentrators (FPCs) and EX Series switches, you must include the <b>tri-color</b> statement at the <b>[edit class-of-service]</b> hierarchy level to commit a PLP configuration with any of the four levels specified. If the <b>tri-color</b> statement is not enabled, you can only configure the <b>high</b> and <b>low</b> levels. This applies to all protocol families.</p> <p>For information about the <b>tri-color</b> statement and about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see <i>Understanding How Forwarding Classes Assign Classes to Output Queues</i>.</p> |
| <b>loss-priority-except <i>level</i></b> | <p>Do not match on the packet loss priority level. Specify a single level or multiple levels: <b>low</b>, <b>medium-low</b>, <b>medium-high</b>, or <b>high</b>.</p> <p>For information about using behavior aggregate (BA) classifiers to set the PLP level of incoming packets, see <i>Understanding How Behavior Aggregate Classifiers Prioritize Trusted Traffic</i>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>port <i>number</i></b>                | (MX Series routers and EX Series switches only) TCP or UDP source or destination port. You cannot specify both the <b>port</b> match condition and either the <b>destination-port</b> or <b>source-port</b> match condition in the same term.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>port-except <i>number</i></b>         | (MX Series routers and EX Series switches only) Do not match on the TCP or UDP source or destination port. You cannot specify both the <b>port</b> match condition and either the <b>destination-port</b> or <b>source-port</b> match condition in the same term.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>prefix-list <i>name</i></b>           | <p>(MX Series routers and EX Series switches only) Match the destination or source prefixes in the specified list. Specify the name of a prefix list defined at the <b>[edit policy-options prefix-list <i>prefix-list-name</i>]</b> hierarchy level.</p> <p><b>NOTE:</b> VPLS prefix lists support only IPV4 addresses. IPV6 addresses included in a VPLS prefix list will be discarded.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>prefix-list <i>name</i> except</b>    | (MX Series routers and EX Series switches only) Do not match the destination or source prefixes in the specified list. For more information, see the <b>destination-prefix-list</b> match condition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>source-mac-address <i>address</i></b> | Source MAC address of a VPLS packet.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>source-port <i>number</i></b>         | (MX Series routers and EX Series switches only) TCP or UDP source port field. You cannot specify the <b>port</b> and <b>source-port</b> match conditions in the same term.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>source-port-except <i>number</i></b>  | (MX Series routers and EX Series switches only) Do not match on the TCP or UDP source port field. You cannot specify the <b>port</b> and <b>source-port</b> match conditions in the same term.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Table 34: Firewall Filter Match Conditions for VPLS Traffic (*continued*)

| Match Condition                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>source-prefix-list <i>name</i></b>             | <p>(ACX Series routers, MX Series routers, and EX Series switches only) Match the source prefixes in the specified prefix list. Specify a prefix list name defined at the <b>[edit policy-options prefix-list <i>prefix-list-name</i>]</b> hierarchy level.</p> <p><b>NOTE:</b> VPLS prefix lists support only IPv4 addresses. IPv6 addresses included in a VPLS prefix list will be discarded.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>source-prefix-list <i>name</i> except</b>      | <p>(MX Series routers and EX Series switches only) Do not match the source prefixes in the specified prefix list. For more information, see the <b>source-prefix-list</b> match condition.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>tcp-flags <i>flags</i></b>                     | <p>Match one or more of the low-order 6 bits in the 8-bit TCP flags field in the TCP header.</p> <p>To specify individual bit fields, you can specify the following text synonyms or hexadecimal values:</p> <ul style="list-style-type: none"> <li>• <b>fin</b> (0x01)</li> <li>• <b>syn</b> (0x02)</li> <li>• <b>rst</b> (0x04)</li> <li>• <b>push</b> (0x08)</li> <li>• <b>ack</b> (0x10)</li> <li>• <b>urgent</b> (0x20)</li> </ul> <p>In a TCP session, the SYN flag is set only in the initial packet sent, while the ACK flag is set in all packets sent after the initial packet.</p> <p>You can string together multiple flags using the bit-field logical operators.</p> <p>If you configure this match condition for IPv6 traffic, we recommend that you also configure the <b>next-header tcp</b> match condition in the same term to specify that the TCP protocol is being used on the port.</p> |
| <b>traffic-type <i>type-name</i></b>              | <p>(MX Series routers and EX Series switches only) Traffic type. Specify <b>broadcast</b>, <b>multicast</b>, <b>unknown-unicast</b>, or <b>known-unicast</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>traffic-type-except <i>type-name</i></b>       | <p>(MX Series routers and EX Series switches only) Do not match on the traffic type. # Monitoring and Tracing VPLS

- [Configuring Port Mirroring for VPLS Traffic on page 1607](#)
- [Configuring Y.1731 Functionality for VPLS to Support Delay and Delay Variation on page 1607](#)
- [Tracing VPLS Traffic and Operations on page 1608](#)

## Configuring Port Mirroring for VPLS Traffic

---

You can configure port mirroring for VPLS traffic on the M7, M10i, M120, M320, and the MX Series routers. VPLS port mirroring is supported only M7i and M0i routers with the Enhanced Compact Forwarding Engine Board (CFEB-E). In addition, on M320 routers, VPLS port mirroring is supported only on Enhanced III Flexible PIC Concentrators (FPCs).

To configure port mirroring for VPLS include the **port-mirroring** statement at the **[edit forwarding-options]** hierarchy level. For more information about configuring port mirroring for VPLS for all platforms supported, see *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

## Configuring Y.1731 Functionality for VPLS to Support Delay and Delay Variation

---

For VPLS, you can configure the Ethernet frame delay measurement (ETH-DM) functionality to trigger two-way ETH-DM and allow concurrent ETH-DM CLI sessions from the same local maintenance association end point (MEP). The feature also provides the option to perform ETH-DM for a given 802.1q priority, to set the size of the data type, length, and value (TLV), to disable the **session-id-tlv** option, and to generate XML output.

This feature complements the ITU-T Y.1731 Ethernet service OAM feature. On-demand delay measurement for VPLS is supported on MX Series routers installed with Rev-B DPCs. Only the two-way delay measurement feature is supported for VPLS connections.

MX Series routers with modular port concentrators (MPCs) and 10-Gigabit Ethernet MPCs with SFP+ support ITU-T Y.1731 functionality on VPLS for frame-delay and delay-variation.

This feature is currently supported only for up MEPs. Set the MEP direction to up by configuring the **up** option for the **direction** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id*]** hierarchy level.

This feature also provides support for an optional configuration where you can delegate the server-side processing (for two-way delay measurement) to the Packet Forwarding Engine (PFE) to prevent overloading on the Routing Engine. To enable this feature, include the **delegate-server-processing** statement at the **[edit protocols oam ethernet connectivity-fault-management performance-monitoring]** hierarchy level. By default, the server-side processing is done by the Routing Engine.

The following commands enable you to monitor and maintain the Y.1731 feature for VPLS:

- To display the delay measurement values across a VPLS connection, use the **monitor ethernet delay-measurement two-way (remote-mac-address | mep mep-id) maintenance-domain name maintenance-association name count count wait time priority 802.1p-value size no-session-id-tlv xml** command.
- The feature also provides support for enhanced continuity measurement by using an existing continuity check protocol. The continuity for every remote MEP is measured as the percentage of time that a remote MEP was operationally up over the total administratively enabled time.

To display the continuity measurement information, use the **show oam ethernet connectivity-fault-management mep-database maintenance-domain name maintenance-association name local-mep identifier remote-mep identifier** command.

- You can restart the continuity measurement by clearing the currently measured operational uptime and administrative enabled time. To clear the existing continuity measurement and restart counting the operational uptime, use the **clear oam ethernet connectivity-fault-management continuity-measurement maintenance-domain name maintenance-association name local-mep identifier remote-mep identifier** command.
- To clear the delay statistics, issue a **clear oam ethernet connectivity-fault-management statistics** command or a **clear oam ethernet connectivity-fault-management delay-statistics two-way maintenance-domain md-name maintenance-association ma-name** command.

## Tracing VPLS Traffic and Operations

To trace VPLS traffic, include the **traceoptions** statement:

```
traceoptions {
 file filename <files number> <size size> <world-readable | no-world-readable>;
 flag flag <flag-modifier> <disable>;
}
```

You can include this statement at the following hierarchy levels:

- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls]
- [edit routing-instances *routing-instance-name* protocols vpls]

The following trace flags display the operations associated with VPLS:

- **all**—All VPLS tracing options
- **connections**—VPLS connections (events and state changes)
- **error**—Error conditions
- **nlri**—VPLS advertisements received or sent using BGP
- **route**—Trace-routing information
- **topology**—VPLS topology changes caused by reconsideration or advertisements received from other PE routers using BGP

## Layer 2 VPN to Layer 2 VPN Connections

---

As the need to link different Layer 2 services to one another for expanded service offerings grows, Layer 2 MPLS VPN services are increasingly in demand. Junos OS enables you to terminate Layer 2 VPN into Layer 2 VPN (also known as Layer 2 VPN stitching) using the Layer 2 interworking (iw0) interface.

Another way to do this is to use a Tunnel Services PIC to loop packets out and back from the Packet Forwarding Engine (PFE), to link together Layer 2 networks. The Layer 2 interworking software interface avoids the need for the Tunnel Services PIC and overcomes the limitation of bandwidth constraints imposed by the Tunnel Services PIC.

### Related Documentation

- [Example: Interconnecting a Layer 2 VPN with a Layer 2 VPN on page 1615](#)

## Using the Layer 2 Interworking Interface to Interconnect a Layer 2 VPN to a Layer 2 VPN

---

Instead of using a physical Tunnel PIC for looping the packet received from the Layer 2 VPN to another Layer 2 VPN, the Layer 2 Interworking interface uses Junos OS to stitch together both Layer 2 VPN routes.

To configure the interworking interface, include the **iw0** statement. The **iw0** statement is configured at the **[edit interfaces]** hierarchy level.

```
[edit interfaces]
iw0 {
 unit 0 {
 peer 1;
 }
}
```

```

unit 1 {
 peer 0;
}

```

**NOTE:** You must always create and delete (or deactivate) interworking (iw) interfaces in pairs, such as:

```

set interfaces iw0 unit 0 peer-unit 1
set interfaces iw0 unit 1 peer-unit 0

```

An error message displays if you delete or deactivate only one of the interworking interfaces. To successfully deactivate the interfaces and avoid any configuration errors, you must deactivate both.

The configuration of an interworking (iw) interface is similar to the configuration of a logical tunnel (lt) interface. In this example, the logical interfaces must be associated with the endpoints of both Layer 2 VPN connections terminating on this router. To make the association, include the **interfaces** statement and specify **iw0** as the interface name. Include the statement at the **[edit routing-instances *routing-instances-name* protocols l2vpn site *site-name*]** hierarchy level for each routing instance. The **routing-instances** statement is configured at the **[edit routing-instances]** hierarchy level.

```

[edit routing-instances]
L2VPN-PE1 {
 instance-type l2vpn;
 interface iw0.0;
 route-distinguisher 65000:3;
 vrf-target target:65000:2;
 protocols {
 l2vpn {
 encapsulation-type ethernet;
 site CE3 {
 site-identifier 3;
 interface iw0.0 {
 remote-site-id 1;
 }
 }
 }
 }
}
L2VPN-PE5 {
 instance-type l2vpn;
 interface iw0.1;
 route-distinguisher 65000:33;
 vrf-target target:65000:2;
 protocols {
 l2vpn {
 encapsulation-type ethernet;
 site CE3 {
 site-identifier 3;
 interface iw0.1 {
 remote-site-id 5;
 }
 }
 }
 }
}

```

```

 }
 }
}

```

In addition to the **iw0** interface configuration, Layer 2 interworking **l2iw** protocols need to be configured. Without the **l2iw** configuration, the **l2iw** routes will not be formed, regardless of whether any **iw** interfaces are present. Only standard trace options can be configured within the **l2iw** protocol. The minimum configuration necessary for the feature to work is shown below:

```

[edit]
protocols {
 l2iw;
}

```

  - [Example: Interconnecting a Layer 2 VPN with a Layer 2 VPN on page 1615](#)

## Example: Interconnecting a Layer 2 VPN with a Layer 2 VPN

This example provides a step-by-step procedure for interconnecting and verifying a Layer 2 VPN with a Layer 2 VPN. It contains the following sections:

- [Requirements on page 1615](#)
- [Overview and Topology on page 1615](#)
- [Configuration on page 1616](#)

### Requirements

This example uses the following hardware and software components:

- Junos OS Release 9.3 or later
- 2 MX Series 3D Universal Edge Routers
- 2 M Series Multiservice Edge Routers
- 1 T Series Core Routers
- 1 EX Series Ethernet Switches

### Overview and Topology

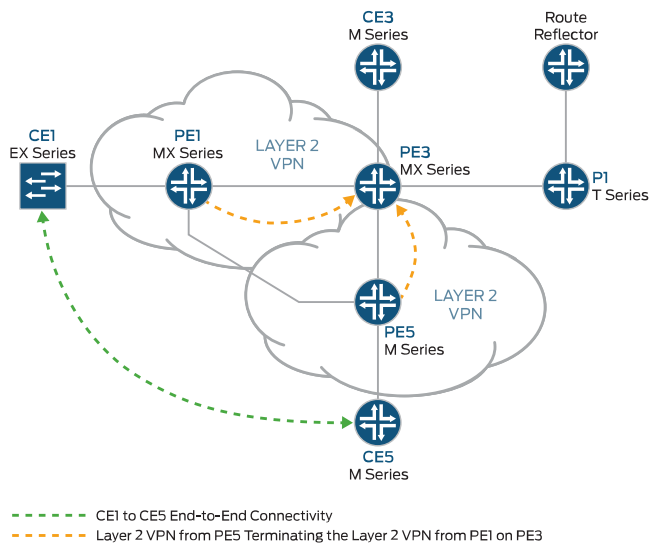

The physical topology of the Layer 2 VPN to Layer 2 VPN connection example is shown in [Figure 150 on page 1616](#).

Figure 150: Physical Topology of a Layer 2 VPN to Layer 2 VPN Connection

The logical topology of a Layer 2 VPN to Layer 2 VPN connection is shown in [Figure 151 on page 1616](#).

Figure 151: Logical Topology of a Layer 2 VPN to Layer 2 VPN Connection

## Configuration

**NOTE:** In any configuration session, it is good practice to verify periodically that the configuration can be committed using the `commit check` command.

In this example, the router being configured is identified using the following command prompts:

- **CE1** identifies the customer edge 1 (CE1) router
- **PE1** identifies the provider edge 1 (PE1) router
- **CE3** identifies the customer edge 3 (CE3) router
- **PE3** identifies the provider edge 3 (PE3) router
- **CE5** identifies the customer edge 5 (CE5) router
- **PE5** identifies the provider edge 5 (PE5) router

This example is organized in the following sections:

- [Configuring Protocols on the PE and P Routers on page 1617](#)
- [Verifying the Layer 2 VPN to Layer 2 VPN Connection on Router PE3 on page 1622](#)
- [Verifying the Layer 2 VPN to Layer 2 VPN Connection on Router PE3 on page 1625](#)
- [Results on page 1627](#)

### Configuring Protocols on the PE and P Routers

#### Step-by-Step Procedure

All of the PE routers and P routers are configured with OSPF as the IGP protocol. The MPLS, LDP, and BGP protocols are enabled on all of the interfaces except **fxp0.0**. Core-facing interfaces are enabled with the MPLS address and inet address.

1. Configure all the PE and P routers with OSPF as the IGP. Enable the MPLS, LDP, and BGP protocols on all interfaces except **fxp0.0**. The following configuration snippet shows the protocol configuration for Router PE1:

```
[edit]
protocols {
 mpls {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 bgp {
 group RR {
 type internal;
 local-address 192.0.2.1;
 family l2vpn {
 signaling;
 }
 neighbor 192.0.2.7;
 }
 }
 ospf {
 traffic-engineering;
 area 0.0.0.0 {
 interface all;
 interface fxp0.0 {
```

```

 disable;
 }
}
ldp {
 interface all;
 interface fxp0.0 {
 disable;
 }
}
}

```

2. Configure the PE and P routers with OSPF as the IGP. Enable the MPLS, LDP, and BGP protocols on all interfaces except **fxp0.0**. The following configuration snippet shows the protocol configuration for Router PE3:

```

[edit]
protocols {
 mpls {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 bgp {
 group RR {
 type internal;
 local-address 192.0.2.3;
 family l2vpn {
 signaling;
 }
 neighbor 192.0.2.7;
 }
 }
 ospf {
 traffic-engineering;
 area 0.0.0.0 {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 }
 ldp {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
}

```

### Step-by-Step Procedure

#### Configuring the Layer 2 VPN Protocol and Interfaces

1. On Router PE1, configure the **ge-1/0/0** interface encapsulation. To configure the interface encapsulation, include the **encapsulation** statement and specify the **ethernet-ccc** option (vlan-ccc encapsulation is also supported). Configure the **ge-1/0/0.0** logical interface family for circuit cross-connect functionality. To configure the logical interface family, include the **family** statement and specify the **ccc** option. The encapsulation should be configured the same way for all routers in the Layer 2 VPN domain.

```
[edit interfaces]
ge-1/0/0 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
}
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.1/24;
 }
 }
}
```

2. On Router PE1, configure the Layer 2 VPN protocols. Configure the remote site ID as 3. Site ID 3 represents Router PE3 (Hub-PE). To configure the Layer 2 VPN protocols, include the **l2vpn** statement at the **[edit routing-instances routing-instances-name protocols]** hierarchy level. Layer 2 VPNs use BGP as the signaling protocol.

```
[edit routing-instances]
L2VPN {
 instance-type l2vpn;
 interface ge-1/0/0.0;
 route-distinguisher 65000:1;
 vrf-target target:65000:2;
 protocols {
 l2vpn {
 encapsulation-type ethernet;
 site CE1 {
 site-identifier 1;
 interface ge-1/0/0.0 {
 remote-site-id 3;
 }
 }
 }
 }
}
```

3. On Router PE5, configure the **ge-2/0/0** interface encapsulation by including the **encapsulation** statement and specify the **ethernet-ccc** option. Configure the

ge-1/0/0.0 logical interface family for circuit cross-connect functionality by including the **family** statement and specifying the **ccc** option.

```
[edit interfaces]
ge-2/0/0 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
}
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.5/24;
 }
 }
}
```

4. On Router PE5, configure the Layer 2 VPN protocols by including the **l2vpn** statement at the **[edit routing-instances *routing-instances-name* protocols]** hierarchy level. Configure the remote site ID as **3**.

```
[edit routing-instances]
L2VPN {
 instance-type l2vpn;
 interface ge-2/0/0.0;
 route-distinguisher 65000:5;
 vrf-target target:65000:2;
 protocols {
 l2vpn {
 encapsulation-type ethernet;
 site CE5 {
 site-identifier 5;
 interface ge-2/0/0.0 {
 remote-site-id 3;
 }
 }
 }
 }
}
```

5. On Router PE3, configure the **iw0** interface with two logical interfaces. To configure the **iw0** interface, include the **interfaces** statement and specify **iw0** as the interface name. For the unit 0 logical interface, include the **peer-unit** statement and specify the logical interface **unit 1** as the peer interface. For the unit 1 logical interface, include the **peer-unit** statement and specify the logical interface **unit 0** as the peer interface.

```
[edit interfaces]
iw0 {
 unit 0 {
 encapsulation ethernet-ccc;
 peer-unit 1;
 }
 unit 1 {
```

```

 encapsulation ethernet-ccc;
 peer-unit 0;
 }
}

```

6. On Router PE3, configure the edge-facing **ge-1/0/1** interface encapsulation by including the **encapsulation** statement and specifying the **ethernet-ccc** option.

```

[edit interfaces]
ge-1/0/1 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
}

```

7. On Router PE3, configure the logical loopback interface. The loopback interface is used to establish the targeted LDP sessions to Routers PE1 and Router PE5.

```

[edit interfaces]
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.3/24;
 }
 }
}

```

8. On Router PE3, enable the Layer 2 interworking protocol. To enable the Layer 2 interworking protocol, include the **l2iw** statement at the **[edit protocols]** hierarchy level.

```

[edit protocols]
l2iw;

```

9. On Router PE3, configure two Layer 2 VPN routing instances to terminate the Layer 2 VPN virtual circuits from Router PE1 and Router PE5, as shown.

```

[edit routing-instances]
L2VPN-PE1 {
 instance-type l2vpn;
 interface iw0.0;
 route-distinguisher 65000:3;
 vrf-target target:65000:2;
 protocols {
 l2vpn {
 encapsulation-type ethernet;
 site CE3 {
 site-identifier 3;
 interface iw0.0 {
 remote-site-id 1;
 }
 }
 }
 }
}

```

```

 }
 }
 L2VPN-PE5 {
 instance-type l2vpn;
 interface iw0.1;
 route-distinguisher 65000:33;
 vrf-target target:65000:2;
 protocols {
 l2vpn {
 encapsulation-type ethernet;
 site CE3 {
 site-identifier 3;
 interface iw0.1 {
 remote-site-id 5;
 }
 }
 }
 }
 }
}

```

### Verifying the Layer 2 VPN to Layer 2 VPN Connection on Router PE3

#### Step-by-Step Procedure

1. BGP is used for control plane signaling in a Layer 2 VPN. On Router PE1, use the **show bgp** command to verify that the BGP control plane for the Layer 2 VPN, has established a neighbor relationship with the route reflector that has IP address **192.0.2.7**.

Three Layer 2 VPN routes are received from the route reflector for each PE router in the topology.

```
user@PE1> show bgp summary
```

```
Groups: 1 Peers: 1 Down peers: 0
```

| Table                                     | Tot Paths | Act Paths | Suppressed | History | Damp  | State       | Pending |
|-------------------------------------------|-----------|-----------|------------|---------|-------|-------------|---------|
| bgp.l2vpn.0                               | 3         | 3         | 0          | 0       | 0     | 0           | 0       |
| Peer                                      | AS        | InPkt     | OutPkt     | OutQ    | Flaps | Last Up/Dwn |         |
| State #Active/Received/Accepted/Damped... |           |           |            |         |       |             |         |
| 192.0.2.7                                 | 65000     | 190       | 192        | 0       | 0     | 1:24:40     | Establ  |
| bgp.l2vpn.0: 3/3/3/0                      |           |           |            |         |       |             |         |
| L2VPN.l2vpn.0: 3/3/3/0                    |           |           |            |         |       |             |         |

2. On Router PE1, use the **show route** command to verify that the BGP Layer 2 VPN routes are stored in the **L2VPN.l2vpn.0** routing table for each PE router.

```
user@PE1> show route table L2VPN.l2vpn.0
```

```
L2VPN.l2vpn.0: 4 destinations, 4 routes (4 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```

65000:1:1:3/96
 *[L2VPN/170/-101] 01:31:53, metric2 1
 Indirect
65000:3:3:1/96
 *[BGP/170] 01:24:58, localpref 100, from 192.0.2.7
 AS path: I
 > to 10.10.1.2 via xe-0/3/0.0
65000:5:5:3/96

```

```

 *[BGP/170] 01:24:58, localpref 100, from 192.0.2.7
 AS path: I
 > to 10.10.3.2 via xe-0/2/0.0
65000:33:3:5/96
 *[BGP/170] 01:24:58, localpref 100, from 192.0.2.7
 AS path: I
 > to 10.10.1.2 via xe-0/3/0.0

```

3. On Router PE1, use the **show ldp session** command to verify that targeted LDP sessions are established to the PE routers in the network and that the state is **Operational**.

```

user@PE1> show ldp session
 Address State Connection Hold time
192.0.2.2 Operational Open 24
192.0.2.3 Operational Open 22
192.0.2.5 Operational Open 28

```

4. On Router PE1, use the **show l2vpn connections** command to verify that the Layer 2 VPN to site 3 on Router PE3 (Hub-PE) is **Up**.

```
user@PE1> show l2vpn connections
```

Layer-2 VPN connections:

Legend for connection status (St)

|                                  |                                                |

```

### Verifying the Layer 2 VPN to Layer 2 VPN Connection on Router PE3

- Step-by-Step Procedure**
1. On Router PE3, use the **show l2vpn connections** command to verify that the Layer 2 VPN connections from Router PE1 and Router PE5 are **Up** and are using the **iw0** interface.

```
user@PE3> show l2vpn connections
```

```
Instance: L2VPN-PE1
```

```
Local site: CE3 (3)
```

| connection-site                                             | Type | St | Time last up        | # Up trans |
|-------------------------------------------------------------|------|----|---------------------|------------|
| 1                                                           | rmt  | Up | Jan 5 18:08:22 2010 | 1          |
| Remote PE: 192.0.2.1, Negotiated control-word: Yes (Null)   |      |    |                     |            |
| Incoming label: 800000, Outgoing label: 800000              |      |    |                     |            |
| Local interface: iw0.0, Status: Up, Encapsulation: ETHERNET |      |    |                     |            |
| 5                                                           | rmt  | OR |                     |            |

```
Instance: L2VPN-PE5
```

```
Local site: CE3 (3)
```

| connection-site                                             | Type | St | Time last up        | # Up trans |
|-------------------------------------------------------------|------|----|---------------------|------------|
| 1                                                           | rmt  | CN |                     |            |
| 5                                                           | rmt  | Up | Jan 5 18:08:22 2010 | 1          |
| Remote PE: 192.0.2.5, Negotiated control-word: Yes (Null)   |      |    |                     |            |
| Incoming label: 800002, Outgoing label: 800000              |      |    |                     |            |
| Local interface: iw0.1, Status: Up, Encapsulation: ETHERNET |      |    |                     |            |

2. On Router PE3, use the **show ldp neighbor** command to verify that the targeted LDP session neighbor IP addresses are shown.

```
user@PE3> show ldp neighbor
```

| Address   | Interface | Label space ID | Hold time |
|-----------|-----------|----------------|-----------|
| 192.0.2.1 | lo0.0     | 192.0.2.1:0    | 44        |
| 192.0.2.2 | lo0.0     | 192.0.2.2:0    | 42        |
| 192.0.2.4 | lo0.0     | 192.0.2.4:0    | 31        |
| 192.0.2.5 | lo0.0     | 192.0.2.5:0    | 44        |

3. On Router PE3, use the **show bgp summary** command to verify that the BGP control plane for the Layer 2 VPN, has established a neighbor relationship with the route reflector that has IP address **192.0.2.7**.

```
user@PE3> show bgp summary
```

```
Groups: 1 Peers: 1 Down peers: 0
```

| Table                                     | Tot Paths | Act Paths | Suppressed | History | Damp  | State       | Pending |
|-------------------------------------------|-----------|-----------|------------|---------|-------|-------------|---------|
| bgp.l2vpn.0                               | 2         | 2         | 0          | 0       | 0     | 0           | 0       |
| Peer                                      | AS        | InPkt     | OutPkt     | OutQ    | Flaps | Last Up/Dwn |         |
| State #Active/Received/Accepted/Damped... |           |           |            |         |       |             |         |
| 192.0.2.7                                 | 65000     | 10092     | 10195      | 0       | 0     | 3d 4:23:27  | Establ  |
| bgp.l2vpn.0: 2/2/2/0                      |           |           |            |         |       |             |         |
| L2VPN-PE1.l2vpn.0: 2/2/2/0                |           |           |            |         |       |             |         |
| L2VPN-PE5.l2vpn.0: 2/2/2/0                |           |           |            |         |       |             |         |

4. On Router PE3, use the **show ldp session** command to verify that targeted LDP sessions are established to all of the PE routers in the network and that the state is **Operational**.

```
user@PE3> show ldp session
```

| Address   | State       | Connection | Hold time |
|-----------|-------------|------------|-----------|
| 192.0.2.1 | Operational | Open       | 24        |
| 192.0.2.2 | Operational | Open       | 22        |
| 192.0.2.4 | Operational | Open       | 20        |
| 192.0.2.5 | Operational | Open       | 24        |

- On Router PE3, use the **show route** command to verify that the **mpls.0** routing table is populated with the Layer 2 VPN routes used to forward the traffic using an LDP label. Notice that in this example, the router is swapping label **800000**. Also notice the two **iw0** interfaces that are used for the Layer 2 interworking routes.

```

user@PE3>show route table mpls.0
mpls.0: 16 destinations, 18 routes (16 active, 2 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

```

### Step-by-Step Procedure

#### Testing Layer 2 VPN to Layer 2 VPN Connectivity (CE1 to CE5)

1. On Router CE1, use the **ping** command to test connectivity to Router CE5. Notice that the response time is in milliseconds, confirming that the ping response is returned.

```
user@CE1>ping 198.51.100.11
PING 198.51.100.11 (198.51.100.11): 56 data bytes
64 bytes from 198.51.100.11: icmp_seq=1 ttl=64 time=22.425 ms
64 bytes from 198.51.100.11: icmp_seq=2 ttl=64 time=1.299 ms
64 bytes from 198.51.100.11: icmp_seq=3 ttl=64 time=1.032 ms
64 bytes from 198.51.100.11: icmp_seq=4 ttl=64 time=1.029 ms
```

2. On Router CE5, use the **ping** command to test connectivity to Router CE1. Notice that the response time is in milliseconds, confirming that the ping response is returned.

```
user@CE5>ping 198.51.100.1
PING 198.51.100.1 (198.51.100.1): 56 data bytes
64 bytes from 198.51.100.1: icmp_seq=0 ttl=64 time=1.077 ms
64 bytes from 198.51.100.1: icmp_seq=1 ttl=64 time=0.957 ms
64 bytes from 198.51.100.1: icmp_seq=2 ttl=64 time=1.057 ms 1.017 ms
```

### Results

The configuration and verification of this example have been completed. The following section is for your reference.

The relevant sample configuration for Router PE1 follows.

## Interconnecting Layer 2 VPNs with Layer 3 VPNs Overview

As MPLS-based Layer 2 services grow in demand, new challenges arise for service providers to be able to interoperate with Layer 2 and Layer 3 services and give their customers value-added services. Junos OS has various features to address the needs of service providers. One of these features is the use of a logical tunnel interface. This Junos OS functionality makes use of a tunnel PIC to loop packets out and back from the Packet Forwarding Engine to link the Layer 2 network with the Layer 3 network. The solution is limited by the logical tunnel bandwidth constraints imposed by the tunnel PIC.

### Interconnecting Layer 2 VPNs with Layer 3 VPNs Applications

Interconnecting a Layer 2 VPN with a Layer 3 VPN provides the following benefits:

- **A single access line to provide multiple services**—Traditional VPNs over Layer 2 circuits require the provisioning and maintenance of separate networks for IP and for VPN services. In contrast, Layer 2 VPNs enable the sharing of a provider's core network infrastructure between IP and Layer 2 VPN services, thereby reducing the cost of providing those services.
- **Flexibility**—Many different types of networks can be accommodated by the service provider. If all sites in a VPN are owned by the same enterprise, this is an intranet. If various sites are owned by different enterprises, the VPN is an extranet. A site can be located in more than one VPN.
- **Wide range of possible policies**—You can give every site in a VPN a different route to every other site, or you can force traffic between certain pairs of sites routed via a third site and so pass certain traffic through a firewall.
- **Scalable network**—This design enhances the scalability because it eliminates the need for provider edge (PE) routers to maintain all of the service provider's VPN routes. Each PE router maintains a VRF table for each of its directly connected sites. Each customer connection (such as a Frame Relay PVC, an ATM PVC, or a VLAN) is mapped to a specific VRF table. Thus, it is a port on the PE router and not a site that is associated with a VRF table. Multiple ports on a PE router can be associated with a single VRF table. It is the ability of PE routers to maintain multiple forwarding tables that supports the per-VPN segregation of routing information.

- Use of route reflectors—Provider edge routers can maintain IBGP sessions to route reflectors as an alternative to a full mesh of IBGP sessions. Deploying multiple route reflectors enhances the scalability of the RFC 2547bis model because it eliminates the need for any single network component to maintain all VPN routes.
- Multiple VPNs are kept separate and distinct from each other—The customer edge routers do not peer with each other. Two sites have IP connectivity over the common backbone only, and only if there is a VPN which contains both sites. This feature keeps the VPNs separate and distinct from each other, even if two VPNs have an overlapping address space.
- Simple for customers to use—Customers can obtain IP backbone services from a service provider, and they do not need to maintain their own backbones.

## Example: Interconnecting a Layer 2 VPN with a Layer 3 VPN

---

This example provides a step-by-step procedure and commands for interconnecting and verifying a Layer 2 VPN with a Layer 3 VPN. It contains the following sections:

- [Requirements on page 1633](#)
- [Overview and Topology on page 1633](#)
- [Configuration on page 1636](#)
- [Verification on page 1652](#)

### Requirements

This example uses the following hardware and software components:

- Junos OS Release 9.3 or later
- Five MX Series routers
- Three M Series routers
- Two T Series routers

### Overview and Topology

A Layer 2 VPN is a type of virtual private network (VPN) that uses MPLS labels to transport data. The communication occurs between the provider edge (PE) routers.

Layer 2 VPNs use BGP as the signaling protocol and, consequently, have a simpler design and require less provisioning overhead than traditional VPNs over Layer 2 circuits. BGP signaling also enables autodiscovery of Layer 2 VPN peers. Layer 2 VPNs can have either a full-mesh or a hub-and-spoke topology. The tunneling mechanism in the core network is, typically, MPLS. However, Layer 2 VPNs can also use other tunneling protocols, such as GRE.

Layer 3 VPNs are based on RFC 2547bis, *BGP/MPLS IP VPNs*. RFC 2547bis defines a mechanism by which service providers can use their IP backbones to provide VPN services to their customers. A Layer 3 VPN is a set of sites that share common routing information and whose connectivity is controlled by a collection of policies. The sites that make up a Layer 3 VPN are connected over a provider's existing public Internet backbone. RFC 2547bis VPNs are also known as BGP/MPLS VPNs because BGP is used to distribute VPN routing information across the provider's backbone, and MPLS is used to forward VPN traffic across the backbone to remote VPN sites.

Customer networks, because they are private, can use either public addresses or private addresses, as defined in RFC 1918, *Address Allocation for Private Internets*. When customer networks that use private addresses connect to the public Internet infrastructure, the private addresses might overlap with the same private addresses used by other network users. MPLS/BGP VPNs solve this problem by adding a *route distinguisher*. A route distinguisher is a VPN identifier prefix that is added to each address from a particular VPN site, thereby creating an address that is unique both within the VPN and within the Internet.

In addition, each VPN has its own VPN-specific routing table that contains the routing information for that VPN only. To separate a VPN's routes from routes in the public Internet or those in other VPNs, the PE router creates a separate routing table for each VPN called a VPN routing and forwarding (VRF) table. The PE router creates one VRF table for each VPN that has a connection to a customer edge (CE) router. Any customer or site that belongs to the VPN can access only the routes in the VRF tables for that VPN. Every VRF table has one or more extended community attributes associated with it that identify the route as belonging to a specific collection of routers. One of these, the *route target* attribute, identifies a collection of sites (VRF tables) to which a PE router distributes routes. The PE router uses the route target to constrain the import of remote routes into its VRF tables.

When an ingress PE router receives routes advertised from a directly connected CE router, it checks the received route against the VRF export policy for that VPN.

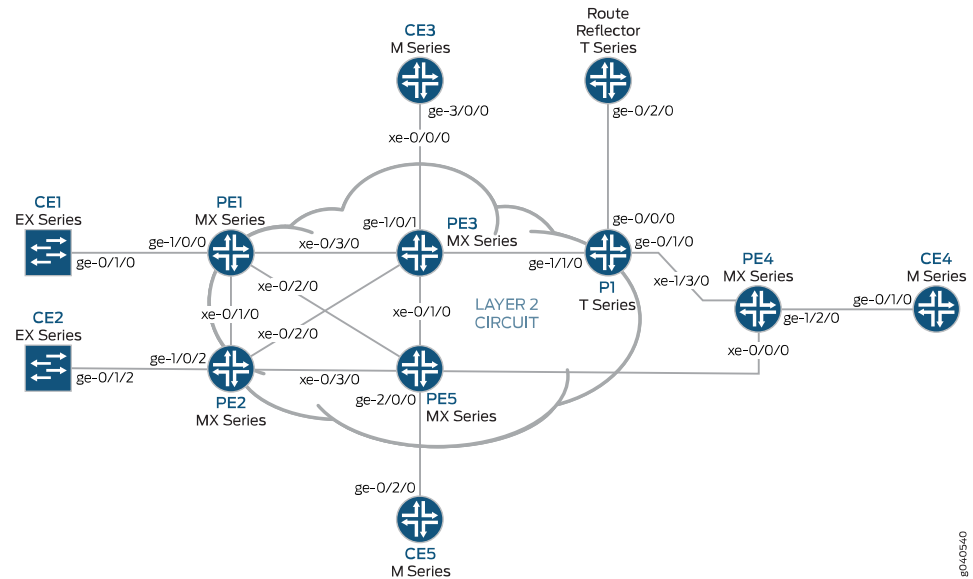

- If it matches, the route is converted to VPN-IPv4 format—that is, the route distinguisher is added to the route. The PE router then announces the route in VPN-IPv4 format to the remote PE routers. It also attaches a route target to each route learned from the directly connected sites. The route target attached to the route is based on the value of the VRF table's configured export target policy. The routes are then distributed using IBGP sessions, which are configured in the provider's core network.
- If the route from the CE router does not match, it is not exported to other PE routers, but it can still be used locally for routing, for example, if two CE routers in the same VPN are directly connected to the same PE router.

When an egress PE router receives a route, it checks it against the import policy on the IBGP session between the PE routers. If it is accepted, the router places the route into its `bgp.l3vpn.0` table. At the same time, the router checks the route against the VRF import policy for the VPN. If it matches, the route distinguisher is removed from the route and the route is placed into the VRF table (the *routing-instance-name.inet.0* table) in IPv4 format.

Figure 144 on page 1443 shows the physical topology of a Layer 2 VPN-to-Layer 3 VPN interconnection.

**Figure 152: Physical Topology of a Layer 2 VPN Terminating into a Layer 3 VPN**

The logical topology of a Layer 2 VPN-to-Layer 3 VPN interconnection is shown in Figure 143 on page 1442.

**Figure 153: Logical Topology of a Layer 2 VPN Terminating into a Layer 3 VPN**

The following definitions describe the meaning of the device abbreviations used in [Figure 144 on page 1443](#) and [Figure 143 on page 1442](#).

- Customer edge (CE) device—A device at the customer premises that provides access to the service provider's VPN over a data link to one or more provider edge (PE) routers.

Typically the CE device is an IP router that establishes an adjacency with its directly connected PE routers. After the adjacency is established, the CE router advertises the site's local VPN routes to the PE router and learns remote VPN routes from the PE router.

- Provider edge (PE) device—A device, or set of devices, at the edge of the provider network that presents the provider's view of the customer site.

PE routers exchange routing information with CE routers. PE routers are aware of the VPNs that connect through them, and PE routers maintain VPN state. A PE router is only required to maintain VPN routes for those VPNs to which it is directly attached. After learning local VPN routes from CE routers, a PE router exchanges VPN routing information with other PE routers using IBGP. Finally, when using MPLS to forward VPN data traffic across the provider's backbone, the ingress PE router functions as the ingress label-switching router (LSR) and the egress PE router functions as the egress LSR.

- Provider (P) device—A device that operates inside the provider's core network and does not directly interface to any CE.

Although the P device is a key part of implementing VPNs for the service provider's customers and may provide routing for many provider-operated tunnels that belong to different VPNs, it is not itself VPN-aware and does not maintain VPN state. Its principal role is allowing the service provider to scale its VPN offerings, for example, by acting as an aggregation point for multiple PE routers.

P routers function as MPLS transit LSRs when forwarding VPN data traffic between PE routers. P routers are required only to maintain routes to the provider's PE routers; they are not required to maintain specific VPN routing information for each customer site.

## Configuration

To interconnect a Layer 2 VPN with a Layer 3 VPN, perform these tasks:

- [Configuring the Base Protocols and Interfaces on page 1636](#)
- [Configuring the VPN Interfaces on page 1640](#)

---

### Configuring the Base Protocols and Interfaces

---

#### Step-by-Step Procedure

1. On each PE and P router, configure OSPF with traffic engineering extensions on all interfaces. Disable OSPF on the fxp0.0 interface.

```
[edit protocols]
ospf {
 traffic-engineering;
 area 0.0.0.0 {
 interface all;
```

```

 interface fxp0.0 {
 disable;
 }
 }
}

```

2. On all the core routers, enable MPLS on all interfaces. Disable MPLS on the fxp0.0 interface.

```

[edit protocols]
mpls {
 interface all;
 interface fxp0.0 {
 disable;
 }
}

```

3. On all the core routers, create an internal BGP peer group and specify the route reflector address (192.0.2.7) as the neighbor. Also enable BGP to carry Layer 2 VPLS network layer reachability information (NLRI) messages for this peer group by including the **signaling** statement at the **[edit protocols bgp group group-name family l2vpn]** hierarchy level.

```

[edit protocols]
bgp {
 group RR {
 type internal;
 local-address 192.0.2.2;
 family l2vpn {
 signaling;
 }
 neighbor 192.0.2.7;
 }
}

```

4. On Router PE3, create an internal BGP peer group and specify the route reflector IP address (192.0.2.7) as the neighbor. Enable BGP to carry Layer 2 VPLS NLRI messages for this peer group and enable the processing of VPN-IPv4 addresses by including the **unicast** statement at the **[edit protocols bgp group group-name family inet-vpn]** hierarchy level.

```

[edit protocols]
bgp {
 group RR {
 type internal;
 local-address 192.0.2.3;
 family inet-vpn {
 unicast;
 }
 family l2vpn {
 signaling;
 }
 neighbor 192.0.2.7;
 }
}

```

```
}
```

5. For the Layer 3 VPN domain on Router PE3 and Router PE5, enable RSVP on all interfaces. Disable RSVP on the fxp0.0 interface.

```
[edit protocols]
rsvp {
 interface all;
 interface fxp0.0 {
 disable;
 }
}
```

6. On Router PE3 and Router PE5, create label-switched paths (LSPs) to the route reflector and the other PE routers. The following example shows the configuration on Router PE5.

```
[edit protocols]
mpls {
 label-switched-path to-RR {
 to 192.0.2.7;
 }
 label-switched-path to-PE2 {
 to 192.0.2.2;
 }
 label-switched-path to-PE3 {
 to 192.0.2.3;
 }
 label-switched-path to-PE4 {
 to 192.0.2.4;
 }
 label-switched-path to-PE1 {
 to 192.0.2.1;
 }
}
```

7. On Routers PE1, PE2, PE3, and PE5, configure the core interfaces with an IPv4 address and enable the MPLS address family. The following example shows the configuration of the xe-0/1/0 interface on Router PE2.

```
[edit]
interfaces {
 xe-0/1/0 {
 unit 0 {
 family inet {
 address 10.10.2.2/30;
 }
 family mpls;
 }
 }
}
```

8. On Router PE2 and Router PE3, configure LDP for the Layer 2 VPN MPLS signaling protocol for all interfaces. Disable LDP on the fxp0.0 interface. (RSVP can also be used.)

```
[edit protocols]
ldp {
 interface all;
 interface fxp0.0 {
 disable;
 }
}
```

9. On the route reflector, create an internal BGP peer group and specify the PE routers IP addresses as the neighbors.

```
[edit]
protocols {
 bgp {
 group RR {
 type internal;
 local-address 192.0.2.7;
 family inet {
 unicast;
 }
 family inet-vpn {
 unicast;
 }
 family l2vpn {
 signaling;
 }
 cluster 192.0.2.7;
 neighbor 192.0.2.1;
 neighbor 192.0.2.2;
 neighbor 192.0.2.4;
 neighbor 192.0.2.5;
 neighbor 192.0.2.3;
 }
 }
}
```

10. On the route reflector, configure MPLS LSPs towards Routers PE3 and PE5 to resolve the BGP next hops from inet.3 routing table.

```
[edit]
protocols {
 mpls {
 label-switched-path to-pe3 {
 to 192.0.2.3;
 }
 label-switched-path to-pe5 {
 to 192.0.2.5;
 }
 interface all;
 }
}
```

## Configuring the VPN Interfaces

### Step-by-Step Procedure

Router PE2 is one end of the Layer 2 VPN. Router PE3 is performing the Layer 2 VPN stitching between the Layer 2 VPN and the Layer 3 VPN. Router PE3 uses the logical tunnel interface (lt interface) configured with different logical interface units applied under two different Layer 2 VPN instances. The packet is looped though the lt interface configured on Router PE3. The configuration of Router PE5 contains the PE-CE interface.

1. On Router PE2, configure the ge-1/0/2 interface encapsulation. Include the encapsulation statement and specify the **ethernet-ccc** option (**vlan-ccc** encapsulation is also supported) at the **[edit interfaces ge-1/0/2]** hierarchy level. The encapsulation should be the same in a whole Layer 2 VPN domain (Routers PE2 and PE3). Also, configure interface lo0.
 

```
[edit]
interfaces {
 ge-1/0/2 {
 encapsulation ethernet-ccc;
 unit 0;
 }
 lo0 {
 unit 0 {
 family inet {
 address 192.0.2.2/24;
 }
 }
 }
}
```
2. On Router PE2, configure the routing instance at the **[edit routing-instances]** hierarchy level. Also, configure the Layer 2 VPN protocol at the **[edit routing-instances routing-instances-name protocols]** hierarchy level. Configure the remote site ID as 3. Site ID 3 represents Router PE3 (Hub-PE). The Layer 2 VPN is using LDP as the signaling protocol. Be aware that in the following example, both the routing instance and the protocol are named **l2vpn**.
 

```
[edit]
routing-instances {
 l2vpn { # routing instance
 instance-type l2vpn;
 interface ge-1/0/2.0;
 route-distinguisher 65000:2;
 vrf-target target:65000:2;
 protocols {
 l2vpn { # protocol
 encapsulation-type ethernet;
 site CE2 {
 site-identifier 2;
 interface ge-1/0/2.0 {
 remote-site-id 3;
 }
 }
 }
 }
 }
}
```

```

 }
 }
}

```

3. On Router PE5, configure the Gigabit Ethernet interface for the PE-CE link **ge-2/0/0** and configure the **lo0** interface.

```

[edit interfaces]
ge-2/0/0 {
 unit 0 {
 family inet {
 address 198.51.100.8/24;
 }
 }
}
lo0 {
 unit 0 {
 }
}

```

4. On Router PE5, configure the Layer 3 VPN routing instance (**L3VPN**) at the **[edit routing-instances]** hierarchy level. Also configure BGP at the **[edit routing-instances L3VPN protocols]** hierarchy level.

```

[edit]
routing-instances {
 L3VPN {
 instance-type vrf;
 interface ge-2/0/0.0;
 route-distinguisher 65000:5;
 vrf-target target:65000:2;
 vrf-table-label;
 protocols {
 bgp {
 group ce5 {
 neighbor 198.51.100.2 {
 peer-as 200;
 }
 }
 }
 }
 }
}

```

5. In an MX Series router, such as Router PE3, you must create the tunnel services interface to be used for tunnel services. To create the tunnel service interface, include the **bandwidth** statement and specify the amount of bandwidth to reserve for tunnel services in gigabits per second at the **[edit chassis fpc slot-number pic slot-number tunnel-services]** hierarchy level.

```

[edit]
chassis {
 dump-on-panic;
 fpc 1 {

```

```

pic 1 {
 tunnel-services {
 bandwidth 1g;
 }
}

```

6. On Router PE3, configure the Gigabit Ethernet interface.

Include the **address** statement at the **[edit interfaces ge-1/0/1.0 family inet]** hierarchy level and specify **198.51.100.9/24** as the IP address.

```

[edit]
interfaces {
 ge-1/0/1 {
 unit 0 {
 family inet {
 address 198.51.100.9/24;
 }
 }
 }
}

```

7. On Router PE3, configure the **lt-1/1/10.0** logical tunnel interface at the **[edit interfaces lt-1/1/10 unit 0]** hierarchy level. Router PE3 is the router that is *stitching* the Layer 2 VPN to the Layer 3 VPN using the logical tunnel interface. The configuration of the peer unit interfaces is what makes the interconnection.

To configure the interface, include the **encapsulation** statement and specify the **ethernet-ccc** option. Include the **peer-unit** statement and specify the logical interface unit 1 as the peer tunnel interface. Include the **family** statement and specify the **ccc** option.

```

[edit]
interfaces {
 lt-1/1/10 {
 unit 0 {
 encapsulation ethernet-ccc;
 peer-unit 1;
 family ccc;
 }
 }
}

```

8. On Router PE3, configure the **lt-1/1/10.1** logical tunnel interface at the **[edit interfaces lt-1/1/10 unit 1]** hierarchy level.

To configure the interface, include the **encapsulation** statement and specify the **ethernet** option. Include the **peer-unit** statement and specify the logical interface unit 0 as the peer tunnel interface. Include the **family** statement and specify the **inet** option. Include the **address** statement at the **[edit interfaces lt-1/1/10 unit 0]** hierarchy level and specify **198.51.100.7/24** as the IPv4 address.

```
[edit]
interfaces {
 lt-1/1/10 {
 unit 1 {
 encapsulation ethernet;
 peer-unit 0;
 family inet {
 address 198.51.100.7/24;
 }
 }
 }
}
```

9. On Router PE3, add the **lt** interface unit 1 to the routing instance at the **[edit routing-instances L3VPN]** hierarchy level. Configure the instance type as **vrf** with **lt** peer-unit 1 as a PE-CE interface to terminate the Layer 2 VPN on Router PE2 into the Layer 3 VPN on Router PE3.

```
[edit]
routing-instances {
 L3VPN {
 instance-type vrf;
 interface ge-1/0/1.0;
 interface lt-1/1/10.1;
 route-distinguisher 65000:33;
 vrf-target target:65000:2;
 vrf-table-label;
 protocols {
 bgp {
 export direct;
 group ce3 {
 neighbor 198.51.100.10 {
 peer-as 100;
 }
 }
 }
 }
 }
}
```

10. On Router PE3, add the **lt** interface unit 0 to the routing instance at the **[edit routing-instances protocols l2vpn]** hierarchy level. Also configure the same vrf target for the Layer 2 VPN and Layer 3 VPN routing instances, so that the routes can be leaked between the instances. The example configuration in the previous step shows the vrf target for the **L3VPN** routing instance. The following example shows the vrf target for the **l2vpn** routing instance.

```
[edit]
routing-instances {
 l2vpn {
 instance-type l2vpn;
 interface lt-1/1/10.0;
 route-distinguisher 65000:3;
 vrf-target target:65000:2;
 }
}
```

```

protocols {
 l2vpn {
 encapsulation-type ethernet;
 site CE3 {
 site-identifier 3;
 interface lt-1/1/10.0 {
 remote-site-id 2;
 }
 }
 }
}

```

11. On Router PE3, configure the **policy-statement** statement to export the routes learned from the directly connected **lt** interface unit 1 to all the CE routers for connectivity, if needed.

```

[edit]
policy-options {
 policy-statement direct {
 term 1 {
 from protocol direct;
 then accept;
 }
 }
}

```

**Results** The following output shows the full configuration of Router PE2:

```

Router PE2 interfaces {
 xe-0/1/0 {
 unit 0 {
 family inet {
 address 10.10.2.2/30;
 }
 family mpls;
 }
 }
 xe-0/2/0 {
 unit 0 {
 family inet {
 address 10.10.5.1/30;
 }
 family mpls;
 }
 }
 xe-0/3/0 {
 unit 0 {
 family inet {
 address 10.10.4.1/30;
 }
 family mpls;
 }
 }
}

```

```

 }
 }
 ge-1/0/2 {

## Verification

Verify the Layer 2 VPN-to-Layer 3 VPN interconnection:

- [Verifying Router PE2 VPN Interface on page 1652](#)
- [Verifying Router PE3 VPN Interface on page 1653](#)
- [Verifying End-to-End connectivity from Router CE2 to Router CE5 and Router CE3 on page 1655](#)

### Verifying Router PE2 VPN Interface

**Purpose** Check that the Layer 2 VPN is up and working at the Router PE2 interface and that all the routes are there.

- Action** 1. Use the **show l2vpn connections** command to verify that the connection site ID is 3 for Router PE3 and that the status is **Up**.

```
user@PE2> show l2vpn connections
Layer-2 VPN connections:
Legend for connection status (St)
EI -- encapsulation invalid NC -- interface encapsulation not CCC/TCC/VPLS
EM -- encapsulation mismatch WE -- interface and instance encaps not same
VC-Dn -- Virtual circuit down NP -- interface hardware not present
CM -- control-word mismatch -> -- only outbound connection is up
CN -- circuit not provisioned <- -- only inbound connection is up
OR -- out of range Up -- operational
OL -- no outgoing label Dn -- down
LD -- local site signaled down CF -- call admission control failure
RD -- remote site signaled down SC -- local and remote site ID collision
LN -- local site not designated LM -- local site ID not minimum designated
RN -- remote site not designated RM -- remote site ID not minimum designated
XX -- unknown connection status IL -- no incoming label
MM -- MTU mismatch MI -- Mesh-Group ID not available
BK -- Backup connection ST -- Standby connection
PF -- Profile parse failure PB -- Profile busy
RS -- remote site standby
```

Legend for interface status

```
Up -- operational
Dn -- down
```

Instance: l2vpn

Local site: CE2 (2)

| connection-site | Type | St | Time last up        | # Up trans |
|-----------------|------|----|---------------------|------------|
| 3               | rmt  | Up | Jan 7 14:14:37 2010 | 1          |

Remote PE: 192.0.2.3, Negotiated control-word: Yes (Null)  
Incoming label: 800000, Outgoing label: 800001  
Local interface: ge-1/0/2.0, Status: Up, Encapsulation: ETHERNET

2. Use the **show route table** command to verify that the Layer 2 VPN route is present and that there is a next hop of **10.10.5.2** through the **xe-0/2/0.0** interface. The following output verifies that the Layer 2 VPN routes are present in the l2vpn.l2vpn.0 table. Similar output should be displayed for Router PE3.

```

user@PE2> show route table l2vpn.l2vpn.0
l2vpn.l2vpn.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

65000:2:2:3/96
* [L2VPN/170/-101] 02:40:35, metric2 1
 Indirect
65000:3:3:1/96
* [BGP/170] 02:40:35, localpref 100, from 192.0.2.7
 AS path: I
 > to 10.10.5.2 via xe-0/2/0.0

```

3. Verify that Router PE2 has a Layer 2 VPN MPLS label pointing to the LDP label to Router PE3 in both directions (PUSH and POP).

```

user@PE2> show route table mpls.0
mpls.0: 13 destinations, 13 routes (13 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0
* [MPLS/0] 1w3d 08:57:41, metric 1
 Receive
1
* [MPLS/0] 1w3d 08:57:41, metric 1
 Receive
2
* [MPLS/0] 1w3d 08:57:41, metric 1
 Receive
300560
* [LDP/9] 19:45:53, metric 1
 > to 10.10.2.1 via xe-0/1/0.0, Pop
300560(S=0)
* [LDP/9] 19:45:53, metric 1
 > to 10.10.2.1 via xe-0/1/0.0, Pop
301008
* [LDP/9] 19:45:53, metric 1
 > to 10.10.4.2 via xe-0/3/0.0, Swap 299856
301536
* [LDP/9] 19:45:53, metric 1
 > to 10.10.4.2 via xe-0/3/0.0, Pop
301536(S=0)
* [LDP/9] 19:45:53, metric 1
 > to 10.10.4.2 via xe-0/3/0.0, Pop
301712
* [LDP/9] 16:14:52, metric 1
 > to 10.10.5.2 via xe-0/2/0.0, Swap 315184
301728
* [LDP/9] 16:14:52, metric 1
 > to 10.10.5.2 via xe-0/2/0.0, Pop
301728(S=0)
* [LDP/9] 16:14:52, metric 1
 > to 10.10.5.2 via xe-0/2/0.0, Pop
800000
* [L2VPN/7] 02:40:35
 > via ge-1/0/2.0, Pop Offset: 4
ge-1/0/2.0
* [L2VPN/7] 02:40:35, metric2 1
 > to 10.10.5.2 via xe-0/2/0.0, Push 800001 Offset: -4

```

**Meaning** The `l2vpn` routing instance is up at interface `ge-1/0/2` and the Layer 2 VPN route is shown in table `l2vpn.l2vpn.0`. Table `mpls.0` shows the Layer 2 VPN routes used to forward the traffic using an LDP label.

### Verifying Router PE3 VPN Interface

**Purpose** Check that the Layer 2 VPN connection from Router PE2 and Router PE3 is **Up** and working.

- Action** 1. Verify that the BGP session with the route reflector for the family **l2vpn-signaling** and the family **inet-vpn** is established.

```
user@PE3> show bgp summary
```

```
Groups: 2 Peers: 2 Down peers: 0
```

| Table       | Tot Paths | Act Paths | Suppressed | History | Damp | State | Pending |
|-------------|-----------|-----------|------------|---------|------|-------|---------|
| bgp.l2vpn.0 | 1         | 1         | 0          | 0       | 0    | 0     | 0       |
| bgp.L3VPN.0 | 1         | 1         | 0          | 0       | 0    | 0     | 0       |

| Peer      | AS    | InPkt | OutPkt | OutQ | Flaps | Last Up/Dwn | State  | #Active | /Received/Accepted/Damped... |
|-----------|-------|-------|--------|------|-------|-------------|--------|---------|------------------------------|
| 192.0.2.7 | 65000 | 2063  | 2084   | 0    | 1     | 15:35:16    | Establ |         |                              |

```

 bgp.l2vpn.0: 1/1/1/0
 bgp.L3VPN.0: 1/1/1/0
 L3VPN.inet.0: 1/1/1/0
 l2vpn.l2vpn.0: 1/1/1/0

```

2. The following output verifies the Layer 2 VPN route and the label associated with it.

```
user@PE3> show route table l2vpn.l2vpn.0 detail
```

```

### Verifying End-to-End connectivity from Router CE2 to Router CE5 and Router CE3

**Purpose** Check the connectivity between Routers CE2, CE3, and CE5.

- Action** 1. Ping the Router CE3 IP address from Router CE2.

```
user@CE2> ping 198.51.100.10 # CE3 IP address
PING 198.51.100.10 (198.51.100.10): 56 data bytes
64 bytes from 198.51.100.10: icmp_seq=0 ttl=63 time=0.708 ms
64 bytes from 198.51.100.10: icmp_seq=1 ttl=63 time=0.610 ms
```

2. Ping the Router CE5 IP address from Router CE2.

```
user@CE2> ping 198.51.100.2 # CE5 IP address
PING 198.51.100.2 (198.51.100.2): 56 data bytes
64 bytes from 198.51.100.2: icmp_seq=0 ttl=62 time=0.995 ms
64 bytes from 198.51.100.2: icmp_seq=1 ttl=62 time=1.005 ms
```

## Using the Layer 2 Interworking Interface to Interconnect a Layer 2 Circuit to a Layer 2 VPN

---

Instead of using a physical Tunnel PIC for looping the packet received from the Layer 2 circuit, the Layer 2 interworking interface uses Junos OS to stitch together both Layer 2 VPN routes.

To configure the interworking interface, include the **iw0** statement. The **iw0** statement is configured at the **[edit interfaces]** hierarchy level. This specifies the peering between two logical interfaces. This configuration is similar to the configuration for a logical tunnel interface. The logical Interfaces must be associated with the endpoints of a Layer 2 circuit and Layer 2 VPN connections.

```
[edit interfaces]
iw0 {
 unit 0 {
 peer-unit 1;
 }
 unit 1 {
 peer-unit 0;
 }
}
```

Configure the Layer 2 circuit protocol by including the **l2circuit** statement at the **[edit protocols]** hierarchy level and specifying the **neighbor** and **iw0** interface.

```
[edit protocols]
l2circuit {
 neighbor 192.0.2.0 {
 interface iw0.0;
 }
}
```

```
}
```

Configure the Layer 2 VPN connection, by including the ***routing-instance-name*** statement at the **[edit routing-instances]** hierarchy level and specifying the **instance-type l2vpn** option.

```
[edit routing-instances]
routing-instance-name {
 instance-type l2vpn;
 interface iw0.1;
 ...
 protocols {
 l2vpn {
 <l2vpn configuration>;
 }
 }
}
```

In addition to the **iw0** interface configuration, Layer 2 interworking **l2iw** protocols must be enabled. Without the **l2iw** configuration, the **l2iw** routes will not be formed, regardless of whether any **iw** interfaces are present. Within the **l2iw** protocols, only trace options can be configured in the standard fashion. The minimum configuration necessary for the feature to work is shown below:

```
[edit]
protocols {
 l2iw;
}
```

---

## Applications for Interconnecting a Layer 2 Circuit with a Layer 2 Circuit

MPLS-based Layer 2 services are growing in demand among enterprise and service providers. This creates new challenges for service providers who want to provide end-to-end value-added services. There are various reasons to stitch different Layer 2 services to one another and to Layer 3 services, for example, to expand the service offerings and to expand geographically. Junos OS has various features to address the needs of the service provider.

In Layer 2 circuits with structure-aware TDM Circuit Emulation Service over Packet-Switched Network (CESoPSN) encapsulation, you can configure the payload size for virtual circuits that terminate on Layer 2 interworking (iw) logical interfaces. The payload size must be specified to enable stitching of LDP-signaled TDM pseudowires in environments where an interconnection between two Layer 2 circuits is required. You can include the **payload-size bytes** statement at the **[edit interfaces interface-name cesopsn-options]** hierarchy level, to define the size in bytes (from 32 through 1024 bytes).

Interconnecting a Layer 2 circuit with a Layer 2 circuit includes the following benefits:

- Interconnecting a Layer 2 circuit with a Layer 2 circuit enables the sharing of a service provider's core network infrastructure between Layer 2 circuit services, reducing the

cost of providing those services. A Layer 2 MPLS circuit enables service providers to create a Layer 2 circuit service over an existing IP and MPLS backbone.

- Service providers do not have to invest in separate Layer 2 equipment to provide Layer 2 circuit service. A service provider can configure a provider edge router to run any Layer 2 protocol. Customers who prefer to maintain control over most of the administration of their own networks want Layer 2 circuit connections with their service provider instead of a Layer 3 VPN connection.

---

## Example: Interconnecting a Layer 2 Circuit with a Layer 2 VPN

---

This example provides a step-by-step procedure and commands for configuring and verifying a Layer 2 circuit to a Layer 2 VPN. It contains the following sections:

- [Requirements on page 1659](#)
- [Overview and Topology on page 1659](#)
- [Configuration on page 1661](#)

### Requirements

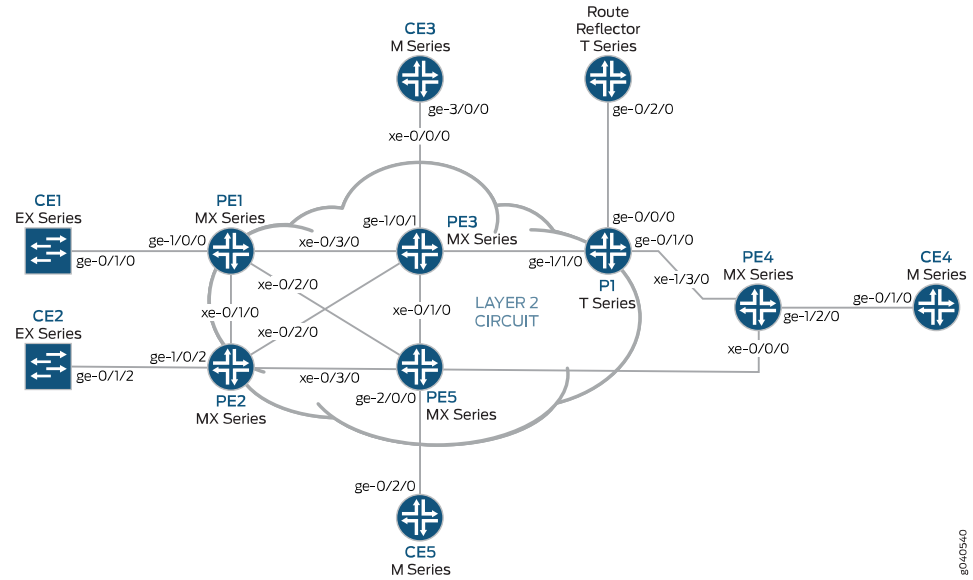

This example uses the following hardware and software components:

- Junos OS Release 9.3 or later
- 2 MX Series 3D Universal Edge Routers
- 2 M Series Multiservice Edge Router
- 1 T Series Core Router
- 1 EX Series Ethernet Switch

### Overview and Topology

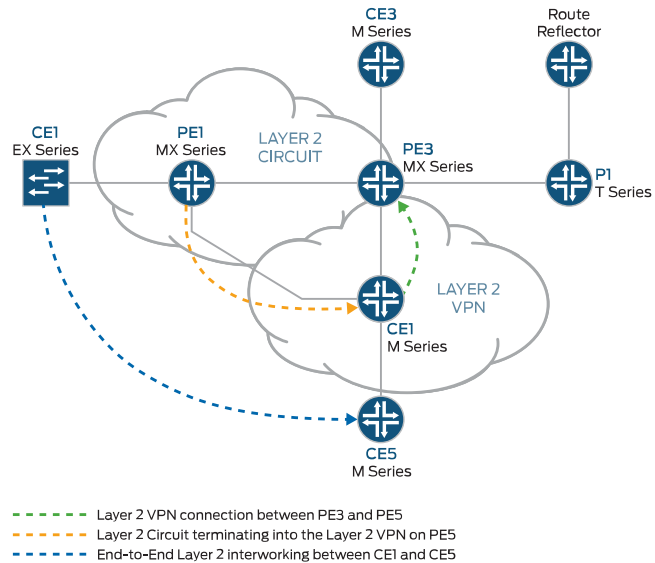

The physical topology of a Layer 2 circuit to a Layer 2 VPN connection is shown in [Figure 154 on page 1660](#).

**Figure 154: Physical Topology of a Layer 2 Circuit to a Layer 2 VPN Connection**

The logical topology of a Layer 2 circuit to a Layer 2 VPN connection is shown in [Figure 155 on page 1660](#).

**Figure 155: Logical Topology of a Layer 2 Circuit to a Layer 2 VPN Connection**

## Configuration

**NOTE:** In any configuration session, it is good practice to verify periodically that the configuration can be committed using the `commit check` command.

In this example, the router being configured is identified using the following command prompts:

- **CE1** identifies the customer edge 1 (CE1) router
- **PE1** identifies the provider edge 1 (PE1) router
- **CE3** identifies the customer edge 3 (CE3) router
- **PE3** identifies the provider edge 3 (PE3) router
- **CE5** identifies the customer edge 5 (CE5) router
- **PE5** identifies the provider edge 5 (PE5) router

This example is organized in the following sections:

- [Configuring Protocols on the PE and P Routers on page 1661](#)
- [Verification on page 1666](#)

### Configuring Protocols on the PE and P Routers

#### Step-by-Step Procedure

In this example, all of the PE routers and P routers are configured with OSPF as the IGP protocol. The MPLS, LDP, and BGP protocols are enabled on all of the interfaces except **fxp0.0**. Core-facing interfaces are enabled with the MPLS address and inet address.

1. Configure all the PE and P routers with OSPF as the IGP. Enable the MPLS, LDP, and BGP protocols on all interfaces except **fxp0.0**. LDP is used as the signaling protocol on Router PE1 for the Layer 2 circuit. The following configuration snippet shows the protocol configuration for Router PE1:

```
[edit]
protocols {
 mpls {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 bgp {
 group RR {
 type internal;
 local-address 192.0.2.1;
 family l2vpn {
 signaling;
 }
 neighbor 192.0.2.7;
 }
 }
}
```

```
}
ospf {
 traffic-engineering;
 area 0.0.0.0 {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
}
ldp {
 interface all;
 interface fxp0.0 {
 disable;
 }
}
}
```

2. Configure the PE and P routers with OSPF as the IGP. Enable the MPLS, LDP, and BGP protocols on all interfaces except **fxp0.0**. BGP is used as the signaling protocol on Router PE3 for the Layer 2 VPN. The following configuration snippet shows the protocol configuration for Router PE3:

```
[edit]
protocols {
 mpls {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 bgp {
 group RR {
 type internal;
 local-address 192.0.2.3;
 family l2vpn {
 signaling;
 }
 neighbor 192.0.2.7;
 }
 }
 ospf {
 traffic-engineering;
 area 0.0.0.0 {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 }
 ldp {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
}
```

```

 }
}

```

### Step-by-Step Procedure

#### Configuring Interfaces

1. On Router PE1, configure the **ge-1/0/0** interface encapsulation. To configure the interface encapsulation, include the **encapsulation** statement and specify the **ethernet-ccc** option (vlan-ccc encapsulation is also supported). Configure the **ge-1/0/0.0** logical interface family for circuit cross-connect functionality. To configure the logical interface family, include the **family** statement and specify the **ccc** option. The encapsulation should be configured the same way for all routers in the Layer 2 circuit domain.

```

[edit interfaces]
ge-1/0/0 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
}
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.1/24;
 }
 }
}

```

2. Router PE5 is the router that is *stitching* the Layer 2 circuit to the Layer 2 VPN using the interworking interface. The configuration of the peer unit interfaces is what makes the interconnection.

On Router PE5, configure the **iw0** interface with two logical interfaces. To configure the **iw0** interface, include the **interfaces** statement and specify **iw0** as the interface name. For the unit 0 logical interface, include the **peer-unit** statement and specify the logical interface **unit 1** as the peer interface. For the unit 1 logical interface, include the **peer-unit** statement and specify the logical interface **unit 0** as the peer interface.

```

[edit interfaces]
iw0 {
 unit 0 {
 encapsulation ethernet-ccc;
 peer-unit 1;
 }
 unit 1 {
 encapsulation ethernet-ccc;
 peer-unit 0;
 }
}

```

3. On Router PE5, configure the logical loopback interface. The loopback interface is used to establish the targeted LDP sessions to Routers PE1 and PE5.

```
[edit interfaces]
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.5/24;
 }
 }
}
```

### Step-by-Step Procedure

#### Configuring the Layer 2 circuit protocol

1. On Router PE1, configure the IP address of the remote PE router with the **neighbor** statement. The loopback address and router ID of the PE neighbor is commonly the neighbor's IP address. To allow a Layer 2 circuit to be established even though the maximum transmission unit (MTU) configured on the PE router does not match the MTU configured on the remote PE router, include the **ignore-mtu-mismatch** statement.

```
[edit]
protocols {
 l2circuit {
 neighbor 192.0.2.5 {
 interface ge-1/0/0.0 {
 virtual-circuit-id 100;
 no-control-word;
 ignore-mtu-mismatch;
 }
 }
 }
}
```

2. On Router PE5, configure the IP address of the remote PE router. To configure the IP address of the remote PE router, include the **neighbor** statement and specify the IP address of the loopback interface on Router PE1. Configure the virtual circuit ID to be the same as the virtual circuit ID on the neighbor router. To allow a Layer 2 circuit to be established even though the MTU configured on the local PE router does not match the MTU configured on the remote PE router, include the **ignore-mtu-mismatch** statement. Also disable the use of the control word for demultiplexing by including the **no-control-word** statement.

```
[edit protocols]
l2circuit {
 neighbor 192.0.2.1 {
 interface iw0.0 {
 virtual-circuit-id 100;
 no-control-word;
 ignore-mtu-mismatch;
 }
 }
}
```

3. On Router PE5, configure the Layer 2 VPN protocols by including the **l2vpn** statement at the **[edit routing-instances routing-instances-name protocols]** hierarchy level. To configure the **iw0** interface, include the **interfaces** statement and specify **iw0** as the interface name. The **iw0** interface is configured under the Layer 2 VPN protocols to receive the looped packet from the **iw0.1** logical interface. The **l2vpn** protocol is configured on Router PE5 with site CE5, which is configured in the BGP L2VPN routing instance. Router CE1 has communication to Router CE5, through the Layer 2 interworking configuration on Router PE5.

```
[edit]
routing-instances {
 L2VPN {
 instance-type l2vpn;
 interface ge-2/0/0.0;
 interface iw0.1;
 route-distinguisher 65000:5;
 vrf-target target:65000:2;
 protocols {
 l2vpn {
 no-control-word;
 encapsulation-type ethernet;
 site CE5 {
 site-identifier 5;
 interface ge-2/0/0.0 {
 remote-site-id 3;
 }
 }
 site l2-circuit {
 site-identifier 6;
 interface iw0.1 {
 remote-site-id 3;
 }
 }
 }
 }
 }
}
```

4. In addition to the **iw0** interface configuration, the Layer 2 interworking **l2iw** protocol must be configured. Without the **l2iw** protocol configuration, the Layer 2 interworking routes are not formed, regardless of whether any **iw** interfaces are present.

On Router PE5, configure the **l2iw** protocol. To configure the protocol, include the **l2iw** statement at the **[edit protocols]** hierarchy level.

```
[edit]
protocols {
 l2iw;
}
```

## Verification

### Step-by-Step Procedure Verifying the Layer 2 Circuit Connection on Router PE1.

#### Procedure

1. On Router PE1, use the **show l2circuit connections** command to verify that the Layer 2 Circuit from Router PE1 to Router PE5 is **Up**.

```
user@PE1> show l2circuit connections
Layer-2 Circuit Connections:
Legend for connection status (St)
EI -- encapsulation invalid NP -- interface h/w not present
MM -- mtu mismatch Dn -- down
EM -- encapsulation mismatch VC-Dn -- Virtual circuit Down
CM -- control-word mismatch Up -- operational
VM -- vlan id mismatch CF -- Call admission control failure
OL -- no outgoing label IB -- TDM incompatible bitrate
NC -- intf encaps not CCC/TCC TM -- TDM misconfiguration
BK -- Backup Connection ST -- Standby Connection
CB -- rcvd cell-bundle size bad XX -- unknown
SP -- Static Pseudowire
```

#### Legend for interface status

Up -- operational

Dn -- down

Neighbor: 192.0.2.5

| Interface          | Type | St | Time last up        | # Up trans |
|--------------------|------|----|---------------------|------------|
| ge-1/0/0.0(vc 100) | rmt  | Up | Jan 3 22:00:49 2010 | 1          |

Remote PE: 192.0.2.5, Negotiated control-word: No  
Incoming label: 301328, Outgoing label: 300192  
Local interface: ge-1/0/0.0, Status: Up, Encapsulation: ETHERNET

2. On Router PE5, use the **show l2vpn connections** command to verify that the Layer 2 VPN connection is **Up** using the **iw0** peer interface of the Layer 2 circuit.

```
user@PE5> show l2vpn connections
Instance: L2VPN
Local site: CE5 (5)
connection-site Type St Time last up # Up trans
l2-circuit (6) loc OR
3 rmt Up
Jan 3 22:51:12 2010 1
Remote PE: 192.0.2.3, Negotiated control-word: No
Incoming label: 800258, Outgoing label: 800000
Local interface: ge-2/0/0.0, Status: Up, Encapsulation: ETHERNET
Local site: l2-circuit (6)
connection-site Type St Time last up # Up trans
CE5 (5) loc OR
3 rmt Up
Jan 3 22:56:38 2010 1
Remote PE: 192.0.2.3, Negotiated control-word: No
Incoming label: 800262, Outgoing label: 800001
Local interface: iw0.1, Status: Up, Encapsulation: ETHERNET
```

### Step-by-Step Procedure

Verifying that the Layer 2 Circuit is terminating into the Layer 2 VPN connection.

1. On Router PE5, use the **show l2circuit connections** command to verify that the Layer 2 circuit is **Up** using the **iw0** interface. This will be looped through the **iw0.1** interface to the Layer 2 VPN.

```
user@PE5> show l2circuit connections
```

Layer-2 Circuit Connections:

Neighbor: 192.0.2.1

```
Interface Type St Time last up # Up trans
iw0.0(vc 100) rmt Up Jan 3 21:59:07 2010 1
Remote PE: 192.0.2.1, Negotiated control-word: No
Incoming label: 300192, Outgoing label: 301328
```

2. On Router PE 5, use the **show route table mpls.0** command to verify the Layer 2 circuit and Layer 2 VPN routes. In the example below, the Layer 2 circuit is associated with LDP label **301328** and the Layer 2 VPN is associated with LDP label **800001**. Notice the two **iw0** interfaces that are used for the Layer 2 interworking route.

```
user@PE5>show route table mpls.0
```

mpls.0: 18 destinations, 20 routes (18 active, 2 holddown, 0 hidden)

+ = Active Route, - = Last Active, \* = Both

```

## Example: Interconnecting a Layer 2 Circuit with a Layer 2 Circuit

This example provides a step-by-step procedure and commands for configuring and verifying a Layer 2 circuit to a Layer 2 circuit interconnection. It contains the following sections:

- [Requirements on page 1668](#)
- [Overview and Topology on page 1668](#)
- [Configuration on page 1669](#)

### Requirements

This example uses the following hardware and software components:

- Junos OS Release 9.3 or later
- 2 MX Series routers
- 2 M Series routers
- 1 T Series router
- 1 EX Series router

### Overview and Topology

The physical topology of a Layer 2 circuit to Layer 2 circuit interconnection is shown in [Figure 156 on page 1668](#)

**Figure 156: Physical Topology of a Layer 2 Circuit Terminating into a Layer 2 Circuit**

The logical topology of a Layer 2 circuit to Layer 2 circuit interconnection is shown in [Figure 157 on page 1669](#)

**Figure 157: Logical Topology of a Layer 2 Circuit Terminating into a Layer 2 Circuit**

## Configuration

**NOTE:** In any configuration session, it is good practice to verify periodically that the configuration can be committed using the `commit check` command.

In this example, the router being configured is identified using the following command prompts:

- **CE2** identifies the customer edge 2 (CE2) router
- **PE1** identifies the provider edge 1 (PE1) router
- **CE3** identifies the customer edge 3 (CE3) router
- **PE3** identifies the provider edge 3 (PE3) router
- **CE5** identifies the customer edge 5 (CE5) router
- **PE5** identifies the provider edge 5 (PE5) router

This example contains the following procedures:

- [Configuring PE Router Customer-facing and Loopback Interfaces on page 1670](#)
- [Configuring Core-facing Interfaces on page 1671](#)
- [Configuring Protocols on page 1672](#)
- [Configuring the Layer 2 Circuits on page 1674](#)

- [Interconnecting the Layer 2 Circuits on page 1675](#)
- [Verifying the Layer 2 Circuit to Layer 2 Circuit Interconnection on page 1676](#)
- [Results on page 1679](#)

### Configuring PE Router Customer-facing and Loopback Interfaces

#### Step-by-Step Procedure

To begin building the interconnection, configure the interfaces on the PE routers. If your network contains provider (P) routers, configure the interfaces on the P routers also. This example shows the configuration for Router PE1 and Router PE5.

1. On Router PE1, configure the **ge-1/0/0** interface encapsulation. To configure the interface encapsulation, include the **encapsulation** statement and specify the **ethernet-ccc** option (vlan-ccc encapsulation is also supported). Configure the **ge-1/0/0.0** logical interface family for circuit cross-connect functionality. To configure the logical interface family, include the **family** statement and specify the **ccc** option.

```
[edit interfaces]
ge-1/0/0 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
}
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.1/24;
 }
 }
}
```

2. On Router PE5, configure the **ge-2/0/0** interface encapsulation. To configure the interface encapsulation, include the **encapsulation** statement and specify the **ethernet-ccc** option. Configure the **ge-2/0/0.0** logical interface family for circuit cross-connect functionality. To configure the logical interface family, include the **family** statement and specify the **ccc** option

```
[edit interfaces]
ge-2/0/0 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
}
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.5/24;
 }
 }
}
```

3. On Router PE3, configure the logical loopback interface. The loopback interface is used to establish the targeted LDP sessions to Routers PE1 and PE5.

```
[edit interfaces]
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.3/24;
 }
 }
}
```

### Configuring Core-facing Interfaces

**Step-by-Step Procedure** This procedure describes how to configure the core-facing interfaces on the PE routers. This example does not include all the core-facing interfaces shown in the physical topology illustration. Enable the **mpls** and **inet** address families on the core-facing interfaces.

1. On Router PE1, configure the **xe-0/3/0** interface. Include the **family** statement and specify the **inet** address family. Include the **address** statement and specify **10.10.1.1/30** as the interface address. Include the **family** statement and specify the **mpls** address family.

```
[edit interfaces]
xe-0/3/0 {
 unit 0 {
 family inet {
 address 10.10.1.1/30;
 }
 family mpls;
 }
}
```

2. On Router PE3, configure the core-facing interfaces. Include the **family** statement and specify the **inet** address family. Include the **address** statement and specify the IPv4 addresses shown in the example as the interface addresses. Include the **family** statement and specify the **mpls** address family. In the example, the **xe-0/0/0** interface is connected to the route reflector, the **xe-0/1/0** interface is connected to Router PE5, the **xe-0/2/0** interface is connected to Router PE2, and the **xe-0/3/0** interface is connected to Router PE1.

```
[edit interfaces]
xe-0/0/0 {
 unit 0 {
 family inet {
 address 10.10.20.2/30;
 }
 family mpls;
 }
}
xe-0/1/0 {
 unit 0 {
```

```
 family inet {
 address 10.10.6.1/30;
 }
 family mpls;
 }
}
xe-0/2/0 {
 unit 0 {
 family inet {
 address 10.10.5.2/30;
 }
 family mpls;
 }
}
xe-0/3/0 {
 unit 0 {
 family inet {
 address 10.10.1.2/30;
 }
 family mpls;
 }
}
```

3. On Router PE5, configure the **xe-0/1/0** interface. Include the **family** statement and specify the **inet** address family. Include the **address** statement and specify **10.10.6.2/30** as the interface address. Include the **family** statement and specify the **mpls** address family.

```
[edit interfaces]
xe-0/1/0 {
 unit 0 {
 family inet {
 address 10.10.6.2/30;
 }
 family mpls;
 }
}
```

---

## Configuring Protocols

### Step-by-Step Procedure

This procedure describes how to configure the protocols used in this example. If your network contains P routers, configure the protocols on the P routers also.

Configure all of the PE routers and P routers with OSPF as the IGP protocol. Enable MPLS and LDP protocols on all of the interfaces except **fxp.0**.

1. On Router PE1, enable OSPF as the IGP. Enable the MPLS and LDP protocols on all interfaces except **fxp.0**. LDP is used as the signaling protocol on Router PE1 for the Layer 2 circuit. The following configuration snippet shows the protocol configuration for Router PE1:

```
[edit]
protocols {
 mpls {
```

```

 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 ospf {
 traffic-engineering;
 area 0.0.0.0 {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 }
 ldp {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
}

```

2. Configure the PE and P routers with OSPF as the IGP. Enable the MPLS and LDP protocols on all interfaces except **fxp0.0**. The following configuration snippet shows the protocol configuration for Router PE3:

```

[edit]
protocols {
 mpls {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 ospf {
 traffic-engineering;
 area 0.0.0.0 {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 }
 ldp {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
}

```

## Configuring the Layer 2 Circuits

### Step-by-Step Procedure

This procedure describes how to configure the Layer 2 circuits.

**NOTE:** In this example the **ignore-mtu-mismatch** statement is required for the circuit to come up.

1. On Router PE1, configure the Layer 2 circuit. Include the **l2circuit** statement. Include the **neighbor** statement and specify the loopback IPv4 address of Router PE3 as the neighbor. Include the interface statement and specify **ge-1/0/0.0** as the logical interface that is participating in the Layer 2 circuit. Include the **virtual-circuit-id** statement and specify **100** as the identifier. Include the **ignore-mtu-mismatch** statement to allow a Layer 2 circuit to be established even though the maximum transmission unit (MTU) configured on the local PE router does not match the MTU configured on the remote PE router.

```
[edit]
protocols {
 l2circuit {
 neighbor 192.0.2.3 {
 interface ge-1/0/0.0 {
 virtual-circuit-id 100;
 ignore-mtu-mismatch;
 }
 }
 }
}
```

2. On Router PE5, configure the Layer 2 circuit. Include the **l2circuit** statement. Include the **neighbor** statement and specify the loopback IPv4 address of Router PE3 as the neighbor. Include the interface statement and specify **ge-2/0/0.0** as the logical interface that is participating in the Layer 2 circuit. Include the **virtual-circuit-id** statement and specify **200** as the identifier. Include the **ignore-mtu-mismatch** statement to allow a Layer 2 circuit to be established even though the MTU configured on the local PE router does not match the MTU configured on the remote PE router.

```
[edit]
protocols {
 l2circuit {
 neighbor 192.0.2.3 {
 interface ge-2/0/0.0 {
 virtual-circuit-id 200;
 ignore-mtu-mismatch;
 }
 }
 }
}
```

- On Router PE3, configure the Layer 2 circuit to Router PE1. Include the **l2circuit** statement. Include the **neighbor** statement and specify the loopback IPv4 address of Router PE1 as the neighbor. Include the interface statement and specify **iw0.0** as the logical interworking interface that is participating in the Layer 2 circuit. Include the **virtual-circuit-id** statement and specify **100** as the identifier. Include the **ignore-mtu-mismatch** statement to allow a Layer 2 circuit to be established even though the MTU configured on the local PE router does not match the MTU configured on the remote PE router.

On Router PE3, configure the Layer 2 circuit to Router PE5. Include the **l2circuit** statement. Include the **neighbor** statement and specify the loopback IPv4 address of Router PE5 as the neighbor. Include the interface statement and specify **iw0.1** as the logical interworking interface that is participating in the Layer 2 circuit. Include the **virtual-circuit-id** statement and specify **200** as the identifier. Include the **ignore-mtu-mismatch** statement.

```
[edit protocols]
l2circuit {
 neighbor 192.0.2.1 {
 interface iw0.0 {
 virtual-circuit-id 100;
 ignore-mtu-mismatch;
 }
 }
 neighbor 192.0.2.5 {
 interface iw0.1 {
 virtual-circuit-id 200;
 ignore-mtu-mismatch;
 }
 }
}
```

### Interconnecting the Layer 2 Circuits

**Step-by-Step Procedure** Router PE3 is the router that is *stitching* the Layer 2 circuits together using the interworking interface. The configuration of the peer unit interfaces is what makes the interconnection.

- On Router PE3, configure the **iw0.0** interface. Include the **encapsulation** statement and specify the **ethernet-ccc** option. Include the **peer-unit** statement and specify the logical interface unit 1 as the peer tunnel interface.

On Router PE3, configure the **iw0.1** interface. Include the **encapsulation** statement and specify the **ethernet-ccc** option. Include the **peer-unit** statement and specify the logical interface unit 0 as the peer tunnel interface.

```
[edit interfaces]
iw0 {
 unit 0 {
 encapsulation ethernet-ccc;
 peer-unit 1;
 }
 unit 1 {
 encapsulation ethernet-ccc;
```

```

 peer-unit 0;
 }
}

```

- On Router PE3, configure the Layer 2 interworking **l2iw** protocol. To configure the Layer 2 interworking protocol, include the **l2iw** statement at the **[edit protocols]** hierarchy level.

```

[edit]
protocols {
 l2iw;
}

```

- On each router, commit the configuration.

```

user@host> commit check
configuration check succeeds
user@host> commit

```

### Verifying the Layer 2 Circuit to Layer 2 Circuit Interconnection

**Step-by-Step Procedure** Verify that the Layer 2 circuit connection on Router PE1 is up, the LDP neighbors are correct, and the MPLS label operations are correct.

- On Router PE1, use the **show l2circuit connections** command to verify that the Layer 2 circuit from Router PE1 to Router PE3 is **Up**.

```

user@PE1> show l2circuit connections
Layer-2 Circuit Connections:
Legend for connection status (St)
EI -- encapsulation invalid NP -- interface h/w not present
MM -- mtu mismatch Dn -- down
EM -- encapsulation mismatch VC-Dn -- Virtual circuit Down
CM -- control-word mismatch Up -- operational
VM -- vlan id mismatch CF -- Call admission control failure
OL -- no outgoing label IB -- TDM incompatible bitrate
NC -- intf encaps not CCC/TCC TM -- TDM misconfiguration
BK -- Backup Connection ST -- Standby Connection
CB -- rcvd cell-bundle size bad XX -- unknown
SP -- Static Pseudowire

Legend for interface status
Up -- operational
Dn -- down
Neighbor: 192.0.2.3
 Interface Type St Time last up # Up trans
 ge-1/0/0.0(vc 100) rmt Up Jan 5 22:00:49 2010 1
 Remote PE: 192.0.2.3, Negotiated control-word: Yes (Null)
 Incoming label: 301328, Outgoing label: 314736
 Local interface: ge-1/0/0.0, Status: Up, Encapsulation: ETHERNET

```

- On Router PE1, use the **show ldp neighbor** command to verify that the IPv4 address of Router PE3 is shown as the LDP neighbor.

```

user@PE1> show ldp neighbor

```

| Address   | Interface | Label space ID | Hold time |
|-----------|-----------|----------------|-----------|
| 192.0.2.3 | lo0.0     | 192.0.2.3:0    | 41        |

- On Router PE1, use the **show route table mpls.0** command to verify the Layer 2 circuit is using the LDP label to Router PE3 in both directions (Push and Pop). In the example below, the Layer 2 circuit is associated with LDP label **301328**.

```
user@PE1> show route table mpls.0
```

```
mpls.0: 13 destinations, 13 routes (13 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0 *[MPLS/0] 1w1d 08:25:39, metric 1
 Receive
1 *[MPLS/0] 1w1d 08:25:39, metric 1
 Receive
2 *[MPLS/0] 1w1d 08:25:39, metric 1
 Receive
300432 *[LDP/9] 3d 01:13:57, metric 1
 > to 10.10.2.2 via xe-0/1/0.0, Pop
300432(S=0) *[LDP/9] 3d 01:13:57, metric 1
 > to 10.10.2.2 via xe-0/1/0.0, Pop
300768 *[LDP/9] 3d 01:13:57, metric 1
 > to 10.10.3.2 via xe-0/2/0.0, Pop
300768(S=0) *[LDP/9] 3d 01:13:57, metric 1
 > to 10.10.3.2 via xe-0/2/0.0, Pop
300912 *[LDP/9] 3d 01:13:57, metric 1
 > to 10.10.3.2 via xe-0/2/0.0, Swap 299856
301264 *[LDP/9] 3d 01:13:53, metric 1
 > to 10.10.1.2 via xe-0/3/0.0, Swap 308224
301312 *[LDP/9] 3d 01:13:56, metric 1
 > to 10.10.1.2 via xe-0/3/0.0, Pop
301312(S=0) *[LDP/9] 3d 01:13:56, metric 1
 > to 10.10.1.2 via xe-0/3/0.0, Pop
301328 *[L2CKT/7] 02:33:26 > via ge-1/0/0.0, Pop Offset: 4
ge-1/0/0.0 *[L2CKT/7] 02:33:26, metric2 1 > to 10.10.1.2 via xe-0/3/0.0,
Push 314736 Offset: -4
```

- On Router PE3, use the **show l2circuit connections** command to verify that the Layer 2 circuit from Router PE3 to Router PE5 is **Up**, that the Layer 2 circuit from Router PE3 to Router PE1 is **Up**, that the connections to Router PE1 and Router PE5 use the iw0 interface, and that the status for both local iw0 interfaces is **Up**.

```
user@PE3> show l2circuit connections
```

```
Layer-2 Circuit Connections:

 Incoming label: 314752, Outgoing label: 300208
 Local interface: iw0.1, Status: Up, Encapsulation: ETHERNET

```

5. On Router PE3, use the **show ldp neighbor** command to verify that the correct IPv4 addresses are shown as the LDP neighbor.

```

user@PE3> show ldp neighbor
Address Interface Label space ID Hold time
192.0.2.1 lo0.0 192.0.2.1:0 44
192.0.2.2 lo0.0 192.0.2.2:0 42
192.0.2.4 lo0.0 192.0.2.4:0 31
192.0.2.5 lo0.0 192.0.2.5:0 44

```

6. On Router PE3, use the **show route table mpls.0** command to verify that the **mpls.0** routing table is populated with the Layer 2 interworking routes. Notice that in this example, the router is swapping label **314736** received from Router PE1 on the **iw0.0** to label **301328**.

```

user@PE3> show route table mpls.0
mpls.0: 16 destinations, 18 routes (16 active, 2 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0 *[MPLS/0] 1w1d 08:28:24, metric 1
 Receive
1 *[MPLS/0] 1w1d 08:28:24, metric 1
 Receive
2 *[MPLS/0] 1w1d 08:28:24, metric 1
 Receive
308160 *[LDP/9] 3d 01:16:55, metric 1
 > to 10.10.1.1 via xe-0/3/0.0, Pop

308176(S=0) *[LDP/9] 3d 01:16:54, metric 1
 > to 10.10.6.2 via xe-0/1/0.0, Pop
308192 *[LDP/9] 00:21:40, metric 1
 > to 10.10.20.1 via xe-0/0/0.0, Swap 601649
 > to 10.10.6.2 via xe-0/1/0.0, Swap 299856
308208 *[LDP/9] 3d 01:16:54, metric 1
 > to 10.10.5.1 via xe-0/2/0.0, Pop
308208(S=0) *[LDP/9] 3d 01:16:54, metric 1
 > to 10.10.5.1 via xe-0/2/0.0, Pop
308224 *[LDP/9] 3d 01:16:52, metric 1
 > to 10.10.20.1 via xe-0/0/0.0, Pop
308224(S=0) *[LDP/9] 3d 01:16:52, metric 1
 > to 10.10.20.1 via xe-0/0/0.0, Pop

```

```

314736 *[L2IW/6] 02:35:31, metric2 1
 > to 10.10.6.2 via xe-0/1/0.0, Swap 300208
 [L2CKT/7] 02:35:31
 > via iw0.0, Pop Offset: 4
314752 *[L2IW/6] 02:35:31, metric2 1
 > to 10.10.1.1 via xe-0/3/0.0, Swap 301328
 [L2CKT/7] 02:35:47
 > via iw0.1, Pop Offset: 4
iw0.0 *[L2CKT/7] 02:35:31, metric2 1
 > to 10.10.1.1 via xe-0/3/0.0, Push 301328 Offset: -4
iw0.1 *[L2CKT/7] 02:35:47, metric2 1
 > to 10.10.6.2 via xe-0/1/0.0, Push 300208 Offset: -4

```

7. Verify that Router CE1 can send traffic to and receive traffic from Router CE5 across the interconnection, using the **ping** command.

```

user@CE1>ping 198.51.100.11
PING 198.51.100.11 (198.51.100.11): 56 data bytes
64 bytes from 198.51.100.11: icmp_seq=1 ttl=64 time=22.425 ms
64 bytes from 198.51.100.11: icmp_seq=2 ttl=64 time=1.299 ms
64 bytes from 198.51.100.11: icmp_seq=3 ttl=64 time=1.032 ms
64 bytes from 198.51.100.11: icmp_seq=4 ttl=64 time=1.029 ms

```

8. Verify that Router CE5 can send traffic to and receive traffic from Router CE1 across the interconnection, using the **ping** command.

```

user@CE5>ping 198.51.100.1
PING 198.51.100.1 (198.51.100.1): 56 data bytes
64 bytes from 198.51.100.1: icmp_seq=0 ttl=64 time=1.077 ms
64 bytes from 198.51.100.1: icmp_seq=1 ttl=64 time=0.957 ms
64 bytes from 198.51.100.1: icmp_seq=2 ttl=64 time=1.057 ms 1.017 ms

```

## Results

The configuration and verification of this example has been completed. The following section is for your reference.

The relevant sample configuration for Router PE1 follows.

```

Router PE1 [edit]
 interfaces {
 xe-0/1/0 {
 unit 0 {
 family inet {
 address 10.10.2.1/30;
 }
 family mpls;
 }
 }
 xe-0/2/0 {
 unit 0 {
 family inet {
 address 10.10.3.1/30;
 }
 }
 }

```

```
 family mpls;
 }
}

## Applications for Interconnecting a Layer 2 Circuit with a Layer 3 VPN

MPLS-based Layer 2 services are growing in demand among enterprise and service providers. This creates new challenges related to interoperability between Layer 2 and Layer 3 services for service providers who want to provide end-to-end value-added services. There are various reasons to stitch different Layer 2 services to one another and to Layer 3 services. For example, to expand the service offerings and to expand geographically. The Junos OS has various features to address the needs of the service provider.

You can enable pseudowire services and configure a pseudowire service interface as an access point for interconnecting layer 2 circuits to layer 3 VPNs. For more information, see *Pseudowire Subscriber Logical Interfaces Overview*.

Interconnecting a Layer 2 Circuit with a Layer 3 VPN provides the following benefits:

- Interconnecting a Layer 2 Circuit with a Layer 3 VPN enables the sharing of a service provider's core network infrastructure between IP and Layer 2 circuit services, reducing the cost of providing those services. A Layer 2 MPLS circuit allows service providers to create a Layer 2 circuit service over an existing IP and MPLS backbone.
- Service providers do not have to invest in separate Layer 2 equipment to provide Layer 2 circuit service. A service provider can configure a provider edge router to run any Layer 3 protocol in addition to the Layer 2 protocols. Customers who prefer to maintain control over most of the administration of their own networks want Layer 2 circuit connections with their service provider instead of a Layer 3 VPN connection.

**Related Documentation**

## Example: Interconnecting a Layer 2 Circuit with a Layer 3 VPN

This example provides a step-by-step procedure and commands for configuring and verifying a Layer 2 circuit to Layer 3 VPN interconnection. It contains the following sections:

- [Requirements on page 1684](#)
- [Overview and Topology on page 1684](#)
- [Configuration on page 1685](#)
- [Verifying the Layer 2 Circuit to Layer 3 VPN Interconnection on page 1696](#)

### Requirements

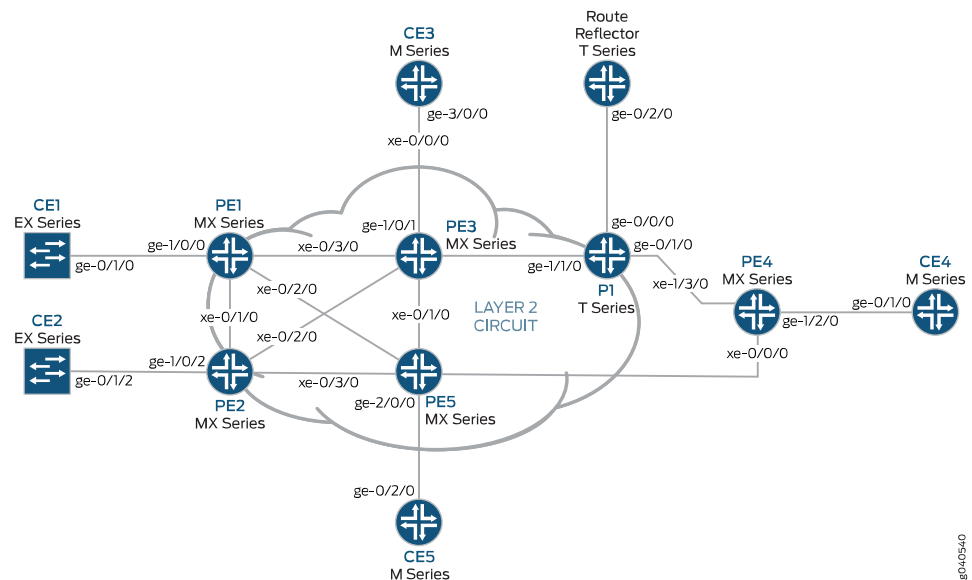

This example uses the following hardware and software components:

- Junos OS Release 9.3 or later
- 3 MX Series 3D Universal Edge Routers
- 1 M Series Multiservice Edge Router
- 1 T Series Core Router
- 1 EX Series Ethernet Switch

### Overview and Topology

The physical topology of a Layer 2 circuit to Layer 3 VPN interconnection is shown in [Figure 158 on page 1684](#).

**Figure 158: Physical Topology of a Layer 2 Circuit to Layer 3 VPN Interconnection**

The logical topology of a Layer 2 circuit to Layer 3 VPN interconnection is shown in [Figure 159 on page 1685](#).

**Figure 159: Logical Topology of a Layer 2 Circuit to Layer 3 VPN Interconnection**

## Configuration

**NOTE:** In any configuration session, it is good practice to verify periodically that the configuration can be committed using the `commit check` command.

In this example, the router being configured is identified using the following command prompts:

- **CE2** identifies the customer edge 2 (CE2) router
- **PE1** identifies the provider edge 1 (PE1) router
- **CE3** identifies the customer edge 3 (CE3) router
- **PE3** identifies the provider edge 3 (PE3) router
- **CE5** identifies the customer edge 5 (CE5) router
- **PE5** identifies the provider edge 5 (PE5) router

This example contains the following procedures:

- [Configuring PE Router Customer-facing and Loopback Interfaces on page 1686](#)
- [Configuring Core-facing Interfaces on page 1687](#)
- [Configuring Protocols on page 1689](#)
- [Configuring Routing Instances and Layer 2 Circuits on page 1692](#)

- [Configuring the Route Reflector on page 1693](#)
- [Interconnecting the Layer 2 Circuit with the Layer 3 VPN on page 1695](#)

---

### Configuring PE Router Customer-facing and Loopback Interfaces

---

#### Step-by-Step Procedure

To begin building the interconnection, configure the interfaces on the PE routers. If your network contains provider (P) routers, configure the interfaces on the P routers also. This example shows the configuration for Router PE2, Router PE3, and Router PE5.

1. On Router PE2, configure the **ge-1/0/2** interface encapsulation. To configure the interface encapsulation, include the **encapsulation** statement and specify the **ethernet-ccc** option (**vlan-ccc** encapsulation is also supported). Configure the **ge-1/0/2.0** logical interface family for circuit cross-connect functionality. To configure the logical interface family, include the **family** statement and specify the **ccc** option. The encapsulation should be configured the same way for all routers in the Layer 2 circuit domain.

```
[edit interfaces]
ge-1/0/2 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
}
```

2. On Router PE2, configure the **lo0.0** interface. Include the **family** statement and specify the **inet** option. Include the **address** statement and specify **192.0.2.2/24** as the loopback IPv4 address.

```
[edit interfaces]
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.2/24;
 }
 }
}
```

3. On Router PE3, configure the **ge-1/0/1** interface. Include the **family** statement and specify the **inet** option. Include the **address** statement and specify **198.51.100.1/24** as the interface address for this device.

```
[edit interfaces]
ge-1/0/1 {
 unit 0 {
 family inet {
 address 198.51.100.1/24;
 }
 }
}
```

- On Router PE3, configure the **lo0.0** loopback interface. Include the **family** statement and specify the **inet** option. Include the **address** statement and specify **192.0.2.3/24** as the loopback IPv4 address for this router.

```
[edit interfaces]
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.3/24;
 }
 }
}
```

- On Router PE5, configure the **ge-2/0/0** interface. Include the **family** statement and specify the **inet** option. Include the **address** statement and specify **198.51.100.8/24** as the interface address.

```
[edit interfaces]
ge-2/0/0 {
 unit 0 {
 family inet {
 address 198.51.100.8/24;
 }
 }
}
```

- On Router PE5, configure the **lo0.0** interface. Include the **family** statement and specify the **inet** option. Include the **address** statement and specify **192.0.2.5/24** as the loopback IPv4 address for this router.

```
[edit interfaces]
lo0 {
 unit 0 {
 family inet {
 address 192.0.2.5/24;
 }
 }
}
```

### Configuring Core-facing Interfaces

#### Step-by-Step Procedure

This procedure describes how to configure the core-facing interfaces on the PE routers. This example does not include all the core-facing interfaces shown in the physical topology illustration. Enable the **mpls** and **inet** address families on the core-facing interfaces.

- On Router PE2, configure the **xe-0/2/0** interface. Include the **family** statement and specify the **inet** address family. Include the **address** statement and specify **10.10.5.1/30** as the interface address. Include the **family** statement and specify the **mpls** address family.

```
[edit interfaces]
```

```
xe-0/2/0 {
 unit 0 {
 family inet {
 address 10.10.5.1/30;
 }
 family mpls;
 }
}
```

2. On Router PE3, configure the core-facing interfaces. Include the **family** statement and specify the **inet** address family. Include the **address** statement and specify the IPv4 addresses shown in the example as the interface addresses. Include the **family** statement and specify the **mpls** address family. In the example, the **xe-2/1/0** interface is connected to Router PE5, and the **xe-2/2/0** interface is connected to Router PE2.

```
[edit interfaces]
xe-2/0/0 {
 unit 0 {
 family inet {
 address 10.10.20.2/30;
 }
 family mpls;
 }
}
xe-2/1/0 {
 unit 0 {
 family inet {
 address 10.10.6.1/30;
 }
 family mpls;
 }
}
xe-2/2/0 {
 unit 0 {
 family inet {
 address 10.10.5.2/30;
 }
 family mpls;
 }
}
xe-2/3/0 {
 unit 0 {
 family inet {
 address 10.10.1.2/30;
 }
 family mpls;
 }
}
```

3. On Router PE5, configure the **xe-0/1/0** interface. Include the **family** statement and specify the **inet** address family. Include the **address** statement and specify **10.10.6.2/30** as the interface address. Include the **family** statement and specify the **mpls** address family.

```
[edit interfaces]
xe-0/1/0 {
 unit 0 {
 family inet {
 address 10.10.6.2/30;
 }
 family mpls;
 }
}
```

### Configuring Protocols

#### Step-by-Step Procedure

This procedure describes how to configure the protocols used in this example. If your network contains P routers, configure the interfaces on the P routers also.

1. On Router PE3, enable OSPF as the IGP. Enable the MPLS, LDP, and BGP protocols on all interfaces except **fxp0.0**. LDP is used as the signaling protocol for the Layer 2 circuit to Router PE2. The following configuration snippet shows the protocol configuration for Router PE3:

```
[edit]
protocols {
 rsvp {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 mpls {
 label-switched-path to-RR {
 to 192.0.2.7;
 }
 label-switched-path to-PE2 {
 to 192.0.2.2;
 }
 label-switched-path to-PE5 {
 to 192.0.2.5;
 }
 label-switched-path to-PE4 {
 to 192.0.2.4;
 }
 label-switched-path to-PE1 {
 to 192.0.2.1;
 }
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 bgp {
 group RR {
 type internal;
 local-address 192.0.2.3;
 family inet-vpn {
```

```
 unicast;
 }
 family l2vpn {
 signaling;
 }
 neighbor 192.0.2.7;
 }
 }
 ospf {
 traffic-engineering;
 area 0.0.0.0 {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 }
}
ldp {
 interface all;
 interface fxp0.0 {
 disable;
 }
}
}
```

2. On Router PE2, configure the MPLS, OSPF, and LDP protocols.

```
[edit]
protocols {
 mpls {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 ospf {
 traffic-engineering;
 area 0.0.0.0 {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 }
}
ldp {
 interface all;
 interface fxp0.0 {
 disable;
 }
}
}
```

3. On Router PE5, enable OSPF as the IGP. Enable the MPLS, RSVP, and BGP protocols on all interfaces except **fxp0.0**. Enable core-facing interfaces with the **mpls** and **inet** address families.

```
[edit]
protocols {
 rsvp {
 interface all {
 link-protection;
 }
 interface fxp0.0 {
 disable;
 }
 }
 mpls {
 label-switched-path to-RR {
 to 192.0.2.7;
 }
 label-switched-path to-PE2 {
 to 192.0.2.2;
 }
 label-switched-path to-PE3 {
 to 192.0.2.3;
 }
 label-switched-path to-PE4 {
 to 192.0.2.4;
 }
 label-switched-path to-PE1 {
 to 192.0.2.1;
 }
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 bgp {
 group to-rr {
 type internal;
 local-address 192.0.2.5;
 family inet-vpn {
 unicast;
 }
 family l2vpn {
 signaling;
 }
 neighbor 192.0.2.7;
 }
 }
 ospf {
 traffic-engineering;
 area 0.0.0.0 {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 }
}
```

```
 }
}
```

## Configuring Routing Instances and Layer 2 Circuits

### Step-by-Step Procedure

This procedure describes how to configure the Layer 2 circuit and the Layer 3 VPN.

1. On Router PE2, configure the Layer 2 circuit. Include the **l2circuit** statement. Include the **neighbor** statement and specify the loopback IPv4 address of Router PE3 as the neighbor. Include the interface statement and specify **ge-1/0/2.0** as the logical interface that is participating in the Layer 2 circuit. Include the **virtual-circuit-id** statement and specify **100** as the identifier. Include the **no-control-word** statement for equipment that does not support the control word.

```
[edit]
protocols {
 l2circuit {
 neighbor 192.0.2.3 {
 interface ge-1/0/2.0 {
 virtual-circuit-id 100;
 no-control-word;
 }
 }
 }
}
```

2. On Router PE3, configure the Layer 2 circuit to Router PE2. Include the **l2circuit** statement. Include the **neighbor** statement and specify the loopback IPv4 address of Router PE2 as the neighbor. Include the interface statement and specify **lt-1/1/10.0** as the logical tunnel interface that is participating in the Layer 2 circuit. Include the **virtual-circuit-id** statement and specify **100** as the identifier. Include the **no-control-word** statement.

```
[edit]
protocols {
 l2circuit {
 neighbor 192.0.2.2 {
 interface lt-1/1/10.0 {
 virtual-circuit-id 100;
 no-control-word;
 }
 }
 }
}
```

3. On Router PE3, configure the Layer 3 VPN (**L3VPN**) routing instance to Router PE5 at the **[edit routing-instances]** hierarchy level. Also configure the BGP peer group at the **[edit routing-instances L3VPN protocols]** hierarchy level.

```
[edit]
routing-instances {
 L3VPN {
```

```

instance-type vrf;
interface ge-1/0/1.0;
interface lt-1/1/10.1;
route-distinguisher 65000:33;
vrf-target target:65000:2;
vrf-table-label;
protocols {
 bgp {
 export direct;
 group ce3 {
 neighbor 198.51.100.6 {
 peer-as 100;
 }
 }
 }
}
}
}

```

4. On Router PE5, configure the Layer 3 VPN routing instance (**L3VPN**) at the **[edit routing-instances]** hierarchy level. Also configure the BGP peer group at the **[edit routing-instances L3VPN protocols]** hierarchy level.

```

[edit]
routing-instances {
 L3VPN {
 instance-type vrf;
 interface ge-2/0/0.0;
 route-distinguisher 65000:5;
 vrf-target target:65000:2;
 vrf-table-label;
 protocols {
 bgp {
 group ce5 {
 neighbor 198.51.100.10 {
 peer-as 200;
 }
 }
 }
 }
 }
}
}

```

### Configuring the Route Reflector

#### Step-by-Step Procedure

Although a route reflector is not required to interconnect a Layer 2 circuit with a Layer 3 VPN, this example uses a route reflector. This procedure shows the relevant portion of the route reflector configuration.

1. Configure the route reflector with RSVP, MPLS, BGP and OSPF. The route reflector is a BGP peer with the PE routers. Notice that the BGP peer group configuration includes the **family** statement and specifies the **inet-vpn** option. The **inet-vpn** option enables BGP to advertise network layer reachability information (NLRI) for the Layer

3 VPN routes. The configuration also includes the **family** statement and specifies the **l2vpn** option. The **l2vpn** option enables BGP to advertise NLRI for the Layer 2 circuit. Layer 2 circuits use the same internal BGP infrastructure as Layer 2 VPNs.

```
[edit]
protocols {
 rsvp {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 mpls {
 label-switched-path to-pe3 {
 to 192.0.2.3;
 }
 label-switched-path to-pe5 {
 to 192.0.2.5;
 }
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 bgp {
 group RR {
 type internal;
 local-address 192.0.2.7;
 family inet {
 unicast;
 }
 family inet-vpn {
 unicast;
 }
 family l2vpn {
 signaling;
 }
 cluster 192.0.2.7;
 neighbor 192.0.2.1;
 neighbor 192.0.2.2;
 neighbor 192.0.2.4;
 neighbor 192.0.2.5;
 neighbor 192.0.2.3;
 }
 }
 ospf {
 traffic-engineering;
 area 0.0.0.0 {
 interface all;
 interface fxp0.0 {
 disable;
 }
 }
 }
}
```

## Interconnecting the Layer 2 Circuit with the Layer 3 VPN

### Step-by-Step Procedure

Before you can configure the logical tunnel interface in an MX Series router, you must create the tunnel services interface to be used for tunnel services.

1. Create the tunnel service interface on Router PE3. Include the **bandwidth** statement at the **[edit chassis fpc slot-number pic slot-number tunnel-services]** hierarchy level and specify the amount of bandwidth to reserve for tunnel services in gigabits per second.

```
[edit chassis]
fpc 1 {
 pic 1 {
 tunnel-services {
 bandwidth 1g;
 }
 }
}
```

2. On Router PE3, configure the **lt-1/1/10** logical tunnel interface unit 0.

Router PE3 is the router that is *stitching* the Layer 2 circuit to the Layer 3 VPN using the logical tunnel interface. The configuration of the peer unit interfaces is what makes the interconnection.

Include the **encapsulation** statement and specify the **ethernet-ccc** option. Include the **peer-unit** statement and specify the logical interface unit 1 as the peer tunnel interface. Include the **family** statement and specify the **ccc** option.

Configure the **lt-1/1/10** logical interface unit 1 with **ethernet** encapsulation. Include the **peer-unit** statement and specify the logical interface unit 0 as the peer tunnel interface. Include the **family** statement and specify the **inet** option. Also include the **address** statement and specify **198.51.100.11/24** as the IPv4 address of the interface.

**NOTE:** The peering logical interfaces must belong to the same logical tunnel interface derived from the Tunnel Services PIC.

```
[edit interfaces]
lt-1/1/10 {
 unit 0 {
 encapsulation ethernet-ccc;
 peer-unit 1;
 family ccc;
 }
 unit 1 {
 encapsulation ethernet;
 peer-unit 0;
 family inet {
 address 198.51.100.11/24;
 }
 }
}
```

```
}
```

3. On each router, commit the configuration.

```
user@host> commit check
configuration check succeeds
user@host> commit
```

## Verifying the Layer 2 Circuit to Layer 3 VPN Interconnection

To verify that the interconnection is working properly, perform these tasks:

- [Verifying That the Layer 2 Circuit Connection to Router PE3 is Up on page 1696](#)
- [Verifying LDP Neighbors and Targeted LDP LSPs on Router PE2 on page 1697](#)
- [Verifying the Layer 2 Circuit Routes on Router PE2 on page 1697](#)
- [Verifying That the Layer 2 Circuit Connection to Router PE2 is Up on page 1698](#)
- [Verifying LDP Neighbors and Targeted LDP LSPs on Router PE3 on page 1699](#)
- [Verifying a BGP Peer Session with the Route Reflector on Router PE3 on page 1699](#)
- [Verifying the Layer 3 VPN Routes on Router PE3 on page 1700](#)
- [Verifying the Layer 2 Circuit Routes on Router PE3 on page 1700](#)
- [Verifying the MPLS Routes on Router PE3 on page 1701](#)
- [Verifying Traffic Flow Between Router CE2 and Router CE3 on page 1702](#)
- [Verifying Traffic Flow Between Router CE2 and Router CE5 on page 1702](#)

### Verifying That the Layer 2 Circuit Connection to Router PE3 is Up

**Purpose** To verify that the Layer 2 circuit connection from Router PE2 to Router PE3 is **Up**. To also document the incoming and outgoing LDP labels and the circuit ID used by this Layer 2 circuit connection.

**Action** Verify that the Layer 2 circuit connection is up, using the **show l2circuit connections** command.

```
user@PE2> show l2circuit connections
```

Legend for connection status (St)

|                                 |                                      |
|---------------------------------|--------------------------------------|
| EI -- encapsulation invalid     | NP -- interface h/w not present      |
| MM -- mtu mismatch              | Dn -- down                           |
| EM -- encapsulation mismatch    | VC-Dn -- Virtual circuit Down        |
| CM -- control-word mismatch     | Up -- operational                    |
| VM -- vlan id mismatch          | CF -- Call admission control failure |
| OL -- no outgoing label         | IB -- TDM incompatible bitrate       |
| NC -- intf encaps not CCC/TCC   | TM -- TDM misconfiguration           |
| BK -- Backup Connection         | ST -- Standby Connection             |
| CB -- rcvd cell-bundle size bad | SP -- Static Pseudowire              |
| LD -- local site signaled down  | RS -- remote site standby            |
| RD -- remote site signaled down | XX -- unknown                        |

Legend for interface status

```

Up -- operational
Dn -- down
Neighbor: 192.0.2.3
Interface Type St Time last up # Up trans
ge-1/0/2.0(vc 100) rmt Up Jan 7 02:14:13 2010 1
Remote PE: 192.0.2.3, Negotiated control-word: No
Incoming label: 301488, Outgoing label: 315264
Negotiated PW status TLV: No
Local interface: ge-1/0/2.0, Status: Up, Encapsulation: ETHERNET

```

**Meaning** The output shows that the Layer 2 circuit connection from Router PE2 to Router PE3 is **Up** and the connection is using the **ge-1/0/2.0** interface. Note that the outgoing label is **315264** and the incoming label is **301488**, the virtual circuit (VC) identifier is **100** and the encapsulation is **ETHERNET**.

### Verifying LDP Neighbors and Targeted LDP LSPs on Router PE2

**Purpose** To verify that Router PE2 has a targeted LDP LSP to Router PE3 and that Router PE2 and Router PE3 are LDP neighbors.

**Action** Verify that Router PE2 has a targeted LDP LSP to Router PE3 and that Router PE2 and Router PE3 are LDP neighbors, using the **show ldp neighbor** command.

```

user@PE2> show ldp neighbor
Address Interface Label space ID Hold time
192.0.2.3 lo0.0 192.0.2.3:0 38

```

**Meaning** The output shows that Router PE2 has an LDP neighbor with the IPv4 address of **192.0.2.3**. Address 192.0.2.3 is the lo0.0 interface address of Router PE3. Notice that Router PE2 uses the local **lo0.0** interface for the LSP.

Verifying that the routers are LDP neighbors also verifies that the targeted LSP is established.

### Verifying the Layer 2 Circuit Routes on Router PE2

**Purpose** To verify that Router PE2 has a route for the Layer 2 circuit and that the route uses the LDP MPLS label to Router PE3.

**Action** Verify that Router PE2 has a route for the Layer 2 circuit and that the route uses the LDP MPLS label to Router PE3, using the **show route table mpls.0** command.

```

user@PE2> show route table mpls.0
mpls.0: 13 destinations, 13 routes (13 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0 *[MPLS/0] 1w3d 05:24:11, metric 1
 Receive

```

```

1 *[MPLS/0] 1w3d 05:24:11, metric 1
 Receive
2 *[MPLS/0] 1w3d 05:24:11, metric 1
 Receive
300560 *[LDP/9] 16:12:23, metric 1
 > to 10.10.2.1 via xe-0/1/0.0, Pop
300560(S=0) *[LDP/9] 16:12:23, metric 1
 > to 10.10.2.1 via xe-0/1/0.0, Pop
301008 *[LDP/9] 16:12:23, metric 1
 > to 10.10.4.2 via xe-0/3/0.0, Swap 299856
301488 *[L2CKT/7] 11:07:28
 > via ge-1/0/2.0, Pop
301536 *[LDP/9] 16:12:23, metric 1
 > to 10.10.4.2 via xe-0/3/0.0, Pop
301536(S=0) *[LDP/9] 16:12:23, metric 1
 > to 10.10.4.2 via xe-0/3/0.0, Pop
301712 *[LDP/9] 12:41:22, metric 1
 > to 10.10.5.2 via xe-0/2/0.0, Swap 315184
301728 *[LDP/9] 12:41:22, metric 1
 > to 10.10.5.2 via xe-0/2/0.0, Pop
301728(S=0) *[LDP/9] 12:41:22, metric 1
 > to 10.10.5.2 via xe-0/2/0.0, Pop
ge-1/0/2.0 *[L2CKT/7] 11:07:28, metric2 1
 > to 10.10.5.2 via xe-0/2/0.0, Push 315264

```

**Meaning** The output shows that Router PE2 pushes the **315264** outgoing label on the **L2CKT** route going out interface **ge-1/0/2.0**. The output also shows that Router PE2 pops the **301488** incoming label on the **L2CKT** coming from interface **ge-1/0/2.0**

### Verifying That the Layer 2 Circuit Connection to Router PE2 is Up

**Purpose** To verify that the Layer 2 circuit connection from Router PE3 to Router PE2 is **Up**, To also document the incoming and outgoing LDP labels and the circuit ID used by this Layer 2 circuit connection.

**Action** Verify that the Layer 2 circuit connection is up, using the **show l2circuit connections** command.

user@PE3> show l2circuit connections

Layer-2 Circuit Connections:

Legend for connection status (St)

|                                 |                                      |
|---------------------------------|--------------------------------------|
| EI -- encapsulation invalid     | NP -- interface h/w not present      |
| MM -- mtu mismatch              | Dn -- down                           |
| EM -- encapsulation mismatch    | VC-Dn -- Virtual circuit Down        |
| CM -- control-word mismatch     | Up -- operational                    |
| VM -- vlan id mismatch          | CF -- Call admission control failure |
| OL -- no outgoing label         | IB -- TDM incompatible bitrate       |
| NC -- intf encaps not CCC/TCC   | TM -- TDM misconfiguration           |
| BK -- Backup Connection         | ST -- Standby Connection             |
| CB -- rcvd cell-bundle size bad | XX -- unknown                        |

Legend for interface status

Up -- operational  
Dn -- down

Neighbor: 192.0.2.2

```

Interface Type St Time last up # Up trans
lt-1/1/10.0(vc 100) rmt Up Jan 7 02:15:03 2010 1
Remote PE: 192.0.2.2, Negotiated control-word: No
Incoming label: 315264, Outgoing label: 301488
Local interface: lt-1/1/10.0, Status: Up, Encapsulation: ETHERNET

```

**Meaning** The output shows that the Layer 2 circuit connection from Router PE3 to Router PE2 is **Up** and the connection is using the logical tunnel (**lt**) interface. Note that the incoming label is **315264** and the outgoing label is **301488**, the virtual circuit (VC) identifier is **100**, and that the encapsulation is **ETHERNET**.

### Verifying LDP Neighbors and Targeted LDP LSPs on Router PE3

**Purpose** To verify that Router PE3 has a targeted LDP LSP to Router PE2 and that Router PE3 and Router PE2 are LDP neighbors.

**Action** Verify that Router PE2 has a targeted LDP LSP to Router PE3 and that Router PE2 and Router PE3 are LDP neighbors, using the **show ldp neighbor** command.

```

user@PE2> show ldp neighbor
Address Interface Label space ID Hold time
192.0.2.2 lo0.0 192.0.2.2:0 43
192.0.2.4 lo0.0 192.0.2.4:0 33

```

**Meaning** The output shows that Router PE3 has an LDP neighbor with the IPv4 address of **192.0.2.2**. Address 192.0.2.2 is the lo0.0 interface address of Router PE2. The output also shows that the interface used on Router PE3 for the LSP is **lo0.0**. Verifying that the routers are LDP neighbors also verifies that the targeted LSP is established.

### Verifying a BGP Peer Session with the Route Reflector on Router PE3

**Purpose** To verify that Router PE3 has a peer session established with the route reflector.

**Action** Verify that Router PE3 has a peer session established with the route reflector, using the **show bgp summary** command.

user@PE2> show bgp summary

```

Groups: 2 Peers: 2 Down peers: 0
Table Tot Paths Act Paths Suppressed History Damp State Pending
bgp.13vpn.0 1 1 0 0 0 0
Peer AS InPkt OutPkt OutQ Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
192.0.2.7 65000 1597 1612 0 1 12:03:21 Establ
 bgp.12vpn.0: 0/0/0/0
 bgp.13vpn.0: 1/1/1/0
 L3VPN.inet.0: 1/1/1/0

```

**Meaning** The output shows that Router PE3 has a peer session with the router with the IPv4 address of **192.0.2.7**. Address 192.0.2.7 is the lo0.0 interface address of the route reflector. The output also shows that the peer session state is **Establ**, meaning that the session is established.

---

### Verifying the Layer 3 VPN Routes on Router PE3

---

**Purpose** To verify that Router PE3 has Layer 3 VPN routes to Router CE2, Router CE3, and Router CE5.

**Action** Verify that Router PE3 has routes to Router CE2, Router CE3, and Router CE5 in the Layer 3 VPN route table, using the **show route table L3VPN.inet.0** command. In this example, **L3VPN** is the name configured for the routing instance.

```
user@PE3> show route table L3VPN.inet.0
L3VPN.inet.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

198.51.100.10/24 *[Direct/0] 11:13:59
 > via lt-1/1/10.1
198.51.100.11/24 *[Local/0] 11:13:59
 Local via lt-1/1/10.1
198.51.100.12/24 *[BGP/170] 11:00:41, localpref 100, from 192.0.2.7
 AS path: I
 > to 10.10.6.2 via xe-2/1/0.0, Push 16
198.51.100.13/24 *[Direct/0] 11:54:41
 > via ge-1/0/1.0
198.51.100.1/24 *[Local/0] 11:54:41
 Local via ge-1/0/1.0
```

**Meaning** The output shows that Router PE3 has a route to the IPv4 subnetwork address of **198.51.100.10**. Address 198.51.100.15 is the interface address of Router CE2. The output shows that Router PE3 has a route to the IPv4 subnetwork address of **198.51.100.12**. Address 198.51.100.10 is the interface address of Router CE5. The output shows that Router PE3 has a route to the IPv4 subnetwork address of **198.51.100.13**. Address 198.51.100.6 is the interface address of Router CE3.

---

### Verifying the Layer 2 Circuit Routes on Router PE3

---

**Purpose** To verify that Router PE3 has a route to Router PE2 in the Layer 2 circuit route table.

**Action** Verify that Router PE3 has a route to Router PE2 in the Layer 2 circuit route table, using the **show route table l2circuit.0** command.

```
user@PE3> show route table l2circuit.0
192.0.2.2:NoCtrlWord:5:100:Local/96 (1 entry, 1 announced)
 *L2CKT Preference: 7
 Next hop type: Indirect
 Next-hop reference count: 1
 Next hop type: Router
```

```

Next hop: 10.10.5.1 via xe-2/2/0.0, selected
Protocol next hop: 192.0.2.2
Indirect next hop: 8cae0a0 -
State: <Active Int>
Local AS: 65000
Age: 11:16:50 Metric2: 1
Task: 12 circuit
Announcement bits (1): 0-LDP
AS path: I
VC Label 315264, MTU 1500

```

**Meaning** The output shows that Router PE3 has a route to the IPv4 address of **192.0.2.2**. Address 192.0.2.2 is the lo0.0 interface address of Router PE2. Note that the VC label is **315264**. This label is the same as the incoming MPLS label displayed using the **show l2circuit connections** command.

### Verifying the MPLS Routes on Router PE3

**Purpose** To verify that Router PE3 has a route to Router PE2 in the MPLS route table.

**Action** Verify Router PE3 has a route to Router PE2 in the MPLS route table, using the **show route table mpls.0** command.

```

user@PE3> show route table mpls.0
mpls.0: 21 destinations, 21 routes (21 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0 *[MPLS/0] 1w3d 05:29:02, metric 1
 Receive
1 *[MPLS/0] 1w3d 05:29:02, metric 1
 Receive
2 *[MPLS/0] 1w3d 05:29:02, metric 1
 Receive
16 *[VPN/0] 12:22:45

lt-1/1/10.0 *[L2CKT/7] 11:11:20, metric2 1
> to 10.10.5.1 via xe-2/2/0.0, Push 301488

```

**Meaning** The output shows that Router PE3 has a route for the Layer 2 circuit and that the route uses the LDP MPLS label to Router PE2. Notice that the **301488** label is the same as the outgoing label displayed on Router PE2 using the **show l2circuit connections** command.

### Verifying Traffic Flow Between Router CE2 and Router CE3

**Purpose** To verify that the CE routers can send and receive traffic across the interconnection.

**Action** Verify that Router CE2 can send traffic to and receive traffic from Router CE3 across the interconnection, using the **ping** command.

```

user@CE2>ping 198.51.100.6
PING 198.51.100.6 (198.51.100.6): 56 data bytes
64 bytes from 198.51.100.6: icmp_seq=0 ttl=63 time=0.708 ms
64 bytes from 198.51.100.6: icmp_seq=1 ttl=63 time=0.610 ms

```

**Meaning** The output shows that Router CE2 can send an ICMP request to and receive a response from Router CE3 across the interconnection.

### Verifying Traffic Flow Between Router CE2 and Router CE5

**Purpose** To verify that the CE routers can send and receive traffic across the interconnection.

**Action** Verify that Router CE2 can send traffic to and receive traffic from Router CE5 across the interconnection, using the **ping** command.

```

user@CE2>ping 198.51.100.10
PING 198.51.100.10 (198.51.100.10): 56 data bytes
64 bytes from 198.51.100.10: icmp_seq=0 ttl=62 time=0.995 ms
64 bytes from 198.51.100.10: icmp_seq=1 ttl=62 time=1.005 ms

```

**Meaning** The output shows that Router CE2 can send an ICMP request to and receive a response from Router CE5 across the interconnection.

| <b>Release Information</b>      | Statement introduced before Junos OS Release 7.4.<br>Statement introduced in Junos OS Release 9.0 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b>              | Specify matching criteria (in the form of a community) such that all routes which match are assigned the same VPN label, selected from one of the several routes in the set defined by this criteria. This reduces the number of VPN labels that the router must consider, and aggregates the received labels.                                                                                                                                                                                                                                                                                      |
| <b>Options</b>                  | <b>community <i>community-name</i></b> —Specify the name of the community to which to apply the aggregate label.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Release Information</b>      | <p>Statement introduced in Junos OS Release 9.2.</p> <p>Statement introduced in Junos OS Release 12.2 for ACX Series routers.</p> <p>Statement introduced in Junos OS Release 12.3 at the <b>[edit protocols l2circuit local-switching interface interface-name]</b> hierarchy level.</p>                                                                                                                                                                                                                                                                                     |
| <b>Description</b>              | <p>Configure pseudowire redundancy for Layer 2 circuits and VPLS. A redundant pseudowire can act as a backup connection and can be configured between a PE router and a CE device or between PE routers, maintaining Layer 2 circuit and VPLS services after certain types of failures. This feature can help improve the reliability of certain types of networks where a single point of failure could interrupt service for customers.</p>                                                                                                                                 |
|                                 | <p> <b>NOTE:</b> VPLS is not supported on ACX Series routers. The <code>psn-tunnel-endpoint</code> statement is not supported at the <b>[edit protocols l2circuit local-switching interface interface-name end-interface interface interface-name]</b> hierarchy level.</p>                                                                                                                                                                                                                |
| <b>Options</b>                  | <p><b>address</b>—Specifies the address for the backup neighbor.</p> <p>The remaining statements are explained separately. | <b>Description</b>              | <p>Enable BGP route target filtering on the VPN.</p> <p>The <b>family route-target</b> statement is useful for filtering VPN routes before they are sent. Provider edge (PE) routers inform the route reflector (RR) which routes to send, using <b>family route-target</b> to provide the route-target-interest information. The RR then sends to the PE router only the advertisements containing the specified route target.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Options</b>                  | <p><b>advertise-default</b>—Cause the router to advertise the default route target route (0:0:0/0) and suppress all routes that are more specific. This can be used by a route reflector on BGP groups consisting of neighbors that act as provider edge (PE) routers only. PE routers often need to advertise all routes to the route reflector. Suppressing all route target advertisements other than the default route reduces the amount of information exchanged between the route reflector and the PE routers. The Junos OS further helps to reduce route target advertisement overhead by not maintaining dependency information unless a nondefault route is received.</p> <p><b>external-paths <i>number</i></b>—Cause the router to advertise the VPN routes that reference a given route target. The number you specify with the <b>external-paths</b> statement determines the number of external peer routers (currently advertising that route target) that receive the VPN routes. The default value is 1.</p> <p><b>prefix-limit <i>number</i></b>—The number of prefixes that can be received from a peer router.</p> <p>The remaining statement is described separately.</p> |
| <b>Required Privilege Level</b> | <p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Release Information</b> | <p>Statement introduced before Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 9.0 for EX Series switches.</p> <p>Statement introduced in Junos OS Release 12.1 for the QFX Series.</p> <p>Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.</p>                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b>         | <p>You configure the graceful restart routing option globally to enable the feature, but not to enable graceful restart for all routing protocols in a routing instance. Because all routing protocols are not usually run on every routing instance, you must also configure graceful restart for individual routing protocols running on a routing instance, including the main routing instance. You can, optionally, modify the global settings at the individual protocol level.</p>                                                                                                                                                           |
|                            | <div>  <p><b>NOTE:</b></p> <ul style="list-style-type: none"> <li>For VPNs, the <code>graceful-restart</code> statement allows a router whose VPN control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers.</li> <li>For BGP, if you configure graceful restart after a BGP session has been established, the BGP session restarts and the peers negotiate graceful restart capabilities.</li> <li>LDP sessions flap when <code>graceful-restart</code> configurations change.</li> </ul> </div> |
| <b>Default</b>             | Graceful restart is disabled by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Options</b>             | The remaining statements are explained separately. See <a href="#">CLI Explorer</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b>         | Define the type of routing instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### Options

**NOTE:** On ACX Series routers, you can configure only the forwarding, virtual router, and VRF routing instances.

**type**—Can be one of the following:

- **evpn**—(MX 3D Series routers and QFX switches only) Enable an Ethernet VPN (EVPN) on the routing instance.  
You cannot configure the **evpn** option under the `[edit logical-systems logical-system-name routing-instances routing-instance-name instance-type]` hierarchy level.
- **evpn-vpws**—Enable an Ethernet VPN (EVPN) Virtual Private Wire Service (VPWS) on the routing instance.
- **forwarding**—Provide support for filter-based forwarding, where interfaces are not associated with instances. All interfaces belong to the default instance. Other instances are used for populating RPD learned routes. For this instance type, there is no one-to-one mapping between an interface and a routing instance. All interfaces belong to the default instance inet.0.
- **l2backhaul-vpn**—Provide support for Layer 2 wholesale VLAN packets with no existing corresponding logical interface. When using this instance, the router learns both the outer tag and inner tag of the incoming packets, when the **instance-role** statement is defined as **access**, or the outer VLAN tag only, when the **instance-role** statement is defined as **nni**.

- **l2vpn**—Enable a Layer 2 VPN on the routing instance. You must configure the **interface**, **route-distinguisher**, **vrf-import**, and **vrf-export** statements for this type of routing instance.
- **layer2-control**—(MX Series routers only) Provide support for RSTP or MSTP in customer edge interfaces of a VPLS routing instance. This instance type cannot be used if the customer edge interface is multihomed to two provider edge interfaces. If the customer edge interface is multihomed to two provider edge interfaces, use the default BPDU tunneling.
- **mpls-forwarding**—(MX Series routers only) Allow filtering and translation of route distinguisher (RD) values in IPv4 and IPv6 VPN address families on both routes received and routes sent for selected BGP sessions. In particular, for Inter-AS VPN Option-B networks, this option can prevent the malicious injection of VPN labels from one peer AS boundary router to another.
- **mpls-internet-multicast**—(EX Series, M Series, MX Series, and T Series routers only) Provide support for ingress replication provider tunnels to carry IP multicast data between routers through an MPLS cloud, using MBGP or next-generation MVPN.
- **no-forwarding**—This is the default routing instance. Do not create a corresponding forwarding instance. Use this routing instance type when a separation of routing table information is required. There is no corresponding forwarding table. All routes are installed into the default forwarding table. IS-IS instances are strictly nonforwarding instance types.
- **virtual-router**—Enable a virtual router routing instance. This instance type is similar to a VPN routing and forwarding instance type, but used for non-VPN-related applications. You must configure the **interface** statement for this type of routing instance. You do not need to configure the **route-distinguisher**, **vrf-import**, and **vrf-export** statements.
- **virtual-switch**—(MX Series routers, EX9200 switches, and QFX switches only) Provide support for Layer 2 bridging. Use this routing instance type to isolate a LAN segment with its Spanning Tree Protocol (STP) instance and to separate its VLAN identifier space.
- **vpls**—Enable VPLS on the routing instance. Use this routing instance type for point-to-multipoint LAN implementations between a set of sites in a VPN. You must configure the **interface**, **route-distinguisher**, **vrf-import**, and **vrf-export** statements for this type of routing instance.
- **vrf**—VPN routing and forwarding (VRF) instance. Provides support for Layer 3 VPNs, where interface routes for each instance go into the corresponding forwarding table only. Required to create a Layer 3 VPN. Create a VRF table (**instance-name.inet.0**) that contains the routes originating from and destined for a particular Layer 3 VPN. For this instance type, there is a one-to-one mapping between an interface and a routing instance. Each VRF instance corresponds with a forwarding table. Routes on an interface go into the corresponding forwarding table. You must configure the **interface**, **route-distinguisher**, **vrf-import**, and **vrf-export** statements for this type of routing instance.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

## interface (Routing Instances)

**Syntax** `interface interface-name {  
    description text;  
}`

**Hierarchy Level** [edit logical-systems *logical-system-name* routing-instances *routing-instance-name*],  
[edit routing-instances *routing-instance-name*]

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 9.2 for EX Series switches.  
Statement introduced in Junos OS Release 12.3 for ACX Series routers.  
Statement introduced in Junos OS Release 13.2 for MX 3D Series routers.

**Description** Specify the interface over which the VPN traffic travels between the PE device and CE device. You configure the interface on the PE device. If the value **vrf** is specified for the **instance-type** statement included in the routing instance configuration, this statement is required.

**Options** *interface-name*—Name of the interface.  
  
The remaining statement is explained separately. See [CLI Explorer](#).

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b>              | Enable proxy BGP route target filtering (also known as proxy route target constrain, or proxy RTC). This feature is useful if you have a network environment where route target filtering is not widely deployed or fully supported. When configured for proxy BGP route target filtering, the device creates route target membership (RT membership) on behalf of its peers that do not have the route target filtering functionality. The device then distributes the RT membership advertisements from incoming BGP VPN routes to other devices in the network that need them. |
| <b>Options</b>                  | <b>route-target-policy <i>route-target-policy-name</i></b> —(Optional) Apply a routing policy that defines a subset of VPN routes to be used in your proxy BGP route target filter. The subset of VPN routes control which proxy BGP route targets are used to create the proxy BGP route target routes.                                                                                                                                                                                                                                                                          |

| <b>Release Information</b> | Statement introduced in Junos OS Release 10.2.<br><b>maximum</b> option introduced in Junos OS Release 13.2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b>         | <p>Specify a revert time for redundant Layer 2 circuits and VPLS pseudowires. When you have configured redundant pseudowires for Layer 2 circuits or VPLS, traffic is switched to the backup connection in the event that the primary connection fails. If you configure a revert time, when the configured time expires traffic is reverted to the primary path, assuming the primary path has been restored.</p> <p>With the <b>maximum</b> option, specify a maximum reversion interval to add after the <b>revert-time</b> delay. If a revert-time delay is defined but a maximum timer is not defined, VCs are restored upon the revert-timer's expiration.</p> <p>To reduce as much as possible the amount of traffic discarded, and potential data-path asymmetries observed during primary-to-backup transition periods, you can use this restoration timer. This restoration timer is activated when the backup path is performing as active, and then the primary path is restored. The goal is to avoid moving traffic back to the primary path right away, to make sure that the control plane's related tasks (such as IGP, LDP, RSVP, and internal BGP) have enough time to complete their updating cycle.</p> <p>By enabling a gradual return of traffic to the primary path, you can ensure that the relatively-slow control-plane processing and updating does not have a negative impact on the restoration process.</p> <p>The <b>maximum</b> option extends the revert timer's functionality to provide a jittered interval over which a certain number of circuits can be transitioned back to the primary path. By making use of this maximum value, you can define a time interval during which circuits are expected to switch over. As a consequence, circuits' effective transitions are scattered during restoration periods.</p> <p>When making use of <b>revert-time x maximum y</b> statement, you can ensure that the corresponding circuit that is active is moved to the primary path within a time-slot (t1) such as that: <math>x \leq t1 \leq y</math>. In other words, by activating this statement, you can ensure the following:</p> <ul style="list-style-type: none"><li>• VCs stay in the backup path for at least x seconds after the primary path comes back up.</li><li>• VCs are moved back to the primary path before y seconds have elapsed.</li></ul> |

- $y \text{ maximum value} = x \text{ maximum value} * 2 = 1200 \text{ seconds}$ .

The ideal values for x and y will be conditioned to internal aspects of your network. For this reason, there are no default values for these settings. If no revert-time is set, the default behavior is non-revertive. That is, circuits are not returned to the primary path upon restoration. They are kept on the backup path.

**Default** Without the **revert-time** statement, virtual circuit (VC) traffic is not transitioned to the primary path upon restoration of the primary path.

**Options** *seconds*—Revert time in seconds.

**Range:** 0 through 600 seconds

*maximum seconds*—Number of seconds to delay path restoration after the **revert-time** delay.

**Range:** 0 through 1200 seconds

**Required Privilege** routing—To view this statement in the configuration.

**Level** routing-control—To add this statement to the configuration.

| <b>Description</b>         | <p>Specify an identifier attached to a route, enabling you to distinguish to which VPN or virtual private LAN service (VPLS) the route belongs. Each routing instance must have a unique route distinguisher (RD) associated with it. The RD is used to place bounds around a VPN so that the same IP address prefixes can be used in different VPNs without having them overlap. If the instance type is <b>vrf</b>, the <b>route-distinguisher</b> statement is required.</p> <p>For Layer 2 VPNs and VPLS, if you configure the <b>l2vpn-use-bgp-rules</b> statement, you must configure a unique RD for each PE router participating in the routing instance.</p> <p>For other types of VPNs, we recommend that you use a unique RD for each provider edge (PE) router participating in specific routing instance. Although you can use the same RD on all PE routers for the same VPN routing instance, if you use a unique RD, you can determine the customer edge (CE) router from which a route originated within the VPN.</p> <p>For Layer 2 VPNs and VPLSs, if you configure mesh groups, the RD in each mesh group must be unique.</p> |

**CAUTION:** We strongly recommend that if you change an RD that has already been configured, make the change during a maintenance window, as follows:

1. Deactivate the routing instance.
2. Change the RD.
3. Activate the routing instance.

This is not required if you are configuring the RD for the first time.

**Options** *as-number:number*—*as-number* is an assigned AS number, and *number* is any 2-byte or 4-byte value. The AS number can be from 1 through 4,294,967,295. If the AS number is a 2-byte value, the administrative number is a 4-byte value. If the AS number is a 4-byte value, the administrative number is a 2-byte value. An RD consisting of a 4-byte AS number and a 2-byte administrative number is defined as a type 2 RD in RFC 4364 *BGP/MPLS IP VPNs*.

**NOTE:** In Junos OS Release 9.1 and later, the numeric range for AS numbers is extended to provide BGP support for 4-byte AS numbers, as defined in RFC 4893, *BGP Support for Four-octet AS Number Space*. All releases of Junos OS support 2-byte AS numbers. To configure an RD that includes a 4-byte AS number, append the letter “L” to the end of the AS number. For example, an RD with the 4-byte AS number 7,765,000 and an administrative number of 1,000 is represented as 77765000L:1000.

In Junos OS Release 9.2 and later, you can also configure a 4-byte AS number using the AS dot notation format of two integer values joined by a period: *<16-bit high-order value in decimal>.<16-bit low-order value in decimal>*. For example, the 4-byte AS number of 65,546 in the plain-number format is represented as 1.10 in AS dot notation format.

*ip-address:id*—IP address (*ip-address* is a 4-byte value) within your assigned prefix range and a 2-byte value for the *id*. The IP address can be any globally unique unicast address.

**Range:** 0 through 4,294,967,295 ( $2^{32} - 1$ ). If the router you are configuring is a BGP peer of a router that does not support 4-byte AS numbers, you need to configure a local AS number. For more information, see *Using 4-Byte Autonomous System Numbers in BGP Networks Technology Overview*.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>              | Statically configure route target filtering. Route target filtering allows you to distribute VPN routes to only the routers that need them. In VPN networks without route target filtering configured, BGP distributes all static VPN routes to all of the VPN peer routers. You can add static routes to the bgp.rtarget.0 routing table with specific NLRI-imposed constraints.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Options</b>                  | <p><b><i>destination</i></b>—Allows you to specify the static route destination. This value must be in the format x:y/len. The x value is either an IP address or an AS number followed by an optional L to indicate a 4 byte AS number, and y is a number (for example, 123456L:100/64).</p> <p><b><i>group group-name(s)</i></b>—Installs an RT-Constrain filter for the destination for all peers in the specified BGP group. The route and corresponding BGP group are displayed in the output of the <b>show bgp group rtf detail</b> command.</p> <p><b><i>local</i></b>—Causes the router to originate the route target constrain NLRI, but does not install any filtering state for the prefix. This behavior can be useful when the router should always receive VPN routes with this route-target regardless of the state of a given BGP peering session or group status. The route is not displayed in the output of the <b>show bgp group rtf detail</b> command unless it is also included in either the BGP neighbor or BGP group configuration.</p> <p><b><i>neighbor address</i></b>—Installs an RT-Constrain filter for the destination for this BGP neighbor. The route is displayed in the output of the <b>show bgp group rtf detail</b> command. Specify the BGP neighbor using the router's IP address.</p> |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Description              | <p>Specify a virtual routing and forwarding (VRF) target community. If you configure the <b>community</b> option only, default VRF import and export policies are generated that accept and tag routes with the specified target community. The purpose of the <b>vrf-target</b> statement is to simplify the configuration by allowing you to configure most statements at the [edit routing-instances] hierarchy level. In effect, this statement configures a single policy for import and a single policy for export to replace the per-VRF policies for every community.</p> <p>You can still create more complex policies by explicitly configuring VRF import and export policies using the <b>import</b> and <b>export</b> options.</p>                                  |
| Options                  | <p><b>community</b>—Community name.</p> <p><b>auto</b>—Automatically derives the route target (RT) for QFX5100 switches.</p> <p><b>import community-name</b>—Allowed communities accepted from neighbors.</p> <p><b>export community-name</b>—Allowed communities sent to neighbors.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b>              | <p>Configure the priority for an interface on which the MAC move is applied. When a MAC move is configured with a corresponding action, and that limit is exceeded, the action is applied to one of the interfaces associated with that MAC address having the highest action priority. If the action configured for the MAC move is <b>shutdown</b>, you can use the action priority to determine which interface is disabled. If an interface is trusted, assign a low action priority to decrease the likelihood that the interface shuts down if the configured action is <b>shutdown</b> or <b>vlan-member-shutdown</b>.</p> <p>If no action priority is configured, or if the interfaces have the same action priority, then the action is applied to the interface to which the MAC address moved last.</p>                                                                                                                                                                                                                                  |
| <b>Options</b>                  | <p><b>value</b>—Value assigned to an interface associated with a MAC address move. The value determines the priority with which an action is applied to the interface if the MAC address move limit is reached. The interface with the highest priority is the interface with the lowest value configured for <b>action-priority</b>.</p> <p>A higher value means lower priority. For example, if a MAC address move occurs between two interfaces with the action priority value set to 5 and 6, the interface with value 5 as the action priority value is blocked.</p> <p>If a VPLS instance has MAC move action enabled, set the <b>action-priority</b> to 8 for the router to detect an interface as a core interface by the VPLS customer edge loop prevention feature. By default, the loop prevention feature supports lsi and vt-type interfaces as core interfaces; however, you can use this special action-priority value to designate any interface as a core interface.</p> <p><b>Default:</b> 4</p> <p><b>Range:</b> 0 through 8</p> |
| <b>Required Privilege Level</b> | <p>system—To view this statement in the configuration.</p> <p>system—control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 17.1 on MX Series routers with MPCs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b>              | Enable the advertisement of Ethernet VPN (EVPN) pure type-5 routes for the IP prefix of the integrated routing and bridging (IRB) interface associated with customer bridge domains or Virtual Extensible LANs (VXLAN). EVPN pure type-5 routing is used when a customer Layer 2 domain is not extended across data centers and the IP subnet for the domain is confined within a single data center. If a BD or VXLAN is not extended to the EVPN, then no EVPN type-5 advertisement for the IP prefix associated with that domain or VXLAN occurs. |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 10.4R2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b>              | <p>Enable the router to process only the autodiscovery network layer reachability information (NLRI) update messages for VPWS and LDP-based Layer 2 VPN and VPLS update messages (BGP_L2VPN_AD_NLRI) (FEC 129).</p> <p>Specifically, the <b>auto-discovery-only</b> statement notifies the routing process (rpd) to expect autodiscovery-related NLRI messages so that information can be deciphered and used by LDP, VPLS, and VPWS.</p> <p>The <b>auto-discovery-only</b> statement must be configured on all provider edge (PE) routers in a VPLS or in a VPWS. If you configure route reflection, the <b>auto-discovery-only</b> statement is also required on provider (P) routers that act as the route reflector in supporting FEC 129-related updates.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Required Privilege Level</b> | <p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Release Information</b> | Statement introduced in Junos OS Release 9.1.                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b>         | <p>Enable automatic site identifiers for VPLS routing instances.</p> <p>When you configure <b>automatic-site-id</b> for the first time, you must deactivate and then activate <b>protocol vpls</b>. However, if you already have <b>automatic-site-id</b> configured, you do not need to deactivate and then activate <b>protocol vpls</b>.</p>                                         |
| <b>Options</b>             | <p><b>collision-detect-time</b>—The time in seconds to wait after a claim advertisement is sent to the other routers in a VPLS instance before a PE router can begin using a site identifier. If the PE router receives a competing claim advertisement for the same site identifier during this time period, it initiates the collision resolution procedure for site identifiers.</p> |

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

**new-site-wait-time**—The time in seconds to wait to receive VPLS information for a newly configured routing instance or a new site. This time interval is also applied whenever the automatic site identifier feature is activated on a VPLS routing instance other than at startup. Effectively, this timer indicates how long to wait before an attempt is made to allocate a site identifier. This timer is also triggered whenever a VPLS routing instance is enabled.

**reclaim-wait-time**—The time in seconds to wait to receive VPLS information for a newly configured routing instance or a new site. This time interval is also applied whenever the automatic site identifier feature is activated on a VPLS routing instance other than at startup. Effectively, this timer indicates how long to wait before an attempt is made to allocate a site identifier. This timer is also triggered whenever a VPLS routing instance is enabled. You can configure two values for this option: the **minimum** wait time and the **maximum** wait time.

**startup-wait-time**—The time in seconds to wait at startup to receive all the VPLS information for the route targets configured on the other PE routers included in the VPLS routing instance.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>              | Specify bandwidth allocation for a Layer 2 circuit or for the class types of a Layer 2 circuit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Options</b>                  | <p><b><i>bandwidth</i></b>—Configure the bandwidth in bits per second for the Layer 2 circuit. You cannot configure the bandwidth for the Layer 2 circuit and for the class types at the same time.</p> <p><b><i>ctnumber bandwidth</i></b>—Configure the bandwidth in bits per second for a class type on the Layer 2 circuit. You can configure bandwidth for up to four class types (<b>ct0</b>, <b>ct1</b>, <b>ct2</b>, <b>ct3</b>) per Layer 2 circuit. If you configure the class types, you must configure them in order, starting with class type <b>ct0</b>.</p> |
| <b>Required Privilege Level</b> | <p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b>         | <p>Configure bidirectional failure detection timers.</p> <p>The BFD failure detection timers are adaptive and can be adjusted to be more or less aggressive. For example, the timers can adapt to a higher value if the adjacency fails, or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the <b>clear bfd adaptation</b> command to return BFD interval timers to their configured values. The <b>clear bfd adaptation</b> command is hitless, meaning that the command does not affect traffic flow on the routing device.</p> <p>The remaining statements are explained separately. See <a href="#">CLI Explorer</a>.</p> |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.3.                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b>              | Enable connection protection on the Layer 2 circuit. Connection protection enables you to configure a redundant pseudowire to act as a backup connection and can be configured between PE routers, maintaining Layer 2 circuit and VPLS services after certain types of failures. This feature helps to improve the reliability of networks where a single point of failure could interrupt service for customers. |

| <b>Description</b>         | <p>Enable BFD failure detection. The BFD failure detection timers are adaptive and can be adjusted to be faster or slower. The lower the BFD failure detection timer value, the faster the failure detection and vice versa. For example, the timers can adapt to a higher value if the adjacency fails (that is, the timer detects failures more slowly). Or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the **clear bfd adaptation** command to return BFD interval timers to their configured values. The **clear bfd adaptation** command is hitless, meaning that the command does not affect traffic flow on the routing device.

The remaining statement is explained separately. See [CLI Explorer](#).

| <b>Release Information</b> | <p>Statement introduced before Junos OS Release 7.4.</p> <p>Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers (<b>ethernet</b>, <b>vlan-ccc</b>, and <b>vlan-tcc</b> options only).</p> <p>Statement introduced in Junos OS Release 12.2 for the ACX Series Universal Access Routers. Only the <b>atm-ccc-cell-relay</b> and <b>atm-ccc-vc-mux</b> options are supported on ACX Series routers.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b>         | Configure a logical link-layer encapsulation type. Not all encapsulation types are supported on the switches. See the switch CLI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Options</b>             | <p><b>atm-ccc-cell-relay</b>—Use ATM cell-relay encapsulation.</p> <p><b>atm-ccc-vc-mux</b>—Use ATM virtual circuit (VC) multiplex encapsulation on CCC circuits. When you use this encapsulation type, you can configure the <b>ccc</b> family only.</p> <p><b>atm-cisco-nlpid</b>—Use Cisco ATM network layer protocol identifier (NLPID) encapsulation. When you use this encapsulation type, you can configure the <b>inet</b> family only.</p> <p><b>atm-mlppp-llc</b>—For ATM2 IQ interfaces only, use Multilink Point-to-Point (MLPPP) over AAL5 LLC. For this encapsulation type, your router must be equipped with a Link Services or Voice Services PIC. MLPPP over ATM encapsulation is not supported on ATM2 IQ OC48 interfaces.</p> <p><b>atm-nlpid</b>—Use ATM NLPID encapsulation. When you use this encapsulation type, you can configure the <b>inet</b> family only.</p> <p><b>atm-ppp-llc</b>—(ATM2 IQ interfaces and MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP only) Use PPP over AAL5 LLC encapsulation.</p> <p><b>atm-ppp-vc-mux</b>—(ATM2 IQ interfaces and MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP only) Use PPP over ATM AAL5 multiplex encapsulation.</p> |

**atm-snap**—(All interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) Use ATM subnetwork attachment point (SNAP) encapsulation.

**atm-tcc-snap**—Use ATM SNAP encapsulation on translational cross-connect (TCC) circuits.

**atm-tcc-vc-mux**—Use ATM VC multiplex encapsulation on TCC circuits. When you use this encapsulation type, you can configure the **tcc** family only.

**atm-vc-mux**—(All interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) Use ATM VC multiplex encapsulation. When you use this encapsulation type, you can configure the **inet** family only.

**ether-over-atm-llc**—(All IP interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) For interfaces that carry IP traffic, use Ethernet over ATM LLC encapsulation. When you use this encapsulation type, you cannot configure multipoint interfaces.

**ether-vpls-over-atm-llc**—For ATM2 IQ interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.

**ether-vpls-over-fr**—For E1, T1, E3, T3, and SONET interfaces only, use the Ethernet virtual private LAN service (VPLS) over Frame Relay encapsulation to support Bridged Ethernet over Frame Relay encapsulated TDM interfaces for VPLS applications, per RFC 2427, *Multiprotocol Interconnect over Frame Relay*.

**NOTE:** The SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP, the Channelized SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP, and the DS3/E3 MIC do not support Ethernet over Frame Relay encapsulation.

---

**ether-vpls-over-ppp**—For E1, T1, E3, T3, and SONET interfaces only, use the Ethernet virtual private LAN service (VPLS) over Point-to-Point Protocol (PPP) encapsulation to support Bridged Ethernet over PPP-encapsulated TDM interfaces for VPLS applications.

**ethernet**—Use Ethernet II encapsulation (as described in RFC 894, *A Standard for the Transmission of IP Datagrams over Ethernet Networks*).

**ethernet-ccc**—Use Ethernet CCC encapsulation on Ethernet interfaces.

**ethernet-vpls**—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard Tag Protocol ID (TPID) values.

**NOTE:** The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.

**ethernet-vpls-fr**—Use in a VPLS setup when a CE device is connected to a PE router over a time-division multiplexing (TDM) link. This encapsulation type enables the PE router to terminate the outer layer 2 Frame Relay connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use the MAC address to forward the packet into a given VPLS instance.

**frame-relay-ccc**—Use Frame Relay encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

**frame-relay-ether-type**—Use Frame Relay ether type encapsulation for compatibility with Cisco Frame Relay. The physical interface must be configured with flexible-frame-relay encapsulation.

**frame-relay-ether-type-tcc**—Use Frame Relay ether type TCC for Cisco-compatible Frame Relay on TCC circuits to connect different media. The physical interface must be configured with flexible-frame-relay encapsulation.

**frame-relay-ppp**—Use PPP over Frame Relay circuits. When you use this encapsulation type, you can configure the **ppp** family only.

**frame-relay-tcc**—Use Frame Relay encapsulation on TCC circuits for connecting different media. When you use this encapsulation type, you can configure the **tcc** family only.

**gre-fragmentation**—For adaptive services interfaces only, use GRE fragmentation encapsulation to enable fragmentation of IPv4 packets in GRE tunnels. This encapsulation clears the do not fragment (DF) bit in the packet header. If the packet's size exceeds the tunnel's maximum transmission unit (MTU) value, the packet is fragmented before encapsulation.

**multilink-frame-relay-end-to-end**—Use MLFR FRF.15 encapsulation. This encapsulation is used only on multilink, link services, and voice services interfaces and their constituent T1 or E1 interfaces, and is supported on LSQ and redundant LSQ interfaces.

**multilink-ppp**—Use MLPPP encapsulation. This encapsulation is used only on multilink, link services, and voice services interfaces and their constituent T1 or E1 interfaces.

**ppp-over-ether**—Use PPP over Ethernet encapsulation to configure an underlying Ethernet interface for a dynamic PPPoE logical interface on M120 and M320 routers with Intelligent Queuing 2 (IQ2) PICs, and on MX Series routers with MPCs.

**ppp-over-ether-over-atm-llc**—(MX Series routers with MPCs using the ATM MIC with SFP only) For underlying ATM interfaces, use PPP over Ethernet over ATM LLC encapsulation. When you use this encapsulation type, you cannot configure the interface address. Instead, configure the interface address on the PPP interface.

**vlan-bridge**—Use Ethernet VLAN bridge encapsulation on Ethernet interfaces that have IEEE 802.1Q tagging, flexible-ethernet-services, and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID.

**vlan-ccc**—Use Ethernet virtual LAN (VLAN) encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

**vlan-vci-ccc**—Use ATM-to-Ethernet interworking encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

**vlan-tcc**—Use Ethernet VLAN encapsulation on TCC circuits. When you use this encapsulation type, you can configure the **tcc** family only.

**vlan-vpls**—Use Ethernet VLAN encapsulation on VPLS circuits.

**vxlan**—Use VXLAN data plane encapsulation for EVPN.

| <b>Description</b>         | Specify the physical link-layer encapsulation type. Not all encapsulation types are supported on the switches. See the switch CLI.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Default</b>             | <b>ppp</b> —Use serial PPP encapsulation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Options**  **NOTE:** Frame Relay, ATM, PPP, SONET, and SATSOP options are not supported on the EX Series switches.

**atm-ccc-cell-relay**—Use ATM cell-relay encapsulation.

**atm-pvc**—Defined in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*. When you configure physical ATM interfaces with ATM PVC encapsulation, an RFC 2684-compliant ATM Adaptation Layer 5 (AAL5) tunnel is set up to route the ATM cells over a Multiprotocol Label Switching (MPLS) path that is typically established between two MPLS-capable routers using the Label Distribution Protocol (LDP).

**cisco-hdlc**—Use Cisco-compatible High-Level Data Link Control (HDLC) framing. E1, E3, SONET/SDH, T1, and T3 interfaces can use Cisco HDLC encapsulation. Two related versions are supported:

- CCC version (**cisco-hdlc-ccc**)—The logical interface does not require an encapsulation statement. When you use this encapsulation type, you can configure the **ccc** family only.
- TCC version (**cisco-hdlc-tcc**)—Similar to CCC and has the same configuration restrictions, but used for circuits with different media on either side of the connection.

**cisco-hdlc-ccc**—Use Cisco-compatible HDLC framing on CCC circuits.

**cisco-hdlc-tcc**—Use Cisco-compatible HDLC framing on TCC circuits for connecting different media.

**ethernet-bridge**—Use Ethernet bridge encapsulation on Ethernet interfaces that have bridging enabled and that must accept all packets.

**ethernet-ccc**—Use Ethernet CCC encapsulation on Ethernet interfaces that must accept packets carrying standard Tag Protocol ID (TPID) values. For 8-port, 12-port, and 48-port Fast Ethernet PICs, CCC is not supported.

**ethernet-over-atm**—For interfaces that carry IPv4 traffic, use Ethernet over ATM encapsulation. When you use this encapsulation type, you cannot configure multipoint interfaces. As defined in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*, this encapsulation type allows ATM interfaces to connect to devices that support only bridge protocol data units (BPDUs). Junos OS does not completely support bridging, but accepts BPDU packets as a default gateway. If you use the router as an edge device, then the router acts as a default gateway. It accepts Ethernet LLC/SNAP frames with IP or ARP in the payload, and drops the rest. For packets destined to the Ethernet LAN, a route lookup is done using the destination IP address. If the route lookup yields a full address match, the packet is encapsulated with an LLC/SNAP and MAC header, and the packet is forwarded to the ATM interface.

**ethernet-tcc**—For interfaces that carry IPv4 traffic, use Ethernet TCC encapsulation on interfaces that must accept packets carrying standard TPID values. For 8-port, 12-port, and 48-port Fast Ethernet PICs, TCC is not supported.

**ethernet-vpls**—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard TPID values. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

**ethernet-vpls-fr**—Use in a VPLS setup when a CE device is connected to a PE device over a time division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer Layer 2 Frame Relay connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use the MAC address to forward the packet into a given VPLS instance.

**ethernet-vpls-ppp**—Use in a VPLS setup when a CE device is connected to a PE device over a time division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer Layer 2 PPP connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use it to forward the packet into a given VPLS instance.

**ether-vpls-over-atm-llc**—For ATM intelligent queuing (IQ) interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.

**extended-frame-relay-ccc**—Use Frame Relay encapsulation on CCC circuits. This encapsulation type allows you to dedicate DLCIs 1 through 1022 to CCC. When you use this encapsulation type, you can configure the **ccc** family only.

**extended-frame-relay-ether-type-tcc**—Use extended Frame Relay ether type TCC for Cisco-compatible Frame Relay for DLCIs 1 through 1022. This encapsulation type is used for circuits with different media on either side of the connection.

**extended-frame-relay-tcc**—Use Frame Relay encapsulation on TCC circuits to connect different media. This encapsulation type allows you to dedicate DLCIs 1 through 1022 to TCC.

**extended-vlan-bridge**—Use extended VLAN bridge encapsulation on Ethernet interfaces that have IEEE 802.1Q VLAN tagging and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID.

**extended-vlan-ccc**—Use extended VLAN encapsulation on CCC circuits with Gigabit Ethernet and 4-port Fast Ethernet interfaces that must accept packets carrying 802.1Q values. Extended VLAN CCC encapsulation supports TPIDs 0x8100, 0x9100, and 0x9901. When you use this encapsulation type, you can configure the **ccc** family only. For 8-port, 12-port, and 48-port Fast Ethernet PICs, extended VLAN CCC is not supported. For 4-port Gigabit Ethernet PICs, extended VLAN CCC is not supported.

**extended-vlan-tcc**—For interfaces that carry IPv4 traffic, use extended VLAN encapsulation on TCC circuits with Gigabit Ethernet interfaces on which you want to use 802.1Q tagging. For 4-port Gigabit Ethernet PICs, extended VLAN TCC is not supported.

**extended-vlan-vpls**—Use extended VLAN VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled and that must accept packets carrying TPIDs 0x8100, 0x9100, and 0x9901. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

**NOTE:** The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.

**flexible-ethernet-services**—For Gigabit Ethernet IQ interfaces and Gigabit Ethernet PICs with small form-factor pluggable transceivers (SFPs) (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), use flexible Ethernet services encapsulation when you want to configure multiple per-unit Ethernet encapsulations. Aggregated Ethernet bundles can use this encapsulation type. This encapsulation type allows you to configure any combination of route, TCC, CCC, Layer 2 virtual private networks (VPNs), and VPLS encapsulations on a single physical port. If you configure flexible Ethernet services encapsulation on the physical interface, VLAN IDs from 1 through 511 are no longer reserved for normal VLANs.

**flexible-frame-relay**—For IQ interfaces only, use flexible Frame Relay encapsulation when you want to configure multiple per-unit Frame Relay encapsulations. This encapsulation type allows you to configure any combination of TCC, CCC, and standard Frame Relay encapsulations on a single physical port. Also, each logical interface can have any DLCI value from 1 through 1022.

**frame-relay**—Use Frame Relay encapsulation is defined in RFC 1490, *Multiprotocol Interconnect over Frame Relay*. E1, E3, link services, SONET/SDH, T1, T3, and voice services interfaces can use Frame Relay encapsulation.

**frame-relay-ccc**—Use Frame Relay encapsulation on CCC circuits. This encapsulation is same as standard Frame Relay for DLCIs 0 through 511. DLCIs 512 through 1022 are dedicated to CCC. The logical interface must also have **frame-relay-ccc** encapsulation. When you use this encapsulation type, you can configure the **ccc** family only.

**frame-relay-ether-type**—Use Frame Relay ether type encapsulation for compatibility with the Cisco Frame Relay. IETF frame relay encapsulation identifies the payload format using NLPID and SNAP formats. Cisco-compatible Frame Relay encapsulation uses the Ethernet type to identify the type of payload.

**NOTE:** When the encapsulation type is set to Cisco-compatible Frame Relay encapsulation, ensure that the LMI type is set to ANSI or Q933-A.

---

**frame-relay-ether-type-tcc**—Use Frame Relay ether type TCC for Cisco-compatible Frame Relay on TCC circuits to connect different media. This encapsulation is Cisco-compatible Frame Relay for DLCIs 0 through 511. DLCIs 512 through 1022 are dedicated to TCC.

**frame-relay-port-ccc**—Use Frame Relay port CCC encapsulation to transparently carry all the DLCIs between two customer edge (CE) routers without explicitly configuring each DLCI on the two provider edge (PE) routers with Frame Relay transport. The connection between the two CE routers can be either user-to-network interface (UNI) or network-to-network interface (NNI); this is completely transparent to the PE routers. When you use this encapsulation type, you can configure the **ccc** family only.

**frame-relay-tcc**—This encapsulation is similar to Frame Relay CCC and has the same configuration restrictions, but used for circuits with different media on either side of the connection.

**generic-services**—Use generic services encapsulation for services with a hierarchical scheduler.

**multilink-frame-relay-uni-nni**—Use MLFR UNI NNI encapsulation. This encapsulation is used on link services, voice services interfaces functioning as FRF.16 bundles, and their constituent T1 or E1 interfaces, and is supported on LSQ and redundant LSQ interfaces.

**ppp**—Use serial PPP encapsulation. This encapsulation is defined in RFC 1661, *The Point-to-Point Protocol (PPP) for the Transmission of Multiprotocol Datagrams over Point-to-Point Links*. PPP is the default encapsulation type for physical interfaces. E1, E3, SONET/SDH, T1, and T3 interfaces can use PPP encapsulation.

**ppp-ccc**—Use serial PPP encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

**ppp-tcc**—Use serial PPP encapsulation on TCC circuits for connecting different media. When you use this encapsulation type, you can configure the **tcc** family only.

**vlan-ccc**—Use Ethernet VLAN encapsulation on CCC circuits. VLAN CCC encapsulation supports TPID 0x8100 only. When you use this encapsulation type, you can configure the **ccc** family only.

**vlan-vci-ccc**—Use ATM-to-Ethernet interworking encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only. All logical interfaces configured on the Ethernet interface must also have the encapsulation type set to **vlan-vci-ccc**.

**vlan-vpls**—Use VLAN VPLS encapsulation on Ethernet interfaces with VLAN tagging and VPLS enabled. Interfaces with VLAN VPLS encapsulation accept packets carrying standard TPID values only. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

#### NOTE:

- Label-switched interfaces (LSIs) do not support VLAN VPLS encapsulation. Therefore, you can only use VLAN VPLS encapsulation on a PE-router-to-CE-router interface and not a core-facing interface.
- Starting with Junos OS release 13.3, a commit error occurs when you configure **vlan-vpls** encapsulation on a physical interface and configure family **inet** on one of the logical units. Previously, it was possible to commit this invalid configuration.

**Required Privilege Level** interface—To view this statement in the configuration.  
 interface-control—To add this statement to the configuration.

| <b>Syntax</b>              | encapsulation vxlan;                                                                                                             |
| <b>Hierarchy Level</b>     | {edit protocols <a href="#">evpn</a> ]<br>[edit routing-instances <i>routing-instance-name</i> protocols <a href="#">evpn</a> ], |
| <b>Release Information</b> | Statement introduced in Junos OS Release 16.1.                                                                                   |
| <b>Description</b>         | Configure a VXLAN encapsulation type. This statement is required for a VXLAN EVPN instance.                                      |

**NOTE:** If you configure the `encapsulation vxlan` statement, then you must also configure the [extended-vni-list](#) statement.

**NOTE:** The `encapsulation vxlan` statement is an exclusive command. You cannot configure the `encapsulation vxlan` statement with the [extended-vlan-list](#) statement, or other commands associated with MPLS EVPN instances.

## end-interface

---

**Syntax**    end-interface {  
              **interface** *interface-name*;  
              **no-revert**;  
              **protect-interface** *interface-name*;  
              }

**Hierarchy Level**    [edit logical-systems *logical-system-name* protocols l2circuit local-switching interface *interface-name*],  
                          [edit protocols l2circuit local-switching interface *interface-name*]

**Release Information**    Statement introduced before Junos OS Release 7.4.

**Description**    Specify the end interface for a local interface switch.

**NOTE:** The protect interface must be configured prior to configuring the **no-revert** statement.

---

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level**    routing—To view this statement in the configuration.  
                                  routing-control—To add this statement to the configuration

| <b>Description</b>              | <p>Establishes which VXLAN Network Identifiers (VNI) will be part of the Virtual Switch (VS) instance. When you issue the <b>commit check</b> command to verify the candidate configuration syntax without committing it, it also checks if the specified VNI(s) is associated with a bridge domain (BD) (<b>bridge-domain <i>name</i> vxlan <i>vni</i></b>).</p> <p>There are different broadcast, unknown unicast, and multicast (BUM) replication options available in Ethernet Virtual Private Network (EVPN). By using the <b>extended-vni-list</b> statement, you forgo a multicast underlay in favor of EVPN and VXLAN ingress-replication.</p> |
|                                 | <p> <b>NOTE:</b> The <b>extended-vni-list</b> statement is an exclusive command. You cannot configure the <b>extended-vni-list</b> statement with either the <a href="#">extended-vlan-list</a> or <a href="#">extended-vni-all</a> statements.</p>                                                                                                                                                                                                                                                                                                                 |
|                                 | <p> <b>NOTE:</b> If you configure the <b>extended-vni-list</b> statement, then you must also configure the <a href="#">encapsulation vxlan</a> statement.</p>                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Options</b>                  | <p><b>list of VNIs</b>—Specify a single VNI or list of VNIs as part of the VS instance, for example <b>extended-vni-list [ 10-50 60 70]</b>.</p> <p><b>all</b>—Include all VNIs as part of the VS instance. By specifying <b>all</b>, you bypass the <b>commit check</b> process and all configured BDs in the EVPN are considered extended.</p>                                                                                                                                                                                                                                                                                                       |
| <b>Required Privilege Level</b> | <p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b>         | <p>Enable multiprotocol BGP (MP-BGP) by configuring BGP to carry network layer reachability information (NLRI) for address families other than unicast IPv4, to specify MP-BGP to carry NLRI for the IPv6 address family, or to carry NLRI for VPNs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

- Options**
- any**—Configure the family type to be both unicast and multicast.
  - evpn**—Configure NLRI parameters for Ethernet VPNs (EVPNs).
  - inet**—Configure NLRI parameters for IPv4.
  - inet6**—Configure NLRI parameters for IPv6.
  - inet-mdt**—Configure NLRI parameters for the multicast distribution tree (MDT) subaddress family identifier (SAFI) for IPv4 traffic in Layer 3 VPNs.
  - inet-mvpn**—Configure NLRI parameters for IPv4 for multicast VPNs.
  - inet6-mvpn**—Configure NLRI parameters for IPv6 for multicast VPNs.
  - inet-vpn**—Configure NLRI parameters for IPv4 for Layer 3 VPNs.
  - inet6-vpn**—Configure NLRI parameters for IPv6 for Layer 3 VPNs.
  - inet6-vpn**—Configure NLRI parameters for IPv6 for Layer 3 VPNs.
  - iso-vpn**—Configure NLRI parameters for IS-IS for Layer 3 VPNs.
  - l2vpn**—Configure NLRI parameters for IPv4 for MPLS-based Layer 2 VPNs and VPLS.
  - labeled-unicast**—Configure the family type to be labeled-unicast. This means that the BGP peers are being used only to carry the unicast routes that are being used by labeled-unicast for resolving the labeled-unicast routes. This statement is supported only with **inet** and **inet6**.
  - multicast**—Configure the family type to be multicast. This means that the BGP peers are being used only to carry the unicast routes that are being used by multicast for resolving the multicast routes.
  - unicast**—Configure the family type to be unicast. This means that the BGP peers only carry the unicast routes that are being used for unicast forwarding purposes. The default family type is **unicast**.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level**

- routing—To view this statement in the configuration.
- routing-control—To add this statement to the configuration.

## family multiservice

```
Syntax family multiservice {
 destination-mac;
 label-1;
 label-2;
 payload {
 ip {
 layer-3 {
 (source-ip-only | destination-ip-only);
 }
 layer-3-only;
 layer-4;
 }
 }
 source-mac;
 symmetric-hash {
 complement;
 }
 }
```

**Hierarchy Level** [edit forwarding-options hash-key]

**Release Information** Statement introduced in Junos OS Release 8.0.  
**ip**, **label-1**, **label-2**, **layer-3-only**, and **payload** options introduced in Junos OS Release 9.4.  
**layer-3**, **layer-**, **source-ip-only**, and **destination-ip-only** options introduced in Junos OS Release 9.5.  
**symmetric-hash** and **complement** options introduced in Junos OS Release 9.6.

**Description** Configure load balancing based on Layer 2 media access control information. On MX Series routers, configure VPLS load balancing. On M120 and M320 routers only, configure VPLS load balancing based on MPLS labels and IP information. For IPv4 traffic, only the IP source and destination addresses are included in the hash key. For MPLS and IPv4 traffic, one or two MPLS labels and IPv4 source and destination addresses are included. For MPLS Ethernet pseudowires, only one or two MPLS labels are included in the hash key.

**Options** You can configure one or more options to load-balance using the packet information that you specify.

**destination-mac**—Include the destination-address MAC information in the hash key for Layer 2 load balancing.

**label-1** (M120 and M320 routers only)—Include the first MPLS label in the hash key. Used for including a one-label packet for per-flow load balancing of IPv4 VPLS traffic based on IP information and MPLS labels.

**label-2** (M120 and M320 routers only)—Include the second MPLS label in the hash key. If both **label-1** and **label-2** are specified, the entire first label and the first 16 bits of the second label are hashed.

**payload** (MX Series, M120, and M320 routers only)—Include the packet's IP payload in the hash key.

- **ip** (MX Series, M120, and M320 routers only)—Include the IP address of the IPv4 or IPv6 payload in the hash key.
- **layer-3** (MX Series routers only)—Use this to include Layer 3 information from the packet's IP payload in the hash key.
  - **destination-ip-only** (MX Series routers only)—Use this to include only the destination IP address in the payload in the hash key.
  - **source-ip-only** (MX Series routers only)—Use this to include only the source IP address in the payload in the hash key.

**NOTE:** You can include either the **source-ip-only** or the **destination-ip-only** statement, not both. They are mutually exclusive.

---

- **layer-3-only** (M120, and M320 routers only)—Include only the Layer 3 information from the packet's IP payload in the hash key.
- **layer-4** (MX Series routers only)—Include Layer 4 information from the packet's IP payload in the hash key.

**NOTE:** On MX Series routers only, you can configure either Layer 3 or Layer 4 load balancing, or both at the same time.

---

**NOTE:** On I chip platforms, an unknown Layer 4 header is excluded from load-balance hashing to avoid undesired packet reordering.

---

**source-mac**—Include the source-address MAC information in the hash key.

**symmetric-hash** (MX Series routers only)—Configure the symmetric hash or symmetric hash complement for configuring symmetrical load balancing on an 802.3ad Link Aggregation Group.

- **complement** —Include the complement of the symmetric hash in the hash key.

**Required Privilege  
Level**

interface—To view this statement in the configuration.

interface-control—To add this statement to the configuration.

| <b>Release Information</b> | Statement introduced in Junos OS Release 12.1.                                                                                                                                           |
| <b>Description</b>         | (M320 routers with Channelized OC3/STM1 Circuit Emulation PIC with SFP only and EX Series switches) Reduce the Automatic Protection Switching (APS) switchover time in Layer 2 circuits. |

### NOTE:

- Configuring this statement reduces the APS switchover time only when the Layer 2 circuit encapsulation type for the interface receiving traffic from a Layer 2 circuit neighbor is SAToP.
- When the fast-aps-switch statement is configured in revertive APS mode, you must configure an appropriate value for revert time to achieve reduction in APS switchover time.
- To prevent the logical interfaces in the data path from being shut down, configure appropriate hold-time values on all the interfaces in the data path that support TDM.
- The fast-aps-switch statement cannot be configured when the APS annex-b option is configured.
- The interfaces that have the fast-aps-switch statement configured cannot be used in virtual private LAN service (VPLS) environments.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 9.5.<br>Statement introduced in Junos OS Release 12.3R2 for EX Series switches.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b>              | Specify the fast reroute priority for a VPLS routing instance. You can configure <b>high</b> , <b>medium</b> , or <b>low</b> fast reroute priority to prioritize specific VPLS routing instances for faster convergence and traffic restoration. Because the router repairs next hops for high-priority VPLS routing instances first, the traffic traversing a VPLS routing instance configured with <b>high</b> fast reroute priority is restored faster than the traffic for VPLS routing instances configured with <b>medium</b> or <b>low</b> fast reroute priority.                                                                                                                        |
|                                 | <div> <b>NOTE:</b> In the VPLS documentation, the word <i>router</i> in terms such as <i>PE router</i> is used to refer to any device that provides routing functions.</div>                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Default</b>                  | low                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Options</b>                  | <b>high</b> —Set the fast reroute priority for a VPLS routing instance to high. During a fast reroute event, the router repairs next hops for high-priority VPLS routing instances first.<br><br><b>low</b> —Set the fast reroute priority for a VPLS routing instance to low, which is the default. During a fast reroute event, the router repairs next hops for low-priority VPLS routing instances last.<br><br><b>medium</b> —Set the fast reroute priority for a VPLS routing instance to medium. During a fast reroute event, the router repairs next hops for medium-priority VPLS instances after high-priority VPLS routing instances but before low-priority VPLS routing instances. |

| <b>Description</b>              | <p>Configure the FEC 128 VPWS pseudowire to statically push the flow label on the pseudowire packets sent to the remote egress provider edge (PE) router. The ingress PE router inserts the flow label in the pseudowire packet, irrespective of the information exchanged in the signaling plane. If the egress PE router cannot handle the pseudowire packet marked with the flow label, the packet is dropped.</p> <p>Flow-aware transport of pseudowires (FAT) flow labels enable load-balancing of MPLS packets across equal-cost multipath (ECMP) paths or link aggregation groups (LAGs) without the need for deep packet inspection of the payload. FAT flow labels can be used for LDP-signaled forwarding equivalence class (FEC) 128 and FEC 129 pseudowires for virtual private LAN service (VPLS) and virtual private wire service (VPWS) networks.</p> |

| <b>Description</b>              | <p>Configure the pseudowire to the specified backup neighbor as the hot-standby. When you configure this statement, traffic flows over both the active and hot-standby pseudowires to the backup device (either a CE device or PE router). The backup device drops the traffic from the hot-standby pseudowire, unless the active pseudowire fails. If the active pseudowire fails, the backup device automatically switches to the hot-standby pseudowire.</p> <p>Configure the <b>hot-standby</b> statement on routers that have both active and standby virtual circuits. Generally, these are access routers. On provider edge routers, configure the <b>hot-standby-vc-on</b> statement to indicate that a hot-standby pseudowire is desired upon arrival of a PW_FWD_STDBY status-TLV.</p>                            |
| <b>Required Privilege Level</b> | <p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b>              | <p>On provider edge (PE) aggregation routers, configure the <b>hot-standby-vc-on</b> statement to indicate that a hot-standby pseudowire is desired upon arrival of a PW_FWD_STDBY status-tlv. This flag indicates the standby state. Configure in conjunction with the <b>hot-standby</b> statement on routers that have both active and standby virtual circuits. Generally, these are access routers.</p> <p>The goal of the <b>hot-standby</b> statement is to reduce the amount of traffic being discarded during primary-to-backup transition periods. This statement enables the possibility of keeping both the active and standby paths open within the Layer 2 domain. By having both the active and standby VCs able to send and receive traffic, traffic loops could potentially occur within the Layer 2 domain. In consequence, Layer 2 VCs are kept open only in the PE-to-access direction. In other words, aggregation PE devices can send traffic toward access devices, but access devices send traffic exclusively through the active VC.</p> <p>In this regard, the <b>hot-standby</b> statement is quite similar to the <b>standby</b> statement. The <b>hot-standby</b> statement allows for a faster forwarding-path switchover during transition periods, as compared to what is allowed by the <b>standby</b> statement.</p> |
| <b>Required Privilege Level</b> | <p>routing—To view this statement in the configuration.</p> <p>routing-control—To add this statement to the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b>              | Configure a Layer 2 VPN or VPLS multihoming identifier (MHID). An identifier needs to be configured for each multihomed site. Multihoming site identifiers are specific to a VPLS domain. They need not be unique on a provider edge (PE) router when multiple VPLS instances are present. The network layer reachability information (NLRI) advertisements sent to a CE device are identified as candidates for designated forwarder selection because the advertisements have the same multihoming identifier. Thus, you should assign the same identifier on all VPLS PE routers that are multihomed to the same customer site. |
|                                 | <p> <b>NOTE:</b> The route distinguisher must be unique among PE routers participating in a multihomed site, so that the RD:MHID combination is unique across multiple VPLS domains. For example, one PE router might have a route distinguisher of 192.0.2.4:1, and another PE router in the same site might have a route distinguisher of 192.0.2.:1. The first number can be, for example, the loopback interface address that identifies the PE router. The second number is the multihoming identifier.</p>                                 |
|                                 | <p> <b>NOTE:</b> In the VPLS documentation, the word <i>router</i> in terms such as <i>PE router</i> is used to refer to any device that provides routing functions.</p>                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b>              | Ignore the MTU configuration set for the physical interface associated with the local switching interface or with the remote PE router. This allows a pseudowire to be brought up between two logical interfaces that are defined on physical interfaces with different MTU values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b>              | <p>(MX Series routers with MPCs and MIC interfaces only) Specify one or more routing instances where MPLS paths (pseudowire labeled routes) are leaked from the mpls.0 routing table in the master routing instance to the local <i>routing-instance-name</i>.mpls.0 routing table.</p> <p>This capability is useful in an L2VPN/VPLS configuration when the remote PE router is learned from the IGP in a nondefault routing instance, because L2VPN/VPLS installs ingress-labeled routes only in the master mpls.0 table.</p> <p>When L2VPN/VPLS traffic is received on the core-facing interface in a nondefault routing instance, the router performs a lookup in the table that corresponds to that interface, <i>routing-instance-name</i>.mpls.0. Because the routes are not leaked by default, no routes are found in the <i>routing-instance-name</i>.mpls.0 routing table and all the incoming traffic is dropped.</p> |
| <b>Options</b>                  | <i>routing-instance-name</i> —Name of a nondefault routing instance where you want routes leaked from the master MPLS routing table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## interface (Protocols Layer 2 Circuit)

**Syntax** interface *interface-name* {  
     **backup-neighbor** *address*;  
     **bandwidth** (*bandwidth* | *ctnumber bandwidth*);  
     **community** *community-name*;  
     **connection-protection**;  
     (**control-word** | **no-control-word**);  
     **description** *text*;  
     **egress-protection**;  
     **encapsulation-type** *type*;  
     **flow-label-receive**;  
     **flow-label-receive-static**;  
     **flow-label-transmit**;  
     **flow-label-transmit-static**;  
     **ignore-encapsulation-mismatch**;  
     **ignore-mtu-mismatch**;  
     **mtu** *mtu-number*;  
     **no-revert**;  
     **oam**;  
     **protect-interface** *interface-name*;  
     **pseudowire-status-tlv** **hot-standby-vc-on**;  
     **psn-tunnel-endpoint** *address*;  
     **revert-time** *seconds*;  
     **static** {  
         **switchover-delay** *milliseconds*;  
         **virtual-circuit-id** *identifier*;  
     }  
 }

**Hierarchy Level** [edit logical-systems *logical-system-name* protocols l2circuit local-switching],  
 [edit logical-systems *logical-system-name* protocols l2circuit neighbor *address*],  
 [edit protocols l2circuit local-switching],  
 [edit protocols l2circuit neighbor *address*]

**Release Information** Statement introduced before Junos OS Release 7.4.  
**flow-label-receive-static** and **flow-label-transmit-static** options introduced in Junos OS Release 14.1.

**Description** Interface over which Layer 2 circuit traffic travels.

**Options** *interface-name*—Name of the interface to configure.

**NOTE:** The commit operation fails, if the same logical interface is configured for both layer 2 circuit and ccc connection.

**connection-protection**—Enable end-to-end protection through OAM failure detection.

**flow-label-receive**—Advertise capability to pop flow label in receive direction to the remote provider edge (PE) device.

**flow-label-receive-static**—Pop flow label on the pseudowire packets received from the remote PE device. The ingress PE inserts the flow label in the pseudowire packet, irrespective of the information exchanged in the signaling plane. If the egress PE cannot handle the pseudowire packet marked with the flow label, the packet is dropped.

**flow-label-transmit**—Advertise capability to push flow label in transmit direction to the remote PE device.

**flow-label-transmit-static**—Push flow label on the pseudowire packets sent to the remote PE device. If the incoming pseudowire packet is not marked with the flow label, the packet is dropped by the egress PE.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

## interface (Protocols Layer 2 VPN)

**Syntax**

```
interface interface-name {
 description text;
 remote-site-id remote-site-id;
}
```

**Hierarchy Level** [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols l2vpn],  
[edit routing-instances *routing-instance-name* protocols l2vpn]

**Release Information** Statement introduced before Junos OS Release 7.4.

**Description** Configure an interface to handle traffic for a circuit configured for the Layer 2 VPN.

**Options** *interface-name*—Name of the interface used for the Layer 2 VPN.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>              | <p>Specify the maximum number of media access control (MAC) addresses that can be learned by the EVPN or VPLS routing instance. You can configure the same limit for all interfaces configured for a routing instance. You can also configure a limit for a specific interface.</p> <p>Starting with Junos OS Release 12.3R4, if you do not configure the parameter to limit the number of MAC addresses to be learned by a VPLS instance, the default value is not effective. Instead, if you do not include the <b>interface-mac-limit</b> option at the [edit logical-systems <i>logical-system-name</i> routing-instances <i>routing-instance-name</i> protocols vpls site <i>site-name</i> interfaces <i>interface-name</i>], hierarchy level, this setting is not present in the configuration with the default value of 1024 addresses. If you upgrade a router running a Junos OS release earlier than Release 12.3R4 to Release 12.3R4 or later, you must configure the <b>interface-mac-limit</b> option with a valid value for it to be saved in the configuration.</p> |
| <b>Options</b>                  | <p><b>limit</b>—Number of MAC addresses that can be learned from each interface.</p> <p><b>Range:</b> 16 through 65,536 MAC addresses</p> <p><b>Default:</b> 1024 addresses</p> <p>The remaining statement is explained separately. See <a href="#">CLI Explorer</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 11.1 for EX Series switches.  
Statement introduced in Junos OS Release 14.1X53-D10 for the QFX Series and for EX4600 switches.

**Description** Enables a Layer 2 circuit.

The remaining statements are explained separately. See [CLI Explorer](#).

| <b>Description</b>              | Enable routers to use both the BGP path selection algorithm and the designated forwarder path selection algorithm when selecting the preferred path to each destination in a Layer 2 VPN or VPLS routing instance. The BGP path selection algorithm is used by all of the Provider routers participating in the routing instance. The designated forwarder path selection algorithm is used by the PE router participating in the routing instance. |
| <b>Default</b>                  | By default, the designated forwarder path selection algorithm is used to select the best path to reach each destination within Layer 2 VPN and VPLS routing instances.                                                                                                                                                                                                                                                                              |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b>              | Specify the LSP template. An LSP template is used as the basis for other dynamically generated LSPs. This feature can be used for a number of applications, including point-to-multipoint LSPs, flooding VPLS traffic, configuring ingress replication for IP multicast using MBGP MVPNs, and to enable RSVP automatic mesh. There is no default setting for the <b>label-switched-path-template</b> statement, so you must configure either the default-template using the <b>default-template</b> option, or you must specify the name of your preconfigured LSP template.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## local-switching (Layer 2 Circuits)

---

**Syntax**

```
local-switching {
 interface interface-name {
 description text;
 encapsulation-type;
 end-interface {
 interface interface-name;
 no-revert;
 protect-interface interface-name;
 }
 ignore-encapsulation-mismatch;
 ignore-mtu-mismatch;
 no-revert;
 protect-interface interface-name;
 }
}
```

**Hierarchy Level** [edit logical-systems *logical-system-name* protocols l2circuit],  
[edit protocols l2circuit]

**Release Information** Statement introduced before Junos OS Release 7.4.

**Description** Configure a local switching interface. A local switching interface allows you to terminate a virtual circuit on the local router.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>              | Allows you to terminate multiple Layer 2 circuit pseudowires at a single VPLS mesh group. Note that when using <a href="#">vpls-id-list</a> , you can enable local-switching to allow local switching of traffic (including BUM traffic) between multiple pseudo wires. Enabling local-switching also eliminates the need to have a dedicated mesh-group for each LDP spoke pseudo wire (which has a limit of 14). |

| <b>Release Information</b> | Statement introduced in Junos OS Release 10.0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b>         | <p>Enable media access control (MAC) flush processing for the virtual private LAN service (VPLS) routing instance or for the mesh group under a VPLS routing instance. MAC flush processing removes MAC addresses from the MAC address database that have been learned dynamically. With the dynamically learned MAC addresses removed, MAC address convergence requires less time to complete.</p>                                                                                                           |

For certain cases where MAC flush processing is not initiated by default, you can also specify *explicit-mac-flush-message-options* that additionally configure the router to send explicit MAC flush messages. To configure the router to send explicit MAC flush messages under specific conditions, include *explicit-mac-flush-message-options* with the statement.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

In certain cases, BGP updates sent by the provider edge (PE) device are delayed for 1 to 5 seconds.

This happens when all of the following conditions are true:

- BGP-based VPLS multihoming sites are configured.
- The **mac-flush** statement is included in the configuration.
- a non-minimum designated-forwarder site (site-x, for example) transitions to non-designated-forwarder status

The BGP update being delayed corresponds to the explicit-MAC flush notification message sent by site-x's PE device (PE2, for example). This BGP update message is not deferred if the designated-forwarder status is lost due to a locally-triggered event (for example, a local attachment-circuit interface going down). In other words, BGP update messages are deferred (in Device PE2) only when the designated-forwarder state is lost due to external events taking place in remote PE devices that also hold site-x (for example, in PE1). Suppose, for example, that Device PE1 is the default designated-forwarder with site-x's local interface in the DOWN state. Device PE2 defers BGP update message after Device PE1's local interface comes back to the UP state.

**Options** *explicit-mac-flush-message-options*—(Optional) You can specify one or more of the following explicit MAC flush message options:

- **any-interface**—(Optional) Send a MAC flush message when any customer-facing attachment circuit interface goes down.
- **any-spoke**—(Optional) Send a MAC FLUSH-FROM-ME flush message to all provider edge (PE) routers in the core when one of the spoke pseudowires between the multitenant unit switch and the other network-facing provider edge (NPE) router goes down, causing the multitenant unit switch to switch to this NPE router.

**NOTE:** This option has a similar effect in a VPLS multihoming environment with multiple multitenant unit switches connected to NPE routers, where both multitenant unit switches have pseudowires that terminate in a mesh group with local-switching configured. If the **any-spoke** option is enabled, then both PE routers send MAC FLUSH-FROM-ME flush messages to all PEs in the core.

- **propagate**—(Optional) Propagate MAC flush to the core.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Release Information</b>      | <p>Statement introduced in Junos OS Release 16.1.</p> <p>Support at [edit routing-instances <i>routing-instance-name</i> protocols evpn] hierarchy introduced in Junos OS Release 17.2R1 on MX Series Routers with MPC and MIC interfaces.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b>              | <p>Enable MAC pinning on an interface. When you enable MAC pinning on an interface in a bridge domain or VPLS domain, MAC addresses learned over that interface cannot be relearned on any other interface in the same bridge domain or VPLS domain until the MAC address is cleared from the MAC table. If the same MAC address is learned over any other interface in the same bridge domain, it is discarded. This, effectively, controls MAC address moves and prevents creation of loops in Layer 2 bridges.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|                                 | <p> <b>NOTE:</b> If the timeout interval for the MAC addresses is not specified by setting the <code>mac-table-aging-time</code> statement, the MAC addresses learned over the MAC pinning interface are pinned to the interface until the default timeout period.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Default</b>                  | MAC pinning is not enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 16.2 for EVPNs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b>              | Sets mac-pinning on the interface, which makes it static. That is, the MAC-pinned address cannot be moved to any other interface in the bridge domain.                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b>              | (MX Series routers, EX Series switches, and QFX Series only) For bridge domains or VLANs, enable MAC accounting either for a specific bridge domain or VLAN, or for a set of bridge domains or VLANs associated with a Layer 2 trunk port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## mac-table-aging-time

**Syntax** `mac-table-aging-time time;`

**Hierarchy Level** [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls],  
[edit routing-instances *routing-instance-name* protocols vpls]  
[edit bridge-options],  
[edit routing-instances *routing-instance-name* protocols evpn]

**NOTE:** For MX Series routers, the configuration statement is supported at the [bridge-options], [protocols vpls], and [protocols evpn] hierarchy levels only.

**Release Information** Statement introduced in Junos OS Release 7.4.  
Statement introduced in Junos OS Release 15.1 for MX Series routers.

**Description** Modify the timeout interval for the MAC table.

For MX Series routers, you can use the **global-mac-table-aging-time** statement at the [edit protocols l2-learning] hierarchy level to configure the timeout interval at the global level or use the **mac-table-aging-time** to configure the timeout interval for a bridge domain or for a specific VPLS or EVPN instance. If multiple timeout interval values are configured on a router, the router determines the timeout interval value in the following order of priority:

- Timeout interval configured at the VPLS or EVPN instance
- Timeout interval configured for the bridge domain
- Global timeout interval configured on the router

**NOTE:** For MX Series routers, the timeout interval configuration feature is supported on routers with MPCs only.

**Options** *time*—Specify the number of seconds to wait between MAC table clearings.  
**Range:** 10 through 1,000,000 seconds  
**Default:** 300 seconds

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

## mesh-group (Protocols VPLS)

**Syntax** `mesh-group mesh-group-name {  
     interface interface-name;  
     l2vpn-id (as-number:id | ip-address:id);  
     local-switching;  
     mac-flush [ explicit-mac-flush-message-options ];  
     neighbor address {...};  
     peer-as all;  
     pseudowire-status-tlv hot-standby-vc-on;  
     route-distinguisher (as-number:id | ip-address:id);  
     vpls-id number;  
     vrf-export [ policy-names ];  
     vrf-import [ policy-names ];  
     vrf-target {  
         community;  
         import community-name;  
         export community-name;  
     }  
}`

**Hierarchy Level** [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls],  
 [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls site *site-name*],  
 [edit routing-instances *routing-instance-name* protocols vpls],  
 [edit routing-instances *routing-instance-name* protocols vpls site *site-name*]

**Release Information** Statement introduced in Junos OS Release 9.0.  
**local-switching**, **mac-tlv-receive**, **mac-tlv-send**, and **peer-as** options introduced in Junos OS Release 9.3.  
**pseudowire-status-tlv** and **mac-flush** options introduced in Junos OS Release 10.0.  
**route-distinguisher**, **vrf-export**, **vrf-import**, and **vrf-target** options introduced in Junos OS Release 11.2.  
**hot-standby-vc-on** and **interface interface-name** options introduced in Junos OS Release 15.1R2.

**Description** Specify the virtual private LAN service (VPLS) mesh group. The statement options allow you to specify each provider edge (PE) router that is a member of the mesh group. This statement is also used in the configuration of inter-autonomous system (AS) VPLS with media access control (MAC) operations.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

**Options** **mesh-group-name**—Name of the VPLS mesh group.

The remaining statements are explained separately. See [CLI Explorer](#).

| <b>Description</b>         | <p>Configure the minimum interval after which the local routing device transmits hello packets and then expects to receive a reply from a neighbor with which it has established a BFD session. Optionally, instead of using this statement, you can specify the minimum transmit and receive intervals separately using the <a href="#">minimum-interval</a> (specified under the <a href="#">transmit-interval</a> statement) and <a href="#">minimum-receive-interval</a> statements.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Options</b>             | <p><i>milliseconds</i>—Specify the minimum interval value for BFD liveliness detection.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Release Information**    Statement introduced in Junos OS Release 8.2.  
Statement introduced in Junos OS Release 9.0 for EX Series switches.  
Support for BFD authentication introduced in Junos OS Release 9.6.  
Statement introduced in Junos OS Release 12.1 for the QFX Series.  
Statement introduced in Junos OS Release 13.2 for Layer 2 VPN and VPLS.  
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

**Description** Configure the minimum interval at which the local routing device transmits hello packets to a neighbor with which it has established a BFD session. Optionally, instead of using this statement at this hierarchy level, you can configure the minimum transmit interval using the [minimum-interval](#) statement at the **bfd-liveness-detection** hierarchy level.

**Options** *milliseconds*—Minimum transmit interval value.  
**Range:** 1 through 255,000

**NOTE:** The threshold value specified in the **threshold** statement must be greater than the value specified in the **minimum-interval** statement for the **transmit-interval** statement.

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>         | Configure the minimum interval after which the local routing device must receive a reply from a neighbor with which it has established a BFD session. Optionally, instead of using this statement, you can configure the minimum receive interval using the <b>minimum-interval</b> statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Options</b>             | <b><i>milliseconds</i></b> —Specify the minimum receive interval value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Release Information**

Statement introduced before Junos OS Release 7.4.

Statement introduced in Junos OS Release 9.0 for EX Series switches.

Support for Layer 2 VPNs and VPLS introduced in Junos OS Release 10.4.

Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers.

Statement introduced in Junos OS Release 12.2 for ACX Series Universal Access Routers.

Support at the `[set interfaces interface-name unit logical-unit-number family ccc]` hierarchy level introduced in Junos OS Release 12.3R3 for MX Series routers.

**Description** Specify the maximum transmission unit (MTU) size for the media or protocol. The default MTU size depends on the device type. Changing the media MTU or protocol MTU causes an interface to be deleted and added again.

To route jumbo data packets on an integrated routing and bridging (IRB) interface or routed VLAN interface (RVI) on EX Series switches, you must configure the jumbo MTU size on the member physical interfaces of the VLAN that you have associated with the IRB interface or RVI, as well as on the IRB interface or RVI itself (the interface named `irb` or `vlan`, respectively).

**CAUTION:** For EX Series switches, setting or deleting the jumbo MTU size on an IRB interface or RVI while the switch is transmitting packets might cause packets to be dropped.

---

**NOTE:**

The MTU for an IRB interface is calculated by removing the Ethernet header overhead [6(DMAC)+6(SMAC)+2(EtherType)]. Because, the MTU is the lower value of the MTU configured on the IRB interface and the MTU configured on the IRB's associated bridge domain IFDs or IFLs, the IRB MTU is calculated as follows:

- In case of Layer 2 IFL configured with the `flexible-vlan-tagging` statement, the IRB MTU is calculated by including 8 bytes overhead (SVLAN+CVLAN).
  - In case of Layer 2 IFL configured with the `vlan-tagging` statement, the IRB MTU is calculated by including a single VLAN 4 bytes overhead.
-

---

**NOTE:**

- If a packet whose size is larger than the configured MTU size is received on the receiving interface, the packet is eventually dropped. The value considered for MRU (maximum receive unit) size is also the same as the MTU size configured on that interface.
- Not all devices allow you to set an MTU value, and some devices have restrictions on the range of allowable MTU values. You cannot configure an MTU for management Ethernet interfaces (fxp0, em0, or me0) or for loopback, multilink, and multicast tunnel devices.
- On ACX Series routers, you can configure the protocol MTU by including the `mtu` statement at the [edit interfaces *interface-name* unit *logical-unit-number* family inet] or [edit interfaces *interface-name* unit *logical-unit-number* family inet6] hierarchy level.
  - If you configure the protocol MTU at any of these hierarchy levels, the configured value is applied to all families that are configured on the logical interface.
  - If you are configuring the protocol MTU for both inet and inet6 families on the same logical interface, you must configure the same value for both the families. It is not recommended to configure different MTU size values for inet and inet6 families that are configured on the same logical interface.
- Starting in Release 14.2, MTU for IRB interfaces is calculated by removing the Ethernet header overhead (6(DMAC)+6(SMAC)+2(EtherType)), and the MTU is a minimum of the two values:
  - Configured MTU
  - Associated bridge domain's physical or logical interface MTU
    - For Layer 2 logical interfaces configured with flexible-vlan-tagging, IRB MTU is calculated by including 8 bytes overhead (SVLAN+CVLAN).
    - For Layer 2 logical interfaces configured with vlan-tagging, IRB MTU is calculated by including single VLAN 4 bytes overhead.

---

**NOTE:** Changing the Layer 2 logical interface option from vlan-tagging to flexible-vlan-tagging or vice versa adjusts the logical interface MTU by 4 bytes with the existing MTU size. As a result, the Layer 2 logical interface is deleted and re-added, and the IRB MTU is re-computed appropriately.

---

For more information about configuring MTU for specific interfaces and router or switch combinations, see *Configuring the Media MTU*.

**Options** *bytes*—MTU size.

**Range:** 256 through 9192 bytes, 256 through 9216 (EX Series switch interfaces), 256 through 9500 bytes (Junos OS 12.1X48R2 for PTX Series routers), 256 through 9500 bytes (Junos OS 16.1R1 for MX Series routers)

**NOTE:** Starting in Junos OS Release 16.1R1, the MTU size for a media or protocol is increased from 9192 to 9500 for Ethernet interfaces on the following MX Series MPCs:

- MPC1
- MPC2
- MPC2E
- MPC3E
- MPC4E
- MPC5E
- MPC6E

**Default:** 1500 bytes (INET, INET6, and ISO families), 1448 bytes (MPLS), 1514 bytes (EX Series switch interfaces)

**Required Privilege Level** interface—To view this statement in the configuration.  
interface-control—To add this statement to the configuration.

| <b>Description</b>         | Configure the number of hello packets not received by a neighbor that causes the originating interface to be declared down.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## multi-homing (VPLS Multihoming for FEC 128)

---

**Syntax** multi-homing;

**Hierarchy Level** [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls site *site-name*],  
[edit routing-instances *routing-instance-name* protocols vpls site *site-name*]

**Release Information** Statement introduced in Junos OS Release 7.5.

**Description** Configuration of this statement tracks BGP peers, such as to prevent isolation of the PE router from the core or split brain.. If no BGP peer is available, all active interfaces for a site are deactivated.

When identical site IDs are used without configuring multihoming, a collision log message is generated at each signaling: **RPD\_L2VPN\_SITE\_COLLISION: Same site ID 2 configured on remote PE (RD 8.8.8.1:1013:) and local PE in VPN 1013 (non-multihomed site 2)**. This is expected behavior.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

---

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

## multi-homing (VPLS Multihoming for FEC 129)

```
Syntax multi-homing {
 peer-active;
 site site-name {
 active-interface interface-name {
 any;
 primary interface-name;
 }
 identifier identifier;
 interface interface-name {
 preference preference-value;
 }
 peer-active;
 preference (preference-value | backup | primary);
 }
}
```

**Hierarchy Level** [edit logical-systems *logical-system-name* routing-instances *instance-name* protocols vpls],  
[edit routing-instances *instance-name* protocols vpls]

**Release Information** Statement introduced in Junos OS Release 12.3.

**Description** For VPLS autodiscovery (FEC 129), specify the parameters for multihoming to two or more provider edge (PE) routers.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

**Release Information** Statement introduced before Junos OS Release 7.4.  
Statement introduced in Junos OS Release 11.1 for EX Series switches.

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b>              | Each Layer 2 circuit is represented by the logical interface connecting the local provider edge (PE) router or switch to the local customer edge (CE) router or switch. All the Layer 2 circuits using a particular remote PE router or switch designated for remote CE routers or switches are listed under the <b>neighbor</b> statement (neighbor designates the PE router or switch). Each neighbor is identified by its IP address and is usually the end-point destination for the LSP tunnel (transporting the Layer 2 circuit). |
| <b>Options</b>                  | <b>address</b> —IP address of a neighboring router or switch.<br><br>The remaining statements are explained separately. See <a href="#">CLI Explorer</a> .                                                                                                                                                                                                                                                                                                                                                                              |

**Release Information** Statement introduced in Junos OS Release 8.4.  
 The **pseudowire-status-tlv** option was added in Junos OS Release 10.0.  
 The **vpls-id-list** option was added in Junos OS Release 14.2 for MX Series routers to provide support for multiple pseudowires between the same pair of PEs in LDP-VPLS.

**Description** Specify each of the PE routers participating in the VPLS domain. Configuring this statement enables LDP for signaling VPLS.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

**Options** *neighbor-id*—Specify the neighbor identifier for each PE router participating in the VPLS domain.

The remaining statements are explained separately. See [CLI Explorer](#).

**Required Privilege Level** routing—To view this statement in the configuration.  
routing-control—To add this statement to the configuration.

| <b>Description</b>              | Configure BFD sessions not to adapt to changing network conditions. We recommend that you <i>do not</i> disable BFD adaptation unless it is preferable to have BFD adaptation disabled in your network.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Release Information</b>      | Statement introduced in Junos OS Release 8.5.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b>              | Prevent CE devices from communicating directly with each other. If the <b>no-local-switching</b> statement is configured, frames arriving on a CE interface are sent to a VPLS edge (VE) device or core-facing interfaces only.                                                                                                                                                                                                                                                                                                                                |
|                                 | <div>  <p><b>NOTE:</b> (MX80, MX104, and the 16x10GE MPC, MPC1, or MPC2 on MX240, MX480, MX960, MX2010, and MX2020 only) If you configure the <b>no-local-switching</b> command at the [edit bridge-domains <i>bridge-domain-name</i>] hierarchy level, it might not prevent multicast traffic from being forwarded between the CE-facing interfaces of the bridge domain. Broadcast, unknown unicast, and known multicast traffic does not exhibit this behavior.</p> </div> |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Release Information** Statement introduced in Junos OS Release 8.4.  
 Support for the **switch-options** statement added in Junos OS Release 9.2.  
 Support for top-level configuration for the **virtual-switch** type of routing instance added in Junos OS Release 9.2. In Junos OS Release 9.1 and earlier, the routing instances hierarchy supported this statement only for a VPLS instance or bridge domain configured within a virtual switch.  
 Support for logical systems added in Junos OS Release 9.6.  
**[edit switch-options]**, **[edit switch-options interface *interface-name*]**, **[edit vlans *vlan-name* switch-options]**, and **[edit vlans *vlan-name* switch-options interface *interface-name*]** hierarchy levels introduced in Junos OS Release 12.3 R2 for EX Series switches.  
 Support for EVPNs added in Junos OS Release 13.2 for MX 3D Series routers.  
 Hierarchy levels **[edit switch-options interface *interface-name*]** and **[edit vlans *vlan-name* switch-options]** introduced in Junos OS Release 13.2X50-D10 for EX Series switches.

**Description** For MX Series routers and EX Series switches, disable MAC learning for a virtual switch, for a bridge domain or VLAN, for a specific logical interface in a bridge domain or VLAN, or for a set of bridge domains or VLANs associated with a Layer 2 trunk port. On platforms that support EVPNs, you can disable MAC learning on an EVPN.

**NOTE:** When MAC learning is disabled for a VPLS routing instance, traffic is not load-balanced and only one of the equal-cost next hops is used.

## no-revert (Local Switching)

---

|                            |                                                                                                                                                                                                  |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>              | no-revert;                                                                                                                                                                                       |
| <b>Hierarchy Level</b>     | [edit protocols l2circuit local-switching interfaces <i>interface-name</i> ]<br>[edit protocols l2circuit local-switching interfaces <i>interface-name</i> end-interface <i>interface-name</i> ] |
| <b>Release Information</b> | Statement introduced in Junos OS Release 11.4.                                                                                                                                                   |
| <b>Description</b>         | (Optional) Prevent the local switching interface from reverting to the primary interface.                                                                                                        |

**NOTE:** The protect interface must be configured prior to configuring the **no-revert** statement.

---

Typically, when the primary interface goes down, the pseudowire starts using the protect interface. By default, when the primary interface comes back online, the interface is switched-over back from the protect interface to the primary interface. To prevent the switchover back to the primary interface, unless the primary interface goes down, include the **no-revert** statement. This prevents loss of traffic during the switchover.

---

**NOTE:** If the protect interface fails, the interface is switched-over back to the primary interface, irrespective of whether or not the **no-revert** statement is included in the configuration.

---

This statement can be configured both for the starting interface and the ending interface.

---

| <b>Release Information</b> | Statement introduced in Junos OS Release 11.3.                                                                                                                                                                              |
| <b>Description</b>         | (Optional) Prevent the protect interface from reverting to the primary interface.                                                                                                                                           |

**NOTE:** The protect interface must be configured prior to configuring the **no-revert** statement.

Typically, when the primary interface goes down, the pseudowire starts using the protect interface. By default, when the primary interface comes back online, the interface is switched-over back from the protect interface to the primary interface. To prevent the switchover back to the primary interface, unless the protect interface goes down, include the **no-revert** statement. This prevents loss of traffic during the switchover.

**NOTE:** If the protect interface fails, the interface is switched-over back to the primary interface, irrespective of whether or not the **no-revert** statement is included in the configuration.

Configuring the <b>no-tunnel-services</b> statement creates a label-switched interface (LSI) to provide VPLS functionality. An LSI MPLS label is used as the inner label for VPLS. This label maps to a VPLS routing instance. On the PE router, the LSI label is stripped and then mapped to a logical LSI interface. The Layer 2 Ethernet frame is then forwarded using the LSI interface to the correct VPLS routing instance. |
| <hr/>                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|  <b>NOTE:</b> In VPLS documentation, the word <i>Router</i> in terms such as <i>PR Router</i> is used to refer to any device that provides routing functions.                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b>              | Allows you to configure bidirectional forwarding detection (BFD) and a control channel for a pseudowire, in addition to the corresponding operations and management functions to be used over that control channel. BFD provides a low resource fault detection mechanism for the continuous monitoring of the pseudowire data path and for detecting data plane failures. The <b>control-channel</b> statement is not applicable to Layer 2 circuit pseudowires.                                                                                                                                                                      |
| <b>Options</b>                  | <p><b>bfd-liveness-detection</b>—The <b>bfd-liveness-detection</b> statement and substatements are described in the <i>Junos OS Routing Protocols Library</i>.</p> <p><b>ping-multiplier <i>ping-count</i></b>—Specify the number of LSP ping packets to delay the virtual circuit connectivity verification (VCCV) Bidirectional Forwarding Detection (BFD) session from going down. The VCCV BFD session is signaled down only after the specified number of LSP ping packets are lost. This feature is supported for Layer 2 Circuit, Layer 2 VPN, and VPLS technologies.</p> <p>The other statements are explained separately.</p> |
| <b>Required Privilege Level</b> | routing—To view this statement in the configuration.<br>routing-control—To add this statement to the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Release Information**

Statement introduced in Junos OS Release 8.4.

Support for the **switch-options** statement added in Junos OS Release 9.2.

Support for top-level configuration for the **virtual-switch** type of routing instance added in Junos OS Release 9.2. In Junos OS Release 9.1 and earlier, the routing instances hierarchy

supported this statement only for a VPLS instance or a bridge domain configured within a virtual switch.

Support for logical systems added in Junos OS Release 9.6.

[edit switch-options interface *interface-name* interface-mac-limit *limit*], [edit switch-options interface-mac-limit *limit*], [edit switch-options mac-table-size *limit*], [edit vlans *vlan-name* switch-options interface *interface-name* interface-mac-limit *limit*], [edit vlans *vlan-name* switch-options interface-mac-limit *limit*], and [edit vlans *vlan-name* switch-options mac-table-size *limit*] hierarchy levels introduced in Junos OS Release 12.3R2 for EX Series switches.

Support for EVPNs introduced in Junos OS Release 13.2 on MX Series 3D Universal Edge Routers.

Support at the [edit switch-options interface *interface-name* interface-mac-limit *limit*] hierarchy level and hierarchy levels under [edit vlans *vlan-name*] introduced in Junos OS Release 13.2X50-D10 for EX Series switches and Junos OS Release 13.2 for the QFX Series.

**Description** Specify the action taken when packets with new source MAC addresses are received after the MAC address limit is reached. If this statement is not configured, packets with new source MAC addresses are forwarded by default.

**Default**

**NOTE:** On a QFX Series Virtual Chassis, if you include the shutdown option at the [edit vlans *vlan-name* switch-options interface *interface-name* interface-mac-limit packet-action] hierarchy level and issue the commit operation, the system generates a commit error. The system does not generate an error if you include the shutdown option at the [edit switch-options interface *interface-name* interface-mac-limit packet-action] hierarchy level.

Disabled. The default is for packets for new source MAC addresses to be forwarded after the MAC address limit is reached.

**Options**

**drop**—Drop packets with new source MAC addresses, and do not learn the new source MAC addresses.

**drop-and-log**—(EX Series switches and QFX Series only) Drop packets with new source MAC addresses, and generate an alarm, an SNMP trap, or a system log entry.

**log**—(EX Series switches and QFX Series only) Hold packets with new source MAC addresses, and generate an alarm, an SNMP trap, or a system log entry.

**none**—(EX Series switches and QFX Series only) Forward packets with new source MAC addresses, and learn the new source MAC address.

**shutdown**—(EX Series switches and QFX Series only) Disable the specified interface, and generate an alarm, an SNMP trap, or a system log entry.

**Required Privilege Level**

routing—To view this statement in the configuration.

routing-control—To add this statement to the configuration.

## peer-active (VPLS Multihoming for FEC 129)

**Syntax** `peer-active;`

**Hierarchy Level** [edit logical-systems *logical-system-name* routing-instances *instance-name* protocols vpls multi-homing],  
 [edit logical-systems *logical-system-name* routing-instances *instance-name* protocols vpls multi-homing site *site-name*],  
 [edit routing-instances *instance-name* protocols vpls multi-homing],  
 [edit routing-instances *instance-name* protocols vpls multi-homing site *site-name*]

**Release Information** Statement introduced in Junos OS Release 12.3.

**Description** Keep customer edge (CE) interfaces in the up state when all BGP peers go down.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

Consider a scenario in which two provider edge (PE) routers are sharing two multihomed sites under one routing instance, with two CE devices, CE1 and CE2.

If the BGP peering session drops between Router PE1 and Router PE2, each one would consider itself to be the designated forwarder (DF) for Device CE1 and Device CE2. This creates a loop through the two CE devices, in which traffic loops from one CE device to the other then back to the first.

Junos OS overcomes this scenario by dropping all multihomed CE interface traffic on all multihoming PE routers when the BGP session drops between the PE routers. This functionality is enabled by default for all sites in a routing instance.

The **peer-active** statement disables the default functionality, so that PE routers keep their multihomed CE interfaces in the up state, even though the BGP peering session is down.

If you configure this statement in the **multi-homing** hierarchy, the default functionality is disabled for all sites. If you configure this statement for a site, the default functionality is disabled only for that particular site.

**Default** If you omit this statement, Junos OS drops all multihomed CE interface traffic on all multihoming PE routers when the BGP session drops between the PE routers.

**Required Privilege** routing—To view this statement in the configuration.  
**Level** routing-control—To add this statement to the configuration.

---

## peer-as (VPLS)

---

**Syntax**

```
peer-as {
 all;
}
```

**Hierarchy Level** [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*],  
[edit routing-instances *routing-instance-name* protocols vpls mesh-group *mesh-group-name*]

**Release Information** Statement introduced in Junos OS Release 9.3.

**Description** Enable the autonomous system border router (ASBR) to establish a single pseudowire to each of the other ASBRs interconnected using inter-AS VPLS with MAC processing at the ASBR.

**NOTE:** In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

---

**Options** **all**—This option is required. All peer routers, the ASBRs, are placed within the same VPLS mesh group.

**Required Privilege** routing—To view this statement in the configuration.  
**Level** routing-control—To add this statement to the configuration.

| <b>Release Information</b>      | Statement introduced in Junos OS Release 12.3.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b>              | <p>Specify a preference for the interface to become the designated forwarder (DF) for a multihomed VPLS site. This <b>preference</b> statement can be useful when you want the interface preference for a site to change dynamically so that the DF election can be influenced depending on the interface state. Among the list of interface preferences, Junos OS advertises the best preference as the VPLS site's preference value. For example, if the site has three interfaces configured with preference values 12, 10, and 9, respectively, 12 is advertised as the site preference. If that interface goes down, 10 is advertised as the site preference.</p> <p>If you configure interface-level preference, you cannot configure site-level preference.</p> |
| <b>Options</b>                  | <p><i>preference-value</i>—Preference value for the interface.</p> <p><b>Range:</b> 1 through 65535</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
