YEAR 2000 NOTICE

Juniper Networks hardware and software products are Year 2000 compliant. Junos OS has no known time-related limitations through the year 2038. However, the NTP application is known to have some difficulty in the year 2036.

END USER LICENSE AGREEMENT

The Juniper Networks product that is the subject of this technical documentation consists of (or is intended for use with) Juniper Networks software. Use of such software is subject to the terms and conditions of the End User License Agreement ("EULA") posted at <http://www.juniper.net/support/eula.html>. By downloading, installing or using such software, you agree to the terms and conditions of that EULA.

Table of Contents

	About the Documentation	xxxvii
	Documentation and Release Notes	xxxvii
	Supported Platforms	xxxvii
	Using the Examples in This Manual	xxxvii
	Merging a Full Example	xxxviii
	Merging a Snippet	xxxviii
	Documentation Conventions	xxxix
	Documentation Feedback	xli
	Requesting Technical Support	xli
	Self-Help Online Tools and Resources	xli
	Opening a Case with JTAC	xlii
Part 1	Common Configuration for All VPNs	
Chapter 1	VPNs Overview	3
	VPLS	3
	Types of VPNs	4
	Layer 2 VPNs	4
	Layer 3 VPNs	5
	VPLS	5
	Virtual-Router Routing Instances	6
	VPNs and Logical Systems	7
	Layer 2 VPNs	7
	Routers in a VPN	7
Chapter 2	Assigning Routing Instances to VPNs	9
	Configuring Routing Instances on PE Routers in VPNs	9
	Configuring the Routing Instance Name for a VPN	10
	Configuring the Description	10
	Configuring the Instance Type	10
	Configuring Interfaces for VPN Routing	11
	General Configuration for VPN Routing	11
	Configuring Interfaces for Layer 3 VPNs	12
	Configuring Interfaces for Carrier-of-Carriers VPNs	12
	Configuring Unicast RPF on VPN Interfaces	13
	Configuring the Route Distinguisher	13
	Configuring Automatic Route Distinguishers	14
	Configuring Virtual-Router Routing Instances in VPNs	14
	Configuring a Routing Protocol Between the Service Provider Routers	15
	Configuring Logical Interfaces Between Participating Routers	15

	Configuring Path MTU Checks for VPN Routing Instances	16
	Enabling Path MTU Checks for a VPN Routing Instance	17
	Assigning an IP Address to the VPN Routing Instance	17
Chapter 3	Distributing Routes in VPNs	19
	Enabling Routing Information Exchange for VPNs	19
	Configuring IBGP Sessions Between PE Routers in VPNs	19
	Configuring Aggregate Labels for VPNs	21
	Configuring a Signaling Protocol and LSPs for VPNs	22
	Using LDP for VPN Signaling	22
	Using RSVP for VPN Signaling	24
	Configuring Policies for the VRF Table on PE Routers in VPNs	25
	Configuring the Route Target	26
	Configuring the Route Origin	26
	Configuring an Import Policy for the PE Router's VRF Table	27
	Configuring an Export Policy for the PE Router's VRF Table	29
	Applying Both the VRF Export and the BGP Export Policies	30
	Configuring a VRF Target	31
	Configuring the Route Origin for VPNs	32
	Configuring the Site of Origin Community on CE Router A	33
	Configuring the Community on CE Router A	33
	Applying the Policy Statement on CE Router A	33
	Configuring the Policy on PE Router D	34
	Configuring the Community on PE Router D	34
	Applying the Policy on PE Router D	35
Chapter 4	Distributing VPN Routes with Target Filtering	37
	Configuring BGP Route Target Filtering for VPNs	37
	BGP Route Target Filtering Overview	37
	Configuring BGP Route Target Filtering for VPNs	38
	Example: BGP Route Target Filtering for VPNs	39
	Example: Configuring BGP Route Target Filtering for VPNs	41
	Configure BGP Route Target Filtering on Router PE1	42
	Configure BGP Route Target Filtering on Router PE2	43
	Configure BGP Route Target Filtering on the Route Reflector	46
	Configure BGP Route Target Filtering on Router PE3	47
	Configuring Static Route Target Filtering for VPNs	50
	Understanding Proxy BGP Route Target Filtering for VPNs	50
	Example: Configuring Proxy BGP Route Target Filtering for VPNs	51
	Example: Configuring an Export Policy for BGP Route Target Filtering for VPNs	67
	Reducing Network Resource Use with Static Route Target Filtering for VPNs	84
Chapter 5	Configuring Forwarding Options for VPNs	85
	Chained Composite Next Hops for Transit Devices for VPNs	85
	Example: Configuring Chained Composite Next Hops for Direct PE-PE Connections in VPNs	87

Chapter 6	Configuring Graceful Restart for VPNs	101
	VPN Graceful Restart	101
	Configuring Graceful Restart for VPNs	102
	Enabling Unicast Reverse-Path Forwarding Check for VPNs	104
	Example: Configuring Unicast Reverse-Path-Forwarding Check	105
	Understanding Unicast Reverse Path Forwarding	105
	Example: Configuring Unicast Reverse-Path-Forwarding Check	105
Chapter 7	Configuring Class of Service for VPNs	115
	VPNs and Class of Service	115
	Rewriting Class of Service Markers and VPNs	115
Chapter 8	Pinging VPNs	117
	Pinging VPNs, VPLS, and Layer 2 Circuits	117
	Setting the Forwarding Class of the Ping Packets	118
	Pinging a VPLS Routing Instance	118
	Pinging a Layer 2 VPN	119
	Pinging a Layer 3 VPN	119
	Pinging a Layer 2 Circuit	119
Part 2	Common Configuration for Layer 2 VPNs and VPLS	
Chapter 9	Overview	123
	Understanding Layer 2 VPNs	123
	Layer 2 VPN Applications	124
	Supported Layer 2 VPN Standards	125
Chapter 10	Layer 2 VPNs Configuration Overview	127
	Introduction to Configuring Layer 2 VPNs	127
	Configuring the Local Site on PE Routers in Layer 2 VPNs	128
	Configuring a Layer 2 VPN Routing Instance	129
	Configuring the Site	130
	Configuring the Remote Site ID	130
	Configuring the Encapsulation Type	132
	Configuring a Site Preference and Layer 2 VPN Multihoming	133
	Tracing Layer 2 VPN Traffic and Operations	133
	Disabling Normal TTL Decrementing for VPNs	134
	Layer 2 VPN Configuration Example	134
	Simple Full-Mesh Layer 2 VPN Overview	135
	Enabling an IGP on the PE Routers	135
	Configuring MPLS LSP Tunnels Between the PE Routers	135
	Configuring IBGP on the PE Routers	137
	Configuring Routing Instances for Layer 2 VPNs on the PE Routers	138
	Configuring CCC Encapsulation on the Interfaces	140
	Configuring VPN Policy on the PE Routers	141
	Layer 2 VPN Configuration Summarized by Router	144
	Summary for Router A (PE Router for Sunnyvale)	144
	Summary for Router B (PE Router for Austin)	146

	Summary for Router C (PE Router for Portland)	148
	Example: Configuring MPLS-Based Layer 2 VPNs	151
	Transmitting Nonstandard BPDUs in Layer 2 VPNs and VPLS	166
Chapter 11	Configuring Layer 2 Interfaces	167
	Configuring CCC Encapsulation for Layer 2 VPNs	167
	Configuring TCC Encapsulation for Layer 2 VPNs and Layer 2 Circuits	168
	Configuring the MTU for Layer 2 Interfaces	170
	Disabling the Control Word for Layer 2 VPNs	171
Chapter 12	Configuring Path Selection for Layer 2 VPNs and VPLS	173
	Understanding BGP Path Selection	173
	Routing Table Path Selection	175
	Effects of Advertising Multiple Paths to a Destination	177
	Enabling BGP Path Selection for Layer 2 VPNs and VPLS	178
	VPLS Path Selection Process for PE Routers	180
Chapter 13	Creating Backup Connections with Redundant Pseudowires	183
	Redundant Pseudowires for Layer 2 Circuits and VPLS	183
	Types of Redundant Pseudowire Configurations	184
	Pseudowire Failure Detection	185
	Configuring Redundant Pseudowires for Layer 2 Circuits and VPLS	185
	Configuring Pseudowire Redundancy on the PE Router	186
	Configuring the Switchover Delay for the Pseudowires	186
	Configuring a Revert Time for the Redundant Pseudowire	187
Chapter 14	Configuring Class of Service for Layer 2 VPNs	189
	Configuring Traffic Policing in Layer 2 VPNs	189
Chapter 15	Monitoring Layer 2 VPNs Using BFD	191
	Configuring BFD for Layer 2 VPN and VPLS	192
	BFD Support for VCCV for Layer 2 VPNs, Layer 2 Circuits, and VPLS	194
	Configuring BFD for VCCV for Layer 2 VPNs, Layer 2 Circuits, and VPLS	195
Part 3	Configuring Group VPNs	
Chapter 16	Configuring Group VPN	199
	Group VPN Overview	199
	Group VPN Technology Overview	199
	Understanding Group VPN	199
	Group VPN and Standard IPsec VPN	200
	Understanding the GDOI Protocol	202
	GDOI Protocol and Group VPN	203
	Group VPN Traffic	204
	Group Security Association	205
	Group Controller/Key Server	205
	Group Member	205
	Group VPN Implementation Overview	206
	Enabling Group VPN	206
	Registering a Group Member	207
	Rekeying a Group Member	208

	Authenticating a Group Member	208
	Fragmenting Group VPN Traffic	209
	Encrypting Group VPN Traffic	209
	Decrypting Group VPN Traffic	210
	Configuring a Routing Instance for Group VPN	210
	Establishing Multiple Groups, Policies, and SAs	210
	Connecting with Multiple Cooperative GC/KS	210
	Changing a Group VPN Configuration	211
	Bypassing a Group VPN Configuration	211
	Supported GDOI IPsec Parameters	211
	Supported GDOI IKEv1 Parameters	212
	Applying Dynamic Policies	213
	Supporting TOS and DSCP	214
	Interoperability of Group Members	214
	Group VPN Limitations	214
	Configuring Group VPNs on Routing Devices	216
	Example: Configuring Group VPNs on Routing Devices	218
Chapter 17	Configuring Group VPNv2	235
	Group VPNv2 Overview	235
	Group VPNv2 Technology Overview	235
	Understanding Group VPNv2	236
	Group VPNv2 and Standard IPsec VPN	236
	Understanding the GDOI Protocol	238
	GDOI Protocol and Group VPNv2	240
	Group VPNv2 Traffic	241
	Group Security Association	241
	Group Controller/Key Server	241
	Group Member	242
	Anti-Replay Protection for Group VPNv2 Traffic	242
	Partial Fail-Open on MX Series Member Routers	242
	Group VPNv2 Implementation Overview	243
	Enabling Group VPNv2	243
	Registering a Group Member	244
	Rekeying a Group Member (groupkey-push Method)	245
	Rekeying a Group Member (groupkey-pull Method)	246
	Authenticating a Group Member	247
	Fragmenting Group VPNv2 Traffic	247
	Encrypting Group VPNv2 Traffic	248
	Decrypting Group VPNv2 Traffic	248
	Configuring a Routing Instance for Group VPNv2	249
	Establishing Multiple Groups, Policies, and SAs	249
	Connecting with Multiple Cooperative GC/KSs	249
	Implementing IP Delivery Delay Detection Protocol (Time-Based Anti-Replay Protection)	249
	Changing Group VPNv2 Configuration	250
	Bypassing Group VPNv2 Configuration	250
	Implementing Partial Fail-open on MX Series Member Routers	250
	Supported GDOI IPsec Parameters	251

	Supported GDOI IKEv1 Parameters	252
	Applying Dynamic Policies	253
	Supporting TOS and DSCP	253
	Interoperability of Group Members	253
	Group VPNv2 Limitations	254
	Configuring Group VPNs in Group VPNv2 on Routing Devices	255
	Use Case for Configuring Group VPNv2	258
	Example: Configuring Group VPNs in Group VPNv2 on Routing Devices	259
Part 4	Configuring Public Key Infrastructure	
Chapter 18	Configuring Digital Certificate Validation	279
	Understanding Digital Certificate Validation	279
	Policy Validation	279
	Policy OIDs Configured on MX Series Devices	280
	No Policy OIDs Configured on MX Series Devices	280
	Path Length Validation	281
	Key Usage	282
	EE Certificates	282
	CA Certificates	282
	Issuer and Subject Distinguished Name Validation	283
	Example: Improving Digital Certificate Validation by Configuring Policy OIDs on an MX Series Device	284
Chapter 19	Configuring a Device for Certificate Chains	289
	Understanding Certificate Chains	289
	Multilevel Hierarchy for Certificate Authentication	289
	Dynamic CRL Download and Checking	291
	Example: Configuring a Device for Peer Certificate Chain Validation	292
Chapter 20	Managing Certificate Revocation	301
	Understanding Online Certificate Status Protocol	301
	Comparison of Online Certificate Status Protocol and Certificate Revocation List	302
	Example: Improving Security by Configuring OCSP for Certificate Revocation Status	303
Part 5	Configuring Ethernet VPNs (EVPNs)	
Chapter 21	Overview	321
	EVPN Overview	321
	Supported EVPN Standards	323
	EVPN-ETREE Overview	323
Chapter 22	Configuring Routing Instances for EVPN	327
	Configuring EVPN Routing Instances	327
	EVPN Type-5 Route with VXLAN encapsulation for EVPN-VXLAN	330
	EVPN Type-5 Route with MPLS encapsulation for EVPN-MPLS	331
	Tracing EVPN Traffic and Operations	331

Chapter 23	Configuring EVPN Multihoming	335
	EVPN Multihoming Overview	335
	Introduction to EVPN Multihoming	335
	Understanding EVPN Multihoming Concepts	338
	EVPN Multihoming Mode of Operation	339
	EVPN Multihoming Implementation	341
	New BGP NLRIs	341
	New Extended Communities	344
	New EVPN Route Types	346
	Update to the MAC Forwarding Table	347
	Traffic Flow	347
	Aliasing	349
	EVPN Active-Active Multihoming and Multichassis Link Aggregation	351
	EVPN Active-Active Multihoming and IRB	351
	Sample Configuration	351
	Designated Forwarder Election	352
	DF Election Roles	353
	DF Election Procedure	353
	DF Election Trigger	354
	DF Election for Virtual Switch	354
	Handling Failover	355
	Convergence in an EVPN Network	355
	Configuring EVPN Active-Standby Multihoming	358
	Example: Configuring EVPN Active-Standby Multihoming	361
	Example: Configuring Basic EVPN Active-Active Multihoming	394
	Example: Configuring EVPN Active-Active Multihoming	403
	Example: Configuring LACP for EVPN Active-Active Multihoming	451
Chapter 24	Configuring Integrated Bridging and Routing Using EVPNs	469
	EVPN with IRB Solution Overview	470
	Need for an EVPN IRB Solution	470
	Implementing the EVPN IRB Solution	471
	Benefits of Implementing the EVPN IRB Solution	473
	Gateway MAC and IP Synchronization	473
	Layer 3 VPN Interworking	474
	Configuring EVPN with IRB Solution	475
	Example: Configuring EVPN with IRB Solution	477
	EVPN with IRB Solution Overview	478
	Need for an EVPN IRB Solution	478
	Implementing the EVPN IRB Solution	479
	Benefits of Implementing the EVPN IRB Solution	481
	Example: Configuring EVPN with IRB Solution	483
	NSR and Unified ISSU Support for EVPN Overview	497
Chapter 25	Configuring EVPN Bundle Services and EVPN Bundle-Aware Services	501
	Overview of VLAN Bundle Service and VLAN-Aware Bundle Service for EVPN	501
	VLAN Bundle Service for EVPN	502
	Configuring EVPN VLAN Bundle Services	503

	Virtual Switch Support for EVPN Overview	506
	Configuring EVPN with Support for Virtual Switch	507
	Example: Configuring EVPN with Support for Virtual Switch	510
	Example: Configuring EVPN with Support for Virtual Switch	510
Chapter 26	Configuring EVPN with VXLAN Data Plane Encapsulation	521
	Understanding EVPN with VXLAN Data Plane Encapsulation	521
	Understanding EVPN	522
	Understanding VXLAN	524
	EVPN-VXLAN Integration Overview	525
	Understanding Contrail Virtual Networks Use with EVPN-VXLAN	526
	EVPN-VXLAN Packet Format	527
	Q & A	528
	EVPN-VXLAN Constraints on QFX Series Switches	529
	EVPN-over-VXLAN Supported Functionality	529
	VXLAN Encapsulation	529
	EVPN BGP Routes and Attributes	530
	EVPN Multihoming Procedure	530
	Local Bias and Split-Horizon Filtering Rule	531
	Aliasing	531
	Next-Hop Forwarding	531
	Control Plane MAC Learning Method	532
	Contrail vRouters and the L3-VRF Table	532
	Subnet Routes for an IRB Interface	532
	Virtual Machine Host Routes	533
	Bare-Metal Server Host Routes	533
	Designated Forwarder Election	533
	EVPN Over VXLAN Encapsulation Configuration Overview for QFX5100 Series	534
	Understanding MX Series Router and Gateway Functionality Between Virtual Networks Traffic	536
	MX Series Router as the Default Gateway	536
	MX Series Router as the Default Gateway for Known Intersubnet Traffic Between Virtual Networks	538
	MX Series Router as the Default Gateway for Unknown Intersubnet Traffic Between Virtual Networks	539
	MX Series Router as the Redundant Default Gateway	539
	MX Series Gateway and Dynamic ARP Processing	539
	Example: Configuring an EVPN Control Plane and VXLAN Data Plane	541
	PIM NSR and Unified ISSU Support for VXLAN Overview	608
Chapter 27	Configuring EVPN with VXLAN Data Center Interconnect	611
	VXLAN Data Center Interconnect Using EVPN Overview	611
	Technology Overview of VXLAN-EVPN Integration for DCI	611
	Understanding VXLAN	611
	Understanding EVPN	613
	VXLAN-EVPN Integration Overview	614
	VXLAN-EVPN Packet Format	616

	VXLAN-EVPN Packet Walkthrough	616
	Implementation Overview of VXLAN-EVPN Integration for DCI	622
	VNI Base Service Use Case	622
	VNI Aware Service Use Case	622
	VXLAN-VLAN Interworking Use Case	623
	Inter VXLAN Routing Use Case	624
	Redundancy Use Case	625
	Supported and Unsupported Features for VXLAN DCI Using EVPN	625
	Example: Configuring VXLAN Data Center Interconnect Using EVPN	626
Chapter 28	Interconnecting EVPN-based VXLAN Data Center Networks Through a WAN Running EVPN-based MPLS	641
	EVPN-VXLAN Data Center Interconnect Through EVPN-MPLS WAN	
	Overview	641
	Interconnection of Data Center Networks Through WAN Overview	641
	Multi-homing on Data Center Gateways	644
	EVPN Designated Forwarder (DF) Election	644
	Split Horizon	644
	Aliasing	644
	VLAN-Aware Bundle Service	645
	Data Center Network Design and Considerations	647
	Example: Interconnecting EVPN-VXLAN Data Center Networks Through a WAN	
	Running EVPN-based MPLS	649
Chapter 29	Configuring MAC Pinning for EVPNs	787
	EVPN MAC Pinning Overview	788
	Configuring EVPN MAC Pinning	790
Part 6	Configuring Provider Backbone Bridging (PBB)-EVPN	
Chapter 30	Configuring PBB-EVPN Integration	793
	Provider Backbone Bridging (PBB) and EVPN Integration Overview	793
	Technology Overview of PBB-EVPN Integration	793
	Understanding Provider Backbone Bridging (PBB)	794
	Understanding EVPN	796
	PBB-EVPN Integration	798
	PBB-EVPN Packet Walkthrough	804
	Implementation Overview of PBB-EVPN Integration	812
	PBB-EVPN Failure Scenarios	812
	PBB-EVPN I-SID Use Case Scenarios	815
	VPLS Integration with PBB-EVPN Use Case Scenario	816
	PBB-EVPN Redundancy Use Case Scenarios	817
	Configuration Overview of PBB-EVPN Integration	818
	Supported and Unsupported Features on PBB-EVPN	821
	Example: Configuring PBB with Single-Homed EVPN	822
	Example: Configuring PBB with Multihomed EVPN	844
Chapter 31	Configuring MAC Pinning for PBB-EVPNs	877
	PBB-EVPN MAC Pinning Overview	877
	Configuring PBB-EVPN MAC Pinning	879

Part 7	Configuring Layer 2 Circuits	
Chapter 32	Overview	885
	Layer 2 Circuit Overview	885
Chapter 33	Layer 2 Circuits Configuration Overview	887
	Configuring Static Layer 2 Circuits	887
	Configuring Local Interface Switching in Layer 2 Circuits	888
	Configuring the Interfaces for the Local Interface Switch	889
	Enabling Local Interface Switching When the MTU Does Not Match	890
	Configuring Interfaces for Layer 2 Circuits	890
	Configuring the Address for the Neighbor of the Layer 2 Circuit	890
	Configuring the Neighbor Interface for the Layer 2 Circuit	891
	Configuring a Community for the Layer 2 Circuit	892
	Configuring the Control Word for Layer 2 Circuits	892
	Configuring the Encapsulation Type for the Layer 2 Circuit Neighbor Interface	893
	Enabling the Layer 2 Circuit When the Encapsulation Does Not Match	894
	Configuring the Protect Interface	894
	Configuring the Protect Interface From Switching Over to the Primary Interface	894
	Configuring the Pseudowire Status TLV	895
	Configuring Layer 2 Circuits over Both RSVP and LDP LSPs	895
	Configuring the Virtual Circuit ID	896
	Configuring the Interface Encapsulation Type for Layer 2 Circuits	897
	Configuring ATM2 IQ Interfaces for Layer 2 Circuits	897
	Configuring Policies for Layer 2 Circuits	898
	Configuring the Layer 2 Circuit Community	898
	Configuring the Policy Statement for the Layer 2 Circuit Community	899
	Example: Configuring a Policy for a Layer 2 Circuit Community	900
	Verifying the Layer 2 Circuit Policy Configuration	900
	Configuring LDP for Layer 2 Circuits	901
Chapter 34	Configuring Class of Service with Layer 2 Circuits	903
	Configuring ATM Trunking on Layer 2 Circuits	903
	Layer 2 Circuit Bandwidth Accounting and Call Admission Control	905
	Bandwidth Accounting and Call Admission Control Overview	905
	Selecting an LSP Based on the Bandwidth Constraint	905
	LSP Path Protection and CAC	906
	Secondary Paths and CAC	906
	Fast Reroute and CAC	907
	Link and Node Protection and CAC	907
	Layer 2 Circuits Trunk Mode	907
	Configuring Bandwidth Allocation and Call Admission Control in Layer 2 Circuits	908

Chapter 35	Configuring Pseudowire Redundancy for Layer 2 Circuits	909
	Understanding Pseudowire Redundancy Mobile Backhaul Scenarios	909
	Sample Topology	910
	Benefits of Pseudowire Redundancy Mobile Backhaul	910
	Layer 2 Virtual Circuit Status TLV Extension	910
	How It Works	911
	Example: Configuring Pseudowire Redundancy in a Mobile Backhaul	
	Scenario	913
	Extension of Pseudowire Redundancy Condition Logic to Pseudowire Service	
	Logical Interface Overview	936
	Sample Topology	936
	Functionality	937
	Policy Condition for Pseudowire Service Logical Interfaces	937
Chapter 36	Configuring Load Balancing for Layer 2 Circuits	941
	Reducing APS Switchover Time in Layer 2 Circuits	941
	Configuring Per-Packet Load Balancing	942
	Configuring Fast APS Switchover	942
Chapter 37	Configuring Protection Features for Layer 2 Circuits	945
	Egress Protection LSPs for Layer 2 Circuits	945
	Configuring Egress Protection Service Mirroring for BGP Signaled Layer 2	
	Services	947
	Example: Configuring an Egress Protection LSP for a Layer 2 Circuit	951
	Example: Configuring Layer 2 Circuit Protect Interfaces	962
	Configuring Router PE1	963
	Configuring Router PE2	964
	Configuring Router CE1	966
	Configuring Router CE2	966
	Example: Configuring Layer 2 Circuit Switching Protection	967
Chapter 38	Monitoring Layer 2 Circuits with BFD	983
	Configuring BFD for VCCV for Layer 2 Circuits	983
	Example: Configuring BFD for VCCV for Layer 2 Circuits	985
Chapter 39	Troubleshooting Layer 2 Circuits	995
	Tracing Layer 2 Circuit Operations	995
Part 8	Configuring VPWS VPNs	
Chapter 40	Overview	999
	Understanding VPWS	999
	Supported and Unsupported Features	1001
	Supported VPWS Standards	1002
	FAT Flow Labels Overview	1003
	Understanding Multisegment Pseudowire for FEC 129	1004
	Understanding Multisegment Pseudowire	1004
	Using FEC 129 for Multisegment Pseudowire	1006
	Establishing a Multisegment Pseudowire Overview	1006

	Pseudowire Status Support for Multisegment Pseudowire	1007
	Pseudowire Status Behavior on T-PE	1007
	Pseudowire Status Behavior on S-PE	1007
	Pseudowire TLV Support for MS-PW	1008
	Supported and Unsupported Features	1008
Chapter 41	Configuring VPWS VPNs	1011
	Understanding FEC 129 BGP Autodiscovery for VPWS	1011
	Supported Standards in FEC 129 BGP Autodiscovery for VPWS	1011
	Routes and Routing Table Interaction in FEC 129 BGP Autodiscovery for VPWS	1011
	Layer 2 VPN Behavior in FEC 129 BGP Autodiscovery for VPWS	1012
	BGP Autodiscovery Behavior in FEC 129 BGP Autodiscovery for VPWS	1013
	LDP Signaling Behavior in VPWS in FEC 129 BGP Autodiscovery for VPWS	1013
	Example: Configuring FEC 129 BGP Autodiscovery for VPWS	1013
	Example: Configuring MPLS Egress Protection Service Mirroring for BGP Signaled Layer 2 Services	1025
	Understanding Multisegment Pseudowire for FEC 129	1043
	Understanding Multisegment Pseudowire	1043
	Using FEC 129 for Multisegment Pseudowire	1044
	Establishing a Multisegment Pseudowire Overview	1045
	Pseudowire Status Support for Multisegment Pseudowire	1045
	Pseudowire Status Behavior on T-PE	1045
	Pseudowire Status Behavior on S-PE	1046
	Pseudowire TLV Support for MS-PW	1046
	Supported and Unsupported Features	1047
	Example: Configuring a Multisegment Pseudowire	1047
	Configuring the FAT Flow Label for FEC 128 VPWS Pseudowires for Load-Balancing MPLS Traffic	1091
	Configuring the FAT Flow Label for FEC 129 VPWS Pseudowires for Load-Balancing MPLS Traffic	1094
Chapter 42	Configuring VPWS Service with EVPN Mechanisms	1097
	Overview of VPWS with EVPN Signaling Mechanisms	1098
	Configuring VPWS with EVPN Signaling Mechanisms	1101
	Example: Configuring VPWS with EVPN Signaling Mechanisms	1103
Part 9	Configuring VPLS	
Chapter 43	Overview	1125
	Introduction to VPLS	1125
	Supported VPLS Standards	1126
	Supported Platforms and PICs	1126
Chapter 44	VPLS Configuration Overview	1129
	Introduction to Configuring VPLS	1129
	Configuring an Ethernet Switch as the CE Device for VPLS	1130

Chapter 45	Configuring Signaling Protocols for VPLS	1131
	VPLS Routing and Virtual Ports	1131
	BGP Signaling for VPLS PE Routers Overview	1133
	Control Word for BGP VPLS Overview	1134
	Configuring a Control Word for BGP VPLS	1135
	BGP Route Reflectors for VPLS	1136
	Interoperability Between BGP Signaling and LDP Signaling in VPLS	1138
	LDP-Signaled and BGP-Signaled PE Router Topology	1138
	Flooding Unknown Packets Across Mesh Groups	1140
	Unicast Packet Forwarding	1140
	Configuring Interoperability Between BGP Signaling and LDP Signaling in VPLS	1140
	LDP BGP Interworking Platform Support	1141
	Configuring FEC 128 VPLS Mesh Groups for LDP BGP Interworking	1141
	Configuring FEC 129 VPLS Mesh Groups for LDP BGP Interworking	1142
	Configuring Switching Between Pseudowires Using VPLS Mesh Groups	1142
	Configuring Integrated Routing and Bridging Support for LDP BGP Interworking with VPLS	1143
	Configuring Inter-AS VPLS with MAC Processing at the ASBR	1143
	Inter-AS VPLS with MAC Operations Configuration Summary	1144
	Configuring the ASBRs for Inter-AS VPLS	1144
	Example: VPLS Configuration (BGP Signaling)	1145
	Verifying Your Work	1152
	Example: VPLS Configuration (BGP and LDP Interworking)	1156
	Verifying Your Work	1166
Chapter 46	Assigning Routing Instances to VPLS	1173
	Configuring VPLS Routing Instances	1173
	Configuring BGP Signaling for VPLS	1175
	Configuring the VPLS Site Name and Site Identifier	1175
	Configuring Automatic Site Identifiers for VPLS	1176
	Configuring the Site Range	1177
	Configuring the VPLS Site Interfaces	1179
	Configuring the VPLS Site Preference	1179
	Configuring LDP Signaling for VPLS	1180
	Configuring LDP Signaling for the VPLS Routing Instance	1182
	Configuring LDP Signaling on the Router	1183
	Configuring VPLS Routing Instance and VPLS Interface Connectivity	1183
	Configuring the VPLS Encapsulation Type	1184
	Configuring the MPLS Routing Table to Leak Routes a Nondefault Routing Instance	1184
	Configuring the VPLS MAC Table Timeout Interval	1185
	Configuring the Size of the VPLS MAC Address Table	1185
	Limiting the Number of MAC Addresses Learned from an Interface	1186

	Removing Addresses from the MAC Address Database	1188
	Configuring a VPLS Routing Instance	1189
	Support of Inner VLAN List and Inner VLAN Range for Qualified BUM Pruning on a Dual-Tagged Interface for a VPLS Routing Instance Overview	1191
	Configuring Qualified BUM Pruning for a Dual-Tagged Interface with Inner VLAN list and InnerVLAN range for a VPLS Routing Instance	1194
	Configuring a Layer 2 Control Protocol Routing Instance	1195
	PE Router Mesh Groups for VPLS Routing Instances	1196
	Configuring VPLS Fast Reroute Priority	1197
	Specifying the VT Interfaces Used by VPLS Routing Instances	1198
	Understanding PIM Snooping for VPLS	1199
	Example: Configuring PIM Snooping for VPLS	1200
	VPLS Label Blocks Operation	1212
	Elements of Network Layer Reachability Information	1212
	Requirements for NLRI Elements	1213
	How Labels are Used in Label Blocks	1213
	Label Block Composition	1213
	Label Blocks in Junos OS	1214
	VPLS Label Block Structure	1214
	Configuring the Label Block Size for VPLS	1216
	Example: Building a VPLS From Router 1 to Router 3 to Validate Label Blocks . .	1217
Chapter 47	Associating Interfaces with VPLS	1223
	Configuring Interfaces for VPLS Routing	1223
	Configuring the VPLS Interface Name	1224
	Configuring VPLS Interface Encapsulation	1224
	Enabling VLAN Tagging	1227
	Configuring VLAN IDs for Logical Interfaces	1227
	Enabling VLANs for Hub and Spoke VPLS Networks	1228
	Configuring Aggregated Ethernet Interfaces for VPLS	1228
	VPLS and Aggregated Ethernet Interfaces	1230
	Enabling VLAN Tagging	1231
	Configuring VPLS Without a Tunnel Services PIC	1231
Chapter 48	Configuring Pseudowires	1233
	Configuring Static Pseudowires for VPLS	1233
	VPLS Path Selection Process for PE Routers	1235
	BGP and VPLS Path Selection for Multihomed PE Routers	1237
	Dynamic Profiles for VPLS Pseudowires	1239
	Use Cases for Dynamic Profiles for VPLS Pseudowires	1240
	Example: Configuring VPLS Pseudowires with Dynamic Profiles—Basic Solutions	1241
	VPLS Pseudowire Interfaces Without Dynamic Profiles	1241
	VPLS Pseudowire Interfaces and Dynamic Profiles	1242
	CE Routers Without Dynamic Profiles	1243

	CE Routers and Dynamic Profiles	1244
	Example: Configuring VPLS Pseudowires with Dynamic Profiles—Complex Solutions	1245
	Configuration of Routing Instance and Interfaces Without Dynamic Profiles	1245
	Configuration of Routing Instance and Interfaces Using Dynamic Profiles	1246
	Configuration of Tag Translation Using Dynamic Profiles	1248
	Configuring the FAT Flow Label for FEC 128 VPLS Pseudowires for Load-Balancing MPLS Traffic	1250
	Configuring the FAT Flow Label for FEC 129 VPLS Pseudowires for Load-Balancing MPLS Traffic	1252
	Example: Configuring H-VPLS BGP-Based and LDP-Based VPLS Interoperation	1253
	Example: Configuring BGP-Based H-VPLS Using Different Mesh Groups for Each Spoke Router	1275
	Example: Configuring LDP-Based H-VPLS Using a Single Mesh Group to Terminate the Layer 2 Circuits	1297
	Example: Configuring H-VPLS With VLANs	1303
	Example: Configuring H-VPLS Without VLANs	1316
Chapter 49	Configuring Multihoming	1329
	VPLS Multihoming Overview	1329
	Advantages of Using Autodiscovery for VPLS Multihoming	1332
	Example: Configuring FEC 129 BGP Autodiscovery for VPWS	1332
	Understanding VPWS	1332
	Supported and Unsupported Features	1335
	Understanding FEC 129 BGP Autodiscovery for VPWS	1335
	Supported Standards in FEC 129 BGP Autodiscovery for VPWS	1335
	Routes and Routing Table Interaction in FEC 129 BGP Autodiscovery for VPWS	1336
	Layer 2 VPN Behavior in FEC 129 BGP Autodiscovery for VPWS	1337
	BGP Autodiscovery Behavior in FEC 129 BGP Autodiscovery for VPWS	1337
	LDP Signaling Behavior in VPWS in FEC 129 BGP Autodiscovery for VPWS	1337
	Example: Configuring FEC 129 BGP Autodiscovery for VPWS	1337
	Example: Configuring BGP Autodiscovery for LDP VPLS	1350
	Example: Configuring BGP Autodiscovery for LDP VPLS with User-Defined Mesh Groups	1367
	VPLS Multihoming Reactions to Network Failures	1378
	Configuring VPLS Multihoming (FEC 128)	1379
	VPLS Multihomed Site Configuration	1380
	Specifying an Interface as the Active Interface	1381
	Configuring Multihoming on the PE Router	1381
	VPLS Single-Homed Site Configuration	1382

	Example: VPLS Multihoming, Improved Convergence Time	1382
	Example: Configuring VPLS Multihoming (FEC 129)	1394
	VPLS Multihoming Overview	1394
	Example: Configuring VPLS Multihoming (FEC 129)	1396
	Next-Generation VPLS for Multicast with Multihoming Overview	1408
	Operation of Next-Generation VPLS for Multicast with Multihoming Using BGP	1409
	Implementation of Redundancy Using VPLS Multihomed Links Between PE and CE Devices	1412
	Example: Next-Generation VPLS for Multicast with Multihoming	1414
Chapter 50	Configuring Point-to-Multipoint LSPs	1435
	Next-Generation VPLS Point-to-Multipoint Forwarding Overview	1435
	Next-Generation VPLS Point-to-Multipoint Forwarding Applications	1436
	Implementation	1439
	Example: NG-VPLS Using Point-to-Multipoint LSPs	1441
	Flooding Unknown Traffic Using Point-to-Multipoint LSPs in VPLS	1474
	Configuring Static Point-to-Multipoint Flooding LSPs	1475
	Configuring Dynamic Point-to-Multipoint Flooding LSPs	1476
	Configuring Dynamic Point-to-Multipoint Flooding LSPs with the Default Template	1476
	Configuring Dynamic Point-to-Multipoint Flooding LSPs with a Preconfigured Template	1477
	Example: Configuring Ingress Replication for IP Multicast Using MBGP MVPNs	1477
	Mapping VPLS Traffic to Specific LSPs	1492
Chapter 51	Configuring Inter-AS VPLS and IRB VPLS	1495
	Example: Configuring Inter-AS VPLS with MAC Processing at the ASBR	1495
	Configuring VPLS and Integrated Routing and Bridging	1521
	Configuring MAC Address Flooding and Learning for VPLS	1522
	Configuring MSTP for VPLS	1523
	Configuring Integrated Routing and Bridging in a VPLS Instance (MX Series Routers Only)	1523
Chapter 52	Configuring Load Balancing and Performance	1525
	Configuring VPLS Load Balancing	1526
	Configuring VPLS Load Balancing Based on IP and MPLS Information	1528
	Configuring VPLS Load Balancing on MX Series 3D Universal Edge Routers	1529
	MAC Moves Loop Prevention in VPLS Network Overview	1530
	Configuring VPLS Loop Prevention Due to MAC Moves	1532
	Example: Configuring Loop Prevention in VPLS Network Due to MAC Moves	1534
	MAC Moves Loop Prevention in VPLS Network Overview	1534
	Example: Configuring Loop Prevention in VPLS Network Due to MAC Moves	1535
	Understanding MAC Pinning	1549
	Configuring MAC Pinning on Access Interfaces for Bridge Domains	1551
	Configuring MAC Pinning on Trunk Interfaces for Bridge Domains	1552
	Configuring MAC Pinning on Access Interfaces for Bridge Domains in a Virtual Switch	1553

	Configuring MAC Pinning on Trunk Interfaces for Bridge Domains in a Virtual Switch	1555
	Configuring MAC Pinning for All Pseudowires of the VPLS Routing Instance (LDP and BGP)	1557
	Configuring MAC Pinning on VPLS CE Interface	1558
	Configuring MAC Pinning for All Pseudowires of the VPLS Site in a BGP-Based VPLS Routing Instance	1560
	Configuring MAC Pinning on All Pseudowires of a Specific Neighbor of LDP-Based VPLS Routing Instance	1561
	Configuring MAC Pinning on Access Interfaces for Logical Systems	1563
	Configuring MAC Pinning on Trunk Interfaces for Logical Systems	1564
	Configuring MAC Pinning on Access Interfaces in Virtual Switches for Logical Systems	1566
	Configuring MAC Pinning on Trunk Interfaces in Virtual Switches for Logical Systems	1568
	Configuring MAC Pinning for All Pseudowires of the VPLS Routing Instance (LDP and BGP) for Logical Systems	1570
	Configuring MAC Pinning on VPLS CE Interface for Logical Systems	1571
	Configuring MAC Pinning for All Pseudowires of the VPLS Site in a BGP-Based VPLS Routing Instance for Logical Systems	1573
	Configuring MAC Pinning on All Pseudowires of a Specific Neighbor of LDP-Based VPLS Routing Instance for Logical Systems	1574
	Example: Prevention of Loops in Bridge Domains by Enabling the MAC Pinning Feature on Access Interfaces	1576
	Example: Prevention of Loops in Bridge Domains by Enabling the MAC Pinning Feature on Trunk Interfaces	1580
	Configuring Improved VPLS MAC Address Learning on T4000 Routers with Type 5 FPCs	1587
Chapter 53	Configuring Class of Service and Firewall Filters in VPLS	1589
	Configuring EXP-Based Traffic Classification for VPLS	1589
	Configuring Firewall Filters and Policers for VPLS	1589
	Configuring a VPLS Filter	1590
	Configuring an Interface-Specific Counter for VPLS	1591
	Configuring an Action for the VPLS Filter	1591
	Configuring VPLS FTFs	1591
	Changing Precedence for Spanning-Tree BPDU Packets	1592
	Applying a VPLS Filter to an Interface	1592
	Applying a VPLS Filter to a VPLS Routing Instance	1592
	Configuring a Filter for Flooded Traffic	1593
	Configuring a VPLS Policer	1593
	Firewall Filter Match Conditions for VPLS Traffic	1594
Chapter 54	Monitoring and Tracing VPLS	1607
	Configuring Port Mirroring for VPLS Traffic	1607
	Configuring Y.1731 Functionality for VPLS to Support Delay and Delay Variation	1607
	Tracing VPLS Traffic and Operations	1608

Part 10	Connecting Layer 2 VPNs and Circuits to Other VPNs	
Chapter 55	Connecting Layer 2 VPNs to Other VPNs	1613
	Layer 2 VPN to Layer 2 VPN Connections	1613
	Using the Layer 2 Interworking Interface to Interconnect a Layer 2 VPN to a Layer 2 VPN	1613
	Example: Interconnecting a Layer 2 VPN with a Layer 2 VPN	1615
	Interconnecting Layer 2 VPNs with Layer 3 VPNs Overview	1632
	Interconnecting Layer 2 VPNs with Layer 3 VPNs Applications	1632
	Example: Interconnecting a Layer 2 VPN with a Layer 3 VPN	1633
Chapter 56	Connecting Layer 2 Circuits to Other VPNs	1657
	Using the Layer 2 Interworking Interface to Interconnect a Layer 2 Circuit to a Layer 2 VPN	1657
	Applications for Interconnecting a Layer 2 Circuit with a Layer 2 Circuit	1658
	Example: Interconnecting a Layer 2 Circuit with a Layer 2 VPN	1659
	Example: Interconnecting a Layer 2 Circuit with a Layer 2 Circuit	1668
	Applications for Interconnecting a Layer 2 Circuit with a Layer 3 VPN	1683
	Example: Interconnecting a Layer 2 Circuit with a Layer 3 VPN	1684

About the Documentation

- [Documentation and Release Notes on page xxxvii](#)
- [Supported Platforms on page xxxvii](#)
- [Using the Examples in This Manual on page xxxvii](#)
- [Documentation Conventions on page xxxix](#)
- [Documentation Feedback on page xli](#)
- [Requesting Technical Support on page xli](#)

Documentation and Release Notes

To obtain the most current version of all Juniper Networks® technical documentation, see the product documentation page on the Juniper Networks website at <http://www.juniper.net/techpubs/>.

If the information in the latest release notes differs from the information in the documentation, follow the product Release Notes.

Juniper Networks Books publishes books by Juniper Networks engineers and subject matter experts. These books go beyond the technical documentation to explore the nuances of network architecture, deployment, and administration. The current list can be viewed at <http://www.juniper.net/books>.

Supported Platforms

For the features described in this document, the following platforms are supported:

- [ACX Series](#)
- [M Series](#)
- [MX Series](#)
- [PTX Series](#)
- [T Series](#)

Using the Examples in This Manual

If you want to use the examples in this manual, you can use the **load merge** or the **load merge relative** command. These commands cause the software to merge the incoming

configuration into the current candidate configuration. The example does not become active until you commit the candidate configuration.

If the example configuration contains the top level of the hierarchy (or multiple hierarchies), the example is a *full example*. In this case, use the **load merge** command.

If the example configuration does not start at the top level of the hierarchy, the example is a *snippet*. In this case, use the **load merge relative** command. These procedures are described in the following sections.

Merging a Full Example

To merge a full example, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration example into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following configuration to a file and name the file **ex-script.conf**. Copy the **ex-script.conf** file to the **/var/tmp** directory on your routing platform.

```
system {
  scripts {
    commit {
      file ex-script.xsl;
    }
  }
}
interfaces {
  fxp0 {
    disable;
    unit 0 {
      family inet {
        address 10.0.0.1/24;
      }
    }
  }
}
```

2. Merge the contents of the file into your routing platform configuration by issuing the **load merge** configuration mode command:

```
[edit]
user@host# load merge /var/tmp/ex-script.conf
load complete
```

Merging a Snippet

To merge a snippet, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration snippet into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following snippet to a file and name the file **ex-script-snippet.conf**. Copy the **ex-script-snippet.conf** file to the **/var/tmp** directory on your routing platform.

```
commit {
  file ex-script-snippet.xml; }
```

2. Move to the hierarchy level that is relevant for this snippet by issuing the following configuration mode command:

```
[edit]
user@host# edit system scripts
[edit system scripts]
```

3. Merge the contents of the file into your routing platform configuration by issuing the **load merge relative** configuration mode command:

```
[edit system scripts]
user@host# load merge relative /var/tmp/ex-script-snippet.conf
load complete
```

For more information about the **load** command, see [CLI Explorer](#).

Documentation Conventions

Table 1 on page xxxix defines notice icons used in this guide.

Table 1: Notice Icons

Icon	Meaning	Description
	Informational note	Indicates important features or instructions.
	Caution	Indicates a situation that might result in loss of data or hardware damage.
	Warning	Alerts you to the risk of personal injury or death.
	Laser warning	Alerts you to the risk of personal injury from a laser.
	Tip	Indicates helpful information.
	Best practice	Alerts you to a recommended use or implementation.

Table 2 on page xl defines the text and syntax conventions used in this guide.

Table 2: Text and Syntax Conventions

Convention	Description	Examples
Bold text like this	Represents text that you type.	To enter configuration mode, type the configure command: user@host> configure
Fixed-width text like this	Represents output that appears on the terminal screen.	user@host> show chassis alarms No alarms currently active
<i>Italic text like this</i>	<ul style="list-style-type: none"> Introduces or emphasizes important new terms. Identifies guide names. Identifies RFC and Internet draft titles. 	<ul style="list-style-type: none"> A policy <i>term</i> is a named structure that defines match conditions and actions. <i>Junos OS CLI User Guide</i> RFC 1997, <i>BGP Communities Attribute</i>
<i>Italic text like this</i>	Represents variables (options for which you substitute a value) in commands or configuration statements.	Configure the machine's domain name: [edit] root@# set system domain-name <i>domain-name</i>
Text like this	Represents names of configuration statements, commands, files, and directories; configuration hierarchy levels; or labels on routing platform components.	<ul style="list-style-type: none"> To configure a stub area, include the stub statement at the [edit protocols ospf area area-id] hierarchy level. The console port is labeled CONSOLE.
< > (angle brackets)	Encloses optional keywords or variables.	stub <default-metric <i>metric</i> >;
(pipe symbol)	Indicates a choice between the mutually exclusive keywords or variables on either side of the symbol. The set of choices is often enclosed in parentheses for clarity.	broadcast multicast (<i>string1</i> <i>string2</i> <i>string3</i>)
# (pound sign)	Indicates a comment specified on the same line as the configuration statement to which it applies.	rsvp { # Required for dynamic MPLS only
[] (square brackets)	Encloses a variable for which you can substitute one or more values.	community name members [<i>community-ids</i>]
Indentation and braces ({ })	Identifies a level in the configuration hierarchy.	[edit] routing-options { static { route default { nexthop <i>address</i> ; retain; } } }
;(semicolon)	Identifies a leaf statement at a configuration hierarchy level.	

Table 2: Text and Syntax Conventions (*continued*)

Convention	Description	Examples
GUI Conventions		
Bold text like this	Represents graphical user interface (GUI) items you click or select.	<ul style="list-style-type: none"> In the Logical Interfaces box, select All Interfaces. To cancel the configuration, click Cancel.
> (bold right angle bracket)	Separates levels in a hierarchy of menu selections.	In the configuration editor hierarchy, select Protocols>Ospf .

Documentation Feedback

We encourage you to provide feedback, comments, and suggestions so that we can improve the documentation. You can provide feedback by using either of the following methods:

- Online feedback rating system—On any page of the Juniper Networks TechLibrary site at <http://www.juniper.net/techpubs/index.html>, simply click the stars to rate the content, and use the pop-up form to provide us with information about your experience. Alternately, you can use the online feedback form at <http://www.juniper.net/techpubs/feedback/>.
- E-mail—Send your comments to techpubs-comments@juniper.net. Include the document or topic name, URL or page number, and software version (if applicable).

Requesting Technical Support

Technical product support is available through the Juniper Networks Technical Assistance Center (JTAC). If you are a customer with an active J-Care or Partner Support Service support contract, or are covered under warranty, and need post-sales technical support, you can access our tools and resources online or open a case with JTAC.

- JTAC policies—For a complete understanding of our JTAC procedures and policies, review the *JTAC User Guide* located at <http://www.juniper.net/us/en/local/pdf/resource-guides/7100059-en.pdf>.
- Product warranties—For product warranty information, visit <http://www.juniper.net/support/warranty/>.
- JTAC hours of operation—The JTAC centers have resources available 24 hours a day, 7 days a week, 365 days a year.

Self-Help Online Tools and Resources

For quick and easy problem resolution, Juniper Networks has designed an online self-service portal called the Customer Support Center (CSC) that provides you with the following features:

- Find CSC offerings: <http://www.juniper.net/customers/support/>
- Search for known bugs: <http://www2.juniper.net/kb/>
- Find product documentation: <http://www.juniper.net/techpubs/>
- Find solutions and answer questions using our Knowledge Base: <http://kb.juniper.net/>
- Download the latest versions of software and review release notes: <http://www.juniper.net/customers/csc/software/>
- Search technical bulletins for relevant hardware and software notifications: <http://kb.juniper.net/InfoCenter/>
- Join and participate in the Juniper Networks Community Forum: <http://www.juniper.net/company/communities/>
- Open a case online in the CSC Case Management tool: <http://www.juniper.net/cm/>

To verify service entitlement by product serial number, use our Serial Number Entitlement (SNE) Tool: <https://tools.juniper.net/SerialNumberEntitlementSearch/>

Opening a Case with JTAC

You can open a case with JTAC on the Web or by telephone.

- Use the Case Management tool in the CSC at <http://www.juniper.net/cm/>.
- Call 1-888-314-JTAC (1-888-314-5822 toll-free in the USA, Canada, and Mexico).

For international or direct-dial options in countries without toll-free numbers, see <http://www.juniper.net/support/requesting-support.html>.

CHAPTER 1

VPNs Overview

- [VPLS on page 3](#)
- [Types of VPNs on page 4](#)
- [VPNs and Logical Systems on page 7](#)
- [Layer 2 VPNs on page 7](#)
- [Routers in a VPN on page 7](#)

VPLS

In a Layer 3 network only, you can configure virtual private LAN service (VPLS), which is an Ethernet-based point-to-multipoint Layer 2 VPN. It enables you to connect geographically dispersed Ethernet local area networks (LAN) sites to each other across an MPLS backbone. For ISP customers who implement VPLS, all sites appear to be in the same Ethernet LAN even though traffic travels across the service provider's network.

- Related Documentation**
- *Junos OS VPNs Library for Routing Devices*
 - *MX Series Router Architecture*

Types of VPNs

A virtual private network (VPN) consists of two topological areas: the provider's network and the customer's network. The customer's network is commonly located at multiple physical sites and is also private (non-Internet). A customer site would typically consist of a group of routers or other networking equipment located at a single physical location. The provider's network, which runs across the public Internet infrastructure, consists of routers that provide VPN services to a customer's network as well as routers that provide other services. The provider's network connects the various customer sites in what appears to the customer and the provider to be a private network.

To ensure that VPNs remain private and isolated from other VPNs and from the public Internet, the provider's network maintains policies that keep routing information from different VPNs separate. A provider can service multiple VPNs as long as its policies keep routes from different VPNs separate. Similarly, a customer site can belong to multiple VPNs as long as it keeps routes from the different VPNs separate.

The Junos[®] Operating System (Junos OS) provides several types of VPNs; you can choose the best solution for your network environment. Each of the following VPNs has different capabilities and requires different types of configuration:

- [Layer 2 VPNs on page 4](#)
- [Layer 3 VPNs on page 5](#)
- [VPLS on page 5](#)
- [Virtual-Router Routing Instances on page 6](#)

Layer 2 VPNs

Implementing a Layer 2 VPN on a router is similar to implementing a VPN using a Layer 2 technology such as ATM or Frame Relay. However, for a Layer 2 VPN on a router, traffic is forwarded to the router in Layer 2 format. It is carried by MPLS over the service provider's network and then converted back to Layer 2 format at the receiving site. You can configure different Layer 2 formats at the sending and receiving sites. The security and privacy of an MPLS Layer 2 VPN are equal to those of an ATM or Frame Relay VPN.

On a Layer 2 VPN, routing occurs on the customer's routers, typically on the CE router. The CE router connected to a service provider on a Layer 2 VPN must select the appropriate circuit on which to send traffic. The PE router receiving the traffic sends it across the service provider's network to the PE router connected to the receiving site. The PE routers do not need to store or process the customer's routes; they only need to be configured to send data to the appropriate tunnel.

For a Layer 2 VPN, customers need to configure their own routers to carry all Layer 3 traffic. The service provider needs to know only how much traffic the Layer 2 VPN needs to carry. The service provider's routers carry traffic between the customer's sites using Layer 2 VPN interfaces. The VPN topology is determined by policies configured on the PE routers.

Layer 3 VPNs

In a Layer 3 VPN, the routing occurs on the service provider's routers. Therefore, Layer 3 VPNs require more configuration on the part of the service provider, because the service provider's PE routers must store and process the customer's routes.

In the Junos OS, Layer 3 VPNs are based on RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*. This RFC defines a mechanism by which service providers can use their IP backbones to provide Layer 3 VPN services to their customers. The sites that make up a Layer 3 VPN are connected over a provider's existing public Internet backbone.

VPNs based on RFC 4364 are also known as BGP/MPLS VPNs because BGP is used to distribute VPN routing information across the provider's backbone, and MPLS is used to forward VPN traffic across the backbone to remote VPN sites.

Customer networks, because they are private, can use either public addresses or private addresses, as defined in RFC 1918, *Address Allocation for Private Internets*. When customer networks that use private addresses connect to the public Internet infrastructure, the private addresses might overlap with the private addresses used by other network users. BGP/MPLS VPNs solve this problem by prefixing a VPN identifier to each address from a particular VPN site, thereby creating an address that is unique both within the VPN and within the public Internet. In addition, each VPN has its own VPN-specific routing table that contains the routing information for that VPN only.

VPLS

Virtual private LAN service (VPLS) allows you to connect geographically dispersed customer sites as if they were connected to the same LAN. In many ways, it works like a Layer 2 VPN. VPLS and Layer 2 VPNs use the same network topology and function similarly. A packet originating within a customer's network is sent first to a CE device. It is then sent to a PE router within the service provider's network. The packet traverses the service provider's network over an MPLS LSP. It arrives at the egress PE router, which then forwards the traffic to the CE device at the destination customer site.

The key difference in VPLS is that packets can traverse the service provider's network in a point-to-multipoint fashion, meaning that a packet originating from a CE device can be broadcast to PE routers in the VPLS. In contrast, a Layer 2 VPN forwards packets in a point-to-point fashion only. The destination of a packet received from a CE device by a PE router must be known for the Layer 2 VPN to function properly.

VPLS is designed to carry Ethernet traffic across an MPLS-enabled service provider network. In certain ways, VPLS mimics the behavior of an Ethernet network. When a PE router configured with a VPLS routing instance receives a packet from a CE device, it first checks the appropriate routing table for the destination of the VPLS packet. If the router has the destination, it forwards it to the appropriate PE router. If it does not have the destination, it broadcasts the packet to all the other PE routers that are members of the same VPLS routing instance. The PE routers forward the packet to their CE devices. The CE device that is the intended recipient of the packet forwards it to its final destination. The other CE devices discard it.

Virtual-Router Routing Instances

A virtual-router routing instance, like a VPN routing and forwarding (VRF) routing instance, maintains separate routing and forwarding tables for each instance. However, many configuration steps required for VRF routing instances are not required for virtual-router routing instances. Specifically, you do not need to configure a route distinguisher, a routing table policy (the **vrf-export**, **vrf-import**, and **route-distinguisher** statements), or MPLS between the P routers.

However, you need to configure separate logical interfaces between each of the service provider routers participating in a virtual-router routing instance. You also need to configure separate logical interfaces between the service provider routers and the customer routers participating in each routing instance. Each virtual-router instance requires its own unique set of logical interfaces to all participating routers.

Figure 1 on page 6 shows how this works. The service provider routers G and H are configured for virtual-router routing instances Red and Green. Each service provider router is directly connected to two local customer routers, one in each routing instance. The service provider routers are also connected to each other over the service provider network. These routers need four logical interfaces: a logical interface to each of the locally connected customer routers and a logical interface to carry traffic between the two service provider routers for each virtual-router instance.

Figure 1: Logical Interface per Router in a Virtual-Router Routing Instance

Layer 3 VPNs do not have this configuration requirement. If you configure several Layer 3 VPN routing instances on a PE router, all the instances can use the same logical interface to reach another PE router. This is possible because Layer 3 VPNs use MPLS (VPN) labels that differentiate traffic going to and from various routing instances. Without MPLS and VPN labels, as in a virtual-router routing instance, you need separate logical interfaces to separate traffic from different instances.

One method of providing this logical interface between the service provider routers is by configuring tunnels between them. You can configure IP Security (IPsec), generic routing encapsulation (GRE), or IP-IP tunnels between the service provider routers, terminating the tunnels at the virtual-router instance.

VPNs and Logical Systems

You can partition a single physical router into multiple logical systems that perform independent routing tasks. Because logical systems perform a subset of the tasks once handled by the physical router, logical systems offer an effective way to maximize the use of a single routing platform.

Logical systems perform a subset of the actions of a physical router and have their own unique routing tables, interfaces, policies, and routing instances. A set of logical systems within a single router can handle the functions previously performed by several small routers.

You can configure Layer 2 VPNs, Layer 3 VPNs, VPLS, and Layer 2 circuits within a logical system. For more information about logical systems, see the *Logical Systems Feature Guide*.

NOTE: Beginning with Junos OS Release 9.3, the logical router feature has been renamed logical system.

All configuration statements, operational commands, show command outputs, error messages, log messages, and SNMP MIB objects that contain the string logical-router or logical-routers have been changed to logical-system and logical-systems, respectively.

Layer 2 VPNs

In a Layer 3 network only, you can configure Layer 2 virtual private network (VPN) under a Layer 2 VPN routing instance type **l2vpn**.

In a Layer 2 environment, you can use a **l2vpn** routing instance to transparently carry Layer 2 traffic over an IP/MPLS backbone. Layer 2 traffic is sent to the provider edge (PE) router in Layer 2 format. The PE router encapsulates the frames and transports them over the IP/MPLS backbone to the PE router on the other side of the cloud. The remote PE router removes encapsulation and sends the frames to the receiving site in Layer 2 format.

Routers in a VPN

Figure 2 on page 8 illustrates how VPN functionality is provided by the provider edge (PE) routers; the provider and customer edge (CE) routers have no special configuration requirements for VPNs.

Figure 2: Routers in a VPN

CHAPTER 2

Assigning Routing Instances to VPNs

- [Configuring Routing Instances on PE Routers in VPNs on page 9](#)
- [Configuring Virtual-Router Routing Instances in VPNs on page 14](#)
- [Configuring Path MTU Checks for VPN Routing Instances on page 16](#)

Configuring Routing Instances on PE Routers in VPNs

You need to configure a routing instance for each VPN on each of the PE routers participating in the VPN. The configuration procedures outlined in this section are applicable to Layer 2 VPNs, Layer 3 VPNs, and VPLS. The configuration procedures specific to each type of VPN are described in the corresponding sections in the other configuration chapters.

To configure routing instances for VPNs, include the following statements:

```
description text;  
instance-type type;  
interface interface-name;  
route-distinguisher (as-number:number | ip-address:number);  
vrf-import [ policy-names ];  
vrf-export [ policy-names ];  
vrf-target {  
    export community-name;  
    import community-name;  
}
```

You can include these statements at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name*]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]**

To configure VPN routing instances, you perform the steps in the following sections:

- [Configuring the Routing Instance Name for a VPN on page 10](#)
- [Configuring the Description on page 10](#)
- [Configuring the Instance Type on page 10](#)
- [Configuring Interfaces for VPN Routing on page 11](#)

- [Configuring the Route Distinguisher on page 13](#)
- [Configuring Automatic Route Distinguishers on page 14](#)

Configuring the Routing Instance Name for a VPN

The name of the routing instance for a VPN can be a maximum of 128 characters and can contain letters, numbers, and hyphens. In Junos OS Release 9.0 and later, you can no longer specify **default** as the actual routing-instance name. You also cannot use any special characters (! @ # \$ % ^ & *, + < > : ;) within the name of a routing instance.

NOTE: In Junos OS Release 9.6 and later, you can include a slash (/) in a routing instance name only if a logical system is not configured. That is, you cannot include the slash character in a routing instance name if a logical system other than the default is explicitly configured.

Specify the routing-instance name with the **routing-instance** statement:

```
routing-instance routing-instance-name {...}
```

You can include this statement at the following hierarchy levels:

- **[edit]**
- **[edit logical-systems *logical-system-name*]**

Configuring the Description

To provide a text description for the routing instance, include the **description** statement. If the text includes one or more spaces, enclose them in quotation marks (" "). Any descriptive text you include is displayed in the output of the **show route instance detail** command and has no effect on the operation of the routing instance.

To configure a text description, include the **description** statement:

```
description text;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name*]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]**

Configuring the Instance Type

The instance type you configure varies depending on whether you are configuring Layer 2 VPNs, Layer 3 VPNs, VPLS, or virtual routers. Specify the instance type by including the **instance-type** statement:

- To enable Layer 2 VPN routing on a PE router, include the **instance-type** statement and specify the value **l2vpn**:

```
instance-type l2vpn;
```

- To enable VPLS routing on a PE router, include the **instance-type** statement and specify the value **vpls**:

```
instance-type vpls;
```

- Layer 3 VPNs require that each PE router have a VPN routing and forwarding (VRF) table for distributing routes within the VPN. To create the VRF table on the PE router, include the **instance-type** statement and specify the value **vrf**:

```
instance-type vrf;
```

NOTE: Routing Engine based sampling is not supported on VRF routing instances.

- To enable the virtual-router routing instance, include the **instance-type** statement and specify the value **virtual-router**:

```
instance-type virtual-router;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]

Configuring Interfaces for VPN Routing

On each PE router, you must configure an interface over which the VPN traffic travels between the PE and CE routers.

The sections that follow describe how to configure interfaces for VPNs:

- [General Configuration for VPN Routing on page 11](#)
- [Configuring Interfaces for Layer 3 VPNs on page 12](#)
- [Configuring Interfaces for Carrier-of-Carriers VPNs on page 12](#)
- [Configuring Unicast RPF on VPN Interfaces on page 13](#)

General Configuration for VPN Routing

The configuration described in this section applies to all types of VPNs. For Layer 3 VPNs and carrier-of-carriers VPNs, complete the configuration described in this section before proceeding to the interface configuration sections specific to those topics.

To configure interfaces for VPN routing, include the **interface** statement:

```
interface interface-name;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]

Specify both the physical and logical portions of the interface name, in the following format:

physical.logical

For example, in **at-1/2/1.2**, **at-1/2/1** is the physical portion of the interface name and **2** is the logical portion. If you do not specify the logical portion of the interface name, the value **0** is set by default.

A logical interface can be associated with only one routing instance. If you enable a routing protocol on all instances by specifying **interfaces all** when configuring the master instance of the protocol at the **[edit protocols]** hierarchy level, and if you configure a specific interface for VPN routing at the **[edit routing-instances routing-instance-name]** hierarchy level or at the **[edit logical-systems logical-system-name routing-instances routing-instance-name]** hierarchy level, the latter interface statement takes precedence and the interface is used exclusively for the VPN.

If you explicitly configure the same interface name at the **[edit protocols]** hierarchy level and at either the **[edit routing-instances routing-instance-name]** or **[edit logical-systems logical-system-name routing-instances routing-instance-name]** hierarchy levels, an attempt to commit the configuration fails.

Configuring Interfaces for Layer 3 VPNs

When you configure the Layer 3 VPN interfaces at the **[edit interfaces]** hierarchy level, you must also configure **family inet** when configuring the logical interface:

```
[edit interfaces]
interface-name {
  unit logical-unit-number {
    family inet;
  }
}
```

Configuring Interfaces for Carrier-of-Carriers VPNs

When you configure carrier-of-carriers VPNs, you need to configure the **family mpls** statement in addition to the **family inet** statement for the interfaces between the PE and CE routers. For carrier-of-carriers VPNs, configure the logical interface as follows:

```
[edit interfaces]
interface-name {
  unit logical-unit-number {
    family inet;
    family mpls;
  }
}
```

If you configure **family mpls** on the logical interface and then configure this interface for a non-carrier-of-carriers routing instance, the **family mpls** statement is automatically removed from the configuration for the logical interface, since it is not needed.

Configuring Unicast RPF on VPN Interfaces

For VPN interfaces that carry IP version 4 or version 6 (IPv4 or IPv6) traffic, you can reduce the impact of denial-of-service (DoS) attacks by configuring unicast reverse path forwarding (RPF). Unicast RPF helps determine the source of attacks and rejects packets from unexpected source addresses on interfaces where unicast RPF is enabled.

You can configure unicast RPF on a VPN interface by enabling unicast RPF on the interface and including the **interface** statement at the **[edit routing-instances routing-instance-name]** hierarchy level.

You cannot configure unicast RPF on the core-facing interfaces. You can only configure unicast RPF on the CE router-to-PE router interfaces on the PE router. However, for virtual-router routing instances, unicast RPF is supported on all interfaces you specify in the routing instance.

For information about how to configure unicast RPF on VPN interfaces, see *Configuring Unicast RPF*.

Configuring the Route Distinguisher

Each routing instance that you configure on a PE router must have a unique route distinguisher associated with it. VPN routing instances need a route distinguisher to help BGP to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs. If you configure different VPN routing instances with the same route distinguisher, the commit fails.

For Layer 2 VPNs and VPLS, if you have configured the **l2vpn-use-bgp-rules** statement, you must configure a unique route distinguisher for each PE router participating in a specific routing instance.

For other types of VPNs, we recommend that you use a unique route distinguisher for each PE router participating in the routing instance. Although you can use the same route distinguisher on all PE routers for the same VPN routing instance (except for Layer 2 VPNs and VPLS), if you use a unique route distinguisher, you can determine the CE router from which a route originated within the VPN.

To configure a route distinguisher on a PE router, include the **route-distinguisher** statement:

```
route-distinguisher (as-number:number | ip-address:number);
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The route distinguisher is a 6-byte value that you can specify in one of the following formats:

- **as-number:number**, where **as-number** is an autonomous system (AS) number (a 2-byte value) and **number** is any 4-byte value. The AS number can be in the range 1 through 65,535. We recommend that you use an Internet Assigned Numbers Authority (IANA)-assigned, nonprivate AS number, preferably the Internet service provider's (ISP's) own or the customer's own AS number.

- ***ip-address:number***, where ***ip-address*** is an IP address (a 4-byte value) and ***number*** is any 2-byte value. The IP address can be any globally unique unicast address. We recommend that you use the address that you configure in the **router-id** statement, which is a nonprivate address in your assigned prefix range.

Configuring Automatic Route Distinguishers

If you configure the **route-distinguisher-id** statement at the **[edit routing-options]** hierarchy level, a route distinguisher is automatically assigned to the routing instance. If you also configure the **route-distinguisher** statement in addition to the **route-distinguisher-id** statement, the value configured for **route-distinguisher** supersedes the value generated from **route-distinguisher-id**.

To assign a route distinguisher automatically, include the **route-distinguisher-id** statement:

```
route-distinguisher-id ip-address;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-options]**
- **[edit logical-systems *logical-system-name* routing-options]**

A type 1 route distinguisher is automatically assigned to the routing instance using the format ***ip-address:number***. The IP address is specified by the **route-distinguisher-id** statement and the number is unique for the routing instance.

Related Documentation

- [Configuring Policies for the VRF Table on PE Routers in VPNs on page 25](#)
- [Configuring BGP Route Target Filtering for VPNs on page 37](#)

Configuring Virtual-Router Routing Instances in VPNs

A virtual-router routing instance, like a VRF routing instance, maintains separate routing and forwarding tables for each instance. However, many of the configuration steps required for VRF routing instances are not required for virtual-router routing instances. Specifically, you do not need to configure a route distinguisher, a routing table policy (the **vrf-export**, **vrf-import**, and **route-distinguisher** statements), or MPLS between the service provider routers.

Configure a virtual-router routing instance by including the following statements:

```
description text;  
instance-type virtual-router;  
interface interface-name;  
protocols { ... }
```

You can include these statements at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name*]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]**

The following sections explain how to configure a virtual-router routing instance:

- [Configuring a Routing Protocol Between the Service Provider Routers on page 15](#)
- [Configuring Logical Interfaces Between Participating Routers on page 15](#)

Configuring a Routing Protocol Between the Service Provider Routers

The service provider routers need to be able to exchange routing information. You can configure the following protocols for the virtual-router routing instance **protocols** statement configuration at the **[edit routing-instances *routing-instance-name*]** hierarchy level:

- BGP
- IS-IS
- LDP
- OSPF
- Protocol Independent Multicast (PIM)
- RIP

You can also configure static routes.

IBGP route reflection is not supported for virtual-router routing instances.

If you configure LDP under a virtual-router instance, LDP routes are placed by default in the routing instance's `inet.0` and `inet.3` routing tables (for example, `sample.inet.0` and `sample.inet.3`). To restrict LDP routes to only the routing instance's `inet.3` table, include the **no-forwarding** statement:

```
no-forwarding;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name* protocols *ldp*]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols *ldp*]**

When you restrict the LDP routes to only the `inet.3` routing table, the corresponding IGP route in the `inet.0` routing table can be redistributed and advertised into other routing protocols.

For information about routing tables, see *Understanding Junos OS Routing Tables*.

Configuring Logical Interfaces Between Participating Routers

You must configure an interface to each customer router participating in the routing instance and to each P router participating in the routing instance. Each virtual-router routing instance requires its own separate logical interfaces to all P routers participating in the instance. To configure interfaces for virtual-router instances, include the **interface** statement:

interface *interface-name*;

You can include this statement at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name*]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]**

Specify both the physical and logical portions of the interface name, in the following format:

physical.logical

For example, in **at-1/2/1.2**, **at-1/2/1** is the physical portion of the interface name and **2** is the logical portion. If you do not specify the logical portion of the interface name, **0** is set by default.

You must also configure the interfaces at the **[edit interfaces]** hierarchy level.

One method of providing this logical interface between the provider routers is by configuring tunnels between them. You can configure IP Security (IPsec), generic routing encapsulation (GRE), or IP-IP tunnels between the provider routers, terminating the tunnels at the virtual-router instance.

For information about how to configure tunnels and interfaces, see the *Junos OS Services Interfaces Library for Routing Devices*.

Configuring Path MTU Checks for VPN Routing Instances

By default, the maximum transmission unit (MTU) check for VPN routing instances is disabled on M Series routers (except the M320 router) and enabled for the M320 router and T Series routers. On M Series routers, you can configure path MTU checks on the outgoing interfaces for unicast traffic routed on VRF routing instances and on virtual-router routing instances.

When you enable an MTU check, the routing platform sends an Internet Control Message Protocol (ICMP) message when a packet traversing the routing instance exceeds the MTU size and has the **do-not-fragment** bit set. The ICMP message uses the VRF local address as its source address.

For an MTU check to work in a routing instance, you must both include the **vrf-mtu-check** statement at the **[edit chassis]** hierarchy level and assign at least one interface containing an IP address to the routing instance.

For more information about the path MTU check, see the *Junos OS Administration Library*.

To configure path MTU checks, do the tasks described in the following sections:

- [Enabling Path MTU Checks for a VPN Routing Instance on page 17](#)
- [Assigning an IP Address to the VPN Routing Instance on page 17](#)

Enabling Path MTU Checks for a VPN Routing Instance

To enable path checks on the outgoing interface for unicast traffic routed on a VRF or virtual-router routing instance, include the **vrf-mtu-check** statement at the **[edit chassis]** hierarchy level:

```
[edit chassis]  
vrf-mtu-check;
```

Assigning an IP Address to the VPN Routing Instance

To ensure that the path MTU check functions properly, at least one IP address must be associated with each VRF or virtual-router routing instance. If an IP address is not associated with the routing instance, ICMP reply messages cannot be sent.

Typically, the VRF or virtual-router routing instance IP address is drawn from among the IP addresses associated with interfaces configured for that routing instance. If none of the interfaces associated with a VRF or virtual-router routing instance is configured with an IP address, you need to explicitly configure a logical loopback interface with an IP address. This interface must then be associated with the routing instance. See *Configuring Logical Units on the Loopback Interface for Routing Instances in Layer 3 VPNs* for details.

CHAPTER 3

Distributing Routes in VPNs

- [Enabling Routing Information Exchange for VPNs on page 19](#)
- [Configuring IBGP Sessions Between PE Routers in VPNs on page 19](#)
- [Configuring Aggregate Labels for VPNs on page 21](#)
- [Configuring a Signaling Protocol and LSPs for VPNs on page 22](#)
- [Configuring Policies for the VRF Table on PE Routers in VPNs on page 25](#)
- [Configuring the Route Origin for VPNs on page 32](#)

Enabling Routing Information Exchange for VPNs

For Layer 2 VPNs, Layer 3 VPNs, virtual-router routing instances, VPLS, EVPNs, and Layer 2 circuits to function properly, the service provider's PE and P routers must be able to exchange routing information. For this to happen, you must configure either an IGP (such as OSPF or IS-IS) or static routes on these routers. You configure the IGP on the master instance of the routing protocol process at the **[edit protocols]** hierarchy level, not within the routing instance used for the VPN—that is, not at the **[edit routing-instances]** hierarchy level.

When you configure the PE router, do not configure any summarization of the PE router's loopback addresses at the area boundary. Each PE router's loopback address should appear as a separate route.

Related Documentation

- *Example: Configuring IS-IS*
- *OSPF Feature Guide*

Configuring IBGP Sessions Between PE Routers in VPNs

You must configure an IBGP session between the PE routers to allow the PE routers to exchange information about routes originating and terminating in the VPN. The PE routers rely on this information to determine which labels to use for traffic destined for remote sites.

Configure an IBGP session for the VPN as follows:

```
[edit protocols]
bgp {
```

```
group group-name {  
  type internal;  
  local-address ip-address;  
  family evpn {  
    signaling;  
  }  
  family (inet-vpn | inet6-vpn) {  
    unicast;  
  }  
  family l2vpn {  
    signaling;  
  }  
  neighbor ip-address;  
}
```

The IP address in the **local-address** statement is the address of the loopback interface on the local PE router. The IBGP session for the VPN runs through the loopback address. (You must also configure the loopback interface at the **[edit interfaces]** hierarchy level.)

The IP address in the **neighbor** statement is the loopback address of the neighboring PE router. If you are using RSVP signaling, this IP address is the same address you specify in the **to** statement at the **[edit mpls label-switched-path *lsp-path-name*]** hierarchy level when you configure the MPLS LSP.

The **family** statement allows you to configure the IBGP session for Layer 2 VPNs, VPLS, EVPNs or for Layer 3 VPNs.

- To configure an IBGP session for Layer 2 VPNs and VPLS, include the **signaling** statement at the **[edit protocols bgp group *group-name* family l2vpn]** hierarchy level:

```
[edit protocols bgp group group-name family l2vpn]  
signaling;
```

- To configure an IBGP session for EVPNs, include the **signaling** statement at the **[edit protocols bgp group *group-name* family evpn]** hierarchy level:

```
[edit protocols bgp group group-name family evpn]  
signaling;
```

- To configure an IPv4 IBGP session for Layer 3 VPNs, configure the **unicast** statement at the **[edit protocols bgp group *group-name* family inet-vpn]** hierarchy level:

```
[edit protocols bgp group group-name family inet-vpn]  
unicast;
```

- To configure an IPv6 IBGP session for Layer 3 VPNs, configure the **unicast** statement at the **[edit protocols bgp group *group-name* family inet6-vpn]** hierarchy level:

```
[edit protocols bgp group group-name family inet6-vpn]  
unicast;
```

NOTE: You can configure both `family inet` and `family inet-vpn` or both `family inet6` and `family inet6-vpn` within the same peer group. This allows you to enable support for both IPv4 and IPv4 VPN routes or both IPv6 and IPv6 VPN routes within the same peer group.

Configuring Aggregate Labels for VPNs

Aggregate labels for VPNs allow a Juniper Networks routing platform to aggregate a set of incoming labels (labels received from a peer router) into a single forwarding label that is selected from the set of incoming labels. The single forwarding label corresponds to a single next hop for that set of labels. Label aggregation reduces the number of VPN labels that the router must examine.

For a set of labels to share an aggregate forwarding label, they must belong to the same forwarding equivalence class (FEC). The labeled packets must have the same destination egress interface.

Including the `community community-name` statement with the `aggregate-label` statement lets you specify prefixes with a common origin community. Set by policy on the peer PE, these prefixes represent an FEC on the peer PE router.

CAUTION: If the target community is set by mistake instead of the origin community, forwarding problems at the egress PE can result. All prefixes from the peer PE will appear to be in the same FEC, resulting in a single inner label for all CE routers behind a given PE in the same VPN.

To work with route reflectors in Layer 3 VPN networks, the Juniper Networks M10i router aggregates a set of incoming labels only when the routes:

- Are received from the same peer router
- Have the same site of origin community
- Have the same next hop

The next hop requirement is important because route reflectors forward routes originated from different BGP peers to another BGP peer without changing the next hop of those routes.

To configure aggregate labels for VPNs, include the `aggregate-label` statement:

```
aggregate-label {
  community community-name;
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary for this statement.

For information about how to configure a community, see *Understanding BGP Communities and Extended Communities as Routing Policy Match Conditions*.

Configuring a Signaling Protocol and LSPs for VPNs

For VPNs to function, you must enable a signaling protocol, either the LDP or RSVP on the provider edge (PE) routers and on the provider (P) routers. You also need to configure label-switched paths (LSPs) between the ingress and egress routers. In a typical VPN configuration, you need to configure LSPs from each PE router to all of the other PE routers participating in the VPN in a full mesh.

NOTE: As with any configuration involving MPLS, you cannot configure any of the core-facing interfaces on the PE routers over dense Fast Ethernet PICs.

To enable a signaling protocol, perform the steps in one of the following sections:

- [Using LDP for VPN Signaling on page 22](#)
- [Using RSVP for VPN Signaling on page 24](#)

Using LDP for VPN Signaling

To use LDP for VPN signaling, perform the following steps on the PE and provider (P) routers:

1. Configure LDP on the interfaces in the core of the service provider's network by including the **ldp** statement at the **[edit protocols]** hierarchy level.

You need to configure LDP only on the interfaces between PE routers or between PE and P routers. You can think of these as the “core-facing” interfaces. You do not need to configure LDP on the interface between the PE and customer edge (CE) routers.

```
[edit]
protocols {
  ldp {
    interface type-fpc/pic/port;
  }
}
```

2. Configure the MPLS address family on the interfaces on which you enabled LDP (the interfaces you configured in Step 1) by including the **family mpls** statement at the **[edit interfaces type-fpc/pic/port unit logical-unit-number]** hierarchy level.

```
[edit]
interfaces {
```

```

type-fpc/pic/port {
  unit logical-unit-number {
    family mpls;
  }
}

```

3. Configure OSPF or IS-IS on each PE and P router.

You configure these protocols at the master instance of the routing protocol, not within the routing instance used for the VPN.

- To configure OSPF, include the **ospf** statement at the **[edit protocols]** hierarchy level. At a minimum, you must configure a backbone area on at least one of the router's interfaces.

```

[edit]
protocols {
  ospf {
    area 0.0.0.0 {
      interface type-fpc/pic/port;
    }
  }
}

```

- To configure IS-IS, include the **isis** statement at the **[edit protocols]** hierarchy level and configure the loopback interface and International Organization for Standardization (ISO) family at the **[edit interfaces]** hierarchy level. At a minimum, you must enable IS-IS on the router, configure a network entity title (NET) on one of the router's interfaces (preferably the loopback interface, lo0), and configure the ISO family on all interfaces on which you want IS-IS to run. When you enable IS-IS, Level 1 and Level 2 are enabled by default. The following is the minimum IS-IS configuration. In the **address** statement, **address** is the NET.

```

[edit]
interfaces {
  lo0 {
    unit logical-unit-number {
      family iso {
        address address;
      }
    }
  }
  type-fpc/pic/port {
    unit logical-unit-number {
      family iso;
    }
  }
}
protocols {
  isis {
    interface all;
  }
}

```

For more information about configuring OSPF and IS-IS, see the *OSPF Feature Guide* and *IS-IS Feature Guide*.

Using RSVP for VPN Signaling

To use RSVP for VPN signaling, perform the following steps:

1. On each PE router, configure traffic engineering.

To do this, you must configure an interior gateway protocol (IGP) that supports traffic engineering (either IS-IS or OSPF) and enable traffic engineering support for that protocol.

To enable OSPF traffic engineering support, include the **traffic-engineering** statement at the **[edit protocols ospf]** hierarchy level:

```
[edit protocols ospf]
traffic-engineering {
  shortcuts;
}
```

For IS-IS, traffic engineering support is enabled by default.

2. On each PE and P router, enable RSVP on the interfaces that participate in the label-switched path (LSP).

On the PE router, these interfaces are the ingress and egress points to the LSP. On the P router, these interfaces connect the LSP between the PE routers. Do not enable RSVP on the interface between the PE and the CE routers, because this interface is not part of the LSP.

To configure RSVP on the PE and P routers, include the **interface** statement at the **[edit protocols rsvp]** hierarchy level. Include one **interface** statement for each interface on which you are enabling RSVP.

```
[edit protocols]
rsvp {
  interface interface-name;
  interface interface-name;
}
```

3. On each PE router, configure an MPLS LSP to the PE router that is the LSP's egress point.

To do this, include the **interface** and **label-switched-path** statements at the **[edit protocols mpls]** hierarchy level:

```
[edit protocols]
mpls {
  interface interface-name;
  label-switched-path path-name {
    to ip-address;
  }
}
```

In the **to** statement, specify the address of the LSP's egress point, which is an address on the remote PE router.

In the **interface** statement, specify the name of the interface (both the physical and logical portions). Include one **interface** statement for the interface associated with the LSP.

When you configure the logical portion of the same interface at the **[edit interfaces]** hierarchy level, you must also configure the **family inet** and **family mpls** statements:

```
[edit interfaces]
interface-name {
  unit logical-unit-number {
    family inet;
    family mpls;
  }
}
```

4. On all P routers that participate in the LSP, enable MPLS by including the **interface** statement at the **[edit mpls]** hierarchy level.

Include one **interface** statement for each connection to the LSP.

```
[edit]
mpls {
  interface interface-name;
  interface interface-name;
}
```

5. Enable MPLS on the interface between the PE and CE routers by including the **interface** statement at the **[edit mpls]** hierarchy level.

Doing this allows the PE router to assign an MPLS label to traffic entering the LSP or to remove the label from traffic exiting the LSP.

```
[edit]
mpls {
  interface interface-name;
}
```

For information about configuring MPLS, see the *Configuring the Ingress Router for MPLS-Signaled LSPs*.

Configuring Policies for the VRF Table on PE Routers in VPNs

On each PE router, you must define policies that define how routes are imported into and exported from the router's VRF table. In these policies, you must define the route target, and you can optionally define the route origin.

To configure policy for the VRF tables, you perform the steps in the following sections:

- [Configuring the Route Target on page 26](#)
- [Configuring the Route Origin on page 26](#)
- [Configuring an Import Policy for the PE Router's VRF Table on page 27](#)

- [Configuring an Export Policy for the PE Router's VRF Table on page 29](#)
- [Applying Both the VRF Export and the BGP Export Policies on page 30](#)
- [Configuring a VRF Target on page 31](#)

Configuring the Route Target

As part of the policy configuration for the VPN routing table, you must define a route target, which defines which VPN the route is a part of. When you configure different types of VPN services (Layer 2 VPNs, Layer 3 VPNs, EVPNs, or VPLS) on the same PE router, be sure to assign unique route target values to avoid the possibility of adding route and signaling information to the wrong VPN routing table.

To configure the route target, include the **target** option in the **community** statement:

```
community name members target:community-id;
```

You can include this statement at the following hierarchy levels:

- **[edit policy-options]**
- **[edit logical-systems *logical-system-name* policy-options]**

name is the name of the community.

community-id is the identifier of the community. Specify it in one of the following formats:

- ***as-number:number***, where *as-number* is an AS number (a 2-byte value) and *number* is a 4-byte community value. The AS number can be in the range 1 through 65,535. We recommend that you use an IANA-assigned, nonprivate AS number, preferably the ISP's own or the customer's own AS number. The community value can be a number in the range 0 through 4,294,967,295 ($2^{32} - 1$).
- ***ip-address:number***, where *ip-address* is an IPv4 address (a 4-byte value) and *number* is a 2-byte community value. The IP address can be any globally unique unicast address. We recommend that you use the address that you configure in the **router-id** statement, which is a nonprivate address in your assigned prefix range. The community value can be a number in the range 1 through 65,535.

Configuring the Route Origin

In the import and export policies for the PE router's VRF table, you can optionally assign the route origin (also known as the site of origin) for a PE router's VRF routes using a VRF export policy applied to multiprotocol external BGP (MP-EBGP) VPN IPv4 route updates sent to other PE routers.

Matching on the assigned route origin attribute in a receiving PE's VRF import policy helps ensure that VPN-IPv4 routes learned through MP-EBGP updates from one PE are not reimported to the same VPN site from a different PE connected to the same site.

To configure a route origin, complete the following steps:

1. Include the **community** statement with the **origin** option:

```
community name members origin:community-id;
```

You can include this statement at the following hierarchy levels:

- **[edit policy-options]**
- **[edit logical-systems *logical-system-name* policy-options]**

name is the name of the community.

community-id is the identifier of the community. Specify it in one of the following formats:

- **as-number:number**, where **as-number** is an AS number (a 2-byte value) and **number** is a 4-byte community value. The AS number can be in the range 1 through 65,535. We recommend that you use an IANA-assigned, nonprivate AS number, preferably the ISP's own or the customer's own AS number. The community value can be a number in the range 0 through 4,294,967,295 ($2^{32} - 1$).
 - **ip-address:number**, where **ip-address** is an IPv4 address (a 4-byte value) and **number** is a 2-byte community value. The IP address can be any globally unique unicast address. We recommend that you use the address that you configure in the **router-id** statement, which is a nonprivate address in your assigned prefix range. The community value can be a number in the range 1 through 65,535.
2. Include the community in the import policy for the PE router's VRF table by configuring the **community** statement with the **community-id** identifier defined in Step 1 at the **[edit policy-options policy-statement import-policy-name term import-term-name from]** hierarchy level. See [“Configuring an Import Policy for the PE Router's VRF Table” on page 27](#).

If the policy's **from** clause does not specify a community condition, the **vrf-import** statement in which the policy is applied cannot be committed. The Junos OS commit operation does not pass the validation check.
 3. Include the community in the export policy for the PE router's VRF table by configuring the **community** statement with the **community-id** identifier defined in Step 1 at the **[edit policy-options policy-statement export-policy-name term export-term-name then]** hierarchy level. See [“Configuring an Export Policy for the PE Router's VRF Table” on page 29](#).

See [“Configuring the Route Origin for VPNs” on page 32](#) for a configuration example.

Configuring an Import Policy for the PE Router's VRF Table

Each VPN can have a policy that defines how routes are imported into the PE router's VRF table. An import policy is applied to routes received from other PE routers in the VPN. A policy must evaluate all routes received over the IBGP session with the peer PE router. If the routes match the conditions, the route is installed in the PE router's **routing-instance-name.inet.0** VRF table. An import policy must contain a second term that rejects all other routes.

Unless an import policy contains only a **then reject** statement, it must include a reference to a community. Otherwise, when you try to commit the configuration, the commit fails. You can configure multiple import policies.

An import policy determines what to import to a specified VRF table based on the VPN routes learned from the remote PE routers through IBGP. The IBGP session is configured at the **[edit protocols bgp]** hierarchy level. If you also configure an import policy at the **[edit protocols bgp]** hierarchy level, the import policies at the **[edit policy-options]** hierarchy level and the **[edit protocols bgp]** hierarchy level are combined through a logical AND operation. This allows you to filter traffic as a group.

To configure an import policy for the PE router's VRF table, follow these steps:

1. To define an import policy, include the **policy-statement** statement. For all PE routers, an import policy must always include the **policy-statement** statement, at a minimum:

```
policy-statement import-policy-name {  
  term import-term-name {  
    from {  
      protocol bgp;  
      community community-id;  
    }  
    then accept;  
  }  
  term term-name {  
    then reject;  
  }  
}
```

You can include the **policy-statement** statement at the following hierarchy levels:

- **[edit policy-options]**
- **[edit logical-systems *logical-system-name* policy-options]**

The ***import-policy-name*** policy evaluates all routes received over the IBGP session with the other PE router. If the routes match the conditions in the **from** statement, the route is installed in the PE router's *routing-instance-name*.inet.0 VRF table. The second term in the policy rejects all other routes.

For more information about creating policies, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

2. You can optionally use a regular expression to define a set of communities to be used for the VRF import policy.

For example you could configure the following using the **community** statement at the **[edit policy-options policy-statement *policy-statement-name*]** hierarchy level:

```
[edit policy-options vrf-import-policy-sample]  
community high-priority members *:50
```

Note that you cannot configure a regular expression as a part of a route target extended community. For more information about how to configure regular expressions for

communities, see *Understanding How to Define BGP Communities and Extended Communities*.

3. To configure an import policy, include the **vrf-import** statement:

```
vrf-import import-policy-name;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name*]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]**

Configuring an Export Policy for the PE Router's VRF Table

Each VPN can have a policy that defines how routes are exported from the PE router's VRF table. An export policy is applied to routes sent to other PE routers in the VPN. An export policy must evaluate all routes received over the routing protocol session with the CE router. (This session can use the BGP, OSPF, or Routing Information Protocol [RIP] routing protocols, or static routes.) If the routes match the conditions, the specified community target (which is the route target) is added to them and they are exported to the remote PE routers. An export policy must contain a second term that rejects all other routes.

Export policies defined within the VPN routing instance are the only export policies that apply to the VRF table. Any export policy that you define on the IBGP session between the PE routers has no effect on the VRF table. You can configure multiple export policies.

To configure an export policy for the PE router's VRF table, follow these steps:

1. For all PE routers, an export policy must distribute VPN routes to and from the connected CE routers in accordance with the type of routing protocol that you configure between the CE and PE routers within the routing instance.

To define an export policy, include the **policy-statement** statement. An export policy must always include the **policy-statement** statement, at a minimum:

```
policy-statement export-policy-name {
  term export-term-name {
    from protocol (bgp | ospf | rip | static);
    then {
      community add community-id;
      accept;
    }
  }
  term term-name {
    then reject;
  }
}
```

NOTE: Configuring the **community add** statement is a requirement for Layer 2 VPN VRF export policies. If you change the **community add** statement to the **community set** statement, the router at the egress of the Layer 2 VPN link might drop the connection.

NOTE: When configuring draft-rosen multicast VPNs operating in source-specific mode and using the **vrf-export** statement to specify the export policy, the policy must have a term that accepts routes from the **vrf-name.mdt.0** routing table. This term ensures proper PE autodiscovery using the **inet-mdt** address family.

When configuring draft-rosen multicast VPNs operating in source-specific mode and using the **vrf-target** statement, the VRF export policy is automatically generated and automatically accepts routes from the **vrf-name.mdt.0** routing table.

You can include the **policy-statement** statement at the following hierarchy levels:

- [edit **policy-options**]
- [edit **logical-systems** *logical-system-name* **policy-options**]

The **export-policy-name** policy evaluates all routes received over the routing protocol session with the CE router. (This session can use the BGP, OSPF, or RIP routing protocols, or static routes.) If the routes match the conditions in the **from** statement, the community target specified in the **then community add** statement is added to them and they are exported to the remote PE routers. The second term in the policy rejects all other routes.

For more information about creating policies, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

2. To apply the policy, include the **vrf-export** statement:

```
vrf-export export-policy-name;
```

You can include this statement at the following hierarchy levels:

- [edit **routing-instances** *routing-instance-name*]
- [edit **logical-systems** *logical-system-name* **routing-instances** *routing-instance-name*]

Applying Both the VRF Export and the BGP Export Policies

When you apply a VRF export policy as described in “[Configuring an Export Policy for the PE Router’s VRF Table](#)” on page 29, routes from VPN routing instances are advertised to other PE routers based on this policy, whereas the BGP export policy is ignored.

If you include the **vpn-apply-export** statement in the BGP configuration, both the VRF export and BGP group or neighbor export policies are applied (VRF first, then BGP) before routes are advertised in the VPN routing tables to other PE routers.

When you include the **vpn-apply-export** statement, be aware of the following:

- Routes imported into the `l3vpn.bgp.0` routing table retain the attributes of the original routes (for example, an OSPF route remains an OSPF route even when it is stored in the `l3vpn.bgp.0` routing table). You should be aware of this when you configure an export policy for connections between an IBGP PE router and a PE router, a route reflector and a PE router, or AS boundary router (ASBR) peer routers.
- By default, all routes in the `l3vpn.bgp.0` routing table are exported to the IBGP peers. If the last statement of the export policy is deny all and if the export policy does not specifically match on routes in the `l3vpn.bgp.0` routing table, no routes are exported.

To apply both the VRF export and BGP export policies to VPN routes, include the **vpn-apply-export** statement:

```
vpn-apply-export;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Configuring a VRF Target

Including the **vrf-target** statement in the configuration for a VRF target community causes default VRF import and export policies to be generated that accept and tag routes with the specified target community. You can still create more complex policies by explicitly configuring VRF import and export policies. These policies override the default policies generated when you configure the **vrf-target** statement.

If you do not configure the **import** and **export** options of the **vrf-target** statement, the specified community string is applied in both directions. The **import** and **export** keywords give you more flexibility, allowing you to specify a different community for each direction.

The syntax for the VRF target community is not a name. You must specify it in the format **target:x.y**. A community name cannot be specified because this would also require you to configure the community members for that community using the **policy-options** statement. If you define the **policy-options** statements, then you can just configure VRF import and export policies as usual. The purpose of the **vrf-target** statement is to simplify the configuration by allowing you to configure most statements at the **[edit routing-instances]** hierarchy level.

To configure a VRF target, include the **vrf-target** statement:

```
vrf-target community;
```

You can include this statement at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name*]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]**

An example of how you might configure the **vrf-target** statement follows:

```
[edit routing-instances sample]
vrf-target target:69:102;
```

To configure the **vrf-target** statement with the **export** and **import** options, include the following statements:

```
vrf-target {
  export community-name;
  import community-name;
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]

Configuring the Route Origin for VPNs

You can use route origin to prevent routes learned from one customer edge (CE) router marked with origin community from being advertised back to it from another CE router in the same AS.

In the example, the route origin is used to prevent routes learned from CE Router A that are marked with origin community from being advertised back to CE Router E by AS 200. The example topology is shown in [Figure 3 on page 32](#).

Figure 3: Network Topology of Site of Origin Example

In this topology, CE Router A and CE Router E are in the same AS (AS200). They use EBGP to exchange routes with their respective provider edge (PE) routers, PE Router B and PE Router D. The two CE routers have a back connection.

The following sections describe how to configure the route origin for a group of VPNs:

- [Configuring the Site of Origin Community on CE Router A on page 33](#)
- [Configuring the Community on CE Router A on page 33](#)
- [Applying the Policy Statement on CE Router A on page 33](#)
- [Configuring the Policy on PE Router D on page 34](#)
- [Configuring the Community on PE Router D on page 34](#)
- [Applying the Policy on PE Router D on page 35](#)

Configuring the Site of Origin Community on CE Router A

The following section describes how to configure CE Router A to advertise routes with a site of origin community to PE Router B for this example.

NOTE: In this example, direct routes are configured to be advertised, but any route can be configured.

Configure a policy to advertise routes with **my-soo** community on CE Router A as follows:

```
[edit]
policy-options {
  policy-statement export-to-my-isp {
    term a {
      from {
        protocol direct;
      }
      then {
        community add my-soo;
        accept;
      }
    }
  }
}
```

Configuring the Community on CE Router A

Configure the **my-soo** community on CE Router A as follows:

```
[edit]
policy-options {
  community my-soo {
    members origin:100:1;
  }
}
```

Applying the Policy Statement on CE Router A

Apply the export-to-my-isp policy statement as an export policy to the EBGp peering on the CE Router A as follows:

```
[edit]
protocols {
  bgp {
    group my_isp {
      export export-to-my-isp;
    }
  }
}
```

When you issue the **show route receive-protocol bgp detail** command, you should see the following routes originated from PE Router B with **my-soo** community:

```
user@host> show route receive-protocol bgp 10.12.99.2 detail
inet.0: 16 destinations, 16 routes (15 active, 0 holddown, 1 hidden)
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
vpn_blue.inet.0: 8 destinations, 10 routes (8 active, 0 holddown, 0 hidden)
* 10.12.33.0/30 (2 entries, 1 announced)
    Nexthop: 10.12.99.2
    AS path: 100 I
    Communities: origin:100:1
10.12.99.0/30 (2 entries, 1 announced)
    Nexthop: 10.12.99.2
    AS path: 100 I
    Communities: origin:100:1
* 10.255.71.177/32 (1 entry, 1 announced)
    Nexthop: 10.12.99.2
    AS path: 100 I
    Communities: origin:100:1
* 192.168.64.0/21 (1 entry, 1 announced)
    Nexthop: 10.12.99.2
    AS path: 100 I
    Communities: origin:100:1
iso.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
mpls.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)
bgp.l3vpn.0: 4 destinations, 4 routes (4 active, 0 holddown, 0 hidden)
inet6.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
__juniper_private1__.inet6.0: 1 destinations, 1 routes (1 active, 0 holddown, 0
hidden)
```

Configuring the Policy on PE Router D

Configure a policy on PE Router D that prevents routes with **my-soo** community tagged by CE Router A from being advertised to CE Router E as follows:

```
[edit]
policy-options {
  policy-statement soo-ce1-policy {
    term a {
      from {
        community my-soo;
      }
      then {
        reject;
      }
    }
  }
}
```

Configuring the Community on PE Router D

Configure the community on PE Router D as follows:

```
[edit]
policy-options {
  community my-soo {
    members origin:100:1;
  }
}
```

```

    }
}

```

Applying the Policy on PE Router D

To prevent routes learned from CE Router A from being advertised to CE Router E (the two routers can communicate these routes directly), apply the **soo-ce1-policy** policy statement as an export policy to the PE Router D and CE Router E EBGp session **vpn_blue**.

View the EBGp session on PE Router D using the **show routing-instances** command.

```

user@host# show routing-instances
vpn_blue {
  instance-type vrf;
  interface fe-2/0/0.0;
  vrf-target target:100:200;
  protocols {
    bgp {
      group ce2 {
        advertise-peer-as;
        peer-as 100;
        neighbor 10.12.99.6;
      }
    }
  }
}

```

Apply the **soo-ce1-policy** policy statement as an export policy to the PE Router D and CE Router E EBGp session **vpn_blue** as follows:

```

[edit routing-instances]
vpn_blue {
  protocols {
    bgp {
      group ce2 {
        export soo-ce1-policy;
      }
    }
  }
}

```

CHAPTER 4

Distributing VPN Routes with Target Filtering

Configuring BGP Route Target Filtering for VPNs

BGP route target filtering allows you to distribute VPN routes to only the routers that need them. In VPN networks without BGP route target filtering configured, BGP distributes all VPN routes to all VPN peer routers.

For more information about BGP route target filtering, see RFC 4684, *Constrained Route Distribution for Border Gateway Protocol/MultiProtocol Label Switching (BGP/MPLS) Internet Protocol (IP) Virtual Private Networks (VPNs)*.

The following sections provide an overview of BGP route target filtering and how to configure it for VPNs:

- [BGP Route Target Filtering Overview on page 37](#)
- [Configuring BGP Route Target Filtering for VPNs on page 38](#)

BGP Route Target Filtering Overview

PE routers, unless they are configured as route reflectors or are running an EBGp session, discard any VPN routes that do not include a route target extended community as specified in the local VRF import policies. This is the default behavior of the Junos OS.

However, unless it is explicitly configured not to store VPN routes, any router configured either as a route reflector or border router for a VPN address family must store all of the

VPN routes that exist in the service provider's network. Also, though PE routers can automatically discard routes that do not include a route target extended community, route updates continue to be generated and received.

By reducing the number of routers receiving VPN routes and route updates, BGP route target filtering helps to limit the amount of overhead associated with running a VPN. BGP route target filtering is most effective at reducing VPN-related administrative traffic in networks where there are many route reflectors or AS border routers that do not participate in the VPNs directly (not acting as PE routers for the CE devices).

BGP route target filtering uses standard UPDATE messages to distribute route target extended communities between routers. The use of UPDATE messages allows BGP to use its standard loop detection mechanisms, path selection, policy support, and database exchange implementation.

Configuring BGP Route Target Filtering for VPNs

BGP route target filtering is enabled through the exchange of the **route-target** address family, stored in the `bgp.rtarget.0` routing table. Based on the **route-target** address family, the route target NLRI (address family indicator [AFI]=1, subsequent AFI [SAFI]=132) is negotiated with its peers.

On a system that has locally configured VRF instances, BGP automatically generates local routes corresponding to targets referenced in the **vrf-import** policies.

To configure BGP route target filtering, include the **family route-target** statement:

```
family route-target {  
    advertise-default;  
    external-paths number;  
    prefix-limit number;  
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

The **advertise-default**, **external-paths**, and **prefix-limit** statements affect the BGP route target filtering configuration as follows:

- The **advertise-default** statement causes the router to advertise the default route target route (0:0:0/0) and suppress all routes that are more specific. This can be used by a route reflector on BGP groups consisting of neighbors that act as PE routers only. PE routers often need to advertise all routes to the route reflector.

Suppressing all route target advertisements other than the default route reduces the amount of information exchanged between the route reflector and the PE routers. The Junos OS further helps to reduce route target advertisement overhead by not maintaining dependency information unless a nondefault route is received.

- The **external-paths** statement (which has a default value of 1) causes the router to advertise the VPN routes that reference a given route target. The number you specify determines the number of external peer routers (currently advertising that route target) that receive the VPN routes.

- The **prefix-limit** statement limits the number of prefixes that can be received from a peer router.

The **route-target**, **advertise-default**, and **external-path** statements affect the RIB-OUT state and must be consistent between peer routers that share the same BGP group. The **prefix-limit** statement affects the receive side only and can have different settings between different peer routers in a BGP group.

Example: BGP Route Target Filtering for VPNs

BGP route target filtering is enabled by configuring the **family route-target** statement at the appropriate BGP hierarchy level. This statement enables the exchange of a new **route-target** address family, which is stored in the `bgp.target.0` routing table.

The following configuration illustrates how you could configure BGP route target filtering for a BGP group titled **to_vpn04**:

```
[edit]
protocols {
  bgp {
    group to_vpn04 {
      type internal;
      local-address 10.255.14.182;
      peer-as 200;
      neighbor 10.255.14.174 {
        family inet-vpn {
          unicast;
        }
        family route-target;
      }
    }
  }
}
```

The following configuration illustrates how you could configure a couple of local VPN routing and forwarding (VRF) routing instances to take advantage of the functionality provided by BGP route target filtering. Based on this configuration, BGP would automatically generate local routes corresponding to the route targets referenced in the VRF import policies (note the targets defined by the **vrf-target** statements).

```
[edit]
```

```

routing-instances {
  vpn1 {
    instance-type vrf;
    interface t1-0/1/2.0;
    vrf-target target:200:101;
    protocols {
      ospf {
        export bgp-routes;
        area 0.0.0.0 {
          interface t1-0/1/2.0;
        }
      }
    }
  }
  vpn2 {
    instance-type vrf;
    interface t1-0/1/2.1;
    vrf-target target:200:102;
    protocols {
      ospf {
        export bgp-routes;
        area 0.0.0.0 {
          interface t1-0/1/2.1;
        }
      }
    }
  }
}

```

Issue the **show route table bgp.rtarget.0** show command to verify the BGP route target filtering configuration:

```

user@host> show route table bgp.rtarget.0
bgp.rtarget.0: 4 destinations, 6 routes (4 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
200:200:101/96
    *[RTarget/5] 00:10:00
        Local
200:200:102/96
    *[RTarget/5] 00:10:00
        Local
200:200:103/96
    *[BGP/170] 00:09:48, localpref 100, from 10.255.14.174
        AS path: I
        > t3-0/0/0.0
200:200:104/96
    *[BGP/170] 00:09:48, localpref 100, from 10.255.14.174
        AS path: I
        > t3-0/0/0.0

```

The **show** command display format for route target prefixes is:

AS number:route target extended community/length

The first number represents the autonomous system (AS) of the router that sent this advertisement. The remainder of the display follows the Junos **show** command convention for extended communities.

The output from the **show route table bgp-rtarget.0** command displays the locally generated and remotely generated routes.

The first two entries correspond to the route targets configured for the two local VRF routing instances (**vpn1** and **vpn2**):

- **200:200:101/96**—Community **200:101** in the **vpn1** routing instance
- **200:200:102/96**—Community **200:102** in the **vpn2** routing instance

The last two entries are prefixes received from a BGP peer:

- **200:200:103/96**—Tells the local router that routes tagged with this community (**200:103**) should be advertised to peer **10.255.14.174** through **t3-0/0/0.0**
- **200:200:104/96**—Tells the local router that routes tagged with this community (**200:104**) should be advertised to peer **10.255.14.174** through **t3-0/0/0.0**

Example: Configuring BGP Route Target Filtering for VPNs

BGP route target filtering reduces the number of routers that receive VPN routes and route updates, helping to limit the amount of overhead associated with running a VPN. BGP route target filtering is most effective at reducing VPN-related administrative traffic in networks where there are many route reflectors or AS border routers that do not participate in the VPNs directly (do not act as PE routers for the CE devices).

Figure 4 on page 41 illustrates the topology for a network configured with BGP route target filtering for a group of VPNs.

Figure 4: BGP Route Target Filtering Enabled for a Group of VPNs

The following sections describe how to configure BGP route target filtering for a group of VPNs:

- [Configure BGP Route Target Filtering on Router PE1 on page 42](#)
- [Configure BGP Route Target Filtering on Router PE2 on page 43](#)
- [Configure BGP Route Target Filtering on the Route Reflector on page 46](#)
- [Configure BGP Route Target Filtering on Router PE3 on page 47](#)

Configure BGP Route Target Filtering on Router PE1

This section describes how to enable BGP route target filtering on Router PE1 for this example.

Configure the routing options on router PE1 as follows:

```
[edit]
routing-options {
  route-distinguisher-id 10.255.14.182;
  autonomous-system 198;
}
```

Configure the BGP protocol on Router PE1 as follows:

```
[edit]
protocols {
  bgp {
    group to_VPN_D {
      type internal;
      local-address 10.255.14.182;
      peer-as 198;
      neighbor 10.255.14.174 {
        family inet-vpn {
          unicast;
        }
        family route-target;
      }
    }
  }
}
```

Configure the **vpn1** routing instance as follows:

```
[edit]
routing-instances {
  vpn1 {
    instance-type vrf;
    interface t1-0/1/2.0;
    vrf-target target:198:101;
    protocols {
      ospf {
        export bgp-routes;
        area 0.0.0.0 {
          interface t1-0/1/2.0;
        }
      }
    }
  }
}
```

Configure the **vpn2** routing instance on Router PE1 as follows:

```
[edit]
routing-instances {
  vpn2 {
```

```

instance-type vrf;
interface t1-0/1/2.1;
vrf-target target:198:102;
protocols {
  ospf {
    export bgp-routes;
    area 0.0.0.0 {
      interface t1-0/1/2.1;
    }
  }
}
}
}

```

Once you have implemented this configuration, you should see the following when you issue a **show route table bgp.rtarget.0** command:

```

user@host> show route table bgp.rtarget.0
bgp.rtarget.0: 4 destinations, 6 routes (4 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

198.198:101/96
    *[RTarget/5] 00:27:42
        Local
        [BGP/170] 00:27:30, localpref 100, from
10.255.14.174
    AS path: I
    > via t3-0/0/0.0
198.198:102/96
    *[RTarget/5] 00:27:42
        Local
        [BGP/170] 00:27:30, localpref 100, from
10.255.14.174
    AS path: I
    > via t3-0/0/0.0
198.198:103/96
    *[BGP/170] 00:27:30, localpref 100, from
10.255.14.174
    AS path: I
    > via t3-0/0/0.0
198.198:104/96
    *[BGP/170] 00:27:30, localpref 100, from
10.255.14.174
    AS path: I
    > via t3-0/0/0.0

```

Configure BGP Route Target Filtering on Router PE2

This section describes how to enable BGP route target filtering on Router PE2 for this example.

Configure the routing options on Router PE2 as follows:

```

[edit]
routing-options {
  route-distinguisher-id 10.255.14.176;
  autonomous-system 198;
}

```

Configure the BGP protocol on Router PE2 as follows:

```
[edit]
protocols {
  bgp {
    group to_vpn04 {
      type internal;
      local-address 10.255.14.176;
      peer-as 198;
      neighbor 10.255.14.174 {
        family inet-vpn {
          unicast;
        }
        family route-target;
      }
    }
  }
}
```

Configure the **vpn1** routing instance on Router PE2 as follows:

```
[edit]
routing-instances {
  vpn1 {
    instance-type vrf;
    interface t3-0/0/0.0;
    vrf-target target:198:101;
    protocols {
      bgp {
        group vpn1 {
          type external;
          peer-as 101;
          as-override;
          neighbor 10.49.11.2;
        }
      }
    }
  }
}
```

Configure the **vpn2** routing instance on Router PE2 as follows:

```
[edit]
routing-instances {
  vpn2 {
    instance-type vrf;
    interface t3-0/0/0.1;
    vrf-target target:198:102;
    protocols {
      bgp {
        group vpn2 {
          type external;
          peer-as 102;
          as-override;
          neighbor 10.49.21.2;
        }
      }
    }
  }
}
```

```

    }
  }
}

```

Configure the **vpn3** routing instance on Router PE2 as follows:

```

[edit]
routing-instances {
  vpn3 {
    instance-type vrf;
    interface t3-0/0/0.2;
    vrf-import vpn3-import;
    vrf-export vpn3-export;
    protocols {
      bgp {
        group vpn3 {
          type external;
          peer-as 103;
          as-override;
          neighbor 10.49.31.2;
        }
      }
    }
  }
}

```

Once you have configured router PE2 in this manner, you should see the following when you issue the **show route table bgp.rtarget.0** command:

```

user@host> show route table bgp.rtarget.0
bgp.rtarget.0: 4 destinations, 7 routes (4 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

198.198:101/96
    *[RTarget/5] 00:28:15
        Local
        [BGP/170] 00:28:03, localpref 100, from
10.255.14.174
    AS path: I
    > via t1-0/1/0.0
198.198:102/96
    *[RTarget/5] 00:28:15
        Local
        [BGP/170] 00:28:03, localpref 100, from
10.255.14.174
    AS path: I
    > via t1-0/1/0.0
198.198:103/96
    *[RTarget/5] 00:28:15
        Local
        [BGP/170] 00:28:03, localpref 100, from
10.255.14.174
    AS path: I
    > via t1-0/1/0.0
198.198:104/96
    *[BGP/170] 00:28:03, localpref 100, from
10.255.14.174
    AS path: I
    > via t1-0/1/0.0

```

Configure BGP Route Target Filtering on the Route Reflector

This section illustrates how to enable BGP route target filtering on the route reflector for this example.

Configure the routing options on the route reflector as follows:

```
[edit]
routing-options {
  route-distinguisher-id 10.255.14.174;
  autonomous-system 198;
}
```

Configure the BGP protocol on the route reflector as follows:

```
[edit]
protocols {
  bgp {
    group rr-group {
      type internal;
      local-address 10.255.14.174;
      cluster 10.255.14.174;
      peer-as 198;
      neighbor 10.255.14.182 {
        description to_PE1_vpn12;
        family inet-vpn {
          unicast;
        }
        family route-target;
      }
      neighbor 10.255.14.176 {
        description to_PE2_vpn06;
        family inet-vpn {
          unicast;
        }
        family route-target;
      }
      neighbor 10.255.14.178 {
        description to_PE3_vpn08;
        family inet-vpn {
          unicast;
        }
        family route-target;
      }
    }
  }
}
```

Once you have configured the route reflector in this manner, you should see the following when you issue the **show route table bgp.rtarget.0** command:

```
user@host> show route table bgp.rtarget.0
bgp.rtarget.0: 4 destinations, 8 routes (4 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

198.198:101/96
```

```

10.255.14.176      *[BGP/170] 00:29:03, localpref 100, from
                   AS path: I
                   > via t1-0/2/0.0
10.255.14.178      [BGP/170] 00:29:03, localpref 100, from
                   AS path: I
                   > via t3-0/1/1.0
10.255.14.182      [BGP/170] 00:29:03, localpref 100, from
                   AS path: I
                   > via t3-0/1/3.0
198.198:102/96     *[BGP/170] 00:29:03, localpref 100, from
10.255.14.176      AS path: I
                   > via t1-0/2/0.0
10.255.14.182      [BGP/170] 00:29:03, localpref 100, from
                   AS path: I
                   > via t3-0/1/3.0
198.198:103/96     *[BGP/170] 00:29:03, localpref 100, from
10.255.14.176      AS path: I
                   > via t1-0/2/0.0
10.255.14.178      [BGP/170] 00:29:03, localpref 100, from
                   AS path: I
                   > via t3-0/1/1.0
198.198:104/96     *[BGP/170] 00:29:03, localpref 100, from
10.255.14.178      AS path: I
                   > via t3-0/1/1.0

```

Configure BGP Route Target Filtering on Router PE3

The following section describes how to enable BGP route target filtering on Router PE3 for this example.

Configure the routing options on Router PE3 as follows:

```

[edit]
routing-options {
  route-distinguisher-id 10.255.14.178;
  autonomous-system 198;
}

```

Configure the BGP protocol on Router PE3 as follows:

```

[edit]
protocols {
  bgp {
    group to_vpn04 {
      type internal;
      local-address 10.255.14.178;
      peer-as 198;
      neighbor 10.255.14.174 {

```

```
        family inet-vpn {
            unicast;
        }
        family route-target;
    }
}
}
```

Configure the **vpn1** routing instance on Router PE3 as follows:

```
[edit]
routing-instances {
  vpn1 {
    instance-type vrf;
    interface t3-0/0/0.0;
    vrf-target target:198:101;
    protocols {
      rip {
        group vpn1 {
          export bgp-routes;
          neighbor t3-0/0/0.0;
        }
      }
    }
  }
}
```

Configure the **vpn3** routing instance on Router PE3 as follows:

```
[edit]
routing-instances {
  vpn3 {
    instance-type vrf;
    interface t3-0/0/0.1;
    vrf-target target:198:103;
    protocols {
      rip {
        group vpn3 {
          export bgp-routes;
          neighbor t3-0/0/0.1;
        }
      }
    }
  }
}
```

Configure the **vpn4** routing instance on Router PE3 as follows:

```
[edit]
routing-instances {
  vpn4 {
    instance-type vrf;
    interface t3-0/0/0.2;
    vrf-target target:198:104;
    protocols {
      rip {
```

```

group vpn4 {
  export bgp-routes;
  neighbor t3-0/0/0.2;
}
}
}
}
}

```

Once you have configured Router PE3 in this manner, you should see the following when you issue the **show route table bgp.rtarget.0** command:

```

user@host> show route table bgp.rtarget.0
bgp.rtarget.0: 4 destinations, 7 routes (4 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

198.198:101/96
    *[RTarget/5] 00:29:42
        Local
        [BGP/170] 00:29:30, localpref 100, from
10.255.14.174
    AS path: I
    > via t3-0/0/1.0
198.198:102/96
    *[BGP/170] 00:29:29, localpref 100, from
10.255.14.174
    AS path: I
    > via t3-0/0/1.0
198.198:103/96
    *[RTarget/5] 00:29:42
        Local
        [BGP/170] 00:29:30, localpref 100, from
10.255.14.174
    AS path: I
    > via t3-0/0/1.0
198.198:104/96
    *[RTarget/5] 00:29:42
        Local
        [BGP/170] 00:29:30, localpref 100, from
10.255.14.174
    AS path: I
    > via t3-0/0/1.0

```

Configuring Static Route Target Filtering for VPNs

The BGP VPN route target extended community (RFC 4360, *BGP Extended Communities Attribute*) is used to determine VPN membership. Static route target filtering helps to prevent resources from being consumed in portions of the network where the VPN routes are not needed due to the lack of member PE routers (RFC 4684, *Constrained Route Distribution for Border Gateway Protocol/MultiProtocol Label Switching (BGP/MPLS) Internet Protocol (IP) Virtual Private Networks (VPNs)*). Routers can originate routes into the RT-Constrain protocol to indicate their interest in receiving VPN routes containing route targets that match the RT-Constrain NLRI.

To configure static route target filtering for VPNs:

- Configure the **route-target-filter** statement at the **[edit routing-options rib bgp.rtarget.0 static]** hierarchy level.

The following example illustrates how you could configure the **route-target-filter** statement:

```
[edit routing-options rib bgp.rtarget.0 static]
route-target-filter destination {
  group bgp-group;
  local;
  neighbor bgp-peer;
}
```

- You can display route target filtering information using the **show bgp group rtf detail** command.

Understanding Proxy BGP Route Target Filtering for VPNs

BGP route target filtering (also known as route target constrain, or RTC) allows you to distribute VPN routes to only the devices that need them. In VPN networks without BGP route target filtering configured, BGP distributes all VPN routes to all VPN peer devices, which can strain network resources. The route target filtering feature was introduced to reduce the number of devices receiving VPN routes and VPN routing updates, thereby limiting the amount of overhead associated with running a VPN. The Junos OS implementation for BGP route target filtering is based on RFC 4684, *Constrained Route Distribution for Border Gateway Protocol/MultiProtocol Label Switching (BGP/MPLS) Internet Protocol (IP) Virtual Private Networks (VPNs)*.

What if you have a network environment where route target filtering is not widely deployed, or what if some devices do not support route target filtering? For example, you might have a BGP speaker with route target filtering enabled that is peered with a BGP speaker that does not support or have route target filtering configured. In this case, the BGP speaker with route target filtering configured must advertise default route target

membership (RT membership) on behalf of its peer. The route target filtering resource savings are unrealized because the device supporting the filtering must now send all VPN routes to the device that does not support the filter. Proxy BGP route target filtering (or Proxy RTC) permits the generation of RT membership for devices that do not support route target filtering. This eases the deployment of route target filtering in networks where it is incompletely deployed or not fully supported.

Proxy BGP route target filtering allows you to distribute proxy RT membership advertisements created from the received BGP VPN routes to other devices in the network that need them. These are known as proxy advertisements because the device creates the RT membership on behalf of its peers without the route target filtering functionality. Proxy BGP route target filtering uses BGP route target extended communities that are exported to a specific BGP speaker to generate the route targets. Generated proxy RTC routes are stored in the `bgp.target.0` routing table.

You can also configure a policy to control which VPN routes are used to generate the proxy RTC routes. This can help control which RT membership is generated by the proxying device. In addition, you can configure a policy to reduce the memory overhead associated with proxy RTC. Proxy RTC only uses additional memory on a per-VPN route basis when it is permitted by a policy to be used for generating RT membership.

Example: Configuring Proxy BGP Route Target Filtering for VPNs

This example shows how to configure proxy BGP route target filtering (also known as proxy route target constrain, or proxy RTC).

- [Requirements on page 51](#)
- [Overview on page 52](#)
- [Configuration on page 53](#)
- [Verification on page 66](#)

Requirements

This example uses the following hardware and software components:

- Four Juniper Networks devices that can be a combination of M Series, MX Series, or T Series routers.
- Junos OS Release 12.2 or later on one or more devices configured for proxy BGP route filtering. In this example, you explicitly configure proxy BGP route filtering on the route reflectors.

Before configuring proxy BGP route target filtering, make sure that you are familiar with and understand the following concepts:

- [Layer 2 VPNs on page 123](#)
- [Layer 3 VPNs](#)
- [Route distinguishers](#)
- [Route targets on page 25](#)
- [BGP route target filtering on page 37](#)
- [BGP extended communities](#)

Overview

Route target filtering decreases the number of devices in a network that receive VPN routes that are not needed. Proxy BGP route target filtering allows networks to take advantage of route target filtering in locations where the feature is not currently supported. By configuring this feature, you can realize many of the same network resource savings that are available to you if your network fully supported BGP route target filtering.

To configure proxy BGP route target filtering, you include the **family route-target proxy-generate** statement on the devices that will distribute proxy route target membership (RT membership) advertisements for the devices that do not support BGP route target filtering. The proxy BGP route target filtering routes are then stored in the `bgp.rtarget.0` routing table.

Proxy BGP route target filtering is intended to create RT membership advertisements for devices that do not support the BGP route target filtering feature. If the **proxy-generate** statement is present, but the route target family is negotiated with the BGP peer, the proxy-generate functionality is disabled. This allows simplified configuration of BGP peer groups where a portion of the peers in the group support route target filtering but others do not. In such an example case, the **family route-target proxy-generate** statement might be part of the BGP peer group configuration.

.....

NOTE: When deploying proxy BGP route target filtering in your network, the **advertise-default** statement for BGP route target filtering causes the device to advertise the default route target route (0:0:0/0) and suppress all routes that are more specific. If you have proxy BGP route target filtering configured on one device and one or more peers have the **advertise-default** statement configured as part of their BGP route target filtering configuration, the **advertise-default** configuration is ignored.

.....

Topology Diagram

[Figure 5 on page 53](#) shows the topology used in this example.

Figure 5: Proxy BGP Route Target Filtering Topology

In this example, BGP route target filtering is configured on the route reflectors (Device RR1 and Device RR2) and the provider edge (PE) Device PE2, but the other PE, Device PE1, does not support the BGP route target filtering functionality. Device PE2 has four VPNs configured (vpn1, vpn2, vpn3, and vpn4). Device PE1 has two VPNs configured (vpn1 and vpn2), so this device is only interested in receiving route updates for vpn1 and vpn2. Currently, this is impossible because both route reflectors (Device RR1 and Device RR2) learn and share information about all of the incoming VPN routes (vpn1 through vpn4) with Device PE1. In the sample topology, all devices participate in autonomous system (AS) 203, OSPF is the configured interior gateway protocol (IGP), and LDP is the signaling protocol used by the VPNs. In this example, we use static routes in the VPN routing and forwarding (VRF) instances to generate VPN routes. This is done in place of using a PE to customer edge (CE) protocol such as OSPF or BGP.

To minimize the number of VPN route updates being processed by Device PE1, you include the **family route-target proxy-generate** statement to configure proxy BGP route target filtering on each route reflector. Each route reflector has a peering session with Device PE1 and supports route target filtering to the core. However, Device PE1 does not support route target filtering, so the network resource savings are unrealized by Device PE1 since it receives all of the VPN updates. By configuring proxy BGP route target filtering on the peering sessions facing Device PE1, you limit the number of VPN updates processed by Device PE1, and the route reflectors generate the proxy BGP route target routes for Device PE1 throughout the network.

Configuration

```

Configuring Device PE1**Step-by-Step
Procedure**

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Device PE1:

1. Configure the interfaces.

[edit interfaces]

```
user@PE1# set ge-1/0/0 unit 0 description PE1-to-RR1
user@PE1# set ge-1/0/0 unit 0 family inet address 10.49.0.1/30
user@PE1# set ge-1/0/0 unit 0 family mpls
```

```
user@PE1# set ge-1/0/1 unit 0 description PE1-to-RR2
user@PE1# set ge-1/0/1 unit 0 family inet address 10.49.10.1/30
user@PE1# set ge-1/0/1 unit 0 family mpls
```

2. Configure the route distinguisher and the AS number.

```
[edit routing-options]
user@PE1# set route-distinguisher-id 10.255.163.58
user@PE1# set autonomous-system 203
```

3. Configure LDP as the signaling protocol used by the VPN.

```
[edit protocols ldp]
user@PE1# set interface ge-1/0/0
user@PE1# set interface ge-1/0/1
```

4. Configure BGP.

```
[edit protocols bgp group internal]
user@PE1# set type internal
user@PE1# set local-address 10.255.163.58
user@PE1# set neighbor 10.255.165.220 family inet-vpn unicast
user@PE1# set neighbor 10.255.165.28 family inet-vpn unicast
```

5. Configure OSPF.

```
[edit protocols ospf area 0.0.0.0]
user@PE1# set interface ge-1/0/0
user@PE1# set interface ge-1/0/1
user@PE1# set interface lo0.0 passive
```

6. Configure the VPN routing instances.

```
[edit routing-instances vpn1]
user@PE1# set instance-type vrf
user@PE1# set vrf-target target:203:100
user@PE1# set routing-options static route 203.0.113.1/24 discard

[edit routing-instances vpn2]
user@PE1# set instance-type vrf
user@PE1# set vrf-target target:203:101
user@PE1# set routing-options static route 203.0.113.2/24 discard
```

7. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE1# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@PE1# show interfaces
ge-1/0/0 {
  unit 0 {
    description PE1-to-RR1;
    family inet {
      address 10.49.0.1/30;
    }
    family mpls;
  }
}
ge-1/0/1 {
  unit 0 {
    description PE1-to-RR2;
    family inet {
      address 10.49.10.1/30;
    }
    family mpls;
  }
}

user@PE1# show protocols

    static {
      route 203.0.113.2/24 discard;
    }
  }
}
```

Configuring Device RR1

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Device RR1:

1. Configure the interfaces.

```
[edit interfaces]
user@RR1# set ge-1/0/0 unit 0 description RR1-to-PE1
user@RR1# set ge-1/0/0 unit 0 family inet address 10.49.0.2/30
user@RR1# set ge-1/0/0 unit 0 family mpls
```

```
user@RR1# set ge-1/0/1 unit 0 description RR1-to-PE2
user@RR1# set ge-1/0/1 unit 0 family inet address 10.50.0.2/30
user@RR1# set ge-1/0/1 unit 0 family mpls
```

2. Configure the route distinguisher and the AS number.

```
[edit routing-options]
user@RR1# set route-distinguisher-id 10.255.165.220
user@RR1# set autonomous-system 203
```

3. Configure LDP as the signaling protocol used by the VPN.

```
[edit protocols ldp]
user@RR1# set interface ge-1/0/0
user@RR1# set interface ge-1/0/1
```

4. Configure BGP.

```
[edit protocols bgp group internal]
user@RR1# set type internal
user@RR1# set local-address 10.255.165.220
user@RR1# set cluster 198.51.100.1
user@RR1# set neighbor 10.255.163.58 description vpn1-to-pe1 family inet-vpn
unicast
user@RR1# set neighbor 10.255.168.42 description vpn1-to-pe2 family inet-vpn
unicast
```

5. Configure BGP route target filtering on the peering session with Device PE2.

```
[edit protocols bgp group internal]
user@RR1# set neighbor 10.255.168.42 family route-target
```

6. Configure proxy BGP route target filtering on the peering session with Device PE1.

```
[edit protocols bgp group internal]
user@RR1# set neighbor 10.255.163.58 family route-target proxy-generate
```

7. Configure OSPF.

```
[edit protocols ospf area 0.0.0.0]
user@RR1# set interface ge-1/0/0
user@RR1# set interface ge-1/0/1
user@RR1# set interface lo0.0 passive
```

8. If you are done configuring the device, commit the configuration.

```
[edit]
user@RR1# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols** and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@RR1# show interfaces
ge-1/0/0 {
  unit 0 {
    description RR1-to-PE1;
    family inet {
      address 10.49.0.2/30;
    }
    family mpls;
  }
}
ge-1/0/1 {
  unit 0 {
    description RR1-to-PE2;
    family inet {
      address 10.50.0.2/30;
    }
  }
}
```

```
        family mpls;
    }
}

```

Configuring Device RR2

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Device RR2:

1. Configure the interfaces.

```
[edit interfaces]
user@RR2# set ge-1/0/0 unit 0 description RR2-to-PE1
user@RR2# set ge-1/0/0 unit 0 family inet address 10.49.10.2/30
user@RR2# set ge-1/0/0 unit 0 family mpls
```

```
user@RR2# set ge-1/0/1 unit 0 description RR2-to-PE2
user@RR2# set ge-1/0/1 unit 0 family inet address 10.50.10.2/30
user@RR2# set ge-1/0/1 unit 0 family mpls
```

2. Configure the route distinguisher and the AS number.

```
[edit routing-options]
user@RR2# set route-distinguisher-id 10.255.165.28
user@RR2# set autonomous-system 203
```

3. Configure LDP as the signaling protocol used by the VPN.

```
[edit protocols ldp]
user@RR2# set interface ge-1/0/0
user@RR2# set interface ge-1/0/1
```

4. Configure BGP.

```
[edit protocols bgp group internal]
user@RR2# set type internal
user@RR2# set local-address 10.255.165.28
user@RR2# set cluster 198.51.100.1
user@RR2# set neighbor 10.255.163.58 description vpn2-to-pe1 family inet-vpn
unicast
user@RR2# set neighbor 10.255.168.42 description vpn2-to-pe2 family inet-vpn
unicast
```

5. Configure BGP route target filtering on the peering session with Device PE2.

```
[edit protocols bgp group internal]
user@RR2# set neighbor 10.255.168.42 family route-target
```

6. Configure proxy BGP route target filtering on the peering session with Device PE1.

```
[edit protocols bgp group internal]
user@RR2# set neighbor 10.255.163.58 family route-target proxy-generate
```

7. Configure OSPF.

```
[edit protocols ospf area 0.0.0.0]
user@RR2# set interface ge-1/0/0
user@RR2# set interface ge-1/0/1
user@RR2# set interface lo0.0 passive
```

8. If you are done configuring the device, commit the configuration.

```
[edit]
user@RR2# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

Configuring Device PE2

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Device PE2:

1. Configure the interfaces.

```

[edit interfaces]
user@PE2# set ge-1/0/0 unit 0 description PE2-to-RR1
user@PE2# set ge-1/0/0 unit 0 family inet address 10.50.0.1/30
user@PE2# set ge-1/0/0 unit 0 family mpls

user@PE2# set ge-1/0/1 unit 0 description PE2-to-RR2
user@PE2# set ge-1/0/1 unit 0 family inet address 10.50.10.1/30
user@PE2# set ge-1/0/1 unit 0 family mpls

```

2. Configure the route distinguisher and the AS number.

```

[edit routing-options]
user@PE2# set route-distinguisher-id 10.255.168.42
user@PE2# set autonomous-system 203

```

3. Configure LDP as the signaling protocol used by the VPN.

```

[edit protocols ldp]
user@PE2# set interface ge-1/0/0
user@PE2# set interface ge-1/0/1

```

4. Configure BGP.

```

[edit protocols bgp group internal]
user@PE2# set type internal
user@PE2# set local-address 10.255.168.42
user@PE2# set family inet-vpn unicast
user@PE2# set family route-target
user@PE2# set neighbor 10.255.165.220
user@PE2# set neighbor 10.255.165.28

```

5. Configure OSPF.

```

[edit protocols ospf area 0.0.0.0]
user@PE2# set interface ge-1/0/0

```

```
user@PE2# set interface ge-1/0/1
user@PE2# set interface lo0.0 passive
```

6. Configure the VPN routing instances.

```
[edit routing-instances vpn1]
user@PE2# set instance-type vrf
user@PE2# set vrf-target target:203:100
user@PE2# set routing-options static route 203.0.113.1/24 discard

[edit routing-instances vpn2]
user@PE2# set instance-type vrf
user@PE2# set vrf-target target:203:101
user@PE2# set routing-options static route 203.0.113.2/24 discard

[edit routing-instances vpn3]
user@PE2# set instance-type vrf
user@PE2# set vrf-target target:203:103
user@PE2# set routing-options static route 203.0.113.3/24 discard

[edit routing-instances vpn4]
user@PE2# set instance-type vrf
user@PE2# set vrf-target target:203:104
user@PE2# set routing-options static route 203.0.113.4/24 discard
```

7. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE2# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show interfaces

      route 203.0.113.3/24 discard;
    }
  }
}
```

```

    }
  }
  vpn4 {
    instance-type vrf;
    vrf-target target:203:104;
    routing-options {
      static {
        route 203.0.113.4/24 discard;
      }
    }
  }
}

```

Verification

Confirm that the configuration is working properly.

Verifying the Proxy BGP Route Target Routes

Purpose Verify that the proxy BGP route target routes are displayed in the `bgp.rtarget.0` table on Device RR1.

Action From operational mode, enter the `show route table bgp.rtarget.0` command to display the proxy BGP route targets.

```

user@RR1# show route table bgp.rtarget.0
4 destinations, 6 routes (4 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

203:203:100/96
    * [RTarget/5] 00:01:22
      Type Proxy
      for 10.255.163.58
      Local
      [BGP/170] 00:04:55, localpref 100, from 10.255.168.42
      AS path: I, validation-state: unverified
      > to 10.50.0.1 via ge-1/0/1

203:203:101/96
    * [RTarget/5] 00:01:22
      Type Proxy
      for 10.255.163.58
      Local
      [BGP/170] 00:04:55, localpref 100, from 10.255.168.42
      AS path: I, validation-state: unverified
      > to 10.50.0.1 via ge-1/0/1

203:203:103/96
    * [BGP/170] 00:04:55, localpref 100, from 10.255.168.42
      AS path: I, validation-state: unverified
      > to 10.50.0.1 via ge-1/0/1

203:203:104/96
    * [BGP/170] 00:04:55, localpref 100, from 10.255.168.42
      AS path: I, validation-state: unverified
      > to 10.50.0.1 via ge-1/0/1

```

Meaning Device RR1 is generating the proxy BGP route target routes on behalf of its peer Device PE1. The proxy BGP route target routes are identified with the protocol and preference [RTarget/5] and the route target type of **Proxy**.

Example: Configuring an Export Policy for BGP Route Target Filtering for VPNs

This example shows how to configure an export routing policy for BGP route target filtering (also known as route target constrain, or RTC).

- [Requirements on page 67](#)
- [Overview on page 67](#)
- [Configuration on page 69](#)
- [Verification on page 83](#)

Requirements

This example uses the following hardware and software components:

- Four Juniper Networks devices that support BGP route target filtering.
- Junos OS Release 12.2 or later on one or more devices configured for proxy BGP route filtering. In this example, you explicitly configure proxy BGP route filtering on the route reflectors.

Before configuring an export policy for BGP route target filtering, make sure that you are familiar with and understand the following concepts:

- [Layer 2 VPNs on page 123](#)
- [Layer 3 VPNs](#)
- [Route distinguishers](#)
- [Route targets on page 25](#)
- [BGP route target filtering on page 37](#)
- [BGP extended communities](#)

Overview

BGP route target filtering allows you to reduce network resource consumption by distributing route target membership (RT membership) advertisements throughout the network. BGP uses the RT membership information to send VPN routes only to the devices that need them in the network. Similar to other types of BGP reachability, you can apply

a routing policy to route target filtering routes to influence the network. When route target filtering is configured, restricting the flow of route target filtering routes also restricts the VPN routes that might be attracted by this RT membership. Configuring this policy involves:

- Creating a filter that defines the list of route target prefixes.
- Creating a policy to select a subset of the route target filters to use for BGP route target filtering.

To define the list of route target prefixes:

- You configure the **rtf-prefix-list** statement at the **[edit policy-options]** hierarchy level to specify the name of the route target prefix list and one or more route target prefixes to use. This configuration allows you to specify the incoming route target filtering routes that the device will use and then distribute them throughout the network.

To configure the routing policy and apply the route target prefix list to that policy, you can specify the following policy options:

- **family route-target**—(Optional) The route-target family match condition specifies matching BGP route target filtering routes. You define this criteria in the **from** statement. This example shows how to create an export policy using the **family route-target** match condition.
- **protocol route-target**—(Optional) The route-target protocol match condition defines the criteria that an incoming route must match. You define this criteria in the **from** statement. This statement is primarily useful for restricting the policy to locally generated route target filtering routes.

NOTE: When you use the `show route table bgp.rtarget.0` command to view proxy BGP route target filtering routes, you will see the BGP protocol for received routes and the route target protocol routes for local route target filtering routes.

- **rtf-prefix-list name**—The **rtf-prefix-list** statement applies the list of route target prefixes that you already configured to the policy. You define this criteria in the **from** statement.

Topology Diagram

Figure 6 on page 69 shows the topology used in this example.

Figure 6: BGP Route Target Filtering Export Policy Topology

In this example, BGP route target filtering is configured on the route reflectors (Device RR1 and Device RR2) and provider edge (PE) Device PE2. The other PE, Device PE1, does not support BGP route target filtering. Proxy BGP route target filtering is also configured on the peering sessions between the route reflectors and Device PE1 to minimize the number of VPN route updates processed by Device PE1. Device PE2 has four VPNs configured (vpn1, vpn2, vpn3, and vpn4), and Device PE1 has two VPNs configured (vpn1 and vpn2). In the sample topology, all devices participate in autonomous system (AS) 203, OSPF is the configured interior gateway protocol (IGP), and LDP is the signaling protocol used by the VPNs. In this example, we use static routes in the VPN routing and forwarding (VRF) instances to generate VPN routes. This is done in place of using a PE to customer edge (CE) protocol such as OSPF or BGP.

In this example, you further control the routes being advertised from Device PE2 to Device PE1 by configuring an export policy on Device PE2 to prevent vpn3 routes from being advertised to Device RR1. You create a policy that specifies the **family route-target** match condition, defines the list of route target prefixes, and applies the list of route target prefixes by defining the **rtf-prefix-list** criteria.

Configuring Device PE1

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Device PE1:

1. Configure the interfaces.

```

[edit interfaces]
user@PE1# set ge-1/0/0 unit 0 description PE1-to-RR1
user@PE1# set ge-1/0/0 unit 0 family inet address 10.49.0.1/30
user@PE1# set ge-1/0/0 unit 0 family mpls

```

```
user@PE1#set ge-1/0/1 unit 0 description PE1-to-RR2
user@PE1#set ge-1/0/1 unit 0 family inet address 10.49.10.1/30
user@PE1# set ge-1/0/1 unit 0 family mpls
```

2. Configure the route distinguisher and the AS number.

```
[edit routing-options]
user@PE1# set route-distinguisher-id 10.255.163.58
user@PE1# set autonomous-system 203
```

3. Configure LDP as the signaling protocol used by the VPN.

```
[edit protocols ldp]
user@PE1# set interface ge-1/0/0
user@PE1# set interface ge-1/0/1
```

4. Configure BGP.

```
[edit protocols bgp group internal]
user@PE1# set type internal
user@PE1# set local-address 10.255.163.58
user@PE1# set neighbor 10.255.165.220 family inet-vpn unicast
user@PE1# set neighbor 10.255.165.28 family inet-vpn unicast
```

5. Configure OSPF.

```
[edit protocols ospf area 0.0.0.0]
user@PE1# set interface ge-1/0/0
user@PE1# set interface ge-1/0/1
user@PE1# set interface lo0.0 passive
```

6. Configure the VPN routing instances.

```
[edit routing-instances vpn1]
user@PE1# set instance-type vrf
user@PE1# set vrf-target target:203:100
user@PE1# set routing-options static route 203.0.113.1/24 discard

[edit routing-instances vpn2]
user@PE1# set instance-type vrf
user@PE1# set vrf-target target:203:101
user@PE1# set routing-options static route 203.0.113.2/24 discard
```

7. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE1# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Configuring Device RR1

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Device RR1:

1. Configure the interfaces.

```
[edit interfaces]
user@RR1# set ge-1/0/0 unit 0 description RR1-to-PE1
user@RR1# set ge-1/0/0 unit 0 family inet address 10.49.0.2/30
user@RR1# set ge-1/0/0 unit 0 family mpls
user@RR1# set ge-1/0/1 unit 0 description RR1-to-PE2
user@RR1# set ge-1/0/1 unit 0 family inet address 10.50.0.2/30
user@RR1# set ge-1/0/1 unit 0 family mpls
```

2. Configure the route distinguisher and the AS number.

```
[edit routing-options]
user@RR1# set route-distinguisher-id 10.255.165.220
user@RR1# set autonomous-system 203
```

3. Configure LDP as the signaling protocol used by the VPN.

```
[edit protocols ldp]
user@RR1# set interface ge-1/0/0
user@RR1# set interface ge-1/0/1
```

4. Configure BGP.

```
[edit protocols bgp group internal]
user@RR1# set type internal
user@RR1# set local-address 10.255.165.220
user@RR1# set cluster 198.51.100.1
```

```

user@RR1# set neighbor 10.255.163.58 description vpn1-to-pe1 family inet-vpn
unicast
user@RR1# set neighbor 10.255.168.42 description vpn1-to-pe2 family inet-vpn
unicast

```

5. Configure BGP route target filtering on the peering session with Device PE2.

```

[edit protocols bgp group internal]
user@RR1# set neighbor 10.255.168.42 family route-target

```

6. Configure proxy BGP route target filtering on the peering session with Device PE1.

```

[edit protocols bgp group internal]
user@RR1# set neighbor 10.255.163.58 family route-target proxy-generate

```

7. Configure OSPF.

```

[edit protocols ospf area 0.0.0.0]
user@RR1# set interface ge-1/0/0
user@RR1# set interface ge-1/0/1
user@RR1# set interface lo0.0 passive

```

8. If you are done configuring the device, commit the configuration.

```

[edit]
user@RR1# commit

```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

Configuring Device RR2

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Device RR2:

1. Configure the interfaces.

```
[edit interfaces]
user@RR2# set ge-1/0/0 unit 0 description RR2-to-PE1
user@RR2# set ge-1/0/0 unit 0 family inet address 10.49.10.2/30
user@RR2# set ge-1/0/0 unit 0 family mpls

user@RR2# set ge-1/0/1 unit 0 description RR2-to-PE2
user@RR2# set ge-1/0/1 unit 0 family inet address 10.50.10.2/30
user@RR2# set ge-1/0/1 unit 0 family mpls
```

2. Configure the route distinguisher and the AS number.

```
[edit routing-options]
user@RR2# set route-distinguisher-id 10.255.165.28
user@RR2# set autonomous-system 203
```

3. Configure LDP as the signaling protocol used by the VPN.

```
[edit protocols ldp]
user@RR2# set interface ge-1/0/0
user@RR2# set interface ge-1/0/1
```

4. Configure BGP.

```
[edit protocols bgp group internal]
user@RR2# set type internal
user@RR2# set local-address 10.255.165.28
user@RR2# set cluster 198.51.100.1
user@RR2# set neighbor 10.255.163.58 description vpn2-to-pe1 family inet-vpn
unicast
user@RR2# set neighbor 10.255.168.42 description vpn2-to-pe2 family inet-vpn
unicast
```

5. Configure BGP route target filtering on the peering session with Device PE2.

```
[edit protocols bgp group internal]
user@RR2# set neighbor 10.255.168.42 family route-target
```

6. Configure proxy BGP route target filtering on the peering session with Device PE1.

```
[edit protocols bgp group internal]
user@RR2# set neighbor 10.255.163.58 family route-target proxy-generate
```

7. Configure OSPF.

```
[edit protocols ospf area 0.0.0.0]
user@RR2# set interface ge-1/0/0
user@RR2# set interface ge-1/0/1
user@RR2# set interface lo0.0 passive
```

8. If you are done configuring the device, commit the configuration.

```
[edit]
user@RR2# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

Configuring Device PE2

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Device PE2:

1. Configure the interfaces.

```

[edit interfaces]
user@PE2# set ge-1/0/0 unit 0 description PE2-to-RR1
user@PE2# set ge-1/0/0 unit 0 family inet address 10.50.0.1/30
user@PE2# set ge-1/0/0 unit 0 family mpls

```

```

user@PE2# set ge-1/0/1 unit 0 description PE2-to-RR2
user@PE2# set ge-1/0/1 unit 0 family inet address 10.50.10.2/30
user@PE2# set ge-1/0/1 unit 0 family mpls

```

2. Configure the route distinguisher and the AS number.

```

[edit routing-options]
user@PE2# set route-distinguisher-id 10.255.168.42
user@PE2# set autonomous-system 203

```

3. Configure LDP as the signaling protocol used by the VPN.

```

[edit protocols ldp]
user@PE2# set interface ge-1/0/0
user@PE2# set interface ge-1/0/1

```

4. Configure BGP.

```
[edit protocols bgp group internal]
user@PE2# set type internal
user@PE2# set local-address 10.255.168.42
user@PE2# set family inet-vpn unicast
user@PE2# set family route-target
user@PE2# set neighbor 10.255.165.220
user@PE2# set neighbor 10.255.165.28
```

5. Configure OSPF.

```
[edit protocols ospf area 0.0.0.0]
user@PE2# set interface ge-1/0/0
user@PE2# set interface ge-1/0/1
user@PE2# set interface lo0.0 passive
```

6. Configure the VPN routing instances.

```
[edit routing-instances vpn1]
user@PE2# set instance-type vrf
user@PE2# set vrf-target target:203:100
user@PE2# set routing-options static route 203.0.113.1/24 discard

[edit routing-instances vpn2]
user@PE2# set instance-type vrf
user@PE2# set vrf-target target:203:101
user@PE2# set routing-options static route 203.0.113.2/24 discard

[edit routing-instances vpn3]
user@PE2# set instance-type vrf
user@PE2# set vrf-target target:203:103
user@PE2# set routing-options static route 203.0.113.3/24 discard

[edit routing-instances vpn4]
user@PE2# set instance-type vrf
user@PE2# set vrf-target target:203:104
user@PE2# set routing-options static route 203.0.113.4/24 discard
```

7. Configure and apply the export routing policy.

```
[edit policy-options]
user@PE2# set rtf-prefix-list exclude-103 203:203:103/96

[edit policy-options policy-statement filter-rtc]
user@PE2# set from family route-target
user@PE2# set from rtf-prefix-list exclude-103
user@PE2# set then reject

[edit protocols bgp group internal]
user@PE2# set neighbor 10.255.165.220 export filter-rtc
```

8. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE2# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show policy-options**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@PE2# show interfaces
ge-1/0/0 {
  unit 0 {

    }
  }
}
vpn3 {
  instance-type vrf;
  vrf-target target:203:103;
  routing-options {
    static {
      route 203.0.113.3/24 discard;
    }
  }
}
vpn4 {
  instance-type vrf;
  vrf-target target:203:104;
  routing-options {
    static {
      route 203.0.113.4/24 discard;
    }
  }
}
```

Verification

Confirm that the configuration is working properly.

- Verifying the Route Target Filtering Routes in the `bgp.rtarget.0` Routing Table for Device RR1 on page 83
- Verifying the Route Target Filtering Routes in the `bgp.rtarget.0` Routing Table for Device RR2 on page 83

Verifying the Route Target Filtering Routes in the `bgp.rtarget.0` Routing Table for Device RR1

Purpose Verify that the route prefix for `vpn3` is not in Device RR1's `bgp.rtarget.0` table. Since an export policy on Device PE2 was applied to prevent the advertisement of `vpn3` routes to Device RR1, Device RR1 should not receive those advertisements.

Action From operational mode, enter the `show route advertising-protocol bgp 10.255.165.220 table bgp.rtarget.0` command.

```
user@PE2# show route advertising-protocol bgp 10.255.165.220 table bgp.rtarget.0
bgp.rtarget.0: 4 destinations, 11 routes
(4 active, 0 holddown, 0 hidden)
  Prefix                Nexthop        MED      Lc1pref   AS path
  203:203:100/96         *              Self      100       I
  203:203:101/96         *              Self      100       I
  203:203:104/96         *              Self      100       I
```

Meaning The `bgp.rtarget.0` table does not display `203:203:103/96`, which is the route prefix for `vpn3`. That means the export policy was applied correctly.

Verifying the Route Target Filtering Routes in the `bgp.rtarget.0` Routing Table for Device RR2

Purpose Verify that the route prefix for `vpn3` is in Device RR2's `bgp.rtarget.0` table. Since an export policy was not applied on Device PE2 to prevent the advertisement of `vpn3` routes to Device RR2, Device RR2 should receive advertisements from all of the VPNs.

Action From operational mode, enter the `show route advertising-protocol bgp 10.255.165.28 table bgp.rtarget.0` command.

```
user@PE2# show route advertising-protocol bgp 10.255.165.28 table bgp.rtarget.0
bgp.rtarget.0: 4 destinations, 11 routes (4 active, 0 holddown, 0 hidden)
(4 active, 0 holddown, 0 hidden)
  Prefix                Nexthop        MED      Lc1pref   AS path
  203:203:100/96         *              Self      100       I
  203:203:101/96         *              Self      100       I
  203:203:103/96         *              Self      100       I
  203:203:104/96         *              Self      100       I
```

Meaning The `bgp.rtarget.0` table displays the route prefixes for all of the VPNs.

Reducing Network Resource Use with Static Route Target Filtering for VPNs

The BGP VPN route target extended community (RFC 4360, *BGP Extended Communities Attribute*) is used to determine VPN membership. Static route target filtering helps to prevent resources from being consumed in portions of the network where the VPN routes are not needed due to the lack of member PE routers (RFC 4684, *Constrained Route Distribution for Border Gateway Protocol/MultiProtocol Label Switching (BGP/MPLS) Internet Protocol (IP) Virtual Private Networks (VPNs)*). Routers can originate routes into the RT-Constrain protocol to indicate their interest in receiving VPN routes containing route targets that match the RT-Constrain NLRI.

Normally, for the RT-Constrain feature to function properly, it must be broadly deployed throughout a network. If this is not the case, the feature is less useful, because the RT-Constrain BGP speaker facing a non-RT-Constrain speaker must advertise a default RT-Constrain route to the other RT-Constrain speakers on behalf of the peer that does not support the feature. This effectively removes the resource saving benefits of the feature in portions of the network where it is not supported since a default RT-Constrain route causes the PE router and all intervening PE routers to need to receive all VPN routes.

The static RT-Constrain feature enables you to partially deploy the RT-Constrain feature in a network. The feature is enabled at a boundary in the network where RT-Constrain is configured. However, some BGP VPN peers do not support RT-Constrain, typically PE routers. The route targets of those PE routers must be statically configured on the router. These route targets are disseminated using the RT-Constrain protocol.

The proxy RT-Constrain feature permits BGP VPN peers that do not support the protocol to have their route-targets discovered and disseminated automatically. However, this feature can only support symmetric route-targets. For example, the import and export route-targets for a VRF routing instance are identical. However, for a hub-and-spoke VPN, the import and export route-targets are not identical. In this scenario, the import and export route-target may be statically configured to be disseminated in the RT-Constrain protocol.

CHAPTER 5

Configuring Forwarding Options for VPNs

- [Chained Composite Next Hops for Transit Devices for VPNs on page 85](#)
- [Example: Configuring Chained Composite Next Hops for Direct PE-PE Connections in VPNs on page 87](#)

Chained Composite Next Hops for Transit Devices for VPNs

The Juniper Networks PTX Series Packet Transport Routers, MX Series 3D Universal Edge Routers with MIC and MPC interfaces, T4000 Core Routers, and QFX10000 switches are principally designed to handle large volumes of transit traffic in the core of large networks. Chained composite next hops help to facilitate this capability by allowing the router to process much larger volumes of routes. A chained composite next hop allows the router to direct sets of routes sharing the same destination to a common forwarding next hop, rather than having each route also include the destination. In the event that a network destination is changed, rather than having to update all of the routes sharing that destination with the new information, just the shared forwarding next hop is updated with the new information. The chained composite next hops continue to point to this forwarding next hop which now contains the new destination.

When the next hops for MPLS LSPs are created on the routers, the tag information corresponding to the inner-most MPLS label is extracted into a chained composite next hop. The chained composite next hop is stored in the ingress PFE. The chained composite next hop points to a next hop called the forwarding next hop that resides on the egress PFE. The forwarding next hop contains all of the other information (all of the labels except for the inner-most labels; and the IFA/IP information corresponding to the actual next hop node). Many chained composite next hops can share the same forwarding next hop. Additionally, separating the label from the forwarding next hop and storing it on the ingress PFE (within the chained composite next hop) helps to conserve egress PFE memory by reducing the number of rewrite strings stored on the egress PFE.

The support of chained composite next hops for directly connected Provider Edge (PE) routers varies from one platform to another.

On platforms containing only MPCs, such as PTX Series Packet Transport Routers, the MX80 router, the MX2020 router, and the QFX10000 switches, chained composite next hops are enabled by default for the following MPLS and VPN protocols and applications:

NOTE: Point-to-Multipoint LSPs and Layer 2 VPNs are not supported on the QFX10000 switches.

- Labeled BGP
- Layer 2 VPNs
- Layer 3 VPNs
- LDP
- MPLS
- Point-to-Multipoint LSPs
- RSVP
- Static LSPs

[Warning: element unresolved in stylesheets: <item> (in <body>). This is probably a new element that is not yet supported in the stylesheets.]

[Warning: element unresolved in stylesheets: <item> (in <body>). This is probably a new element that is not yet supported in the stylesheets.]

On MX Series 3D Universal Edge Routers containing both DPC and MPC FPCs, chained composite next hops are disabled by default.

To enable chained composite next hops on the MX Series routers such as: MX80, MX240, MX480, MX960 and MX2020, the chassis must be configured to use the **enhanced-ip** option in network services mode.

[Warning: element unresolved in stylesheets: <item> (in <body>). This is probably a new element that is not yet supported in the stylesheets.]

On T4000 Core Routers containing MPC and FPCs, chained composite next hops are disabled by default.

To enable chained composite next hops on a T4000 router, the chassis must be configured to use the **enhanced-mode** option in network services mode.

For more information about configuring chassis network services, see the *Junos OS Administration Library*.

Example: Configuring Chained Composite Next Hops for Direct PE-PE Connections in VPNs

This example shows how to enable back-to-back Provider Edge (PE) router Layer 3 Virtual Private Network (VPN) connections with chained composite next hops for MIC and MPC interfaces on MX Series and T4000 routers.

- [Requirements on page 87](#)
- [Overview on page 87](#)
- [Configuration on page 88](#)
- [Verification on page 96](#)

Requirements

This example uses the following hardware and software components:

- Six routers that can be a combination of MX240, MX480, MX960, or T4000 routers.
- Junos OS Release 13.3 running on all the devices.

Before you begin:

1. Configure the device interfaces.
2. Configure the following routing protocols on all the routers:
 - a. MPLS
 - b. BGP
 - c. LDP LSPs as tunnels between the PE devices
 - d. OSPF or any other IGP protocol

Overview

Prior to Junos OS Release 13.3, in a degenerated Layer 3 VPN case without the presence of an MPLS core router, previous behavior of flattened out indirect next hop and unicast next hop was utilized because there was no outer label available in the back-to-back PE-PE connection, and the ingress PE only pushed single VPN labels. In a Layer 3 VPN multipath scenario with mixed PE-PE and PE-P-PE paths, chained composite next hops could not be used either.

On platforms that support only MIC and MPC interfaces, chained composite next hops are enabled by default. On platforms that support both DPC and MPC interfaces, the Layer 3 VPN configuration required the **pe-pe-connection** statement to support chained composite next hops for PE-PE connections. However, the **pe-pe-connection** statement was not supported on platforms with MIC and FPC interfaces only.

As a solution to these limitations, starting with Junos OS Release 13.3, the support for chained composite next hops is enhanced to automatically identify the underlying platform capability on composite next hops at startup time, without relying on user

configuration, and to decide the next hop type (composite or indirect) to embed in the Layer 3 VPN label. This enhances the support for back-to-back PE-PE connections in Layer 3 VPN with composite next hops, and eliminates the need for the **pe-pe-connection** statement.

To enable chained composite next hops for directly connected PE devices, in addition to including the **l3vpn** statement at the **[edit routing-options forwarding-table chained-composite-next-hop ingress]** hierarchy level, make the following changes:

- On MX Series 3D Universal Edge Routers containing both DPC and MPC FPCs, chained composite next hops are disabled by default. To enable chained composite next hops on the MX240, MX480, and MX960, the chassis must be configured to use the **enhanced-ip** option in network services mode.
- On T4000 Core Routers containing MPC and FPCs, chained composite next hops are disabled by default. To enable chained composite next hops on a T4000 router, the chassis must be configured to use the **enhanced-mode** option in network services mode.

Configuring Multipath Layer 3 VPN with Chained Composite Next Hop

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure basic Layer 3 VPN with chained composite next hop on the PE1 router:

NOTE: Repeat this procedure for the PE2 and PE3 routers in the MPLS domain, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Configure the interfaces on the PE1 router.

PE1 to CE1

```
[edit interfaces]
user@PE1 # set ge-0/1/1 unit 0 family inet address 192.0.2.1/24
user@PE1 # set ge-0/1/1 unit 0 family mpls
```

PE1 to PE2

```
[edit interfaces]
user@PE1 # set ge-0/0/1 unit 0 family inet address 10.38.0.1/30
user@PE1 # set ge-0/0/1 unit 0 family mpls
```

```
user@PE1 # set ge-0/0/2 unit 0 family inet address 10.38.0.5/30
user@PE1 # set ge-0/0/2 unit 0 family mpls
```

PE1 to P

```
[edit interfaces]
user@PE1 # set ge-0/0/4 unit 0 family inet address 10.32.0.1/30
user@PE1 # set ge-0/0/4 unit 0 family mpls
```

PE1 to PE3

```
[edit interfaces]
user@PE1 # set ge-0/0/3 unit 0 family inet address 10.38.0.9/30
user@PE1 # set ge-0/0/3 unit 0 family mpls
```

Loopback interface

```
[edit interfaces]
user@PE1 # set lo0 unit 0 family inet address 10.255.104.133/32
```

2. Enable enhanced IP mode on the PE1 chassis.

```
[edit chassis]
user@PE1# set network-services enhanced-ip
```

3. Enable chained composite next hop on the global Layer 3 VPN.

```
[edit routing-options]
user@PE1# set forwarding-table chained-composite-next-hop ingress l3vpn
```
4. Configure the autonomous system for PE1.

```
[edit routing-options]
user@PE1# set autonomous-system 200
```
5. Export the policy configured for load balancing.

```
[edit routing-options]
user@PE1# set forwarding-table export lbpp
```
6. Configure MPLS on the PE1 interfaces connecting to the P router and other PE routers.

```
[edit protocols]
user@PE1# set mpls interface 10.38.0.1/30
user@PE1# set mpls interface 10.32.0.1/30
user@PE1# set mpls interface 10.38.0.5/30
user@PE1# set mpls interface 10.38.0.9/30
```
7. Configure the IBGP group for PE1 to peer with the PE2 and PE3 routers.

```
[edit protocols]
user@PE1# set bgp group PEs type internal
user@PE1# set bgp group PEs local-address 10.255.104.133
user@PE1# set bgp group PEs family inet unicast
user@PE1# set bgp group PEs family inet-vpn unicast
user@PE1# set bgp group PEs neighbor 10.255.104.134 local-preference 200
user@PE1# set bgp group PEs neighbor 10.255.104.135
```
8. Configure OSPF with traffic engineering capability on all the interfaces of PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PE1# set ospf area 0.0.0.0 interface lo0.0 passive
```
9. Configure LDP on all the interfaces of PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set ldp interface all
user@PE1# set ldp interface fxp0.0 disable
```
10. Configure a policy to load-balance traffic on a per packet basis.

```
[edit policy-options]
user@PE1# set policy-statement lbpp then load-balance per-packet
```

11. Configure a VRF routing instance on the CE1-facing interface of PE1.

```
[edit routing-instances]
user@PE1# set vpn-a instance-type vrf
user@PE1# set vpn-a interface ge-0/1/1.0
```

12. Configure the routing instance parameters.

```
[edit routing-instances]
user@PE1# set vpn-a route-distinguisher 200:1
user@PE1# set vpn-a vrf-target target:200:1
user@PE1# set vpn-a vrf-table-label
```

13. Configure an EBGP group for the routing instance, so PE1 can peer with CE1.

```
[edit routing-instances]
user@PE1# set vpn-a protocols bgp group CE type external
user@PE1# set vpn-a protocols bgp group CE peer-as 100
user@PE1# set vpn-a protocols bgp group CE neighbor 192.0.2.2
```

Results

From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show protocols**, **show routing-options**, **show routing-instances**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
PE1 user@PE1# show chassis
network-services enhanced-ip;

user@PE1# show interfaces
ge-0/0/1 {
  unit 0 {
    family inet {
      address 10.38.0.1/30;
    }

```

Meaning The PE2 router is the composite next hop for PE1 to reach CE2.

Verifying Chained Next Hop on Direct PE-PE Connection

Purpose Verify that chained next hop is generated for direct PE-PE connection on CE1.

Action From operational mode, run the **ping** command.

```

user@CE1> ping 192.0.2.4
!!!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss

```

Meaning Chained composite next hop is enabled for the PE1 to PE2 connection.

Configuring Graceful Restart for VPNs

- [VPN Graceful Restart on page 101](#)
- [Configuring Graceful Restart for VPNs on page 102](#)
- [Enabling Unicast Reverse-Path Forwarding Check for VPNs on page 104](#)
- [Example: Configuring Unicast Reverse-Path-Forwarding Check on page 105](#)

VPN Graceful Restart

VPN graceful restart allows a router whose VPN control plane is undergoing a restart to continue to forward traffic while recovering its state from neighboring routers. Without graceful restart, a control plane restart disrupts any VPN services provided by the router.

For VPN graceful restart to function properly, the following items need to be configured on the PE router:

- BGP graceful restart must be active on the PE-to-PE sessions carrying any service-signaling data in the session's network layer reachability information (NLRI).
- OSPF, IS-IS, LDP, and RSVP graceful restart must be active, because routes added by these protocols are used to resolve VPN NLRIs.
- For other protocols (static, Routing Information Protocol [RIP], and so on), graceful restart functionality must also be active when these protocols are run between the PE and CE routers. Layer 2 VPNs do not rely on this because protocols are not configured between the PE and CE routers.

In VPN graceful restart, a restarting router completes the following procedures:

- Waits for all the BGP NLRI information from other PE routers before it starts advertising routes to its CE routers.
- Waits for all protocols in all routing instances to converge (or finish graceful restart) before sending CE router information to the other PE routers.

- Waits for all routing instance information (whether it is local configuration or advertisements from a remote peer router) to be processed before sending it to the other PE routers.
- Preserves all forwarding state information in the MPLS routing tables until new labels and transit routes are allocated and then advertises them to other PE routers (and CE routers in carrier-of-carriers VPNs).

Graceful restart is supported on Layer 2 VPNs, Layer 3 VPNs, and virtual-router routing instances.

Configuring Graceful Restart for VPNs

You can configure graceful restart to enable a router to pass through intermediate convergence states that are hidden from the rest of the network. Graceful restart allows a router whose VPN control plane is undergoing a restart (restarting router) to continue to forward traffic while recovering its state from neighboring routers (helper routers).

The restarting router requests a grace period from the neighbor or peer, which can then cooperate with the restarting router. When a restart event occurs and graceful restart is enabled, the restarting router can still forward traffic during the restart period, and convergence in the network is not disrupted. The helper routers hide the restart event from other devices not directly connected to the restarting router. In other words, the restart is not visible to the rest of the network, and the restarting router is not removed from the network topology.

Without graceful restart, a control plane restart disrupts any VPN services provided by the router. Graceful restart is supported on Layer 2 VPNs, Layer 3 VPNs, virtual-router routing instances, and VPLS.

The graceful restart request occurs only if the following conditions are met:

- The network topology is stable.
- The neighbor or peer routers cooperate.
- The restarting router is not already cooperating with another restart already in progress.
- The grace period does not expire.

Before you begin:

- Configure the devices for network communication.
- Configure the device interfaces.

Graceful restart is disabled by default. To enable VPN graceful restart:

1. Configure graceful restart globally.

```
[edit routing-options]  
user@host# set graceful-restart
```

**NOTE:**

- Graceful restart can be enabled on logical systems. To configure graceful restart globally, include the `graceful-restart` statement at the [edit logical-systems *logical-system-name* routing-options] or the [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* routing-options] hierarchy levels.
- To disable graceful restart globally, include the `disable` statement at the [edit routing-options graceful-restart] hierarchy level.

For example:

```
[edit routing-options]
user@host# set graceful-restart disable
```

2. Enable or disable graceful restart on a per-protocol, per-group, or per-neighbor basis, depending on the specific protocol, where the most specific definition is used.

```
[edit protocols]
user@host# set bgp graceful-restart
user@host# set bgp group group-name type internal local-address local-ip-address
neighbor neighbor1-address
user@host# set bgp group group-name type internal local-address local-ip-address
neighbor neighbor2-address graceful-restart disable
```

3. Configure graceful restart for Layer 3 VPNs for all routing and MPLS-related protocols within a routing instance. Because you can configure multi-instance BGP and multi-instance LDP, graceful restart for a carrier-of-carriers scenario is supported.

```
[edit routing-instance]
user@host# set routing-instance-name routing-options graceful-restart
```

**NOTE:**

- To disable graceful restart globally, include the `disable` statement at the [edit routing-instances *routing-instance-name* routing-options graceful-restart] hierarchy level.

For example:

```
[edit routing-instances]
user@host# set instance1 routing-options graceful-restart disable
```

- To disable graceful restart for individual protocols, include the `disable` statement at the [edit routing-instances *routing-instance-name* protocols *protocol-name* graceful-restart] hierarchy level.

For example:

```
[edit routing-instances]
user@host# set instance1 protocols ospf graceful-restart disable
```

4. Configure the duration of the graceful restart period for the routing instance.

```
[edit routing-options]
user@host# set graceful-restart restart-duration seconds
```

The **restart-duration** option sets the period of time that the router waits for a graceful restart to be completed. You can configure a time between 1 through 600 seconds. The default value is 300 seconds. At the end of the configured time period, the router performs a standard restart without recovering its state from the neighboring routers. This disrupts VPN services, but is probably necessary if the router is not functioning normally.

NOTE: You can include the **restart-duration** option at either the global or routing instance level. The routing instance value overrides the global value if both are configured.

Enabling Unicast Reverse-Path Forwarding Check for VPNs

IP spoofing may occur during a denial-of-service (DoS) attack. IP spoofing allows an intruder to pass IP packets to a destination as genuine traffic, when in fact the packets are not actually meant for the destination. This type of spoofing is harmful because it consumes the destination's resources.

Unicast reverse-path forwarding (RPF) check is a tool to reduce forwarding of IP packets that may be spoofing an address. A unicast RPF check performs a route table lookup on an IP packet's source address, and checks the incoming interface. The router determines whether the packet is arriving from a path that the sender would use to reach the destination. If the packet is from a valid path, the router forwards the packet to the destination address. If it is not from a valid path, the router discards the packet. Unicast RPF is supported for the IPv4 and IPv6 protocol families, as well as for the virtual private network (VPN) address family. You can also enable unicast RPF within a VPN routing instance.

To enable unicast RPF check, include the **unicast-reverse-path** statement:

```
unicast-reverse-path (active-paths | feasible-paths);
```

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

To consider only active paths during the unicast RPF check, include the **active-paths** option. To consider all feasible paths during the unicast RPF check, include the **feasible-paths** option.

For more information about how to configure the **unicast-reverse-path** statement, see “[Example: Configuring Unicast Reverse-Path-Forwarding Check](#)” on page 105 and .

Understanding Unicast Reverse Path Forwarding

IP spoofing can occur during a denial-of-service (DoS) attack. IP spoofing allows an intruder to pass IP packets to a destination as genuine traffic, when in fact the packets are not actually meant for the destination. This type of spoofing is harmful because it consumes the destination's resources.

A unicast reverse-path-forwarding (RPF) check is a tool to reduce forwarding of IP packets that might be spoofing an address. A unicast RPF check performs a route table lookup on an IP packet's source address, and checks the incoming interface. The router or switch determines whether the packet is arriving from a path that the sender would use to reach the destination. If the packet is from a valid path, the router or switch forwards the packet to the destination address. If it is not from a valid path, the router or switch discards the packet. Unicast RPF is supported for the IPv4 and IPv6 protocol families, as well as for the virtual private network (VPN) address family.

NOTE: Reverse path forwarding is not supported on the interfaces you configure as tunnel sources. This affects only the transit packets exiting the tunnel.

Example: Configuring Unicast Reverse-Path-Forwarding Check

Unicast reverse path forwarding (RPF) helps protect against DoS and DDoS attacks by verifying the unicast source address of each packet that arrives on an ingress interface where unicast RPF is enabled.

This example shows how to help defend ingress interfaces against denial-of-service (DoS) and distributed denial-of-service (DDoS) attacks by configuring unicast RPF to filter incoming traffic.

- [Requirements on page 106](#)
- [Overview on page 106](#)
- [Configuration on page 107](#)
- [Verification on page 112](#)

Requirements

In this example, no special configuration beyond device initialization is required.

Overview

Large amounts of unauthorized traffic such as attempts to flood a network with fake (bogus) service requests in a DoS attack can consume network resources and deny service to legitimate users. One way to help prevent DoS and DDoS attacks is to verify that incoming traffic originates from legitimate network sources.

Unicast RPF helps ensure that a traffic source is legitimate (authorized) by comparing the source address of each packet that arrives on an interface to the forwarding table entry for its source address. If the device uses the same interface that the packet arrived on to reply to the packet's source, this verifies that the packet originated from an authorized source, and the device forwards the packet. If the device does not use the same interface that the packet arrived on to reply to the packet's source, the packet might have originated from an unauthorized source, and the device discards the packet.

In this example, Device B has unicast RPF configured. Device A is using OSPF to advertise a prefix for the link that connects to Device D. OSPF is enabled on the links between Device B and Device C and the links between Device A and Device C, but not on the links between Device A and Device B. Therefore, Device B learns about the route to Device D through Device C.

If ingress filtering is used in an environment where DHCP or BOOTP is used, it should be ensured that the packets with a source address of 0.0.0.0 and a destination address of 255.255.255.255 are allowed to reach the relay agent in routers when appropriate.

This example also includes a fail filter. When a packet fails the unicast RPF check, the fail filter is evaluated to determine if the packet should be accepted anyway. The fail filter in this example allows Device B's interfaces to accept Dynamic Host Configuration Protocol (DHCP) packets. The filter accepts all packets with a source address of 0.0.0.0 and a destination address of 255.255.255.255.

Figure 8 on page 106 shows the sample network.

Figure 8: Unicast RPF Sample Topology

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Device A

```
set interfaces fe-1/2/0 unit 1 family inet address 10.0.0.1/30
set interfaces fe-0/0/2 unit 5 family inet address 10.0.0.5/30
set interfaces fe-0/0/1 unit 17 family inet address 10.0.0.17/30
set interfaces fe-0/1/1 unit 25 family inet address 10.0.0.25/30
set interfaces fe-1/1/1 unit 29 family inet address 10.0.0.29/30
set protocols ospf export send-direct
set protocols ospf area 0.0.0.0 interface fe-0/1/1.25
set protocols ospf area 0.0.0.0 interface fe-1/1/1.29
set policy-options policy-statement send-direct from protocol direct
set policy-options policy-statement send-direct from route-filter 10.0.0.16/30 exact
set policy-options policy-statement send-direct then accept
```

Device B

```
set interfaces fe-1/2/0 unit 2 family inet rpf-check fail-filter rpf-special-case-dhcp
set interfaces fe-1/2/0 unit 2 family inet address 10.0.0.2/30
set interfaces fe-1/1/1 unit 6 family inet rpf-check fail-filter rpf-special-case-dhcp
set interfaces fe-1/1/1 unit 6 family inet address 10.0.0.6/30
set interfaces fe-0/1/1 unit 9 family inet rpf-check fail-filter rpf-special-case-dhcp
set interfaces fe-0/1/1 unit 9 family inet address 10.0.0.9/30
set interfaces fe-0/1/0 unit 13 family inet rpf-check fail-filter rpf-special-case-dhcp
set interfaces fe-0/1/0 unit 13 family inet address 10.0.0.13/30
set protocols ospf area 0.0.0.0 interface fe-0/1/1.9
set protocols ospf area 0.0.0.0 interface fe-0/1/0.13
set routing-options forwarding-table unicast-reverse-path active-paths
set firewall filter rpf-special-case-dhcp term allow-dhcp from source-address 0.0.0.0/32
set firewall filter rpf-special-case-dhcp term allow-dhcp from destination-address
  255.255.255.255/32
set firewall filter rpf-special-case-dhcp term allow-dhcp then count rpf-dhcp-traffic
set firewall filter rpf-special-case-dhcp term allow-dhcp then accept
set firewall filter rpf-special-case-dhcp term default then log
set firewall filter rpf-special-case-dhcp term default then reject
```

Device C

```
set interfaces fe-1/2/0 unit 10 family inet address 10.0.0.10/30
set interfaces fe-0/0/2 unit 14 family inet address 10.0.0.14/30
set interfaces fe-1/0/2 unit 21 family inet address 10.0.0.21/30
set interfaces fe-1/2/2 unit 26 family inet address 10.0.0.26/30
set interfaces fe-1/2/1 unit 30 family inet address 10.0.0.30/30
set protocols ospf area 0.0.0.0 interface fe-1/2/0.10
set protocols ospf area 0.0.0.0 interface fe-0/0/2.14
set protocols ospf area 0.0.0.0 interface fe-1/2/2.26
set protocols ospf area 0.0.0.0 interface fe-1/2/1.30
```

Device D

```
set interfaces fe-1/2/0 unit 18 family inet address 10.0.0.18/30
```

Device E

```
set interfaces fe-1/2/0 unit 22 family inet address 10.0.0.22/30
```

Configuring Device A

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Device A:

1. Configure the interfaces.

```
[edit interfaces]
user@A# set fe-1/2/0 unit 1 family inet address 10.0.0.1/30

user@A# set fe-0/0/2 unit 5 family inet address 10.0.0.5/30

user@A# set fe-0/0/1 unit 17 family inet address 10.0.0.17/30

user@A# set fe-0/1/1 unit 25 family inet address 10.0.0.25/30

user@A# set fe-1/1/1 unit 29 family inet address 10.0.0.29/30
```

2. Configure OSPF.

```
[edit protocols ospf]
user@A# set export send-direct
user@A# set area 0.0.0.0 interface fe-0/1/1.25
user@A# set area 0.0.0.0 interface fe-1/1/1.29
```

3. Configure the routing policy.

```
[edit policy-options policy-statement send-direct]
user@A# set from protocol direct
user@A# set from route-filter 10.0.0.16/30 exact
user@A# set then accept
```

4. If you are done configuring Device A, commit the configuration.

```
[edit]
user@A# commit
```

Configuring Device B

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Device B:

1. Configure the interfaces.

```
[edit interfaces]
user@B# set fe-1/2/0 unit 2 family inet address 10.0.0.2/30
```

```
user@B# set fe-1/1/1 unit 6 family inet address 10.0.0.6/30
```

```
user@B# set fe-0/1/1 unit 9 family inet address 10.0.0.9/30
```

```
user@B# set fe-0/1/0 unit 13 family inet address 10.0.0.13/30
```

2. Configure OSPF.

```
[edit protocols ospf area 0.0.0.0]
```

```
user@B# set interface fe-0/1/1.9
```

```
user@B# set interface fe-0/1/0.13
```

3. Configure unicast RPF, and apply the optional fail filter.

```
[edit interfaces]
```

```
user@B# set fe-1/2/0 unit 2 family inet rpf-check fail-filter rpf-special-case-dhcp
```

```
user@B# set fe-1/1/1 unit 6 family inet rpf-check fail-filter rpf-special-case-dhcp
```

```
user@B# set fe-0/1/1 unit 9 family inet rpf-check fail-filter rpf-special-case-dhcp
```

```
user@B# set fe-0/1/0 unit 13 family inet rpf-check fail-filter rpf-special-case-dhcp
```

4. (Optional) Configure the fail filter that gets evaluated if a packet fails the RPF check.

```
[edit firewall filter rpf-special-case-dhcp]
```

```
user@B# set term allow-dhcp from source-address 0.0.0.0/32
```

```
user@B# set term allow-dhcp from destination-address 255.255.255.255/32
```

```
user@B# set term allow-dhcp then count rpf-dhcp-traffic
```

```
user@B# set term allow-dhcp then accept
```

```
user@B# set term default then log
```

```
user@B# set term default then reject
```

5. (Optional) Configure only active paths to be considered in the RPF check.

This is the default behavior.

```
[edit routing-options forwarding-table]
```

```
user@B# set unicast-reverse-path active-paths
```

6. If you are done configuring Device B, commit the configuration.

```
[edit]
```

```
user@B# commit
```

Results

Confirm your configuration by issuing the **show firewall**, **show interfaces**, **show protocols**, **show routing-options**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
Device A  user@A# show interfaces
          fe-1/2/0 {
            unit 1 {
              family inet {
                address 10.0.0.1/30;
              }
            }
          }
          fe-0/0/2 {
            unit 5 {
              family inet {
                address 10.0.0.5/30;
              }
            }
          }
          fe-0/0/1 {

```

Enter the configurations on Device C, Device D, and Device E, as shown in [“CLI Quick Configuration” on page 107](#).

Verification

Confirm that the configuration is working properly.

- [Confirm That Unicast RPF Is Enabled on page 112](#)
- [Confirm That the Source Addresses Are Blocked on page 113](#)
- [Confirm That the Source Addresses Are Unblocked on page 113](#)

Confirm That Unicast RPF Is Enabled

Purpose Make sure that the interfaces on Device B have unicast RPF enabled.

Action user@B> show interfaces fe-0/1/0.13 extensive

```

Logical interface fe-0/1/0.13 (Index 73) (SNMP ifIndex 553) (Generation 208)
Flags: SNMP-Traps 0x4000 Encapsulation: ENET2
Traffic statistics:
  Input bytes :          999390
  Output bytes :         1230122
  Input packets:          12563
  Output packets:         12613
Local statistics:
  Input bytes :          998994
  Output bytes :         1230122
  Input packets:          12563
  Output packets:         12613
Transit statistics:
  Input bytes :           396          0 bps
  Output bytes :           0          0 bps
  Input packets:           0          0 pps
  Output packets:          0          0 pps
Protocol inet, MTU: 1500, Generation: 289, Route table: 22
Flags: Sendbcst-pkt-to-re, uRPF
RPF Failures: Packets: 0, Bytes: 0
Addresses, Flags: Is-Preferred Is-Primary
  Destination: 10.0.0.12/30, Local: 10.0.0.13, Broadcast: 10.0.0.15,
Generation: 241

```

Meaning The **uRPF** flag confirms that unicast RPF is enabled on this interface.

Confirm That the Source Addresses Are Blocked

Purpose Use the **ping** command to make sure that Device B blocks traffic from unexpected source addresses.

Action From Device A, ping Device B's interfaces, using 10.0.0.17 as the source address.

```

user@A> ping 10.0.0.6 source 10.0.0.17
PING 10.0.0.6 (10.0.0.6): 56 data bytes
^C
--- 10.0.0.6 ping statistics ---
3 packets transmitted, 0 packets received, 100% packet loss

```

Meaning As expected, the ping operation fails.

Confirm That the Source Addresses Are Unblocked

Purpose Use the **ping** command to make sure that Device B does not block traffic when the RPF check is deactivated.

Action 1. Deactivate the RPF check on one of the interfaces.

2. Rerun the ping operation.

```
user@B> deactivate interfaces fe-1/1/1.6 family inet rpf-check

user@A> ping 10.0.0.6 source 10.0.0.17
PING 10.0.0.2 (10.0.0.2): 56 data bytes
64 bytes from 10.0.0.2: icmp_seq=0 ttl=63 time=1.316 ms
64 bytes from 10.0.0.2: icmp_seq=1 ttl=63 time=1.263 ms
^C
--- 10.0.0.2 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max/stddev = 1.263/1.289/1.316/0.027 ms
```

Meaning As expected, the ping operation succeeds.

CHAPTER 7

Configuring Class of Service for VPNs

- [VPNs and Class of Service on page 115](#)
- [Rewriting Class of Service Markers and VPNs on page 115](#)

VPNs and Class of Service

You can configure Junos class-of-service (CoS) features to provide multiple classes of service for VPNs. The CoS features are supported on Layer2 VPNs, Layer 3 VPNs, and VPLS. On the router, you can configure multiple forwarding classes for transmitting packets, define which packets are placed into each output queue, schedule the transmission service level for each queue, and manage congestion using a random early detection (RED) algorithm.

VPNs use the standard CoS configuration.

Related Documentation • [Class of Service Feature Guide for Routing Devices](#)

Rewriting Class of Service Markers and VPNs

A marker reads the current forwarding class and loss priority information associated with a packet and finds the chosen code point from a table. It then writes the code point information into the packet header. Entries in a marker configuration represent the mapping of the current forwarding class into a new forwarding class, to be written into the header.

You define markers in the rewrite rules section of the class-of-service (CoS) configuration hierarchy and reference them in the logical interface configuration. You can configure different rewrite rules to handle VPN traffic and non-VPN traffic. The rewrite rule can be applied to MPLS and IPv4 packet headers simultaneously, making it possible to initialize MPLS experimental (EXP) and IP precedence bits at LSP ingress.

For a detailed example of how to configure rewrite rules for MPLS and IPv4 packets and for more information about how to configure statements at the **[edit class-of-service]** hierarchy level, see the *Class of Service Feature Guide for Routing Devices*.

Pinging VPNs

- [Pinging VPNs, VPLS, and Layer 2 Circuits on page 117](#)
- [Setting the Forwarding Class of the Ping Packets on page 118](#)
- [Pinging a VPLS Routing Instance on page 118](#)
- [Pinging a Layer 2 VPN on page 119](#)
- [Pinging a Layer 3 VPN on page 119](#)
- [Pinging a Layer 2 Circuit on page 119](#)

Pinging VPNs, VPLS, and Layer 2 Circuits

For testing purposes, you can ping Layer 2 VPNs, Layer 3 VPNs, and Layer 2 circuits by using the **ping mpls** command. The **ping mpls** command helps to verify that a VPN or circuit has been enabled and tests the integrity of the VPN or Layer 2 circuit connection between the PE routers. It does not test the connection between a PE router and a CE router. To ping a VPLS routing instance, you issue a **ping vpls instance** command (see [“Pinging a VPLS Routing Instance” on page 118](#)).

You issue the **ping mpls** command from the ingress PE router of the VPN or Layer 2 circuit to the egress PE router of the same VPN or Layer 2 circuit. When you execute the **ping mpls** command, echo requests are sent as MPLS packets.

The payload is a User Datagram Protocol (UDP) packet forwarded to the address **127.0.0.1**. The contents of this packet are defined in RFC 4379, *Detecting Multi-Protocol Label Switched (MPLS) Data Plane Failures*. The label and interface information for building and sending this information as an MPLS packet is the same as for standard VPN traffic, but the time-to-live (TTL) of the innermost label is set to 1.

When the echo request arrives at the egress PE router, the contents of the packet are checked, and then a reply that contains the correct return is sent by means of UDP. The PE router sending the echo request waits to receive an echo reply after a timeout of 2 seconds (you cannot configure this value).

You must configure MPLS at the **[edit protocols mpls]** hierarchy level on the egress PE router (the router receiving the MPLS echo packets) to be able to ping the VPN or Layer 2 circuit. You must also configure the address **127.0.0.1/32** on the egress PE router's **lo0** interface. If this is not configured, the egress PE router does not have this forwarding entry and therefore simply drops the incoming MPLS pings.

The **ping mpls** command has the following limitations:

- You cannot ping an IPv6 destination prefix.
- You cannot ping a VPN or Layer 2 circuit from a router that is attempting a graceful restart.
- You cannot ping a VPN or Layer 2 circuit from a logical system.

You can also determine whether an LSP linking two PE routers in a VPN is up by pinging the end point address of the LSP. The command you use to ping an MPLS LSP end point is **ping mpls lsp-end-point address**. This command tells you what type of LSP (RSVP or LDP) terminates at the address specified and whether that LSP is up or down.

For a detailed description of this command, see the *Junos Routing Protocols and Policies Command Reference*.

Setting the Forwarding Class of the Ping Packets

When you execute the **ping mpls** command, the ping packets forwarded to the destination include MPLS labels. It is possible to set the value of the forwarding class for these ping packets by using the **exp** option with the **ping mpls** command. For example, to set the forwarding class to 5 when pinging a Layer 3 VPN, issue the following command:

```
ping mpls l3vpn westcoast source 192.0.2.0 prefix 192.0.2.1 exp 5 count 20 detail
```

This command would make the router attempt to ping the Layer 3 VPN **westcoast** using ping packets with an EXP forwarding class of 5. The default forwarding class used for the **ping mpls** command packets is 7.

Pinging a VPLS Routing Instance

The **ping vpls instance** command uses a different command structure and operates in a different fashion than the **ping mpls** command used for VPNs and Layer 2 circuits. The **ping vpls instance** command is only supported on MX Series routers, the M120 router, the M320 router, and the T1600 router.

To ping a VPLS routing instance, use the following command:

```
ping vpls instance instance-name destination-mac address source-ip address <count  
number> <data-plane-response> <detail> <learning-vlan-id number> <logical-system  
logical-system-name>
```

Pinging a VPLS routing instance requires using the **ping vpls instance** command with a combination of the routing instance name, the destination MAC address, and the source IP address (IP address of the outgoing interface).

When you run this command, you are provided feedback on the status of your request. An exclamation point (!) indicates that an echo reply was received. A period (.) indicates that an echo reply was not received within the timeout period. An x indicates that an echo reply was received with an error code; these packets are not counted in the received packets count. They are accounted for separately.

For more details, including argument descriptions and additional options, see [ping vpls instance](#).

Pinging a Layer 2 VPN

To ping a Layer 2 VPN, use one of the following commands:

- **ping mpls l2vpn interface *interface-name***

You ping an interface configured for the Layer 2 VPN on the egress PE router.

- **ping mpls l2vpn instance *l2vpn-instance-name* local-site-id *local-site-id-number* remote-site-id *remote-site-id-number***

You ping a combination of the Layer 2 VPN routing instance name, the local site identifier, and the remote site identifier to test the integrity of the Layer 2 VPN connection (specified by the identifiers) between the ingress and egress PE routers.

Related Documentation

- [Example: Configuring MPLS-Based Layer 2 VPNs on page 151](#)

Pinging a Layer 3 VPN

To ping a Layer 3 VPN, use the following command:

```
ping mpls l3vpn l3vpn-name prefix prefix <count count>
```

You ping a combination of an IPv4 destination prefix and a Layer 3 VPN name on the egress PE router to test the integrity of the VPN connection between the ingress and egress PE routers. The destination prefix corresponds to a prefix in the Layer 3 VPN. However, the ping tests only whether the prefix is present in a PE router's VRF table. It does not test the connection between a PE router and a CE router.

Pinging a Layer 2 Circuit

To ping a Layer 2 circuit, use one of the following commands:

- **ping mpls l2circuit interface *interface-name***

You ping an interface configured for the Layer 2 circuit on the egress PE router.

- **ping mpls l2circuit virtual-circuit neighbor <*prefix*> <*virtual-circuit-id*>**

You ping a combination of the IPv4 prefix and the virtual circuit identifier on the egress PE router to test the integrity of the Layer 2 circuit between the ingress and egress PE routers.

Understanding Layer 2 VPNs

NOTE: On EX9200 switches, graceful Routing Engine switchover (GRES), nonstop active routing (NSR), and logical systems are not supported on Layer 2 VPN configurations. Layer 2 VPN is not supported on the EX9200 Virtual Chassis.

As the need to link different Layer 2 services to one another for expanded service offerings grows, Layer 2 Multiprotocol Label Switching (MPLS) VPN services are increasingly in demand.

Implementing a Layer 2 VPN on a router is similar to implementing a VPN using a Layer 2 technology such as Asynchronous Transfer Mode (ATM) or Frame Relay. However, for a Layer 2 VPN on a router, traffic is forwarded to the router in a Layer 2 format. It is carried by MPLS over the service provider's network, and then converted back to Layer 2 format at the receiving site. You can configure different Layer 2 formats at the sending and receiving sites. The security and privacy of an MPLS Layer 2 VPN are equal to those of an ATM or Frame Relay VPN. The service provisioned with Layer 2 VPNs is also known as Virtual Private Wire Service (VPWS).

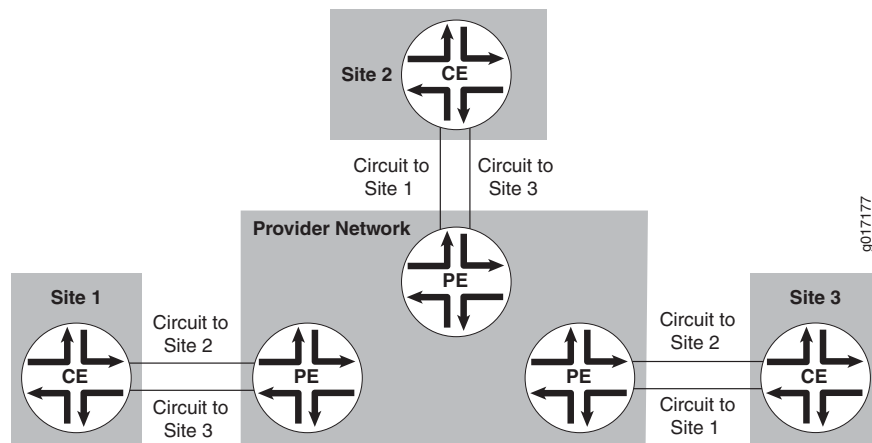

On a Layer 2 VPN, routing occurs on the customer's routers, typically on the customer edge (CE) router. The CE router connected to a service provider on a Layer 2 VPN must select the appropriate circuit on which to send traffic. The provider edge (PE) router receiving the traffic sends it across the service provider's network to the PE router connected to the receiving site. The PE routers do not need to store or process the customer's routes; they only need to be configured to send data to the appropriate tunnel.

For a Layer 2 VPN, customers need to configure their own routers to carry all Layer 3 traffic. The service provider needs to know only how much traffic the Layer 2 VPN will need to carry. The service provider's routers carry traffic between the customer's sites

using Layer 2 VPN interfaces. The VPN topology is determined by policies configured on the PE routers.

Customers need to know only which VPN interfaces connect to which of their own sites. [Figure 9 on page 124](#) illustrates a Layer 2 VPN in which each site has a VPN interface linked to each of the other customer sites.

Figure 9: Layer 2 VPN Connecting CE Routers

Implementing a Layer 2 MPLS VPN includes the following benefits:

- Service providers do not have to invest in separate Layer 2 equipment to provide Layer 2 VPN service. A Layer 2 MPLS VPN allows you to provide Layer 2 VPN service over an existing IP and MPLS backbone.
- You can configure the PE router to run any Layer 3 protocol in addition to the Layer 2 protocols.
- Customers who prefer to maintain control over most of the administration of their own networks might want Layer 2 VPN connections with their service provider instead of a Layer 3 VPN.
- Because Layer 2 VPNs use BGP as the signaling protocol, they have a simpler design and require less overhead than traditional VPNs over Layer 2 circuits. BGP signaling also enables autodiscovery of Layer 2 VPN peers. Layer 2 VPNs are similar to BGP or MPLS VPNs and VPLS in many respects; all three types of services employ BGP for signaling.

Layer 2 VPN Applications

Implementing a Layer 2 VPN includes the following benefits:

- Terminating a Layer 2 VPN into a Layer 2 VPN using the interworking (iw0) software interface eliminates the limitation of bandwidth on the tunnel interfaces used for these configuration scenarios. Instead of using a physical Tunnel PIC for looping the packet received from the Layer 2 VPN to another Layer 2 VPN, Junos OS is used to link both the Layer 2 VPN routes.
- Layer 2 VPNs enable the sharing of a provider's core network infrastructure between IP and Layer 2 VPN services, reducing the cost of providing those services. A Layer 2 MPLS VPN allows you to provide Layer 2 VPN service over an existing IP and MPLS backbone.
- From a service provider's point of view, a Layer 2 MPLS VPN allows the use of a single Layer 3 VPN (such as RFC 2547bis), MPLS traffic engineering, and Differentiated Services (DiffServ).
- Service providers do not have to invest in separate Layer 2 equipment to provide Layer 2 VPN service. You can configure the PE router to run any Layer 3 protocol in addition to the Layer 2 protocols. Customers who prefer to maintain control over most of the administration of their own networks might want Layer 2 VPN connections with their service provider instead of a Layer 3 VPN.

Layer 2 VPNs Configuration Overview

- [Introduction to Configuring Layer 2 VPNs on page 127](#)
- [Configuring the Local Site on PE Routers in Layer 2 VPNs on page 128](#)
- [Layer 2 VPN Configuration Example on page 134](#)
- [Example: Configuring MPLS-Based Layer 2 VPNs on page 151](#)
- [Transmitting Nonstandard BPDUs in Layer 2 VPNs and VPLS on page 166](#)

Introduction to Configuring Layer 2 VPNs

To configure Layer 2 virtual private network (VPN) functionality, you must enable Layer 2 VPN support on the provider edge (PE) router. You must also configure PE routers to distribute routing information to the other PE routers in the VPN and configure the circuits between the PE routers and the customer edge (CE) routers.

Each Layer 2 VPN is configured under a routing instance of type **l2vpn**. An **l2vpn** routing instance can transparently carry Layer 3 traffic across the service provider's network. As with other routing instances, all logical interfaces belonging to a Layer 2 VPN routing instance are listed under that instance.

The configuration of the CE routers is not relevant to the service provider. The CE routers need to provide only appropriate Layer 2 circuits (with appropriate circuit identifiers, such as data-link connection identifier [DLCI], virtual path identifier/virtual channel identifier [VPI/VCI], or virtual LAN [VLAN] ID) to send traffic to the PE router.

To configure Layer 2 VPNs, include the following statements:

NOTE: On the EX9200 switches, replace **encapsulation-type** with the **encapsulation** statement.

```
description text;
instance-type l2vpn;
interface interface-name;
route-distinguisher (as-number:id|ip-address:id);
vrf-export [ policy-names ];
vrf-import [ policy-names ];
vrf-target {
    community;
}
```

```
import community-name;
export community-name;
}
protocols {
  l2vpn {
    (control-word | no-control-word);
    encapsulation-type type;
    site site-name {
      interface interface-name {
        description text;
        remote-site-id remote-site-id;
      }
      site-identifier identifier;
      site-preference preference-value {
        backup;
        primary;
      }
    }
    traceoptions {
      file filename <files number> <size size> <world-readable | no-world-readable>;
      flag flag <flag-modifier> <disable>;
    }
  }
}
```

You can include these statements at the following hierarchy levels:

- [edit routing-instances *routing-instance-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]

For Layer 2 VPNs, only some of the statements in the [edit routing-instances] hierarchy are valid. For the full hierarchy, see *Junos OS Routing Protocols Library*.

In addition to these statements, you must configure MPLS label-switched paths (LSPs) between the PE routers, IBGP sessions between the PE routers, and an interior gateway protocol (IGP) on the PE and provider (P) routers. You must also configure the statements that are required for all types of VPN configuration.

By default, Layer 2 VPNs are disabled.

Many of the configuration procedures for Layer 2 VPNs are identical to the procedures for Layer 3 VPNs and virtual private LAN service (VPLS).

Configuring the Local Site on PE Routers in Layer 2 VPNs

For each local site, the PE router advertises a set of VPN labels to the other PE routers servicing the Layer 2 VPN. The VPN labels constitute a single block of contiguous labels; however, to allow for reprovisioning, more than one such block can be advertised. Each label block consists of a label base, a range (the size of the block), and a remote site ID that identifies the sequence of remote sites that connect to the local site using this label block (the remote site ID is the first site identifier in the sequence). The encapsulation type is also advertised along with the label block.

The following sections explain how to configure the connections to the local site on the PE router.

NOTE: Not all subtasks are supported on all platforms; check the CLI on your device.

- [Configuring a Layer 2 VPN Routing Instance on page 129](#)
- [Configuring the Site on page 130](#)
- [Configuring the Remote Site ID on page 130](#)
- [Configuring the Encapsulation Type on page 132](#)
- [Configuring a Site Preference and Layer 2 VPN Multihoming on page 133](#)
- [Tracing Layer 2 VPN Traffic and Operations on page 133](#)

Configuring a Layer 2 VPN Routing Instance

To configure a Layer 2 VPN on your network, configure a Layer 2 VPN routing instance on the PE router by including the **l2vpn** statement:

NOTE: On the EX9200 switches, replace **encapsulation-type** with the **encapsulation** statement.

```
l2vpn {
  (control-word | no-control-word);
  encapsulation-type type;
  traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
  }
  site site-name {
    site-identifier identifier;
    site-preference preference-value {
      backup;
      primary;
    }
    interface interface-name {
      description text;
      remote-site-id remote-site-id;
    }
  }
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols]

NOTE: You cannot configure a routing protocol (OSPF, RIP, IS-IS or BGP) inside a Layer 2 VPN routing instance (instance-type l2vpn). The Junos CLI disallows this configuration.

Instructions for how to configure the remaining statements are included in the sections that follow.

Configuring the Site

All the Layer 2 circuits provisioned for a local site are listed as the set of logical interfaces (specified by including the **interface** statement) within the **site** statement.

On each PE router, you must configure each site that has a circuit to the PE router. To do this, include the **site** statement:

```
site site-name {
  site-identifier identifier;
  site-preference preference-value {
    backup;
    primary;
  }
  interface interface-name {
    description text;
    remote-site-id remote-site-ID;
  }
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols l2vpn]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols l2vpn]

You must configure the following for each site:

- **site-name**—Name of the site.
- **site-identifier** *identifier*—Unsigned 16-bit number greater than zero that uniquely identifies the local Layer 2 VPN site. The site identifier corresponds to the remote site ID configured on another site within the same VPN.
- **interface** *interface-name*—The name of the interface and, optionally, a remote site ID for remote site connections. See [“Configuring the Remote Site ID” on page 130](#).

Configuring the Remote Site ID

The remote site ID allows you to configure a sparse Layer 2 VPN topology. A sparse topology means that each site does not have to connect to all the other sites in the VPN; thus it is unnecessary to allocate circuits for all the remote sites. Remote site IDs are particularly important if you configure a topology more complicated than full-mesh, such as a hub-and-spoke topology.

The remote site ID (configured with the **remote-site-id** statement) corresponds to the site ID (configured with the **site-identifier** statement) configured at a separate site. [Figure 10 on page 131](#) illustrates the relationship between the site identifier and the remote site ID.

Figure 10: Relationship Between the Site Identifier and the Remote Site ID

As illustrated by the figure, the configuration for Router PE1 connected to Router CE1 is as follows:

```
site-identifier 1;
interface so-0/0/0 {
  remote-site-id 2;
}
```

The configuration for Router PE2 connected to Router CE2 is as follows:

```
site-identifier 2;
interface so-0/0/1 {
  remote-site-id 1;
}
```

The remote site ID (2) on Router PE1 corresponds to the site identifier (2) on Router PE2. On Router PE2, the remote site ID (1) corresponds to the site identifier (1) on Router PE1.

To configure the remote site ID, include the **remote-site-id** statement:

```
remote-site-id remote-site-id;
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols l2vpn site *site-name* interface *interface-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols l2vpn site *site-name* interface *interface-name*]

If you do not explicitly include the **remote-site-id** statement for the interface configured at the [edit routing-instances *routing-instance-name* protocols l2vpn site *site-name*] hierarchy level, a remote site ID is assigned to that interface.

The remote site ID for an interface is automatically set to 1 higher than the remote site ID for the previous interface. The order of the interfaces is based on their **site-identifier** statements. For example, if the first interface in the list does not have a remote site ID, its ID is set to 1. The second interface in the list has its remote site ID set to 2, and the

third has its remote site ID set to 3. The remote site IDs of any interfaces that follow are incremented in the same manner if you do not explicitly configure them.

Configuring the Encapsulation Type

The encapsulation type you configure at each Layer 2 VPN site varies depending on which Layer 2 protocol you choose to configure. If you configure **ethernet-vlan** as the encapsulation type, you need to use the same protocol at each Layer 2 VPN site.

You do not need to use the same protocol at each Layer 2 VPN site if you configure any of the following encapsulation types:

- **atm-aal5**—Asynchronous Transfer Mode (ATM) Adaptation Layer (AAL5)
- **atm-cell**—ATM cell relay
- **atm-cell-port-mode**—ATM cell relay port promiscuous mode
- **atm-cell-vc-mode**—ATM virtual circuit (VC) cell relay nonpromiscuous mode
- **atm-cell-vp-mode**—ATM virtual path (VP) cell relay promiscuous mode
- **cisco-hdlc**—Cisco Systems-compatible High-Level Data Link Control (HDLC)
- **ethernet**—Ethernet
- **ethernet-vlan**—Ethernet virtual LAN (VLAN)
- **frame-relay**—Frame Relay
- **frame-relay-port-mode**—Frame Relay port mode
- **interworking**—Layer 2.5 interworking VPN
- **ppp**—Point-to-Point Protocol (PPP)

If you configure different protocols at your Layer 2 VPN sites, you need to configure a translational cross-connect (TCC) encapsulation type. For more information, see [“Configuring TCC Encapsulation for Layer 2 VPNs and Layer 2 Circuits” on page 168](#).

To configure the Layer 2 protocol accepted by the PE router, specify the encapsulation type by including the **encapsulation-type** statement:

encapsulation-type *type*;

For EX9200 switches, specify the encapsulation type by including the **encapsulation** statement:

encapsulation *type*;

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols l2vpn]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols l2vpn]

Configuring a Site Preference and Layer 2 VPN Multihoming

You can specify the preference value advertised for a particular Layer 2 VPN site. The site preference value is encoded in the BGP local preference attribute. When a PE router receives multiple advertisements with the same CE device identifier, the advertisement with the highest local preference value is preferred.

You can also use the **site-preference** statement to enable multihoming for Layer 2 VPNs. Multihoming allows you to connect a CE device to multiple PE routers. In the event that a connection to the primary PE router fails, traffic can be automatically switched to the backup PE router.

To configure a site preference for a Layer 2 VPN, include the **site-preference** statement:

```
site-preference preference-value {
    backup;
    primary;
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols l2vpn site *site-name*]
- [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols l2vpn site *site-name*]

You can also specify either the **backup** option or the **primary** option for the **site-preference** statement. The backup option specifies the preference value as 1, the lowest possible value, ensuring that the Layer 2 VPN site is the least likely to be selected. The primary option specifies the preference value as 65,535, the highest possible value, ensuring that the Layer 2 VPN site is the most likely to be selected.

For Layer 2 VPN multihoming configurations, specifying the **primary** option for a Layer 2 VPN site designates the connection from the PE router to the CE device as the preferred connection if the CE device is also connected to another PE router. Specifying the **backup** option for a Layer 2 VPN site designates the connection from the PE router to the CE device as the secondary connection if the CE device is also connected to another PE router.

Tracing Layer 2 VPN Traffic and Operations

To trace Layer 2 VPN protocol traffic, specify options for the **traceoptions** statement in the Layer 2 VPN configuration:

```
traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
}
```

You can include this statement at the following hierarchy levels:

- [edit routing-instances *routing-instance-name* protocols l2vpn]

- `[edit logical-systems logical-system-name routing-instances routing-instance-name protocols l2vpn]`

The following trace flags display the operations associated with Layer 2 VPNs:

- **all**—All Layer 2 VPN tracing options.
- **connections**—Layer 2 connections (events and state changes).
- **error**—Error conditions.
- **general**—General events.
- **nlri**—Layer 2 advertisements received or sent by means of the BGP.
- **normal**—Normal events.
- **policy**—Policy processing.
- **route**—Routing information.
- **state**—State transitions.
- **task**—Routing protocol task processing.
- **timer**—Routing protocol timer processing.
- **topology**—Layer 2 VPN topology changes caused by reconfiguration or advertisements received from other PE routers using BGP.

Disabling Normal TTL Decrementing for VPNs

To diagnose networking problems related to VPNs, it can be useful to disable normal time-to-live (TTL) decrementing. In Junos, you can do this with the **no-propagate-ttl** and **no-decrement-ttl** statements. However, when you are tracing VPN traffic, only the **no-propagate-ttl** statement is effective.

For the **no-propagate-ttl** statement to have an effect on VPN behavior, you need to clear the PE-router-to-PE-router BGP session, or disable and then enable the VPN routing instance.

For more information about the **no-propagate-ttl** and **no-decrement-ttl** statements, see the *MPLS Applications Feature Guide*.

Layer 2 VPN Configuration Example

The following sections explain how to configure Layer 2 VPN functionality on the provider edge (PE) routers connected to each site:

- [Simple Full-Mesh Layer 2 VPN Overview on page 135](#)
- [Enabling an IGP on the PE Routers on page 135](#)
- [Configuring MPLS LSP Tunnels Between the PE Routers on page 135](#)
- [Configuring IBGP on the PE Routers on page 137](#)
- [Configuring Routing Instances for Layer 2 VPNs on the PE Routers on page 138](#)

- [Configuring CCC Encapsulation on the Interfaces on page 140](#)
- [Configuring VPN Policy on the PE Routers on page 141](#)
- [Layer 2 VPN Configuration Summarized by Router on page 144](#)

Simple Full-Mesh Layer 2 VPN Overview

In the sections that follow, you configure a simple full-mesh Layer 2 VPN spanning three sites: Sunnyvale, Austin, and Portland. Each site connects to a PE router. The customer edge (CE) routers at each site use Frame Relay to carry Layer 2 traffic to the PE routers. Since this example uses a full-mesh topology between all three sites, each site requires two logical interfaces (one for each of the other CE routers), although only one physical link is needed to connect each PE router to each CE router. [Figure 11 on page 135](#) illustrates the topology of this Layer 2 VPN.

Figure 11: Example of a Simple Full-Mesh Layer 2 VPN Topology

Enabling an IGP on the PE Routers

To allow the PE routers to exchange routing information among themselves, you must configure an interior gateway protocol (IGP) or static routes on these routers. You configure the IGP on the master instance of the routing protocol process (rpd) (that is, at the **[edit protocols]** hierarchy level), not within the Layer 2 VPN routing instance (that is, not at the **[edit routing-instances]** hierarchy level). Turn on traffic engineering on the IGP.

You configure the IGP in the standard way. This example does not include this portion of the configuration.

Configuring MPLS LSP Tunnels Between the PE Routers

In this configuration example, RSVP is used for MPLS signaling. Therefore, in addition to configuring RSVP, you must create an MPLS label-switched path (LSP) to tunnel the VPN traffic.

On Router A, enable RSVP and configure one end of the MPLS LSP tunnel to Router B. When configuring the MPLS LSP, include all interfaces using the **interface all** statement.

```
[edit]
protocols {
  rsvp {
    interface all;
  }
  mpls {
    interface all;
    label-switched-path RouterA-to-RouterB {
      to 192.168.37.5;
      primary Path-to-RouterB;
    }
    label-switched-path RouterA-to-RouterC {
      to 192.168.37.10;
      primary Path-to-RouterC;
    }
  }
}
```

On Router B, enable RSVP and configure the other end of the MPLS LSP tunnel. Again, configure the interfaces by using the **interface all** statement.

```
[edit]
protocols {
  rsvp {
    interface all;
  }
  mpls {
    interface all;
    label-switched-path RouterB-to-RouterA {
      to 192.168.37.1;
      primary Path-to-RouterA;
    }
    label-switched-path RouterB-to-RouterC {
      to 192.168.37.10;
      primary Path-to-RouterC;
    }
  }
}
```

On Router C, enable RSVP and configure the other end of the MPLS LSP tunnel. Again, configure all interfaces using the **interface all** statement.

```
[edit]
protocols {
  rsvp {
    interface all;
  }
  mpls {
    interface all;
    label-switched-path RouterC-to-RouterA {
      to 192.168.37.1;
      primary Path-to-RouterA;
    }
  }
}
```

```

        label-switched-path RouterC-to-RouterB {
            to 192.168.37.5;
            primary Path-to-RouterB;
        }
    }
}

```

Configuring IBGP on the PE Routers

On the PE routers, configure an IBGP session with the following parameters:

- Layer 2 VPN—To indicate that the IBGP session is for a Layer 2 VPN, include the **family l2vpn** statement.
- Local address—The IP address in the **local-address** statement is the same as the address configured in the **to** statement at the **[edit protocols mpls label-switched-path lsp-path-name]** hierarchy level on the remote PE router. The IBGP session for Layer 2 VPNs runs through this address.
- Neighbor address—Include the **neighbor** statement, specifying the IP address of the neighboring PE router.

On Router A, configure IBGP:

```

[edit]
protocols {
    bgp {
        import match-all;
        export match-all;
        group pe-pe {
            type internal;
            neighbor 192.168.37.5 {
                local-address 192.168.37.1;
                family l2vpn {
                    signaling;
                }
            }
            neighbor 192.168.37.10 {
                local-address 192.168.37.1;
                family l2vpn {
                    signaling;
                }
            }
        }
    }
}

```

On Router B, configure IBGP:

```

[edit]
protocols {
    bgp {
        local-address 192.168.37.5;
        import match-all;
        export match-all;
        group pe-pe {

```

```

    type internal;
    neighbor 192.168.37.1 {
        local-address 192.168.37.5;
        family l2vpn {
            signaling;
        }
    }
    neighbor 192.168.37.10 {
        local-address 192.168.37.5;
        family l2vpn {
            signaling;
        }
    }
}
}

```

On Router C, configure IBGP:

```

[edit]
protocols {
  bgp {
    local-address 192.168.37.10;
    import match-all;
    export match-all;
    group pe-pe {
      type internal;
      neighbor 192.168.37.1 {
        local-address 192.168.37.10;
        family l2vpn {
          signaling;
        }
      }
      neighbor 192.168.37.5 {
        local-address 192.168.37.10;
        family l2vpn {
          signaling;
        }
      }
    }
  }
}

```

Configuring Routing Instances for Layer 2 VPNs on the PE Routers

The three PE routers service the Layer 2 VPN, so you need to configure a routing instance on each router. For the VPN, you must define the following in each routing instance:

- Route distinguisher, which must be unique for each routing instance on the PE router. It is used to distinguish the addresses in one VPN from those in another VPN.
- Instance type of **l2vpn**, which configures the router to run a Layer 2 VPN.
- Interfaces connected to the CE routers.
- Virtual routing and forwarding (VRF) import and export policies, which must be the same on each PE router that services the same VPN and are used to control the network

topology. Unless the import policy contains only a **then reject** statement, it must include a reference to a community. Otherwise, when you attempt to commit the configuration, the commit operation fails.

On Router A, configure the following routing instance for the Layer 2 VPN:

```
[edit]
routing-instances {
  VPN-Sunnyvale-Portland-Austin {
    instance-type l2vpn;
    interface so-6/0/0.0;
    interface so-6/0/0.1;
    route-distinguisher 100:1;
    vrf-import vpn-SPA-import;
    vrf-export vpn-SPA-export;
    protocols {
      l2vpn {
        encapsulation-type frame-relay;
        site Sunnyvale {
          site-identifier 1;
          interface so-6/0/0.0 {
            remote-site-id 2;
          }
          interface so-6/0/0.1 {
            remote-site-id 3;
          }
        }
      }
    }
  }
}
```

On Router B, configure the following routing instance for the Layer 2 VPN:

```
[edit]
routing-instances {
  VPN-Sunnyvale-Portland-Austin {
    instance-type l2vpn;
    interface so-6/0/0.2;
    interface so-6/0/0.3;
    route-distinguisher 100:1;
    vrf-import vpn-SPA-import;
    vrf-export vpn-SPA-export;
    protocols {
      l2vpn {
        encapsulation-type frame-relay;
        site Austin {
          site-identifier 2;
          interface so-6/0/0.2 {
            remote-site-id 1;
          }
          interface so-6/0/0.3 {
            remote-site-id 3;
          }
        }
      }
    }
  }
}
```

```

    }
  }
}

```

On Router C, configure the following routing instance for the Layer 2 VPN:

```

[edit]
routing-instances {
  VPN-Sunnyvale-Portland-Austin {
    instance-type l2vpn;
    interface so-6/0/0.4;
    interface so-6/0/0.5;
    route-distinguisher 100:1;
    vrf-import vpn-SPA-import;
    vrf-export vpn-SPA-export;
    protocols {
      l2vpn {
        encapsulation-type frame-relay;
        site Portland {
          site-identifier 3;
          interface so-6/0/0.4 {
            remote-site-id 1;
          }
          interface so-6/0/0.5 {
            remote-site-id 2;
          }
        }
      }
    }
  }
}

```

Configuring CCC Encapsulation on the Interfaces

You need to specify a circuit cross-connect (CCC) encapsulation type for each PE-router-to-CE-router interface running in the Layer 2 VPN. This encapsulation type should match the encapsulation type configured under the routing instance.

Configure the following CCC encapsulation types for the interfaces on Router A:

```

[edit]
interfaces so-6/0/0 {
  encapsulation frame-relay-ccc;
  unit 0 {
    encapsulation frame-relay-ccc;
  }
}
interfaces so-6/0/0 {
  encapsulation frame-relay-ccc;
  unit 1 {
    encapsulation frame-relay-ccc;
  }
}

```

Configure the following CCC encapsulation types for the interfaces on Router B:

```

[edit]

```

```

interfaces so-6/0/0 {
    encapsulation frame-relay-ccc;
    unit 2 {
        encapsulation frame-relay-ccc;
    }
}
interfaces so-6/0/0 {
    encapsulation frame-relay-ccc;
    unit 3 {
        encapsulation frame-relay-ccc;
    }
}

```

Configure the following CCC encapsulation types for the interfaces on Router C:

```

[edit]
interface so-6/0/0 {
    encapsulation frame-relay-ccc;
    unit 4 {
        encapsulation frame-relay-ccc;
    }
}
interface so-6/0/0 {
    encapsulation frame-relay-ccc;
    unit 5 {
        encapsulation frame-relay-ccc;
    }
}

```

Configuring VPN Policy on the PE Routers

You must configure VPN import and export policies on each of the PE routers so that they install the appropriate routes in their VRF tables, which the routers use to forward packets within the VPN.

NOTE: Use the `community add community-name` statement at the `[edit policy-options policy-statement policy-statement-name term term-name then]` hierarchy level to facilitate Layer 2 VPN VRF export policies.

On Router A, configure the following VPN import and export policies:

```

[edit]
policy-options {
    policy-statement match-all {
        term acceptable {
            then accept;
        }
    }
    policy-statement vpn-SPA-export {
        term a {
            then {
                community add SPA-com;
                accept;
            }
        }
    }
}

```

```
    }  
    term b {  
        then reject;  
    }  
}  
policy-statement vpn-SPA-import {  
    term a {  
        from {  
            protocol bgp;  
            community SPA-com;  
        }  
        then accept;  
    }  
    term b {  
        then reject;  
    }  
}  
community SPA-com members target:69:100;  
}
```

On Router B, configure the following VPN import and export policies:

```
[edit]  
policy-options {  
    policy-statement match-all {  
        term acceptable {  
            then accept;  
        }  
    }  
    policy-statement vpn-SPA-import {  
        term a {  
            from {  
                protocol bgp;  
                community SPA-com;  
            }  
            then accept;  
        }  
        term b {  
            then reject;  
        }  
    }  
    policy-statement vpn-SPA-export {  
        term a {  
            then {  
                community add SPA-com;  
                accept;  
            }  
        }  
        term b {  
            then reject;  
        }  
    }  
    community SPA-com members target:69:100;  
}
```

On Router C, configure the following VPN import and export policies:

```
[edit]
policy-options {
  policy-statement match-all {
    term acceptable {
      then accept;
    }
  }
  policy-statement vpn-SPA-import {
    term a {
      from {
        protocol bgp;
        community SPA-com;
      }
      then accept;
    }
    term b {
      then reject;
    }
  }
  policy-statement vpn-SPA-export {
    term a {
      then {
        community add SPA-com;
        accept;
      }
    }
    term b {
      then reject;
    }
  }
  community SPA-com members target:69:100;
}
```

To apply the VPN policies on the routers, include the **vrf-export** and **vrf-import** statements when you configure the routing instance. The VRF import and export policies handle the route distribution across the IBGP session running between the PE routers.

To apply the VPN policies on Router A, include the following statements:

```
[edit]
routing-instances {
  VPN-Sunnyvale-Portland-Austin {
    vrf-import vpn-SPA-import;
    vrf-export vpn-SPA-export;
  }
}
```

To apply the VPN policies on Router B, include the following statements:

```
[edit]
routing-instances {
  VPN-Sunnyvale-Portland-Austin {
    vrf-import vpn-SPA-import;
    vrf-export vpn-SPA-export;
  }
}
```

To apply the VPN policies on Router C, include the following statements:

```
[edit]
routing-instances {
  VPN-Sunnyvale-Portland-Austin {
    vrf-import vpn-SPA-import;
    vrf-export vpn-SPA-export;
  }
}
```

Layer 2 VPN Configuration Summarized by Router

For a summary of the configuration on each router in the examples in this chapter, see the following sections:

- [Summary for Router A \(PE Router for Sunnyvale\) on page 144](#)
- [Summary for Router B \(PE Router for Austin\) on page 146](#)
- [Summary for Router C \(PE Router for Portland\) on page 148](#)

Summary for Router A (PE Router for Sunnyvale)

Routing Instance for Layer 2 VPN

```
[edit]
routing-instances {
  VPN-Sunnyvale-Portland-Austin {
    instance-type l2vpn;
    interface so-6/0/0.0;
    interface so-6/0/0.1;
    route-distinguisher 100:1;
    vrf-import vpn-SPA-import;
    vrf-export vpn-SPA-export;
    protocols {
      l2vpn {
        encapsulation-type frame-relay;
        site Sunnyvale {
          site-identifier 1;
          interface so-6/0/0.0 {
            remote-site-id 2;
          }
          interface so-6/0/0.1 {
            remote-site-id 3;
          }
        }
      }
    }
  }
}
```

Configure CCC Encapsulation Types for Interfaces

```
interfaces {
  interface so-6/0/0 {
    encapsulation frame-relay-ccc;
    unit 0 {
      encapsulation frame-relay-ccc;
    }
  }
}
```

	<pre> interface so-6/0/0 { encapsulation frame-relay-ccc; unit 1 { encapsulation frame-relay-ccc; } } </pre>
Master Protocol Instance	<pre> protocols { } </pre>
Enable RSVP	<pre> rsvp { interface all; } </pre>
Configure MPLS LSPs	<pre> mpls { label-switched-path RouterA-to-RouterB { to 192.168.37.5; primary Path-to-RouterB { cspf; } } label-switched-path RouterA-to-RouterC { to 192.168.37.10; primary Path-to-RouterC { cspf; } } interface all; } </pre>
Configure IBGP	<pre> bgp { import match-all; export match-all; group pe-pe { type internal; neighbor 192.168.37.5 { local-address 192.168.37.1; family l2vpn { signaling; } } neighbor 192.168.37.10 { local-address 192.168.37.1; family l2vpn { signaling; } } } } </pre>
Configure VPN Policy	<pre> policy-options { policy-statement match-all { </pre>

```
    term acceptable {
        then accept;
    }
}
policy-statement vpn-SPA-export {
    term a {
        then {
            community add SPA-com;
            accept;
        }
    }
    term b {
        then reject;
    }
}
policy-statement vpn-SPA-import {
    term a {
        from {
            protocol bgp;
            community SPA-com;
        }
        then accept;
    }
    term b {
        then reject;
    }
}

Example: Configuring MPLS-Based Layer 2 VPNs

You can implement an MPLS-based Layer 2 virtual private network (VPN) using Junos OS routing devices to interconnect customer sites with Layer 2 technology. Layer 2 VPNs give customers complete control of their own routing. To support an MPLS-based Layer 2 VPN, you need to add components to the configuration of the two provider edge (PE) routing devices. You do not need to change the configuration of the provider devices.

This example shows how to configure an MPLS-based Layer 2 VPN.

NOTE: You can configure both an MPLS-based Layer 2 VPN and an MPLS-based Layer 3 VPN on the same device. However, you cannot configure the same customer edge interface to support both a Layer 2 VPN and a Layer 3 VPN. The core interfaces and the loopback interfaces are configured in the same way for Layer 2 VPNs and Layer 3 VPNs.

- [Requirements on page 152](#)
- [Overview and Topology on page 152](#)
- [Configuring the Local PE Routing Device on page 155](#)
- [Configuring the Remote PE Routing Device on page 158](#)
- [Verification on page 161](#)

Requirements

This example uses the following hardware and software components:

- Junos OS Release 11.1 or later if you are using EX Series switches
- Two PE routing devices

Before you configure the Layer 2 VPN components, configure the basic components for an MPLS network:

- Configure two PE routing devices. See *Configuring MPLS on Provider Edge EX8200 and EX4500 Switches Using Circuit Cross-Connect (CLI Procedure)*.
- Configure one or more provider devices. See *Configuring MPLS on EX8200 and EX4500 Provider Switches (CLI Procedure)*.

NOTE: A Layer 2 VPN requires that the PE routing devices be configured using circuit cross-connect (CCC). The provider routing devices are configured in the same way for MPLS using CCC and for IP over MPLS.

Overview and Topology

A Layer 2 VPN provides complete separation between the provider's network and the customer's network—that is, the PE devices and the CE devices do not exchange routing information. Some benefits of a Layer 2 VPN are that it is private, secure, and flexible.

This example shows how to configure Layer 2 VPN components on the local and remote PE devices. This example does not include configuring a provider device, because there are no specific Layer 2 VPN components on the provider devices.

In the basic MPLS configuration of the PE devices using a circuit cross-connect (CCC), the PE devices are configured to use an interior gateway protocol (IGP), such as OSPF or IS-IS, as the routing protocol between the MPLS devices and LDP or RSVP as the signaling protocol. Traffic engineering is enabled. A label-switched path (LSP) is configured within the **[edit protocols]** hierarchy. However, unlike the basic MPLS configuration using a CCC, you do not need to associate the LSP with the customer edge interface. When you are configuring a Layer 2 VPN, you must use BGP signaling. The BGP signaling automates the connections, so manual configuration of the association between the LSP and the customer edge interface is not required.

The following components must be added to the PE routing devices for an MPLS-based Layer 2 VPN:

- BGP group with **family l2vpn signaling**
- Routing instance using instance type **l2vpn**
- The physical layer encapsulation type (**ethernet**) must be specified on the customer edge interface and the encapsulation type must also be specified in the configuration of the routing instance.

Figure 12 on page 153 illustrates the topology of this MPLS-based Layer 2 VPN.

Figure 12: MPLS-Based Layer 2 VPN

Table 3 on page 153 shows the settings of the customer edge interface on the local CE device.

Table 3: Local CE Routing Device in the MPLS-Based Layer 2 VPN Topology

Property	Settings	Description
Local CE routing device hardware	Routing device	CE1
Customer edge interface	ge-0/0/0 unit 0 family inet address 10.0.0.2/16	Interface that connects CE1 to PE1.

Table 4 on page 153 shows the settings of the customer edge interface on the remote CE routing device.

Table 4: Remote CE Routing Device in the MPLS-Based Layer 2 VPN Topology

Property	Settings	Description
Remote CE routing device hardware	Routing device	CE2
Customer edge interface	ge-0/0/0 unit 0 family inet address 10.0.0.1/16	Interface that connects CE2 to PE2.

Table 5 on page 153 shows the Layer 2 VPN components of the local PE routing device.

Table 5: Layer 2 VPN Components of the Local PE Routing Device

Property	Settings	Description
Local PE routing device hardware	Routing device	PE1

Table 5: Layer 2 VPN Components of the Local PE Routing Device (*continued*)

Property	Settings	Description
Customer edge interface	<code>ge-5/0/0</code> <code>encapsulation ethernet-ccc</code> <code>unit 0</code> <code>family ccc</code>	Connects PE1 to CE1. For the Layer 2 VPN, add ethernet-ccc as the physical layer encapsulation type. NOTE: The family ccc should already have been completed as part of the basic MPLS configuration of a PE routing device for circuit cross-connect. It is included here to show what was specified for that portion of the configuration.
Core interface	<code>xe-6/0/0 unit 0</code> <code>family inet address 10.0.0.60/16</code> <code>family iso</code> <code>family mpls</code>	Connects PE1 to P. NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
Loopback interface	<code>lo0 unit 0</code> <code>family inet address 192.0.2.0/24</code> <code>family iso address 49.0001.2102.2021.0210.00</code>	NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
BGP	<code>bgp</code>	Added for the Layer 2 VPN configuration.
Routing instance	<code>vpn1</code>	Added for the Layer 2 VPN configuration

[Table 6 on page 154](#) shows the Layer 2 VPN components of the remote PE routing device.

Table 6: Layer 2 VPN Components of the Remote PE Routing Device

Property	Settings	Description
PE routing device hardware	Routing device	PE2
Customer edge interface	<code>ge-11/0/0</code> <code>encapsulation ethernet-ccc unit 0</code> <code>family ccc</code>	Connects PE2 to CE2. For the Layer 2 VPN, add ethernet-ccc as the physical layer encapsulation type. NOTE: The family ccc should already have been completed as part of the basic MPLS configuration of a PE routing device for circuit cross-connect. It is included here to show what was specified for that portion of the configuration.

Table 6: Layer 2 VPN Components of the Remote PE Routing Device (*continued*)

Property	Settings	Description
Core interface	xe-6/0/0 unit 0 family inet address 10.2.0.61/16 family iso family mpls	Connects PE2 to P. NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
Loopback interface	lo0 unit 0 family inet address 192.0.2.3/24 family iso address 49.0001.2202.2022.0220.00	NOTE: This portion of the configuration should already have been completed as part of the basic MPLS configuration. It is included here to show what was specified for that portion of the configuration.
BGP	bgp	Added for the Layer 2 VPN configuration.
Routing instance	vpn1	Added for the Layer 2 VPN configuration.

Configuring the Local PE Routing Device

CLI Quick Configuration

To quickly configure the Layer 2 VPN components on the local PE routing device, copy the following commands and paste them into the routing device terminal window:

```
[edit]
set interfaces ge-5/0/0 encapsulation ethernet-ccc
set protocols bgp group ibgp local-address 192.0.2.0 family l2vpn signaling
set protocols bgp group ibgp type internal
set protocols bgp group ibgp neighbor 192.0.2.3
set routing-instances vpn1 instance-type l2vpn
set routing-instances vpn1 interface ge-5/0/0
set routing-instances vpn1 route-distinguisher 192.0.2.0:21
set routing-instances vpn1 vrf-target target:21:21
set routing-instances vpn1 protocols l2vpn encapsulation-type ethernet
set routing-instances vpn1 protocols l2vpn interface ge-5/0/0.0 description "BETWEEN PE1 AND CE1"
set routing-instances vpn1 protocols l2vpn site JE-V21 site-identifier 21 interface ge-5/0/0
remote-site-id 26
```

Step-by-Step Procedure

To configure the Layer 2 VPN components on the local PE routing device:

1. Configure the customer edge interface to use the physical encapsulation type **ethernet-ccc**:

```
[edit]
user@PE1# set interfaces ge-5/0/0 encapsulation ethernet-ccc
```

2. Configure BGP, specifying the loopback address as the local address and enabling **family l2vpn signaling**:

```
[edit protocols bgp]
user@PE1# set group ibgp local-address 192.0.2.0 family l2vpn signaling
```

3. Configure the BGP group, specifying the group name and type:

```
[edit protocols bgp]
user@PE1# set group ibgp type internal
```

4. Configure the BGP neighbor, specifying the loopback address of the remote PE routing device as the neighbor's address:

```
[edit protocols bgp]
user@PE1# set group ibgp neighbor 192.0.2.3/24
```

5. Configure the routing instance, specifying the routing-instance name and using **l2vpn** as the instance type:

```
[edit routing-instances]
user@PE1# set vpn1 instance-type l2vpn
```

6. Configure the routing instance to apply to the customer edge interface:

```
[edit routing-instances]
user@PE1# set vpn1 interface ge-5/0/0
```

7. Configure the routing instance to use a route distinguisher:

```
[edit routing-instances]
user@PE1# set vpn1 route-distinguisher 192.0.2.0:21
```

8. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@PE1# set vpn1 vrf-target target:21:21
```

NOTE: You can create more complex policies by explicitly configuring VRF import and export policies using the import and export options. See the [Junos OS VPNs Configuration Guide](#).

9. Configure the protocols and encapsulation type used by the routing instance:

```
[edit routing-instances]
user@PE1# set vpn1 protocols l2vpn encapsulation-type ethernet
```

10. Apply the routing instance to a customer edge interface and specify a description for it:

```
[edit routing-instances]
user@PE1# set vpn1 protocols interface ge-5/0/0.0 description "BETWEEN PE1 AND CE1"
```

11. Configure the routing-instance protocols site:

```
[edit routing-instances]
user@PE1# set vpn1 protocols l2vpn site JE-V21 site-identifier 21 remote-site-id 26
```

NOTE: The remote site ID (configured with the `remote-site-id` statement) corresponds to the site ID (configured with the `site-identifier` statement) configured on the other PE routing device.

Results Display the results of the configuration:

```
user@PE1# show

interfaces {
  ge-5/0/0 {
    encapsulation ethernet-ccc;
    unit 0 {
      family ccc;
    }
  }
  xe-6/0/0 {
    unit 0 {
      family inet {
        address 10.0.0.60/16;
      }
      family mpls;
    }
  }
  lo0 {
    unit 0 {
      family inet {
        address 192.0.2.0/24;
      }
      family iso {
        address 49.0001.2102.2021.0210.00;
      }
    }
  }
}

protocols {
  rsvp {
    interface lo0.0;
    interface xe-0/0/6.0;
  }
  mpls {
    label-switched-path lsp_to_pe2 {
      to 192.0.2.3;
    }
  }
  interface xe-0/0/6.0;
  bgp {
    group ibgp
    type internal
    local-address 192.0.2.0
```

```

        family l2vpn signaling
        unicast
    }
    routing-instances {
    vpn1 {
        instance-type l2vpn;
        interface ge-5/0/0.0;
        route-distinguisher 192.0.2.0:21;
        vrf-target target:21:21;
        protocols {
        l2vpn {
            encapsulation-type ethernet;
            interface ge-5/0/0.0 {
                description "BETWEEN PE1 AND CE1";
            }
            site JE-V21 {
                site-identifier 21;
                interface ge-5/0/0.0 {
                    remote-site-id 26;
                }
            }
        }
        }
    }
    }
}

```

Configuring the Remote PE Routing Device

CLI Quick Configuration To quickly configure the Layer 2 VPN components on the remote PE routing device, copy the following commands and paste them into the routing device terminal window:

```

[edit]
set interfaces ge-11/0/0 encapsulation ethernet-ccc
set protocols bgp group ibgp local-address 192.0.2.3 family l2vpn signaling
set protocols bgp group ibgp type internal
set protocols bgp group ibgp neighbor 192.0.2.0
set routing-instances vpn1 instance-type l2vpn
set routing-instances vpn1 interface ge-11/0/0
set routing-instances vpn1 route-distinguisher 192.0.2.0:21
set routing-instances vpn1 vrf-target target:21:21
set routing-instances vpn1 protocols l2vpn encapsulation-type ethernet
set routing-instances vpn1 protocols l2vpn interface ge-11/0/0.0 description "BETWEEN PE1 AND CE1"
set routing-instances vpn1 protocols l2vpn site T26-VPN1 site-identifier 26 remote-site-id 21

```

Step-by-Step Procedure To configure the Layer 2 VPN components on the remote PE routing device:

1. Configure the customer edge interface to use the physical encapsulation type **ethernet-ccc**:

```

[edit]
user@PE1# set interfaces ge-11/0/0 encapsulation ethernet-ccc

```

2. Configure BGP, specifying the loopback address as the **local-address** and specifying **family l2vpn signaling**:

```
[edit protocols bgp]
user@PE2# set group ibgp local-address 192.0.2.3 family l2vpn signaling
```

3. Configure the BGP group, specifying the group name and type:

```
[edit protocols bgp]
user@PE2# set group ibgp type internal
```

4. Configure the BGP neighbor, specifying the loopback address of the remote PE routing device as the neighbor's address:

```
[edit protocols bgp]
user@PE2# set group ibgp neighbor 192.0.2.0
```

5. Configure the routing instance, specifying the routing-instance name and using **l2vpn** as the **instance-type**:

```
[edit routing-instances]
user@PE2# set vpn1 instance-type l2vpn
```

6. Configure the routing instance to apply to the customer edge interface:

```
[edit routing-instances]
user@PE2# set vpn1 interface ge-11/0/0.0
```

7. Configure the routing instance to use a route distinguisher, using the format *ip-address:number*:

```
[edit routing-instances]
user@PE2# set vpn1 route-distinguisher 192.0.2.0:21
```

8. Configure the VPN routing and forwarding (VRF) target of the routing instance:

```
[edit routing-instances]
user@PE2# set vpn1 vrf-target target:21:21
```

9. Configure the protocols and encapsulation type used by the routing instance:

```
[edit routing-instances]
user@PE2# set vpn1 protocols l2vpn encapsulation-type ethernet
```

10. Apply the routing instance to a customer edge interface and specify a description for it:

```
[edit routing-instances]
user@PE1# set vpn1 protocols interface ge-11/0/0.0 description "BETWEEN PE1 AND CE1"
```

11. Configure the routing-instance protocols site:

```
[edit routing-instances]
user@PE2# set vpn1 protocols l2vpn site T26-VPN1 site-identifier 26 remote-site-id 21
```

NOTE: The remote site ID (configured with the `remote-site-id` statement) corresponds to the site ID (configured with the `site-identifier` statement) configured on the other PE routing device.

Results Display the results of the configuration:

```
user@PE2# show

interfaces {
  ge-11/0/0 {
    encapsulation ethernet-ccc;
    unit 0 {
      family ccc;
    }
  }

  vrf-target target:21:21;
  protocols {
    l2vpn {
      encapsulation-type ethernet;
      interface ge-11/0/0.0 {
        description "BETWEEN PE1 AND CE1";
      }
      site T26-VPN1 {
        site-identifier 26;
        interface ge-11/0/0.0 {
          remote-site-id 21;
        }
      }
    }
  }
}
```

Verification

To confirm that the MPLS-based Layer 2 VPN is working properly, perform these tasks:

- [Verifying the Layer 2 VPN Connection on page 161](#)
- [Verifying the Status of MPLS Label-Switched Paths on page 162](#)
- [Verifying BGP Status on page 163](#)
- [Verifying the Status of the RSVP Sessions on page 163](#)
- [Verifying the Routes in the Routing Table on page 164](#)
- [Pinging the Layer 2 VPN Connections on page 165](#)

Verifying the Layer 2 VPN Connection

Purpose Verify that the Layer 2 VPN connection is up.

Action user@PE1> [show l2vpn connections](#)

Layer-2 VPN connections:

Legend for connection status (St)

EI -- encapsulation invalid	NC -- interface encapsulation not CCC/TCC/VPLS
EM -- encapsulation mismatch	WE -- interface and instance encaps not same
VC-Dn -- Virtual circuit down	NP -- interface hardware not present
CM -- control-word mismatch	-> -- only outbound connection is up
CN -- circuit not provisioned	<- -- only inbound connection is up
OR -- out of range	Up -- operational
OL -- no outgoing label	Dn -- down
LD -- local site signaled down	CF -- call admission control failure
RD -- remote site signaled down	SC -- local and remote site ID collision
LN -- local site not designated	LM -- local site ID not minimum designated
RN -- remote site not designated	RM -- remote site ID not minimum designated
XX -- unknown connection status	IL -- no incoming label
MM -- MTU mismatch	MI -- Mesh-Group ID not available
BK -- Backup connection	ST -- Standby connection
PF -- Profile parse failure	PB -- Profile busy
RS -- remote site standby	SN -- Static Neighbor

Legend for interface status

Up -- operational
Dn -- down

Instance: vpn1

Local site: JE-V21 (21)

connection-site	Type	St	Time last up	# Up trans
26	rmt	Up	Apr 16 05:53:21 2010	1

Remote PE: 192.0.2.3, Negotiated control-word: Yes (Null)
Incoming label: 800000, Outgoing label: 800001
Local interface: ge-5/0/0.0, Status: Up, Encapsulation: ETHERNET

Meaning The **St** field in the output shows that the Layer 2 VPN connection to **Remote PE (192.0.2.3)** is up.

[Verifying the Status of MPLS Label-Switched Paths](#)

Purpose Verify that the MPLS label-switched paths (ingress and egress) are up.

Action user@PE1> show mpls lsp
Ingress LSP: 1 sessions

To	From	State	Rt	P	ActivePath	LSPname
192.0.2.3	192.0.2.0	Up	0	*		lsp_to_pe2

Total 1 displayed, Up 1, Down 0

Egress LSP: 1 sessions

To	From	State	Rt	Style	Labelin	Labelout	LSPname
192.0.2.0	192.0.2.3	Up	0	1 FF	3	-	lsp_to_pe1

Total 1 displayed, Up 1, Down 0

Transit LSP: 0 sessions

Total 0 displayed, Up 0, Down 0

Meaning The **State** field in the output shows that the Ingress LSP to **Remote PE (192.0.2.3)** is up, and the Egress LSP from the remote PE routing device to this PE routing device (**192.0.2.0**) is also up.

Verifying BGP Status

Purpose Verify that BGP is up.

Action user@PE1> show bgp summary

Groups: 1 Peers: 1 Down peers: 0

Table	Tot Paths	Act Paths	Suppressed	History	Damp	State	Pending
bgp.12vpn.0	1	1	0	0	0	0	0
Peer	AS	InPkt	OutPkt	OutQ	Flaps	Last	Up/Dwn
State #Active/Received/Accepted/Damped...							
192.0.2.3	10	33	34	0	1	13:24	Establ

bgp.12vpn.0: 1/1/1/0

vpn2.12vpn.0: 1/1/1/0

Meaning The output shows that the remote PE routing device (**192.0.2.3**) is listed as the BGP peer and that a protocol session has been established. It also shows the number of packets received from the remote PE routing device (**33**) and the number of packets sent (**34**) to the remote PE routing device.

Verifying the Status of the RSVP Sessions

Purpose Verify that the RSVP sessions (ingress and egress) are up.

Action user@PE1> **show rsvp session**

Ingress RSVP: 1 sessions

To	From	State	Rt	Style	Labelin	Labelout	LSPname
192.0.2.3	192.0.2.0	Up	0	1 FF	-	462880	lsp_to_pe2

Total 1 displayed, Up 1, Down 0

Egress RSVP: 1 sessions

To	From	State	Rt	Style	Labelin	Labelout	LSPname
192.0.2.0	192.0.2.3	Up	0	1 FF	3	-	lsp_to_pe1

Total 1 displayed, Up 1, Down 0

Transit RSVP: 0 sessions

Total 0 displayed, Up 0, Down 0

Meaning The output shows that both the ingress RSVP session and the egress RSVP session are up.

Verifying the Routes in the Routing Table

Purpose On routing device PE 1, use the **show route table** command to verify that the routing table is populated with the Layer 2 VPN routes used to forward the traffic.

Action user@PE1> `show route table bgp.l2vpn.0`

```
bgp.l2vpn.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
192:2:27:27/96
    *[BGP/170] 00:13:55, localpref 100, from 192.0.2.3
    AS path: I
    > to 10.2.0.24 via ge-6/0/46.0, label-switched-path lsp_to_pe2
```

user@PE1> `show route table vpn1.l2vpn.0`

```
vpn1.l2vpn.0: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both
```

```
192:2:27:27/96
    *[BGP/170] 00:14:00, localpref 100, from 192.0.2.3
    AS path: I
    > to 10.2.0.24 via ge-6/0/46.0, label-switched-path lsp_to_pe2
192:2:28:27/96
    *[L2VPN/170/-101] 00:15:55, metric2 1
    Indirect
```

Meaning The command `show route table bgp.l2vpn.0` displays all Layer 2 VPN routes that have been created on this routing device. The command `show route table vpn1.l2vpn.0` shows the Layer 2 VPN routes that have been created for the routing instance `vpn1`.

Pinging the Layer 2 VPN Connections

Purpose Verify connectivity.

Action user@PE1> `ping mpls l2vpn interface xe-6/0/0.0 reply-mode ip-udp`
!!!!
--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss

user@PE1> `ping mpls l2vpn instance vpn1 remote-site-id 26 local-site-id 21 detail`
Request for seq 1, to interface 68, labels <800001, 100176>
Reply for seq 1, return code: Egress-ok
Request for seq 2, to interface 68, labels <800001, 100176>
Reply for seq 2, return code: Egress-ok
Request for seq 3, to interface 68, labels <800001, 100176>
Reply for seq 3, return code: Egress-ok
Request for seq 4, to interface 68, labels <800001, 100176>
Reply for seq 4, return code: Egress-ok
Request for seq 5, to interface 68, labels <800001, 100176>
Reply for seq 5, return code: Egress-ok

--- lsping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss

Meaning The output shows that connectivity is established.

Transmitting Nonstandard BPDUs in Layer 2 VPNs and VPLS

Circuit cross-connect (CCC) protocol, Layer 2 circuit, and Layer 2 VPN configurations can transmit nonstandard bridge protocol data units (BPDUs) generated by other vendors' equipment. This is the default behavior on all supported PICs and requires no additional configuration.

The following PICs are supported on T Series Core Routers and the M320 Multiservice Edge router and can transmit nonstandard BPDUs:

- 1-port Gigabit Ethernet PIC
- 2-port Gigabit Ethernet PIC
- 4-port Gigabit Ethernet PIC
- 10-port Gigabit Ethernet PIC

Configuring Layer 2 Interfaces

- [Configuring CCC Encapsulation for Layer 2 VPNs on page 167](#)
- [Configuring TCC Encapsulation for Layer 2 VPNs and Layer 2 Circuits on page 168](#)
- [Configuring the MTU for Layer 2 Interfaces on page 170](#)
- [Disabling the Control Word for Layer 2 VPNs on page 171](#)

Configuring CCC Encapsulation for Layer 2 VPNs

You need to specify a circuit cross-connect (CCC) encapsulation type for each PE-router-to-CE-router interface running a Layer 2 VPN. This encapsulation type should match the encapsulation type configured under the routing instance. For information about how to configure the encapsulation type under the routing instance, see [“Configuring the Encapsulation Type” on page 132](#).

NOTE: A Layer 2 VPN or Layer 2 circuit is not supported if the PE-router-to-P-router interface has VLAN-tagging enabled and uses a nonenhanced Flexible PIC Concentrator (FPC).

For Layer 2 VPNs, you need to configure the CCC encapsulation on the logical interface. You also need to configure an encapsulation on the physical interface. The physical interface encapsulation does not have to be a CCC encapsulation. However, it should match the logical interface encapsulation. For example, if you configure an ATM CCC encapsulation type on the logical interface, you should configure a compatible ATM encapsulation on the physical interface.

NOTE: The EX9200 switches only use `ethernet` and `ethernet-vlan` encapsulation types.

To configure the CCC encapsulation type, include the `encapsulation-type` statement:

```
encapsulation-type ccc-encapsulation-type;
```

On the EX9200 switches, replace `encapsulation-type` with the `encapsulation` statement:

```
encapsulation ccc-encapsulation;
```

To configure the CCC encapsulation type on the physical interface, include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name*]**

To configure the CCC encapsulation type on the logical interface, include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

You configure the encapsulation type at the **[edit interfaces]** hierarchy level differently from the **[edit routing-instances]** hierarchy level. For example, you specify the encapsulation as **frame-relay** at the **[edit routing-instances]** hierarchy level and as **frame-relay-ccc** at the **[edit interfaces]** hierarchy level.

You can run both standard Frame Relay and CCC Frame Relay on the same device. If you specify Frame Relay encapsulation (**frame-relay-ccc**) for the interface, you should also configure the encapsulation at the **[edit interfaces *interface name* unit *unit-number*]** hierarchy level as **frame-relay-ccc**. Otherwise, the logical interface unit defaults to standard Frame Relay.

Configuring TCC Encapsulation for Layer 2 VPNs and Layer 2 Circuits

Also known as Layer 2.5 VPNs, the translation cross-connect (TCC) encapsulation types allow you to configure different encapsulation types at the ingress and egress of a Layer 2 VPN or the ingress and egress of a Layer 2 circuit. For example, a CE router at the ingress of a Layer 2 VPN path can send traffic in a Frame Relay encapsulation. A CE router at the egress of that path can receive the traffic in an ATM encapsulation.

NOTE: The EX9200 switches only use **ethernet** and **ethernet-vlan** encapsulation types.

For information about how to configure encapsulations for Layer 2 circuits, see [“Configuring the Interface Encapsulation Type for Layer 2 Circuits” on page 897](#).

The configuration for TCC encapsulation types is similar to the configuration for CCC encapsulation types. For Layer 2 VPNs, you specify a TCC encapsulation type for each PE-router-to-CE-router interface. The encapsulation type configured for the interface should match the encapsulation type configured under the routing instance. For information about how to configure the encapsulation type under the routing instance, see [“Configuring the Encapsulation Type” on page 132](#).

NOTE: Some platform and FPC combinations can not pass TCC encapsulated ISO traffic. See *Platforms/FPCs That Cannot Forward TCC Encapsulated ISO Traffic* for details.

You need to configure the TCC encapsulation on both the physical and logical interfaces. To configure the TCC encapsulation type, include the **encapsulation-type** statement:

```
encapsulation-type tcc-encapsulation-type;
```

On the EX9200 switches, replace **encapsulation-type** with the **encapsulation** statement:

```
encapsulation tcc-encapsulation;
```

To configure the TCC encapsulation type on the physical interface, include this statement at the following hierarchy levels:

- [edit interfaces *interface-name*]
- [edit logical-systems *logical-system-name* interfaces *interface-name*]

To configure the TCC encapsulation type on the logical interface, include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

You configure the encapsulation type at the [edit interfaces] hierarchy level differently than at the [edit routing-instances] hierarchy level. For example, you specify the encapsulation as **frame-relay** at the [edit routing-instances] hierarchy level and as **frame-relay-tcc** at the [edit interfaces] hierarchy level.

For Layer 2.5 VPNs employing an Ethernet interface as the TCC router, you can configure an Ethernet TCC or an extended VLAN TCC.

To configure an Ethernet TCC or an extended VLAN TCC, include the **proxy** and **remote** statements:

```
proxy inet-address;
remote (inet-address | mac-address);
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number* family tcc]
- [edit logical-interfaces *logical-interface-name* interfaces *interface-name* unit *logical-unit-number* family tcc]

The **proxy inet-address** address statement defines the IP address for which the TCC router is acting as proxy.

The **remote (inet-address | mac-address)** statement defines the location of the remote router.

Ethernet TCC is supported on interfaces that carry IP version 4 (IPv4) traffic only. However, Ethernet TCC encapsulation is not supported on 8-port, 12-port, and 48-port Fast Ethernet PICs.

Configuring the MTU for Layer 2 Interfaces

By default, the MTU used to advertise a Layer 2 pseudowire is determined by taking the interface MTU for the associated physical interface and subtracting the encapsulation overhead for sending IP packets based on the encapsulation. However, encapsulations that support multiple logical interfaces (and multiple Layer 2 pseudowires) rely on the same interface MTU (since they are all associated with the same physical interface). This can prove to be a limitation for VLAN Layer 2 pseudowires using the same Ethernet interface or for Layer 2 pseudowire DLCIs using the same Frame Relay interface.

This can also affect multivendor environments. For example, if you have three PE devices supplied by different vendors and one of the devices only supports an MTU of 1500, even if the other devices support larger MTUs you must configure the MTU as 1500 (the smallest MTU of the three PE devices).

You can explicitly configure which MTU is advertised for a Layer 2 pseudowire, even if the Layer 2 pseudowire is sharing a physical interface with other Layer pseudowires. When you explicitly configure an MTU for a Layer 2 pseudowire, be aware of the following:

- For BGP-based applications such as l2vpn and bgp-vpls, the advertised MTU will be zero unless an MTU value is explicitly set at the **[edit routing-instances routing-instance-name protocols (l2vpn | vpls) site site-name]** hierarchy level.
- An explicitly configured MTU is signaled to the remote PE device. The configured MTU is also compared to the MTU received from the remote PE device. If there is a conflict, the Layer 2 pseudowire is taken down.
- If you configure an MTU for an ATM cell relay interface on an ATM II PIC, the configured MTU is used to compute the cell bundle size advertised for that Layer 2 pseudowire, instead of the default interface MTU.
- A configured MTU is used only in the control plane. It is not enforced in the data plane. You need to ensure that the CE device for a given Layer 2 pseudowire uses the correct MTU for data transmission.

The following procedure describes how to configure the MTU for the Layer 2 interface. This information applies to the following Layer 2 technologies:

- Layer 2 VPNs
- Layer 2 Circuits
- VPLS

1. To configure the MTU for a Layer 2 circuit, include the **mtu** statement:

```
mtu mtu-number;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

2. To allow a Layer 2 pseudowire to be established even though the MTU configured on the local PE router does not match the MTU configured on the remote PE router, include the **ignore-mtu-mismatch** statement:

```
ignore-mtu-mismatch;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

- Related Documentation**

Disabling the Control Word for Layer 2 VPNs

A 4-byte control word provides support for the emulated VC encapsulation for Layer 2 VPNs. This control word is added between the Layer 2 protocol data unit (PDU) being transported and the VC label that is used for demultiplexing. Various networking formats (ATM, Frame Relay, Ethernet, and so on) use the control word in a variety of ways.

On networks with equipment that does not support the control word, you can disable it by including the **no-control-word** statement:

```
no-control-word;
```

You can include this statement at the following hierarchy levels:

- `[edit routing-instances routing-instance-name protocols l2vpn]`
- `[edit logical-systems logical-system-name routing-instances routing-instance-name protocols l2vpn]`

For more information about configuring the control word, see “[Configuring the Control Word for Layer 2 Circuits](#)” on page 892 and the *Layer 2 Circuits Feature Guide*.

NOTE: Use the **no-control-word** statement to disable the control word when the topology uses generic routing encapsulation (GRE) as the connection mechanism between PEs, and one of the PEs is an M Series router.

Configuring Path Selection for Layer 2 VPNs and VPLS

- [Understanding BGP Path Selection on page 173](#)
- [Enabling BGP Path Selection for Layer 2 VPNs and VPLS on page 178](#)
- [VPLS Path Selection Process for PE Routers on page 180](#)

Understanding BGP Path Selection

For each prefix in the routing table, the routing protocol process selects a single best path. After the best path is selected, the route is installed in the routing table. The best path becomes the active route if the same prefix is not learned by a protocol with a lower (more preferred) global preference value, also known as the administrative distance. The algorithm for determining the active route is as follows:

1. Verify that the next hop can be resolved.
2. Choose the path with the lowest preference value (routing protocol process preference).

Routes that are not eligible to be used for forwarding (for example, because they were rejected by routing policy or because a next hop is inaccessible) have a preference of -1 and are never chosen.
3. Prefer the path with higher local preference.

For non-BGP paths, choose the path with the lowest **preference2** value.
4. If the accumulated interior gateway protocol (AIGP) attribute is enabled, prefer the path with the lower AIGP attribute.
5. Prefer the path with the shortest autonomous system (AS) path value (skipped if the **as-path-ignore** statement is configured).

A confederation segment (sequence or set) has a path length of 0. An AS set has a path length of 1.

6. Prefer the route with the lower origin code.

Routes learned from an IGP have a lower origin code than those learned from an exterior gateway protocol (EGP), and both have lower origin codes than incomplete routes (routes whose origin is unknown).

7. Prefer the path with the lowest multiple exit discriminator (MED) metric.

Depending on whether nondeterministic routing table path selection behavior is configured, there are two possible cases:

- If nondeterministic routing table path selection behavior is not configured (that is, if the **path-selection cisco-nondeterministic** statement is not included in the BGP configuration), for paths with the same neighboring AS numbers at the front of the AS path, prefer the path with the lowest MED metric. To always compare MEDs whether or not the peer ASs of the compared routes are the same, include the **path-selection always-compare-med** statement.
- If nondeterministic routing table path selection behavior is configured (that is, the **path-selection cisco-nondeterministic** statement is included in the BGP configuration), prefer the path with the lowest MED metric.

Confederations are not considered when determining neighboring ASs. A missing MED metric is treated as if a MED were present but zero.

NOTE: MED comparison works for single path selection within an AS (when the route does not include an AS path), though this usage is uncommon.

By default, only the MEDs of routes that have the same peer autonomous systems (ASs) are compared. You can configure routing table path selection options to obtain different behaviors.

8. Prefer strictly internal paths, which include IGP routes and locally generated routes (static, direct, local, and so forth).
9. Prefer strictly external BGP (EBGP) paths over external paths learned through internal BGP (IBGP) sessions.
10. Prefer the path whose next hop is resolved through the IGP route with the lowest metric.

NOTE: A path is considered a BGP equal-cost path (and will be used for forwarding) if a tie-break is performed after the previous step. All paths with the same neighboring AS, learned by a multipath-enabled BGP neighbor, are considered.

BGP multipath does not apply to paths that share the same MED-plus-IGP cost yet differ in IGP cost. Multipath path selection is based on the IGP cost metric, even if two paths have the same MED-plus-IGP cost.

BGP compares the type of IGP metric before comparing the metric value itself in `rt_metric2_cmp`. For example, BGP routes that are resolved through IGP are preferred over discarded or rejected next-hops that are of type `RTM_TYPE_UNREACH`. Such routes are declared inactive because of their `metric-type`.

11. If both paths are external, prefer the currently active path to minimize route-flapping. This rule is not used if any one of the following conditions is true:
 - `path-selection external-router-id` is configured.
 - Both peers have the same router ID.
 - Either peer is a confederation peer.
 - Neither path is the current active path.
12. Prefer a primary route over a secondary route. A primary route is one that belongs to the routing table. A secondary route is one that is added to the routing table through an export policy.
13. Prefer the path from the peer with the lowest router ID. For any path with an originator ID attribute, substitute the originator ID for the router ID during router ID comparison.
14. Prefer the path with the shortest cluster list length. The length is 0 for no list.
15. Prefer the path from the peer with the lowest peer IP address.

Routing Table Path Selection

The shortest AS path step of the algorithm, by default, evaluates the length of the AS path and determines the active path. You can configure an option that enables Junos OS to skip this step of the algorithm by including the `as-path-ignore` option.

NOTE: Starting with Junos OS Release 14.1R8, 14.2R7, 15.1R4, 15.1F6, and 16.1R1, the `as-path-ignore` option is supported for routing instances.

To configure routing table path selection behavior, include the `path-selection` statement:

```

path-selection {
  (always-compare-med | cisco-non-deterministic | external-router-id);
  as-path-ignore;
  med-plus-igp {
    igp-multiplier number;
    med-multiplier number;
  }
}

```

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

Routing table path selection can be configured in one of the following ways:

- Emulate the Cisco IOS default behavior (**cisco-non-deterministic**). This mode evaluates routes in the order that they are received and does not group them according to their neighboring AS. With **cisco-non-deterministic** mode, the active path is always first. All inactive, but eligible, paths follow the active path and are maintained in the order in which they were received, with the most recent path first. Ineligible paths remain at the end of the list.

As an example, suppose you have three path advertisements for the 192.168.1.0 /24 route:

- Path 1—learned through EBGp; AS Path of 65010; MED of 200
- Path 2—learned through IBGP; AS Path of 65020; MED of 150; IGP cost of 5
- Path 3—learned through IBGP; AS Path of 65010; MED of 100; IGP cost of 10

These advertisements are received in quick succession, within a second, in the order listed. Path 3 is received most recently, so the routing device compares it against path 2, the next most recent advertisement. The cost to the IBGP peer is better for path 2, so the routing device eliminates path 3 from contention. When comparing paths 1 and 2, the routing device prefers path 1 because it is received from an EBGp peer. This allows the routing device to install path 1 as the active path for the route.

NOTE: We do not recommend using this configuration option in your network. It is provided solely for interoperability to allow all routing devices in the network to make consistent route selections.

- Always comparing MEDs whether or not the peer ASs of the compared routes are the same (**always-compare-med**).
- Override the rule that If both paths are external, the currently active path is preferred (**external-router-id**). Continue with the next step (Step 12) in the path-selection process.
- Adding the IGP cost to the next-hop destination to the MED value before comparing MED values for path selection (**med-plus-igp**).

BGP multipath does not apply to paths that share the same MED-plus-IGP cost, yet differ in IGP cost. Multipath path selection is based on the IGP cost metric, even if two paths have the same MED-plus-IGP cost.

Effects of Advertising Multiple Paths to a Destination

BGP advertises only the active path, unless you configure BGP to advertise multiple paths to a destination.

Suppose a routing device has in its routing table four paths to a destination and is configured to advertise up to three paths (**add-path send path-count 3**). The three paths are chosen based on path selection criteria. That is, the three best paths are chosen in path-selection order. The best path is the active path. This path is removed from consideration and a new best path is chosen. This process is repeated until the specified number of paths is reached.

Release History Table

Release	Description
14.1R8	Starting with Junos OS Release 14.1R8, 14.2R7, 15.1R4, 15.1F6, and 16.1R1, the as-path-ignore option is supported for routing instances.

Enabling BGP Path Selection for Layer 2 VPNs and VPLS

Layer 2 VPNs and VPLS share the same path selection process for determining the optimal path to reach all of the destinations shared within a single routing instance. For Layer 2 VPN and VPLS topologies, the path selection process is straightforward if there is just a single path from each PE router to each CE device. However, the path selection process becomes more complex if the PE routers receive two or more valid paths to reach a specific CE device.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

The following network scenarios provide examples of what might cause a PE router to receive more than one valid path to reach a specific CE device:

- Multihoming—One or more CE devices within a routing instance are multihomed to two or more PE routers. Each multihomed CE device has at least two valid paths.
- Route reflectors—There are multiple route reflectors deployed within the same network and they are supporting PE routers within the same routing instance. Due to time delays in large complex networks, the route reflectors can separately receive a different valid path to reach a CE device at different times. When they readvertise these valid paths, a PE router could receive two or more separate but apparently valid paths to the same CE device.

By default, Juniper Networks routers use just the designated forwarder path selection algorithm to select the best path to reach each Layer 2 VPN or VPLS routing instance destination (for more information, see [“VPLS Path Selection Process for PE Routers” on page 180](#)). However, you can also configure the routers in your network to use both the BGP path selection algorithm and the designated forwarder path selection algorithm as follows:

- On the Provider routers within the service providers network, the standard BGP path selection algorithm is used (for more information, see [“Understanding BGP Path Selection” on page 173](#)). Using the standard BGP path selection for Layer 2 VPN and VPLS routes allows a service provider to leverage the existing Layer 3 VPN network infrastructure to also support Layer 2 VPNs and VPLS. The BGP path selection algorithm also helps to ensure that the service provider’s network behaves predictably with regard to Layer 2 VPN and VPLS path selection. This is particularly important in networks employing route reflectors and multihoming.

When a Provider router receives multiple paths for the same destination prefix (for example, a multihomed CE device), one path is selected based on the BGP path selection algorithm and placed in the `bgp.l2vpn.0` routing table and the appropriate `instance.l2vpn.0` routing table.

- When a PE router receives all of the available paths to each CE device, it runs the designated forwarder path selection algorithm to select the preferred path to reach each CE device, independently of the results of the earlier BGP path selection algorithm run on the Provider router. The VPLS designated forwarder algorithm uses the D-bit, preference, and PE router identifier to determine which of the valid paths to each CE device to use. The PE router might select a path to reach a CE device which is different from the path selected by the BGP-based Provider routers. In this scenario, the following is the expected behavior for traffic sent to the multihomed CE device:
 - If the path selected by the remote PE router is available, traffic will traverse the network to the multihomed CE device using the remote PE router's preferred path (again, ignoring the path selected by the BGP-based Provider routers).
 - If the path selected by the remote PE router fails:
 1. The Provider routers switch the traffic destined for the multihomed CE device to the alternate path as soon as failure is detected.
 2. The Provider routers notify the remote PE routers of the path failure.
 3. The remote PE routers update their routing tables accordingly.

For more information about the VPLS designated forwarder path selection algorithm, see [“VPLS Path Selection Process for PE Routers” on page 180](#). This algorithm is also described in the Internet draft [draft-kompella-l2vpn-vpls-multihoming-03.txt](#), *Multi-homing in BGP-based Virtual Private LAN Service*.

To enable the BGP path selection algorithm for Layer 2 VPN and VPLS routing instances, complete the following steps:

1. Run Junos OS Release 12.3 or later on all of the PE and Provider routers participating in Layer 2 VPN or VPLS routing instances.

Attempting to enable this functionality on a network with a mix of routers that both do and do not support this feature can result in anomalous behavior.

2. Specify a unique route distinguisher on each PE router participating in a Layer 2 VPN or VPLS routing instance.
3. Configure the `l2vpn-use-bgp-rules` statement on all of the PE and Provider routers participating in Layer 2 VPN or VPLS routing instances.

You can configure this statement at the `[edit protocols bgp path-selection]` hierarchy level to apply this behavior to all of the routing instances on the router or at the `[edit routing-instances routing-instance-name protocols bgp path-selection]` hierarchy level to apply this behavior to a specific routing instance.

VPLS Path Selection Process for PE Routers

The VPLS path selection process is used to select the best path between a remote PE router and a local PE router in a VPLS network. This path selection process is applied to routes received from both single-homed and multi-homed PE routers.

NOTE: In the VPLS documentation, the word *router* in terms such as *PE router* is used to refer to any device that provides routing functions.

When the VPLS path selection process is complete, a PE router is made the designated VPLS edge (VE) device. The designated VE device effectively acts as the endpoint for the VPLS pseudowire that is signaled from the remote PE router. Once a PE router is made the designated VE device, a pseudowire can be signaled between the remote PE router and the local PE router and then VPLS packets can begin to flow between the PE routers.

Routes from multihomed PE routers connected to the same customer site share the same site ID, but can have different route distinguishers and block offsets. You can alter the configurations of the route distinguishers and block offsets to make a router more likely or less likely to be selected as the designated VE device.

On each PE router in the VPLS network, the best path to the CE device is determined by completing the following VPLS path selection process on each route advertisement received:

1. If the advertisement has the down bit set to 0, the advertisement is discarded.
2. Select the path with a higher preference. The preference attribute is obtained from the site-preference configured using the **site-preference** statement at the **[edit routing-instances routing-instance-name protocols vpls site site-name]** hierarchy level. If the site preference is 0, the preference attribute is obtained from the local preference.
3. If the preference values are the same, select the path with the lower router ID.
4. If the router IDs are the same, the routes are from the same PE router and the advertisement is considered to be an update. The router ID corresponds to the value of the originator ID for the BGP attribute (if present). Otherwise, the IP address for the remote BGP peer is used.
5. If the block offset values are the same, the advertisement is considered to be an update.

Once the VPLS path selection process has been completed and the designated VE device has been selected, a pseudowire is signaled between the remote PE router and the local PE router.

NOTE: The VPLS path selection process works the same whether or not the route has been received from another PE router, a route reflector, or an autonomous system border router (ASBR).

When the remote PE router establishes or refreshes a pseudowire to the local PE router, it verifies that the prefix is in the range required for the site ID based on the block offset and label range advertised by the designated VE device. If the prefix is out of range, the pseudowire status is set to out of range.

The following cases outline the potential decisions that could be made when a PE router completes the VPLS path selection process for a Layer 2 advertisement in the VPLS network:

- The PE router originated one of the advertisements and selected its own advertisement as the best path.

This PE router has been selected as the designated VE device. Selection as the designated VE device triggers the creation of pseudowires to and from the other PE routers in the VPLS network. If the remote customer site is multihomed, the designated VE device triggers the creation of pseudowires to and from only the designated VE device for the remote site.

- The PE router originated one of the advertisements but did not select its own advertisement as the best path.

This PE router is a redundant PE router for a multihomed site, but it was not selected as the designated VE device. However, if this PE router has just transitioned from being the designated VE device (meaning it was receiving traffic from the remote PE routers addressed to the multihomed customer site), the PE router tears down all the pseudowires that it had to and from the other PE routers in the VPLS network.

- The PE router received the route advertisements and selected a best path. It did not originate any of these advertisements because it was not connected to the customer site.

If the best path to the customer site (the designated VE device) has not changed, nothing happens. If the best path has changed, this PE router brings up pseudowires to and from the newly designated VE device and tears down the pseudowires to and from the previously designated VE device.

If this PE router does not select a best path after running the VPLS path selection process, then the local PE router does not consider the remote site to exist.

When a VE device receives an advertisement for a Layer 2 NLRI that matches its own site ID but the site is not multihomed, the pseudowire between the VE device and the transmitting PE router transitions to a site collision state and is not considered to be up.

Creating Backup Connections with Redundant Pseudowires

- [Redundant Pseudowires for Layer 2 Circuits and VPLS on page 183](#)
- [Configuring Redundant Pseudowires for Layer 2 Circuits and VPLS on page 185](#)

Redundant Pseudowires for Layer 2 Circuits and VPLS

A redundant pseudowire can act as a backup connection between PE routers and CE devices, maintaining Layer 2 circuit and VPLS services after certain types of failures. This feature can help improve the reliability of certain types of networks (metro for example) where a single point of failure could interrupt service for multiple customers. Redundant pseudowires cannot reduce traffic loss to zero. However, they provide a way to gracefully recover from pseudowire failures in such a way that service can be restarted within a known time limit.

NOTE: VPLS is not supported on ACX Series routers.

When you configure redundant pseudowires to remote PE routers, you configure one to act as the primary pseudowire over which customer traffic is being transmitted and you configure another pseudowire to act as a backup in the event the primary fails. You configure the two pseudowires statically. A separate label is allocated for the primary and backup neighbors.

For information about how to configure redundant pseudowires, see [“Configuring Redundant Pseudowires for Layer 2 Circuits and VPLS” on page 185](#).

The following sections provide an overview of redundant pseudowires for Layer 2 circuits and VPLS:

- [Types of Redundant Pseudowire Configurations on page 184](#)
- [Pseudowire Failure Detection on page 185](#)

Types of Redundant Pseudowire Configurations

You can configure redundant pseudowires for Layer 2 circuits and VPLS in either of the following manners:

NOTE: VPLS is not supported on ACX Series routers.

- You can configure a single active pseudowire. The PE router configured as the primary neighbor is given preference and this connection is the one used for customer traffic. For the LDP signalling, labels are exchanged for both incoming and outgoing traffic with the primary neighbor. The LDP label advertisement is accepted from the backup neighbor, but no label advertisement is forwarded to it, leaving the pseudowire in an incomplete state. The pseudowire to the backup neighbor is completed only when the primary neighbor fails. The decision to switch between the two pseudowires is made by the device configured with the redundant pseudowires. The primary remote PE router is unaware of the redundant configuration, ensuring that traffic is always switched using just the active pseudowire.
- Alternatively, you can configure two active pseudowires, one to each of the PE routers. Using this approach, control plane signalling is completed and active pseudowires are established with both the primary and backup neighbors. However, the data plane forwarding is done only over a one of the pseudowires (designated as the active pseudowire by the local device). The other pseudowire is on standby. The active pseudowire is preferably established with the primary neighbor and can switch to the backup pseudowire if the primary fails.

The decision to switch between the active and standby pseudowires is controlled by the local device. The remote PE routers are unaware of the redundant connection, and so both remote PE routers send traffic to the local device. The local device only accepts traffic from the active pseudowire and drops the traffic from the standby. In addition, the local device only sends traffic to the active pseudowire. If the active pseudowire fails, traffic is immediately switched to the standby pseudowire.

The two configurations available for pseudowire redundancy have the following limitations:

- For the single active pseudowire configuration, it takes more time (compared to the two active pseudowire configuration) to switchover to the backup pseudowire when a failure is detected. This approach requires additional control plane signalling to complete the pseudowire with the backup neighbor and traffic can be lost during the switchover from primary to backup.
- If you configure two active pseudowires, bandwidth is lost on the link carrying the backup pseudowire between the remote PE router and the local device. Traffic is always duplicated over both the active and standby pseudowires. The single active pseudowire configuration does not waste bandwidth in this fashion.

Pseudowire Failure Detection

The following events are used to detect a failure (control and data plane) of the pseudowire configured between a local device and a remote PE router and initiates the switch to a redundant pseudowire:

- Manual switchover (user initiated)
- Remote PE router withdraws the label advertisement
- LSP to the remote PE router goes down
- LDP session with the remote PE router goes down
- Local configuration changes
- Periodic pseudowire OAM procedure fails (Layer 2 circuit-based MPLS ping to the PE router fails)

When you configure a redundant pseudowire between a CE device and a PE router, a periodic (once a minute) ping packet is forwarded through the active pseudowire to verify data plane connectivity. If the ping fails, traffic is automatically switched to the redundant pseudowire.

When a failure is detected, traffic is switched from the failed active pseudowire to the redundant pseudowire. The redundant pseudowire is then designated as the active pseudowire. The switch is nonreversible, meaning that once the redundant pseudowire assumes the role of the active pseudowire at the time of a failover, it remains as the active pseudowire even though the previously active pseudowire comes up again.

For example, a primary pseudowire has failed and traffic has been successfully switched to the redundant pseudowire. After a period of time, the cause of the failure of the primary pseudowire has been resolved and it is now possible to reestablish the original connection. However, traffic is not switched back to the original pseudowire unless a failure is detected on the currently active pseudowire.

Configuring Redundant Pseudowires for Layer 2 Circuits and VPLS

A redundant pseudowire can act as a backup connection between PE routers and CE devices, maintaining Layer 2 circuit and VPLS services after certain types of failures. This feature can help improve the reliability of certain types of networks (metro for example) where a single point of failure could interrupt service for multiple customers. Redundant pseudowires cannot reduce traffic loss to zero. However, they provide a way to gracefully recover from pseudowire failures in such a way that service can be restarted within a known time limit.

NOTE: VPLS is not supported on ACX Series routers.

For an overview of how redundant pseudowires work, see “[Redundant Pseudowires for Layer 2 Circuits and VPLS](#)” on page 183.

To configure pseudowire redundancy for Layer 2 circuits and VPLS, complete the procedures in the following sections:

- [Configuring Pseudowire Redundancy on the PE Router on page 186](#)
- [Configuring the Switchover Delay for the Pseudowires on page 186](#)
- [Configuring a Revert Time for the Redundant Pseudowire on page 187](#)

Configuring Pseudowire Redundancy on the PE Router

You configure pseudowire redundancy on the PE router acting as the egress for the primary and standby pseudowires using the **backup-neighbor** statement.

To configure pseudowire redundancy on the PE router, include the **backup-neighbor** statement:

```
backup-neighbor {  
    community name;  
    psn-tunnel-endpoint address;  
    standby;  
    virtual-circuit-id number;  
}
```

For a list of hierarchy levels at which you can include this statement, see the statement summary for this statement.

The **backup-neighbor** statement includes the following configuration options:

- **community**—Specifies the community for the backup neighbor.
- **psn-tunnel-endpoint**—Specifies the endpoint address for the packet switched network (PSN) tunnel on the remote PE router. The PSN tunnel endpoint address is the destination address for the LSP on the remote PE router.
- **standby**—Configures the pseudowire to the specified backup neighbor as the standby. When you configure this statement, traffic flows over both the active and standby pseudowires to the CE device. The CE device drops the traffic from the standby pseudowire, unless the active pseudowire fails. If the active pseudowire fails, the CE device automatically switches to the standby pseudowire.
- **virtual-circuit-id**—Uniquely identifies the primary and standby Layer 2 circuits. This option is configurable for Layer 2 circuits only.

Configuring the Switchover Delay for the Pseudowires

To configure the time the router waits before switching traffic from the failed primary pseudowire to a backup pseudowire, include the **switchover-delay** statement:

```
switchover-delay milliseconds;
```

For a list of hierarchy levels at which you can include this statement, see the statement summary for this statement.

Configuring a Revert Time for the Redundant Pseudowire

You can specify a revert time for redundant Layer 2 circuit and VPLS pseudowires. When you have configured redundant pseudowires for Layer 2 circuits or VPLS, traffic is switched to the backup pseudowire in the event that the primary pseudowire fails. If you configure a revert time, when the configured time expires traffic is reverted back to the primary pseudowire, assuming the primary pseudowire has been restored.

To configure a revert time for redundant pseudowires, specify the time in seconds using the **revert-time** statement:

revert-time (Protocols Layer 2 Circuits) *seconds* maximum *seconds*;

With the **maximum** option, specify a maximum reversion interval to add after the **revert-time** delay. If a revert-time delay is defined but a maximum timer is not defined, VCs are restored upon the revert-timer's expiration.

To reduce as much as possible the amount of traffic discarded, and potential data-path asymmetries observed during primary-to-backup transition periods, you can use this restoration timer. This restoration timer is activated when the backup path is performing as active, and then the primary path is restored. The goal is to avoid moving traffic back to the primary path right away, to make sure that the control plane's related tasks (such as IGP, LDP, RSVP, and internal BGP) have enough time to complete their updating cycle.

By enabling a gradual return of traffic to the primary path, you can ensure that the relatively-slow control-plane processing and updating does not have a negative impact on the restoration process.

The **maximum** option extends the revert timer's functionality to provide a jittered interval over which a certain number of circuits can be transitioned back to the primary path. By making use of this maximum value, you can define a time interval during which circuits are expected to switch over. As a consequence, circuits' effective transitions are scattered during restoration periods.

When making use of **revert-time x maximum y** statement, you can ensure that the corresponding circuit that is active is moved to the primary path within a time-slot ($t1$) such as that: $x \leq t1 \leq y$. In other words, by activating this statement, you can ensure the following:

- VCs stay in the backup path for at least x seconds after the primary path comes back up.
- VCs are moved back to the primary path before y seconds have elapsed.
- y maximum value = x maximum value * 2 = 1200 seconds.

The ideal values for x and y will be conditioned to internal aspects of your network. For this reason, there are no default values for these settings. If no revert-time is set, the default behavior is non-revertive. That is, circuits are not returned to the primary path upon restoration. They are kept on the backup path.

For a list of hierarchy levels at which you can include this statement, see the statement summary for this statement.

Configuring Class of Service for Layer 2 VPNs

- [Configuring Traffic Policing in Layer 2 VPNs on page 189](#)

Configuring Traffic Policing in Layer 2 VPNs

You can use policing to control the amount of traffic flowing over the interfaces servicing a Layer 2 VPN. If policing is disabled on an interface, all the available bandwidth on a Layer 2 VPN tunnel can be used by a single CCC or TCC interface.

For information on how to configure traffic policers, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

To enable Layer 2 VPN policing on an interface, include the **policer** statement:

```
policer {  
    input policer-template-name;  
    output policer-template-name;  
}
```

If you configure CCC encapsulation, you can include the **policer** statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number* family ccc]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family ccc]

If you configure TCC encapsulation, you can include the **policer** statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number* family tcc]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family tcc]

For information about how to configure the encapsulation type, see [“Configuring the Encapsulation Type” on page 132](#).

CHAPTER 15

Monitoring Layer 2 VPNs Using BFD

- [Configuring BFD for Layer 2 VPN and VPLS on page 192](#)
- [BFD Support for VCCV for Layer 2 VPNs, Layer 2 Circuits, and VPLS on page 194](#)
- [Configuring BFD for VCCV for Layer 2 VPNs, Layer 2 Circuits, and VPLS on page 195](#)

Configuring BFD for Layer 2 VPN and VPLS

The following procedure describes how to configure Bidirectional Forwarding Detection (BFD) for Layer 2 VPN and VPLS. For VPNs, you configure the BFD sessions on the interfaces carrying traffic from the PE routers to the CE routers.

The BFD protocol is a simple hello mechanism that detects failures in a network. Hello packets are sent at a specified, regular interval. A neighbor failure is detected when the routing device stops receiving a reply after a specified interval. BFD works with a wide variety of network environments and topologies. The failure detection timers for BFD have shorter time limits than default failure detection mechanisms for BGP, so they provide faster detection.

The BFD failure detection timers are adaptive and can be adjusted to be faster or slower. The lower the BFD failure detection timer value, the faster the failure detection and vice versa. For example, the timers can adapt to a higher value if the adjacency fails (that is, the timer detects failures more slowly). Or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive interval by two if the local BFD instance is the reason for the session flap. The transmission interval is increased by two if the remote BFD instance is the reason for the session flap. You can use the **clear bfd adaptation** command to return BFD interval timers to their configured values. The **clear bfd adaptation** command is hitless, meaning that the command does not affect traffic flow on the routing device.

1. You can enable BFD failure detection. The BFD failure detection timers are adaptive and can be adjusted to be faster or slower. The lower the BFD failure detection timer value, the faster the failure detection and vice versa. For example, the timers can adapt to a higher value if the adjacency fails (that is, the timer detects failures more slowly). Or a neighbor can negotiate a higher value for a timer than the configured value. The timers adapt to a higher value when a BFD session flap occurs more than three times in a span of 15 seconds. A back-off algorithm increases the receive (Rx) interval by two if the local BFD instance is the reason for the session flap. The transmission (Tx) interval is increased by two if the remote BFD instance is the reason for the session flap.

To enable BFD failure detection and specify the threshold for the adaptation of the BFD session detection time, specify a time in milliseconds using the **threshold** statement. When the detection time adapts to a value equal to or greater than the threshold, a single trap and a single system log message are sent.

NOTE: The threshold time must be equal to or greater than the value specified in the **minimum-interval** or the **minimum-receive-interval** statement.

You can use the **clear bfd adaptation** command to return BFD interval timers to their configured values. The **clear bfd adaptation** command is hitless, meaning that the command does not affect traffic flow on the routing device.

2. You can specify the minimum interval after which the local routing device transmits hello packets and then expects to receive a reply from a neighbor with which it has established a BFD session. You specify the interval in milliseconds using the **minimum-interval** statement.

Optionally, instead of using this statement, you can specify the minimum transmit and receive intervals separately using the **minimum-interval** (specified under the **transmit-interval** statement) and **minimum-receive-interval** statements.

3. You can configure the minimum interval after which the local routing device must receive a reply from a neighbor with which it has established a BFD session. Specify the number of milliseconds using the **minimum-receive-interval** statement.
4. You can specify that an interface be declared down when a certain number of hello packets have not been received from a neighboring router through that interface. Specify the number of hello packets by including the **multiplier** statement.
5. You can configure BFD sessions not to adapt to changing network conditions by including the **no-adaptation** statement. We recommend that you *do not* disable BFD adaptation unless it is preferable to have BFD adaptation disabled in your network.
6. Specify the transmit interval options for **bfd-liveness-detection** statement by including the **transmit-interval** statement. The negotiated transmit interval for a peer is the interval between the sending of BFD packets to peers. The receive interval for a peer is the minimum time that it requires between packets sent from its peer; the receive interval is not negotiated between peers. To determine the transmit interval, each peer compares its configured minimum transmit interval with its peer's minimum receive interval. The larger of the two numbers is accepted as the transmit interval for that peer.

The **transmit-interval** statement specifies how often BFD statements are transmitted and includes the following options:

- **minimum-interval milliseconds**—Specify the minimum interval in milliseconds at which the local routing device transmits hello packets to a neighbor with which it has established a BFD session.
- **threshold milliseconds**—Specify the threshold for the adaptation of the BFD session transmit interval. When the transmit interval adapts to a value greater than the threshold, a single trap and a single system message are sent.

NOTE: The threshold value specified in the **threshold** statement must be greater than the value specified in the **minimum-interval** statement for the **transmit-interval** statement.

7. Specify the BFD version by including the **version** statement. You can set BFD to version 0, 1, or allow BFD to determine what version it needs to be by including the **automatic** option.

BFD Support for VCCV for Layer 2 VPNs, Layer 2 Circuits, and VPLS

Bidirectional Forwarding Detection (BFD) support for virtual circuit connectivity verification (VCCV) on MX Series devices enables you to configure a control channel for a pseudowire, in addition to the corresponding operations, administration, and management functions to be used over that control channel.

BFD provides a low resource mechanism for the continuous monitoring of the pseudowire data path and for detecting data plane failures. This feature provides support for asynchronous mode BFD for VCCV as described in RFC 5885, *Bidirectional Forwarding Detection (BFD) for the Pseudowire Virtual Circuit Connectivity Verification (VCCV)*. Alternatively, you can use a ping operation to detect pseudowire failures. However, the processing resources required for a ping operation are greater than what is needed for BFD. In addition, BFD is capable of detecting data plane failure faster than a VCCV ping. BFD for pseudowires is supported for Layer 2 circuits (LDP-based), Layer 2 VPNs (BGP-based), and VPLS (LDP-based or BGP-based).

Starting with Release 12.1, Junos OS introduces a distributed model for the BFD for VCCV. Unlike in previous releases where the BFD for VCCV followed a Routing Engine-based implementation, in Release 12.1 and later, the BFD for VCCV follows a distributed implementation over PIC concentrators, such as DPC, FPC, and MPC.

For distributed BFD, you need to configure the lo0 interface with unit 0 and the appropriate family enabled.

NOTE: For the distributed BFD for VCCV to work, you must configure MPLS family (family mpls) on the loopback interface.

```
user@router# set interfaces lo0 unit 0 family mpls
```

In Junos OS Release 12.1 and later, the periodic packet management process (ppmd) on the PIC concentrators handles the periodic packet management (send and receive) for BFD for VCCV. This enables Junos OS to create more BFD for VCCV sessions, and to reduce the time taken for error detection. Similarly, the distributed implementation improves the performance of Routing Engines because the Routing Engine resources used for BFD for VCCV implementation become available for Routing Engine-related applications when the BFD for VCCV-related processing moves to the PIC concentrators. The distributed BFD for VCCV implementation also enables the BFD for VCCV sessions to remain across graceful restarts.

- [Configuring BFD for VCCV for Layer 2 VPNs, Layer 2 Circuits, and VPLS on page 195](#)
 - [VPLS Feature Guide for EX9200 Switches](#)

Configuring BFD for VCCV for Layer 2 VPNs, Layer 2 Circuits, and VPLS

Bidirectional Forwarding Detection (BFD) support for virtual circuit connection verification (VCCV) allows you to configure a control channel for a pseudowire, in addition to the corresponding operations and management functions to be used over that control channel. BFD provides a low resource mechanism for the continuous monitoring of the pseudowire data path and for detecting data plane failures.

This feature provides support for asynchronous mode BFD for VCCV as described in RFC 5885, *Bidirectional Forwarding Detection (BFD) for the Pseudowire Virtual Circuit Connectivity Verification (VCCV)*. You can also use a ping operation to detect pseudowire failures. However, the processing resources required for a ping operation are greater than what is needed for BFD. In addition, BFD is capable of detecting data plane failure faster than VCCV ping. BFD for pseudowires is supported for Layer 2 circuits (LDP-based), Layer 2 VPNs (BGP-based), and VPLS (LDP-based or BGP-based).

To configure OAM and BFD for Layer 2 VPNs, include the **oam** statement and sub-statements at the **[edit routing-instances routing-instance-name protocols l2vpn]** hierarchy level:

```
oam {
  bfd-liveness-detection;
  ping-interval ;
  ping-multiplier;
}
```

You can configure many of the same OAM statements for VPLS and Layer 2 circuits:

- To enable OAM for VPLS, configure the **oam** statement and substatements at the **[edit routing-instances routing-instance-name protocols vpls]** hierarchy level and at the **[edit routing-instances routing-instance-name protocols vpls neighbor address]** hierarchy level. The **pwe3-control-word** statement configured at the **[edit routing-instances routing-instance-name protocols l2vpn oam control-channel]** hierarchy level is not applicable to VPLS configurations.
- To enable OAM for Layer 2 circuits, configure the **oam** statement and substatements at the **[edit protocols l2circuit neighbor address interface interface-name]** hierarchy level. The **control-channel** statement and sub-statements configured at the **[edit routing-instances routing-instance-name protocols l2vpn oam]** hierarchy level do not apply to Layer 2 circuit configurations.

You can use the **show ldp database extensive** command to display information about the VCCV control channel and the **show bfd session extensive** command to display information about BFD for Layer 2 VPNs, Layer 2 circuits, and VPLS.

Understanding Group VPN

Group virtual private network (VPN) is supported in Junos OS Release 14.2. Starting with Junos OS Release 15.1, Junos OS supports Group VPNv2. For information on Group VPNv2, see [“Group VPNv2 Overview” on page 235](#)

Group virtual private network (VPN) is a new category of VPN that eliminates the need for point-to-point VPN tunnels in a mesh architecture. It is a set of features that are necessary to secure IP multicast group traffic or unicast traffic over a private WAN that originates on or flows through a router.

Group VPN introduces the concept of a trusted group to eliminate point-to-point tunnels and their associated overlay routing. All group members share a common security

association (SA), also known as a group SA (GSA). This enables group members to decrypt traffic that was encrypted by any other group member.

Group VPN provides the following advantages:

- Provides data security and transport authentication, helping to meet security compliance and internal regulation by encrypting all WAN traffic.
- Enables high-scale network meshes and eliminates complex peer-to-peer key management with group encryption keys.
- Maintains network intelligence such as full-mesh connectivity, natural routing path, and quality of service (QoS) in MPLS networks.
- Grants authenticated membership control with a centralized key server.
- Helps to ensure low latency and jitter by enabling full-time, direct communications between sites, without requiring transport through a central hub.
- Reduces traffic loads on customer premises equipment (CPE) and provider-edge (PE) encryption devices by using the core network for replication of multicast traffic, avoiding packet replication at each individual peer site.

Group VPN and Standard IPsec VPN

A group VPN is built on standards-based technologies that integrate routing and encryption together in the network. An IPsec SA is a unidirectional agreement between VPN participants that defines the rules to use for authentication and encryption algorithms, key exchange mechanisms, and secure communications.

Traditional IPsec VPN deployments tackle the problem of securing traffic between gateways in the network by creating an overlay network based on the use of point-to-point tunnels. Traffic carried over these tunnels is normally encrypted and authenticated in order to provide data integrity and confidentiality. Secure group members are managed through the Group Domain of Interpretation protocol (GDOI). The GDOI solution takes a different approach by disassociating the encryption and authentication problem from the transport. By doing this, GDOI-based solutions provide a way to encrypt branch-to-branch communications without the need to configure branch-to-branch tunnels.

With current VPN implementations, the SA is a point-to-point tunnel between two routers. A group VPN extends the IPsec architecture to support SAs that are shared by a group of routers (see [Figure 13 on page 201](#)). A key server distributes keys and policies to all registered and authenticated member routers. By distributing policies from a centralized point and by sharing the same group security association (the entire group has a single Phase 2 IPsec SA) with authenticated group members, key distribution and management are greatly simplified.

Figure 13: Standard IPsec VPN and Group VPN

Group VPN is a client/server architecture. All members have a unique Phase 1 IKE SA with the key server. Hence, if there are n members, there is a total of n Phase 1 IKE SAs. However, the entire group shares a single Phase 2 SA.

In traditional IPsec, tunnel endpoint addresses are used as a new packet source and destination. The packet is then routed over the IP infrastructure, using the encrypting gateway source IP address and the decrypting gateway destination IP address. In the case of group VPN, IPsec-protected data packets encapsulate the original source and destination packet addresses of the host in the outer IP header to preserve the IP address. The biggest advantage of tunnel header preservation is the ability to route encrypted packets using the underlying network routing infrastructure.

Thus, with group VPNs, any-to-any connectivity is achieved by preserving the original source and destination IP addresses in the outer header. Secure multicast packets are

replicated in the same way as cleartext multicast packets in the core network. The external IP header in the group VPN is an exact copy of the IP header of the original packet within the ESP header versus the external IP header in a traditional VPN that contains the IP addresses of the VPN gateways.

Table 7: Group VPN vs Traditional Point-to-Point IPsec

Feature	Traditional Point-to-Point IPsec Tunnels	Group VPN
Scalability	IKE/IPsec tunnels between each pair of peers.	Scalable architecture. Single SA and key pair used for entire any-to-any group.
Any-to-any instant connectivity	Can't be done to scale.	Can be done to high-scale.
Overlay routing	Requires overlay routing.	No overlays-native routing.
IP Header Preservation	New IP Header added to original packet results in limited advanced quality-of-service (QoS).	Keeps original IP header on IPsec packet, and preserves advanced QoS.

Understanding the GDOI Protocol

The Group Domain of Interpretation (GDOI) protocol described in RFC 6407 is used to distribute a set of cryptographic keys and policies to a group of devices. GDOI is defined as the Internet Security Association Key Management Protocol (ISAKMP) Domain of Interpretation (DOI) for group key management. In a group management model, the GDOI protocol operates between a group member and a group controller or key server (GC/KS) and manages group security associations (GSAs) and group keys for a set of security participants. The ISAKMP defines two phases of negotiation. GDOI is a Phase 2 protocol protected by a Phase 1 ISAKMP security association. IKEv1 is specified in RFC 6407 as a Phase 1 protocol.

GDOI introduces two different encryption keys:

- **Key encryption key (KEK)**—Used to secure the control plane. KEK is the name of the key used by the group members to decrypt rekey messages from the GC/KS. This key is part of the Security Association Key Encryption Key (SAK).
- **Traffic encryption key (TEK)**—Used to secure the data plane. TEK is the name of the key used by the group members to encrypt or decrypt communication between other group members. This key is part of the Security Association Transport Encryption Key (SAT).

As with standard IPsec, all keys have a lifetime and have to be rekeyed. The keys distributed through GDOI are group keys and are used by the entire group.

The GSAs and key management are handled through two types of GDOI exchanges:

- **groupkey-pull**—This exchange allows a member to request SAs and keys shared by the group from the server.

In the pull method, the group member requests the group SA and policy from the key server. This request is protected over the IKE SA.

The **groupkey-pull** is the first exchange in the GDOI protocol and is used for group member registration with the GC/KS. The group member specifies the group with which it wants to register, and the GC/KS sends all necessary GSAs and keys to the group member if the member is authorized to join the group. The complete exchange is secured by a Phase 1 SA (IKEv1 SA), which is established with IKEv1 before the **groupkey-pull** exchange begins. The **groupkey-pull** is part of Phase 2 of the GDOI protocol.

- **groupkey-push**—This exchange is a single rekey message that allows the server to send group SAs and keys to members before existing group SAs expire. Rekey messages are unsolicited messages sent from the server to members.

The **groupkey-push** is the second exchange in the GDOI protocol and is used to send new GSAs and keys from the GC/KS to the group members of a group (rekeying). This exchange is secured by an SA KEK (SAK), which is installed during the **groupkey-pull** exchange. The **groupkey-push** is part of Phase 2 of the GDOI protocol.

NOTE: The Junos[®] operating system (Junos OS) uses only the **groupkey-pull** exchange for group member rekeying. The **groupkey-push** exchange is not supported. For information about group VPN rekeying, see [“Rekeying a Group Member” on page 208](#).

GDOI Protocol and Group VPN

Group VPN is the name of the security technology from Juniper Networks. Group VPN uses the GDOI protocol (specified in RFC 6407) as a base, in addition to other functionalities.

The group VPN technology is based on the GDOI protocol to handle the most important functionality. This protocol defines an ISAKMP Domain of Interpretation (DOI) to manage GSAs and keys for a group of security participants. Thus, all members of the group share identical information to encrypt and decrypt traffic among each other. The creation, management, and distribution of GSAs and group keys are centralized and performed by the GC/KS. [Figure 14 on page 204](#) provides a brief overview of the group VPN functionality using GDOI.

Figure 14: Group VPN Using GDOI

The group members use the Encapsulating Security Payload (ESP) protocol in tunnel mode to secure the traffic. However, in group VPN the tunnel mode is modified. Because there is no direct association between the group members, it is not necessary to use special IP addresses in the outer IP header (that is, IP addresses of IPsec gateways). Every group member can decrypt the traffic of every other group member. Thus, the inner IP-Header is copied to the outer IP-Header, and the underlying routing infrastructure and QoS infrastructure can be used. This feature is called Header Preservation and is shown in Figure 15 on page 204.

Figure 15: Header Preservation

To get GSAs and group keys, the group member must register with the GC/KS for a specific group. The result is an IKEv1 SA, which is only needed to secure the registration process. After the registration, the group member has all the information to communicate with the other group members (SAT), as well as the information to successfully decrypt the rekeying messages (SAK). The GC/KS sends out rekeying messages before either the SAT or SAK lifetime expires. It is also possible to send a SAT update as well as a SAK update in the same rekey message. The IKEv1 SA is no longer needed and is deleted after the lifetime expires (no IKEv1 rekeying).

Group VPN Traffic

The group VPN traffic includes:

- Control-plane-traffic—Traffic from the group members to the GC/KS in the group VPN deployment with the GDOI protocol only.

- Data-plane-traffic—Traffic between the group members in the group VPN deployment with the ESP protocol only, that is already known from IPsec.

Group Security Association

Unlike traditional IPsec encryption solutions, group VPN uses the concept of a group security association (GSA). GSA is similar to an IPsec SA in terms of functionality. GSAs are shared among all group members of a common GDOI group. All members in the group VPN group can communicate with each other using a common encryption policy and a shared GSA. With a common encryption policy and a shared GSA, there is no need to negotiate IPsec between group members. This reduces the resource load on the IPsec routers. Traditional group member scalability (number of tunnels and associated SA) does not apply to group VPN group members.

Group Controller/Key Server

A group controller or key server (GC/KS) is a device used for creating and maintaining the group VPN control plane. It is responsible for creation and distribution of GSAs and group keys. All information the group members need to communicate with other group members is provided by the GC/KS. All encryption policies, such as interesting traffic, encryption protocols, security association, rekey timers, and so on, are centrally defined on the GC/KS and are pushed down to all group members at registration time. Group members authenticate with the GC/KS using IKE Phase 1 and then download the encryption policies and keys required for group VPN operation. The GC/KS is also responsible for refreshing and distributing the keys. Unlike traditional IPsec, interesting traffic defined on the GC/KS is downloaded to every group member, whether or not the group member owns that network.

NOTE: The GC/KS functionality is not supported on MX Series routers. The MX Series routers that are configured as group members can connect with Cisco GC/KS only.

Group Member

A group member is a device used for the traffic encryption process and is responsible for the actual encryption and decryption of data traffic. A group member is configured with IKE Phase 1 parameters and GC/KS information. Encryption policies are defined centrally on the GC/KS and downloaded to the group member at the time of registration. Based on these downloaded policies, the group member determines whether traffic needs to be encrypted or decrypted and what keys to use. The group members use the ESP protocol for securing transport data sent to other group members.

From a functionality point of view, a group member is similar to an IPsec gateway. However, the SAs in normal IPsec are handled per connection between both IPsec gateways and in GDOI, whereas in group VPN the SAs are provided by the GC/KS on a per group basis.

The group member registers with the key server to get the IPsec SA or SAs that are necessary to communicate with the group. The group member provides the group ID to

the key server to get the respective policy and keys for this group. The group members re-register with the server before the current IPsec SAs expire as part of the rekeying process, so that there is no loss of traffic.

NOTE: Only groupkey-pull exchange is used for rekeying. The groupkey-push from the GC/KS is not supported. For information about group VPN rekeying, see [“Rekeying a Group Member” on page 208](#).

Group VPN Implementation Overview

This section explains the Juniper Networks solution for implementing group VPN.

Enabling Group VPN

Service set is used to enable group VPN on a particular interface.

- [Configuring the Service Set on page 206](#)
- [Applying the Service Set on page 207](#)
- [Packet Steering on page 207](#)

Configuring the Service Set

The group VPN is configured inside a service set using the `ipsec-group-vpn` statement at the `[edit services service-set service-set-name]` hierarchy level.

The following is a sample service set configuration:

```
[edit services]
service-set service-set-name {
  interface-service {
    service-interface pic-interface;
  }
}
ipsec-group-vpn vpn-name;
```

NOTE:

- Only one group member can be configured per service set.
- Next-hop style service set is not supported with group VPN.

Applying the Service Set

A service set is applied at the interface level.

The following is a sample service set application configuration:

```
[edit interfaces]
interface-name {
  unit 0 {
    family inet {
      service {
        input {
          service-set service-set-name;
        }
        output {
          service-set service-set-name;
        }
      }
    }
    address 10.0.30.2/30;
  }
}
```

Packet Steering

The interface-style service set configuration is used to steer traffic from the Packet Forwarding Engine to the PIC. Packets received on an interface with a service set pointing to the group VPN object are forwarded to the PIC by being injected into the corresponding service interface.

Registering a Group Member

The group member registration to the server starts when the **ipsec-group-vpn** statement is configured for a service set and the service interface is up. When the service interface goes down, all GSAs associated with this PIC are cleared, and no registration is triggered for these group VPNs until the PIC comes up.

Group member registration involves establishing IKE SA with the GC/KS followed by a **groupkey-pull** exchange to download the SAs and the traffic keys for the specified group identifier.

NOTE: Junos OS does not support traffic-based SA negotiation triggering for group VPNs.

Rekeying a Group Member

Junos OS group VPN does not support server-to-member rekeying. If rekeying is done from the GC/KS, the key is ignored by the group member.

For group member rekeying, the group members re-register with the GC/KS at the end of the soft lifetime expiry. After rekeying, both the old key and the new key can be used for decryption. However, the new key is not used for encryption until 30 seconds of lifetime of the old key is remaining.

Taking as an example, the GC/KS is configured with a lifetime of 3600 seconds and is connected to one group member without retransmit. Based on the server configuration, the GC/KS generates a new key when 10 percent of the lifetime is remaining. The group member, however, re-registers with the GC/KS when 5 percent of the lifetime is remaining.

Figure 16 on page 208 represents the rekeying process between the GC/KS and the group member.

Figure 16: Group Member Rekeying

Authenticating a Group Member

Junos OS does not provide Public Key Infrastructure (PKI) support for group VPNs, and as a result, pre-shared keys are used for group member authentication.

Fragmenting Group VPN Traffic

Because of the header preservation functionality and the usage of the underlying routing infrastructure, it is necessary to fragment the packets before encryption occurs (if it cannot be prevented).

Hence, pre-fragmentation is supported and is recommended for all deployments.

To avoid post-fragmentation, set the **clear**, **set**, and **copy** options for the DF bit in the group VPN configuration.

Based on this flag setting, the IPsec header has either the **df-bit** set to **clear**, **set**, or **copy** from the inner packet.

NOTE: The DF bit has the **clear** option set as default.

The following is a sample DF bit configuration:

```
[edit]
security {
  group-vpn {
    member {
      ipsec {
        vpn vpn-group-name {
          df-bit clear;
        }
      }
    }
  }
}
```

Encrypting Group VPN Traffic

Group members encrypt traffic based on the GSAs and keys provided by the GC/KS. The group VPN encryption path is as follows:

1. Packet received by the Packet Forwarding Engine is checked against a flow match. If a match is found, the packet is further processed and transmitted.
2. If a match is not found, a rule lookup is performed. If a match is found, a flow is created, and the packet is further processed and transmitted.
3. If the rule lookup fails, the packet is dropped.

NOTE: GSA is not triggered during packet processing.

Decrypting Group VPN Traffic

After registration is successful and group VPN SAs are installed, an ESP session is created. Unlike IPsec VPN, which creates an ESP session with the source and destination IP to be the gateway address, group VPN creates the ESP session with a zero source and destination IP. Because the ESP session is already created at SA installation, packets are expected to match the existing ESP session.

The group VPN decryption process is as follows:

1. Packet received by the Packet Forwarding Engine undergoes a fragmentation check. If the packet is fragmented, it is assembled for further processing.
2. After packet assembling or if the packet is not fragmented, a zero source and destination IP is used in the 5-tuple decrypt flow lookup. If a match is found, the packet is further processed and transmitted.
3. If the decrypt flow lookup fails, the packet is checked against a security parameter index (SPI) flow with zero source and destination IP.
4. If the SPI flow lookup fails, the packet is dropped.
5. If an SPI flow match is found, a decrypt flow is created to avoid the SPI flow lookup for subsequent packets.

Configuring a Routing Instance for Group VPN

Routing instances are supported for both control and data traffic. To enable routing instance support on control plane traffic for a group member to reach the GC/KS in a given VRF routing instance, add the **routing-instance** statement at the **[edit security group-vpn member ike gateway gateway-name local-address address]** hierarchy level.

No additional CLI input is required to support a routing instance for data plane packets, because it is determined based on the media interface on which the service set is applied.

Establishing Multiple Groups, Policies, and SAs

Junos OS provides support for one group VPN per service set. However, multiple service sets can be created to support multiple groups in a routing instance. Multiple SAs can be configured per group. However, multiple policies for the same traffic key/SPI is not supported. If the server sends two policies for the same TEK, then they must be paired to be accepted; for instance, A-B and B-A, where A and B are IP addresses or subnets. If multiple unpaired policies for a given TEK are received, registration fails and a system log message is generated.

Connecting with Multiple Cooperative GC/KS

For a group member to work with a GC/KS in the cooperative mode, the configuration is extended to allow a maximum of four servers in the server list.

During rekeying, the group member tries to connect to the GC/KS. When the connection to the GC/KS fails, the group member tries to reconnect to the GC/KS. After three retries with an interval of 10 seconds, if the connection to the GC/KS is not restored, the group member tries to establish a connection with the next available server on the server list. This process is repeated until the group member connects to a GC/KS. During this time, the unexpired GDOI IPsec SAs on the group members are not cleaned up, so group VPN traffic is not affected. The time gap between rekeying and hard lifetime expiry provides sufficient time for the group members to connect to the next available server, in such cases.

Changing a Group VPN Configuration

Most group VPN configuration changes result in deleting existing IKE SA and GDOI SA and re-registration, which triggers both phase 1 and SA download with traffic keys.

Bypassing a Group VPN Configuration

If certain traffic like a routing protocol needs to bypass a group VPN, a service filter needs to be configured on the interface on which the service set is applied. Packets matching the service filter will not come to the PIC for service processing and are directly forwarded to the Routing Engine.

The following is a sample service set filter configuration:

```
[edit interfaces]
interface-name {
  unit 0 {
    family inet {
      service {
        input {
          service-set service-set-name service-filter filter-name;
        }
        output {
          service-set service-set-name service-filter filter-name;
        }
      }
    }
  }
}
```

Supported GDOI IPsec Parameters

Every GDOI group has a unique ID. It is used as a common base between GC/KS and the group member to communicate about GSAs and group keys.

During the registration process, the GC/KS sends Security Association Transport Encryption Keys (SATs) to the group members. All parameters regarding the whole group security policy are configured on the GC/KS. The SAT is used by the group members to protect the traffic exchanged among each other. [Table 8 on page 212](#) shows the parameters of the SAT.

Table 8: SAT Parameters

Parameters	Supported Values
Encryption	<ul style="list-style-type: none"> • DES-CBC • 3DES-CBC • AES-CBC 128 • AES-CBC 192 • AES-CBC 256
Integrity	<ul style="list-style-type: none"> • HMAC-MD5-96 • HMAC-SHA1-96
Lifetime	Any supported value

Besides the cryptographic algorithms, the traffic, which should be encrypted by the group members, is part of the SAT policy (traffic selector).

The following statements can be used on a Juniper Networks group member. Thus, the addresses have to be specified under the IKE hierarchy level. The enumeration is also prioritized. Thus, in the following example configuration, KS1 is contacted before KS2.

The following is a sample GDOI IPsec parameters configuration:

```
[edit security]
group-vpn {
  member {
    ike {
      gateway gateway-name {
        ike-policy policy-name;
        server-address <IP_KS1> <IP_KS2> <IP_KS2> <IP_KS4>;
        local-address <IP_GM> routing-instance routing-instance-name;
      }
    }
    ipsec {
      vpn vpn-group-name {
        ike-gateway gateway-name;
        group group-ID;
        match-direction output;
      }
    }
  }
}
```

Supported GDOI IKEv1 Parameters

The group members use only IKEv1 during the registration process in the group VPN environment. [Table 9 on page 213](#) provides an overview of the defined parameters of the IKEv1 SA.

Table 9: IKEv1 SA Parameters of Group Member

Parameter	Supported Values
Encryption	<ul style="list-style-type: none"> • DES-CBC • 3DES-CBC • AES-CBC 128 • AES-CBC 192 • AES-CBC 256
Authentication	Pre-shared key (minimum 20 signs)
Integrity	<ul style="list-style-type: none"> • MD5 • SHA1
Diffie-Hellman Group	<ul style="list-style-type: none"> • Group 1 • Group 2 • Group 5 • Group 14
Lifetime	Any supported value

The following is a sample IKEv1 configuration with the above-mentioned IKEv1 standards:

```
[edit security]
group-vpn {
  member {
    ike {
      proposal proposal-name {
        authentication-algorithm sha1;
        authentication-method pre-shared-keys;
        dh-group group5;
        encryption-algorithm aes-128-cbc;
        lifetime-seconds 3600;
      }
      policy policy-name {
        mode main;
        proposals proposal-name;
        pre-shared-key ascii-text "SECRET DATA";
      }
    }
  }
}
```

Applying Dynamic Policies

The **input** and **output** options under the **ipsec-group-vpn** statement specify if the dynamic policies received from the server are used when the interface on which the service set is applied is the incoming or outgoing interface. This provides flexibility to specify different rules in the incoming and outgoing directions.

Supporting TOS and DSCP

Type of service (TOS) and DiffServ Code Points (DSCP) bits are copied from the inner packet to the ESP packet.

Interoperability of Group Members

Cisco's implementation of GDOI is called Group Encryption Transport (GET) VPN. While group VPN in Junos OS and Cisco's GET VPN are both based on RFC 6407, *The Group Domain of Interpretation*, there are some implementation differences that you need to be aware of when deploying GDOI in a networking environment that includes both Juniper Networks security and routing devices and Cisco routers. For more information, see the current Junos OS release notes.

Group VPN interoperability is as follows:

- Junos OS provides minimal interoperability support with Cisco IOS GC/KS support.
- The MX Series group member is able to communicate with the SRX Series group member and Cisco group member.
- Junos OS does not provide support for group VPN interoperability with the SRX Series group VPN server.

Table 10: Group VPN Interoperability

Group Member (GM)	SRX GM	MX GM	Cisco GM	SRX GS	Cisco GS
MX GM	Yes	Yes	Yes	No	Yes

Following are some of the known issues with Cisco IOS GC/KS:

- The unicast **groupkey-push** message does not work because the proprietary ACK is expected by the Cisco GC/KS following unicast push.

As a workaround, the **groupkey-pull** is used for rekey.

- The deny policy is used on a Cisco server to add an exception to the group policy.

As a workaround, an exception to the group policy can be added by configuring firewall rules on an MX Series group member. Also, Junos OS group members can work with the deny policy by not failing the negotiation and simply ignoring the contents. This allows system administrators to easily manage networks where both Cisco group members and Junos OS group members co-exist.

Group VPN Limitations

Junos OS group VPN does not provide support for the following:

- GDOI **groupkey-push** exchange. Hence, both unicast and multicast push are not supported.
- Multicast traffic

- Post-fragmentation of packets
- GDOI SNMP MIBs
- Anti-replay
- GAP payload
- Protocol and port in the policies sent by the server. The group member honors only the IP address/subnet specified in the policy.
- Multiple unpaired policies for the same traffic key/SPI
- Overlapping of both local and remote IP across routing instances in an IKE gateway configuration
- Overlapping group VPN policies that can result in mismatched SAs
- IPv6 for control and data traffic
- Co-existence of IPsec and group VPN on the same service set
- Co-existence of services like NAT and ALG on the same service set. NAT and group VPN can co-exist on different service sets. However, they cannot co-exist on the same service set.
- Site To Site (S2S) VPN and Dynamic End Point (DEP) VPN can co-exist with group VPN on different service sets. However, they cannot co-exist on the same service set.
- Multiple groups on same service set
- Group member support with SRX GC/KS
- Logical Key Hierarchy (LKH)
- Graceful restart
- High availability
- Unified ISSU
- Private key IPsec (PKI) support for authentication
- Aggregated multiservices (AMS) interface and load balancing support
- Multiple groups per service set
- Same gateway for multiple groups, wherein the same local and remote address pair cannot be used for multiple groups.

**Related
Documentation**

- [Example: Configuring Group VPNs on Routing Devices on page 218](#)

Configuring Group VPNs on Routing Devices

You can configure an MX Series router with MS-MIC-16G and MS-MPC-PIC line cards to provide the group VPN member functionality support with one or more Cisco group controllers or key servers (GC/KSs). The group members can connect to a maximum of four Cisco GC/KSs with minimum interoperability with the cooperative servers.

The group VPN feature also provides system logging support for the group VPN functionality, and routing instance support for both control and data traffic.

Before you begin:

1. Configure the routers for network communication.
2. Configure the Cisco GC/KS.
3. Configure the group member device interfaces.
4. Configure a static route to reach the group server.

To configure a group VPN member, complete the following tasks:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@GM1# edit security
```

2. Define the IKE proposal.

```
[edit security]
user@GM1# set group-vpn member ike proposal proposal-name
```

3. Configure the Phase 1 SA for the IKE proposal.

```
[edit security]
user@GM1# set group-vpn member ike proposal proposal-name authentication-method
pre-shared-keys
user@GM1# set group-vpn member ike proposal proposal-name dh-group group
user@GM1# set group-vpn member ike proposal proposal-name
authentication-algorithm sha1
user@GM1# set group-vpn member ike proposal proposal-name encryption-algorithm
3des-cbc
```

4. Define the IKE policy.

```
[edit security]
user@GM1# set group-vpn member ike policy policy-name mode main
user@GM1# set group-vpn member ike policy policy-name proposals proposal-name
user@GM1# set group-vpn member ike policy policy-name pre-shared-key ascii-text
text
```

5. Set the remote gateways for the IKE gateway group.

```
[edit security]
```

```

user@GM1# set group-vpn member ike gateway gateway-group-name ike-policy
policy-name
user@GM1# set group-vpn member ike gateway gateway-group-name server-address
server-IP-address
user@GM1# set group-vpn member ike gateway gateway-group-name local-address
server-facing-interface-IP-address

```

NOTE: To configure a group member to connect to multiple group servers, add the IP address of all the servers to the remote IKE gateway group configuration.

For example,

```

[edit security]
user@GM1# set group-vpn member ike gateway gw-group1 server-address
66.66.66.66
user@GM1# set group-vpn member ike gateway gw-group1 server-address
77.77.77.77

```

6. Configure the group identifier and IKE gateway for the remote gateway group.

```

[edit security]
user@GM1# set group-vpn member ipsec vpn vpn-name ike-gateway
gateway-group-name
user@GM1# set group-vpn member ipsec vpn vpn-name group group-ID
user@GM1# set group-vpn member ipsec vpn vpn-name match-direction output

```

7. In configuration mode, go to the following hierarchy level:

```

[edit]
user@GM1# edit services

```

8. Configure the service set for the remote gateway group.

```

[edit services]
user@GM1# set service-set service-set-name interface-service service-interface
service-interface
user@GM1# set service-set service-set-name ipsec-group-vpn vpn-name

```

NOTE: The service set has to be applied on the interface connecting to the other group member.

For example:

```

[edit interfaces]
user@GM1# set xe-0/3/1 unit 1 family inet service input service-set
gvpn-service-set
user@GM1# set xe-0/3/1 unit 1 family inet service output service-set
gvpn-service-set

```

9. Verify and commit the configuration.

For example:

```
[edit security]
user@GM1# set group-vpn member ike proposal ike-proposal authentication-method
pre-shared-keys
user@GM1# set group-vpn member ike proposal ike-proposal dh-group group2
user@GM1# set group-vpn member ike proposal ike-proposal authentication-algorithm
sha1
user@GM1# set group-vpn member ike proposal ike-proposal encryption-algorithm
3des-cbc
user@GM1# set group-vpn member ike policy ike-policy mode main
user@GM1# set group-vpn member ike policy ike-policy proposals ike-proposal
user@GM1# set group-vpn member ike policy ike-policy pre-shared-key ascii-text
""$9$QEni3/t1RSM87uO87-V4oz36"
user@GM1# set group-vpn member ike gateway gw-group1 ike-policy ike-policy
user@GM1# set group-vpn member ike gateway gw-group1 server-address 66.66.66.66
user@GM1# set group-vpn member ike gateway gw-group1 local-address 101.0.1.1
user@GM1# set group-vpn member ipsec vpn vpn-group1 ike-gateway gw-group1
user@GM1# set group-vpn member ipsec vpn vpn-group1 group 1
user@GM1# set group-vpn member ipsec vpn vpn-group1 match-direction output

[edit services]
user@GM1# set service-set gvpn-service-set interface-service service-interface
ms-4/0/0.1
user@GM1# set service-set gvpn-service-set ipsec-group-vpn vpn-group1

[edit]
user@GM1# commit
commit complete
```

Example: Configuring Group VPNs on Routing Devices

This example shows how to configure group VPNs to extend the IP Security (IPsec) architecture to support group security associations (GSAs) that are shared by a group of routers.

- [Requirements on page 218](#)
- [Overview on page 219](#)
- [Configuration on page 220](#)
- [Verification on page 229](#)
- [Troubleshooting on page 231](#)

Requirements

This example uses the following hardware and software components:

- Two MX Series 3D Universal Edge Routers with MS-MIC-16G or MS-MPC-PIC line cards
- Reachability to one or more Cisco Group Controllers or Key Servers (GC/KS)
- Junos OS Release 14.1 or later running on the MX Series routers

Before you begin:

1. Configure the routers for network communication.
2. Configure the Cisco GC/KS.
3. Configure the group member device interfaces.

Overview

Starting with Junos OS Release 14.1, MX Series routers with MS-MIC-16G and MS-MPC-PIC line cards provide the group VPN member functionality support with one or more Cisco Group Controllers or Key Servers (GC/KS). The group members can connect to a maximum of four Cisco GC/KSs with minimum interoperability with the cooperative servers.

This feature also provides system logging support for group VPN functionality, and routing instance support for both control and data traffic.

Topology

In [Figure 17 on page 219](#), a group VPN is configured between a Cisco group server, GC/KS – and two group members, GM1 and GM2. The group members are connected to host devices.

In [Figure 18 on page 220](#), a group VPN is configured between GM1 and GM2, and GC/KS1 and GC/KS2 are the primary and secondary group servers, respectively.

Figure 17: Group VPN with Single GC/KS

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure GM1:

1. Configure the Router GM1 interfaces.

```

[edit interfaces]
user@GM1# set ms-4/0/0 unit 1 family inet

```

```

user@GM1# set ge-0/1/9 vlan-tagging
user@GM1# set ge-0/1/9 unit 1 vlan-id 11
user@GM1# set ge-0/1/9 unit 1 family inet address 198.51.100.0/24

```

```

user@GM1# set xe-0/3/1 vlan-tagging

```

```
user@GM1# set xe-0/3/1 unit 1 vlan-id 1
user@GM1# set xe-0/3/1 unit 1 family inet service input service-set gvpn-service-set
user@GM1# set xe-0/3/1 unit 1 family inet service output service-set gvpn-service-set
user@GM1# set xe-0/3/1 unit 1 family inet address 10.0.1.2/24
```

```
user@GM1# set interfaces xe-4/3/1 unit 0 family inet address 203.0.113.1/24
```

2. Configure static routes to reach the group server and member 2.

```
[edit routing-options]
user@GM1# set static route 192.0.2.0/24 next-hop 198.51.100.2
user@GM1# set static route 203.0.113.0/24 next-hop 10.0.1.1
```

3. Define the IKE proposal.

```
[edit security]
user@GM1# set group-vpn member ike proposal ike-proposal
```

4. Configure the Phase 1 SA for ike-proposal.

```
[edit security]
user@GM1# set group-vpn member ike proposal ike-proposal authentication-method
pre-shared-keys
user@GM1# set group-vpn member ike proposal ike-proposal dh-group group2
user@GM1# set group-vpn member ike proposal ike-proposal
authentication-algorithm sha1
user@GM1# set group-vpn member ike proposal ike-proposal encryption-algorithm
3des-cbc
```

5. Define the IKE policy.

```
[edit security]
user@GM1# set group-vpn member ike policy ike-policy mode main
user@GM1# set group-vpn member ike policy ike-policy proposals ike-proposal
user@GM1# set group-vpn member ike policy ike-policy pre-shared-key ascii-text
""$9$QEni3/t1RSM87uO87-V4oz36"
```

6. Set the remote gateways for gw-group1.

```
[edit security]
user@GM1# set group-vpn member ike gateway gw-group1 ike-policy ike-policy
user@GM1# set group-vpn member ike gateway gw-group1 server-address 192.0.2.0
user@GM1# set group-vpn member ike gateway gw-group1 local-address
198.51.100.0
```

7. Configure the group identifier and IKE gateway for gw-group1.

```
[edit security]
user@GM1# set group-vpn member ipsec vpn vpn-group1 ike-gateway gw-group1
user@GM1# set group-vpn member ipsec vpn vpn-group1 group 1
user@GM1# set group-vpn member ipsec vpn vpn-group1 match-direction output
```

8. Configure the service set for gw-group1.

```
[edit services]
user@GM1# set service-set gvpn-service-set interface-service service-interface
ms-4/0/0.1
user@GM1# set service-set gvpn-service-set ipsec-group-vpn vpn-group1
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show security**, and **show services** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
GM1 user@GM1# show interfaces
ge-0/1/9 {
  vlan-tagging;
  unit 1 {
    vlan-id 11;
    family inet {
      address 198.51.100.0/24;
    }
  }
}
xe-0/3/1 {

}

```

Configuring Group VPN with Multiple GC/KS

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then **commit** the configuration.

```

GM1 set interfaces ms-4/0/0 unit 1 family inet
    set interfaces ge-0/1/9 vlan-tagging
    set interfaces ge-0/1/9 unit 1 vlan-id 11
    set interfaces ge-0/1/9 unit 1 family inet address 198.51.100.0/24
    set interfaces xe-0/3/1 vlan-tagging
    set interfaces xe-0/3/1 unit 1 vlan-id 1

```

```

set interfaces xe-0/3/1 unit 1 family inet service input service-set gvpn-service-set
set interfaces xe-0/3/1 unit 1 family inet service output service-set gvpn-service-set
set interfaces xe-0/3/1 unit 1 family inet address 10.0.1.2/24
set interfaces xe-4/3/1 unit 0 family inet address 203.0.113.1/24
set routing-options static route 192.0.2.0/24 next-hop 198.51.100.2
set routing-options static route 203.0.113.0/24 next-hop 10.0.1.1
set security group-vpn member ike proposal ike-proposal authentication-method
    pre-shared-keys
set security group-vpn member ike proposal ike-proposal dh-group group2
set security group-vpn member ike proposal ike-proposal authentication-algorithm sha1
set security group-vpn member ike proposal ike-proposal encryption-algorithm 3des-cbc

set security group-vpn member ipsec vpn vpn-group1 match-direction output
set services service-set gvpn-service-set interface-service service-interface ms-0/2/0.1
set services service-set gvpn-service-set ipsec-group-vpn vpn-group1

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure GM1:

1. Configure the Router GM1 interfaces.

```
[edit interfaces]
```

```
user@GM1# set ms-4/0/0 unit 1 family inet
```

```
user@GM1# set ge-0/1/9 vlan-tagging
```

```
user@GM1# set ge-0/1/9 unit 1 vlan-id 11
```

```
user@GM1# set ge-0/1/9 unit 1 family inet address 198.51.100.0/24
```

```
user@GM1# set xe-0/3/1 vlan-tagging
```

```
user@GM1# set xe-0/3/1 unit 1 vlan-id 1
```

```
user@GM1# set xe-0/3/1 unit 1 family inet service input service-set gvpn-service-set
```

```
user@GM1# set xe-0/3/1 unit 1 family inet service output service-set gvpn-service-set
```

```
user@GM1# set xe-0/3/1 unit 1 family inet address 10.0.1.2/24
```

```
user@GM1# set xe-4/3/1 unit 0 family inet address 203.0.113.1/24
```

2. Configure static routes to reach the group server and member 2.

```
[edit routing-options]
```

```
user@GM1# set static route 192.0.2.0/24 next-hop 198.51.100.2
```

```
user@GM1# set static route 203.0.1.0/24 next-hop 10.0.1.1
```

3. Define the IKE proposal.

```
[edit security]
```

```
user@GM1# set group-vpn member ike proposal ike-proposal
```

4. Configure the Phase 1 SA for ike-proposal.

```
[edit security]
```

```
user@GM1# set group-vpn member ike proposal ike-proposal authentication-method  
pre-shared-keys
```

```
user@GM1# set group-vpn member ike proposal ike-proposal dh-group group2
```

```
user@GM1# set group-vpn member ike proposal ike-proposal
```

```
authentication-algorithm sha1
```

```
user@GM1# set group-vpn member ike proposal ike-proposal encryption-algorithm  
3des-cbc
```

5. Define the IKE policy.

```
[edit security]
```

```
user@GM1# set group-vpn member ike policy ike-policy mode main
```

```
user@GM1# set group-vpn member ike policy ike-policy proposals ike-proposal
```

```
user@GM1# set group-vpn member ike policy ike-policy pre-shared-key ascii-text
```

```
""$9$QEni3/t1RSM87uO87-V4oz36"
```

6. Set the remote gateways for gw-group1.

```
[edit security]
user@GM1# set group-vpn member ike gateway gw-group1 ike-policy ike-policy
user@GM1# set group-vpn member ike gateway gw-group1 server-address 192.0.2.0
user@GM1# set group-vpn member ike gateway gw-group1 server-address 172.16.0.0
user@GM1# set group-vpn member ike gateway gw-group1 local-address
198.51.100.0
```

7. Configure the group identifier and IKE gateway for gw-group1.

```
[edit security]
user@GM1# set group-vpn member ipsec vpn vpn-group1 ike-gateway gw-group1
user@GM1# set group-vpn member ipsec vpn vpn-group1 group 1
user@GM1# set group-vpn member ipsec vpn vpn-group1 match-direction output
```

8. Configure the service set for gw-group1.

```
[edit services]
user@GM1# set service-set gvpn-service-set interface-service service-interface
ms-4/0/0.1
user@GM1# set service-set gvpn-service-set ipsec-group-vpn vpn-group1
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show security**, and **show services** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
GM1 user@GM1# show interfaces
ge-0/1/9 {
  vlan-tagging;

```

Verification

Confirm that the configuration is working properly.

- [Verifying the Group Member IKE SA on page 229](#)
- [Verifying the Group Member IPsec SA on page 229](#)
- [Verifying the Group Member IPsec Statistics on page 230](#)

Verifying the Group Member IKE SA

Purpose Verify the IKE SAs on Router GM1.

Action From operational mode, run the **show security group-vpn member ike security-associations detail** command.

```

user@GM1> show security group-vpn member ike security-associations detail
IKE peer 192.0.2.0, Index 2994970, Gateway Name: gw-group1
  Role: Initiator, State: UP
  Initiator cookie: 7fad16089a123bcd, Responder cookie: 536b33ffe89799de
  Exchange type: Main, Authentication method: Pre-shared-keys
  Local:198.51.100.0:848, Remote:192.0.2.0:848
  Lifetime: Expires in 175 seconds
  Peer ike-id: 192.0.2.0
  Xauth user-name: not available
  Xauth assigned IP: 0.0.0.0
  Algorithms:
    Authentication      : hmac-sha1-96
    Encryption          : 3des-cbc
    Pseudo random function: hmac-sha1
    Diffie-Hellman group : DH-group-2
  Traffic statistics:
    Input bytes  :          752
    Output bytes :          716
    Input packets:           5
    Output packets:          5
  Flags: IKE SA is created
  IPSec security associations: 0 created, 0 deleted
  Phase 2 negotiations in progress: 0

```

Meaning Router GM1 has established the IKE SA with the GC/KS for the group.

Verifying the Group Member IPsec SA

Purpose Verify the IPsec SAs on Router GM1.

Action From operational mode, run the **show security group-vpn member ipsec security-associations detail** command.

```
user@GM1> show security group-vpn member ipsec security-associations detail
Virtual-system: root Group VPN Name: vpn-group1
Local Gateway: 198.51.100.1, GDOI Server: 192.0.2.0
Group Id: 1
Rule Match Direction: output, Tunnel-MTU: 1500
Routing Instance: default
DF-bit: clear
Stats:
  Pull Succeeded           : 18
  Pull Failed              : 0
  Pull Timeout             : 0
  Pull Aborted             : 0
  Server Failover          : 0
  Delete Received          : 0
  Exceed Maximum Keys(4)   : 0
  Exceed Maximum Policies(1): 0
  Unsupported Algo         : 0
Flags:
  Rekey Needed: no

List of policies received from server:
Tunnel-id: 10001
Source IP: ipv4_subnet(any:0,[0..7]=203.0.2.0/24)
Destination IP: ipv4_subnet(any:0,[0..7]=203.0.1.0/24)

Direction: bi-directional, SPI: e1c117c7
Protocol: ESP, Authentication: sha1, Encryption: 3des
Hard lifetime: Expires in 2526 seconds
Lifesize Remaining: Unlimited
Soft lifetime: Expires in 2366 seconds
Mode: Tunnel, Type: Group VPN, State: installed
Anti-replay service: N/A
```

Meaning Router GM1 has established the IPsec SA with the GC/KS.

Verifying the Group Member IPsec Statistics

Purpose Verify the IPsec statistics on Router GM1.

Action From operational mode, run the **show security group-vpn member ipsec statistics** command.

```
user@GM1> show security group-vpn member ipsec statistics
PIC: ms-0/2/0, Service set: gvpn-service-set
```

```
ESP Statistics:
  Encrypted bytes:          264
  Decrypted bytes:         264
  Encrypted packets:        3
  Decrypted packets:        3
AH Statistics:
  Input bytes:              0
  Output bytes:             0
  Input packets:            0
  Output packets:           0
Errors:
  AH authentication failures: 0
  ESP authentication failures: 0
  ESP decryption failures:    0
  Bad headers: 0, Bad trailers: 0
  Replay before window drops: 0, Replayed pkts: 0
  IP integrity errors: 0, Exceeds tunnel MTU: 0
  Rule lookup failures: 0, No SA errors: 0
  Flow errors: 0, Misc errors: 0
```

Meaning **ESP Statistics** shows that packet flows have been encrypted and decrypted between the group members. Router GM1 has encrypted 3 packets and has received 3 decrypted packets from Router GM2.

Troubleshooting

To troubleshoot the group VPN configuration, see:

- [Negotiating the IKE SA on page 231](#)
- [Establishing the IKE SA on page 232](#)
- [Downloading the GDOI IPsec SA on page 233](#)
- [Traffic Encryption and Decryption on page 233](#)
- [Troubleshooting System Log Messages on page 234](#)

Negotiating the IKE SA

Problem The IKE SA negotiation is not triggered on the group member.

The output of the **show ike** and **show security group-vpn member ike security-associations** commands does not display the IKE negotiations.

Solution To troubleshoot the IKE negotiation issue:

1. Check if the service interface status is up.

Use **show interfaces terse | match ms** to check if the MS interface is down. An MS interface goes down when the PIC is rebooting.

2. Look for **Ignore gvpn vpn_name** since it is inactive in the log file `/var/log/gkmd`.
Check if the group VPN is referenced by any service set in the configuration.
 - a. Enable **security group-vpn member ike traceoptions**.
 - b. Look for the following system log messages in the trace log file:
 - Dec 2 16:09:54 GVPN:iked_pm_gvpn_trigger called for gvpn200
 - Dec 2 16:09:54 GVPN:PM NULL for gvpn gvpn200
 - Dec 2 16:09:54 GVPN:Ignore gvpn gvpn200 since it is inactive

This means either the service set is inactive or the service interface is down.

Establishing the IKE SA

Problem The IKE SA is not getting established with the GC/KS.

In this scenario, the IKE SA state is down in the **show security group-vpn member ike security-associations** command output:

```
user@GM1> show security group-vpn member ike security-associations
Index   State   Initiator cookie   Responder cookie   Mode           Remote Address
-----
          5295626 DOWN    2d47c125d2a9805e  0000000000000000  Main
192.0.2.2
```

Solution To troubleshoot the IKE SA issue:

1. Check if the server address configured under **[edit security group-vpn member ike gateway]** is the correct one and is reachable.
2. Use the **ping** command between the remote devices to check network connectivity.
3. Check if the local address in the **group-vpn** configuration is also a configured address on any of the physical interfaces in the configuration.
4. Check if the IKE proposals match between the group member and the GC/KS.
If there is a misconfiguration on the IKE SA negotiation, then do the following:
 - a. Enable **security group-vpn member ike traceoption**.
 - b. Look for the following message in the trace log file:

Dec 2 15:39:54 ikev2_fb_negotiation_done_isakmp: Entered IKE error code No proposal chosen (14), IKE SA 8dd7000 (neg 8dda800).

5. Look for a **No proposal chosen** error in the log file `/var/log/gkmd`.

Downloading the GDOI IPsec SA

Problem The GDOI IPsec SAs are not downloaded from the GC/KS.

In this scenario, the GDOI **groupkey-pull** with the configured GC/KS fails, and the **show security group-vpn member ipsec sa** command output does not display anything.

Solution To troubleshoot the GDOI IPsec SA issue:

1. Check if the IKE SA has been established with the GC/KS.
2. Check if the group ID configured on the GC/KS and the group member match.
3. Look for any group SA installation failures or other failures in the log file `/var/log/gkmd`.

Look for the following syslog messages to confirm use of an unsupported GDOI SA algorithm:

- Dec 2 15:32:49 simpleman gkmd[1701]: Failed to install SA because of unsupported algo(encr: 3des-cbc, auth : (null)) for SPI 0x6645cdb5 from server 192.0.2.1
- Dec 2 15:32:49 simpleman gkmd[1701]: Member registration failed with key server 192.0.2.1 for group vpn gvpn200, reason SA unusable

Look for the following syslog messages to confirm use of unsupported GDOI policies:

- Dec 2 15:34:34 simpleman gkmd[1701]: Failed to install SA because of too many(2) policies for SPI 0x6951550c from server 192.0.2.1
- Dec 2 15:34:34 simpleman gkmd[1701]: Member registration failed with key server 192.0.2.1 for group vpn gvpn200, reason SA unusable

Traffic Encryption and Decryption

Problem The CLI shows IPsec SAs as installed, but traffic does not go through the SAs.

In this scenario, traffic matching the rules received from the server fails to get encrypted or decrypted. The **show security group-vpn member ipsec statistics** command output displays a zero value for encrypt and decrypt packet count.

Solution Look for **Rule lookup failures** counter in the error section of the CLI output.

Troubleshooting System Log Messages

Problem System log messages are generated to record the different group VPN events.

Solution To interpret the system log messages, refer to the following:

- Dec 2 15:29:10 simpleman gkmd[1701]: Member registration succeeded with key server 192.0.2.1 for group vpn gvpn200—GDOI pull was successful.
- Dec 2 15:21:18 simpleman gkmd[1701]: Member registration failed with key server 192.0.2.1 for group vpn gvpn200, reason Timed out—GDOI pull failed.
- Dec 2 15:34:34 simpleman gkmd[1701]: Failed to install SA because of too many(2) policies for SPI 0x6951550c from server 192.0.2.1—GDOI SA installation failed because of too many policies.
- Dec 2 15:21:18 simpleman gkmd[1701]: Server 192.0.2.1 is unreachable for group vpn gvpn200—Single GC/KS failed (Non-COOP).
- Dec 2 15:51:49 simpleman gkmd[1701]: Current key server 192.0.2.1 is unreachable and will try registering with next Key Server 192.1.1.2 for group vpn gvpn200—Particular GC/KS is not responding (COOP).
- Dec 2 15:56:24 simpleman gkmd[1701]: All servers are unreachable for group vpn gvpn200—None of the GC/KS are responding (COOP).
- Dec 2 16:01:43 simpleman gkmd[1701]: Member re-registering with Key Server 192.0.2.1 for group-vpn gvpn200—Member re-registration with the GC/KS.
- Dec 2 16:01:43 simpleman gkmd[1701]: Creating TEK with SPI 0xb35200ac tunnel_id 10001 for group vpn gvpn200—GDOI SA TEK creation was successful.
- Dec 2 16:29:01 simpleman gkmd[1701]: Deleting TEK with SPI 0x6dba2a76 tunnel_id 10001 for group vpn gvpn200 and reason cleared from CLI—GDOI SA TEK destroy was successful with reason.

Different reasons for the GDOI SA TEK destroy are as follows:

- Cleared from CLI
- Hard lifetime expired
- Too many TEKs
- Configuration change
- SA install error
- Stale SA
- Interface down

Group VPNv2 Technology Overview

NOTE: Group VPNv2 is the name of the Group VPN technology on MX5, MX10, MX40, MX80, MX240, MX480, and MX960 routers. Group VPNv2 is different from the Group VPN technology implemented on SRX Security Gateways. The term Group VPN is sometimes used in this document to refer to the technology in general, not to the SRX technology.

For more information about Group VPN on SRX Security Gateway devices, see *Group VPNv2 Overview*.

This section explains the technological concepts of Group VPNv2.

Understanding Group VPNv2

Starting in Junos OS Release 15.1, Junos OS supports Group VPNv2. Group VPNv2 is a category of VPN that eliminates the need for point-to-point VPN tunnels in a mesh architecture. It is a set of features that are necessary to secure unicast traffic over a private WAN that originates on or flows through a router.

Group VPNv2 introduces the concept of a trusted group to eliminate point-to-point tunnels and their associated overlay routing. All group members share a common security association (SA), also known as a group SA. This enables group members to decrypt traffic that was encrypted by any other group member.

Group VPNv2 provides the following advantages:

- Provides data security and transport authentication, helping to meet security compliance and internal regulation by encrypting all WAN traffic.
- Enables high-scale network meshes and eliminates complex peer-to-peer key management with group encryption keys.
- Reduces the number of endpoint changes that need to be made due to group member change or policy change.
- Maintains network intelligence such as full-mesh connectivity, natural routing path, and quality of service (QoS) in MPLS networks.
- Grants authenticated membership control with a centralized key server.
- Allows encryption and decryption of traffic among all group members defined in the group policy.
- Helps to ensure low latency and jitter by enabling full-time, direct communications between sites, without requiring transport through a central hub.
- Reduces traffic loads on customer premises equipment (CPE) and provider edge (PE) encryption devices by using the core network for traffic replication, avoiding packet replication at each individual peer site.

Group VPNv2 and Standard IPsec VPN

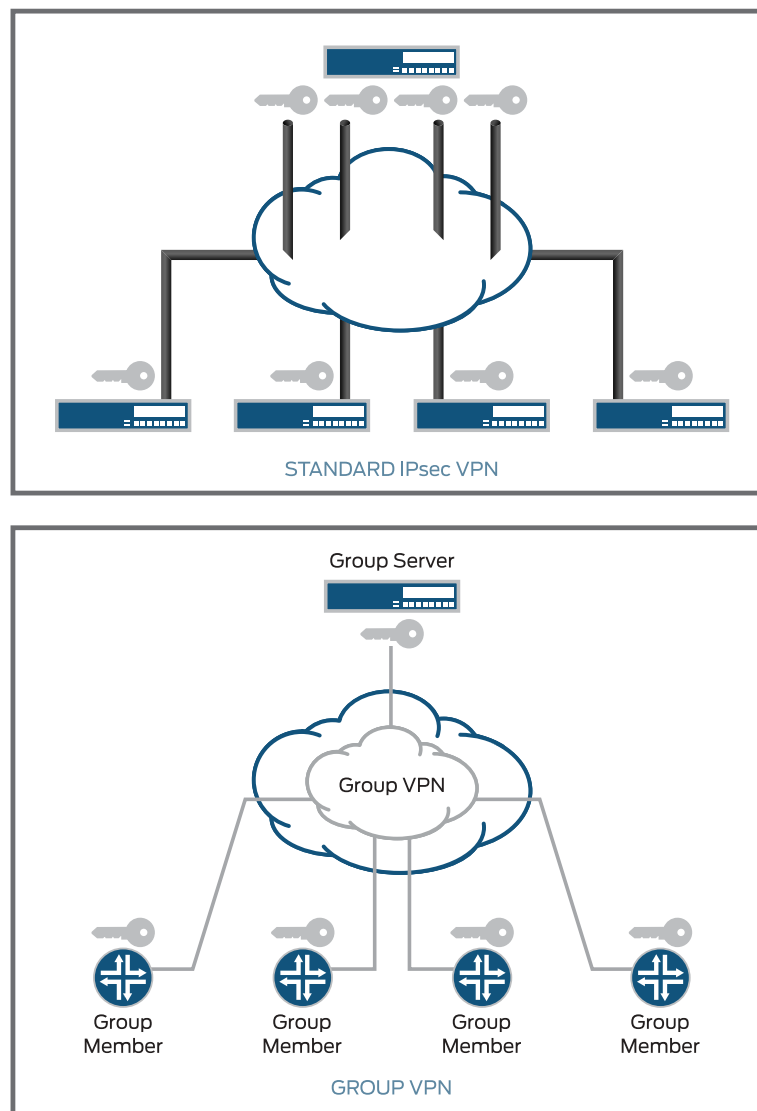

Group VPNv2 is built on standards-based technologies that integrate routing and encryption together in the network. An IPsec security SA is a unidirectional agreement between VPN participants that defines the rules to use for authentication and encryption algorithms, key exchange mechanisms, and secure communications.

Traditional IPsec VPN deployments tackle the problem of securing traffic between gateways in the network by creating an overlay network based on the use of point-to-point tunnels. Traffic carried over these tunnels is normally encrypted and authenticated in order to provide data integrity and confidentiality. Secure group members are managed through the Group Domain of Interpretation protocol (GDOI). The GDOI solution takes a different approach by disassociating the encryption and authentication problem from

the transport. By doing this, GDOI-based solutions provide a way to encrypt branch-to-branch communications without the need to configure branch-to-branch tunnels.

With current VPN implementations, the SA is a point-to-point tunnel between two end points. Group VPNv2 extends the IPsec architecture to support SAs that are shared by a group of routers (see [Figure 13 on page 201](#)). A key server distributes keys and policies to all registered and authenticated member routers. By distributing policies from a centralized point and by sharing the same group security association (the entire group has a single Phase 2 SA) with authenticated group members, key distribution and management are greatly simplified.

Figure 19: Standard IPsec VPN and Group VPNv2

8042234

Group VPNv2 is a client/server architecture. All members have a unique Phase 1 IKE SA with the key server. Hence, if there are n members, there is a total of n Phase 1 IKE SAs. However, the entire group shares a single Phase 2 SA.

In traditional IPsec, the tunnel endpoint addresses are used as a new packet source and destination. The packet is then routed over the IP infrastructure, using the encrypting end point source IP address and the decrypting end point destination IP address. In the case of Group VPN, IPsec-protected data packets preserve the original source and destination addresses of the host in the outer IP header in order to preserve the IP address. This is known as tunnel header preservation. The biggest advantages of tunnel header preservation is the ability to route encrypted packets using the underlying network routing infrastructure.

Table 11: Group VPN vs Traditional Point-to-Point IPsec

Feature	Traditional Point-to-Point IPsec Tunnels	Group VPN
Scalability	IKE/IPsec tunnels between each pair of peers increases management and configuration complexity.	Single SA and key pair used for the entire any-to-any group. Reduced management and configuration complexity.
Any-to-any instant connectivity	Cannot be done to scale due to management and configuration complexity.	Scales well due to the use of GDOI and shared SA within the group.
Overlay routing	Requires overlay routing.	No overlays-native routing.
IP Header Preservation	New IP Header added to original packet results in limited advanced quality of service (QoS). Will work in NAT environments.	Keeps original IP header on IPsec packet. Preserves advanced QoS capabilities. Will not work in NAT environments.

Understanding the GDOI Protocol

The Group Domain of Interpretation (GDOI) protocol described in RFC 6407 is used to distribute a set of cryptographic keys and policies to a group of devices. GDOI is defined as the Internet Security Association Key Management Protocol (ISAKMP) Domain of Interpretation (DOI) for group key management. In a group management model, the GDOI protocol operates between a group member and a group controller or key server (GC/KS) and manages group security associations and group-keys for a set of security participants. The ISAKMP defines two phases of negotiation. GDOI is a Phase 2 protocol protected by a Phase 1 ISAKMP security association. IKEv1 is specified in RFC 6407 as a Phase 1 protocol.

GDOI introduces two different encryption keys:

- Key encryption key (KEK)—Used to secure the control plane. KEK is the name of the key used by the group members to decrypt rekey messages from the GC/KS. This key is part of the Security Association Key Encryption Key (SAK).
- Traffic encryption key (TEK)—Used to secure the data plane. TEK is the name of the key used by the group members to encrypt or decrypt communication between other

group members. This key is part of the Security Association Transport Encryption Key (SA TEK).

As with standard IPsec, all keys have a lifetime and have to be rekeyed. The keys distributed through GDOI are group keys and are used by the entire group.

The group SAs and key management are handled through two types of GDOI exchanges:

- **groupkey-pull**—This exchange allows a member to request SAs and keys shared by the group from the server.

In the pull method, the group member requests the group SA and policy from the key server. This request is protected over the IKE SA.

The **groupkey-pull** is the first exchange in the GDOI protocol and is used for group member registration with the GC/KS. The group member specifies the group with which it wants to register, and the GC/KS sends all necessary group SAs and keys to the group member if the member is authorized to join the group. The complete exchange is secured by a Phase 1 SA (IKEv1 SA), which is established with IKEv1 before the **groupkey-pull** exchange begins. The **groupkey-pull** is part of Phase 2 of the GDOI protocol.

- **groupkey-push**—This exchange is a single rekey message that allows the server to send group SAs and keys to members before existing group SAs expire. Rekey messages are unsolicited messages sent from the server to members.

The **groupkey-push** is the second exchange in the GDOI protocol and is initiated by the GC/KS to all registered members of the group. [Table 12 on page 239](#) shows the payloads that the MX Series group member expects to receive in **groupkey-push** messages.

Table 12: groupkey-push Message Payloads

Payload	Description
group associated policy (GAP)	A GAP payload allows for the distribution of group-wide policy, such as instructions as to when to activate and deactivate SAs. This payload contains values for activation time delay (ATD) and deactivation time delay (DTD) for the traffic encryption key (TEK) as well as IP-Delivery Delayed Detection Protocol window type and window size for the IPsec traffic.
Security Association Transport Encryption Key (SA TEK)	Traffic selectors.
Security Association Key Encryption Key (SAK) (Optional)	The security association (SA) for the key encryption key (KEK). Also known as SA KEK. NOTE: groupkey-push messages that do not include the optional payloads are still valid messages.
traffic encryption key (TEK) (Optional)	Key for encrypting the data traffic between group members.
key encryption key (KEK) (Optional)	Used to protect the TEK.

The **groupkey-push** exchange is secured by an SA KEK (SAK), which is installed during the **groupkey-pull** exchange. The **groupkey-push** is part of Phase 2 of the GDOI protocol.

GDOI Protocol and Group VPNv2

Group VPNv2 is the name of the security technology implemented on the MX5, MX10, MX40, MX240, MX480, MX960 routers from Juniper Networks. Group VPNv2 uses the GDOI protocol (RFC 6407) as a base, in addition to other functionalities.

Group VPNv2 technology is based on the GDOI protocol to handle the most important functionality. This protocol is specified in RFC 6407 and defines an ISAKMP Domain of Interpretation (DOI) to manage group SAs and keys for a group of security participants. Thus, all members of the group share identical information to encrypt and decrypt traffic among each other. The creation, management, and distribution of group SAs and group keys are centralized and performed by the GC/KS. [Figure 14 on page 204](#) provides a brief overview of the Group VPNv2 functionality using GDOI.

Figure 20: Group VPNv2 Using GDOI

The group members use the Encapsulating Security Payload (ESP) protocol in tunnel mode to secure the traffic. However, in Group VPN the tunnel mode is modified. Because there is no direct association between the group members, it is not necessary to use special IP addresses in the outer IP header (that is, IP addresses of IPsec gateways). Every group member can decrypt the traffic of every other group member. Thus, the inner IP-Header is copied to the outer IP-Header, and the underlying routing infrastructure and QoS infrastructure can be used. This feature is called Header Preservation and is shown in [Figure 15 on page 204](#).

Figure 21: Header Preservation

To get group SAs and group keys, the group member must register with the GC/KS for a specific group. The result is an IKEv1 SA, which is only needed to secure the registration process. After the registration, the group member has all the information to communicate with the other group members (SA TEK), as well as the information to successfully decrypt the rekeying messages (SAK). The GC/KS sends out rekeying messages before either the SA TEK or SAK lifetime expires. It is also possible to send an SA TEK update as well as a SAK update in the same rekey message. The IKEv1 SA is no longer needed and is deleted after the lifetime expires (no IKEv1-rekeying).

Group VPNv2 Traffic

Group VPNv2 traffic includes:

- Control-plane-traffic—Traffic from the group members to the GC/KS in the Group VPNv2 deployment with the GDOI protocol only.
- Data-plane-traffic—Traffic between the group members in the Group VPNv2 deployment with the ESP protocol only which is already known from IPsec.

Group Security Association

Unlike traditional IPsec encryption solutions, Group VPN uses the concept of group security association. A group SA is similar to an SA in terms of functionality. Group SAs are shared among all group members of a common GDOI group. All members in the Group VPN group can communicate with each other using a common encryption policy and a shared group SA. With a common encryption policy and a shared group SA, there is no need to negotiate IPsec between group members. This reduces the resource load on the group members. Traditional IPsec scalability issues (number of tunnels and associated SAs) do not apply to Group VPN group members.

Group Controller/Key Server

A group controller or key server (GC/KS) is a device used for creating and maintaining the Group VPNv2 control plane. It is responsible for creation and distribution of group SAs and group keys. All information the group members need to communicate with other group members is provided by the GC/KS. All encryption policies, such as interesting traffic, encryption protocols, security association, rekey timers, and so on, are centrally defined on the GC/KS and are pushed down to all group members at registration time. Group members authenticate with the GC/KS using IKE Phase 1 and then download the encryption policies and keys required for Group VPN operation. The GC/KS is also responsible for refreshing and distributing the keys.

NOTE: The GC/KS functionality is not supported on MX Series routers. The MX Series routers that are configured as group members can connect with Cisco GC/KS only. There is no support for MX Series group members to interact with the Juniper Networks SRX Series acting as GC/KS. See [Table 15 on page 254](#) for compatibility between the various types of group members and GC/KSs.

Group Member

A group member is an IPsec endpoint device used for the traffic encryption process and is responsible for the actual encryption and decryption of data traffic. A group member is configured with IKE Phase 1 parameters and GC/KS information. Encryption policies are defined centrally on the GC/KS and downloaded to the group member at the time of successful registration. Each group member then determines whether incoming and outgoing traffic should be decrypted or encrypted (using its SA) based on its group membership.

From a functionality point of view, a group member is similar to an IPsec gateway. However, the SAs in normal IPsec exist between two IPsec gateways. In GDOI, the group member registers with the GC/KS in order to participate in the Group VPN. During registration, the group member provides the group ID to the GC/KS to get the respective policies, SAs, and keys needed for this group. Rekeying is accomplished by the group members through the **groupkey-pull** method (re-registration) or by the GC/KS through the **groupkey-push** method.

Anti-Replay Protection for Group VPNv2 Traffic

Since Group VPN communication is essentially any-to-any communication over the same shared security association, the use of sequence numbers for anti-replay protection does not work. Because of this, Junos OS supports an IETF draft specification for a time-based anti-replay mechanism, draft-weis-delay-detection-01. It is available at <http://tools.ietf.org/html/draft-weis-delay-detection-01>.

To implement this feature, MX Series member routers make use of a new IP Delivery Delay Detection Protocol time-stamp header within the packet. See [“Implementing IP Delivery Delay Detection Protocol \(Time-Based Anti-Replay Protection\)” on page 249](#) for details.

Partial Fail-Open on MX Series Member Routers

Group members in a Group VPN rely on the GC/KS to generate keying material for the shared SA. Therefore, connectivity between the group members and GC/KSs is required to initially protect traffic and to continually protect traffic over rekey events. In the event of communication failure between the group member and the GC/KS, the default behavior of the group members is to stop forwarding traffic. This is known as fail-closed.

A nondefault configuration option is available to permit some specifically defined traffic to flow through the group member without being encrypted until such time as the member is able to contact the GC/KS and retrieve the active SA. This is known as partial fail-open.

The partial fail-open feature requires a policy configuration option that creates a rule on the applicable MX Series group member for a particular Group VPNv2 defined by source and destination addresses. This fail-open rule is active only when group SA is in disabled state because of connectivity failure with the key server. Traffic that would normally pass through the Group VPN but does not match the fail-open rule is dropped. More than one fail-open rule can be defined for the Group VPN object. If no fail-open rules are configured, then the fail-open feature is disabled.

Enabling Group VPNv2

A service set is used to enable Group VPNv2 on a particular interface on applicable MX Series routers.

- [Configuring the Service Set on page 244](#)
- [Applying the Service Set on page 244](#)
- [Packet Steering on page 244](#)

Configuring the Service Set

Group VPNv2 is configured inside a service set using the **ipsec-group-vpn** statement at the **[edit services service-set service-set-name]** hierarchy level.

Sample Service Set Configuration

```
[edit services]
service-set service-set-name {
  interface-service {
    service-interface service-interface-name;
  }
}
ipsec-group-vpn vpn-name;
```

NOTE:

- Only one group member can be configured per service set.
- Next-hop style service set is not supported with Group VPNv2.

Applying the Service Set

A service set is applied at the interface level.

Sample Applying Service Set Configuration

```
[edit interfaces]
interface-name {
  unit 0 {
    family inet {
      service {
        input {
          service-set service-set-name;
        }
        output {
          service-set service-set-name;
        }
      }
      address 10.0.30.2/30;
    }
  }
}
```

Packet Steering

The interface-style service set configuration is used to steer traffic from the Packet Forwarding Engine to the PIC. Packets received on an interface with a service set pointing to the Group VPNv2 object are forwarded to the PIC by being injected into the corresponding service interface.

Registering a Group Member

The group member registration to the server starts when the **ipsec-group-vpn** statement is configured for a service set and the service interface is up. When the service interface

goes down, all group SAs associated with this interface are cleared, and no registration is triggered for these Group VPNs until the interface comes up.

Group member registration involves establishing IKE SA with the GC/KS followed by a **groupkey-pull** exchange to download the SAs and the traffic keys for the specified group identifier.

NOTE: Junos OS does not support traffic-based SA negotiation triggering for Group VPNs in Group VPNv2.

Rekeying a Group Member (groupkey-push Method)

The GC/KS will send out a unicast **groupkey-push** message to registered group members in order to:

- Send new key encryption keys (KEKs) or traffic encryption keys (TEKs).

The push messages can contain all or only some of the payload elements shown in [Table 12 on page 239](#). When the GAP payload contains both old SAs and new replacement SAs, the group member router will apply the ATD and DTD values as a normal rekey by means of push. If there is no ATD value in the update, the member router installs the new SAs immediately. If there is no DTD value, the old SAs will remain in place until their expiration.

- Update group associated policy (GAP) for an existing SA.

A GC/KS can send a unicast push message to update the configuration to group members at any time. The GAP payload can include configuration changes to the IP Delivery Delay Detection Protocol, encryption algorithm, lifetime, and so on. The updated configuration is either applied immediately or with a delay. ATD and DTD values are used to achieve the timing for the activation of the new TEK and deletion of the existing TEK, respectively. If the existing TEK lifetime has to be reduced, then the DTD value is set accordingly in the push message. The new TEK in the push message is activated based on the ATD value in the payload.

- Send delete key notifications for TEK or KEK.

The GC/KS can send the optional delete notification payload in the push message for deleting keys and SAs on the member. The push message contains the protocol ID that indicates whether the delete notification is for TEK or KEK. The group member router deletes the key based on the group ID and SPI value contained in the payload. Deleting a specific TEK or KEK can be done with a delay value specified in the DTD attribute. If the delay value is 0, and the payload contains a specific SPI, then the matching TEK or KEK is deleted immediately. If all the TEKs or KEKs (or both) need to be deleted in the group, then the SPI value is set to 0 for the corresponding protocol ID in the payload.

- Remove a member router from the Group VPN in Group VPNv2.

The push messages are used to allow the GC/KS to delete members from the Group VPN. In one case, the GC/KS sends a rekey message with only the old SAs and a smaller DTD value. The group member router installs the new, smaller DTD value. Since it did

not receive new SA keys, the member router tries to re-register using the **groupkey-pull** method. This re-registration attempt is rejected by the GC/KS, thus deleting the member from the Group VPN. In the second case, the GC/KS sends a delete payload for the SPI of the old SA. The group member router deletes the SA immediately and attempts to re-register using the **groupkey-pull** method. This re-registration attempt is rejected by the GC/KS, thus deleting the member from the Group VPN.

Registered MX Series group members send a unicast PUSH ACK message back to the GC/KS to acknowledge the receipt of the original push message.

Rekeying a Group Member (groupkey-pull Method)

For group member rekeying, using the **groupkey-pull** method, the group members typically re-register with the GC/KS when there is between 7 percent and 5 percent remaining in the existing TEK or KEK soft lifetime. If the existing IKE SA is available, it is used in the pull message. After the GC/KS responds with a new key, both the old key and the new key can be used for decryption. However, the new key is not used for encryption until 30 seconds of lifetime of the old key is remaining. If the existing IKE SA is not available, the pull message results in new IKE negotiations between the group member and the GC/KS.

Upon receiving the pull message regarding a specific Group VPN from the group member, the GC/KS responds with all the TEKs and the KEK for that group.

If any existing SA is not included in the response from the GC/KS, then the missing SAs are deleted by the group member.

Taking as an example, the GC/KS is configured with a lifetime of 3600 seconds and is connected to one group member without retransmit. Based on the server configuration, the GC/KS generates a new key when 10 percent of the lifetime is remaining. The group member, however, re-registers with the GC/KS when 5 percent to 7 percent of the lifetime is remaining.

[Figure 16 on page 208](#) represents the rekeying process between the GC/KS and the group member.

Figure 22: Group Member Rekeying

Authenticating a Group Member

Junos OS does not provide public key infrastructure (PKI) support for Group VPN in Group VPNv2. As a result, pre-shared keys are used for group member authentication.

Fragmenting Group VPNv2 Traffic

Because of the header preservation functionality and the usage of the underlying routing infrastructure, it is necessary to fragment the packets before encryption occurs (if it cannot be prevented).

Hence, pre-fragmentation is supported and is recommended for all deployments.

To avoid post-fragmentation, set the **clear**, **set**, and **copy** options for the DF bit in the Group VPNv2 configuration.

Based on this flag setting, the IPsec header has either the **df-bit** set to **clear**, **set**, or **copy** from the inner packet.

NOTE: The DF bit has the clear option set as default.

Sample DF Bit Configuration

```
[edit]
security {
  group-vpn {
    member {
      ipsec {
        vpn group-vpn-name {
          df-bit clear;
        }
      }
    }
  }
}
```

Encrypting Group VPNv2 Traffic

Group members encrypt traffic based on the group SAs and keys provided by the GC/KS. The Group VPNv2 encryption path is as follows:

1. Packet received by the Packet Forwarding Engine is checked against a flow match. If a match is found, the packet is further processed and transmitted.
2. If a match is not found, a rule lookup is performed. If a match is found, a flow is created, and the packet is further processed and transmitted.
3. If the rule lookup fails, the packet is dropped.

NOTE: Group SA is not triggered during packet processing.

Decrypting Group VPNv2 Traffic

After registration is successful and Group VPN SAs are installed, an ESP session is created. Group VPNv2 creates the ESP session with a zero source and destination IP. Because the ESP session is already created at SA installation, packets are expected to match the existing ESP session.

The Group VPNv2 decryption path is as follows:

1. Packet received by the Packet Forwarding Engine undergoes a fragmentation check. If the packet is fragmented, it is assembled for further processing.
2. After packet assembling or if the packet is not fragmented, a zero source and destination IP is used in the 5-tuple decrypt flow lookup. If a match is found, the packet is further processed and transmitted.

3. If the decrypt flow lookup fails, the packet is checked against an SPI flow with zero source and destination IP.
4. If the SPI flow lookup fails, the packet is dropped.
5. If an SPI flow match is found, a decrypt flow is created to avoid the SPI flow lookup for subsequent packets.

Configuring a Routing Instance for Group VPNv2

Routing instances are supported for both control and data traffic. To enable routing instance support on control plane traffic for a group member to reach the GC/KS in a given VRF routing instance, add the **routing-instance** statement at the **[edit security group-vpn member ike gateway gateway-name local-address address]** hierarchy level.

No additional CLI is required to support a routing instance for data-plane packets, as it is determined based on the media interface on which the service set is applied.

Establishing Multiple Groups, Policies, and SAs

Junos OS provides support for one Group VPN per service set in Group VPNv2. However, multiple service sets can be created to support multiple groups in a routing instance. Multiple SAs can be configured per group. However, multiple policies for the same traffic key/SPI is not supported. If the server sends two policies for the same TEK, then they must be paired to be accepted, for instance, A-B and B-A, where A and B are IP addresses or subnets. If multiple unpaired policies for a given TEK are received, registration fails and a system log message is generated.

Connecting with Multiple Cooperative GC/KSs

For a group member to work with a GC/KS in the cooperative mode, the configuration is extended to allow a maximum of four servers in the server list.

During rekeying when using the **groupkey-pull** method, the group member tries to connect to the GC/KS. When the connection to the GC/KS fails, the group member tries to reconnect to the GC/KS. After three retries with an interval of 10 seconds, if the connection to the GC/KS is not restored, the group member tries to establish a connection with the next available server on the server list. This process is repeated until the group member connects to a GC/KS. During this time, the unexpired GDOI SAs on the group members are not cleaned up, so Group VPN traffic is not affected. The time gap between rekeying and hard lifetime expiry provides sufficient time for the group members to connect to the next available server, in such cases.

Implementing IP Delivery Delay Detection Protocol (Time-Based Anti-Replay Protection)

There is no configuration needed to implement the IP Delivery Delay Detection Protocol. MX Series group members get the replay window size to use as a part of the GAP payload in push or pull messages from the key server. If the received window size is 0, time-based anti-replay protection is disabled.

If IP Delivery Delay Detection Protocol is enabled, the sender adds its current timestamp and encrypts the packet. The receiver decrypts the packet and compares its current time with the timestamp in the packet. Packets that fall outside of the window size are dropped. Because of this, all group members should have their clocks synchronized using Network Time Protocol (NTP).

IP Delivery Delay Detection Protocol times are measured in seconds. See [IP Delivery Delay Detection Protocol-draft-weis-delay-detection-01](#) for more information.

NOTE: All latency issues associated with NTP also apply within IP Delivery Delay Detection Protocol. Thus, a minimum window size of 1 second is recommended.

Changing Group VPNv2 Configuration

Most Group VPNv2 configuration changes result in deleting both existing SAs and re-registration. This triggers both phase 1 and SA download with new traffic keys.

Bypassing Group VPNv2 Configuration

If certain traffic like a routing protocol needs to bypass a Group VPN in Group VPNv2, a service filter needs to be configured on the interface on which the service set is applied. Packets matching the service filter do not come to the PIC for service processing and are directly forwarded to the Routing Engine.

Sample Service Set Filter Configuration

```
[edit interfaces]
interface-name {
  unit 0 {
    family inet {
      service {
        input {
          service-set service-set-name service-filter filter-name;
        }
        output {
          service-set service-set-name service-filter filter-name;
        }
      }
    }
  }
}
```

Implementing Partial Fail-open on MX Series Member Routers

By default, packets are dropped if a group member router is unable to get SAs from the GC/KS due to loss of connectivity. If you want to allow some traffic to pass unencrypted in the event of a communication failure between the group member and the GC/KS, you must configure a **fail-open** rule at the `[edit security group-vpn member ipsec vpn vpn-name]` hierarchy level.

Fail-open rules will be applied to the traffic only in the event of loss of server connectivity. Fail-open rules will be deactivated once connectivity is restored and keys are received from the GC/KS.

Sample Fail-Open Rule Configuration

```
[edit security group-vpn member ipsec vpn vpn-name]  
fail-open {  
  rule rule-name{  
    source-address source-ip-address  
    destination-address destination-ip-address}  
  }  
}
```

A maximum of 10 fail-open rules can be configured for any given group.

Supported GDOI IPsec Parameters

Every GDOI group has a unique ID. It is used as a common base between GC/KS and the group member to communicate about group SAs and group keys.

During the registration process, the GC/KS sends Security Association Transport Encryption Keys (SA TEKs) to the group members. All parameters regarding the whole group security policy are configured on the GC/KS. The SA TEK is used by the group members to protect the traffic exchanged among each other. [Table 8 on page 212](#) shows the parameters of the SA TEK.

Table 13: SA TEK Parameters

Parameters	Supported Values
Encryption	<ul style="list-style-type: none">• DES-CBC• 3DES-CBC• AES-CBC 128• AES-CBC 192• AES-CBC 256
Integrity	<ul style="list-style-type: none">• HMAC-MD5-96• HMAC-SHA1-96• HMAC-SHA-256-128
Lifetime	Any supported value

Besides the cryptographic algorithms, the traffic, which should be encrypted by the group members, is part of the SA TEK policy (traffic selector).

The following statements can be used on a Juniper Networks group member. Thus, the addresses have to be specified under the IKE hierarchy level. The enumeration is also prioritized. Thus, in the following example configuration, KS1 is contacted before KS2.

Sample GDOI IPsec Parameters Configuration

```
[edit security]
group-vpn {
  member {
    ike {
      gateway gateway-name {
        ike-policy policy-name;
        server-address <IP_KS1> <IP_KS2> <IP_KS3> <IP_KS4>;
        local-address <IP_GM> routing-instance routing-instance-name;
      }
    }
  }
  ipsec {
    vpn vpn-group-name {
      ike-gateway gateway-name;
      fail-open {
        rule rule-name {
          source-address 198.51.100.1/24
          destination-address 192.0.2.1/24
        }
      }
      group group-ID;
      match-direction output;
    }
  }
}
```

Supported GDOI IKEv1 Parameters

The group members use only IKEv1 during the registration process in the Group VPNv2 environment. [Table 9 on page 213](#) provides an overview of the defined parameters of the IKEv1 SA.

Table 14: IKEv1 SA Parameters of Group Member

Parameter	Supported Values
Encryption	<ul style="list-style-type: none"> DES-CBC 3DES-CBC AES-CBC 128 AES-CBC 192 AES-CBC 256
Authentication	Pre-shared key (minimum 20 signs)
Integrity	<ul style="list-style-type: none"> MD5 SHA1 SHA256

Table 14: IKEv1 SA Parameters of Group Member (*continued*)

Parameter	Supported Values
Diffie-Hellman Group	<ul style="list-style-type: none"> Group 1 Group 2 Group 5 Group 14
Lifetime	Any supported value

The above-mentioned IKEv1 standards are configured as follows:

Sample IKEv1 Configuration

```
[edit security]
group-vpn {
  member {
    ike {
      proposal proposal-name {
        authentication-algorithm sha1;
        authentication-method pre-shared-keys;
        dh-group group5;
        encryption-algorithm aes-128-cbc;
        lifetime-seconds 3600;
      }
      policy policy-name {
        mode main;
        proposals proposal-name;
        pre-shared-key ascii-text "SECRET DATA";
      }
    }
  }
}
```

Applying Dynamic Policies

The **input** and **output** options under the **ipsec-group-vpn** statement specify if the dynamic policies received from the server are used when the interface on which the service set is applied is the incoming or outgoing interface. This provides flexibility to specify different rules in the incoming and outgoing directions.

Supporting TOS and DSCP

Type of service (TOS) and DiffServ Code Points (DSCP) bits are copied from the inner packet to the ESP packet.

Interoperability of Group Members

Cisco's implementation of GDOI is called Group Encryption Transport (GET) VPN. While Group VPNv2 in Junos OS and Cisco's GET VPN are both based on RFC 6407, *The Group Domain of Interpretation*, there are some implementation differences that you need to be aware of when deploying GDOI in a networking environment that includes both Juniper

Networks security and routing devices and Cisco routers. For more information, see the current Junos OS release notes.

Group VPNv2 interoperability is as follows:

- Junos OS provides interoperability support with Cisco IOS GC/KS support.
- Junos OS does not provide support for Group VPNv2 interoperability with the SRX Series Group VPN server.

Table 15: Group VPNv2 Interoperability

Group Member	SRX Group Member	MX Group VPNv2 Member	Cisco Group Member	SRX GC/KS	Cisco GC/KS
MX Group VPNv2 Member	No	Yes	Yes	No	Yes
SRX Group Member	Yes	No	No	Yes	Yes

Junos OS does not support the deny policy used on a Cisco GC/SK server to add an exception to the group policy. As a workaround, this can be done by configuring firewall rules on an MX Series group member. Also, Junos OS group members can work with the deny policy by not failing the negotiation and simply ignoring the contents. This allows system administrators to easily manage networks where both Cisco group members and Junos OS group members co-exist.

Group VPNv2 Limitations

Junos OS Group VPNv2 does not provide support for the following:

- Multicast push messages
- Multicast traffic
- GDOI SNMP MIBs
- Protocol and port in the policies sent by the server. The group member honors only the IP address/subnet specified in the policy.
- Multiple unpaired policies for the same traffic key/SPI
- Overlapping of both local and remote IP across routing instances in an IKE gateway configuration
- Overlapping Group VPNv2 policies that can result in mismatched SAs
- IPv6 for control and data traffic
- Co-existence of IPsec and Group VPN on the same service set
- Co-existence of services like NAT and ALG on the same service set. NAT and Group VPN can co-exist on different service sets. However, they cannot co-exist on the same service set.
- Site To Site (S2S) VPN and dynamic end point (DEP) VPN can co-exist with Group VPN on different service sets. However, they cannot co-exist on the same service set.

- Multiple groups on same service set
- Group member support with SRX Series GC/KS
- Group member support with SRX Series group member
- Logical Key Hierarchy (LKH)
- Graceful restart
- High availability
- Unified ISSU
- PKI support for authentication
- AMS interface and load-balancing support

Release History Table

Release	Description
15.1	Starting in Junos OS Release 15.1, Junos OS supports Group VPNv2.

- [Example: Configuring Group VPNs in Group VPNv2 on Routing Devices on page 259](#)

Configuring Group VPNs in Group VPNv2 on Routing Devices

You can configure an MX Series router with MS-MIC-16G and MS-MPC-PIC line cards to provide the Group VPNv2 member functionality support with one or more Cisco group controllers or key servers (GC/KSs). The group members can connect to a maximum of four Cisco GC/KSs with minimum interoperability with the cooperative servers.

The Group VPNv2 feature also provides system logging support for the Group VPNv2 functionality, and routing instance support for both control and data traffic.

Before you begin:

1. Configure the routers for network communication.
2. Configure the Cisco GC/KS.
3. Configure the group member device interfaces.
4. Configure a static route to reach the group server.

To configure a Group VPNv2 member, complete the following tasks:

1. In configuration mode, go to the following hierarchy level:

```
[edit]
user@GM1# edit security
```

2. Define the IKE proposal.

```
[edit security]
```

```
user@GM1# set group-vpn member ike proposal proposal-name
```

3. Configure the Phase 1 SA for the IKE proposal.

```
[edit security]
user@GM1# set group-vpn member ike proposal proposal-name authentication-method
  pre-shared-keys
user@GM1# set group-vpn member ike proposal proposal-name dh-group group
user@GM1# set group-vpn member ike proposal proposal-name
  authentication-algorithm sha1
user@GM1# set group-vpn member ike proposal proposal-name encryption-algorithm
  3des-cbc
```

4. Define the IKE policy.

```
[edit security]
user@GM1# set group-vpn member ike policy policy-name mode main
user@GM1# set group-vpn member ike policy policy-name proposals proposal-name
user@GM1# set group-vpn member ike policy policy-name pre-shared-key ascii-text
  text
```

5. Set the remote gateways for the IKE gateway group.

```
[edit security]
user@GM1# set group-vpn member ike gateway gateway-group-name ike-policy
  policy-name
user@GM1# set group-vpn member ike gateway gateway-group-name server-address
  server-IP-address
user@GM1# set group-vpn member ike gateway gateway-group-name local-address
  server-facing-interface-IP-address
```

NOTE: To configure a group member to connect to multiple group servers, add the IP address of all the servers to the remote IKE gateway group configuration.

For example,

```
[edit security]
user@GM1# set group-vpn member ike gateway gw-group1 server-address
  203.0.113.0
user@GM1# set group-vpn member ike gateway gw-group1 server-address
  203.0.113.1
```

6. Configure the group identifier and IKE gateway for the remote gateway group.

```
[edit security]
user@GM1# set group-vpn member ipsec vpn vpn-name ike-gateway
  gateway-group-name
user@GM1# set group-vpn member ipsec vpn vpn-name group group-ID
user@GM1# set group-vpn member ipsec vpn vpn-name match-direction output
```

7. In configuration mode, go to the following hierarchy level:

```
[edit]
user@GM1# edit services
```

8. Configure the service set for the remote gateway group.

```
[edit services]
user@GM1# set service-set service-set-name interface-service service-interface
service-interface
user@GM1# set service-set service-set-name ipsec-group-vpn vpn-name
```

NOTE: The service set has to be applied on the interface connecting to the other group member.

For example:

```
[edit interfaces]
user@GM1# set xe-0/3/1 unit 1 family inet service input service-set
gvpn-service-set
user@GM1# set xe-0/3/1 unit 1 family inet service output service-set
gvpn-service-set
```

9. Verify and commit the configuration.

For example:

```
[edit security]
user@GM1# set group-vpn member ike proposal ike-proposal authentication-method
pre-shared-keys
user@GM1# set group-vpn member ike proposal ike-proposal dh-group group2
user@GM1# set group-vpn member ike proposal ike-proposal authentication-algorithm
sha1
user@GM1# set group-vpn member ike proposal ike-proposal encryption-algorithm
3des-cbc
user@GM1# set group-vpn member ike policy ike-policy mode main
user@GM1# set group-vpn member ike policy ike-policy proposals ike-proposal
user@GM1# set group-vpn member ike policy ike-policy pre-shared-key ascii-text
""$9$QEni3/t1RSM87uO87-V4oz36"
user@GM1# set group-vpn member ike gateway gw-group1 ike-policy ike-policy
user@GM1# set group-vpn member ike gateway gw-group1 server-address 203.0.113.0
user@GM1# set group-vpn member ike gateway gw-group1 local-address 192.0.2.0
user@GM1# set group-vpn member ipsec vpn vpn-group1 ike-gateway gw-group1
user@GM1# set group-vpn member ipsec vpn vpn-group1 group 1
user@GM1# set group-vpn member ipsec vpn vpn-group1 match-direction output

[edit services]
user@GM1# set service-set gvpn-service-set interface-service service-interface
ms-4/0/0.1
user@GM1# set service-set gvpn-service-set ipsec-group-vpn vpn-group1

[edit]
user@GM1# commit
commit complete
```

Use Case for Configuring Group VPNv2

NOTE: Group VPNv2 is the name of the Group VPN technology on MX5, MX10, MX40, MX80, MX240, MX480, and MX960 routers. Group VPNv2 is different from the Group VPN technology implemented on SRX Security Gateways. The term Group VPN is sometimes used in this document to refer to the technology in general, not to the SRX technology.

Today's networks support critical applications such as distributed computing, voice, and video over IP, which all require real-time branch-to-branch communication. With the increasing use of applications that are highly sensitive to latency and other delays, enterprise networks are tending toward meshed configurations where remote sites are directly connected to each other rather than through a central site. To provide the required infrastructure for supporting such applications and technologies, large service provider and enterprise networks implement any-to-any connectivity through IP VPNs and MPLS networks.

Although IP VPN and MPLS services separate enterprise traffic from the public Internet to provide security, there is an increasing need for enterprises to also encrypt private WANs that are built using service provider networks such as BGP over MPLS. In recent years, government regulations, such as the Health Insurance Portability and Accountability Act (HIPAA), Gramm-Leach-Bliley Act (GLBA), and Payment Card Industry Data Security Standard (PCI DSS), mandate encryption even over private IP networks.

Hub and spoke VPNs solve the problem of secure communication for enterprise WANs over the public Internet. For private IP and MPLS networks, Group VPNv2 addresses the above-mentioned issues across multiple sites using a group IPsec security paradigm.

Group VPNv2 on certain MX Series routers with MS-MIC-16G or MS-MPC-PIC line cards provides tunnel-less any-to-any encryption between devices in a private IP and MPLS network. Each device is a group member, using the same IPsec security association (SA) pair and keys provided by one or more Cisco Group Controllers or Key Servers (GC/KS).

Group VPNv2 is manageable and scalable. It provides any-to-any encrypted communication by replacing statically configured pair-wise IKE connections per peer with a dynamic group key management system. By providing encryption across private IP and MPLS networks, the Group VPNv2 implementation simplifies the management of secure branch-to-branch communication.

In addition to simplified key management, reduced latency, and improved any-to-any connectivity capabilities, Group VPNv2 also provides encryption for all WAN traffic, providing security compliance for internal governance and regulations.

Configuring Group VPNv2 provides an innovative and scalable solution to protect enterprise traffic as it passes through the meshed private WAN. Group VPNv2 optimizes network utilization and provides increased revenue by maintaining full-mesh connectivity

and routing paths with existing MPLS backbones, eliminating the management and performance cost of a traditional full-mesh VPN network.

- [Overview on page 259](#)
- [Configuration on page 261](#)
- [Verification on page 269](#)
- [Troubleshooting on page 272](#)

Requirements

This example uses the following hardware and software components:

- Two MX Series 3D Universal Edge Routers with MS-MIC-16G or MS-MPC-PIC line cards
- Reachability to one or more Cisco Group Controllers or Key Servers (GC/KS)
- Junos OS Release 14.1 or later running on the MX Series routers

Before you begin:

1. Configure the routers for network communication.
2. Configure the Cisco GC/KS.
3. Configure the group member device interfaces.

Overview

Starting with Junos OS Release 14.1, MX Series routers with MS-MIC-16G and MS-MPC-PIC line cards provide the Group VPNv2 member functionality support with one or more Cisco Group Controllers or Key Servers (GC/KS). The group members can connect to a

maximum of four Cisco GC/KSs with minimum interoperability with the cooperative servers.

This feature also provides system logging support for Group VPNv2 functionality, and routing instance support for both control and data traffic.

Topology

In [Figure 17 on page 219](#), a Group VPN is configured between a Cisco group server, GC/KS – and two group members, GM1 and GM2. The group members are connected to host devices.

In [Figure 18 on page 220](#), a Group VPN is configured between GM1 and GM2, and GC/KS1 and GC/KS2 are the primary and secondary group servers, respectively.

Figure 23: Group VPN with Single GC/KS

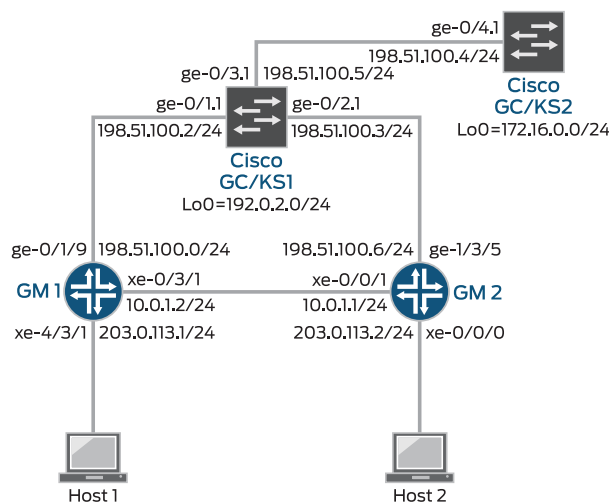

Figure 24: Group VPN with Multiple GC/KS

Configuration

Configuring Group VPNv2 with a Single GC/KS

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then **commit** the configuration.

```

GM1  set interfaces ms-4/0/0 unit 1 family inet
      set interfaces ge-0/1/9 vlan-tagging
      set interfaces ge-0/1/9 unit 1 vlan-id 11
      set interfaces ge-0/1/9 unit 1 family inet address 198.51.100.0/24
      set interfaces xe-0/3/1 vlan-tagging
      set interfaces xe-0/3/1 unit 1 vlan-id 1
      set interfaces xe-0/3/1 unit 1 family inet service input service-set gvpn-service-set
      set interfaces xe-0/3/1 unit 1 family inet service output service-set gvpn-service-set
      set interfaces xe-0/3/1 unit 1 family inet address 10.0.1.2/24
      set interfaces xe-4/3/1 unit 0 family inet address 203.0.113.1/24
      set routing-options static route 192.0.2.0/24 next-hop 198.51.100.2
      set routing-options static route 203.0.113.0/24 next-hop 10.0.1.1
      set security group-vpn member ike proposal ike-proposal authentication-method
        pre-shared-keys
      set security group-vpn member ike proposal ike-proposal dh-group group2
      set security group-vpn member ike proposal ike-proposal authentication-algorithm sha1

set services service-set gvpn-service-set ipsec-group-vpn vpn-group1

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure GM1:

1. Configure the Router GM1 interfaces.

```
[edit interfaces]
```

```
user@GM1# set ms-4/0/0 unit 1 family inet
```

```
user@GM1# set ge-0/1/9 vlan-tagging
```

```
user@GM1# set ge-0/1/9 unit 1 vlan-id 11
```

```
user@GM1# set ge-0/1/9 unit 1 family inet address 198.51.100.0/24
```

```
user@GM1# set xe-0/3/1 vlan-tagging
```

```
user@GM1# set xe-0/3/1 unit 1 vlan-id 1
```

```
user@GM1# set xe-0/3/1 unit 1 family inet service input service-set gvpn-service-set
```

```
user@GM1# set xe-0/3/1 unit 1 family inet service output service-set gvpn-service-set
```

```
user@GM1# set xe-0/3/1 unit 1 family inet address 10.0.1.2/24
```

```
user@GM1# set interfaces xe-4/3/1 unit 0 family inet address 203.0.113.1/24
```

2. Configure static routes to reach the group server and member 2.

```
[edit routing-options]
```

```
user@GM1# set static route 192.0.2.0/24 next-hop 198.51.100.2
```

```
user@GM1# set static route 203.0.113.0/24 next-hop 10.0.1.1
```

3. Define the IKE proposal.

```
[edit security]
```

```
user@GM1# set group-vpn member ike proposal ike-proposal
```

4. Configure the Phase 1 SA for ike-proposal.

```
[edit security]
user@GM1# set group-vpn member ike proposal ike-proposal authentication-method
pre-shared-keys
user@GM1# set group-vpn member ike proposal ike-proposal dh-group group2
user@GM1# set group-vpn member ike proposal ike-proposal
authentication-algorithm sha1
user@GM1# set group-vpn member ike proposal ike-proposal encryption-algorithm
3des-cbc
```

5. Define the IKE policy.

```
[edit security]
user@GM1# set group-vpn member ike policy ike-policy mode main
user@GM1# set group-vpn member ike policy ike-policy proposals ike-proposal
user@GM1# set group-vpn member ike policy ike-policy pre-shared-key ascii-text
""$9$QEni3/t1RSM87uO87-V4oz36"
```

6. Set the remote gateways for gw-group1.

```
[edit security]
user@GM1# set group-vpn member ike gateway gw-group1 ike-policy ike-policy
user@GM1# set group-vpn member ike gateway gw-group1 server-address 192.0.2.0
user@GM1# set group-vpn member ike gateway gw-group1 local-address
198.51.100.0
```

7. Configure the group identifier and IKE gateway for gw-group1.

```
[edit security]
user@GM1# set group-vpn member ipsec vpn vpn-group1 ike-gateway gw-group1
user@GM1# set group-vpn member ipsec vpn vpn-group1 group 1
user@GM1# set group-vpn member ipsec vpn vpn-group1 match-direction output
```

8. Configure the service set for gw-group1.

```
[edit services]
user@GM1# set service-set gvpn-service-set interface-service service-interface
ms-4/0/0.1
user@GM1# set service-set gvpn-service-set ipsec-group-vpn vpn-group1
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show security**, and **show services** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
GM1 user@GM1# show interfaces
ge-0/1/9 {

```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure GM1:

1. Configure the Router GM1 interfaces.

```
[edit interfaces]
```

```
user@GM1# set ms-4/0/0 unit 1 family inet
```

```
user@GM1# set ge-0/1/9 vlan-tagging
```

```
user@GM1# set ge-0/1/9 unit 1 vlan-id 11
```

```
user@GM1# set ge-0/1/9 unit 1 family inet address 198.51.100.0/24
```

```
user@GM1# set xe-0/3/1 vlan-tagging
```

```
user@GM1# set xe-0/3/1 unit 1 vlan-id 1
```

```
user@GM1# set xe-0/3/1 unit 1 family inet service input service-set gvpn-service-set
```

```
user@GM1# set xe-0/3/1 unit 1 family inet service output service-set gvpn-service-set
user@GM1# set xe-0/3/1 unit 1 family inet address 10.0.1.2/24
```

```
user@GM1# set xe-4/3/1 unit 0 family inet address 203.0.113.1/24
```

2. Configure static routes to reach the group server and member 2.

```
[edit routing-options]
user@GM1# set static route 192.0.2.0/24 next-hop 198.51.100.2
user@GM1# set static route 203.0.1.0/24 next-hop 10.0.1.1
```

3. Define the IKE proposal.

```
[edit security]
user@GM1# set group-vpn member ike proposal ike-proposal
```

4. Configure the Phase 1 SA for ike-proposal.

```
[edit security]
user@GM1# set group-vpn member ike proposal ike-proposal authentication-method
pre-shared-keys
user@GM1# set group-vpn member ike proposal ike-proposal dh-group group2
user@GM1# set group-vpn member ike proposal ike-proposal
authentication-algorithm sha1
user@GM1# set group-vpn member ike proposal ike-proposal encryption-algorithm
3des-cbc
```

5. Define the IKE policy.

```
[edit security]
user@GM1# set group-vpn member ike policy ike-policy mode main
user@GM1# set group-vpn member ike policy ike-policy proposals ike-proposal
user@GM1# set group-vpn member ike policy ike-policy pre-shared-key ascii-text
""$9$QEni3/t1RSM87uO87-V4oz36"
```

6. Set the remote gateways for gw-group1.

```
[edit security]
user@GM1# set group-vpn member ike gateway gw-group1 ike-policy ike-policy
user@GM1# set group-vpn member ike gateway gw-group1 server-address 192.0.2.0
user@GM1# set group-vpn member ike gateway gw-group1 server-address 172.16.0.0
user@GM1# set group-vpn member ike gateway gw-group1 local-address
198.51.100.0
```

7. Configure the group identifier and IKE gateway for gw-group1.

```
[edit security]
user@GM1# set group-vpn member ipsec vpn vpn-group1 ike-gateway gw-group1
user@GM1# set group-vpn member ipsec vpn vpn-group1 group 1
user@GM1# set group-vpn member ipsec vpn vpn-group1 match-direction output
```

8. Configure the service set for gw-group1.

```
[edit services]
```

```

user@GM1# set service-set gvpn-service-set interface-service service-interface
ms-4/0/0.1
user@GM1# set service-set gvpn-service-set ipsec-group-vpn vpn-group1

```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show security**, and **show services** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

Traffic statistics:
Input  bytes   :           752
Output bytes   :           716
Input  packets :            5
Output packets :            5
Flags: IKE SA is created
IPSec security associations: 0 created, 0 deleted
Phase 2 negotiations in progress: 0
```

Meaning Router GM1 has established the IKE SA with the GC/KS for the group.

Verifying the Group Member IPsec SA

Purpose Verify the IPsec SAs on Router GM1.

Action From operational mode, run the **show security group-vpn member ipsec security-associations detail** command.

```
user@GM1> show security group-vpn member ipsec security-associations detail
Virtual-system: root Group VPN Name: vpn-group1
Local Gateway: 198.51.100.1, GDOI Server: 192.0.2.0
Group Id: 1
Rule Match Direction: output, Tunnel-MTU: 1500
Routing Instance: default
DF-bit: clear
Stats:
  Pull Succeeded           : 18
  Pull Failed              : 0
  Pull Timeout             : 0
  Pull Aborted             : 0
  Server Failover          : 0
  Delete Received          : 0
  Exceed Maximum Keys(4)   : 0
  Exceed Maximum Policies(1): 0
  Unsupported Algo         : 0
Flags:
  Rekey Needed: no

List of policies received from server:
Tunnel-id: 10001
Source IP: ipv4_subnet(any:0,[0..7]=203.0.2.0/24)
Destination IP: ipv4_subnet(any:0,[0..7]=203.0.1.0/24)

Direction: bi-directional, SPI: e1c117c7
Protocol: ESP, Authentication: sha1, Encryption: 3des
Hard lifetime: Expires in 2526 seconds
Lifesize Remaining: Unlimited
Soft lifetime: Expires in 2366 seconds
Mode: Tunnel, Type: Group VPN, State: installed
Anti-replay service: N/A
```

Meaning Router GM1 has established the IPsec SA with the GC/KS.

Verifying the Group Member IPsec Statistics

Purpose Verify the IPsec statistics on Router GM1.

Action From operational mode, run the **show security group-vpn member ipsec statistics** command.

```
user@GM1> show security group-vpn member ipsec statistics
PIC: ms-0/2/0, Service set: gvpn-service-set
```

```
ESP Statistics:
  Encrypted bytes:          264
  Decrypted bytes:         264
  Encrypted packets:        3
  Decrypted packets:        3
AH Statistics:
  Input bytes:              0
  Output bytes:             0
  Input packets:            0
  Output packets:           0
Errors:
  AH authentication failures: 0
  ESP authentication failures: 0
  ESP decryption failures:    0
  Bad headers: 0, Bad trailers: 0
  Replay before window drops: 0, Replayed pkts: 0
  IP integrity errors: 0, Exceeds tunnel MTU: 0
  Rule lookup failures: 0, No SA errors: 0
  Flow errors: 0, Misc errors: 0
```

Meaning **ESP Statistics** shows that packet flows have been encrypted and decrypted between the group members. Router GM1 has encrypted 3 packets and has received 3 decrypted packets from Router GM2.

Troubleshooting

To troubleshoot the Group VPNv2 configuration, see:

- [Negotiating the IKE SA on page 272](#)
- [Establishing the IKE SA on page 273](#)
- [Downloading the GDOI IPsec SA on page 274](#)
- [Traffic Encryption and Decryption on page 274](#)
- [Troubleshooting System Log Messages on page 275](#)

Negotiating the IKE SA

Problem The IKE SA negotiation is not triggered on the group member.

The output of the **show ike** and **show security group-vpn member ike security-associations** commands does not display the IKE negotiations.

Solution To troubleshoot the IKE negotiation issue:

1. Check if the service interface status is up.

Use **show interfaces terse | match ms** to check if the MS interface is down. An MS interface goes down when the PIC is rebooting.

2. Look for **Ignore gvpn vpn_name** since it is inactive in the log file `/var/log/gkmd`.
Check if the Group VPN is referenced by any service set in the configuration.
 - a. Enable **security group-vpn member ike traceoptions**.
 - b. Look for the following system log messages in the trace log file:
 - Dec 2 16:09:54 GVPN:iked_pm_gvpn_trigger called for gvpn200
 - Dec 2 16:09:54 GVPN:PM NULL for gvpn gvpn200
 - Dec 2 16:09:54 GVPN:Ignore gvpn gvpn200 since it is inactive

This means either the service set is inactive or the service interface is down.

Establishing the IKE SA

Problem The IKE SA is not getting established with the GC/KS.

In this scenario, the IKE SA state is down in the **show security group-vpn member ike security-associations** command output:

```
user@GM1> show security group-vpn member ike security-associations
Index   State   Initiator cookie   Responder cookie   Mode           Remote Address
-----
          5295626 DOWN    2d47c125d2a9805e  0000000000000000  Main
192.0.2.2
```

Solution To troubleshoot the IKE SA issue:

1. Check if the server address configured under **[edit security group-vpn member ike gateway]** is the correct one and is reachable.
2. Use the **ping** command between the remote devices to check network connectivity.
3. Check if the local address in the **group-vpn** configuration is also a configured address on any of the physical interfaces in the configuration.
4. Check if the IKE proposals match between the group member and the GC/KS.
If there is a misconfiguration on the IKE SA negotiation, then do the following:
 - a. Enable **security group-vpn member ike traceoption**.
 - b. Look for the following message in the trace log file:

Dec 215:39:54 ikev2_fb_negotiation_done_isakmp: Entered IKE error code No proposal chosen (14), IKE SA 8dd7000 (neg 8dda800).

5. Look for a **No proposal chosen** error in the log file `/var/log/gkmd`.

Downloading the GDOI IPsec SA

Problem The GDOI IPsec SAs are not downloaded from the GC/KS.

In this scenario, the GDOI **groupkey-pull** with the configured GC/KS fails, and the **show security group-vpn member ipsec sa** command output does not display anything.

Solution To troubleshoot the GDOI IPsec SA issue:

1. Check if the IKE SA has been established with the GC/KS.
2. Check if the group ID configured on the GC/KS and the group member match.
3. Look for any group SA installation failures or other failures in the log file `/var/log/gkmd`.

Look for the following syslog messages to confirm use of an unsupported GDOI SA algorithm:

- Dec 2 15:32:49 simpleman gkmd[1701]: Failed to install SA because of unsupported algo(encr: 3des-cbc, auth : (null)) for SPI 0x6645cdb5 from server 192.0.2.1
- Dec 2 15:32:49 simpleman gkmd[1701]: Member registration failed with key server 192.0.2.1 for group vpn gvpn200, reason SA unusable

Look for the following syslog messages to confirm use of unsupported GDOI policies:

- Dec 2 15:34:34 simpleman gkmd[1701]: Failed to install SA because of too many(2) policies for SPI 0x6951550c from server 192.0.2.1
- Dec 2 15:34:34 simpleman gkmd[1701]: Member registration failed with key server 192.0.2.1 for group vpn gvpn200, reason SA unusable

Traffic Encryption and Decryption

Problem The CLI shows IPsec SAs as installed, but traffic does not go through the SAs.

In this scenario, traffic matching the rules received from the server fails to get encrypted or decrypted. The **show security group-vpn member ipsec statistics** command output displays a zero value for encrypt and decrypt packet count.

Solution Look for **Rule lookup failures** counter in the error section of the CLI output.

Troubleshooting System Log Messages

Problem System log messages are generated to record the different Group VPNv2 events.

Solution To interpret the system log messages, refer to the following:

- Dec 2 15:29:10 simpleman gkmd[1701]: Member registration succeeded with key server 192.0.2.1 for group vpn gvpn200—GDOI pull was successful.
- Dec 2 15:21:18 simpleman gkmd[1701]: Member registration failed with key server 192.0.2.1 for group vpn gvpn200, reason Timed out—GDOI pull failed.
- Dec 2 15:34:34 simpleman gkmd[1701]: Failed to install SA because of too many(2) policies for SPI 0x6951550c from server 192.0.2.1—GDOI SA installation failed because of too many policies.
- Dec 2 15:21:18 simpleman gkmd[1701]: Server 192.0.2.1 is unreachable for group vpn gvpn200—Single GC/KS failed (Non-COOP).
- Dec 2 15:51:49 simpleman gkmd[1701]: Current key server 192.0.2.1 is unreachable and will try registering with next Key Server 192.1.1.2 for group vpn gvpn200—Particular GC/KS is not responding (COOP).
- Dec 2 15:56:24 simpleman gkmd[1701]: All servers are unreachable for group vpn gvpn200—None of the GC/KS are responding (COOP).
- Dec 2 16:01:43 simpleman gkmd[1701]: Member re-registering with Key Server 192.0.2.1 for group-vpn gvpn200—Member re-registration with the GC/KS.
- Dec 2 16:01:43 simpleman gkmd[1701]: Creating TEK with SPI 0xb35200ac tunnel_id 10001 for group vpn gvpn200—GDOI SA TEK creation was successful.
- Dec 2 16:29:01 simpleman gkmd[1701]: Deleting TEK with SPI 0x6dba2a76 tunnel_id 10001 for group vpn gvpn200 and reason cleared from CLI—GDOI SA TEK destroy was successful with reason.

Different reasons for the GDOI SA TEK destroy are as follows:

- Cleared from CLI
- Hard lifetime expired
- Too many TEKs
- Configuration change
- SA install error
- Stale SA
- Interface down

CHAPTER 18

Configuring Digital Certificate Validation

- [Understanding Digital Certificate Validation on page 279](#)
- [Example: Improving Digital Certificate Validation by Configuring Policy OIDs on an MX Series Device on page 284](#)

Understanding Digital Certificate Validation

Starting in Junos OS Release 16.1R3, MX Series devices support digital certificate validation. During IKE negotiation, the PKI daemon on an MX Series device validates X509 certificates received from VPN peers. The certificate validation performed is specified in RFC 5280, *Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile*. Basic certificate and certificate chain validations include signature and date validation as well as revocation checks. This topic describes additional digital certificate validations performed by the PKI daemon.

- [Policy Validation on page 279](#)
- [Path Length Validation on page 281](#)
- [Key Usage on page 282](#)
- [Issuer and Subject Distinguished Name Validation on page 283](#)

Policy Validation

X509 certificates can include optional policy validation fields. If a policy validation field is present, policy validation is performed for the entire certificate chain including the end entity (EE) certificate and intermediate certificate authority (CA) certificates. Policy validation is not applicable to the root certificate. Policy validation ensures that the EE and intermediate CA certificates have a common policy. If no common policy exists for the certificate chain being validated, certificate validation fails.

Prior to policy validation, a certificate chain containing the self-signed root certificate, intermediate CA certificates, and EE certificate must be built. The policy validation starts with the intermediate CA certificate issued by the self-signed root certificate and continues through the EE certificate.

The following optional certificate fields are used for policy validation:

- **policy-oids**
- **requireExplicitPolicy**

- **skipCerts**

These fields are described in the following sections.

Policy OIDs Configured on MX Series Devices

In some situations, it might be desirable to only accept certificates with known policy object identifiers (OIDs) from peers. This optional configuration allows certificate validation to succeed only if the certificate chain received from the peer contains at least one policy OID that is configured on the MX Series device.

On the MX Series device, policy OIDs are configured in an IKE policy with the **policy-oids** configuration statement at the `[edit security ike policy policy-name certificate]` hierarchy level. You can configure up to five policy OIDs. For a peer's certificate to be validated successfully, the peer's certificate chain must contain at least one of the policy OIDs configured on the MX Series device. Note that the **policy-oids** field in a certificate is optional. If you configure policy OIDs on the MX Series device but the peer's certificate chain does not contain any policy OIDs, certificate validation fails.

No Policy OIDs Configured on MX Series Devices

If no policy OID is configured on the MX Series device, policy validation starts whenever the **requireExplicitPolicy** field is encountered in the certificate chain. A certificate may contain one or more certificate policy OIDs. For policy validation to succeed, there must be a common policy OID in the certificate chain.

Figure 25 on page 280 shows a certificate chain that consists of certificates for a root CA, three intermediate CAs, and an EE. The CA certificate for Int-CA-2 contains the **requireExplicitPolicy** field; therefore, policy validation starts with Int-CA-2 and continues through EE-1. The certificate for Int-CA-2 contains policy OIDs P1, P2, and P3. The certificate for Int-CA-3 contains policy OIDs P2, P3, and P4. The certificate for EE-1 contains policy OIDs P2 and P5. Because the policy OID P2 is common to the certificates being validated, policy validation succeeds.

Figure 25: Policy Validation with requireExplicitPolicy Field

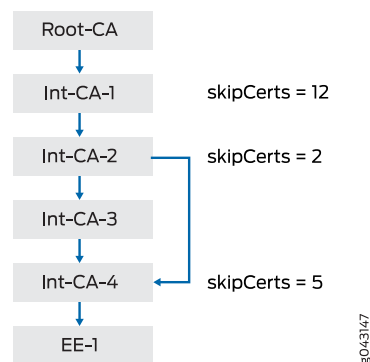

The optional **skipCerts** field in an intermediate CA certificate indicates the number of certificates, including the current CA certificate, that are to be excluded from policy validation. If **skipCerts** is 0, policy validation starts from the current certificate. If **skipCerts** is 1, the current certificate is excluded from policy validation. The value of the **skipCerts**

field is checked in every intermediate CA certificate. If a **skipCerts** value is encountered that is lower than the current number of certificates being excluded, the lower **skipCerts** value is used.

Figure 26 on page 281 shows a certificate chain consisting of a root CA, four intermediate CAs, and an EE. The **skipCerts** value in Int-CA-1 is 12, which skips 12 certificates including the certificate for Int-CA-1. However, the **skipCerts** value is checked in every intermediate CA certificate in the chain. The **skipCerts** value in Int-CA-2 is 2, which is lower than 12, so now 2 certificates are skipped. The **skipCerts** value in Int-CA-4 is 5, which is greater than 2, so the Int-CA-4 **skipCerts** value is ignored.

Figure 26: Policy Validation with skipCerts Field

When policy OIDs are configured on the MX Series device, the certificate fields **requireExplicitPolicy** and **skipCerts** are ignored.

Path Length Validation

Certificate validation can involve a certificate chain that includes a root CA, one or more optional intermediate CAs, and an EE certificate. The number of intermediate CAs can grow depending upon the deployment scenario. Path length validation provides a mechanism to limit the number of intermediate certificates involved in certificate validation. **path-length** is an optional field in an X509 certificate. The value of **path-length** indicates the number of non-self-signed intermediate CA certificates allowed for certificate validation. The last certificate, which is generally the EE certificate, is not included in the path limit. If the root certificate contains a **path-length** value of 0, no intermediate CA certificates are allowed. If the **path-length** value is 1, there can be 0 or 1 intermediate CA certificates.

path-length can be present in multiple CA certificates in the certificate chain. The path length validation always begins with the self-signed root certificate. The path limit is decremented by 1 at each intermediate certificate in the chain. If an intermediate certificate contains a **path-length** value less than the current path limit, the new limit is enforced. On the other hand, if the **path-length** value is larger than the current path limit, it is ignored.

Figure 27 on page 282 shows a certificate chain that consists of a root CA, four intermediate CAs, and an EE. The **path-length** value in Root-CA is 10, therefore the initial path limit of non-self-signed intermediate CA certificates allowed for certificate validation is 10. At

Int-CA-1, the path limit is 10-1 or 9. The **path-length** value in Int-CA-1 is 4, which is less than the path limit of 9, so the new path limit becomes 4. At Int-CA-2, the path limit is 4-1 or 3. The **path-length** value in Int-CA-2 is 5, which is larger than the path limit of 3, so it is ignored. At Int-CA-3, the path limit is 3-1 or 2. The **path-length** value in Int-CA-3 is 20, which is larger than the path limit of 2, so it is also ignored.

Figure 27: Path Length Validation

Key Usage

The key usage field in an EE or CA certificate defines the purpose of the key contained in the certificate.

EE Certificates

For EE certificates, if the key usage field is present but the certificate does not contain **digitalSignature** or **nonrepudiation** flags, the certificate is rejected. If the key usage field is not present, then key usage is not checked.

CA Certificates

The key can be used for certificate or CRL signature validation. Because the PKI daemon is responsible for both X509 certificate validation and CRL downloads, key usage must be checked before validating the certificate or CRL.

Certificate Signature Validation

The **keyCertSign** flag indicates that a CA certificate can be used for certificate signature validation. If this flag is not set, certificate validation is aborted.

CRL Signature Validation

In Phase 1 negotiations, participants check the certificate revocation list (CRL) to see if certificates received during an IKE exchange are still valid. The CRL is periodically downloaded for CA profiles configured with CRL as the certificate revocation check. Downloaded CRL files must be verified before they are downloaded into the device. One of the verification steps is to validate the CRL signature using a CA certificate. The downloaded CRL is signed with the CA certificate's private key and it must be verified with the CA certificate's public key stored in the device. The key usage field in the CA

certificate must contain the **CRLSign** flag to verify the downloaded CRL. If this flag is not present, the CRL is discarded.

Issuer and Subject Distinguished Name Validation

Signature validation is performed for certificates received from a peer as well as for the CRL file downloaded from a CA server. Signature validation involves looking up the CA certificate in a CA database based on the issuer's distinguished name (DN) in the certificate or the CRL being verified.

Figure 28 on page 283 shows the lookup for CA certificates based on the issuer DN. In the EE certificate, the issuer DN is CA-1, which is the subject DN of the intermediate CA certificate in the chain. In the intermediate CA certificate, the issuer DN is CA-Root, which is the subject DN of the self-signed Root-CA certificate in the chain. In the CRL, the issuer DN is CA-Root, which is the subject DN of the self-signed Root-CA certificate.

Figure 28: Issuer and Subject DN Validation

The lookup for the issuer or subject DN must follow these rules for attribute values:

- Attribute values encoded in different ASN.1 types (for example, PrintableString and BMPString) are assumed to represent different strings.
- Attribute values encoded in PrintableString types are not case-sensitive. These attribute values are compared after removing leading and trailing white spaces and converting internal substrings of one or more consecutive white spaces to a single space.
- Attribute values encoded in types other than PrintableString are case-sensitive.

Release History Table

Release	Description
16.1R3	Starting in Junos OS Release 16.1R3, MX Series devices support digital certificate validation.

Example: Improving Digital Certificate Validation by Configuring Policy OIDs on an MX Series Device

In some situations, it might be desirable to only accept certificates with known policy object identifiers (OIDs) from peers. This optional configuration allows certificate validation to succeed only if the certificate chain received from the peer contains at least one policy OID that is configured on the MX Series device. This example shows how to configure policy OIDs in the IKE policy on an MX Series device.

NOTE: You must ensure that at least one of the policy OIDs configured on the MX Series device is included in a peer's certificate or certificate chain. Note that the `policy-oids` field in a peer's certificate is optional. If you configure policy OIDs in an IKE policy and the peer's certificate chain does not contain any policy OIDs, certificate validation for the peer fails.

- [Requirements on page 284](#)
- [Overview on page 284](#)
- [Configuration on page 285](#)
- [Verification on page 285](#)

Requirements

Before you begin:

- Ensure that you are using Junos OS Release 16.1 or later for MX Series devices.
- Configure an IPsec VPN tunnel.

Overview

This example shows an IKE policy configuration where policy OIDs 2.16.840.1.101.3.1.48.2 and 5.16.40.1.101.3.1.55.2 are specified. The IKE policy `ike_cert_pol` references the IKE proposal `ike_cert_prop`, which is not shown. The local certificate on the MX Series device is `lc-igloo-root`.

Configuration

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set services ipsec-vpn ike policy ike_cert_pol mode main
set services ipsec-vpn ike policy ike_cert_pol proposals ike_cert_prop
set services ipsec-vpn ike policy ike_cert_pol certificate local-certificate lc-igloo-root
set services ipsec-vpn ike policy ike_cert_pol certificate policy-oids 2.16.840.1.101.3.1.48.2
set services ipsec-vpn ike policy ike_cert_pol certificate policy-oids 5.16.40.1.101.3.1.55.2
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure policy OIDs for certificate validation:

- Configure the IKE policy:

```
[edit services ipsec-vpn ike policy ike_cert_pol]
user@host# set mode main
user@host# set proposals ike_cert_prop
user@host# set certificate local-certificate lc-igloo-root
user@host# set certificate policy-oids 2.16.840.1.101.3.1.48.2
user@host# set certificate policy-oids 5.16.40.1.101.3.1.55.2
```

Results From configuration mode, confirm your configuration by entering the **show services ipsec-vpn ike policy ike_cert_pol** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@host# show services ipsec-vpn ike policy ike_cert_pol
mode main;
proposals ike_cert_prop;
certificate {
  local-certificate lc-igloo-root;
  policy-oids [ 2.16.840.1.101.3.1.48.2 5.16.40.1.101.3.1.55.2 ];
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

Verifying the CA Certificate

Purpose Display the CA certificate configured on the device.

Action From operational mode, enter the **show security pki ca-certificate ca-profile ca-tmp** command.

```

user@host> show security pki ca-certificate ca-profile ca-tmp detail
Certificate identifier: ca-tmp
Certificate version: 3

>218365954 ESP:aes-cbc-192/sha256 97611813 1726/ unlim - root 1495 198.51.100.0
```

Meaning The `show services ipsec-vpn ike security-associations` command lists all active IKE Phase 1 SAs. If no SAs are listed, there was a problem with Phase 1 establishment. In this case, check for the `PKID_CERT_POLICY_CHECK_FAIL` message in the system logs. This message indicates that the peer's certificate chain does not contain a policy OID that is configured on the MX Series device. Check the **policy-oids** values in the peer's certificate chain with the values configured on the MX Series device.

It might also be that the peer's certificate chain does not contain any **policy-oids** fields, which are optional fields. If this is the case, certificate validation fails if there are any policy OIDs configured on the MX Series device.

Multilevel Hierarchy for Certificate Authentication

Certificate-based authentication is an authentication method supported on SRX Series devices during IKE negotiation. In large networks, multiple certificate authorities (CAs) can issue end entity (EE) certificates to their respective end devices. It is common to have separate CAs for individual locations, departments, or organizations.

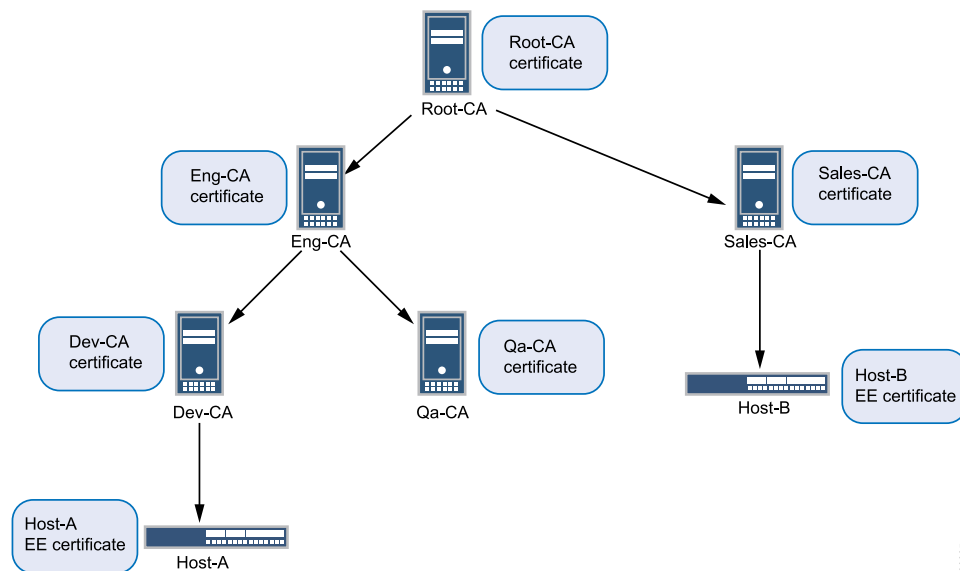

When a single-level hierarchy for certificate-based authentication is employed, all EE certificates in the network must be signed by the same CA. All firewall devices must have the same CA certificate enrolled for peer certificate validation. The certificate payload sent during IKE negotiation only contains EE certificates.

Alternatively, the certificate payload sent during IKE negotiation can contain a chain of EE and CA certificates. A certificate chain is the list of certificates required to validate a peer's EE certificate. The certificate chain includes the EE certificate and any CA certificates that are not present in the local peer.

The network administrator needs to ensure that all peers participating in an IKE negotiation have at least one common trusted CA in their respective certificate chains. The common trusted CA does not have to be the root CA. The number of certificates in the chain, including certificates for EEs and the topmost CA in the chain, cannot exceed 10.

In the example CA hierarchy shown in [Figure 29 on page 290](#), Root-CA is the common trusted CA for all devices in the network. Root-CA issues CA certificates to the engineering and sales CAs, which are identified as Eng-CA and Sales-CA, respectively. Eng-CA issues CA certificates to the development and quality assurance CAs, which are identified as Dev-CA and Qa-CA, respectively. Host-A receives its EE certificate from Dev-CA while Host-B receives its EE certificate from Sales-CA.

Figure 29: Multilevel Hierarchy for Certificate-Based Authentication

Each end device needs to be loaded with the CA certificates in its hierarchy. Host-A must have Root-CA, Eng-CA, and Dev-CA certificates; Sales-CA and Qa-CA certificates are not necessary. Host-B must have Root-CA and Sales-CA certificates. Certificates can be loaded manually in a device or enrolled using the Simple Certificate Enrollment Process (SCEP).

Each end device must be configured with a CA profile for each CA in the certificate chain. The following output shows the CA profiles configured on Host-A:

```

admin@host-A# show security
pki {
  ca-profile Root-CA {
    ca-identity Root-CA;
    enrollment {
      url "www.example.net/scep/Root/";
    }
  }
  ca-profile Eng-CA {
    ca-identity Eng-CA;
    enrollment {
      url "www.example.net/scep/Eng/";
    }
  }
  ca-profile Dev-CA {
    ca-identity Dev-CA;
    enrollment {
      url "www.example.net/scep/Dev/";
    }
  }
}

```

The following output shows the CA profiles configured on Host-B:

```
admin@host-B# show security
pki {
  ca-profile Root-CA {
    ca-identity Root-CA;
    enrollment {
      url "www.example.net/scep/Root/";
    }
  }
  ca-profile Sales-CA {
    ca-identity Sales-CA;
    enrollment {
      url "www.example.net/scep/Sales/";
    }
  }
}
```

Dynamic CRL Download and Checking

Digital certificates are issued for a set period of time and are invalid after the specified expiration date. A CA can revoke an issued certificate by listing it in a certificate revocation list (CRL). During peer certificate validation, the revocation status of a peer certificate is checked by downloading the CRL from a CA server to the local device.

A VPN device must be able to check a peer's certificate for its revocation status. A device can use the CA certificate received from its peer to extract the URL to dynamically download the CA's CRL and check the revocation status of the peer's certificate. A dynamic CA profile is automatically created on the local device with the format **dynamic-*nnn***. A dynamic CA profile allows the local device to download the CRL from the peer's CA and check the revocation status of the peer's certificate. In [Figure 29 on page 290](#), Host-A can use the Sales-CA and EE certificates received from Host-B to dynamically download the CRL for Sales-CA and check the revocation status of Host-B's certificate.

To enable dynamic CA profiles, the **revocation-check crl** option must be configured on a parent CA profile at the **[edit security pki ca-profile *profile-name*]** hierarchy level.

The properties of a parent CA profile are inherited for dynamic CA profiles. In [Figure 29 on page 290](#), the CA profile configuration on Host-A for Root-CA enables dynamic CA profiles as shown in the following output:

```
admin@host-A# show security
pki {
  ca-profile Root-CA {
    ca-identity Root-CA;
    enrollment {
      url "www.example.net/scep/Root/";
    }
    revocation-check {
      crl;
    }
  }
}
```

A dynamic CA profile is created on Host-A for Sales-CA. Revocation checking is inherited for the Sales-CA dynamic CA profile from Root-CA.

If the **revocation-check disable** statement is configured in a parent CA profile, dynamic CA profiles are not created and dynamic CRL download and checking is not performed.

The data for CRLs downloaded from dynamic CA profiles are displayed with the **show security pki crl** command in the same way as CRLs downloaded by configured CA profiles. The CRL from a dynamic CA profile is updated periodically as are those for CA profiles that are configured in the device.

NOTE: The CA certificate is required to validate the CRL received from a CA server; therefore, the CA certificate received from a peer is stored on the local device. Because the CA certificate is not enrolled by an administrator, it is used only for validating the CRL received from the CA server and not for validating the peer certificate.

Example: Configuring a Device for Peer Certificate Chain Validation

This example shows how to configure a device for certificate chains used to validate peer devices during IKE negotiation.

- [Requirements on page 292](#)
- [Overview on page 292](#)
- [Configuration on page 293](#)
- [Verification on page 298](#)
- [IKE and IPsec SA Failure for a Revoked Certificate on page 299](#)

Requirements

Before you begin, obtain the address of the certificate authority (CA) and the information they require (such as the challenge password) when you submit requests for local certificates.

Overview

This example shows how to configure a local device for certificate chains, enroll CA and local certificates, check the validity of enrolled certificates, and check the revocation status of the peer device.

This example shows the configuration and operational commands on Host-A, as shown in Figure 30 on page 293. A dynamic CA profile is automatically created on Host-A to allow Host-A to download the CRL from Sales-CA and check the revocation status of Host-B's certificate.

Figure 30: Certificate Chain Example

NOTE: The IPsec VPN configuration for Phase 1 and Phase 2 negotiation is shown for Host-A in this example. The peer device (Host-B) must be properly configured so that Phase 1 and Phase 2 options are successfully negotiated and security associations (SAs) are established.

Configuration

To configure a device for certificate chains:

- [Configure CA Profiles on page 293](#)
- [Enroll Certificates on page 295](#)
- [Configure IPsec VPN Options on page 297](#)

Configure CA Profiles

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

set security pki ca-profile Root-CA ca-identity CA-Root
set security pki ca-profile Root-CA enrollment url http://10.157.88.230:8080/scep/Root/
set security pki ca-profile Root-CA revocation-check use-crl
set security pki ca-profile Eng-CA ca-identity Eng-CA

```

```
set security pki ca-profile Eng-CA enrollment url http://10.157.88.230:8080/scep/Eng/  
set security pki ca-profile Eng-CA revocation-check use-crl  
set security pki ca-profile Dev-CA ca-identity Dev-CA  
set security pki ca-profile Dev-CA enrollment url http://10.157.88.230:8080/scep/Dev/  
set security pki ca-profile Dev-CA revocation-check use-crl
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure CA profiles:

1. Create the CA profile for Root-CA.

```
[edit security pki]  
user@host# set ca-profile Root-CA ca-identity CA-Root  
user@host# set ca-profile Root-CA enrollment url  
http://10.157.88.230:8080/scep/Root/  
user@host# set ca-profile Root-CA revocation-check use-crl
```

2. Create the CA profile for Eng-CA.

```
[edit security pki]  
user@host# set ca-profile Eng-CA ca-identity Eng-CA  
user@host# set ca-profile Eng-CA enrollment url  
http://10.157.88.230:8080/scep/Eng/  
user@host# set ca-profile Eng-CA revocation-check use-crl
```

3. Create the CA profile for Dev-CA.

```
[edit security pki]  
user@host# set ca-profile Dev-CA ca-identity Dev-CA  
user@host# set ca-profile Dev-CA enrollment url  
http://10.157.88.230:8080/scep/Dev/  
user@host# set ca-profile Dev-CA revocation-check use-crl
```

Results From configuration mode, confirm your configuration by entering the **show security pki** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]  
user@host# show security pki  
ca-profile Root-CA {  
  ca-identity Root-CA;  
  enrollment {  
    url "http://10.157.88.230:8080/scep/Root/";  
  }  
  revocation-check {  
    use-crl;  
  }  
}  
ca-profile Eng-CA {  
  ca-identity Eng-CA;
```

```

enrollment {
  url "http://10.157.88.230:8080/scep/Eng/";
}
revocation-check {
  use-crl;
}
}
ca-profile Dev-CA {
  ca-identity Dev-CA;
  enrollment {
    url "http://10.157.88.230:8080/scep/Dev/";
  }
  revocation-check {
    use-crl;
  }
}
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Enroll Certificates

Step-by-Step Procedure

To enroll certificates:

1. Enroll the CA certificates.

```
user@host> request security pki ca-certificate enroll ca-profile Root-CA
```

```
user@host> request security pki ca-certificate enroll ca-profile Eng-CA
```

```
user@host> request security pki ca-certificate enroll ca-profile Dev-CA
```

Type **yes** at the prompts to load the CA certificate.

2. Verify that the CA certificates are enrolled in the device.

```
user@host> show security pki ca-certificate ca-profile Root-CA
```

```
Certificate identifier: Root-CA
```

```
Issued to: Root-CA, Issued by: C = us, O = juniper, CN = Root-CA
```

```
Validity:
```

```
Not before: 07- 3-2015 10:54 UTC
```

```
Not after: 07- 1-2020 10:54 UTC
```

```
Public key algorithm: rsaEncryption(2048 bits)
```

```
user@host> show security pki ca-certificate ca-profile Eng-CA
```

```
Certificate identifier: Eng-CA
```

```
Issued to: Eng-CA, Issued by: C = us, O = juniper, CN = Root-CA
```

```
Validity:
```

```
Not before: 07- 3-2015 10:54 UTC
```

```
Not after: 07- 1-2020 10:54 UTC
```

```
Public key algorithm: rsaEncryption(2048 bits)
```

```
user@host> show security pki ca-certificate ca-profile Dev-CA
```

```
Certificate identifier: Dev-CA
```

```
Issued to: Dev-CA, Issued by: C = us, O = juniper, CN = Eng-CA
```

```
Validity:
```

```
Not before: 07- 3-2015 10:54 UTC
```

```
Not after: 07- 1-2020 10:54 UTC
```

```
Public key algorithm: rsaEncryption(2048 bits)
```

3. Verify the validity of the enrolled CA certificates.

```
user@host> request security pki ca-certificate verify ca-profile Root-CA
CA certificate Root-CA verified successfully
```

```
user@host> request security pki ca-certificate verify ca-profile Eng-CA
CA certificate Eng-CA verified successfully
```

```
user@host> request security pki ca-certificate verify ca-profile Dev-CA
CA certificate Dev-CA verified successfully
```

4. Enroll the local certificate.

```
user@host> request security pki local-certificate enroll certificate-id Host-A
ca-profile Dev-CA challenge-password juniper domain-name host-a.company.net
email host-a@company.net subject DC=juniper,CN=Host-A,
OU=DEV,O=PKI,L=Sunnyvale,ST=CA,C=US
```

5. Verify that the local certificate is enrolled in the device.

```
user@host> show security pki local-certificate
Issued to: Host-A, Issued by: C = us, O = juniper, CN = Dev-CA
Validity:
  Not before: 07- 3-2015 10:54 UTC
  Not after: 07- 1-2020 10:54 UTC
  Public key algorithm: rsaEncryption(1024 bits)
```

6. Verify the validity of the enrolled local certificate.

```
user@host> request security pki local-certificate verify certificate-id Host-A
Local certificate Host-A verification success
```

7. Check the CRL download for configured CA profiles.

```
user@host> show security pki crl
CA profile: Root-CA
  CRL version: V00000001
  CRL issuer: C = us, O = juniper, CN = Root-CA
  Effective date: 09- 9-2015 13:08
  Next update: 09-21-2015 02:55

CA profile: Eng-CA
  CRL version: V00000001
  CRL issuer: C = us, O = juniper, CN = Eng-CA
  Effective date: 08-22-2015 17:46
  Next update: 10-24-2015 03:33

CA profile: Dev-CA
  CRL version: V00000001
  CRL issuer: C = us, O = juniper, CN = Dev-CA
  Effective date: 09-14-2015 21:15
  Next update: 09-26-2012 11:02
```

Configure IPsec VPN Options

CLI Quick Configuration To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
set services ipsec-vpn ike proposal ike_cert_prop_01 authentication-method rsa-signatures
set services ipsec-vpn ike proposal ike_cert_prop_01 dh-group group5
set services ipsec-vpn ike proposal ike_cert_prop_01 authentication-algorithm sha1
set services ipsec-vpn ike proposal ike_cert_prop_01 encryption-algorithm aes-256-cbc
set services ipsec-vpn ike policy ike_cert_pol_01 mode main
set services ipsec-vpn ike policy ike_cert_pol_01 proposals ike_cert_prop_01
set services ipsec-vpn ike policy ike_cert_pol_01 certificate local-certificate Host-A
set services ipsec-vpn ipsec proposal ipsec_prop_01 protocol esp
set services ipsec-vpn ipsec proposal ipsec_prop_01 authentication-algorithm
    hmac-sha1-96
set services ipsec-vpn ipsec proposal ipsec_prop_01 encryption-algorithm 3des-cbc
set services ipsec-vpn ipsec proposal ipsec_prop_01 lifetime-seconds 300
set services ipsec-vpn ipsec policy ipsec_pol_01 proposals ipsec_prop_01
set services ipsec-vpn ipsec vpn ipsec_cert_vpn_01 ike ipsec-policy ipsec_pol_01
```

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure IPsec VPN options:

1. Configure Phase 1 options.

```
[edit services ipsec-vpn ike proposal ike_cert_prop_01]
user@host# set authentication-method rsa-signatures
user@host# set dh-group group5
user@host# set authentication-algorithm sha1
user@host# set encryption-algorithm aes-256-cbc
```

```
[edit services ipsec-vpn ike policy ike_cert_pol_01]
user@host# set mode main
user@host# set proposals ike_cert_prop_01
user@host# set certificate local-certificate Host-A
```

2. Configure Phase 2 options.

```
[edit services ipsec-vpn ipsec proposal ipsec_prop_01]
user@host# set protocol esp
user@host# set authentication-algorithm hmac-sha1-96
user@host# set encryption-algorithm 3des-cbc
user@host# set lifetime-seconds 300
```

```
[edit services ipsec-vpn ipsec policy ipsec_pol_01]
user@host# set proposals ipsec_prop_01
```

```
[edit services ipsec-vpn ipsec vpn ipsec_cert_vpn_01]
user@host# set ike ipsec-policy ipsec_pol_01
```

Results From configuration mode, confirm your configuration by entering the **show security ike** and **show security ipsec** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show services ipsec-vpn ike
proposal ike_cert_prop_01 {
  authentication-method rsa-signatures;
  dh-group group5;
  authentication-algorithm sha1;
  encryption-algorithm aes-256-cbc;
}
policy ike_cert_pol_01 {
  mode main;
  proposals ike_cert_prop_01;
  certificate {
    local-certificate Host-A;
  }
}
[edit]
user@host# show services ipsec-vpn ipsec
proposal ipsec_prop_01 {
  protocol esp;
  authentication-algorithm hmac-sha1-96;
  encryption-algorithm 3des-cbc;
  lifetime-seconds 300;
}
policy ipsec_pol_01 {
  proposals ipsec_prop_01;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

If certificate validation is successful during IKE negotiation between peer devices, both IKE and IPsec security associations (SAs) are established.

- [Verifying IKE Phase 1 Status on page 298](#)
- [Verifying IPsec Phase 2 Status on page 299](#)

Verifying IKE Phase 1 Status

Purpose Verify the IKE Phase 1 status.

Action Enter the **show services ipsec-vpn ike security-associations** command from operational mode.

```
user@host> show services ipsec-vpn ike security-associations
```

Remote Address	State	Initiator cookie	Responder cookie	Exchange type
192.0.2.0	Matured	63b3445edda507fb	2715ee5895ed244d	Main

Verifying IPsec Phase 2 Status

Purpose Verify the IPsec Phase 2 status.

Action Enter the **show services ipsec-vpn ipsec security-associations** command from operational mode.

```
user@host> show services ipsec-vpn ipsec security-associations
```

Service set: ips_ssl, IKE Routing-instance: default

Rule: vpn_rule_ms_2_2_01, Term: term11, Tunnel index: 1

Local gateway: 10.0.1.2, Remote gateway: 172.16.0.0

IKE and IPsec SA Failure for a Revoked Certificate

- [Checking for Revoked Certificates on page 299](#)

Checking for Revoked Certificates

Problem If certificate validation fails during IKE negotiation between peer devices, check to make sure that the peer's certificate has not been revoked. A dynamic CA profile allows the local device to download the CRL from the peer's CA and check the revocation status of the peer's certificate. To enable dynamic CA profiles, the **revocation-check crl** option must be configured on a parent CA profile.

Solution To check the revocation status of a peer's certificate:

1. Identify the dynamic CA profile that will show the CRL for the peer device by entering the **show security pki crl** command from operational mode.

```
user@host> show security pki crl
```

CA profile: Root-CA

CRL version: V00000001

CRL issuer: C = us, O = juniper, CN = Root-CA

Effective date: 09- 9-2012 13:08

Next update: 09-21-2012 02:55

```
CA profile: Eng-CA
  CRL version: V00000001
  CRL issuer: C = us, O = juniper, CN = Eng-CA
  Effective date: 08-22-2012 17:46
  Next update: 10-24-2015 03:33

CA profile: Dev-CA
  CRL version: V00000001
  CRL issuer: C = us, O = juniper, CN = Dev-CA
  Effective date: 09-14-2012 21:15
  Next update: 09-26-2012 11:02

CA profile: dynamic-001
  CRL version: V00000001
  CRL issuer: C = us, O = juniper, CN = Sales-CA
  Effective date: 09-14-2012 21:15
  Next update: 09-26-2012 11:02
```

The CA profile **dynamic-001** is automatically created on Host-A so that Host-A can download the CRL from Host-B's CA (Sales-CA) and check the revocation status of the peer's certificate.

2. Display CRL information for the dynamic CA profile by entering the **show security pki crl ca-profile dynamic-001 detail** command from operational mode.

Enter

```
user@host> show security pki crl ca-profile dynamic-001 detail
CA profile: dynamic-001
  CRL version: V00000001
  CRL issuer: C = us, O = juniper, CN = Sub11
  Effective date: 09-19-2012 17:29
  Next update: 09-20-2012 01:49
  Revocation List:
    Serial number      Revocation date
    10647C84           09-19-2012 17:29 UTC
```

Host-B's certificate (serial number 10647084) has been revoked.

CHAPTER 20

Managing Certificate Revocation

- [Understanding Online Certificate Status Protocol on page 301](#)
- [Comparison of Online Certificate Status Protocol and Certificate Revocation List on page 302](#)
- [Example: Improving Security by Configuring OCSP for Certificate Revocation Status on page 303](#)

Understanding Online Certificate Status Protocol

OCSP is used to check the revocation status of X509 certificates. OCSP provides revocation status on certificates in real time and is useful in time-sensitive situations such as bank transactions and stock trades.

The revocation status of a certificate is checked by sending a request to an OCSP server that resides outside of an SRX Series device. Based on the response from the server, the VPN connection is allowed or denied. OCSP responses are not cached on SRX Series devices.

The OCSP server can be the certificate authority (CA) that issues a certificate or a designated authorized responder. The location of the OCSP server can be configured manually or extracted from the certificate that is being verified. Requests are sent first to OCSP server locations that are manually configured in CA profiles with the **ocsp url** statement at the **[edit security pki ca-profile *profile-name* revocation-check]** hierarchy level; up to two locations can be configured for each CA profile. If the first configured OCSP server is not reachable, the request is sent to the second OCSP server. If the second OCSP server is not reachable, the request is then sent to the location in the certificate's AuthorityInfoAccess extension field. The **use-ocsp** option must also be configured, as certificate revocation list (CRL) is the default checking method.

SRX Series devices accept only signed OCSP responses from the CA or authorized responder. The response received is validated using trusted certificates. The response is validated as follows:

1. The CA certificate enrolled for the configured CA profile is used to validate the response.
2. The OCSP response might contain a certificate to validate the OCSP response. The received certificate must be signed by a CA certificate enrolled in the SRX Series

device. After the received certificate is validated by the CA certificate, it is used to validate the OCSP response.

The response from the OCSP server can be signed by different CAs. The following scenarios are supported:

- The CA server that issues the end entity certificate for a device also signs the OCSP revocation status response. The SRX Series device verifies the OCSP response signature using the CA certificate enrolled in the SRX Series device. After the OCSP response is validated, the certificate revocation status is checked.
- An authorized responder signs the OCSP revocation status response. The certificate for the authorized responder and the end entity certificate being verified must be issued by the same CA. The authorized responder is first verified using the CA certificate enrolled in the SRX Series device. The OCSP response is validated using the responder's CA certificate. The SRX Series device then uses the OCSP response to check the revocation status of the end entity certificate.
- There are different CA signers for the end entity certificate being verified and the OCSP response. The OCSP response is signed by a CA in the certificate chain for the end entity certificate being verified. (All peers participating in an IKE negotiation need to have at least one common trusted CA in their respective certificate chains.) The OCSP responder's CA is verified using a CA in the certificate chain. After validating the responder CA certificate, the OCSP response is validated using the responder's CA certificate.

To prevent replay attacks, a nonce payload can be sent in an OCSP request. Nonce payloads are sent by default unless it is explicitly disabled. If enabled, the SRX Series device expects the OCSP response to contain a nonce payload, otherwise the revocation check fails. If OCSP responders are not capable of responding with a nonce payload, then the nonce payload must be disabled on the SRX Series device.

- *Improving Security by Configuring OCSP for Certificate Revocation Status*

Comparison of Online Certificate Status Protocol and Certificate Revocation List

Online Certificate Status Protocol (OCSP) and certificate revocation list (CRL) can both be used to check the revocation status of a certificate. There are advantages and disadvantages to each method.

- OCSP provides certificate status in real time, while CRL uses cached data. For time-sensitive applications, OCSP is the preferred approach.
- CRL checking is faster because lookup for certificate status is done on information cached on the VPN device. OCSP requires time to obtain the revocation status from an external server.

- CRL requires additional memory to store the revocation list received from a CRL server. OCSP does not require additional memory to save the revocation status of certificates.
- OCSP requires that the OCSP server be available at all times. CRL can use cached data to check the revocation status of certificates when the server is unreachable.

NOTE: On MX Series and SRX Series devices, CRL is the default method used to check the revocation status of a certificate.

Example: Improving Security by Configuring OCSP for Certificate Revocation Status

This example shows how to improve security by configuring two peers using the Online Certificate Status Protocol (OCSP) to check the revocation status of the certificates used in Phase 1 negotiations for the IPsec VPN tunnel.

- [Requirements on page 303](#)
- [Overview on page 303](#)
- [Configuration on page 305](#)
- [Verification on page 313](#)

Requirements

On each device:

- Obtain and enroll a local certificate. This can be done either manually or by using the Simple Certificate Enrollment Protocol (SCEP).
- Optionally, enable automatic renewal of the local certificate.
- Configure security policies to permit traffic to and from the peer device.

Overview

On both peers, a certificate authority (CA) profile Root is configured with the following options:

- CA name is Root.
- Enrollment URL is `http://1.1.1.1:8080/scep/Root/`. This is the URL where SCEP requests to the CA are sent.
- The URL for the OCSP server is `http://10.157.88.56:8210/Root/`.

- OCSP is used first to check the certificate revocation status. If there is no response from the OCSP server, then the certificate revocation list (CRL) is used to check the status. The CRL URL is `http://1.1.1.1:8080/crl-as-der/currentcrl-45.crlid=45`.
- The CA certificate received in an OCSP response is not checked for certificate revocation. Certificates received in an OCSP response generally have shorter lifetimes and a revocation check is not required.

[Table 16 on page 304](#) shows the Phase 1 options used in this example.

Table 16: Phase 1 Options for OCSP Configuration Example

Option	Peer A	Peer B
IKE proposal	ike_policy_ms_2_2_0	ike_proposal_ms_2_0_0
Authentication method	rsa-signatures	rsa-signatures
DH group	group2	group2
Authentication algorithm	SHA 1	SHA 1
Encryption algorithm	3des-cbc	3des-cbc
Lifetime seconds	3000	3000
IKE policy	ike_policy_ms_2_2_0	ike_policy_ms_2_0_0
Mode	main	main
Proposal	ike_proposal_ms_2_2_0	ike_proposal_ms_2_0_0
Certificate	local7_neg	local7_moji
Policy	ike_policy	ike_policy
Gateway address	10.0.1.2	192.0.2.0
Remote identity	fqdn company.net	fqdn company.net
Local identity	fqdn company.net	fqdn company.net
External interface	ge-1/3/0	ge-1/3/0
Version	1	1

[Table 17 on page 305](#) shows the Phase 2 options used in this example.

Table 17: Phase 2 Options for OCSP Configuration Example

Option	Peer A	Peer B
IPsec proposal	ipsec_proposal_ms_2_2_0	ipsec_proposal_ms_2_0_0
Protocol	esp	esp
Authentication algorithm	hmac-sha1-96	hmac-sha1-96
Encryption algorithm	3des-cbc	3des-cbc
Lifetime seconds	2000	2000

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure VPN peer A to use OCSP:

1. Configure interfaces.

```
[edit interfaces]
set interfaces ge-1/3/0 unit 0 family inet address 10.0.1.2
set interfaces ms-2/2/0 unit 0 family inet
set interfaces ms-2/2/0 unit 1 family inet
set interfaces ms-2/2/0 unit 1 family inet6
set interfaces ms-2/2/0 unit 1 service-domain inside
set interfaces ms-2/2/0 unit 2 family inet
set interfaces ms-2/2/0 unit 2 family inet6
set interfaces ms-2/2/0 unit 2 service-domain outside
```

2. Configure the CA profile.

```
[edit security pki ca-profile Root]
set security pki ca-profile Root ca-identity Root
set security pki ca-profile Root enrollment url http://1.1.1.1:8080/scep/Root/
set security pki ca-profile Root revocation-check ocsf url
    http://10.157.88.56:8210/Root/
set security pki ca-profile Root revocation-check use-ocsp
set security pki ca-profile Root revocation-check ocsf
    disable-responder-revocation-check
set security pki ca-profile Root revocation-check ocsf connection-failure fallback-crl
```

3. Configure Phase 1 options.

```
[edit services ipsec-vpn ike proposal ike_proposal_ms_2_2_0]
set services ipsec-vpn ike proposal ike_proposal_ms_2_2_0 authentication-method
    rsa-signatures
set services ipsec-vpn ike proposal ike_proposal_ms_2_2_0 dh-group group2
set services ipsec-vpn ike proposal ike_proposal_ms_2_2_0 lifetime-seconds 3000
```

```
[edit services ipsec-vpn ike policy ike_policy_ms_2_2_0]
set services ipsec-vpn ike policy ike_policy_ms_2_2_0 mode main
set services ipsec-vpn ike policy ike_policy_ms_2_2_0 version 1
set services ipsec-vpn ike policy ike_policy_ms_2_2_0 proposals
    ike_proposal_ms_2_2_0
set services ipsec-vpn ike policy ike_policy_ms_2_2_0 local-id fqdn company.net
set services ipsec-vpn ike policy ike_policy_ms_2_2_0 local-certificate local7_neg
set services ipsec-vpn ike policy ike_policy_ms_2_2_0 remote-id fqdn company.net
```

4. Configure Phase 2 options.

```
[edit services ipsec-vpn ipsec proposal ipsec_proposal_ms_2_2_0]
set services ipsec-vpn ipsec proposal ipsec_proposal_ms_2_2_0 protocol esp
set services ipsec-vpn ipsec proposal ipsec_proposal_ms_2_2_0
    authentication-algorithm hmac-sha1-96
set services ipsec-vpn ipsec proposal ipsec_proposal_ms_2_2_0 encryption-algorithm
    3des-cbc
```

```
set services ipsec-vpn ipsec proposal ipsec_proposal_ms_2_2_0 lifetime-seconds
2000
```

```
[edit services ipsec-vpn ipsec policy ipsec_policy_ms_2_2_0]
set services ipsec-vpn ipsec policy ipsec_policy_ms_2_2_0 proposals
ipsec_proposal_ms_2_2_0
```

```
[edit services service-set ips_ssl]
set services service-set ips_ssl next-hop-service inside-service-interface ms-2/2/0.1
set services service-set ips_ssl next-hop-service outside-service-interface
ms-2/2/0.2
set services service-set ips_ssl ipsec-vpn-options local-gateway 10.0.1.2
set services service-set ips_ssl ipsec-vpn-rules vpn_rule_ms_2_2_01
```

```
[edit services ipsec-vpn rule vpn_rule_ms_2_2_01]
set services ipsec-vpn rule vpn_rule_ms_2_2_01 term term11 from source-address
203.0.113.0/24
set services ipsec-vpn rule vpn_rule_ms_2_2_01 term term11 from destination-address
198.51.100.0/24
set services ipsec-vpn rule vpn_rule_ms_2_2_01 term term11 then remote-gateway
192.0.2.0
set services ipsec-vpn rule vpn_rule_ms_2_2_01 term term11 then dynamic ike-policy
ike_policy_ms_2_2_0
set services ipsec-vpn rule vpn_rule_ms_2_2_01 term term11 then dynamic ipsec-policy
ipsec_policy_ms_2_2_0
set services ipsec-vpn rule vpn_rule_ms_2_2_01 match-direction input
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show security pki ca-profile Root**, **show services ipsec-vpn ike**, and **show services ipsec-vpn ipsec** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@host# show interfaces

```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure VPN peer B to use OCSP:

1. Configure interfaces.

```
[edit interfaces]
set interfaces ge-1/3/0 unit 0 family inet address 192.0.2.0/24
set interfaces ms-2/0/0 unit 0 family inet
set interfaces ms-2/0/0 unit 1 family inet
set interfaces ms-2/0/0 unit 1 family inet6
set interfaces ms-2/0/0 unit 1 service-domain inside
set interfaces ms-2/0/0 unit 2 family inet
set interfaces ms-2/0/0 unit 2 family inet6
set interfaces ms-2/0/0 unit 2 service-domain outside
```

2. Configure the CA profile.

```
[edit security pki ca-profile Root]
set security pki ca-profile Root ca-identity Root
set security pki ca-profile Root enrollment url http://1.1.1.1:8080/scep/Root/
set security pki ca-profile Root revocation-check ocsp url
    http://10.157.88.56:8210/Root/
set security pki ca-profile Root revocation-check use-ocsp
set security pki ca-profile Root revocation-check ocsp
    disable-responder-revocation-check
set security pki ca-profile Root revocation-check ocsp connection-failure fallback-crl
```

3. Configure Phase 1 options.

```
[edit services ipsec-vpn ike proposal ike_proposal_ms_2_0_0]
set services ipsec-vpn ike proposal ike_proposal_ms_2_0_0 authentication-method
    rsa-signatures
set services ipsec-vpn ike proposal ike_proposal_ms_2_0_0 dh-group group2
set services ipsec-vpn ike proposal ike_proposal_ms_2_0_0 lifetime-seconds 3000

[edit services ipsec-vpn ike policy ike_policy_ms_2_0_0]
set services ipsec-vpn ike policy ike_policy_ms_2_0_0 mode main
set services ipsec-vpn ike policy ike_policy_ms_2_0_0 version 1
set services ipsec-vpn ike policy ike_policy_ms_2_0_0 proposals
    ike_proposal_ms_2_0_0
set services ipsec-vpn ike policy ike_policy_ms_2_0_0 local-id fqdn company.net
set services ipsec-vpn ike policy ike_policy_ms_2_0_0 local-certificate local7_moji
set services ipsec-vpn ike policy ike_policy_ms_2_0_0 remote-id fqdn company.net
```

4. Configure Phase 2 options.

```
[edit services ipsec-vpn ipsec proposal ipsec_proposal_ms_2_0_0]
set services ipsec-vpn ipsec proposal ipsec_proposal_ms_2_0_0 protocol esp
set services ipsec-vpn ipsec proposal ipsec_proposal_ms_2_0_0
    authentication-algorithm hmac-sha1-96
set services ipsec-vpn ipsec proposal ipsec_proposal_ms_2_0_0 encryption-algorithm
    3des-cbc
set services ipsec-vpn ipsec proposal ipsec_proposal_ms_2_0_0 lifetime-seconds
    2000

[edit services ipsec-vpn ipsec policy ipsec_policy_ms_2_0_0]
set services ipsec-vpn ipsec policy ipsec_policy_ms_2_0_0 proposals
    ipsec_proposal_ms_2_0_0
```

```

[edit services service-set ips_ssl]
set services service-set ips_ssl next-hop-service inside-service-interface ms-2/0/0.1
set services service-set ips_ssl next-hop-service outside-service-interface
  ms-2/0/0.2
set services service-set ips_ssl ipsec-vpn-options local-gateway 192.0.2.0
set services service-set ips_ssl ipsec-vpn-rules vpn_rule_ms_2_0_01

[edit services ipsec-vpn rule vpn_rule_ms_2_0_01]
set services ipsec-vpn rule vpn_rule_ms_2_0_01 term term11 from source-address
  203.0.113.0/24
set services ipsec-vpn rule vpn_rule_ms_2_0_01 term term11 from destination-address
  198.51.100.0/24
set services ipsec-vpn rule vpn_rule_ms_2_0_01 term term11 then remote-gateway
  10.0.1.2
set services ipsec-vpn rule vpn_rule_ms_2_0_01 term term11 then dynamic ike-policy
  ike_policy_ms_2_0_0
set services ipsec-vpn rule vpn_rule_ms_2_0_01 term term11 then dynamic ipsec-policy
  ipsec_policy_ms_2_0_0
set services ipsec-vpn rule vpn_rule_ms_2_0_01 match-direction input

```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show security pki ca-profile Root**, **show services ipsec-vpn ike**, and **show services ipsec-vpn ipsec** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

[edit]
user@host# show interfaces

}
policy ipsec_policy_ms_2_0_0 {
  proposals ipsec_proposal_ms_2_0_0;
}

```

If you are done configuring the device, enter **commit** from configuration mode.

Verification

Confirm that the configuration is working properly.

- [Verifying CA Certificates on page 313](#)
- [Verifying Local Certificates on page 315](#)
- [Verifying IKE Phase 1 Status on page 316](#)
- [Verifying IPsec Phase 2 Status on page 317](#)

Verifying CA Certificates

Purpose Verify the validity of a CA certificate on each peer device.

Action From operational mode, enter the **show security pki ca-certificate ca-profile Root** or **show security pki ca-certificate ca-profile Root detail** command.

```

user@host> show security pki ca-certificate ca-profile Root
Certificate identifier: Root

```

NOTE: In this example, IP addresses are used in the URLs in the CA profile configuration. If IP addresses are not used with CA-issued certificates or CA certificates, DNS must be configured in the device's configuration. DNS must be able to resolve the host in the distribution CRL and in the CA URL in the CA profile configuration. Additionally, you must have network reachability to the same host to receive revocation checks.

Meaning The output shows the details and validity of CA certificate on each peer as follows:

- C—Country.
- O—Organization.
- CN—Common name.
- **Not before**—Begin date of validity.
- **Not after**—End date of validity.

Verifying Local Certificates

Purpose Verify the validity of a local certificate on each peer device.

Action From operational mode, enter the **show security pki local-certificate certificate-id localcert1 detail** command.

```
user@host> show security pki local-certificate certificate-id local7_neg detail

```

Meaning The output shows the details and validity of a local certificate on each peer as follows:

- **DC**—Domain component.
- **CN**—Common name.
- **OU**—Organizational unit.
- **O**—Organization.
- **L**—Locality
- **ST**—State.
- **C**—Country.
- **Not before**—Begin date of validity.
- **Not after**—End date of validity.

Verifying IKE Phase 1 Status

Purpose Verify the IKE Phase 1 status on each peer device.

Action From operational mode, enter the **show services ipsec-vpn ike security-associations** command.

```
user@host> show services ipsec-vpn ike security-associations
```

Remote Address	State	Initiator cookie	Responder cookie	Exchange type
192.0.2.0	Matured	63b3445edda507fb	2715ee5895ed244d	Main

From operational mode, enter the **show services ipsec-vpn ike security-associations detail** command.

```
user@host> show services ipsec-vpn ike security-associations detail
```

```
IKE peer 192.0.2.0
Role: Initiator, State: Matured
Initiator cookie: 63b3445edda507fb, Responder cookie: 2715ee5895ed244d
Exchange type: Main, Authentication method: RSA-signatures
Local: 10.0.1.2, Remote: 192.0.2.0
Lifetime: Expires in 788 seconds
Algorithms:
Authentication      : hmac-sha1-96
Encryption          : 3des-cbc
Pseudo random function: hmac-sha1
Diffie-Hellman group : 2
Traffic statistics:
Input bytes  :          3100
Output bytes :          4196
Input packets:           7
Output packets:          9
Flags: IKE SA created
IPSec security associations: 4 created, 4 deleted
```

Meaning The **flags** field in the output shows that, IKE security association is created.

Verifying IPsec Phase 2 Status

Purpose Verify the IPsec Phase 2 status on each peer device.

Action From operational mode, enter the **show services ipsec-vpn ipsec security-associations** command.

```
user@host> show services ipsec-vpn ipsec security-associations
```

```

EVPN Overview

An Ethernet VPN (EVPN) enables you to connect dispersed customer sites using a Layer 2 virtual bridge. As with other types of VPNs, an EVPN consists of customer edge (CE) devices (host, router, or switch) connected to provider edge (PE) routers. The PE routers can include an MPLS edge switch (MES) that acts at the edge of the MPLS infrastructure. Either an MX Series 3D Universal Edge Router or a standalone switch can be configured to act as an MES. You can deploy multiple EVPNs within a service provider network, each providing network connectivity to a customer while ensuring that the traffic sharing on that network remains private. [Figure 32 on page 321](#) illustrates a typical EVPN deployment. Traffic from Data Center 1 is transported over the service provider's network through MES1 to MES2 and then onto Data Center 2. DCS1, DCS2, DCS3, and DCS4 are the data center switches.

Figure 32: EVPN Connecting Data Center 1 and Data Center 2

The MESs are interconnected within the service provider's network using label-switched paths (LSPs). The MPLS infrastructure allows you to take advantage of the MPLS functionality provided by the Junos OS, including fast reroute, node and link protection, and standby secondary paths. For EVPNs, learning between MESs takes place in the control plane rather than in the data plane (as is the case with traditional network bridging). The control plane provides greater control over the learning process, allowing you to restrict which devices discover information about the network. You can also apply policies on the MESs, allowing you to carefully control how network information is distributed and processed. EVPNs utilize the BGP control plane infrastructure, providing greater scale and the ability to isolate groups of devices (hosts, servers, virtual machines, and so on) from each other.

The MESs attach an MPLS label to each MAC address learned from the CE devices. This label and MAC address combination is advertised to the other MESs in the control plane. Control plane learning enables load balancing and improves convergence times in the event of certain types of network failures. The learning process between the MESs and the CE devices is completed using the method best suited to each CE device (data plane learning, IEEE 802.1, LLDP, 802.1aq, and so on).

The policy attributes of an EVPN are similar to an IP VPN (for example, Layer 3 VPNs). Each EVPN routing instance requires that you configure a route distinguisher (RD) and one or more route targets (RTs). A CE device attaches to an EVPN routing instance on an MES through an Ethernet interface that might be configured for one or more VLANs.

The following features are available for EVPNs:

- Ethernet connectivity between data centers spanning metropolitan area networks (MANs) and WANs
- One VLAN for each MAC VPN
- Automatic RDs
- Dual-homed EVPN connection with active/standby multihoming
- Active/active multihoming is supported in Junos OS Releases 14.2R6 and above and 16.2 R1 and above. It is not supported in either Junos OS Release 15.1 or Junos OS Release 16.1.

The following feature is not supported for EVPNs:

- Graceful restart, graceful Routing Engine switchover (GRES), and nonstop active routing (NSR) is not supported in releases prior to Junos OS Release 16.1.

**Related
Documentation**

- [Supported EVPN Standards on page 323](#)
- [EVPN Overview on page 321](#)

Supported EVPN Standards

Junos OS supports the following RFCs and Internet drafts that define standards for EVPNs:

- RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*
- RFC 4761, *Virtual Private LAN Service (VPLS) Using BGP for Auto-Discovery and Signaling*
- RFC 7432, *BGP MPLS-Based Ethernet VPN*

The following features are not supported:

- Automatic derivation of Ethernet segment (ES) values. Only static ES configurations are supported.
- Host proxy ARP.
- MAC mobility extended community.
- VLAN bundle service interface.

- [EVPN Overview on page 321](#)
 - *Accessing Standards Documents on the Internet*

EVPN-ETREE Overview

The EVPN-ETREE service is a VPN service where each attachment circuit is designated as either root or leaf. The EVPN E-Tree feature implements E-Tree service as defined by the Metro Ethernet Forum (MEF) in draft-sajassi-l2vpn-evpn-etree-03. The E-Tree service is a rooted-multipoint service that is supported only with EVPN over MPLS in the core. The EVPN E-Tree feature provides a way to categorize the interfaces as either “root” or “leaf” in a routing instance. In an EVPN E-Tree service, each Customer Edge devices attached the service is either a root or a leaf. The EVPN E-Tree service adheres to the following forwarding rules:

- A leaf can send or receive traffic only from a root.
- A root can send traffic to another root or any of the leaves.
- A leaf or root can be connected to provider edge (PE) devices in singlehoming mode or multihoming mode.

Figure 33: EVPN E-TREE Service

The EVPN ETREE service has all the benefits of EVPN such as active-active multihoming, load balancing loop detection for E-Tree

In an EVPN ETREE service, the forwarding rule depends on the traffic source and destination. Table 1 shows the forwarding rules within the ETREE service.

Type of Traffic	Allowed/Not-Allowed	Filtering Location
Known Unicast Traffic from Root to Root	Allowed	
Known Unicast Traffic from Root to Leaf	Allowed	
BUM Traffic from Root to Root	Allowed	
BUM Traffic from Root to Leaf	Allowed	
Known Unicast Traffic from Leaf to Leaf	Not Allowed	At the ingress Packet Forwarding Engine
Known Unicast Traffic from Leaf to Root	Allowed	
BUM Traffic from Leaf to Leaf	Not Allowed	At the Egress Packet Forwarding Engine
BUM Traffic from Leaf to Root	Allowed	

If you do not configure a role for an interface, it will be assigned the role of “root” by default. All leaf interfaces are assigned a new mesh group with no local switching set to TRUE. This enables the ingress filtering for unicast traffic and all the leaf-to-leaf traffic will get dropped at ingress leaf interface. For BUM traffic, the filtering will happen at the egress Provider Edge based on the root/leaf label being carried in the packet.

NSR and Unified ISSU Support for EVPN-ETREE

Nonstop active routing (NSR) and graceful Routing Engine switchover (GRES) minimize traffic loss when there is a Routing Engine switchover. When a Routing Engine fails, NSR and GRES enable a routing platform with redundant Routing Engines to switch over from a primary Routing Engine to a backup Routing Engine and continue forwarding packets. Unified in-service software upgrade (ISSU) allows you to upgrade your Junos OS software on your MX Series router with no disruption on the control plane and with minimal disruption of traffic. Both GRES and NSR must be enabled to use unified ISSU.

To enable GRES, include the **graceful-switchover** statement at the **[edit chassis redundancy]** hierarchy level.

Junos OS mirrors essential data when NSR is enabled. For EVPN ETREE, the local EVPN ETREE leaf label that is advertised to other PE as part of the ETREE extended community will be mirrored on the standby Routing Engine. For information on other mirrored data and NSR data flow, see [“NSR and Unified ISSU Support for EVPN Overview” on page 497](#).

To enable NSR, include the **nonstop-routing** statement at the **[edit routing-options]** hierarchy level and the **commit synchronize** statement at the **[edit system]** hierarchy level.

Configuring Routing Instances for EVPN

- [Configuring EVPN Routing Instances on page 327](#)
- [EVPN Type-5 Route with VXLAN encapsulation for EVPN-VXLAN on page 330](#)
- [EVPN Type-5 Route with MPLS encapsulation for EVPN-MPLS on page 331](#)
- [Tracing EVPN Traffic and Operations on page 331](#)

Configuring EVPN Routing Instances

To configure an EVPN routing instance, complete the following configuration on the PE router (or on the MPLS edge switch) within the EVPN service provider's network:

1. Configure the EVPN routing instance name using the **routing-instances** statement at the **[edit]** hierarchy level:

```
routing-instances routing-instance-name {...}
```

2. Configure the **evpn** option for the **instance-type** statement at the **[edit routing-instances routing-instance-name]** hierarchy level:

```
instance-type evpn;
```

NOTE: For MX Series devices and EX Series switches, you can include multiple IFLs of an Ethernet segment identifier (ESI) across different bridge-domains of an EVPN routing instance in all-active mode. However, you cannot include multiple IFLs of the same ESI within the same bridge-domain.

3. Configure the interfaces for handling EVPN traffic between the MES and the CE device using the **interface** statement at the **[edit routing-instances routing-instance-name]** hierarchy level:

```
interface interface-name;
```

4. Configure a VLAN identifier for the EVPN routing instance using the **vlan-id** statement at the **[edit routing-instances routing-instance-name]** hierarchy level:

```
vlan-id (vlan-id | all | none);
```

5. Configure a route distinguisher on a PE router by including the **route-distinguisher** statement:

route-distinguisher (*as-number:number* | *ip-address:number*);

Each routing instance that you configure on a PE router must have a unique route distinguisher associated with it. VPN routing instances need a route distinguisher to help BGP to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs. If you configure different VPN routing instances with the same route distinguisher, the commit fails.

For a list of the hierarchy levels at which you can include this statement, see the statement summary for this statement.

The route distinguisher is a 6-byte value that you can specify in one of the following formats:

- **as-number:number**, where **as-number** is an autonomous system (AS) number (a 2-byte value) and **number** is any 4-byte value. The AS number can be in the range 1 through 65,535. We recommend that you use an Internet Assigned Numbers Authority (IANA)-assigned, nonprivate AS number, preferably the Internet service provider's (ISP's) own or the customer's own AS number.

NOTE: The automatic derivation of the BGP route target (auto-RT) for advertised prefixes is supported on a 2-byte AS number only.

- **ip-address:number**, where **ip-address** is an IP address (a 4-byte value) and **number** is any 2-byte value. The IP address can be any globally unique unicast address. We recommend that you use the address that you configure in the **router-id** statement, which is a nonprivate address in your assigned prefix range.

6. Configure either import and export policies for the EVPN routing table, or configure the default policies using the **vrf-target** statement configured at the **[edit routing-instances routing-instance-name]** hierarchy level.

See "Configuring Policies for the VRF Table on PE Routers in VPNs" on page 25.

7. Configure each EVPN interface for the EVPN routing instance:

NOTE: When adding a trunk port with dual tags to an EVPN and MPLS routing instance, or an EVPN and VXLAN routing instance, the CLI commit check configuration fails and generates an error. To avoid configuration check errors, use sub-interface style interface configuration with dual tags for the routing instances.

- a. Configure each interface using the **interface** statement at the **[edit routing-instances routing-instance-name protocols evpn]** hierarchy level.
- b. Configure interface encapsulation for the CE facing interfaces at the **[edit interfaces interface-name encapsulation]** hierarchy level. Supported encapsulations, except

for EX9200 switches, are: (**ethernet-bridge** | **vlan-bridge** | **extended-vlan-bridge**). Supported encapsulations for EX9200 switches are: (**extended-vlan-bridge** | **flexible-ethernet-services**).

- c. (Optional) Allow the EVPN to establish a connection to the CE device even if the CE device interface encapsulation and the EVPN interface encapsulations do not match by including the **ignore-encapsulation-mismatch** statement at the **[edit routing-instances routing-instance-name protocols evpn interface interface-name]** hierarchy level.
- d. (Optional) (Not available on EX9200 switches) Specify a static MAC address for a logical interface in a bridge domain using the **static-mac** statement at the **[edit routing-instances routing-instance-name protocols evpn interface interface-name]** hierarchy level.

- 8. Specify the maximum number of media access control (MAC) addresses that can be learned by the EVPN routing instance by including the **interface-mac-limit** statement.

You can configure the same limit for all interfaces configured for a routing instance by including this statement at the **[edit routing-instances routing-instance-name protocols evpn]** hierarchy level. You can also configure a limit for a specific interface by including this statement at the **[edit routing-instances routing-instance-name protocols evpn interface interface-name]** hierarchy level.

By default, packets with new source MAC addresses are forwarded after the MAC address limit is reached. You can alter this behavior by including the **packet-action drop** statement at either the **[edit routing-instances routing-instance-name protocols evpn interface-mac-limit]** or the **[edit routing-instances routing-instance-name protocols evpn interface interface-name]** hierarchy level. If you configure this statement, packets from new source MAC addresses are dropped once the configured MAC address limit is reached.

- 9. Specify the MPLS label allocation setting for the EVPN by including the **label-allocation** statement with the **per-instance** option at the **[edit routing-instances routing-instance-name protocols evpn]** hierarchy level.

If you configure this statement, one MPLS label is allocated for the specified EVPN routing instance.

- 10. Enable MAC accounting for the EVPN by including the **mac-statistics** statement at the **[edit routing-instances routing-instance-name protocols evpn]** hierarchy level.
- 11. Specify the number of addresses that can be stored in the MAC routing table using the **mac-table-size** statement at the **[edit routing-instances routing-instance-name protocols evpn]** hierarchy level.

You can optionally configure the **packet-action drop** option to specify that packets for new source MAC addresses be dropped once the MAC address limit is reached. If you do not configure this option, packets for new source MAC addresses are forwarded.

12. Disable MAC learning by including the **no-mac-learning** statement at either the **[edit routing-instances routing-instance-name protocols evpn]** hierarchy level to apply this behavior to all of the devices configured for an EVPN routing instance or at the **[edit routing-instances routing-instance-name protocols evpn interface interface-name]** hierarchy level to apply this behavior to just one of the CE devices.

EVPN Type-5 Route with VXLAN encapsulation for EVPN-VXLAN

EVPN is a flexible solution that uses Layer 2 overlays to interconnect multiple edges (virtual machines) within a data center. Traditionally, the data center is built as a flat Layer 2 network with issues such as flooding, limitations in redundancy and provisioning, and high volumes of MAC addresses learned, which cause churn at node failures. EVPN is designed to address these issues without disturbing flat MAC connectivity.

VXLAN is an overlay technology that encapsulates MAC frames into a UDP header at Layer 2. Communication is established between two virtual tunnel endpoints (VTEPs). VTEPs encapsulate the virtual machine traffic into a VXLAN header, as well as strip off the encapsulation. Virtual machines can only communicate with each other when they belong to the same VXLAN segment. A 24-bit virtual network identifier (VNID) uniquely identifies the VXLAN segment. This enables having the same MAC frames across multiple VXLAN segments without traffic crossover. Multicast in VXLAN is implemented as Layer 3 multicast, in which endpoints subscribe to groups.

When a Bridge Domain (BD) is not L2 extended across Data Centers (DC), the IP subnet belonging to the BD is confined within a single DC. If all BDs within each DC network satisfy this requirement, there is no longer a need to advertise MAC+IP route for each tenant between data centers as host routes for the tenants can be aggregated. Thus the L2 inter-DC connectivity issue can be simply transformed to an inter-DC L3 IP prefix reachability issue.

Starting with Junos OS Release 17.1, the EVPN type-5 IP prefix route advertises the IP prefixes between the DCs. Unlike the type-2 EVPN MAC advertisement route, the EVPN type-5 IP prefix route separates the host MAC address from its IP address and provides a clean advertisement of an IP prefix for the bridge domain.

Junos OS Release 17.1 also supports:

- Inter-DC connectivity with VXLAN encapsulation for EVPN/VXLAN by using the EVPN type 5 IP prefix route. Each BD within a DC is not L2 extended. If EVPN/VXLAN is enabled

between DC GW (Data Center Gateway) router and ToR while providing inter-DC connectivity, the spine, which acts as a DC GW router, is capable of performing L3 routing and IRB functions.

- Inter-pod connectivity with VXLAN encapsulation by using the EVPN type-5 IP prefix route. The solution provided does not address the L2 extension problem when a BD is stretched across different pods. The spines that provide the inter-pod connectivity is able to perform L3 routing and IRB functions.

EVPN Type-5 Route with MPLS encapsulation for EVPN-MPLS

EVPN is a flexible solution that uses Layer 2 overlays to interconnect multiple edges (virtual machines) within a data center. Traditionally, the data center is built as a flat Layer 2 network with issues such as flooding, limitations in redundancy and provisioning, and high volumes of MAC addresses learned, which cause churn at node failures. EVPN is designed to address these issues without disturbing flat MAC connectivity.

The MPLS infrastructure allows you to take advantage of the MPLS functionality provided by the Junos operating system (Junos OS), including fast reroute, node and link protection, and standby secondary paths.

Starting with Junos OS Release 17.1, to support the interconnection through EVPN type-5 route in the metro service application using EVPN/MPLS, an MPLS tunnel is required instead of a VXLAN tunnel.

NOTE: L3VPN forwarding based on pure type-5 without overlay next-hop is only supported.

In the control plane EVPN type-5 is used to advertise IP prefix for inter-subnet connectivity across metro peering points. To reach the end host through the connectivity provided by the EVPN type-5 prefix route, data packets are sent out as an IP packet encapsulated in the MPLS across the metro peering points.

Tracing EVPN Traffic and Operations

To configure the EVPN routing instance to trace a variety of different parameters related to EVPN operation:

1. Specify the name of one or more EVPN trace files using the **file** option for the **traceoptions** statement at the **[edit routing-instances routing-instance-name protocols evpn]** hierarchy level:

```
traceoptions {
```

```
    file filename <files number> <size size> <world-readable | no-world-readable>;  
}
```

The **file** option includes the following sub-options:

- **filename**—Specify the name of the file to receive the output of the tracing operation. Enclose the name within quotation marks. All files are placed in the directory **/var/log**.
- **files *number***—(Optional) Maximum number of trace files. When a trace file named **trace-file** reaches its maximum **size**, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the specified maximum **number** of trace files specified is reached. Then the oldest trace file is overwritten.
- **size *size***—(Optional) Maximum size of each trace file. When a trace file named **trace-file** reaches its maximum size, it is renamed **trace-file.0**, then **trace-file.1**, and so on, until the maximum number of trace files is reached. Then the oldest trace file is overwritten.
- **world-readable | no-world-readable**—(Optional) Enable unrestricted file access or restrict file access to the user who created the file.

2. Specify the **flag** option for the **traceoptions** statement:

```
traceoptions {  
    flag flag <flag-modifier> <disable>;  
}
```

The **flag** option allows you to specify the scope of the trace by including one of the following sub-options:

- **all**—All EVPN tracing options
- **error**—Error conditions
- **general**—General events
- **mac-database**—MAC route database in the EVPN routing instance
- **nlri**—EVPN advertisements received or sent by means of the BGP
- **normal**—Normal events
- **oam**—OAM messages
- **policy**—Policy processing
- **route**—Routing information
- **state**—State transitions
- **task**—Routing protocol task processing
- **timer**—Routing protocol timer processing
- **topology**—EVPN topology changes caused by reconfiguration or advertisements received from other PE routers using BGP

You can also specify one of the following modifiers for any of the traceoptions flags:

- **detail**—Provide detailed trace information.
- **disable**—Disable this trace flag.
- **receive**—Trace received packets.
- **send**—Trace sent packets.

Introduction to EVPN Multihoming

An Ethernet VPN (EVPN) comprises of customer edge (CE) devices that are connected to provider edge (PE) devices, which form the edge of the MPLS infrastructure. A CE device can be a host, a router, or a switch. The PE devices provide Layer 2 virtual bridge connectivity between the CE devices. There can be multiple EVPNs in the provider network. Learning between the PE routers occurs in the control plane using BGP, unlike traditional bridging, where learning occurs in the data plane.

NOTE: In releases earlier than Junos OS Release 15.1, EVPN functionality support on MX Series routers was limited to routers using MPC and MIC interfaces only. Starting with Junos OS Release 15.1, MX Series routers using DPCs can be leveraged to provide EVPN support on the CE device-facing interface.

DPC support for EVPN is provided with the following considerations:

- DPCs provide support for EVPN in the active-standby mode of operation including support for the following:
 - EVPN instance (EVI)
 - Virtual switch
 - Integrated routing and bridging (IRB) interfaces
- DPCs intended for providing the EVPN active-standby support must be the CE device-facing line card. The PE device in the EVPN domain must be MPC interfaces or MIC interfaces.

The EVPN multihoming feature enables you to connect a customer site to two or more PE devices to provide redundant connectivity. A CE device can be multihomed to different PE devices or the same PE device. A redundant PE device can provide network service to the customer site as soon as a failure is detected. Thus, EVPN multihoming helps to maintain EVPN service and traffic forwarding to and from the multihomed site in the event of the following types of network failures:

- PE device to CE device link failure
- PE device failure
- MPLS-reachability failure between the local PE device and a remote PE device

Starting in Junos OS Release 17.1, the EVPN multihoming feature enables you to connect a customer site to two or more provider edge (PE) devices to provide redundant connectivity. A customer edge (CE) device can be multihomed to different PE devices or the same PE device. A redundant PE device can provide network service to the customer site as soon as a failure is detected. Thus, EVPN multihoming helps maintain EVPN service and traffic forwarding to and from the multihomed site in case of network failures such as:

- Failure of the link between PE device to CE device.
- PE device failure.
- MPLS-reachability failure between the local PE device and a remote PE device.

[Figure 34 on page 337](#) illustrates how a CE device can multihomed to two PE routers. Device CE 1 is multihomed to Routers PE 1 and PE 2. Device CE 2 has two potential paths to reach Device CE 1, and depending on the multihoming mode of redundancy, only one path or both the paths are active at any time. The multihoming mode of operation also determines which PE router or routers forward traffic to the CE device. The PE router

forwarding traffic to the CE device (also called a designated forwarder) uses MPLS LSP or GRE tunnels to forward traffic. If a failure occurs over this path, a new designated forwarder is elected to forward the traffic to Device CE 1.

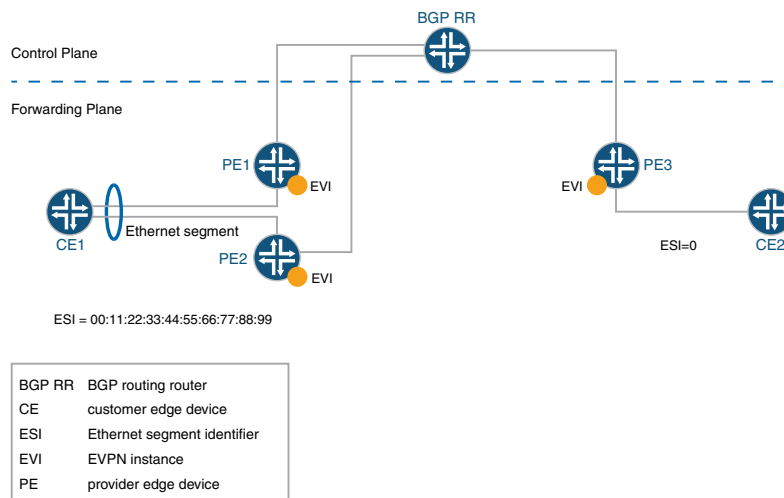

Figure 34: CE Device Multihomed to Two PE Routers

Understanding EVPN Multihoming Concepts

Figure 35 on page 338 shows a simple EVPN network topology to define EVPN multihoming concepts. .

Figure 35: Simple EVPN Topology

- **Ethernet segment**—When a CE device is multihomed to two or more PE routers, the set of Ethernet links constitutes an Ethernet segment. An Ethernet segment appears as a link aggregation group (LAG) to the CE device.

The links from Routers PE1 and PE2 to Device CE1 form an Ethernet segment.

In active-standby multihoming, the links that constitute an Ethernet segment form a bridge domain. In active-active multihoming, an Ethernet segment appears as a LAG to the CE device.

- **ESI**—An Ethernet segment must have a unique nonzero identifier, called the Ethernet segment identifier (ESI). The ESI is encoded as a 10-octet integer. When manually configuring an ESI value, the most significant octet, known as the type byte, must be 00. When a single-homed CE device is attached to an Ethernet segment, the entire ESI value is zero.

The Ethernet segment of the multihomed Device CE1 has an ESI value of 00:11:22:33:44:55:66:77:88:99 assigned. The single-homed Device CE2 has an ESI value of 0.

- **EVI**—An EVPN instance (EVI) is an EVPN routing and forwarding instance spanning all the PE routers participating in that VPN. An EVI is configured on the PE routers on a per-customer basis. Each EVI has a unique route distinguisher and one or more route targets.

An EVI is configured on Routers PE1, PE2, and PE3.

- **Ethernet tag**—An Ethernet tag identifies a particular broadcast domain, such as a VLAN. An EVPN instance consists of one or more broadcast domains. Ethernet tags

are assigned to the broadcast domains of a given EVPN instance by the provider of that EVPN. Each PE router in that EVPN instance performs a mapping between broadcast domain identifiers understood by each of its attached CE devices and the corresponding Ethernet tag.

- **Ethernet segment route**—The PE routers that are connected to a multihomed CE device use BGP Ethernet segment route messages to discover that each of the PE routers is connected to the same Ethernet segment. The PE routers advertise the Ethernet segment route, which consists of an ESI and ES-import extended community.

Routers PE1 and PE2 advertise an ES route with an ES-import extended community (along with other extended communities like the route target). The PE routers also construct a filter that is based on an ES-import extended community, which results in only these PE routers importing the ES route and identifying that they are connected to the same Ethernet segment.

- **Extended community**—An extended community is similar in most ways to a regular community. EVPNs use extended communities because the 4-octet regular community value does not provide enough expansion and flexibility. An extended community is an 8-octet value divided into two main sections.
- **BUM traffic**—This type of traffic is sent to multiple destinations, including broadcast traffic, unknown unicast traffic that is broadcast in the Ethernet segment, and multicast traffic.
- **DF**—When a CE device is multihomed to two or more PE routers, either one or all of the multihomed PE routers are used to reach the customer site depending on the multihoming mode of operation. The PE router that assumes the primary role for forwarding BUM traffic to the CE device is called the designated forwarder (DF).
- **BDF**—Each router in the set of other PE routers advertising the autodiscovery route per Ethernet segment for the same ESI, and serving as the backup path in case the DF encounters a failure, is called a backup designated forwarder (BDF). A BDF is also called a non-DF router.
- **DF election**—On every Ethernet segment, the PE routers participate in a procedure called *designated forwarder* election to select the DF and the BDF PE routers.

EVPN Multihoming Mode of Operation

The different modes of operation for EVPN multihoming include:

- **Single**—When a PE router is connected to a single-homed customer site, this mode is in operation. The *single* mode is the default mode of operation, and does not require Ethernet segment values to be configured.
- **Active-standby**—When only a single PE router, among a group of PE routers attached to an Ethernet segment, is allowed to forward traffic to and from that Ethernet segment, the Ethernet segment is defined to be operating in the *active-standby* redundancy mode.

To configure the active-standby mode, include the ESI value and the **single-active** statement under the **[edit interfaces]** hierarchy level.

- Active-active—When all PE routers attached to an Ethernet segment are allowed to forward traffic to and from the Ethernet segment, the Ethernet segment is defined to be operating in the *active-active* redundancy mode.

NOTE: In Junos OS Release 14.2 and earlier, the EX9200 Series switch supports only the active-standby mode of operation for EVPN multihoming.

NOTE: Starting with Junos OS Release 14.1x53-D30, QFX5100 switches support the active-active mode of operation for EVPN multihoming. In this scenario, QFX5100 switches function as top-of-rack (ToR) switches in the data center for virtual networks. EVPN multihoming active-active functionality is used to provide access to the bare-metal servers connected to the top-of-rack switches.

NOTE: Starting with Junos OS Release 14.1R4, 14.2, 15.1F6, and 16.1R1, Junos OS supports the active-active mode for EVPN multihoming on MX Series routers.

Starting with Junos OS Releases 16.1R4 and 16.2R2, all EX9200 switches support the active-active mode for EVPN multihoming.

To configure the active-active mode, include the ESI value and the **all-active** statement at the **[edit interfaces]** hierarchy level.

Figure 36 on page 340 shows a reference topology for EVPN active-active multihoming. The ESI1 Ethernet segment for Device CE2 is multihomed to Routers PE1, PE2, and PE3. The Ethernet segment on the CE device can either be configured as a link aggregation group (LAG) or as an ECMP path. Devices CE1 and CE3 are the single-homed customer edge devices and have an ESI value of 0.

Figure 36: Active-Active EVPN Multihoming

EVPN Multihoming Implementation

The EVPN active-standby multihoming mode of operation provides redundancy for access link failures and PE node failure for the multihomed CE device, and is based on the EVPN *draft-ietf-l2vpn-evpn-03*.

The Junos OS implementation of the EVPN multihoming active-standby and active-active modes of operation includes the following:

- [New BGP NLRIs on page 341](#)
- [New Extended Communities on page 344](#)
- [New EVPN Route Types on page 346](#)
- [Update to the MAC Forwarding Table on page 347](#)
- [Traffic Flow on page 347](#)
- [Aliasing on page 349](#)
- [EVPN Active-Active Multihoming and Multichassis Link Aggregation on page 351](#)
- [EVPN Active-Active Multihoming and IRB on page 351](#)
- [Sample Configuration on page 351](#)

New BGP NLRIs

To support EVPN multihoming, the following new BGP network layer reachability information (NLRI) routes have been introduced:

- [Autodiscovery Route per Ethernet Segment on page 341](#)
- [Ethernet Segment Route on page 343](#)
- [Autodiscovery Route per EVPN Instance on page 343](#)

Autodiscovery Route per Ethernet Segment

- [Autodiscovery Route Features on page 341](#)
- [Autodiscovery Route Advertisement on page 342](#)
- [Autodiscovery Route Withdrawal on page 342](#)

Autodiscovery Route Features

The autodiscovery route NLRI features include:

- This is a Type 1 mandatory route, used for fast convergence and for advertising the split horizon label. It is also known as the mass withdraw route.
- Type 1 route distinguishers are used with the IP address (loopback) of the originating PE router as the route distinguisher value.
- This route carries the ESI in the NLRI (nonzero when it is a multihomed PE, zero otherwise).
- The split horizon label is per ESI only, and carries an explicit NULL (0).
- The bit in the active-standby flag field in the ESI label extended community is used for signaling the active-standby mode (bit set).

- The 3-byte label values in the NLRI and the Ethernet tag is zero.
- This route is advertised and imported by all multihomed and remote PE routers that share the same EVI on the advertising ESI.

Autodiscovery Route Advertisement

- Active-standby mode

In active-standby mode, the designated forwarder (DF) advertises the autodiscovery route per Ethernet segment with an ESI MPLS label extended community that has the standby bit set to 1. The autodiscovery route is advertised per ESI, and the ESI label is set to 0 when active-standby mode is in operation.

The autodiscovery route is imported by all the multihomed and remote PE routers that are part of the EVI. On receiving the autodiscovery route, the PE routers in the network topology learn that active-standby multihoming mode is in operation for the ESI advertised.

- Active-active mode

In active-active mode, each of the multihomed PE device advertises a mandatory autodiscovery route per Ethernet segment as in the active-standby state. However, in the active-active state, the autodiscovery route per Ethernet segment is modified such that the active-standby bit carried in the MPLS extended community is cleared to indicate that the active-active mode is in operation. The autodiscovery route per Ethernet segment in the active-active mode also includes the split horizon label.

In [Figure 36 on page 340](#), for the ESI1 Ethernet segment, Routers PE1, PE2, and PE3 advertise the autodiscovery route. Router PE4 receives this autodiscovery route.

Autodiscovery Route Withdrawal

The autodiscovery route per Ethernet segment withdrawal is also referred to as the mass withdrawal. The mass withdrawal feature is used when there is a link failure on the ESI, or when the ESI configuration changes.

When the link between a multihomed CE device and a multihomed PE device fails, the PE device withdraws the autodiscovery route per Ethernet segment. In such a case, the mass withdrawal feature is handled in the following ways by the other PE devices:

- Remote PE device

When a remote PE device receives the BGP update for mass withdrawal, the following is performed at the remote PE device:

1. The current next hop to reach the remote ESI or CE device is deleted.
2. A new next hop through the remaining multihomed PE devices is created to reach the remote ESI or CE device.
3. All the MAC routes behind the CE device are updated with the newly created next hop.

- Other multihomed PE device

As a result of the mass withdrawal, load balancing on the multihomed CE device happens because of the following:

- When the other multihomed PE devices receive the same set of MAC addresses on the link to the concerned ESI.

In this case, the local routes are preferred. If the remote routes learned from the DF PE device gets withdrawn, it does not affect routes pointing to the local ESI.

- When the other multihomed PE devices have not received the same set of MAC addresses on the link to the concerned ESI.

In this case, the PE devices install the MAC routes pointing to the concerned ESI, although the MACs are remotely learned from the DF PE device. When the DF PE device withdraws these routes, the withdrawn routes are flushed. Packets that are destined to the flushed MAC addresses are flooded on all the local segments.

Ethernet Segment Route

- [Ethernet Segment Route Features on page 343](#)
- [Ethernet Segment Route Advertisement on page 343](#)

Ethernet Segment Route Features

The Ethernet segment route NRLI features include:

- This is a Type 4 route. The purpose of this route is to enable the PE routers connected to the same Ethernet segment to automatically discover each other with minimal configuration on exchanging this route.
- This route is associated with an ES-import extended community with an ESI value condensed to 6 bytes, similar to a route target.
- This route is advertised and imported only by PE routers that are multihomed on the advertising Ethernet segment.

Ethernet Segment Route Advertisement

The Ethernet segment route is exchanged among all the PE routers within a data center with the ES-import extended community. The ES-import extended community is constructed based on the ESI PE routers that are multihomed, and the Ethernet segment route carries the ESI value related to the Ethernet segment on which the PE routers are multihomed.

The Ethernet segment routes are filtered based on the ES-import extended community, such that only the PE routers that are multihomed on the same Ethernet segment import this route. Each PE router that is connected to a particular Ethernet segment constructs an import filtering rule to import a route that carries the ES-import extended community.

Autodiscovery Route per EVPN Instance

In active-active mode, each of the multihomed PE devices advertise an autodiscovery route per EVPN instance (EVI) with a valid MPLS label. This route is advertised per ESI

and is imported by the remote PE devices. The MPLS label included in the autodiscovery route per EVI is used later for aliasing.

New Extended Communities

An extended community is similar in most ways to a regular community. Some networking implementations, such as virtual private networks (VPNs), use extended communities because the 4-octet regular community value does not provide enough expansion and flexibility. An extended community is an 8-octet value divided into two main sections.

To support active-standby multihoming, the following extended communities have been introduced:

- [ESI-Import on page 344](#)
- [Split Horizon on page 344](#)

ESI-Import

This extended community is attached to the ES route, and is populated from the ESI-import value extracted from the configured ESI value under the interface. To solve the problem of a conflict with another regular route target, the type is set to 0x06, which has been allocated by IANA.

The ESI-import extended community route target populates the list of import route targets configured for the special instance from where the ES route using this community is advertised.

Therefore, incoming ESI routes with the same ESI-import value in the extended community are imported by the PE routers, if the PE router is configured with an Ethernet segment that has the same ESI value. Once the PE router receives a set of these ESI routes that have the same ESI-import extended community value, the DF and BDF election can be done locally.

NOTE: When the ESI-import extended community is not created implicitly, a policy must be configured to attach all the route targets to the autodiscovery route per Ethernet segment.

Split Horizon

With reference to [Figure 36 on page 340](#) for example, when a CE device that is multihomed to two or more PE devices on an Ethernet segment (ESI1) and operating in the active-active redundancy mode sends a BUM packet to one of the non-DF PE devices (say PE1), then Device PE1 forwards that packet to all or a subset of the other PE devices in that EVPN instance, including the DF PE device for that Ethernet segment. In this case the DF PE device that the CE device is multihomed to drops the packet without forwarding it back to the CE device. This filtering is referred to as split horizon.

- Split horizon signaling

The split horizon extended community is attached to the autodiscovery route per Ethernet segment. The value of the extended community is the split horizon or the Poisson label itself, which is 3 bytes, and is advertised as an opaque attribute.

- Split horizon advertisement
 - In active-standby mode, the standby bit in the split horizon extended community is set to 1, and the ESI split horizon label is set to 0.
 - In the active-active mode, the split horizon extended community is modified to clear the standby bit to 0 and includes a valid ESI label used for split horizon purposes.

- Split horizon MPLS routes

The DF PE device advertises an autodiscovery route per Ethernet segment with a split horizon label A, and an inclusive multicast route with label B for BUM traffic forwarding. On the DF, the BUM packet from the core can come with following labels:

- When the non-DF PE devices receive a BUM packet on their single-homed ESIs, the BUM packet is sent to the DF PE device with multicast label B.
- When the non-DF PE devices receive a BUM packet on ESII, the BUM packet is sent to the DF PE device with two MPLS labels — the multicast label B as the outer label, and the split horizon label A as the inner label.

In the EVPN multihoming scenario, the multicast label B has the S-bit set to 1 when it is the only label in the label stack. In this case, the BUM packet needs to be flooded on all the local ESIs on the DF PE device. But the label B has the S-bit set to 0 when split horizon label A is the innermost label in the label stack. In this case, the BUM packets need to be flooded on all local ESIs on the DF PE device, except the ESI that maps to the split horizon label A.

Assuming that packets originated from a multihomed CE device to a non-DF PE device on multihomed segment ESII, when the non-DF PE device sends this packet to the DF PE device, the ESI label that the DF advertised to the non-DF PE device in its autodiscovery route per Ethernet segment is pushed first. The non-DF PE device also pushes the inclusive multicast label that the DF PE device advertised in its inclusive multicast route and further pushes the LSP label. The MPLS header thus contains two labels within a 32-bit field.

The base EVPN functionality uses a table-next hop to stitch the MPLS table with its corresponding EVPN EVI table. In the EVPN EVI table, the mac-lookup is performed to switch the packet.

The following routes are programmed in the mpls.0 table for EVPN multicast:

- The (multicast-label, S=1) route points to the EVPN-EVI table-next hop.
- The (multicast-label, S=0) route points to the MPLS table-next hop. This route loops the packet back to the MPLS table after popping the multicast-label.
- The (split horizon-label) route points to the EVPN-EVI table-next hop. This is the same table-next hop that is used by the multicast-label, S=1 route.

New EVPN Route Types

EVPN multihoming mode supports the following EVPN route types:

- Autodiscovery route per Ethernet segment
- Autodiscovery route per EVPN instance (EVI)
- Ethernet segment route

These route types conform to the following naming convention:

<route-type>:<RD>::<esi>::<route-specific>/304

For example:

Autodiscovery route per Ethernet
segment—1:10.255.0.2:0::112233445566778899::0/304

Autodiscovery route per EVI—1:100.100.100.1:1::22222222222222222222::0/304

Ethernet segment route—4:10.255.0.1:0::112233445566778899:10.255.0.1/304

where:

- **route-type**—Type of EVPN route.
 - 1—Autodiscovery route per Ethernet segment.
 - 1—Autodiscovery route per EVI.
 - 4—Ethernet segment route.
 - 5—Route with VXLAN/MPLS encapsulation
- **RD**—Route distinguisher value.

The route distinguisher value is set to the IP address of the PE router followed by 0.
- **esi**—Ethernet segment identifier. Displayed as 10 bytes of hexadecimal bytes, and leading 00 bytes are not displayed.
- **route-specific**—Differs per route type.
 - Autodiscovery route per Ethernet segment and autodiscovery route per EVI—This value is an MPLS label.

NOTE: The MPLS label is displayed in the extensive output, although it is not included in the prefix.

- Ethernet segment route—This value is the originating IP address.
- **304**—Maximum number of bits in an EVPN route. This is not very useful information and could be removed from the display. However, it might be useful in quickly identifying an EVPN route, either visually or with match operators.

Update to the MAC Forwarding Table

In active-standby EVPN multihoming, the MAC addresses are treated as routable addresses, and the MP-IBGP protocol is used to carry the customer MAC addresses. MAC learning at the PE routers does not occur in the data plane but in the control plane. This leads to more control applied in terms of the learning mechanism.

A PE router performs MAC learning in the data plane for packets coming from a customer network for a particular EVI. For CE MAC addresses that are behind other PE routers, the MAC addresses are advertised in BGP NLRI using a new MAC advertisement route type.

The MAC learning is of two types:

- Local MAC learning—PE routers must support the local MAC learning process through standard protocols.
- Remote MAC learning—Once the local learning process is completed, the PE routers can advertise the locally learned MAC address to remote PE router nodes through MP-IBGP. This process of receiving the remote MAC addresses of attached customers through MP-IBGP is known as the remote MAC learning process.

The MAC advertisement route type is used to advertise locally learned MAC addresses in BGP to remote PE routers. If an individual MAC address is advertised, the IP address field corresponds to that MAC address. If the PE router sees an ARP request for an IP address from a CE device, and if the PE router has the MAC address binding for that IP address, the PE router performs ARP proxy and responds to the ARP request.

NOTE: The ARP proxy is performed only for the gateway and not for the host.

The MPLS label field depends on the type of allocation. The PE router can advertise a single MPLS label for all MAC addresses per EVI, which requires the least number of MPLS labels and saves the PE router memory. However, when forwarding to the customer network, the PE router must perform a MAC lookup which can cause a delay and increase the number of CPU cycles.

Traffic Flow

In EVPN multihoming, traffic flow is performed in the forwarding-plane. Flood routes are created for flooding the packets, and are used in the following scenarios:

- When a packet is received on a local ESI
- When a packet is received from the core

The traffic flows in EVPN multihoming can be based on the two traffic types:

- Unicast traffic

Unicast traffic is a point-to-point communication with one sender and one receiver. In a multihomed EVPN, unicast traffic is forwarded as follows:

- In active-standby mode

- CE to core—Traffic is learned and forwarded by the DF PE router.
- Core to CE—The remote PE router learns the MAC addresses from the DF, and forwards all unicast traffic to the DF PE router.
- In active-active mode
 - CE to core—Traffic is load-balanced to all the connected multihomed PE devices.
 - Core to CE—Traffic from the remote PE devices is load-balanced to all the multihomed PE devices connected to the remote CE device.
- BUM traffic

Traffic that is sent to multiple destinations, including broadcast traffic, unknown unicast traffic that is broadcast in the Ethernet segment, and multicast traffic is known as BUM traffic. In a multihomed EVPN, BUM traffic is forwarded as follows:

- In active-standby mode
 - CE to core—The CE device floods any BUM traffic to all the links in the Ethernet segment. The DF PE router with the active path forwards the BUM packets to the core. The BDF PE router in the standby mode drops all the traffic from the CE device, because the EVPN multihomed status of the interface is in blocking state.
 - Core to CE—The remote PE routers flood all BUM traffic to both the DF and BDF PE routers. Only the DF forwards the BUM traffic to the CE device. The BDF PE router drops all the traffic, because the EVPN multihomed status of the interface is in blocking state.

- In active-active mode

Based on the requirements, flooding and switching among local ESIs can be enabled or disabled in the active-active mode. This is referred to as the no-local-switching behavior.

The core of EVPN service provides a full-mesh connectivity among the multihomed PE devices. Because of this, EVPN uses split horizon in the core, so a packet received from the core is never switched or flooded back to the core. Instead, ingress replication is used to replicate the packets to the remote PE devices.

To flood packets to remote PE devices, the multicast and the split horizon next hops are used. The multicast next hop tunnels the packet with the inclusive multicast label, and the split horizon next hop tunnels the packet with a multicast-label and a split horizon label. One such next hop is required per multihomed ESI per remote PE device.

The following flood routes are used in the active-active mode:

- All-CE flood route

This flood route is used by the local ESIs for the following:

- Flooding the packet on the local ESIs (when local-switching is allowed).
- Flooding the packet to the remote PE devices. The remote PE devices flood the packet on their local ESIs.

Because BUM traffic is forwarded only by the Designated Forwarder (DF), and not by the non-DF multihomed PE devices, the non-DFs use the split horizon next hop to flood this packet to other PE devices. However, the multihomed local ESIs for which the PE device is a non-DF does not participate in the flooding.

The all-CE flood route is not used by the non-DF ESIs, and the next hop for these flood routes is created accordingly. In such cases, the non-DF ESI flood route is used.

- All-VE flood route

This flood route is used when the packet is received from the core. It is used for flooding the packet received from the core to the local ESIs. Because the packet received from the core can come with multicast-label only or with both multicast-label and split horizon label, appropriate forwarding rules must be followed to drop the packet on the multihomed ESI that maps to the split horizon label.

- Non-DF flood route

This flood route is used for the following:

- Flooding the packet on the local ESIs.
- Flooding the packet to the remote PE devices using ingress replication with SH-label for the DF for the ESI.

Aliasing

Starting in Junos OS Release 15.1, Junos OS supports aliasing in an EVPN. Aliasing is the ability of a remote PE device to load balance Layer 2 unicast traffic on all the other PE devices that have same Ethernet segment towards a CE device.

- [Aliasing in the Active-Active Mode on page 349](#)
- [Aliasing and Autodiscovery Routes on page 350](#)
- [Aliasing and Label Route on page 350](#)
- [Aliasing and Unicast Packet Forwarding on page 350](#)

Aliasing in the Active-Active Mode

In [Figure 36 on page 340](#), aliasing in the active-active mode works as follows:

1. ESI1 is configured on Routers PE1, PE2, and PE3. Routers PE1, PE2, and PE3 advertise the autodiscovery route per Ethernet segment for ESI1.
2. Device CE1 sends Layer 2 traffic with source MAC address (MAC1) to Router PE1.
3. Router PE1 learns the MAC1 address on (ESI1, vlan X) and advertises it to all PE routers using BGP.

4. Router PE4 receives the MAC1 route through BGP.
5. Because Router PE4 also received the autodiscovery route per EVI from Routers PE2 and PE3, it knows that MAC1 must be reachable through Routers PE2 and PE3. Router PE4 builds its forwarding state to load-balance the Layer 2 traffic for MAC1 among Routers PE1, PE2, and PE3.

Aliasing and Autodiscovery Routes

Autodiscovery routes from Routers PE2 and PE3 can come in any order. As a result, these routes are installed by the Layer 2 process as follows:

1. After receiving MAC1 from Router PE1, and if any autodiscovery routes have not been received by Router PE4, MAC1 is programmed by PE4 with a next hop pointing toward Router PE1. When PE4 receives the autodiscovery route from Router PE2 for the same ESI, the next hop is installed so the traffic for MAC1 is load-balanced to Routers PE1 and PE2. When PE4 receives the autodiscovery route from Router PE3 for the same ESI, the next hop is updated to load-balance the traffic for MAC1 among Routers PE1, PE2, and PE3.
2. If Router PE4 has already received the autodiscovery routes from more than one PE device (PE1, PE2, and PE3), PE4 installs the MAC routes with the multi-destination next hop.

Aliasing and Label Route

Any PE device that advertises the autodiscovery route per EVI with a valid MPLS label programs the advertised label in the mpls.0 routing table. For instance, if Router PE2 advertised the autodiscovery route per EVI with label A, the mpls.0 entry is as follows:

Label A route points to the EVPN-EVI table-next hop.

When the remote Router PE4 sends a unicast data packet toward Router PE2 with this label A, lookup is done in Router PE2's forwarding table, and as a result of this lookup, the packet is forwarded on ESI1.

Aliasing and Unicast Packet Forwarding

When the unicast packets for MAC1 come from the remote Router PE4 to Router PE2, there could be two cases:

- Router PE2 also received the same set of MACs on its link to ESI1—In this case, local routes are preferred and as a result of the MAC lookup, packets are forwarded to ESI1.
- Router PE2 has not received the same set of MACs on its link to ESI1—In this case, Router PE2 still installs MAC routes pointing to ESI1, although MACs are remotely learned from Router PE1. As a result, the packets are forwarded to ESI1.

EVPN Active-Active Multihoming and Multichassis Link Aggregation

When a CE device is configured with a LAG toward the PE devices, the following two options are available to run LACP on the PE devices:

- Configure the same LACP system ID on all the PE devices.
- Configure multichassis link aggregation on the PE devices.

When multichassis link aggregation is configured with EVPN, a reduced set of procedures for active-active multichassis link aggregation are required. These procedures provide link and node level redundancy. The multichassis link aggregation is completely transparent to the CE device, and is realized as pure LAG. Multichassis link aggregation operates at the port level as well. This essentially means that if multichassis link aggregation is configured as active-active, all VLANs on the multichassis link aggregation ports work in the active-active multihoming mode.

When multichassis link aggregation is configured along with EVPN, the following is considered:

- Both multichassis link aggregation and EVPN ESI must be enabled to work in the active-active mode only.
- The following functions are not required for multichassis link aggregation with EVPN:
 - Mac synchronization—This is performed in the BGP control plane of EVPN.
 - ICL linking—This is handled by the aliasing feature of EVPN.
 - ARP synchronization—This is handled by the BGP control plane with IRB functionality.

EVPN Active-Active Multihoming and IRB

When IRB is configured, the EVPN routes contain both MAC and IP information. The active-active multihoming requires ARP synchronization among the multihomed PE devices because the ARP responses can get hashed to a particular PE device.

Sample Configuration

The following is a sample configuration for EVPN active-standby multihoming on the following types of interfaces:

- Ethernet interface configuration

```
ge-0/1/2 {
  encapsulation ethernet-bridge;
  esi XX:XX:XX:XX:XX:XX:XX:XX:XX:XX;
  unit 0 {
    family bridge;
  }
}
```
- Single VLAN interface configuration

```
ge-0/1/3 {
  encapsulation extended-vlan-bridge;
```

```
esi XX:XX:XX:XX:XX:XX:XX:XX:XX;
vlan-tagging
unit 0 {
    family bridge;
    vlan-id 1;
}
}
```

**NOTE:**

- An ESI value of 0 and all FFs are reserved and are not used for configuring a multihomed Ethernet segment.
- Two interfaces in the same EVI cannot be configured with the same ESI value.

The following is a sample routing instance configuration for EVPN active-standby multihoming:

- Routing instance configuration

```
routing-instances {
    evpn-0 {
        instance-type evpn;
        route-distinguisher value;
        vrf-target value;
        vlan-id vlan-ID;
        interface ge-0/1/2.0;
        interface ge-1/1/1.0;
        interface ge-2/2/2.0;
        protocols {
            evpn {
                designated-forwarder-election hold-time time;
            }
        }
    }
}
```

NOTE: With the active-standby mode configuration, the autodiscovery route per Ethernet segment is advertised with the active-standby bit set to 1 for each Ethernet segment.

Designated Forwarder Election

The following sections discuss DF election:

- [DF Election Roles on page 353](#)
- [DF Election Procedure on page 353](#)
- [DF Election Trigger on page 354](#)

- [DF Election for Virtual Switch on page 354](#)
- [Handling Failover on page 355](#)

DF Election Roles

The designated forwarder (DF) election process involves selecting the designated forwarder (DF) PE router and the backup designated forwarder (BDF) or a non-DF (non-designated forwarder PE router roles.

- **DF**—The MAC address from the customer site is reachable only through the PE router announcing the associated MAC advertisement route. This PE router is the primary PE router that is selected to forward BUM traffic to the multihomed CE device, and is called the designated forwarder (DF) PE router.
- **BDF**—Each PE router in the set of other PE routers advertising the autodiscovery route per Ethernet segment for the same ESI, and serving as the backup path in case the DF encounters a failure, is called a backup designated forwarder (BDF) or a non-DF (non-designated forwarder) PE router.

As a result of the DF election process, if a local PE router is elected as the BDF, the multihomed interface connecting to the customer site is put into a blocking state for the active-standby mode. The interface remains in the blocking state until the PE router is elected as the DF for the Ethernet segment that the interface belongs to.

DF Election Procedure

The default procedure for DF election at the granularity of the ESI and EVI is referred to as service carving. With *service carving*, it is possible to elect multiple DFs per Ethernet segment (one per EVI) in order to perform load-balancing of multidestination traffic destined for a given Ethernet segment. The load-balancing procedures carve up the EVI space among the PE nodes evenly, in such a way that every PE is the DF for a disjoint set of EVIs.

The procedure for service carving is as follows:

1. When a PE router discovers the ESI of the attached Ethernet segment, it advertises an autodiscovery route per Ethernet segment with the associated ES-import extended community attribute.
2. The PE router then starts a timer (default value of 3 seconds) to allow the reception of the autodiscovery routes from other PE nodes connected to the same Ethernet segment. This timer value must be the same across all the PE routers connected to the same Ethernet segment.

The default wait timer can be overwritten using the **designated-forwarder-election hold-time** configuration statement.

3. When the timer expires, each PE router builds an ordered list of the IP addresses of all the PE nodes connected to the Ethernet segment (including itself), in increasing numeric order. Every PE router is then given an ordinal indicating its position in the ordered list, starting with 0 as the ordinal for the PE with the numerically lowest IP

address. The ordinals are used to determine which PE node is the DF for a given EVI on the Ethernet segment.

4. The PE router that is elected as the DF for a given EVI unblocks traffic for the Ethernet tags associated with that EVI. The DF PE unblocks multideestination traffic in the egress direction toward the Ethernet segment. All the non-DF PE routers continue to drop multideestination traffic (for the associated EVIs) in the egress direction toward the Ethernet segment.

In [Figure 36 on page 340](#), the election of the DF for active-active multihoming is performed among Routers PE1, PE2, and PE3. As a result of this DF election, each one of these routers can become the DF for a particular VLAN from a range of VLANs configured on ESI1. The DF is responsible for forwarding BUM traffic on that ESI and VLAN for which it is elected as the DF. The non-DF PE routers block the BUM traffic on that particular Ethernet segment.

DF Election Trigger

In general, a DF election process is triggered in the following conditions:

- When an interface is newly configured with a nonzero ESI, or when the PE router transitions from an isolated-from-the-core (no BGP session) state to a connected-to-the-core (has established BGP session) state, a wait timer is imposed. By default, the interface is put into a blocking state until the PE router is elected as the DF.
- After completing a DF election process, a PE router receives a new Ethernet segment route or detects the withdrawal of an existing Ethernet segment route, without an imposed wait timer.
- When an interface of a non-DF PE router recovers from a link failure, the PE router has no knowledge of the wait time imposed by other PE routers. As a result, no wait timer is imposed for the recovered PE router to avoid traffic loss.

DF Election for Virtual Switch

The virtual switch allows multiple bridge domains in a single EVPN instance (EVI). The virtual switch also supports trunk and access ports. Junos OS allows flexible Ethernet services on the port, therefore different VLANs on a single port can be part of different EVIs.

The DF election for virtual switch depends on the following:

- Port mode—Sub-interface, trunk interface, and access port
- EVI mode—Virtual switch with EVPN and EVPN-EVI

In the virtual switch, multiple Ethernet tags can be associated with a single EVI, wherein the numerically lowest Ethernet tag value in the EVI is used for the DF election.

Handling Failover

A failover can occur when:

- The DF PE router loses its DF role.
- There is a link or port failure on the DF PE router.

On losing the DF role, the customer-facing interface on the DF PE router is put in the blocking state.

In the case of link or port failure, a DF election process is triggered, resulting in the BDF PE router to be selected as the DF. At that time, unicast traffic and BUM flow of traffic are affected as follows:

- [Unicast Traffic on page 355](#)
- [BUM Traffic on page 355](#)

Unicast Traffic

- CE to Core—The CE device continues to flood traffic on all the links. The previous BDF PE router changes the EVPN multihomed status of the interface from the blocking state to the forwarding state, and traffic is learned and forwarded through this PE router.
- Core to CE—The failed DF PE router withdraws the autodiscovery route per Ethernet segment and the locally-learned MAC routes, causing the remote PE routers to redirect traffic to the BDF.

NOTE: The transition of the BDF PE router to the DF role can take some time, causing the EVPN multihomed status of the interface to continue to be in the blocking state, resulting in traffic loss.

BUM Traffic

- CE to Core—All the traffic is routed toward the BDF.
- Core to CE—The remote PE routers flood the BUM traffic in the core.

Convergence in an EVPN Network

When there are changes in the network topology in a large-scale EVPN system, the convergence time might be significant. You can prioritize NLRI updates that are critical to route selection in routing policies to improve convergence. [Table 18 on page 355](#) lists the NLRI route types and the priority that must be configured in the routing policy.

Table 18: Priority for NLRI Route Type

NLRI Route Type	Description	Priority
NLRI Route Type 1	Ethernet auto-discovery route—Type 1 supports fast convergence and aliasing and is used to signal MAC mass withdrawal.	High

Table 18: Priority for NLRI Route Type (*continued*)

NLRI Route Type	Description	Priority
NLRI Route Type 2	MAC/IP advertisement route—Type 2 is used to advertise MAC addresses and IP addresses in EVPN networks.	Low
NLRI Route Type 3	Inclusive multicast Ethernet tag—Type 3 is used to set up a path for BUM traffic.	Low
NLRI Route Type 4	Ethernet segment route—Type 4 is used in the selection of a designated forwarder.	High

To prioritize the NLRI route type, set the **bgp-output-queue-priority priority** for **nlri-route-type** at the [edit policy-options policy-statement] hierarchy level on all provider edge routers and route reflectors in the EVPN network. In this example, a high priority was configured for NRLI route type 1 and NRLI route type 4.

```

user@PE1#show policy-options
policy-statement evpn-rt-priority-policy {
  term 1 {
    from {
      family evpn;
      nlri-route-type 1;
    }
    then {
      bgp-output-queue-priority priority 16;
    }
  }
  term 2 {
    from {
      family evpn;
      nlri-route-type 2;
    }
    then {
      bgp-output-queue-priority priority 1;
    }
  }
  term 3 {
    from {
      family evpn;
      nlri-route-type 3;
    }
    then {
      bgp-output-queue-priority priority 2;
    }
  }
  term 4 {
    from {
      family evpn;
      nlri-route-type 4;
    }
    then {
      bgp-output-queue-priority priority 16;
    }
  }
}

```

NOTE: There are 17 prioritized output queues: an expedited queue that has the highest priority, and 16 numbered queues for which 1 is the lowest priority and 16 is the highest.

For more information about how to configure routing policies, see *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

Release History Table

Release	Description
16.1R4	Starting with Junos OS Releases 16.1R4 and 16.2R2, all EX9200 switches support the active-active mode for EVPN multihoming.
15.1	Starting in Junos OS Release 15.1, Junos OS supports aliasing in an EVPN.
14.1x53-D30	Starting with Junos OS Release 14.1x53-D30, QFX5100 switches support the active-active mode of operation for EVPN multihoming.
14.1R4	Starting with Junos OS Release 14.1R4, 14.2, 15.1F6, and 16.1R1, Junos OS supports the active-active mode for EVPN multihoming on MX Series routers.

- [Example: Configuring EVPN Active-Active Multihoming on page 403](#)

Configuring EVPN Active-Standby Multihoming

You can configure an Ethernet VPN (EVPN) with multihoming support to provide multihoming functionality with active-standby redundancy mode of operation in the EVPN and virtual switch routing instance. This mode enables autodiscovery of Ethernet segments, Ethernet segment route construction, and Ethernet segment identifier (ESI) label assignment.

When configuring active-standby EVPN multihoming, be aware of the following limitations:

- An interface or ESI can be attached to more than one EVPN instance (EVI), with a maximum limit of 200 EVIs per ESI.
- For an EVPN routing instance, only one logical interface per physical interface or ESI can be attached to an EVI.
- For a virtual switch routing instance, only one logical interface per physical interface or ESI can be configured under a bridge domain.
- All the PE routers in the network topology should be running Junos OS Release 14.1 or later releases, which are based on the EVPN draft-ietf-l2vpn-evpn-03. Junos OS releases prior to 14.1 support the older version of the EVPN draft, causing interoperability issues when Junos OS Release 14.1 and a previous release are running.

Before you begin:

1. Configure the router interfaces.
2. Configure the router ID and autonomous system number for the device.
3. Configure OSPF or any other IGP protocol.
4. Configure a BGP internal group.
5. Include the EVPN signaling network layer reachability information (NLRI) to the internal BGP group.
6. Configure LDP.
7. Configure MPLS.
8. Configure RSVP MPLS LSP or GRE tunnels.

To configure the PE device:

1. Enable EVPN active-standby multihoming on the multihomed interfaces.

```
[edit interfaces]
user@PE1# set interface-name vlan-tagging
user@PE1# set interface-name encapsulation flexible-ethernet-services
user@PE1# set interface-name esi esi-value
user@PE1# set interface-name esi single-active
user@PE1# set interface-name unit 0 encapsulation vlan-bridge
user@PE1# set interface-name unit 0 vlan-id VLAN-ID
```

For example:

```
[edit interfaces]
user@PE1# set ge-0/0/4 vlan-tagging
user@PE1# set ge-0/0/4 encapsulation flexible-ethernet-services
user@PE1# set ge-0/0/4 esi 00:22:44:66:88:00:22:44:66:88
user@PE1# set ge-0/0/4 esi single-active
user@PE1# set ge-0/0/4 unit 0 encapsulation vlan-bridge
user@PE1# set ge-0/0/4 unit 0 vlan-id 300
```

2. In configuration mode, go to the following hierarchy level:

```
[edit]
user@PE1# edit routing-instances
```

3. Configure the virtual switch routing instance.

```
[edit routing-instances]
user@PE1# set virtual-switch-instance instance-type virtual-switch
```

4. Configure the extended VLAN list for the virtual switch routing instance.

```
[edit routing-instances]
user@PE1# set virtual-switch-instance protocols evpn extended-vlan-list VLAN-ID
```

5. Set the type for the bridging domain in the virtual switch routing instance.

```
[edit routing-instances]
user@PE1# set virtual-switch-instance bridge-domains bridge-domain-name
domain-type bridge
```

6. Set the VLAN identifier for the bridging domain in the virtual switch routing instance.

```
[edit routing-instances]
user@PE1# set virtual-switch-instance bridge-domains bridge-domain-name vlan-id
VLAN-ID
```

7. Configure the interfaces for the virtual switch routing instance.

```
[edit routing-instances]
user@PE1# set virtual-switch-instance bridge-domains bridge-domain-name interface
interface-name
user@PE1# set virtual-switch-instance bridge-domains bridge-domain-name
routing-interface interface-name
```

8. Configure the route distinguisher for the virtual switch routing instance.

```
[edit routing-instances]
user@PE1# set virtual-switch-instance route-distinguisher route-distinguisher-value
```

9. Configure the VPN routing and forwarding (VRF) target community for the virtual switch routing instance.

```
[edit routing-instances]
user@PE1# set virtual-switch-instance vrf-target vrf-target
```

10. Configure the EVPN routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance instance-type evpn
```

11. Set the VLAN identifier for the bridging domain in the EVPN routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance vlan-id VLAN-ID
```

12. Configure the interface names for the EVPN routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance interface interface-name
user@PE1# set evpn-instance routing-interface interface-name
```

13. Configure the route distinguisher for the EVPN routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance route-distinguisher route-distinguisher-value
```

14. Configure the VPN routing and forwarding (VRF) target community for the EVPN routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance vrf-target vrf-target
```

15. Configure the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vrf-instance instance-type vrf
```

16. Configure the interface names for the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vrf-instance interface interface-name
```

17. Configure the route distinguisher for the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vrf-instance route-distinguisher route-distinguisher-value
```

18. Configure the VPN routing and forwarding (VRF) target community for the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vrf-instance vrf-target vrf-target
user@PE1# set vrf-instance vrf-table-label
```

19. Verify and commit the configuration.

For example:

```
[edit routing-instances]
```

```

user@PE1# set ALPHA instance-type virtual-switch
user@PE1# set ALPHA route-distinguisher 10.255.0.1:100
user@PE1# set ALPHA vrf-target target:100:100
user@PE1# set ALPHA protocols evpn extended-vlan-list 100
user@PE1# set ALPHA bridge-domains ONE domain-type bridge
user@PE1# set ALPHA bridge-domains ONE vlan-id 100
user@PE1# set ALPHA bridge-domains ONE interface ae0.0
user@PE1# set ALPHA bridge-domains ONE interface ge-0/0/2.0
user@PE1# set ALPHA bridge-domains ONE routing-interface irb.0
user@PE1# set BETA instance-type evpn
user@PE1# set BETA vlan-id 300
user@PE1# set BETA interface ge-0/0/4.0
user@PE1# set BETA interface ae1.0
user@PE1# set BETA routing-interface irb.1
user@PE1# set BETA route-distinguisher 10.255.0.1:300
user@PE1# set BETA vrf-target target:300:300
user@PE1# set DELTA instance-type vrf
user@PE1# set DELTA interface irb.0
user@PE1# set DELTA interface irb.1
user@PE1# set DELTA route-distinguisher 10.255.0.1:200
user@PE1# set DELTA vrf-target target:200:200
user@PE1# set DELTA vrf-table-label

[edit]
user@PE1# commit
commit complete

Example: Configuring EVPN Active-Standby Multihoming

This example shows how to configure Ethernet VPN (EVPN) for multihomed customer edge (CE) devices in an EVPN, virtual switch, and VRF routing instance, and with an integrated routing and bridging (IRB) interface configuration.

- [Requirements on page 361](#)
- [Overview and Topology on page 362](#)
- [Configuration on page 364](#)
- [Verification on page 376](#)

Requirements

This example uses the following hardware and software components:

- Four MX Series 3D Universal Edge Routers with MPC interfaces only, where:
 - Two devices are configured as provider edge (PE) routers connected to a common multihomed customer site.
 - One device is configured as a remote PE router connected to a single-homed customer site.

- Eight customer edge (CE) devices, where:
 - Two CE devices are multihomed.
 - Two CE devices are single-homed for each of the PE routers.
- Junos OS Release 14.1 or later running on all the PE routers.

NOTE: Junos OS Release 14.1 and later releases are based on the EVPN draft-ietf-l2vpn-evpn-03. Releases prior to 14.1, support the older version of the EVPN draft, causing interoperability issues when Junos OS Release 14.1 and a previous release are running.

Before you begin:

1. Configure the router interfaces.
2. Configure OSPF or any other IGP protocol.
3. Configure BGP.
4. Configure LDP.
5. Configure MPLS.
6. Configure RSVP MPLS LSP or GRE tunnels.

Overview and Topology

Starting with Junos OS Release 14.1, the EVPN solution on MX Series routers with MPC interfaces is extended to provide multihoming functionality with active-standby mode of operation. The multihoming functions include autodiscovery of Ethernet segments, Ethernet segment route construction, and Ethernet segment identifier (ESI) label assignment.

NOTE: Prior to Junos OS Release 15.1, the EVPN functionality support on MX Series Routers was limited to routers using MPC and MIC interfaces only. However, starting with Junos OS Release 15.1, MX Series Routers using DPCs can be leveraged to provide EVPN support on the CE device-facing interface.

The DPC support for EVPN is provided with the following considerations:

- DPCs provide support for EVPN in the active-standby mode of operation including support for the following:
 - a. EVPN instance (EVI)
 - b. Virtual switch (VS)
 - c. Integrated routing and bridging (IRB) interfaces
- DPCs intended for providing the EVPN active-standby support should be the CE device-facing line card. The PE device interfaces in the EVPN domain should use only MPC and MIC interfaces.

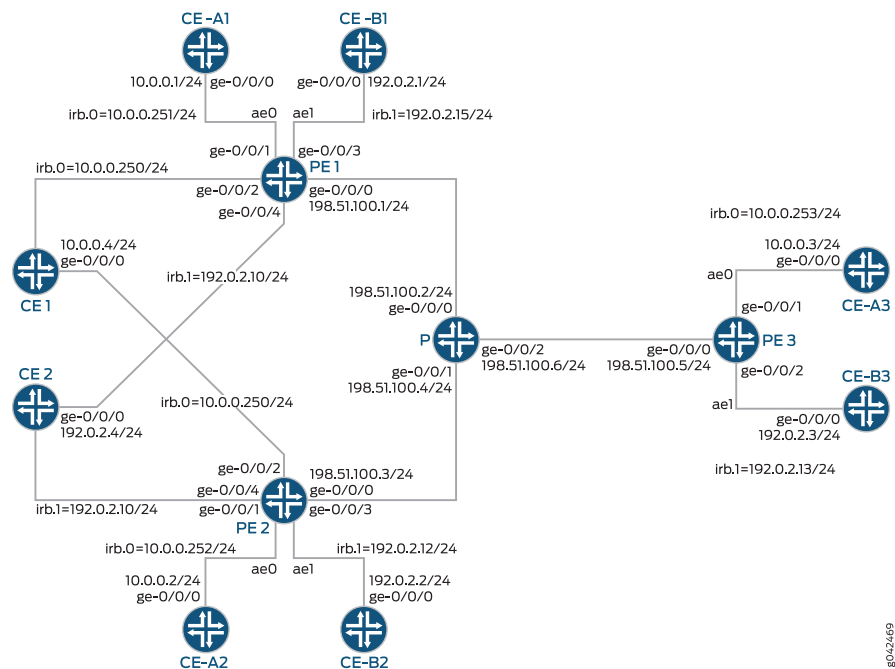

NOTE:

When configuring active-standby EVPN multihoming, be aware of the following limitations:

- An interface or ESI can be attached to more than one EVI, with a maximum limit of 200 EVIs per ESI.
- For an EVPN routing instance, only one logical interface per physical interface or ESI can be attached to an EVI.
- For a virtual switch routing instance, only one logical interface per physical interface or ESI can be configured under a bridge domain.
- All the PE routers in the network topology should be running Junos OS Release 14.1 or later releases, which are based on the EVPN draft-ietf-l2vpn-evpn-03. Junos OS releases prior to 14.1 support the older version of the EVPN draft, causing interoperability issues when Junos OS Release 14.1 and a previous release are running.

Figure 37: EVPN Active-Standby Multihoming

In Figure 37 on page 364, Routers PE1 and PE2 are provider edge (PE) routers connected to multihomed customer edge (CE) devices, Device CE1 and CE2. Router PE3 is a remote PE router connected to a single-homed customer site, and Router P is the provider router connected to Routers PE1, PE2, and PE3.

There are three routing instances running in the topology – ALPHA, BETA, and DELTA, with the virtual switch, EVPN, and VRF type of routing instance, respectively. All the PE routers are connected to one single-homed CE device each for the ALPHA and BETA routing instances. Device CE1 belongs to the ALPHA routing instance, and Device CE2 belongs to the BETA routing instance.

For Router PE1, Device CE-A1 and Device CE-B1 are the single-homed CE devices for the routing instances ALPHA and BETA, respectively. In the same way, Device CE-A2 and Device CE-A3 belong to the ALPHA routing instance, and Device CE-B2 and Device CE-B3 belong to the BETA routing instances connected to Routers PE2 and PE3, respectively.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
CE1 set interfaces ge-0/0/0 vlan-tagging
CE1 set interfaces ge-0/0/0 mac 00:00:00:00:00:04
CE1 set interfaces ge-0/0/0 unit 0 vlan-id 100
CE1 set interfaces ge-0/0/0 unit 0 family inet address 10.0.0.4/24
```

```

set routing-options static route 0.0.0.0/0 next-hop 10.0.0.250

CE-A1  set chassis aggregated-devices ethernet device-count 1

Step-by-Step Procedure The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router PE1:

NOTE: Repeat this procedure for Router PE2 after modifying the appropriate interface names, addresses, and other parameters.

1. Configure Router PE1 interfaces.

[edit interfaces]

```
user@PE1# set ge-0/0/0 unit 0 family inet address 198.51.100.1/24
user@PE1# set ge-0/0/0 unit 0 family mpls
```

```
user@PE1# set ge-0/0/1 gigether-options 802.3ad ae0
```

```
user@PE1# set ge-0/0/2 vlan-tagging
user@PE1# set ge-0/0/2 encapsulation flexible-ethernet-services
user@PE1# set ge-0/0/2 unit 0 encapsulation vlan-bridge
user@PE1# set ge-0/0/2 unit 0 vlan-id 100
```

```
user@PE1# set ge-0/0/3 gigether-options 802.3ad ae1
```

```
user@PE1# set ge-0/0/4 vlan-tagging
user@PE1# set ge-0/0/4 encapsulation flexible-ethernet-services
user@PE1# set ge-0/0/4 esi 00:22:44:66:88:00:22:44:66:88
user@PE1# set ge-0/0/4 esi single-active
user@PE1# set ge-0/0/4 unit 0 encapsulation vlan-bridge
user@PE1# set ge-0/0/4 unit 0 vlan-id 300
```

```
user@PE1# set ae0 vlan-tagging
user@PE1# set ae0 encapsulation flexible-ethernet-services
user@PE1# set ae0 esi 00:11:22:33:44:55:66:77:88:99
user@PE1# set ae0 esi single-active
user@PE1# set ae0 unit 0 encapsulation vlan-bridge
user@PE1# set ae0 unit 0 vlan-id 100
```

```
user@PE1# set ae1 vlan-tagging
user@PE1# set ae1 encapsulation flexible-ethernet-services
user@PE1# set ae1 unit 0 encapsulation vlan-bridge
user@PE1# set ae1 unit 0 vlan-id 300
```

```
user@PE1# set irb unit 0 family inet address 10.0.0.250/24
user@PE1# set irb unit 0 family inet address 10.0.0.251/24
user@PE1# set irb unit 0 mac 00:11:22:33:44:55
user@PE1# set irb unit 1 family inet address 192.0.2.10/24
user@PE1# set irb unit 1 family inet address 192.0.2.15/24
user@PE1# set irb unit 1 mac 00:22:44:66:88:00
```

```

user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32 primary
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32 preferred

```

2. Configure the loopback address of Router PE1 as the router ID.

```

[edit routing-options]
user@PE1# set router-id 10.255.0.1

```

3. Set the autonomous system number for Router PE1.

```

[edit routing-options]
user@PE1# set autonomous-system 100

```

4. Enable chained composite next hop for the EVPN.

```

[edit routing-options]
user@PE1# set forwarding-table chained-composite-next-hop ingress evpn

```

5. Enable MPLS on the loopback interface of Router PE1 and the interface connecting PE1 to Router P.

```

[edit protocols]
user@PE1# set mpls interface lo0.0
user@PE1# set mpls interface ge-0/0/0.0

```

6. Configure the BGP group for Router PE1.

```

[edit protocols]
user@PE1# set bgp group EVPN-PE type internal

```

7. Assign local and neighbor addresses to the EVPN-PE BGP group for Router PE1 to peer with Routers PE2 and PE3.

```

[edit protocols]
user@PE1# set bgp group EVPN-PE local-address 10.255.0.1
user@PE1# set bgp group EVPN-PE neighbor 10.255.0.2
user@PE1# set bgp group EVPN-PE neighbor 10.255.0.3

```

8. Include the EVPN signaling Network Layer Reachability Information (NLRI) to the EVPN-PE group.

```

[edit protocols]
user@PE1# set bgp group EVPN-PE family evpn signaling

```

9. Configure OSPF on the loopback interface of Router PE1 and the interface connecting PE1 to Router P.

```

[edit protocols]
user@PE1# set ospf area 0.0.0.0 interface lo0.0 passive
user@PE1# set ospf area 0.0.0.0 interface ge-0/0/0.0

```

10. Enable LDP on the loopback interface of Router PE1 and the interface connecting PE1 to Router P.

[edit protocols]
user@PE1# set ldp interface lo0.0
user@PE1# set ldp interface ge-0/0/0.0
11. Configure the virtual switch routing instance – ALPHA.

[edit routing-instances]
user@PE1# set ALPHA instance-type virtual-switch
12. Configure the extended VLAN list for the ALPHA routing instance.

[edit routing-instances]
user@PE1# set ALPHA protocols evpn extended-vlan-list 100
13. Set the type for the bridging domain in the ALPHA routing instance.

[edit routing-instances]
user@PE1# set ALPHA bridge-domains ONE domain-type bridge
14. Set the VLAN for the bridging domain in the ALPHA routing instance.

[edit routing-instances]
user@PE1# set ALPHA bridge-domains ONE vlan-id 100
15. Configure the interface names for the ALPHA routing instance.

[edit routing-instances]
user@PE1# set ALPHA bridge-domains ONE interface ae0.0
user@PE1# set ALPHA bridge-domains ONE interface ge-0/0/2.0
user@PE1# set ALPHA bridge-domains ONE routing-interface irb.0
16. Configure the route distinguisher for the ALPHA routing instance.

[edit routing-instances]
user@PE1# set ALPHA route-distinguisher 10.255.0.1:100
17. Configure the VPN routing and forwarding (VRF) target community for the ALPHA routing instance.

[edit routing-instances]
user@PE1# set ALPHA vrf-target target:100:100
18. Configure the EVPN routing instance – BETA.

[edit routing-instances]
user@PE1# set BETA instance-type evpn
19. Set the VLAN identifier for the bridging domain in the BETA routing instance.

[edit routing-instances]
user@PE1# set BETA vlan-id 300

20. Configure the interface names for the BETA routing instance.

```
[edit routing-instances]
user@PE1# set BETA interface ge-0/0/4.0
user@PE1# set BETA interface ae1.0
user@PE1# set BETA routing-interface irb.1
```

21. Configure the route distinguisher for the BETA routing instance.

```
[edit routing-instances]
user@PE1# set BETA route-distinguisher 10.255.0.1:300
```

22. Configure the VPN routing and forwarding (VRF) target community for the BETA routing instance.

```
[edit routing-instances]
user@PE1# set BETA vrf-target target:300:300
```

23. Configure the VRF routing instance – DELTA.

```
[edit routing-instances]
user@PE1# set DELTA instance-type vrf
```

24. Configure the interface names for the DELTA routing instance.

```
[edit routing-instances]
user@PE1# set DELTA interface irb.0
user@PE1# set DELTA interface irb.1
```

25. Configure the route distinguisher for the DELTA routing instance.

```
[edit routing-instances]
user@PE1# set DELTA route-distinguisher 10.255.0.1:200
```

26. Configure the VPN routing and forwarding (VRF) target community for the DELTA routing instance.

```
[edit routing-instances]
user@PE1# set DELTA vrf-target target:200:200
user@PE1# set DELTA vrf-table-label
```

Results

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-0/0/0 {
  unit 0 {
    family inet {
```

```

```

Verification

Confirm that the configuration is working properly in the following different areas on all the PE routers, where Router PE1 is the designated forwarder (DF), Router PE2 is the non-DF, and Router PE3 is the remote PE:

- a. EVPN routing instance configuration
- b. EVPN multihoming routes

- c. DF election process
- d. IRB and virtual switch routing instance configuration
- e. Host route entries
- [Verifying the EVPN Instance Status on page 377](#)
- [Verifying the Autodiscovery Routes per Ethernet Segment on page 382](#)
- [Verifying the Ethernet Segment Route on page 386](#)
- [Verifying the DF Status on page 387](#)
- [Verifying the BDF Status on page 388](#)
- [Verifying Remote IRB MAC on page 388](#)
- [Verifying Remote IRB and Host IP on page 389](#)
- [Verifying ARP Table on page 391](#)
- [Verifying Bridge ARP Table on page 392](#)
- [Verifying Bridge MAC Table on page 393](#)

Verifying the EVPN Instance Status

Purpose Verify the EVPN routing instances and their status.

Router PE1 Action

From operational mode, run the **show evpn instance extensive** command.

```

user@PE1> show evpn instance extensive
Instance: ALPHA
Route Distinguisher: 10.255.0.1:100
Per-instance MAC route label: 300144

Ethernet auto-discovery:           1
Number of ethernet segments: 0

Instance: __default_evpn__
Route Distinguisher: 10.255.0.3:0
VLAN ID: 0
Per-instance MAC route label: 299840
Per-instance multicast route label: 299856
MAC database status      Local  Remote
Total MAC addresses:      0      0
Default gateway MAC addresses: 0      0
Number of local interfaces: 0 (0 up)
Number of IRB interfaces: 0 (0 up)
Number of neighbors: 0
Number of ethernet segments: 0

```

Meaning The output provides the following information:

- List of EVPN and virtual switch routing instances.
- Mode of operation of each interface
- Neighbors of each routing instance.
- Number of different routes received from each neighbor.
- ESI attached to each routing instance.
- Number of Ethernet segments on each routing instance.
- DF election roles for each ESI in an EVI.
- VLAN ID and MAC labels for each routing instance.
- IRB interface details
- Number of default gateway MAC addresses received for the virtual switch routing instance (ALPHA).

Verifying the Autodiscovery Routes per Ethernet Segment

Purpose Verify that the autodiscovery routes per Ethernet segment are received.

Router PE1 Action

From operational mode, run the **show route table ALPHA.evpn.0** command.

```
user@PE1> show route table ALPHA.evpn.0
ALPHA.evpn.0: 20 destinations, 20 routes (20 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

Meaning The output displays the local and remote type 1 (autodiscovery) and type 4 (Ethernet segment) routes:

- **1:10.255.0.1:0::112233445566778899::0/304**—Autodiscovery route per Ethernet segment for each local ESI attached to Router PE1 and Router PE2.
- **4:10.255.0.1:0::112233445566778899:10.255.0.1/304**—Ethernet segment route for each local ESI attached to Router PE1 and Router PE2.
- **4:10.255.0.2:0::112233445566778899:10.255.0.2/304**—Remote Ethernet segment route from Router PE2.

Verifying the DF Status

Purpose Confirm which PE router is the designated forwarder (DF).

Action From operational mode, run the **show evpn instance ALPHA esi esi/ designated-forwarder** command.

```

user@PE1> show evpn instance ALPHA esi 00:11:22:33:44:55:66:77:88:99
designated-forwarder
Instance: ALPHA
  Number of ethernet segments: 1
  ESI: 00:11:22:33:44:55:66:77:88:99
  Designated forwarder: 10.255.0.1

```

Meaning Router PE1 is the DF for the ALPHA routing instance.

Verifying the BDF Status

- Purpose** Confirm which PE router is the backup designated forwarder (BDF).
- Action** From operational mode, run the **show evpn instance ALPHA esi esi backup-forwarder** command.
- ```
user@PE1> show evpn instance ALPHA esi 00:11:22:33:44:55:66:77:88:99
backup-forwarder
Instance: ALPHA
 Number of ethernet segments: 1
 ESI: 00:11:22:33:44:55:66:77:88:99
 Backup forwarder: 10.255.0.2
```
- Meaning** Router PE2 is the BDF for the ALPHA routing instance.

### Verifying Remote IRB MAC

---

- Purpose** Verify that the remote gateway MAC addresses are synchronized among all the PE routers.

#### Router PE1

##### Action

From operational mode, run the **show bridge evpn peer-gateway-mac** command.

```
user@PE1> show bridge evpn peer-gateway-mac
Routing instance : ALPHA
Bridging domain : ONE, VLAN : 100
Installed GW MAC addresses:
00:05:86:71:79:f0
```

#### Router PE2

From operational mode, run the **show bridge evpn peer-gateway-mac** command.

```
user@PE2> show bridge evpn peer-gateway-mac
Routing instance : ALPHA
Bridging domain : ONE, VLAN : 100
Installed GW MAC addresses:
00:05:86:71:79:f0
```

#### Router PE3

From operational mode, run the **show bridge evpn peer-gateway-mac** command.

```
user@PE2> show bridge evpn peer-gateway-mac
Routing instance : ALPHA
Bridging domain : ONE, VLAN : 100
Installed GW MAC addresses:
00:11:22:33:44:55
```

**Meaning** The remote gateway MAC addresses are synchronized:

- Router PE3 gateway MAC is installed in Routers PE1 and PE2 peer-gateway-mac table.
- Routers PE1 and PE2 gateway MAC addresses are installed in Router PE3 peer-gateway-mac table.

### Verifying Remote IRB and Host IP

**Purpose** Verify that the remote IRB IP and the host IP are received.

#### Router PE1 Action

From operational mode, run the **show route table DELTA** command.

```
user@PE1> show route table DELTA
DELTA.inet.0: 16 destinations, 18 routes (16 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

10.0.0.0/24 *[Direct/0] 11:25:54

 Local via irb.0
192.0.2.0/24 *[Direct/0] 11:42:15
> via irb.1
192.0.2.1/24 *[EVPN/7] 11:25:43, metric2 1
> to 198.51.100.6 via ge-0/0/0.0, Push 300176, Push 299776(top)
192.0.2.2/24 *[EVPN/7] 11:24:17, metric2 1
> to 198.51.100.6 via ge-0/0/0.0, Push 300240, Push 299808(top)
192.0.2.3/24 *[EVPN/7] 11:42:04
> via irb.1
192.0.2.4/24 *[EVPN/7] 11:29:03, metric2 1
> to 198.51.100.6 via ge-0/0/0.0, Push 300176, Push 299776(top)
192.0.2.10/24 *[EVPN/7] 11:30:08, metric2 1
> to 198.51.100.6 via ge-0/0/0.0, Push 300240, Push 299808(top)
192.0.2.12/24 *[EVPN/7] 11:30:08, metric2 1
> to 198.51.100.6 via ge-0/0/0.0, Push 300240, Push 299808(top)
192.0.2.13/24 *[Local/0] 11:42:57
 Local via irb.1

```

**Meaning** The output displays the local and remote IRB interfaces. It also displays the local and remote hosts that are installed in the VRF table:

On Router PE1:

- **10.0.0.1/32**—Local host in the virtual switch routing instance.
- **10.0.0.2/32** and **10.0.0.3/32**—Remote host in the virtual switch routing instance.
- **10.0.0.250/32**—Local IRB in the virtual switch routing instance.
- **10.0.0.253/32**—Remote IRB in the virtual switch routing instance.

### Verifying ARP Table

**Purpose** Verify the ARP table entries.

**Router PE1**      **Action**

From operational mode, run the **show evpn arp-table** command.

```

user@PE1> show evpn arp-table
INET MAC Logical Routing Bridging
address address interface instance domain
192.0.2.1 00:00:00:00:00:01 irb.1 BETA __BETA__
192.0.2.4 00:00:00:00:00:04 irb.1 BETA __BETA__

```

## Router PE2

From operational mode, run the **show evpn arp-table** command.

```
user@PE2> show evpn arp-table
INET MAC Logical Routing Bridging
address address interface instance domain
192.0.2.2 00:00:00:00:00:02 irb.1 BETA __BETA__
```

## Router PE3

From operational mode, run the **show evpn arp-table** command.

```
user@PE3> show evpn arp-table
INET MAC Logical Routing Bridging
address address interface instance domain
192.0.2.3 00:00:00:00:00:03 irb.1 BETA __BETA__
```

**Meaning** The EVPN instance and ARP are synchronized with the host MAC and IP address for local hosts.

### Verifying Bridge ARP Table

**Purpose** Verify the bridge ARP table entries.

## Router PE1      Action

From operational mode, run the **show bridge evpn arp-table** command.

```
user@PE3> show bridge evpn arp-table
INET MAC Logical Routing Bridging
address address interface instance domain
10.0.0.1 00:00:00:00:00:01 irb.0 ALPHA ONE
10.0.0.4 00:00:00:00:00:04 irb.0 ALPHA ONE
```

## Router PE2

From operational mode, run the **show bridge evpn arp-table** command.

```
user@PE3> show bridge evpn arp-table
INET MAC Logical Routing Bridging
address address interface instance domain
10.0.0.2 00:00:00:00:00:02 irb.0 ALPHA ONE
```

## Router PE3

From operational mode, run the **show bridge evpn arp-table** command.

```
user@PE3> show bridge evpn arp-table
INET MAC Logical Routing Bridging
address address interface instance domain
10.0.0.3 00:00:00:00:00:03 irb.0 ALPHA ONE
```

**Meaning** The virtual switch instance and ARP are synchronized with the local host MAC and IP address.

### Verifying Bridge MAC Table

**Purpose** Verify the bridge MAC table entries.

#### Router PE1 Action

From operational mode, run the **show bridge mac-table** command.

```
user@PE1> show bridge mac-table
MAC flags (S -static MAC, D -dynamic MAC, L -locally learned, C -Control MAC
 SE -Statistics enabled, NM -Non configured MAC, R -Remote PE MAC)

Routing instance : ALPHA
Bridging domain : ONE, VLAN : 100
 MAC MAC Logical NH RTR
 address flags interface Index ID
00:00:00:00:00:01 D ge-0/0/2.0 1048583 1048583
00:00:00:00:00:02 DC 1048574 1048574
00:00:00:00:00:03 DC 1048574 1048574
00:00:00:00:00:04 D ae0.0
```

#### Router PE2

From operational mode, run the **show bridge mac-table** command.

```
user@PE2> show bridge mac-table
MAC flags (S -static MAC, D -dynamic MAC, L -locally learned, C -Control MAC
 SE -Statistics enabled, NM -Non configured MAC, R -Remote PE MAC)

Routing instance : ALPHA
Bridging domain : ONE, VLAN : 100
 MAC MAC Logical NH RTR
 address flags interface Index ID
00:00:00:00:00:01 DC 1048577 1048577
00:00:00:00:00:02 D ge-0/0/2.0 1048578 1048578
00:00:00:00:00:03 DC 1048577 1048577
00:00:00:00:00:04 DC 1048577 1048577
```

#### Router PE3

From operational mode, run the **show bridge mac-table** command.

```
user@PE3> show bridge mac-table
MAC flags (S -static MAC, D -dynamic MAC, L -locally learned, C -Control MAC
 SE -Statistics enabled, NM -Non configured MAC, R -Remote PE MAC)

Routing instance : ALPHA
Bridging domain : ONE, VLAN : 100
 MAC MAC Logical NH RTR
 address flags interface Index ID
00:00:00:00:00:01 DC 1048575 1048575
00:00:00:00:00:02 DC 1048582 1048582
00:00:00:00:00:03 D ae0.0
00:00:00:00:00:04 DC 1048575 1048575
```

**Meaning** The virtual switch instance installed local and remote host MAC addresses in the bridge MAC table.

---

## Example: Configuring Basic EVPN Active-Active Multihoming

---

This example shows how to configure an active-active multihomed customer edge (CE) devices and provider edge (PE) devices in an Ethernet VPN (EVPN).

- [Requirements on page 394](#)
- [Overview on page 394](#)
- [Configuration on page 395](#)

### Requirements

This example uses the following hardware and software components:

- Four MX Series 3D Universal Edge Routers with MPC interfaces only, where:
  - Two devices are configured as provider edge (PE) routers connected to a common multihomed customer site.
  - One device is configured as a remote PE router connected to a single-homed customer site.
  - One device is configured as a provider router.
- Two customer edge (CE) devices, where:
  - Two CE devices that are multihomed.
  - One CE devices that is single-homed .

Before you begin:

1. Configure the router interfaces.
2. Configure OSPF or any other IGP protocol.
3. Configure a BGP internal group.
4. Configure MPLS.

### Overview

[Figure 38 on page 395](#) illustrates a simple EVPN topology. Routers PE1 and PE2 are provider edge (PE) routers connected to multihomed customer edge (CE) router CE1. Router P is the provider router connected to Routers PE1, PE2, and PE3. Router PE3 is connected to customer edge router CE2.

Figure 38: Simple EVPN Multihomed Topology

## Configuration

**CLI Quick Configuration** The configurations parameters for the routers are as follows:

```
CE1

## Example: Configuring EVPN Active-Active Multihoming

This example shows how to configure Ethernet VPN (EVPN) for multihomed customer edge devices in the active-active redundancy mode, so the Layer 2 unicast traffic can be load-balanced across all the multihomed links on and toward the CE device.

- [Requirements on page 403](#)
- [Overview and Topology on page 404](#)
- [Configuration on page 405](#)
- [Verification on page 434](#)

## Requirements

This example uses the following hardware and software components:

- Five MX Series 3D Universal Edge Routers with MPC interfaces only, where:
  - Three devices are configured as provider edge (PE) routers connected to a common multihomed customer site.
  - One device is configured as a remote PE router connected to a single-homed customer site.
- Six customer edge (CE) devices, with one multihomed CE device and the rest of the CE devices being single-homed to each of the PE routers.
- Junos OS Release 16.1 or later running on all the PE routers.

**NOTE:** The EVPN multihoming active-active mode of operation is supported in Junos OS Releases 16.1 and later releases.

Starting with Junos OS Release 16.1R4, EVPN multihoming active-active mode is supported on all EX9200 switches. For information about configuration specific to EX9200 switches, see [“Step-by-Step Procedure” on page 426](#).

Before you begin:

1. Configure the router interfaces.
2. Configure IS-IS or any other IGP protocol.
3. Configure BGP.
4. Configure LDP.
5. Configure MPLS.
6. Configure RSVP MPLS LSP or GRE tunnels.

## Overview and Topology

Starting with Junos OS Release 15.1, the EVPN solution on MX Series routers with MPC interfaces is extended to provide multihoming functionality in the active-active redundancy mode of operation. This feature enables load balancing of Layer 2 unicast traffic across all the multihomed links on and toward a customer edge device.

The EVPN active-active multihoming feature provides link-level and node-level redundancy along with effective utilization of resources.

To enable EVPN active-active multihoming, include the **all-active** statement at the **[edit interfaces esi]** hierarchy level.

In [Figure 39 on page 405](#), the core consists of four provider edge (PE) routers and a provider router (P) that is configured as a route reflector (RR). Router CE10 is multihomed to Routers PE1, PE2, and PE3. Each PE router is also connected to a single-homed customer site.

There are three routing instances running in the topology – VS-1, VS-2, and mhevpn, along with the default routing instance. The routing instances share nine VLANs with three ESIs each. The VS-1 and VS-2 routing instances are configured as a virtual switch type of routing instance, and the mhevpn routing instance is an EVPN routing instance.

Three aggregated bundles – ae0, ae1, and ae2 – are used to connect the multihomed CE device, CE10, to Routers PE1, PE2, and PE3. These aggregated bundles are configured for three ESIs each. The aggregated bundles, ae12 and ae13, are used to interconnect Routers PE1 and PE2, and PE1 and PE3, respectively.

Figure 39: EVPN Active-Active Multihoming Topology

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router PE1:

**NOTE:** Repeat this procedure for all other multihomed PE routers after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the MX Series router to operate in the enhanced-ip mode because the EVPN active-active functionality is supported on routers with MPCs and MIC interfaces only.

A system reboot is required on committing this configuration.

```

[edit chassis]
user@PE1# set network-services enhanced-ip

```

2. Specify the number of aggregated Ethernet interfaces to be created.

```

[edit chassis]
user@PE1# set aggregated-devices ethernet device-count 20

```

3. Configure Router PE1 interfaces within the ae0 aggregated bundle toward the multihomed customer site, Router CE10.

- a. Assign interfaces ge-1/2/3 and ge-1/2/4 within the ae0 aggregated bundle.

```

[edit interfaces]
user@PE1# set ge-1/2/3 gigether-options 802.3ad ae0
user@PE1# set ge-1/2/4 gigether-options 802.3ad ae0

```

- b. Configure the ae0 aggregated bundle parameters for VLAN tagging and encapsulation.

```

[edit interfaces]
user@PE1# set ae0 flexible-vlan-tagging

```

```
user@PE1# set ae0 encapsulation flexible-ethernet-services
```

- c. Assign an ESI value for the first Ethernet segment and enable EVPN active-active multihoming for the ae0 aggregated bundle.

```
[edit interfaces]
user@PE1# set ae0 esi 00:11:11:11:11:11:11:11
user@PE1# set ae0 esi all-active
```

- d. Configure a trunk interface on the bridge network for the ae0 aggregated bundle.

```
[edit interfaces]
user@PE1# set ae0 unit 0 encapsulation vlan-bridge
user@PE1# set ae0 unit 0 vlan-id 10
user@PE1# set ae0 unit 110 family bridge interface-mode trunk
user@PE1# set ae0 unit 110 family bridge vlan-id-list 110
user@PE1# set ae0 unit 210 family bridge interface-mode trunk
user@PE1# set ae0 unit 210 family bridge vlan-id-list 210
```

- 4. Configure the other Router PE1 interfaces toward the multihomed customer site, Router CE10.

- a. Configure the VLAN tagging and encapsulation parameters for the ge-1/2/2 PE1 interface.

```
[edit interfaces]
user@PE1# set ge-1/2/2 flexible-vlan-tagging
user@PE1# set ge-1/2/2 encapsulation flexible-ethernet-services
```

- b. Assign an ESI value for the second Ethernet segment and enable EVPN active-active multihoming for the ge-1/2/2 PE1 interface.

```
[edit interfaces]
user@PE1# set ge-1/2/2 esi 00:22:22:22:22:22:22:22
user@PE1# set ge-1/2/2 esi all-active
```

- c. Configure a trunk interface on the bridge network for the ge-1/2/2 PE1 interface.

```
[edit interfaces]
user@PE1# set ge-1/2/2 unit 0 encapsulation vlan-bridge
user@PE1# set ge-1/2/2 unit 0 vlan-id 20
user@PE1# set ge-1/2/2 unit 120 family bridge interface-mode trunk
user@PE1# set ge-1/2/2 unit 120 family bridge vlan-id-list 120
user@PE1# set ge-1/2/2 unit 220 family bridge interface-mode trunk
user@PE1# set ge-1/2/2 unit 220 family bridge vlan-id-list 220
```

- d. Configure the VLAN tagging and encapsulation parameters for the ge-1/2/1 PE1 interface.

```
[edit interfaces]
user@PE1# set ge-1/2/1 flexible-vlan-tagging
user@PE1# set ge-1/2/1 encapsulation flexible-ethernet-services
```

- e. Assign an ESI value for the third Ethernet segment and enable EVPN active-active multihoming for the ge-1/2/1 PE1 interface.

```
[edit interfaces]
user@PE1# set ge-1/2/1 esi 00:33:33:33:33:33:33:33
user@PE1# set ge-1/2/1 esi all-active
```

- f. Configure a trunk interface on the bridge network for the ge-1/2/1 PE1 interface.

```
[edit interfaces]
user@PE1# set ge-1/2/1 unit 0 encapsulation vlan-bridge
user@PE1# set ge-1/2/1 unit 0 vlan-id 30
user@PE1# set ge-1/2/1 unit 130 family bridge interface-mode trunk
user@PE1# set ge-1/2/1 unit 130 family bridge vlan-id-list 130
user@PE1# set ge-1/2/1 unit 230 family bridge interface-mode trunk
user@PE1# set ge-1/2/1 unit 230 family bridge vlan-id-list 230
```

5. Configure Router PE1 interfaces toward Router PE2.
  - a. Assign the interfaces ge-1/0/5 and ge-1/1/6 within the ae12 aggregated bundle.

```
[edit interfaces]
user@PE1# set ge-1/0/5 gigether-options 802.3ad ae12
user@PE1# set ge-1/1/6 gigether-options 802.3ad ae12
```

- b. Specify the minimum number of links for the ae12 aggregated bundle to be labeled “up”.

```
[edit interfaces]
user@PE1# set ae12 aggregated-ether-options minimum-links 1
```

- c. Assign an IP address for the ae12 aggregated bundle and enable MPLS and IS-IS protocol families on the bundle.

```
[edit interfaces]
user@PE1# set ae12 unit 0 family inet address 198.51.100.12/24
user@PE1# set ae12 unit 0 family iso
user@PE1# set ae12 unit 0 family mpls
```

- d. Configure the VLAN tagging and encapsulation parameters for the ae12 aggregated bundle and assign VLAN ID 1200 for the bundle.

```
[edit interfaces]
user@PE1# set ae12 flexible-vlan-tagging
user@PE1# set ae12 encapsulation flexible-ethernet-services
user@PE1# set ae12 unit 0 vlan-id 1200
```

6. Configure Router PE1 interfaces toward Router PE3.
  - a. Assign the interfaces ge-1/0/3 and ge-1/0/4 within the ae13 aggregated bundle.

```
[edit interfaces]
user@PE1# set ge-1/0/3 gigether-options 802.3ad ae13
user@PE1# set ge-1/0/4 gigether-options 802.3ad ae13
```

- b. Specify the minimum number of links for the ae13 aggregated bundle to be labeled “up”.

```
[edit interfaces]
user@PE1# set ae13 aggregated-ether-options minimum-links 1
```

- c. Assign an IP address for the ae13 aggregated bundle and enable MPLS and IS-IS protocol families on the bundle.

```
[edit interfaces]
user@PE1# set ae13 unit 0 family inet address 198.51.100.13/24
user@PE1# set ae13 unit 0 family iso
user@PE1# set ae13 unit 0 family mpls
```

- d. Configure the VLAN tagging and encapsulation parameters for the ae12 aggregated bundle and assign the inner and outer VLAN tags for the bundle.

```
[edit interfaces]
user@PE1# set ae13 flexible-vlan-tagging
user@PE1# set ae13 encapsulation flexible-ethernet-services
user@PE1# set ae13 unit 0 vlan-tags outer 1300
user@PE1# set ae13 unit 0 vlan-tags inner 13
```

7. Configure the Router PE1 interface toward the single-homed customer site, Router CE1.

- a. Configure the VLAN tagging and encapsulation parameters for the ge-1/3/0 PE1 interface.

```
[edit interfaces]
user@PE1# set ge-1/3/0 flexible-vlan-tagging
user@PE1# set ge-1/3/0 encapsulation flexible-ethernet-services
```

- b. Configure a trunk interface on the bridge network for the ge-1/3/0 PE1 interface.

```
[edit interfaces]
user@PE1# set ge-1/3/0 unit 0 encapsulation vlan-bridge
user@PE1# set ge-1/3/0 unit 0 vlan-id 10
user@PE1# set ge-1/3/0 unit 100 family bridge interface-mode trunk
user@PE1# set ge-1/3/0 unit 100 family bridge vlan-id-list 110
user@PE1# set ge-1/3/0 unit 100 family bridge vlan-id-list 120
user@PE1# set ge-1/3/0 unit 100 family bridge vlan-id-list 130
user@PE1# set ge-1/3/0 unit 200 family bridge interface-mode trunk
user@PE1# set ge-1/3/0 unit 200 family bridge vlan-id-list 210
user@PE1# set ge-1/3/0 unit 200 family bridge vlan-id-list 220
user@PE1# set ge-1/3/0 unit 200 family bridge vlan-id-list 230
```

8. Configure the Router PE1 interface toward Router P (RR) and enable the MPLS and IS-IS protocol families for the interface.

```
[edit interfaces]
user@PE1# set ge-1/1/4 unit 0 family inet address 192.0.2.1/24
user@PE1# set ge-1/1/4 unit 0 family iso
user@PE1# set ge-1/1/4 unit 0 family mpls
```

9. Configure an IRB interface for Router PE1.

```
[edit interfaces]
user@PE1# set irb unit 0 family inet address 192.0.2.9/24
user@PE1# set irb unit 0 mac 00:99:99:99:01:99
user@PE1# set irb unit 1 family inet address 192.0.2.10/24
user@PE1# set irb unit 1 mac 00:99:99:99:02:99
user@PE1# set irb unit 2 family inet address 192.0.2.11/24
user@PE1# set irb unit 2 mac 00:99:99:99:03:99
user@PE1# set irb unit 10 family inet address 192.0.2.12/24
user@PE1# set irb unit 10 mac 00:99:99:99:01:90
```

10. Configure the loopback interface for Router PE1.

```
[edit interfaces]
user@PE1# set lo0 unit 0 family inet address 198.51.100.1/24 primary
user@PE1# set lo0 unit 0 family iso
```

11. Assign a router ID and the autonomous system number for Router PE1.  

```
[edit routing-options]
user@PE1# set router-id 198.51.100.1
user@PE1# set autonomous-system 65221
```
12. Assign a load-balancing policy to the forwarding table of Router PE1.  

```
[edit routing-options]
user@PE1# set forwarding-table export load-balancing-policy
```
13. Configure IS-IS on Router PE1.  

```
[edit protocols]
user@PE1# set isis level 1 disable
user@PE1# set isis interface all level 2 metric 10
user@PE1# set isis interface fxp0.0 disable
user@PE1# set isis interface lo0.0 level 2 metric 0
```
14. Configure an internal BGP group for Router PE1 to peer with route reflector, Router P.  

```
[edit protocols]
user@PE1# set bgp group RR type internal
user@PE1# set bgp group RR local-address 198.51.100.1
user@PE1# set bgp group RR neighbor 203.0.113.0
```
15. Enable EVPN signaling for the RR BGP group on Router PE1.  

```
[edit protocols]
user@PE1# set bgp group RR family evpn signaling
```
16. Configure RSVP, LDP, MPLS, EVPN, and L2 learning on Router PE1.  

```
[edit protocols]
user@PE1# set rsvp interface all
user@PE1# set rsvp interface fxp0.0 disable

user@PE1# set ldp deaggregate
user@PE1# set ldp interface all
user@PE1# set ldp interface fxp0.0 disable

user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable

user@PE1# set evpn

user@PE1# set l2-learning global-mac-table-aging-time 18000
```
17. Configure label-switched paths between the PE routers.  

```
[edit protocols]
user@PE1# set mpls label-switched-path pe1tope2 from 198.51.100.1
```

```
user@PE1# set mpls label-switched-path pe1tope2 to 198.51.100.2
user@PE1# set mpls label-switched-path pe1tope2 primary direct_to_pe2
```

```
user@PE1# set mpls label-switched-path pe1tope3 from 198.51.100.1
user@PE1# set mpls label-switched-path pe1tope3 to 198.51.100.3
user@PE1# set mpls label-switched-path pe1tope3 primary direct_to_pe3
```

```
user@PE1# set mpls label-switched-path pe1tope4 from 198.51.100.1
user@PE1# set mpls label-switched-path pe1tope4 to 198.51.100.4
user@PE1# set mpls label-switched-path pe1tope4 primary direct_to_pe4
```

18. Configure MPLS paths from Router PE1 to other PE routers.

```
user@PE1# set mpls path pe4_to_pe3 198.51.100.4 strict
user@PE1# set mpls path pe4_to_pe3 198.51.100.3 strict
```

```
user@PE1# set mpls path direct_to_pe2 198.51.100.5 strict
user@PE1# set mpls path direct_to_pe3 198.51.100.6 strict
```

```
user@PE1# set mpls path direct_to_pe4 198.51.100.9 strict
```

```
user@PE1# set mpls path pe2_to_pe3 198.51.100.2 strict
user@PE1# set mpls path pe2_to_pe3 198.51.100.3 strict
```

19. Configure the load-balancing policy to enable load balancing per packet.

```
[edit policy-options]
user@PE1# set policy-statement load-balancing-policy then load-balance per-packet
```

20. Configure the first virtual switch routing instance.

- a. Configure the routing-instance type and assign Router PE1 interfaces to the routing instance.

```
[edit routing-instances]
user@PE1# set VS-1 instance-type virtual-switch
user@PE1# set VS-1 interface ge-1/2/1.130
user@PE1# set VS-1 interface ge-1/2/2.120
user@PE1# set VS-1 interface ge-1/3/0.100
user@PE1# set VS-1 interface ae0.110
```

- b. Configure the route distinguisher and the VPN routing and forwarding (VRF) target for the VS-1 routing instance.

```
[edit routing-instances]
user@PE1# set VS-1 route-distinguisher 198.51.100.1:101
user@PE1# set VS-1 vrf-target target:100:101
```

- c. Configure EVPN and assign VLANs to the VS-1 routing instance.

```
[edit routing-instances]
user@PE1# set VS-1 protocols evpn extended-vlan-list 110
user@PE1# set VS-1 protocols evpn extended-vlan-list 120
user@PE1# set VS-1 protocols evpn extended-vlan-list 130
user@PE1# set VS-1 protocols evpn default-gateway do-not-advertise
```

- d. Configure the bridge domains and their associated VLANs and IRB interfaces for the VS-1 routing instance.

```
[edit routing-instances]
user@PE1# set VS-1 bridge-domains bd-110 vlan-id 110
user@PE1# set VS-1 bridge-domains bd-110 routing-interface irb.0
user@PE1# set VS-1 bridge-domains bd-120 vlan-id 120
user@PE1# set VS-1 bridge-domains bd-120 routing-interface irb.1
user@PE1# set VS-1 bridge-domains bd-130 vlan-id 130
user@PE1# set VS-1 bridge-domains bd-130 routing-interface irb.2
```

- 21. Configure the second virtual switch routing instance.

- a. Configure the routing-instance type and assign Router PE1 interfaces to the routing instance.

```
[edit routing-instances]
user@PE1# set VS-2 instance-type virtual-switch
user@PE1# set VS-2 interface ge-1/2/1.230
user@PE1# set VS-2 interface ge-1/2/2.220
user@PE1# set VS-2 interface ge-1/3/0.200
user@PE1# set VS-2 interface ae0.210
```

- b. Configure the route distinguisher and the VPN routing and forwarding (VRF) target for the VS-2 routing instance.

```
[edit routing-instances]
user@PE1# set VS-2 route-distinguisher 198.51.100.1:201
user@PE1# set VS-2 vrf-target target:100:201
```

- c. Configure EVPN and assign VLANs to the VS-2 routing instance.

```
[edit routing-instances]
user@PE1# set VS-2 protocols evpn extended-vlan-list 210
user@PE1# set VS-2 protocols evpn extended-vlan-list 220
user@PE1# set VS-2 protocols evpn extended-vlan-list 230
```

- d. Configure the bridge domains and their associated VLANs for the VS-2 routing instance.

```
[edit routing-instances]
user@PE1# set routing-instances VS-2 bridge-domains bd-a vlan-id-list 210
user@PE1# set routing-instances VS-2 bridge-domains bd-a vlan-id-list 220
user@PE1# set routing-instances VS-2 bridge-domains bd-a vlan-id-list 230
```

- 22. Configure the multihomed EVPN routing instance.

- a. Configure the routing-instance type and assign VLANs and Router PE1 interfaces to the routing instance.

```
[edit routing-instances]
user@PE1# set mhevpn instance-type evpn
user@PE1# set mhevpn vlan-id 10
user@PE1# set mhevpn interface ge-1/2/1.0
user@PE1# set mhevpn interface ge-1/2/2.0
user@PE1# set mhevpn interface ge-1/3/0.0
user@PE1# set mhevpn interface ae0.0
user@PE1# set mhevpn routing-interface irb.10
```

- b. Configure the route distinguisher and the VPN routing and forwarding (VRF) target for the mhevpn routing instance.

```
[edit routing-instances]
user@PE1# set mhevpn route-distinguisher 198.51.100.1:1
user@PE1# set mhevpn vrf-target target:100:1
```

- c. Configure EVPN to the mhevpn routing instance.

```
[edit routing-instances]
user@PE1# set routing-instances mhevpn protocols evpn default-gateway
do-not-advertise
```

23. Configure the default routing instance.

- a. Configure the routing-instance type and assign IRB interfaces to the routing instance.

```
[edit routing-instances]
user@PE1# set vrf instance-type vrf
user@PE1# set vrf interface irb.0
user@PE1# set vrf interface irb.1
user@PE1# set vrf interface irb.2
user@PE1# set vrf interface irb.10
```

- b. Configure the route distinguisher and the VPN routing and forwarding (VRF) target for the vrf routing instance.

```
[edit routing-instances]
user@PE1# set vrf route-distinguisher 198.51.100.1:11
user@PE1# set vrf vrf-target target:100:11
user@PE1# set vrf vrf-table-label
```

---

### Configuration on EX9200 Switches

#### Step-by-Step Procedure

Several configuration statements used to configure active-active mode differ on EX9200 switches from those used on MX Series routers. This procedure shows which configuration statements are specific to EX9200 switches. All other configuration in this example applies both to EX9200 switches and MX Series routers.

1. To configure a trunk interface, include the **family ethernet-switching** statements instead of the **family bridge** statements in all occurrences.

```
[edit interfaces]
user@PE#1# set interfaces ge-1/2/1 unit 130 family ethernet-switching
interface-mode trunk
```

2. To configure the Layer 2 Ethernet switching domain, include the **vlan members (vlan-id | name)** statement instead of the **vlan-id-list vlan-id** statement in all occurrences.

```
[edit interfaces]
user@PE#1# set interfaces ge-1/2/1 unit 130 family ethernet-switching vlan members
130
```

3. To configure the VLAN domain and associated VLANs for each routing instance, include the **vlan** *name* statement, instead of the **bridge-domains** statement in all occurrences.

[edit]

```
user@PE#1# set routing-instances VS-1 vlans bd-110 vlan-id 110
```

4. To configure the IRB interface in each routing instance, include the **l3-interface** *irb-interface-name* statement instead of the **routing-interface** statement in all occurrences.

[edit]

```
user@PE#1# set routing-instances VS-1 vlans bd-110 l3-interface irb.0
```

## Results

From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show routing-options**, **show protocols**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1 show chassis
aggregated-devices {
 ethernet {
 device-count 20;
 }
}
network-services enhanced-ip;

user@PE1 show interfaces

- [Verifying the BDF Status on page 446](#)
- [Verifying the Remote IRB and Host IP on page 447](#)

### Verifying VPN Services in the Core

---

**Purpose** Ensure that the protocols in the VPN core are functioning properly.

**Action** From operational mode, enter the **show isis adjacency** command.

```
user@PE1> show isis adjacency
Interface System L State Hold (secs) SNPA
ge-1/2/4.0 CE10 2 Up 24
5c:5e:ab:e:6f:4
```

From operational mode, enter the **show bgp summary** command.

```
user@PE1> show bgp summary
Groups: 1 Peers: 1 Down peers: 0
Table Tot Paths Act Paths Suppressed History Damp State Pending
bgp.evpn.0
 45 45 0 0 0 0
Peer AS InPkt OutPkt OutQ Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
203.0.113.0 65221 90 26 0 0 3:18
Establ
 bgp.evpn.0: 45/45/45/0
 VS-1.evpn.0: 19/19/19/0
 VS-2.evpn.0: 19/19/19/0
 mhevpn.evpn.0: 13/13/13/0
 __default__evpn__.evpn.0: 4/4/4/0
```

```
user@P> show bgp summary
Groups: 1 Peers: 4 Down peers: 0
Table Tot Paths Act Paths Suppressed History Damp State Pending
bgp.evpn.0
 68 68 0 0 0 0
Peer AS InPkt OutPkt OutQ Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...

To From State Rt Style Labelin Labelout LSPName
198.51.100.1 198.51.100.3 Up 0 1 FF 3 - pe3tope1
198.51.100.1 198.51.100.4 Up 0 1 FF 3 - pe4tope1
198.51.100.1 198.51.100.2 Up 0 1 FF 3 - pe2tope1
```

Total 3 displayed, Up 3, Down 0

Transit LSP: 0 sessions

Total 0 displayed, Up 0, Down 0

From operational mode, enter the **show interface ae\* terse** command.

```
user@PE1> show interface ae* terse
Interface Admin Link Proto Local Remote
ae0 up up
ae0.0 up up bridge
ae0.110 up up bridge
ae0.210 up up bridge
ae0.32767 up up multiservice
ae12 up up
ae12.0 up up inet 198.51.100.12/24
 iso
 mpls
 multiservice
ae12.32767 up up multiservice
ae13 up up
ae13.0 up up inet 198.51.100.13/24
 iso
 mpls
 multiservice
ae13.32767 up up multiservice
```

**Meaning** The protocols IS-IS, BGP and MPLS are up and running. The aggregated bundles configured on Router PE1 are up.

### Verifying the EVPN Instance Status

**Purpose** Verify the EVPN routing instances and their status.

**Action** From operational mode, run the **show evpn instance extensive** command.

```
user@PE1> show evpn instance extensive
Instance: VS-1

 198.51.100.4 0 305200 all-active

```

**Meaning** The output provides the following information:

- List of EVPN and virtual switch routing instances
- Mode of operation of each interface
- Neighbors of each routing instance
- Number of different routes received from each neighbor
- ESI attached to each routing instance
- Number of Ethernet segments on each routing instance
- DF election roles for each ESI in an EVI
- VLAN ID and MAC labels for each routing instance
- IRB interface details
- Number of default gateway MAC addresses received for the virtual switch routing instance (VS-1 and VS-2)

### Verifying the Autodiscovery Routes per Ethernet Segment

**Purpose** Verify that the autodiscovery routes per Ethernet segment are received.

**Action** From operational mode, run the **show route table mhevpn.evpn.0** command.

#### Router PE1

```
user@PE1> show route table mhevpn.evpn.0
mhevpn.evpn.0: 17 destinations, 17 routes (17 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

```

**Meaning** The output displays the local and remote type 1 (autodiscovery) and type 4 (Ethernet segment) routes.

### Verifying the DF Status

**Purpose** Confirm which PE router is the designated forwarder (DF) for each routing instance.

**Action** From operational mode, run the **show evpn instance designated-forwarder** command.

```

user@PE1> show evpn instance designated forwarder
Instance: VS-1
 Number of ethernet segments: 4
 ESI: 00:11:11:11:11:11:11:11:11:11
 Designated forwarder: 198.51.100.3
 ESI: 00:22:22:22:22:22:22:22:22:22
 Designated forwarder: 198.51.100.1
 ESI: 00:33:33:33:33:33:33:33:33:33
 Designated forwarder: 198.51.100.1
 ESI: 00:44:44:44:44:44:44:44:44:44
 Designated forwarder: No local attachment to ethernet segment

Instance: VS-2
 Number of ethernet segments: 4
 ESI: 00:11:11:11:11:11:11:11:11:11
 Designated forwarder: 198.51.100.1
 ESI: 00:22:22:22:22:22:22:22:22:22
 Designated forwarder: 198.51.100.1
 ESI: 00:33:33:33:33:33:33:33:33:33
 Designated forwarder: 198.51.100.1
 ESI: 00:44:44:44:44:44:44:44:44:44
 Designated forwarder: No local attachment to ethernet segment

Instance: mhevpn
 Number of ethernet segments: 4
 ESI: 00:11:11:11:11:11:11:11:11:11
 Designated forwarder: 198.51.100.2
 ESI: 00:22:22:22:22:22:22:22:22:22
 Designated forwarder: 198.51.100.1

```

```
ESI: 00:33:33:33:33:33:33:33:33:33
 Designated forwarder: 198.51.100.1
ESI: 00:44:44:44:44:44:44:44:44:44
 Designated forwarder: No local attachment to ethernet segment
```

**Meaning** The designated forwarder is displayed for each routing instance and ESI.

---

### Verifying the BDF Status

**Purpose** Confirm which PE router is the backup designated forwarder (BDF) for each routing instance.

**Action** From operational mode, run the **show evpn instance backup-forwarder** command.

```
user@PE1> show evpn instance backup-forwarder
Instance: VS-1
 Number of ethernet segments: 4
 ESI: 00:11:11:11:11:11:11:11:11:11
 Backup forwarder: 198.51.100.1
 Backup forwarder: 198.51.100.2
 ESI: 00:22:22:22:22:22:22:22:22:22
 Backup forwarder: 198.51.100.2
 ESI: 00:33:33:33:33:33:33:33:33:33
 Backup forwarder: 198.51.100.2
 ESI: 00:44:44:44:44:44:44:44:44:44
 Backup forwarder: No local attachment to ethernet segment

Instance: VS-2
 Number of ethernet segments: 4
 ESI: 00:11:11:11:11:11:11:11:11:11
 Backup forwarder: 198.51.100.2
 Backup forwarder: 198.51.100.3
 ESI: 00:22:22:22:22:22:22:22:22:22
 Backup forwarder: 198.51.100.2
 ESI: 00:33:33:33:33:33:33:33:33:33
 Backup forwarder: 198.51.100.2
 ESI: 00:44:44:44:44:44:44:44:44:44
 Backup forwarder: No local attachment to ethernet segment

Instance: mhevpn
 Number of ethernet segments: 4
 ESI: 00:11:11:11:11:11:11:11:11:11
 Backup forwarder: 198.51.100.1
 Backup forwarder: 198.51.100.3
 ESI: 00:22:22:22:22:22:22:22:22:22
 Backup forwarder: 198.51.100.2
 ESI: 00:33:33:33:33:33:33:33:33:33
 Backup forwarder: 198.51.100.2
 ESI: 00:44:44:44:44:44:44:44:44:44
 Backup forwarder: No local attachment to ethernet segment
```

**Meaning** The backup designated forwarder is displayed for each routing instance and ESI.

## Verifying the Remote IRB and Host IP

**Purpose** Verify that the remote IRB IP and the host IP are received.

### Router PE1 Action

From operational mode, run the **show route table mhevpn** command.

```
user@PE1> show route table mhevpn
mhevpn.evpn.0: 17 destinations, 17 routes (17 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

1:198.51.100.1:1::1111111111111111::0/304
 *[EVPN/170] 01:34:26
 Indirect
1:198.51.100.1:1::2222222222222222::0/304
 *[EVPN/170] 01:34:26

**Meaning** The output displays the local and remote IRB interfaces. It also displays the local and remote hosts that are installed in the VRF table.

#### Release History Table

| Release | Description                                                                                                     |
|---------|-----------------------------------------------------------------------------------------------------------------|
| 16.1R4  | Starting with Junos OS Release 16.1R4, EVPN multihoming active-active mode is supported on all EX9200 switches. |

#### Related Documentation

## Example: Configuring LACP for EVPN Active-Active Multihoming

This example shows how to configure the Link Aggregation Control Protocol (LACP) on multihomed customer edge (CE) and provider edge (PE) devices in an Ethernet VPN (EVPN) active-active multihomed network.

- [Requirements on page 451](#)
- [Overview on page 451](#)
- [Configuration on page 454](#)
- [Verification on page 464](#)

### Requirements

This example uses the following hardware and software components:

- Four MX Series 3D Universal Edge Routers with MPC interfaces only, of which:
  - Two routers are configured as PE devices connected to a common multihomed customer site.
  - One router is configured as a remote PE device connected to a single-homed customer site.
  - One router is configured as the core provider device.
- Two CE devices, of which:
  - One CE device is multihomed to the two PE devices.
  - One CE device is single-homed to the remote PE device.
- Junos OS Release 17.1 or later running on all the PE devices.

Before you begin:

1. Configure the device interfaces and enable MPLS on all the interfaces of the PE devices.
2. Configure OSPF or any other IGP between the core provider device and the PE devices.
3. Configure MPLS and a label-switched path (LSP) from the ingress PE device to the remote egress PE device.
4. Configure an internal BGP session between the PE devices.

**NOTE:** We recommend that you configure Bidirectional Forwarding Detection (BFD) on the BGP session for faster detection of core isolation and better convergence.

### Overview

Starting with Junos OS Release 17.1, an extra level of redundancy can be achieved in an EVPN active-active multihoming environment by configuring LACP on both the endpoints

of the multihomed CE-PE link. The multihomed devices are configured with aggregated trunk links, where the link aggregation group (LAG) interfaces of the CE-PE link can either be in the active or in the standby state. When the LAG interface is in the active state, data traffic is transmitted over the CE-PE link. When the LAG interface is in the standby state, data traffic is blocked and only control traffic for communicating LAG interface state is transmitted over the link.

The LAG interface state is monitored and operated by LACP to ensure fast convergence on isolation of a multihomed PE device from the core. When there is a core failure, a traffic black hole can occur at the isolated PE device. However, with the support for LACP on the CE-PE link, at the time of core isolation, the CE-facing interface of the multihomed PE device is set to the standby state, thereby blocking data traffic transmission from and toward the multihomed CE device. After the core recovers from the failure, the interface state is switched back from standby to active.

The support for LACP for EVPN active-active multihoming is applicable to both EVPN with MPLS and EVPN with VXLAN.

When LACP is configured on the CE-PE link, isolation of the multihomed PE device from the core is handled as follows:

1. When the EVPN BGP peers are null for a multihomed PE device, the PE device is isolated from the core. The CE devices connected to the isolated PE device are notified about the core failure by the isolated PE device.
2. On learning about the core failure, data traffic is not forwarded from the CE device to the isolated multihomed PE device. Instead, the traffic is diverted to the other multihomed PE devices that belong to the same LAG. This helps in preventing traffic black holes at the isolated PE device.
3. If the multihomed CE device uses the LAG for load balancing traffic to multiple active multihomed PE devices, then the LACP configuration along with the same system ID configured on all the multihomed PE devices for that given LAG, triggers an LACP out-of-sync to all the attached multihomed CE links.

When configuring LACP on the multihomed devices, be aware of the following considerations:

- The LAG link can operate either in the active or in the standby state regardless of the UP/DOWN operational state.
- On system reboot, the LACP link on the multihomed PE device is in the active state.
- When the control plane goes down or when the BGP-EVPN session is down, LACP is notified to run multiplexer state machine for the aggregation port and move the link from active to standby.
- An interface is not treated as up unless it operates in the active state and its operational state is also up.
- The following features are not supported with LACP on EVPN active-active multihoming:

- Ethernet segment identifier (ESI) value auto-derivation from LACP system ID.
- Redundancy coverage for non-LAG interfaces.
- Redundancy coverage for core isolation with static LAGs.
- Node isolation.
- Access failures for LACP with EVPN active-active multihoming.

## Topology

Figure 40 on page 453 illustrates an EVPN active-active multihoming network with LACP configured on the multihomed CE and PE devices. Device CE1 is single-homed and is connected to a remote PE device, PE1. Device PE2 and Device PE3 connect to a common multihomed CE—CE2. Device P is the core device to which all the PE devices (PE1, PE2, and PE3) are connected.

The endpoints of the multihomed devices—Device CE2, Device PE2, and Device PE3—are configured with LACP on the CE-PE link.

**Figure 40: LACP Support in EVPN Active-Active Multihoming**

Core isolation of Device PE3 is handled as follows:

1. After LACP is configured on the multihomed CE-PE links, the LACP configuration and operational data is synchronized between the LACP peers to operate as a LAG.

The synchronization between the LACP peers happens with the exchange of control PDUs, and is required for the following reasons:

- To determine the state of the links in the Ethernet bundle—all-active or standby.
  - To detect and handle CE device misconfiguration when LACP Port Key is configured on the PE device.
  - To detect and handle miswiring between CE and PE devices when LACP Port Key is configured on the PE device.
  - To detect and react to actor or partner churn when the LACP speakers are not able to converge.
2. After Device PE2 and Device PE3 establish BGP session with at least one peer, the state of the CE-PE link is set to unblocking mode by LACP.

3. When there is a core failure, and the BGP EVPN peers of Device PE2 becomes null, Device PE2 is isolated from the core. This can cause a traffic black hole at Device PE2. To prevent this situation, the LAG interface of Device PE2 that is facing Device CE2 is changed from the active state to the standby state by LACP.
4. An out-of-sync notification is sent from LACP on the attached multihomed CE2 link to block traffic transmission between Device CE2 and Device PE2.
5. When the control plane recovers, that is when Device PE2 establishes BGP session with other EVPN PEs, the LAG interface of Device PE2 is switched back from standby to active by LACP.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

**Device CE1**

```
set interfaces ge-0/0/0 vlan-tagging
set interfaces ge-0/0/0 mac 00:00:00:00:00:01
set interfaces ge-0/0/0 unit 0 vlan-id 100
set interfaces ge-0/0/0 unit 0 family inet address 10.0.0.1/8
set interfaces lo0 unit 0 family inet address 127.0.0.8/8
set routing-options static route 0.0.0.0/0 next-hop 10.0.0.251
```

**Device CE2**

```
set chassis aggregated-devices ethernet device-count 1
set interfaces ge-0/0/0 gigether-options 802.3ad ae0
set interfaces ge-0/0/1 gigether-options 802.3ad ae0
set interfaces ae0 flexible-vlan-tagging
set interfaces ae0 encapsulation flexible-ethernet-services
set interfaces ae0 mac 00:00:00:00:00:03
set interfaces ae0 aggregated-ether-options lacp active
set interfaces ae0 unit 0 vlan-id 100
set interfaces ae0 unit 0 family inet address 10.0.0.3/8
set interfaces ae0 unit 0 family inet address 10.0.0.4/8
set interfaces lo0 unit 0 family inet address 127.0.0.9/8
set routing-options static route 0.0.0.0/0 next-hop 10.0.0.253
```

**Device PE1**

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE2:

**NOTE:** Repeat this procedure for other multihomed PE devices after modifying the appropriate interface names, addresses, and other parameters.

1. Specify the number of aggregated Ethernet interfaces to be created on Device PE2.

```
[edit chassis]
user@PE2# set aggregated-devices ethernet device-count 1
```

2. Configure Device PE2 interfaces that connect to Device P and Device PE3, respectively.

```
[edit interfaces]
user@PE2# set ge-0/0/0 unit 0 family inet address 172.16.0.2/12
user@PE2# set ge-0/0/0 unit 0 family iso
user@PE2# set ge-0/0/0 unit 0 family mpls

user@PE2# set ge-0/0/2 unit 0 family inet address 203.0.113.2/24
user@PE2# set ge-0/0/2 unit 0 family iso
user@PE2# set ge-0/0/2 unit 0 family mpls
```

3. Configure Device PE2 interfaces within the ae0 aggregated bundle toward the multihomed Device CE2.

```
[edit interfaces]
user@PE2# set ge-0/0/1 gigether-options 802.3ad ae0
user@PE2# set ae0 vlan-tagging
user@PE2# set ae0 encapsulation flexible-ethernet-services
user@PE2# set ae0 unit 0 encapsulation vlan-bridge
user@PE2# set ae0 unit 0 vlan-id 100
```

4. Configure active-active multihoming on the aggregated Ethernet interface.

```
[edit interfaces]
user@PE2# set ae0 esi 00:11:22:33:44:55:66:77:88:99
user@PE2# set ae0 esi all-active
```

5. Configure LACP on the CE-PE link of Device PE2.

```
[edit interfaces]
user@PE2# set ae0 aggregated-ether-options lacp active
user@PE2# set ae0 aggregated-ether-options lacp system-id 00:01:02:03:04:05
```

6. Configure the loopback interface of Device PE2.

```
[edit interfaces]
```

```
user@PE2# set lo0 unit 0 family inet address 127.0.0.2/8
```

7. Configure the router ID and autonomous system number for Device PE2.

```
[edit routing-options]
user@PE2# set router-id 127.0.0.2
user@PE2# set autonomous-system 100
```

8. Enable chained composite next hop for EVPN on Device PE2.

```
[edit routing-options]
user@PE2# set forwarding-table chained-composite-next-hop ingress evpn
```

9. Configure MPLS on all the interfaces of Device PE2, excluding the management interface.

```
[edit protocols]
user@PE2# set mpls interface all
user@PE2# set mpls interface fxp0.0 disable
```

10. Configure an internal BGP group for Device PE1 to peer with the other EVPN PE devices.

```
[edit protocols]
user@PE2# set bgp local-address 127.0.0.2
user@PE2# set bgp family inet unicast
user@PE2# set bgp family l2vpn signaling
user@PE2# set bgp group ibgp type internal
user@PE2# set bgp group ibgp local-address 127.0.0.2
user@PE2# set bgp group ibgp family evpn signaling
user@PE2# set bgp group ibgp neighbor 127.0.0.3
user@PE2# set bgp group ibgp neighbor 127.0.0.1
```

11. Configure OSPF and LDP on all the interfaces of Device PE2, excluding the management interface.

```
[edit protocols]
user@PE2# set ospf area 0.0.0.0 interface all
user@PE2# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PE2# set ospf area 0.0.0.0 interface lo0.0 passive
```

```
user@PE2# set ldp interface all
user@PE2# set ldp interface fxp0.0 disable
user@PE2# set ldp interface lo0.0
```

12. Disable distributed PPM processing for only LACP packets.

```
[edit protocols]
user@PE2# set lacp ppm centralized
```

13. Configure an EVPN routing instance on Device PE2 and assign the routing instance parameters.

```
[edit routing-instances]
user@PE2# set ALPHA instance-type evpn
user@PE2# set ALPHA vlan-id 100
user@PE2# set ALPHA interface ae0.0
user@PE2# set ALPHA route-distinguisher 127.0.0.2:100
user@PE2# set ALPHA vrf-target target:100:100
user@PE2# set ALPHA protocols evpn traceoptions file evpn-alpha.txt
user@PE2# set ALPHA protocols evpn traceoptions file size 4294967295
user@PE2# set ALPHA protocols evpn traceoptions flag all
```

14. Specify the service identifier for each multichassis aggregated Ethernet interface that belongs to the link aggregation group (LAG).

```
[edit switch-options]
user@PE2# set service-id 1
```

**Results** From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show routing-options**, **show protocols**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE2# show chassis

If you are done configuring the device, enter **commit** from configuration mode.

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device CE2:

**NOTE:** Repeat this procedure for other multihomed CE devices after modifying the appropriate interface names, addresses, and other parameters.

1. Specify the number of aggregated Ethernet interfaces to be created on Device CE2.

```
[edit chassis]
user@CE2# set aggregated-devices ethernet device-count 1
```

2. Configure Device CE2 interfaces within the ae0 aggregated bundle toward Device PE2 and Device PE3.

```
[edit interfaces]
user@CE2# set ge-0/0/0 gigether-options 802.3ad ae0

user@CE2# set ge-0/0/1 gigether-options 802.3ad ae0

user@CE2# set ae0 flexible-vlan-tagging
user@CE2# set ae0 encapsulation flexible-ethernet-services
user@E2# set ae0 mac 00:00:00:00:00:03
user@E2# set ae0 unit 0 vlan-id 100
user@CE2# set ae0 unit 0 family inet address 10.0.0.3/8
user@CE2# set ae0 unit 0 family inet address 10.0.0.4/8
```

3. Configure LACP on the CE-PE links on Device CE2.

```
[edit interfaces]
user@CE2# set ae0 aggregated-ether-options lacp active
```

4. Configure the loopback interface of Device CE2.

```
[edit interfaces]
user@CE2# set interfaces lo0 unit 0 family inet address 127.0.0.9/8
```

5. Configure a static route for transmitting data traffic from Device CE2 to the attached PE devices.

```
[edit routing-options]
user@CE2# set static route 0.0.0.0/0 next-hop 10.0.0.253
```

**Results** From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show routing-options**, **show protocols**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE2# show chassis
aggregated-devices {
 ethernet {
 device-count 1;
 }
}

user@CE2# show interfaces
ge-0/0/0 {
 gigether-options {
 802.3ad ae0;
 }
}
ge-0/0/1 {
 gigether-options {
 802.3ad ae0;
 }
}
ae0 {
 flexible-vlan-tagging;
 encapsulation flexible-ethernet-services;
 mac 00:00:00:00:00:03;
 aggregated-ether-options {
 lacp {
 active;
 }
 }
 unit 0 {
 vlan-id 100;
 family inet {
 address 10.0.0.3/8;
 address 10.0.0.4/8;
 }
 }
}
lo0 {
 unit 0 {
 family inet {
 address 127.0.0.9/8;
 }
 }
}

user@CE2# show routing-options
static {
 route 0.0.0.0/0 next-hop 10.0.0.253;
}
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying BGP Session Status on page 465](#)
- [Verifying LACP Interface Status of Multihomed PE Device on page 465](#)

- [Verifying LACP Interface State of Isolated PE Device on page 466](#)
- [Verifying EVPN Routing Instance on page 467](#)

### Verifying BGP Session Status

**Purpose** Verify that Device PE2 has established BGP peering with other EVPN PE devices.

**Action** From operational mode, run the **show bgp summary** command.

```
user@PE2> show bgp summary
Groups: 1 Peers: 2 Down peers: 0
Table Tot Paths Act Paths Suppressed History Damp State Pending
inet.0
 0 0 0 0 0 0 0
bgp.l2vpn.0
 0 0 0 0 0 0 0
bgp.evpn.0
 5 5 0 0 0 0 0
Peer AS InPkt OutPkt OutQ Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
127.0.0.1 100 6316 6333 0 0 1d 23:33:03 Establ
 bgp.evpn.0: 1/1/1/0
 ALPHA.evpn.0: 1/1/1/0
 __default_evpn__.evpn.0: 0/0/0/0
127.0.0.3 100 6318 6332 0 0 1d 23:32:56 Establ
 bgp.evpn.0: 4/4/4/0
 ALPHA.evpn.0: 3/3/3/0
 __default_evpn__.evpn.0: 1/1/1/0
```

**Meaning** Device PE2 has established BGP peering with the other EVPN PE devices—Device PE1 and Device PE3.

### Verifying LACP Interface Status of Multihomed PE Device

**Purpose** Verify the LACP interface state on Device PE2.

**Action** From operational mode, run the **show lacp interfaces** and **show interfaces ae\* terse** commands.

```
user@PE2> show lacp interfaces
Aggregated interface: ae0
LACP state: Role Exp Def Dist Col Syn Aggr Timeout Activity
ge-0/0/1 Actor No No Yes Yes Yes Yes Fast Active
ge-0/0/1 Partner No No Yes Yes Yes Yes Fast Active
LACP protocol: Receive State Transmit State Mux State
ge-0/0/1 Current Fast periodic Collecting distributing
```

```
user@PE2> show interfaces ae* terse
Interface Admin Link Proto Local Remote
ae0 up up
ae0.0 up up bridge
ae0.32767 up up multiservice
```

**Meaning** The LACP LAG interface state is active when there is BGP peering with other EVPN PE devices. The physical interface state of the aggregated Ethernet interfaces are up and operational.

### Verifying LACP Interface State of Isolated PE Device

**Purpose** Verify the LACP interface state of Device PE2 when no BGP EVPN peers have been established.

**Action** From operational mode, run the **show lacp interfaces** and **show interfaces ae\* terse** commands.

```
user@PE2> show lacp interfaces
Aggregated interface: ae0
LACP state: Role Exp Def Dist Col Syn Aggr Timeout Activity
ge-0/0/1 Actor No No No No No Yes Fast Active
ge-0/0/1 Partner No No No No Yes Yes Fast Active
LACP protocol: Receive State Transmit State Mux State
ge-0/0/1 Current Fast periodic Waiting
```

```
user@PE2> show interfaces ae* terse
Interface Admin Link Proto Local Remote
ae0 up down
ae0.0 up down bridge
ae0.32767 up down multiservice
```

**Meaning** Because of core isolation, the LAG interface state is in standby, blocking traffic to-and-from Device CE2. As a result, the physical interface state of the aggregated Ethernet interface is also down until the LACP link state switches back to active on core failure recovery.

## Verifying EVPN Routing Instance

**Purpose** Verify the EVPN routing instance parameters on Device PE2.

**Action** From operational mode, run the **show evpn instance extensive** command.

```

user@PE2> show evpn instance extensive
Instance: ALPHA
Route Distinguisher: 127.0.0.2:100
VLAN ID: 100
Per-instance MAC route label: 299776
MAC database status

## EVPN with IRB Solution Overview

---

A Data Center Service Provider (DCSP) hosts the data center for its multiple customers on a common physical network. To each customer (also called a tenant), the service looks like a full-fledged data center that can expand to 4094 VLANs and all private subnets. For disaster recovery, high availability, and optimization of resource utilization, it is common for the DCSP to span across the data center to more than one site. To deploy the data center services, a DCSP faces the following main challenges:

- Extending Layer 2 domains across more than one data center site. This requires optimal intra-subnet traffic forwarding.
- Supporting optimal inter-subnet traffic forwarding and optimal routing in the event of virtual machine (VM).
- Supporting multiple tenants with independent VLAN and subnet space.

Ethernet VPN (EVPN) is targeted to handle all of the above mentioned challenges, wherein:

- The basic EVPN functionality enables optimal intra-subnet traffic forwarding
- Implementing the integrated routing and bridging (IRB) solution in an EVPN deployment enables optimal inter-subnet traffic forwarding
- Configuring EVPN with virtual switch support enables multiple tenants with independent VLAN and subnet space

The following sections describe the IRB solution for EVPNs:

- [Need for an EVPN IRB Solution on page 470](#)
- [Implementing the EVPN IRB Solution on page 471](#)
- [Benefits of Implementing the EVPN IRB Solution on page 473](#)

### Need for an EVPN IRB Solution

EVPN is a technology used to provide Layer 2 extension and interconnection across an IP/MPLS core network to different physical sites belonging to a single Layer 2 domain. In a data center environment with EVPN, there is a need for both Layer 2 (intra-subnet traffic) and Layer 3 (inter-subnet traffic) forwarding and potentially interoperation with tenant Layer 3 VPNs.

With only a Layer 2 solution, there is no optimum forwarding of inter-subnet traffic, even when the traffic is local, for instance, when both the subnets are on the same server.

With only a Layer 3 solution, the following issues for intra-subnet traffic can arise:

- MAC address aliasing issue where duplicate MAC addresses are not detected.
- TTL issue for applications that use TTL 1 to confine traffic within a subnet.
- IPv6 link-local addressing and duplicate address detection that relies on Layer 2 connectivity.

- Layer 3 forwarding does not support the forwarding semantics of a subnet broadcast.
- Support of non-IP applications that require Layer 2 forwarding.

Because of the above mentioned shortcomings of a pure Layer 2 and Layer 3 solution, there is a need for a solution incorporating optimal forwarding of both Layer 2 and Layer 3 traffic in the data center environment when faced with operational considerations such as Layer 3 VPN interoperability and virtual machine (VM) mobility.

An EVPN-based integrated routing and bridging (IRB) solution provides optimum unicast and multicast forwarding for both intra-subnets and inter-subnets within and across data centers.

The EVPN IRB feature is useful for service providers operating in an IP/MPLS network that provides both Layer 2 VPN or VPLS services and Layer 3 VPN services who want to extend their service to provide cloud computation and storage services to their existing customers.

## Implementing the EVPN IRB Solution

An EVPN IRB solution provides the following:

- Optimal forwarding for intra-subnet (Layer 2) traffic.
- Optimal forwarding for inter-subnet (Layer 3) traffic.
- Support for ingress replication for multicast traffic.
- Support for network-based as well as host-based overlay models.
- Support for consistent policy-based forwarding for both Layer 2 and Layer 3 traffic.

Junos OS supports several models of EVPN configuration to satisfy the individual needs of EVPN and data center cloud services customers. To provide flexibility and scalability, multiple bridge domains can be defined within a particular EVPN instance. Likewise, one or more EVPN instances can be associated with a single Layer 3 VPN virtual routing and forwarding (VRF). In general, each data center tenant is assigned a unique Layer 3 VPN VRF, while a tenant could comprise one or more EVPN instances and one or more bridge domains per EVPN instance. To support this model, each configured bridge domain (including the default bridge domain for an EVPN instance) requires an IRB interface to perform the Layer 2 and Layer 3 functions. Each bridge domain or IRB interface maps to a unique IP subnet in the VRF.

**NOTE:** You can associate an IRB interface with the master instance inet.0 table instead of a VRF in an EVPN IRB solution.

---

There are two major functions that are supported for IRB in EVPN.

- Host MAC-IP synchronization

This includes:

- Advertising the IP address along with the MAC advertisement route in EVPN. This is done by using the IP field in the EVPN MAC advertisement route.
- The receiving PE router installs MAC into the EVPN instance (EVI) table and installs IP into the associated VRF.
- Gateway MAC-IP synchronization

This includes:

- Advertising all local IRB MAC and IP addresses in an EVPN. This is achieved by including the default gateway extended community in the EVPN MAC advertisement route.
- The receiving PE creates a forwarding state to route packets destined for the gateway MAC, and a proxy ARP is done for the gateway IP with the MAC advertised in the route.

Figure 41 on page 472 illustrates the inter-subnet traffic forwarding between two provider edge (PE) devices – PE1 and PE2. The IRB1 and IRB2 interfaces on each PE device belong to a different subnet, but they share a common VRF.

**Figure 41: Inter-Subnet Traffic Forwarding**

The inter-subnet traffic forwarding is performed as follows:

1. PE2 advertises H3-M3 and H4-M4 binding to PE1. Similarly PE1 advertises H1-M1 and H2-M2 binding to PE2.
2. PE1 and PE2 install the MAC address in the corresponding EVI MAC table, whereas the IP routes are installed in the shared VRF.
3. The advertising PE device is set as the next hop for the IP routes.
4. If H1 sends packets to H4, the packets are sent to IRB1 on PE1.

5. IP lookup for H4 happens in the shared VRF on PE1. Because the next hop for the H4 IP is PE2 (the advertising PE), an IP unicast packet is sent to PE2.
6. PE1 rewrites the MAC header based on the information in the VRF route, and PE2 performs a MAC lookup to forward the packet to H4.

## Benefits of Implementing the EVPN IRB Solution

The main goal of the EVPN IRB solution is to provide optimal Layer 2 and Layer 3 forwarding. The solution is required to efficiently handle inter-subnet forwarding as well as virtual machine (VM) mobility. VM mobility refers to the ability of a VM to migrate from one server to another within the same or a different data center while retaining its existing MAC and IP address. Providing optimal forwarding for inter-subnet traffic and effective VM mobility involves solving two problems – the default gateway problem and the triangular routing problem.

Starting in Junos OS Release 17.1R1, IPv6 addresses are supported on IRB interfaces with EVPN using the Neighbor Discovery Protocol (NDP). The following capabilities are introduced for IPv6 support with EVPN:

- IPv6 addresses on IRB interfaces in master routing instances
- Learning IPv6 neighborhood from solicited NA message
- NS and NA packets on the IRB interfaces are disabled from network core
- Virtual gateway addresses are used as Layer 3 addresses
- Host MAC-IP synchronization for IPv6

You can configure the IPv6 addresses in the IRB interface at the **[edit interfaces irb]** hierarchy level.

- [Gateway MAC and IP Synchronization on page 473](#)
- [Layer 3 VPN Interworking on page 474](#)

### Gateway MAC and IP Synchronization

---

In an EVPN IRB deployment, the IP default gateway for a VM is the IP address configured on the IRB interface of the provider edge (PE) router corresponding to the bridge domain or VLAN of which the VM is a member. The default gateway problem arises because a VM does not flush its ARP table when relocating from one server to another and continues sending packets with the destination MAC address set to that of the original gateway. If the old and new servers are not part of the same Layer 2 domain (the new Layer 2 domain could be within the current data center or a new data center), the gateway previously identified is no longer the optimal or local gateway. The new gateway needs to identify packets containing the MAC addresses of other gateways on remote PE routers and forward the traffic as if the packets were destined to the local gateway itself. At the minimum, this functionality requires each PE router to advertise its gateway or IRB MAC and IP addresses to all other PE routers in the network. The gateway address exchange can be accomplished using the standard MAC route advertisement message (including the IP address parameter) and tagging that route with the default gateway extended

community so that the remote PE routers can distinguish the gateway MAC advertisement routes from normal MAC advertisement routes.

### Layer 3 VPN Interworking

---

The inter-data center aspect of the EVPN IRB solution involves routing between VMs that are present in different data centers or routing between a host site completely outside of the data center environment and a VM within a data center. This solution relies on the ability of EVPN MAC route advertisements to carry both MAC address and IP address information. The local MAC learning functionality of the PE router is extended to also capture IP address information associated with MAC addresses learned locally. That IP-MAC address mapping information is then distributed to each PE router through normal EVPN procedures. When a PE router receives such MAC and IP information, it installs the MAC route in the EVPN instance as well as a host route for the associated IP address in the Layer 3 VPN VRF corresponding to that EVPN instance. When a VM moves from one data center to another, normal EVPN procedures result in the MAC and IP address being advertised from the new PE router which the VM resides behind. The host route installed in the VRF associated with an EVPN solicits Layer 3 traffic destined to that VM to the new PE router and avoids triangular routing between the source, the former PE router the VM resided behind, and the new PE router.

BGP scalability is a potential concern with the inter-data center triangular routing avoidance solution because of the potential for injection of many host routes into Layer 3 VPN. With the method previously described, in the worst case there is an IP host route for each MAC address learned through the local EVPN MAC learning procedures or through a MAC advertisement message received from a remote PE router. BGP route target filtering can be used to limit distribution of such routes.

The following functional elements are required to implement the inter-data center triangular routing avoidance using Layer 3 inter-subnet forwarding procedures:

1. The source host sends an IP packet using its own source MAC and IP address with the destination MAC of the IRB interface of the local PE router and the IP address of the destination host.
2. When the IRB interface receives the frame with its MAC as the destination, it performs a Layer 3 lookup in the VRF associated with the EVPN instance to determine where to route the packet.
3. In the VRF, the PE router finds the Layer 3 route derived from a MAC plus an IP EVPN route received from the remote PE router earlier. The destination MAC address is then changed to the destination MAC address corresponding to the destination IP.
4. The packet is then forwarded to the remote PE router serving the destination host using MPLS, using the label corresponding to the EVPN instance of which the destination host is a member.

5. The egress PE router receiving the packet performs a Layer 2 lookup for the destination host's MAC and sends the packet to the destination host on the attached subnet via the egress PE router's IRB interface.
6. Because the ingress PE router is performing Layer 3 routing, the IP TTL is decremented.

## Configuring EVPN with IRB Solution

You can configure an Ethernet VPN (EVPN) with IRB solution to enable Layer 2 switching and Layer 3 routing operations within a single node, thus avoiding extra hops for inter-subnet traffic. The EVPN IRB solution eliminates the default gateway problem using the gateway MAC and IP synchronization, and avoids the triangular routing problem with Layer 3 interworking by creating IP host routes for virtual machines (VMs) in the tenant virtual routing and forwarding (VRF) routing instances.

Before you begin:

1. Configure the router interfaces.
2. Configure the router ID and autonomous system number for the device.
3. Enable chained composite next hop for EVPN.
4. Configure OSPF or any other IGP protocol.
5. Configure a BGP internal group.
6. Include the EVPN signaling network layer reachability information (NLRI) to the internal BGP group.
7. Configure RSVP or LDP.
8. Configure MPLS.
9. Create a label-switched path between the provider edge (PE) devices.

To configure the PE device:

1. Configure the EVPN routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance instance-type evpn
```

2. Set the VLAN identifier for the bridging domain in the EVPN routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance vlan-id VLAN-ID
```

3. Configure the interface name for the EVPN routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance interface CE-facing-interface
```

4. Configure the IRB interface as the routing interface for the EVPN routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance routing-interface irb.0
```

5. Configure the route distinguisher for the EVPN routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance route-distinguisher route-distinguisher-value
```

6. Configure the VPN routing and forwarding (VRF) target community for the EVPN routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance vrf-target vrf-target-value
```

7. Assign the interface name that connects the PE device site to the VPN.

```
[edit routing-instances]
user@PE1# set evpn-instance protocols evpn interface CE-facing-interface
```

8. Configure the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vrf-instance instance-type vrf
```

9. Configure the IRB interface as the routing interface for the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vrf-instance interface irb.0
```

10. Configure the route distinguisher for the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vrf-instance route-distinguisher route-distinguisher-value
```

11. Configure the VRF label for the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vrf-instance vrf-table-label
```

12. Verify and commit the configuration.

For example:

```
[edit routing-instances]
user@PE1# set evpna instance-type evpn
user@PE1# set evpna vlan-id 10
user@PE1# set evpna interface ge-1/1/8.0
```

```
user@PE1# set evpna routing-interface irb.0
user@PE1# set evpna route-distinguisher 192.0.2.1:100
user@PE1# set evpna vrf-target target:100:100
user@PE1# set evpna protocols evpn interface ge-1/1/8.0
user@PE1# set vrf instance-type vrf
user@PE1# set vrf interface irb.0
user@PE1# set vrf route-distinguisher 192.0.2.1:300
user@PE1# set vrf vrf-target target:100:300
user@PE1# set vrf vrf-table-label

[edit]
user@PE1# commit
commit complete
```

### Need for an EVPN IRB Solution

EVPN is a technology used to provide Layer 2 extension and interconnection across an IP/MPLS core network to different physical sites belonging to a single Layer 2 domain. In a data center environment with EVPN, there is a need for both Layer 2 (intra-subnet traffic) and Layer 3 (inter-subnet traffic) forwarding and potentially interoperability with tenant Layer 3 VPNs.

With only a Layer 2 solution, there is no optimum forwarding of inter-subnet traffic, even when the traffic is local, for instance, when both the subnets are on the same server.

With only a Layer 3 solution, the following issues for intra-subnet traffic can arise:

- MAC address aliasing issue where duplicate MAC addresses are not detected.
- TTL issue for applications that use TTL 1 to confine traffic within a subnet.
- IPv6 link-local addressing and duplicate address detection that relies on Layer 2 connectivity.

- Layer 3 forwarding does not support the forwarding semantics of a subnet broadcast.
- Support of non-IP applications that require Layer 2 forwarding.

Because of the above mentioned shortcomings of a pure Layer 2 and Layer 3 solution, there is a need for a solution incorporating optimal forwarding of both Layer 2 and Layer 3 traffic in the data center environment when faced with operational considerations such as Layer 3 VPN interoperability and virtual machine (VM) mobility.

An EVPN-based integrated routing and bridging (IRB) solution provides optimum unicast and multicast forwarding for both intra-subnets and inter-subnets within and across data centers.

The EVPN IRB feature is useful for service providers operating in an IP/MPLS network that provides both Layer 2 VPN or VPLS services and Layer 3 VPN services who want to extend their service to provide cloud computation and storage services to their existing customers.

### Implementing the EVPN IRB Solution

---

An EVPN IRB solution provides the following:

- Optimal forwarding for intra-subnet (Layer 2) traffic.
- Optimal forwarding for inter-subnet (Layer 3) traffic.
- Support for ingress replication for multicast traffic.
- Support for network-based as well as host-based overlay models.
- Support for consistent policy-based forwarding for both Layer 2 and Layer 3 traffic.

Junos OS supports several models of EVPN configuration to satisfy the individual needs of EVPN and data center cloud services customers. To provide flexibility and scalability, multiple bridge domains can be defined within a particular EVPN instance. Likewise, one or more EVPN instances can be associated with a single Layer 3 VPN virtual routing and forwarding (VRF). In general, each data center tenant is assigned a unique Layer 3 VPN VRF, while a tenant could comprise one or more EVPN instances and one or more bridge domains per EVPN instance. To support this model, each configured bridge domain (including the default bridge domain for an EVPN instance) requires an IRB interface to perform the Layer 2 and Layer 3 functions. Each bridge domain or IRB interface maps to a unique IP subnet in the VRF.

**NOTE:** You can associate an IRB interface with the master instance inet.0 table instead of a VRF in an EVPN IRB solution.

---

There are two major functions that are supported for IRB in EVPN.

- Host MAC-IP synchronization

This includes:

- Advertising the IP address along with the MAC advertisement route in EVPN. This is done by using the IP field in the EVPN MAC advertisement route.
- The receiving PE router installs MAC into the EVPN instance (EVI) table and installs IP into the associated VRF.
- Gateway MAC-IP synchronization

This includes:

- Advertising all local IRB MAC and IP addresses in an EVPN. This is achieved by including the default gateway extended community in the EVPN MAC advertisement route.
- The receiving PE creates a forwarding state to route packets destined for the gateway MAC, and a proxy ARP is done for the gateway IP with the MAC advertised in the route.

Figure 41 on page 472 illustrates the inter-subnet traffic forwarding between two provider edge (PE) devices – PE1 and PE2. The IRB1 and IRB2 interfaces on each PE device belong to a different subnet, but they share a common VRF.

**Figure 42: Inter-Subnet Traffic Forwarding**

The inter-subnet traffic forwarding is performed as follows:

1. PE2 advertises H3-M3 and H4-M4 binding to PE1. Similarly PE1 advertises H1-M1 and H2-M2 binding to PE2.
2. PE1 and PE2 install the MAC address in the corresponding EVI MAC table, whereas the IP routes are installed in the shared VRF.
3. The advertising PE device is set as the next hop for the IP routes.
4. If H1 sends packets to H4, the packets are sent to IRB1 on PE1.

5. IP lookup for H4 happens in the shared VRF on PE1. Because the next hop for the H4 IP is PE2 (the advertising PE), an IP unicast packet is sent to PE2.
6. PE1 rewrites the MAC header based on the information in the VRF route, and PE2 performs a MAC lookup to forward the packet to H4.

### **Benefits of Implementing the EVPN IRB Solution**

---

The main goal of the EVPN IRB solution is to provide optimal Layer 2 and Layer 3 forwarding. The solution is required to efficiently handle inter-subnet forwarding as well as virtual machine (VM) mobility. VM mobility refers to the ability of a VM to migrate from one server to another within the same or a different data center while retaining its existing MAC and IP address. Providing optimal forwarding for inter-subnet traffic and effective VM mobility involves solving two problems – the default gateway problem and the triangular routing problem.

Starting in Junos OS Release 17.1R1, IPv6 addresses are supported on IRB interfaces with EVPN using the Neighbor Discovery Protocol (NDP). The following capabilities are introduced for IPv6 support with EVPN:

- IPv6 addresses on IRB interfaces in master routing instances
- Learning IPv6 neighborhood from solicited NA message
- NS and NA packets on the IRB interfaces are disabled from network core
- Virtual gateway addresses are used as Layer 3 addresses
- Host MAC-IP synchronization for IPv6

You can configure the IPv6 addresses in the IRB interface at the **[edit interfaces irb]** hierarchy level.

- [Gateway MAC and IP Synchronization on page 481](#)
- [Layer 3 VPN Interworking on page 482](#)

#### **Gateway MAC and IP Synchronization**

In an EVPN IRB deployment, the IP default gateway for a VM is the IP address configured on the IRB interface of the provider edge (PE) router corresponding to the bridge domain or VLAN of which the VM is a member. The default gateway problem arises because a VM does not flush its ARP table when relocating from one server to another and continues sending packets with the destination MAC address set to that of the original gateway. If the old and new servers are not part of the same Layer 2 domain (the new Layer 2 domain could be within the current data center or a new data center), the gateway previously identified is no longer the optimal or local gateway. The new gateway needs to identify packets containing the MAC addresses of other gateways on remote PE routers and forward the traffic as if the packets were destined to the local gateway itself. At the minimum, this functionality requires each PE router to advertise its gateway or IRB MAC and IP addresses to all other PE routers in the network. The gateway address exchange can be accomplished using the standard MAC route advertisement message (including the IP address parameter) and tagging that route with the default gateway extended

community so that the remote PE routers can distinguish the gateway MAC advertisement routes from normal MAC advertisement routes.

### ***Layer 3 VPN Interworking***

The inter-data center aspect of the EVPN IRB solution involves routing between VMs that are present in different data centers or routing between a host site completely outside of the data center environment and a VM within a data center. This solution relies on the ability of EVPN MAC route advertisements to carry both MAC address and IP address information. The local MAC learning functionality of the PE router is extended to also capture IP address information associated with MAC addresses learned locally. That IP-MAC address mapping information is then distributed to each PE router through normal EVPN procedures. When a PE router receives such MAC and IP information, it installs the MAC route in the EVPN instance as well as a host route for the associated IP address in the Layer 3 VPN VRF corresponding to that EVPN instance. When a VM moves from one data center to another, normal EVPN procedures result in the MAC and IP address being advertised from the new PE router which the VM resides behind. The host route installed in the VRF associated with an EVPN solicits Layer 3 traffic destined to that VM to the new PE router and avoids triangular routing between the source, the former PE router the VM resided behind, and the new PE router.

BGP scalability is a potential concern with the inter-data center triangular routing avoidance solution because of the potential for injection of many host routes into Layer 3 VPN. With the method previously described, in the worst case there is an IP host route for each MAC address learned through the local EVPN MAC learning procedures or through a MAC advertisement message received from a remote PE router. BGP route target filtering can be used to limit distribution of such routes.

The following functional elements are required to implement the inter-data center triangular routing avoidance using Layer 3 inter-subnet forwarding procedures:

1. The source host sends an IP packet using its own source MAC and IP address with the destination MAC of the IRB interface of the local PE router and the IP address of the destination host.
2. When the IRB interface receives the frame with its MAC as the destination, it performs a Layer 3 lookup in the VRF associated with the EVPN instance to determine where to route the packet.
3. In the VRF, the PE router finds the Layer 3 route derived from a MAC plus an IP EVPN route received from the remote PE router earlier. The destination MAC address is then changed to the destination MAC address corresponding to the destination IP.
4. The packet is then forwarded to the remote PE router serving the destination host using MPLS, using the label corresponding to the EVPN instance of which the destination host is a member.

5. The egress PE router receiving the packet performs a Layer 2 lookup for the destination host's MAC and sends the packet to the destination host on the attached subnet via the egress PE router's IRB interface.
6. Because the ingress PE router is performing Layer 3 routing, the IP TTL is decremented.

## Example: Configuring EVPN with IRB Solution

This example shows how to configure an integrated routing and bridging (IRB) solution in an Ethernet VPN (EVPN) deployment.

- [Requirements on page 483](#)
- [Overview on page 483](#)
- [Configuration on page 484](#)
- [Verification on page 490](#)

---

### Requirements

This example uses the following hardware and software components:

- Two MX Series 3D Universal Edge Routers containing MPC FPCs configured as PE routers.
- Two customer edge (CE) routers, each connected to the PE routers.
- Junos OS Release 14.1 or later running on all the PE routers.

Before you begin:

1. Configure the router interfaces.
2. Configure OSPF or any other IGP protocol.
3. Configure BGP.
4. Configure RSVP or LDP.
5. Configure MPLS.

---

### Overview

In an EVPN solution, multiple bridge domains can be defined within a particular EVPN instance, and one or more EVPN instances can be associated with a single Layer 3 VPN VRF. In general, each data center tenant is assigned a unique Layer 3 VPN virtual route forwarding (VRF), although the tenant can be comprised of one or more EVPN instances or bridge domains per EVPN instance.

To support this flexibility and scalability factor, the EVPN solution provides support for the IRB interfaces on MX Series routers containing MPC FPCs to facilitate optimal Layer 2 and Layer 3 forwarding along with virtual machine mobility. The IRB interfaces are configured on each configured bridge domain including the default bridge domain for an EVPN instance.

IRB is the ability to do Layer 2 switching and Layer 3 routing within a single node, thus avoiding extra hops for inter-subnet traffic. The EVPN IRB solution eliminates the default gateway problem using the gateway MAC and IP synchronization, and avoids the triangular routing problem with Layer 3 interworking by creating IP host routes for virtual machines (VMs) in the tenant VRFs.

### Topology

Figure 43 on page 484 illustrates a simple EVPN topology with IRB solution. Routers PE1 and PE2 are the provider edge routers that connect to two customer edge (CE) routers each – CE1 and CE2.

Figure 43: EVPN with IRB Solution

### Configuration

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
CE1 set interfaces ge-1/1/7 vlan-tagging
 set interfaces ge-1/1/7 unit 0 vlan-id 10
 set interfaces ge-1/1/7 unit 0 family inet address 10.0.0.1/24
 set routing-options static route 192.0.2.0/24 next-hop 10.0.0.251

PE1 set interfaces ge-1/0/8 unit 0 family inet address 10.0.0.1/30
 set interfaces ge-1/0/8 unit 0 family mpls
 set interfaces ge-1/1/8 flexible-vlan-tagging
 set interfaces ge-1/1/8 encapsulation flexible-ethernet-services
 set interfaces ge-1/1/8 unit 0 encapsulation vlan-bridge
 set interfaces ge-1/1/8 unit 0 vlan-id 10
 set interfaces irb unit 0 family inet address 10.0.0.251/24
 set interfaces lo0 unit 0 family inet address 10.255.0.1/32
 set routing-options router-id 10.255.0.1
 set routing-options autonomous-system 100
 set routing-options forwarding-table chained-composite-next-hop ingress evpn
 set protocols rsvp interface all
 set protocols rsvp interface fxp0.0 disable
 set protocols mpls label-switched-path PE1-to-PE2 from 10.255.0.1
 set protocols mpls label-switched-path PE1-to-PE2 to 10.255.0.2
 set protocols mpls interface all
 set protocols mpls interface fxp0.0 disable
 set protocols bgp group ibgp type internal
 set protocols bgp group ibgp local-address 10.255.0.1
 set protocols bgp group ibgp family evpn signaling
 set protocols bgp group ibgp neighbor 10.255.0.2
 set protocols ospf area 0.0.0.0 interface all
 set protocols ospf area 0.0.0.0 interface fxp0.0 disable
```

```

set routing-instances evpna instance-type evpn
set routing-instances evpna vlan-id 10
set routing-instances evpna interface ge-1/1/8.0
set routing-instances evpna routing-interface irb.0
set routing-instances evpna route-distinguisher 10.255.0.1:100
set routing-instances evpna vrf-target target:100:100

 set routing-instances vrf vrf-target target:200:300
 set routing-instances vrf vrf-table-label

```

```

CE2 set interfaces ge-2/1/7 unit 0 vlan-id 20
 set interfaces ge-2/1/7 unit 0 family inet address 192.0.2.0/24
 set routing-options static route 10.0.0.0/24 next-hop 192.0.2.5

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router PE1:

**NOTE:** Repeat this procedure for Router PE2, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure Router PE1 interfaces.

**[edit interfaces]**

```
user@PE1# set ge-1/0/8 unit 0 family inet address 10.0.0.1/30
user@PE1# set ge-1/0/8 unit 0 family mpls
```

```
user@PE1# set ge-1/1/8 flexible-vlan-tagging
user@PE1# set ge-1/1/8 encapsulation flexible-ethernet-services
user@PE1# set ge-1/1/8 unit 0 encapsulation vlan-bridge
user@PE1# set ge-1/1/8 unit 0 vlan-id 10
```

```
user@PE1# set irb unit 0 family inet address 10.0.0.251/24
```

```
user@PE1# set lo0 unit 0 family inet address 10.255.0.1/32
```

2. Set the router ID and autonomous system number for Router PE1.

**[edit routing-options]**

```
user@PE1# set router-id 10.255.0.1
user@PE1# set autonomous-system 100
```

3. Configure the chained composite next hop for EVPN.

**[edit routing-options]**

```
user@PE1# set forwarding-table chained-composite-next-hop ingress evpn
```

4. Enable RSVP on all the interfaces of Router PE1, excluding the management interface.

**[edit protocols]**

```
user@PE1# set rsvp interface all
user@PE1# set rsvp interface fxp0.0 disable
```

5. Create label-switched path for Router PE1 to reach Router PE2.

**[edit protocols]**

```
user@PE1# set mpls label-switched-path PE1-to-PE2 from 10.255.0.1
user@PE1# set mpls label-switched-path PE1-to-PE2 to 10.255.0.2
```

6. Enable MPLS on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls mpls interface fxp0.0 disable
```

7. Configure the BGP group for Router PE1.

```
[edit protocols]
user@PE1# set bgp group ibgp type internal
```

8. Assign local and neighbor addresses to the ibgp BGP group for Router PE1 to peer with Router PE2.

```
[edit protocols]
user@PE1# set bgp group ibgp local-address 10.255.0.1
user@PE1# set bgp group ibgp neighbor 10.255.0.2
```

9. Include the EVPN signaling Network Layer Reachability Information (NLRI) to the ibgp BGP group.

```
[edit protocols]
user@PE1# set bgp group ibgp family evpn signaling
```

10. Configure OSPF on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

11. Configure the EVPN routing instance.

```
[edit routing-instances]
user@PE1# set evpn instance-type evpn
```

12. Set the VLAN identifier for the bridging domain in the evpn routing instance.

```
[edit routing-instances]
user@PE1# set evpn vlan-id 10
```

13. Configure the interface name for the evpn routing instance.

```
[edit routing-instances]
user@PE1# set evpn interface ge-1/1/8.0
```

14. Configure the IRB interface as the routing interface for the evpn routing instance.

```
[edit routing-instances]
user@PE1# set evpn routing-interface irb.0
```

15. Configure the route distinguisher for the evpn routing instance.

```
[edit routing-instances]
user@PE1# set evpn route-distinguisher 10.255.0.1:100
```

16. Configure the VPN routing and forwarding (VRF) target community for the evpna routing instance.

```
[edit routing-instances]
user@PE1# set evpna vrf-target target:100:100
```

17. Assign the interface name that connects the PE1 site to the VPN.

```
[edit routing-instances]
user@PE1# set evpna protocols evpn interface ge-1/1/8.0
```

18. Configure the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vrf instance-type vrf
```

19. Configure the IRB interface as the routing interface for the vrf routing instance.

```
[edit routing-instances]
user@PE1# set vrf interface irb.0
```

20. Configure the route distinguisher for the vrf routing instance.

```
[edit routing-instances]
user@PE1# set vrf route-distinguisher 10.255.0.1:300
```

21. Configure the VRF label for the vrf routing instance.

```
[edit routing-instances]
user@PE1# set vrf vrf-table-label
```

### **Results**

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-1/0/8 {
 unit 0 {
 family inet {
 address 10.0.0.1/30;
 }
 family mpls;
 }
}
ge-1/1/8 {
 flexible-vlan-tagging;
 encapsulation flexible-ethernet-services;
 unit 0 {
 encapsulation vlan-bridge;
 vlan-id 10;
 }
}
```

```

 }
 }
 irb {
 unit 0 {
 family inet {
 address 10.0.0.251/24;
 }
 }
 }
 lo0 {
 unit 0 {
 family inet {
 address 10.255.0.1/32 {
 }
 }
 }
 }
}

user@PE1# show routing-options
router-id 10.255.0.1;
autonomous-system 100;
forwarding-table {
 chained-composite-next-hop {
 ingress {
 evpn;
 }
 }
}

user@PE1# show protocols
rsvp {
 interface all;
 interface fxp0.0 {
 disable;
 }
}
mpls {
 label-switched-path PE1-to-PE2 {
 from 10.255.0.1;
 to 10.255.0.2;
 }
 interface all;
 interface fxp0.0 {
 disable;
 }
}
bgp {
 group ibgp {
 type internal;
 local-address 10.255.0.1;
 family evpn {
 signaling;
 }
 neighbor 10.255.0.2;
 }
}
ospf {

```

```
area 0.0.0.0 {
 interface all;
 interface fxp0.0 {
 disable;
 }
}

user@PE1# show routing-instances
evpna {
 instance-type evpn;
 vlan-id 10;
 interface ge-1/1/8.0;
 routing-interface irb.0;
 route-distinguisher 10.255.0.1:100;
 vrf-target target:100:100;
 protocols {
 evpn {
 interface ge-1/1/8.0;
 }
 }
}
vrf {
 instance-type vrf;
 interface irb.0;
 route-distinguisher 10.255.0.1:300;
 vrf-target target:100:300;
 vrf-table-label;
}
```

- [Verifying CE-PE Inter-Subnet Forwarding on page 495](#)
- [Verifying PE-PE Inter-Subnet Forwarding on page 496](#)

#### ***Verifying Local IRB MACs***

**Purpose** Verify that the local IRB MACs are learned from L2ALD.

**Action** On Router PE1, determine the MAC address of the local IRB interface.

From operational mode, run the **show interfaces irb extensive | match "Current address"** command.

```
user@PE1> show interfaces irb extensive | match "Current address"
```

Current address: a8:d0:e5:54:0d:10, Hardware address: a8:d0:e5:54:0d:10

From operational mode, run the **show route table evpn.evpn.0 extensive | find "a8:d0:e5:54:0d:10"** command.

```
user@PE1> show route table evpn.evpn.0 extensive | find "a8:d0:e5:54:0d:10"
2:10.255.0.1:100::0::100::a8:d0:e5:54:0d:10/384 (1 entry, 1 announced)
TSI:
Page 0 idx 0, (group PE type Internal) Type 1 val 0x2736568 (adv_entry)
 Advertised metrics:
 Flags: Nexthop Change
 Nexthop: Self
 Localpref: 100
 AS path: [100] I

 Route Label: 299776
```

**Meaning** The MAC-only route for the local IRB interface appears in the EVPN instance route table on Router PE1 and is learned from EVPN and tagged with the default gateway extended community.

### *Verifying Remote IRB MACs*

**Purpose** Verify that the remote IRB MACs are learned from BGP.

**Action** On Router PE1, determine the MAC address of the local IRB interface.

From operational mode, run the **show interfaces irb extensive | match "Current address"** command.

```
user@PE1> show interfaces irb extensive | match "Current address"
Current address: a8:d0:e5:54:0d:10, Hardware address: a8:d0:e5:54:0d:10
```

On Router PE2, verify that the remote IRB MACs are learned.

From operational mode, run the **show route table evpn.evpn.0 extensive | find "a8:d0:e5:54:0d:10"** command.

```
user@PE2> show route table evpn.evpn.0 extensive | find "a8:d0:e5:54:0d:10"
```

```

**Meaning** The MAC-only route for the remote IRB interface appears in the EVPN instance route table on Router PE2 and is learned from BGP and tagged with the default gateway extended community.

### *Verifying Local IRB IPs*

**Purpose** Verify that the local IRB IPs are learned locally by RPD.

**Action** On Router PE1, determine the MAC and IP addresses of the local IRB interface.

From operational mode, run the **show interfaces irb extensive | match "Current address"** command.

```

user@PE1> show interfaces irb extensive | match "Current address"
Current address: a8:d0:e5:54:0d:10, Hardware address: a8:d0:e5:54:0d:10

```

From operational mode, run the **show interfaces irb.0 terse | match inet** command.

```

user@PE1> show interfaces irb.0 terse | match inet
irb.0 up up inet 10.0.0.251/24

```

From operational mode, run the **show route table evpn.evpn.0 extensive | find "a8:d0:e5:54:0d:10::10.0.0.251"** command.

```
user@PE2> show route table evpn.evpn.0 extensive | find "a8:d0:e5:54:0d:10::10.0.0.251"
2:10.255.0.1:100::0::100::a8:d0:e5:54:0d:10::10.0.0.251/384 (1 entry, 1 announced)

### *Verifying Remote IRB IPs*

**Purpose** Verify that the remote IRB IPs are learned from BGP.

**Action** On Router PE1, determine the MAC and IP addresses of the local IRB interface.

From operational mode, run the **show interfaces irb extensive | match "Current address"** command.

```
user@PE1> show interfaces irb extensive | match "Current address"
Current address: a8:d0:e5:54:0d:10, Hardware address: a8:d0:e5:54:0d:10

**Meaning** The MAC plus IP route for the remote IRB interface appears in the EVPN instance route table on Router PE2 and is tagged with the default gateway extended community.

### *Verifying CE-CE Inter-Subnet Forwarding*

**Purpose** Verify inter-subnet forwarding between Routers CE1 and CE2.

**Action** From operational mode, run the **show route table inet.0** command.

```
user@CE1> show route table inet.0
inet.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

0.0.0.0/0 *[Static/5] 00:15:09
 > to 10.0.0.251 via ge-1/1/7.0
10.0.0.0/24 *[Direct/0] 1d 23:24:30
 > via ge-1/1/7.0
10.0.0.1/32 *[Local/0] 1d 23:24:38
 Local via ge-1/1/7.0
```

From operational mode, run the **ping** command.

```
user@CE1> ping 192.0.2.0 interval 0.1 count 10
PING 192.0.2.0 (192.0.2.0): 56 data bytes
64 bytes from 192.0.2.0: icmp_seq=0 ttl=63 time=0.919 ms

round-trip min/avg/max/stddev = 0.666/1.959/12.967/3.670 ms
```

**Meaning** Ping from Router CE1 to Router CE2 is successful.

### *Verifying CE-PE Inter-Subnet Forwarding*

**Purpose** Verify inter-subnet forwarding between Routers CE1 and PE2.

**Action** From operational mode, run the **show route table inet.0** command.

```
user@CE1> show route table inet.0
inet.0: 3 destinations, 3 routes (3 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

round-trip min/avg/max/stddev = 0.695/2.288/9.613/3.142 ms
```

**Meaning** Ping from Router PE1 to Router PE2's IRB interface is successful.

## NSR and Unified ISSU Support for EVPN Overview

Starting in Release 16.2, Junos OS ensures minimal loss of traffic when a Routing Engine switchover occurs with nonstop active routing (NSR) and graceful Routing Engine switchover (GRES) enabled. The forwarding state of the Packet Forwarding Engine (PFE) remains intact during switchover. The signaling state on the primary Routing Engine and on the standby Routing Engine are built in parallel.

EVPN reproduces dynamically generated data (such as labels and sequence numbers), and data obtained from peers on the primary Routing Engine, and on the standby Routing Engine. EVPN also monitors BGP ingress and egress routing table messages on the standby Routing Engine to populate its signaling plane data structures. Local MAC addresses are obtained by the Layer 2 address learning process (l2ald), which transfers the data to the EVPN module in the route processing software. In the network layer reachability information (NLRI) fields of its packets, BGP transfers the MAC addresses to peers in the network.

In earlier releases, the l2ald did not run on the standby Routing Engine. Consequently, the l2ald did not inform the routing protocol process on the standby Routing Engine about locally learned MAC addresses. With this feature, the routing protocol process learns

acquires-learned MAC addresses by listening to the BGP ingress and egress routing table messages and then populates its data structures.

Following a switchover, when the l2ald becomes active on the new primary Routing Engine, it sends all locally-learned MAC addresses to the routing protocol process, which can then verify the MAC addresses learned from the l2ald with MAC addresses derived from the BGP routing table egress messages.

**NOTE:** Expect a traffic loss pertaining to a topology change if the topology change occurs during a switchover.

This feature mirrors the following data to the standby Routing Engine:

- MAC route labels—EVPN allocates a MAC route label per EVPN instance (EVI) and per Ethernet segment Identifier (ESI). MAC labels, including the EVI and ESI are mirrored to the standby Routing Engine.
- Inclusive multicast (IM) route labels—EVPN allocates an IM label per VLAN. An IM label, including the EVI name and VLAN ID are mirrored to the standby Routing Engine.
- Split horizon labels—EVPN mirrors a split horizon label and the EVI name to the standby Routing Engine.
- Aliasing labels—EVPN mirrors an aliasing label and EVI name to the standby Routing Engine.
- Dummy labels—EVPN creates a dummy label with which it adds the egress route to the mpls.0 table. EVPN mirrors a dummy label and the EVI name to the standby Routing Engine so the mpls.0 table is identical on the primary and standby Routing Engines.

#### **NSR Data Flow Pre-Switchover**

The EVPN configuration on the standby Routing Engine directs it to operate identically to the primary Routing Engine except that it does not allocate any labels. Label information is updated on the standby Routing Engine when it receives the information from its label information base mirror (libmirror).

BGP updates remote MAC addresses in the instance.EVPN table on the standby Routing Engine. Just as EVPN operates on the primary Routing Engine, the standby Routing Engine derives information from its flash drive to update its data structures.

To gather local MAC addresses and update data structures, EVPN on the standby Routing Engine listens to routing information base (RIB, also known as routing table) egress messages. All MAC addresses that the standby Routing Engine learns from the BGP RIB egress messages are marked as stale. Following a switchover, when the l2ald becomes active, if it sends MAC addresses that are identical to those marked stale, the addresses are retained. If the l2ald does not send the same MAC addresses learned from BGP RIB egress messages, it deletes the addresses.

#### **NSR Data Flow Post Switchover**

Following a switchover, when the standby Routing Engine becomes the primary Routing Engine, it establishes connection with the l2ald. When the l2ald becomes active, it sends local MAC addresses to the routing protocol process. The routing protocol process removes the stale bit from the MAC addresses it receives from the l2ald.

MAC addresses that were not derived from BGP RIB egress messages, but were sent to the routing protocol process by the l2ald, are treated as newly learned MAC addresses. BGP advertises such MAC addresses.

When the l2ald sends the end marker of the MAC address to the routing protocol process, all local MAC addresses marked as stale are deleted.

### Unified ISSU Support

Starting in Junos OS Release 17.2R1, unified in-service software upgrade is supported for VXLAN on MX Series routers. ISSU enables you to upgrade your Junos OS software on your MX Series router with no disruption on the control plane and with minimal disruption of traffic. Unified ISSU is supported only on dual Routing Engine platforms. In addition, the graceful Routing Engine switchover (GRES) and nonstop active routing (NSR) features must be enabled. Unified ISSU allows you to eliminate network downtime, reduce operating costs, and deliver higher levels of services. See *Getting Started with Unified In-Service Software Upgrade*.

To enable GRES, include the **graceful-switchover** statement at the **[edit chassis redundancy]** hierarchy level.

To enable NSR, include the **nonstop-routing** statement at the **[edit routing-options]** hierarchy level and the **commit synchronize** statement at the **[edit system]** hierarchy level.

## Overview of VLAN Bundle Service and VLAN-Aware Bundle Service for EVPN

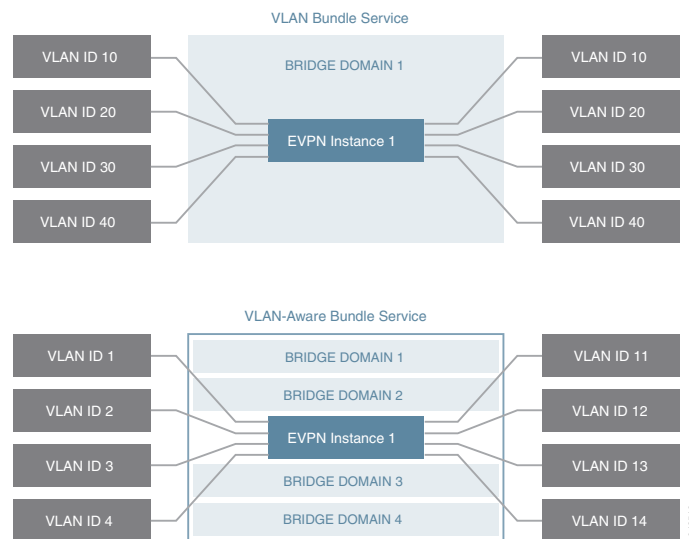

---

A Data Center Service Provider (DCSP) hosts the data center for its multiple customers on a common physical network. To each customer (also called a tenant), the service looks like a full-fledged data center that can expand to 4094 VLANs and all private subnets. For disaster recovery, high availability, and optimization of resource utilization, it is common for the DCSP to span across the data center to more than one site. When deploying the data center services, a DCSP faces the following main challenges:

- Extending Layer 2 domains across more than one data center site. This requires optimal intra-subnet traffic forwarding.
- Supporting optimal inter-subnet traffic forwarding and optimal routing in the event of virtual machine (VM).
- Supporting multiple tenants with independent VLAN and subnet space.

The DCSP might require Ethernet VLAN services to be extended over a WAN with a single EVPN instance (EVI). Junos OS supports both VLAN bundle service and VLAN-aware bundle service, which maintain data and control plane separation. [Figure 44 on page 502](#) illustrates the relationship between VLANs and EVIs in VLAN bundle service and VLAN-aware bundle service. Both support the mapping of one EVI to many VLAN IDs (VIDs), but VLAN bundle service supports only one bridge domain and the bridge table is shared among the different VLANs, while VLAN-aware bundle service supports multiple bridge tables, with each bridge table corresponding to a different VLAN.

Figure 44: VLAN Bundle Service and VLAN-Aware Bundle Service

  - [Virtual Switch Support for EVPN Overview on page 506](#)

## VLAN Bundle Service for EVPN

Starting with Junos OS Release 17.1, VLAN bundle service allows multiple broadcast domains to map to a single bridge domain. Multiple VLANs are mapped to a single EVPN instance (EVI) and share the same bridge table in the MAC-VRF table, thus reducing the number of routes and labels stored in the table. This lowers the control plane overhead on the router. Having a single bridge domain requires all CE devices in the VLAN network to have unique MAC addresses. VLAN ID translation is not permitted as the MPLS encapsulated frames must retain the originating VLAN ID. As such the Ethernet Tag ID in all EVPN routes is set to zero. A VLAN range cannot be specified. The entire VLAN from 1 to 4095 must be bundled on the interface.

[Figure 45 on page 502](#) illustrates a topology where VID 100 and VID 200 are bundled and assigned to EVI1. The service provider creates a single broadcast domain for the customer and assigns a preconfigured number of CE-VIDs on the ingress PE routers (PE1 through PE5) to EVI 1. All CE devices use the same CE-VIDs for the EVI.

Figure 45: VLAN Bundle Network Topology

Using the VLAN bundle service reduces the number of routes and labels, which in turn, reduces the control plane overhead. The trade-off for the ease of provisioning in a customer network is that the service provider has no control over the customer broadcast domain since there is a single inclusive multicast tree and no CE-VID translation. .

**NOTE:** Junos OS also supports port-based VLAN bundle service where all of the VLANs on a port are part of the same service and are mapped to the same bundle.

**NOTE:** Integrated routing and bridging (IRB) is not supported for VLAN bundle service.

## Configuring EVPN VLAN Bundle Services

To configure EVPN VLAN bundle services, complete the following configuration on all PE routers within the EVPN service provider's network:

1. Configure the EVPN routing instance name using the **routing-instances** statement at the **[edit]** hierarchy level:

```
routing-instances routing-instance-name {...}
```

2. Configure the **evpn** option for the **instance-type** statement at the **[edit routing-instances *routing-instance-name*]** hierarchy level:

```
instance-type evpn;
```

3. Configure a route distinguisher on a PE router by including the **route-distinguisher** statement:

```
route-distinguisher (as-number:number | ip-address:number);
```

Each routing instance that you configure on a PE router must have a unique route distinguisher associated with it. VPN routing instances need a route distinguisher to help BGP to distinguish between potentially identical network layer reachability information (NLRI) messages received from different VPNs. If you configure different VPN routing instances with the same route distinguisher, the commit fails.

For a list of the hierarchy levels at which you can include the **route-distinguisher** statement, see [route-distinguisher](#).

The route distinguisher is a 6-byte value that you can specify in either of the following formats:

- **as-number:number**, where **as-number** is an autonomous system (AS) number (a 2-byte value) and **number** is any 4-byte value. The AS number can be in the range 1 through 65,535. We recommend that you use an Internet Assigned Numbers Authority (IANA)-assigned, nonprivate AS number, preferably the ISP's own or the customer's own AS number.

**NOTE:** The automatic derivation of the BGP route target (auto-RT) for advertised prefixes is supported on 2-byte AS numbers only.

- **ip-address:number**, where **ip-address** is an IP address (a 4-byte value) and **number** is any 2-byte value. The IP address can be any globally unique unicast address. We recommend that you use the address that you configure in the **router-id** statement, which is a nonprivate address in your assigned prefix range.
4. Configure either import and export policies for the EVPN routing table, or configure the default policies using the **vrf-target** statement at the **[edit routing-instances routing-instance-name]** hierarchy level.

See “[Configuring Policies for the VRF Table on PE Routers in VPNs](#)” on page 25.

5. Configure each EVPN interface for the EVPN routing instance:

**NOTE:** Adding a trunk port with dual tags to an EVPN and MPLS routing instance to an EVPN and VXLAN routing instance causes the CLI commit check configuration to fail and generate an error. To avoid configuration check errors, use sub-interface style interface configuration with dual tags for the routing instances.

- a. Configure each interface using the **interface** statement at the **[edit routing-instances routing-instance-name protocols evpn]** hierarchy level.
- b. Configure interface encapsulation for the CE-facing interfaces at the **[edit interfaces interface-name encapsulation]** hierarchy level. Supported encapsulations are ethernet-bridge, vlan-bridge, and extended-vlan-bridge. .

**NOTE:** If you are configuring the port-based VLAN bundle service, you will need to also configure the interface encapsulation ethernet-bridge unit to 0.

- c. (Optional) Include the **ignore-encapsulation-mismatch** statement at the **[edit routing-instances routing-instance-name protocols evpn interface interface-name]**

hierarchy level to allow the EVPN to establish a connection to the CE device even if the CE device interface encapsulation and the EVPN interface encapsulations do not match.

- d. Specify a static MAC address for a logical interface in a bridge domain using the `static-mac` statement at the `[edit routing-instances routing-instance-name protocols evpn interface interface-name]` hierarchy level.
6. Specify the maximum number of media access control (MAC) addresses that can be learned by the EVPN routing instance by including the `interface-mac-limit` statement.

You can configure the same limit for all interfaces configured for a routing instance by including the `interface-mac-limit` statement at the `[edit routing-instances routing-instance-name protocols evpn]` hierarchy level. You can also configure a limit for a specific interface by including this statement at the `[edit routing-instances routing-instance-name protocols evpn interface interface-name]` hierarchy level.

By default, packets with new source MAC addresses are forwarded after the MAC address limit is reached. You can alter this behavior by including the `packet-action drop` statement at either the `[edit routing-instances routing-instance-name protocols evpn interface-mac-limit]` or the `[edit routing-instances routing-instance-name protocols evpn interface interface-name]` hierarchy level. If you configure this statement, packets from new source MAC addresses are dropped after the configured MAC address limit is reached.

7. Specify the MPLS label allocation setting for the EVPN by including the `label-allocation` statement with the `per-instance` option at the `[edit routing-instances routing-instance-name protocols evpn]` hierarchy level.

If you configure this statement, one MPLS label is allocated for the specified EVPN routing instance.

8. Enable MAC accounting for the EVPN by including the `mac-statistics` statement at the `[edit routing-instances routing-instance-name protocols evpn]` hierarchy level.
9. Disable MAC learning by including the `no-mac-learning` statement at either the `[edit routing-instances routing-instance-name protocols evpn]` hierarchy level to apply this behavior to all of the devices configured for an EVPN routing instance or at the `[edit routing-instances routing-instance-name protocols evpn interface interface-name]` hierarchy level to apply this behavior to only one of the CE devices.

The following output shows a sample EVPN VLAN bundle services configuration.

```
user@router1# show routing-instances evpn_1
 instance-type evpn;
 interface xe-2/3/3.300;
 route-distinguisher 7.7.7.7:3;
 vrf-target target:65221:3;
 protocols evpn;
 label-allocation per-instance;
 }
```

---

## Virtual Switch Support for EVPN Overview

---

Starting with Junos OS Release 14.1, VLAN-aware bundle service is introduced. .. This feature allows Ethernet VLANs over a WAN to share a single EVPN instance while maintaining data-plane separation between the different VLANs.

Junos OS has a highly flexible and scalable virtual switch interface. With a virtual switch, a single MX Series router can be divided into multiple logical switches. Layer 2 domains (also called *bridge-domains*) can be defined independently in each virtual switch. To configure VLAN-aware bundle service, an EVPN must run in a virtual-switch routing instance.

A single EVPN instance can stretch up to 4094 bridge domains defined in a virtual switch to remote sites. A virtual switch can have more than 4094 bridge domains with a combination of none, single, and dual VLANs. However, because EVPN signaling deals only with single VLAN tags, a maximum of 4094 bridge domains can be stretched. The EVPN virtual switch also provides support for trunk and access interfaces.

### NOTE:

- The none VLAN option is not supported with bridge domains under the virtual switch instance type for EVPNs.
  - Dual VLANs are not supported with EVPN although they can be configured.
- 

There are two types of VLAN-aware bundle service:

- VLAN-aware bundle without translation

The service interface provides bundling of customer VLANs into a single Layer 2 VPN service instance with a guarantee end-to-end customer VLAN transparency. The data-plane separation between the customer VLANs is maintained by creating a dedicated bridge-domain for each VLAN.

- VLAN-aware bundle with translation

The service interface provides bundling of customer VLANs into a single Layer 2 VPN service instance. The data-plane separation between the customer VLANs is maintained by creating a dedicated bridge-domain for each VLAN. The service interface supports customer VLAN translation to handle the scenario where different VLAN Identifiers (VIDs) are used on different interfaces to designate the same customer VLAN.

EVPN with virtual switch provides support for VLAN-aware bundle with translation only.

## Configuring EVPN with Support for Virtual Switch

You can configure an Ethernet VPN (EVPN) with virtual switch support to enable multiple tenants with independent VLAN and subnet space within an EVPN instance. Virtual switch provides the ability to extend Ethernet VLANs over a WAN using a single EVPN instance while maintaining data-plane separation between the various VLANs associated with that instance. A single EVPN instance can stretch up to 4094 bridge domains defined in a virtual switch to remote sites.

When configuring virtual switch for EVPN, be aware of the following considerations:

- Due to default ARP policing, some of the ARP packets not destined for the device can be missed. This can lead to delayed ARP learning and synchronization.
- Clearing ARP for an EVPN can lead to inconsistency between the ARP table and the EVPN ARP table. To avoid this situation, clear both ARP and EVPN ARP tables.
- The **vlan-tag** can be configured for local switching. However, vlan-tagged VLANs should not be extended over the EVPN cloud.

Before you begin:

1. Configure the router interfaces.
2. Configure the router ID and autonomous system number for the device.
3. Enable chained composite next hop for EVPN.
4. Configure OSPF or any other IGP protocol.
5. Configure a BGP internal group.
6. Include the EVPN signaling network layer reachability information (NLRI) to the internal BGP group.
7. Configure RSVP or LDP.
8. Configure MPLS.
9. Create a label-switched path between the provider edge (PE) devices.

To configure the PE device:

1. Configure the virtual switch routing instance.

```
[edit routing-instances]
```

```
user@PE1# set evpn-instance instance-type virtual-switch
```

2. Configure the interface names for the virtual switch routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance interface interface-name
```

3. Configure the route distinguisher for the virtual switch routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance route-distinguisher route-distinguisher-value
```

4. Configure the VPN routing and forwarding (VRF) target community for the virtual switch routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance vrf-target vrf-target
```

5. List the VLAN identifiers that are to be EVPN extended.

```
[edit routing-instances]
user@PE1# set evpn-instance protocols evpn extended-vlan-list [vlan-id-range]
```

6. Configure the bridge domain for the first virtual switch routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance bridge-domains first-bridge-domain-name domain-type
bridge
```

7. Assign the VLAN ID for the first bridge domain.

```
[edit routing-instances]
user@PE1# set evpn-instance bridge-domains first-bridge-domain-name vlan-id 10
```

8. Configure the IRB interface as the routing interface for the first bridge domain.

```
[edit routing-instances]
user@PE1# set evpn-instance bridge-domains first-bridge-domain-name
routing-interface irb.0
```

9. Configure the interface name for the first bridge domain.

```
[edit routing-instances]
user@PE1# set evpn-instance bridge-domains first-bridge-domain-name bridge-options
interface CE-facing-interface
```

10. Configure the bridge domain for the second virtual switch routing instance.

```
[edit routing-instances]
user@PE1# set evpn-instance bridge-domains second-bridge-domain-name
domain-type bridge
```

11. Assign the VLAN ID for the second bridge domain.

```
[edit routing-instances]
```

```
user@PE1# set evpn-instance bridge-domains second-bridge-domain-name vlan-id
VLAN-ID
```

12. Configure the IRB interface as the routing interface for the second bridge domain.

```
[edit routing-instances]
user@PE1# set evpn-instance bridge-domains second-bridge-domain-name
routing-interface irb.1
```

13. Configure the interface name for the second bridge domain.

```
[edit routing-instances]
user@PE1# set evpn-instance bridge-domains second-bridge-domain-name
bridge-options interface CE-facing-interface
```

14. Configure the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vrf-instance instance-type vrf
```

15. Configure the IRB interface as the routing interface for the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vrf-instance interface irb.0
user@PE1# set vrf-instance interface irb.1
```

16. Configure the route distinguisher for the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vrf-instance route-distinguisher route-distinguisher-value
```

17. Configure the VRF target community for the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vrf-instance vrf-target vrf-target
```

18. Configure the VRF label for the VRF routing instance.

```
[edit routing-instances]
user@PE1# set vrf-instance vrf-table-label
```

19. Verify and commit the configuration.

For example:

```
[edit routing-instances]
user@PE1# set evpna instance-type virtual-switch
user@PE1# set evpna interface ge-0/1/4.0
user@PE1# set evpna interface ge-0/1/4.1
user@PE1# set evpna route-distinguisher 10.255.169.37:1
user@PE1# set evpna vrf-target target:100:1
user@PE1# set evpna protocols evpn extended-vlan-list [10 20]
user@PE1# set evpna bridge-domains bda domain-type bridge
user@PE1# set evpna bridge-domains bda vlan-id 10
```

```
user@PE1# set evpna bridge-domains bda routing-interface irb.0
user@PE1# set evpna bridge-domains bda bridge-options interface ge-0/1/4.0
user@PE1# set evpna bridge-domains bdb domain-type bridge
user@PE1# set evpna bridge-domains bdb vlan-id 20

### Example: Configuring EVPN with Support for Virtual Switch

This example shows how to configure a virtual switch in an Ethernet VPN (EVPN) deployment.

- [Requirements on page 510](#)
- [Overview on page 511](#)
- [Configuration on page 511](#)
- [Verification on page 519](#)

---

#### Requirements

This example uses the following hardware and software components:

- Two MX Series 3D Universal Edge Routers containing MPC FPCs.
- Two customer edge (CE) routers.
- Junos OS Release 14.1 or later.

Before you begin:

1. Configure the router interfaces.
2. Configure OSPF or any other IGP protocol.
3. Configure BGP.
4. Configure RSVP or LDP.
5. Configure MPLS.

## Overview

Starting with Junos OS Release 14.1, the Ethernet VPN (EVPN) solution on MX Series routers with MPC interfaces is extended to provide virtual switch support that enables multiple tenants with independent VLAN and subnet space within an EVPN instance. Virtual switch provides the ability to extend Ethernet VLANs over a WAN using a single EVPN instance while maintaining data-plane separation between the various VLANs associated with that instance. A single EVPN instance can stretch up to 4094 bridge domains defined in a virtual switch to remote sites.

When configuring virtual switch for EVPN, be aware of the following considerations:

- Due to default ARP policing, some of the ARP packets not destined for the device can be missed. This can lead to delayed ARP learning and synchronization.
- Clearing ARP for an EVPN can lead to inconsistency between the ARP table and the EVPN ARP table. To avoid this situation, clear both ARP and EVPN ARP tables.
- The **vlan-tag** can be configured for local switching. However, vlan-tagged VLANs should not be extended over the EVPN cloud.

## Topology

Figure 46 on page 511 illustrates a simple EVPN topology with virtual switch support. Routers PE1 and PE2 are the provider edge (PE) routers that connect to one customer edge (CE) router each – CE1 and CE2.

Figure 46: EVPN with Virtual Switch Support

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```

PE1 set interfaces ge-2/0/9 unit 0 family inet address 10.0.0.1/30
 set interfaces ge-2/0/9 unit 0 family mpls
 set interfaces ge-0/1/4 flexible-vlan-tagging
 set interfaces ge-0/1/4 encapsulation flexible-ethernet-services
 set interfaces ge-0/1/4 unit 0 family bridge interface-mode trunk
 set interfaces ge-0/1/4 unit 0 vlan-id-list 10
 set interfaces ge-0/1/4 unit 1 family bridge interface-mode trunk
 set interfaces ge-0/1/4 unit 1 vlan-id-list 20
 set interfaces irb unit 0 family inet address 192.168.1.1/16
 set interfaces irb unit 1 family inet address 192.168.2.1/16

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Router PE1:

**NOTE:** Repeat this procedure for Router PE2, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the PE1 interfaces.

**[edit interfaces]**

```

user@PE1# set ge-2/0/9 unit 0 family inet address 10.0.0.1/30
user@PE1# set ge-2/0/9 unit 0 family mpls

```

```

user@PE1# set ge-0/1/4 flexible-vlan-tagging
user@PE1# set ge-0/1/4 encapsulation flexible-ethernet-services
user@PE1# set ge-0/1/4 unit 0 family bridge interface-mode trunk
user@PE1# set ge-0/1/4 unit 0 vlan-id-list 10
user@PE1# set ge-0/1/4 unit 1 family bridge interface-mode trunk
user@PE1# set ge-0/1/4 unit 1 vlan-id-list 20

```

```

user@PE1# set irb unit 0 family inet address 192.168.1.1/16
user@PE1# set irb unit 1 family inet address 192.168.2.1/16

```

```
user@PE1# set lo0 unit 0 family inet address 10.255.169.37/32
```

2. Set the router ID and autonomous system number for Router PE1.

```
[edit routing-options]
user@PE1# set router-id 10.255.169.37
user@PE1# set autonomous-system 100
```

3. Configure the chained composite next hop for EVPN.

```
[edit routing-options]
user@PE1# set forwarding-table chained-composite-next-hop ingress evpn
```

4. Enable RSVP on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set rsvp interface all
user@PE1# set rsvp interface fxp0.0 disable
```

5. Create label-switched paths for PE1 to reach PE2.

```
[edit protocols]
user@PE1# set mpls label-switched-path PE1-to-PE2 from 10.255.169.37
user@PE1# set mpls label-switched-path PE1-to-PE2 to 10.255.237.18
```

6. Enable MPLS on all the interfaces of Router PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```

7. Configure the BGP group for Router PE1.

```
[edit protocols]
user@PE1# set bgp group ibgp type internal
```

8. Assign local and neighbor addresses to the ibgp BGP group for Router PE1 to peer with Router PE2.

```
[edit protocols]
user@PE1# set bgp group ibgp local-address 10.255.169.37
user@PE1# set bgp group ibgp neighbor 10.255.237.18
```

9. Include the EVPN signaling Network Layer Reachability Information (NLRI) to the ibgp BGP group.

```
[edit protocols]
user@PE1# set bgp group ibgp family evpn signaling
```

10. Configure OSPF on all the interfaces of Router PE1, excluding the management interface.  

```
[edit protocols]
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```
11. Configure the virtual switch routing instance.  

```
[edit routing-instances]
user@PE1# set evpna instance-type virtual-switch
```
12. Configure the interface name for the evpna routing instance.  

```
[edit routing-instances]
user@PE1# set evpna interface ge-0/1/4.0
user@PE1# set evpna interface ge-0/1/4.1
```
13. Configure the route distinguisher for the evpna routing instance.  

```
[edit routing-instances]
user@PE1# set evpna route-distinguisher 10.255.169.37:1
```
14. Configure the VPN routing and forwarding (VRF) target community for the evpna routing instance.  

```
[edit routing-instances]
user@PE1# set evpna vrf-target target:100:1
```
15. List the VLAN identifiers that are to be EVPN extended.  

```
[edit routing-instances]
user@PE1# set evpna protocols evpn extended-vlan-list [10 20]
```
16. Configure the bridge domains for the evpna routing instance.  

```
[edit routing-instances]
user@PE1# set evpna bridge-domains bda domain-type bridge
```
17. Assign the VLAN ID for the bda bridge domain.  

```
[edit routing-instances]
user@PE1# set evpna bridge-domains bda vlan-id 10
```
18. Configure the IRB interface as the routing interface for the bda bridge domain.  

```
[edit routing-instances]
user@PE1# set evpna bridge-domains bda routing-interface irb.0
```
19. Configure the interface name for the bda bridge domain.  

```
[edit routing-instances]
user@PE1# set evpna bridge-domains bda bridge-options interface ge-0/1/4.0
```

20. Configure the bridge domains for the evpna routing instance.  

```
[edit routing-instances]
user@PE1# set evpna bridge-domains bdb domain-type bridge
```
21. Assign the VLAN ID for the bdb bridge domain.  

```
[edit routing-instances]
user@PE1# set evpna bridge-domains bdb vlan-id 20
```
22. Configure the IRB interface as the routing interface for the bda bridge domain.  

```
[edit routing-instances]
user@PE1# set evpna bridge-domains bdb routing-interface irb.1
```
23. Configure the interface name for bdb bridge domain.  

```
[edit routing-instances]
user@PE1# set evpna bridge-domains bdb bridge-options interface ge-0/1/4.1
```
24. Configure the VRF routing instance.  

```
[edit routing-instances]
user@PE1# set vrf instance-type vrf
```
25. Configure the IRB interface as the routing interface for the vrf routing instance.  

```
[edit routing-instances]
user@PE1# set vrf interface irb.0
user@PE1# set vrf interface irb.1
```
26. Configure the route distinguisher for the vrf routing instance.  

```
[edit routing-instances]
user@PE1# set vrf route-distinguisher 198.51.100.1:2
```
27. Configure the VRF target community for the vrf routing instance.  

```
[edit routing-instances]
user@PE1# set vrf vrf-target target:100:2
```
28. Configure VRF label for the vrf routing instance.  

```
[edit routing-instances]
user@PE1# set vrf vrf-table-label
```

### **Results**

From configuration mode, confirm your configuration by entering the **show interfaces**, **show routing-options**, **show protocols**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
ge-2/0/9 {

```

### Verification

Confirm that the configuration is working properly.

- [Verifying the Bridge Domain Configuration on page 519](#)
- [Verifying MAC Table Routes on page 520](#)
- [Verifying the Bridge EVPN Peer Gateway MAC on page 520](#)

#### *Verifying the Bridge Domain Configuration*

**Purpose** Verify the bridge domain configuration for the evpna routing instance.

**Action** From operational mode, run the **show bridge domain extensive** command.

```

user@PE1> show bridge domain extensive
Routing instance: evpna
Bridge domain: bda State: Active
Bridge VLAN ID: 10 EVPN extended: Yes
Interfaces:
 ge-0/1/4.0
 pip-10.000010000000
 pip-10.fe0f0f000000
Total MAC count: 2

Bridge domain: bdb State: Active
Bridge VLAN ID: 20 EVPN extended: Yes
Interfaces:
 ge-0/1/4.1
 pip-11.010010000000
 pip-11.ffff0f000000
Total MAC count: 2

```

**Meaning** The configured bridge domains **bda** and **bdb** and their associated VLAN IDs and interfaces are displayed. The bridge domains are also extended with EVPN.

**Verifying MAC Table Routes**

**Purpose** Verify the MACs learned in the data plane and control plane.

**Action** From operational mode, run the **show bridge mac-table** command.

```
user@PE1> show bridge mac-table
MAC flags (S -static MAC, D -dynamic MAC, L -locally learned, C -Control MAC
 SE -Statistics enabled, NM -Non configured MAC, R -Remote PE MAC)

Routing instance : evpna
Bridging domain : bda, VLAN : 10
 MAC MAC Logical NH RTR
 address flags interface Index ID
 00:00:00:aa:01:01 S ge-0/1/4.0 1048574 1048574
 00:00:00:bb:01:01 DC 1048576 1048576
 00:00:00:cc:01:01 DC

Bridging domain : bdb, VLAN : 20
 MAC MAC Logical NH RTR
 address flags interface Index ID
 00:00:00:aa:02:01 S ge-0/1/4.1 1048575 1048575
 00:00:00:bb:02:01 DC 1048577 1048577
 00:00:00:cc:02:01 DC
```

**Meaning** The configured static MACs for the bridge domains are displayed.

**Verifying the Bridge EVPN Peer Gateway MAC**

**Purpose** Verify the bridge EVPN peer gateway MAC for the evpna routing instance.

**Action** From operational mode, run the **show bridge evpn peer-gateway-macs** command.

```
user@PE1> show bridge evpn peer-gateway-macs
Routing instance : evpna
Bridging domain : bda, VLAN : 10
Installed GW MAC addresses:
 00:23:9c:96:af:f0
 a8:d0:e5:5b:02:08

Bridging domain : bdb, VLAN : 20
Installed GW MAC addresses:
 00:23:9c:96:af:f0
 a8:d0:e5:5b:02:08
```

**Meaning** The gateway MACs of the EVPN peers for the evpna routing instance are displayed.

# Configuring EVPN with VXLAN Data Plane Encapsulation

## Understanding EVPN with VXLAN Data Plane Encapsulation

---

Ethernet VPNs (EVPNs) enable you to connect groups of dispersed customer sites using Layer 2 virtual bridges, and Virtual Extensible LANs (VXLANs) allow you to stretch Layer 2 connection over an intervening Layer 3 network, while providing network segmentation like a VLAN, but without the scaling limitation of traditional VLANs. EVPN with VXLAN encapsulation handles Layer 2 connectivity at the scale required by cloud server providers and replaces limiting protocols like Spanning Tree Protocol (STP), freeing up your Layer 3 network to use more robust routing protocols. EVPN with VXLAN data plane encapsulation can be used with and without Juniper Networks Contrail virtualization software—use Contrail with EVPN VXLAN data plane encapsulation when you have an environment that includes both virtual and base-metal devices.

**NOTE:** MX Series Routers interoperate with both QFX5100 Series Switches and QFX5100 Virtual Chassis to provide full EVPN with VXLAN functionality. Junos OS Release 14.2R4 and Junos OS Release 16.1 support MX Series Routers, and Junos OS Release 14.1X53-D30 and Junos OS Release 16.1 support QFX5100 Series Switches.

## Understanding EVPN

Ethernet VPN (EVPN) is a standards-based technology that provides virtual multipoint bridged connectivity between different Layer 2 domains over an IP or IP/MPLS backbone network. Like other VPN technologies, such as IP VPN and virtual private LAN service (VPLS), EVPN instances are configured on provider edge (PE) routers to maintain logical service separation between customers. The PE routers connect to customer edge (CE) devices, which can be routers, switches, or hosts. The PE routers then exchange reachability information using Multiprotocol BGP (MP-BGP) and encapsulated traffic is forwarded between PE routers. Because elements of the architecture are common with other VPN technologies, you can seamlessly introduce and integrate EVPN into existing service environments, as shown in [Figure 47 on page 522](#).

Figure 47: EVPN Overview

The EVPN is used as a Layer 2 overlay solution to provide Layer 2 connection over an IP underlay for the endpoints within a virtual network whenever Layer 2 connectivity is required by an end station such as bare-metal server (BMS). Otherwise, Layer 3 routing is used through VRF tables between Contrail vRouters and MX Series routers. EVPN technology offers multitenancy, flexible services that can be extended on demand, frequently using compute resources of different physical data centers for a single service (Layer 2 extension).

EVPN's MP-BGP control plane enables you to dynamically move live virtual machines from one data center to another, also known as virtual machine (VM) motion. After you move a VM to a destination server or hypervisor, it transmits a gratuitous ARP, which updates the Layer 2 forwarding table of the PE device at the destination data center. The PE device then transmits a MAC route update to all remote PE devices which in turn

update their forwarding tables. An EVPN tracks the movement of the VM, which is also known as MAC mobility.

EVPN also has mechanisms that detect and stop MAC flapping, and prevent the looping of broadcast, unknown unicast, and multicast (BUM) traffic in an all-active multi-homed topology.

The EVPN technology, similar to Layer 3 MPLS VPN, includes the concept of routing MAC addresses using MP-BGP over MPLS core. EVPN provides the following benefits:

- Ability to have an active multihomed edge device
- Aliasing
- Fast convergence
- Load balancing across dual-active links
- MAC address mobility
- Multitenancy

In addition, EVPN uses these techniques:

- *Multihoming* provides redundancy in the event that an access link or one of the PE routing devices fails. In either case, traffic flows from the CE device towards the PE router, using the remaining active links. For traffic in the other direction, the remote PE router updates its forwarding table to send traffic to the remaining active PE routers connected to the multihomed Ethernet segment. EVPN provides a fast convergence mechanism, which reduces traffic restoration time so that the time it takes to make this adjustment is independent of the number of media access control (MAC) addresses learned by the PE router. All-active multihoming enables a CE device to connect to two or more PE routers such that traffic is forwarded using all of the links between the devices. This multihoming enables the CE device to load-balance traffic to multiple PE routers. More importantly, multihoming enables a remote PE router to load-balance traffic to the multihomed PE routers across the core network. This load balancing of traffic flows between data centers is known as *aliasing*, which causes different signals to become indistinguishable—they become aliases of one another. Aliasing is used with digital audio and digital images.
- *Split horizon* prevents the looping of broadcast, unknown unicast, and multicast (BUM) traffic in a network. The split horizon basic principle is simple: Information about the routing for a particular packet is never sent back in the direction from which it was received.
- *Local link bias* conserves bandwidth by using local links to forward unicast traffic exiting a Virtual Chassis or Virtual Chassis Fabric (VCF) that has a link aggregation group (LAG) bundle composed of member links on different member switches in the same Virtual Chassis or VCF. A local link is a member link in the LAG bundle that is on the member switch that received the traffic.
- EVPN with VXLAN encapsulation is used for Layer 2 connectivity between virtual machines and a QFX5100 switch within a Layer 2 domain where the QFX5100 switch is physically connected to top-of-rack.

For Layer 2 connectivity, traffic load balance in the core is achieved using the all-active multihome feature provided by EVPN. Each QFX5100 switch is also multihomed to the top-of-rack switches.

You can use QFX5100 switches to provision for Layer 2 and Layer 3 gateways in a Contrail user interface by using NETCONF. The NETCONF XML management protocol is an XML-based protocol that client applications use to request and change configuration information on routing, switching, and security devices. The NETCONF XML management protocol uses an XML based data encoding for the configuration data and remote procedure calls. The NETCONF protocol defines basic operations that are equivalent to configuration mode commands in the command-line interface (CLI). Applications use the protocol operations to display, edit, and commit configuration statements similarly to how administrators use CLI configuration mode commands to perform those same operations.

## Understanding VXLAN

Virtual extensible LANs (VXLANs) introduced an overlay scheme that expands the Layer 2 network address space from 4K to 16 million, largely solving the scaling issues seen in VLAN-based environments.

Network overlays are created by encapsulating traffic and tunneling the traffic over a physical network. You can use a number of tunneling protocols in the data center to create network overlays—the most common protocol is VXLAN. VXLAN tunneling protocol encapsulates Layer 2 Ethernet frames in Layer 3 UDP packets. This encapsulation enables you to create virtual Layer 2 subnets or segments that can span physical Layer 3 networks.

In a VXLAN overlay network, a VXLAN network identifier (VNI) uniquely identifies each Layer 2 subnet or segment. A VNI segments traffic the same way that an IEEE 802.1Q VLAN ID segments traffic. As is the case with VLAN, virtual machines on the same VNI can communicate directly with each other, whereas virtual machines on different VNIs need a router to communicate with each other.

The entity that performs the encapsulation and decapsulation is called a VXLAN tunnel endpoint (VTEP). In the virtual network, VTEPs typically reside in hypervisor hosts, such as kernel-based virtual machine (KVM) hosts.

Each VTEP has two interfaces.

- One interface is a switching interface that faces the virtual machines in the host and provides communication between VMs on the local LAN segment.
- The other is an IP interface that faces the Layer 3 network.

Each VTEP has a unique IP address that is used for routing the UDP packets between VTEPs. For example, when VTEP1 receives an Ethernet frame from VM1 addressed to VM3, it uses the VNI and the destination MAC to look up in its forwarding table, which VTEP sends the packet to. It then adds a VXLAN header that contains the VNI to the Ethernet frame and encapsulates the frame in a Layer 3 UDP packet and routes the packet to VTEP2 over the Layer 3 network. VTEP2 de-encapsulates the original Ethernet frame and forwards it to VM3. VM1 and VM3 cannot detect the VXLAN tunnel and the Layer 3 network between them.

## EVPN-VXLAN Integration Overview

VXLAN defines a tunneling scheme to overlay Layer 2 networks on top of Layer 3 networks. This tunneling scheme allows for optimal forwarding of Ethernet frames with support for multipathing of unicast and multicast traffic with the use of UDP/IP encapsulation for tunneling, and is mainly used for the intra-data center site connectivity.

A unique characteristic of EVPN is that MAC address learning between PE routers occurs in the control plane. The local PE router detects a new MAC address from a CE device and then, using MP-BGP, advertises the address to all the remote PE routers. This method differs from existing Layer 2 VPN solutions such as VPLS, which learn by flooding unknown unicast in the data plane. This control plane MAC learning method is the key enabler of the many useful features that EVPN provides.

Because MAC learning is handled in the control plane, EVPN has the flexibility to support different data plane encapsulation technologies between PE routers. This flexibility is important because not every backbone network might be running MPLS, especially in enterprise networks.

EVPN addresses many of the challenges faced by network operators building data centers to offer cloud and virtualization services. The main application of EVPN is Data Center Interconnect (DCI), the ability to extend Layer 2 connectivity between different data centers that are deployed to improve the performance of delivering application traffic to end users and for disaster recovery.

Although various DCI technologies are available, EVPN has an advantage over the other MPLS technologies because of its unique features, such as active/active redundancy, aliasing, and mass MAC withdrawal. As a result, to provide a solution for DCI, VXLAN is integrated with EVPN.

As shown in [“Overview” on page 123](#), every VXLAN, which is connected to the MPLS or IP core, runs an independent instance of the interior gateway protocol (IGP) control plane. Each PE router participates in the IGP control plane instance of its VXLAN. Each customer is a data center, so each has its own virtual router for VXLAN underlay.

Each PE node can terminate the VXLAN data plane encapsulation where the VXLAN network identifier (VNI) is mapped to a bridge domain. The PE router performs data plane learning on the traffic received from the VXLAN.

Each PE node implements EVPN to distribute the client MAC addresses learned over the VXLAN tunnel into BGP. Each PE node encapsulates the VXLAN or Ethernet frames with MPLS when sending the packets over the MPLS core and with the VXLAN tunnel header when sending the packets over the VXLAN network.

Figure 48: EVPN-VXLAN Integration Overview

- Every VXLAN network, which is connected to the MPLS or IP core, runs an independent instance of the IGP control plane. Each PE device participates in the IGP control plane instance of its VXLAN network, where each customer is a data center and has its own virtual router for the VXLAN underlay.
- Each PE node may terminate the VXLAN data plane encapsulation, where each VXLAN network identifier (VNI) is mapped to a bridge domain. The PE router performs data plane learning on the traffic received from the VXLAN network.
- Each PE node implements EVPN to distribute the client MAC addresses learned over the VXLAN tunnel into the BGP.
- Each PE node encapsulates the VXLAN or Ethernet frames with MPLS when sending the packets over the MPLS core and with the VXLAN tunnel header when sending the packets over the VXLAN network.

## Understanding Contrail Virtual Networks Use with EVPN-VXLAN

Juniper Networks Contrail virtualization software is a software-defined networking (SDN) solution that automates and orchestrates the creation of highly scalable virtual networks. These virtual networks enable you to harness the power of the cloud—for new services, increased business agility, and revenue growth. MX Series routers can use EVPN-VXLAN to provide both Layer 2 and Layer 3 connectivity for end stations within a Contrail virtual network (VN).

**NOTE:** Contrail does not support the provisioning of Layer 2 and Layer 3 gateways on QFX Series switches.

The Contrail software for virtual networks provides both Layer 2 and Layer 3 connectivity. With Contrail, Layer 3 routing is preferred over Layer 2 bridging whenever possible. Layer 3 routing is used through virtual routing and forwarding (VRF) tables between Contrail vRouters and physical MX Series routers. MX Series routers provide Layer 3 gateway functionality between virtual networks.

Contrail enables you to use EVPN-VXLAN when your network includes both virtual and bare-metal devices.

Two types of encapsulation methods are used in virtual networks.

- MPLS-over-GRE (generic routing encapsulation) is used for Layer 3 routing between Contrail and MX Series routers.
- EVPN-VXLAN is used for Layer 2 connectivity between virtual machines and QFX Series switches within a Layer 2 domain where the QFX Series switch is physically connected to top-of-rack switches. For Layer 2 connectivity, traffic load balancing in the core is achieved using the multihoming all-active feature provided by EVPN. Each QFX switch is also multihomed to top-of-rack switches.

EVPN-VXLAN differs from and MPLS-EVPN in that, with EVPN-VXLAN, Layer 2 creates host entries and no infrastructure method exists to export to Layer 3; whereas, in the MPLS-EVPN solution, the routing protocol process creates host entries which are in the routing information base (RIB), and can be exported into a VRF table or inet.0. The ability to advertise /32 host routes is not available with EVPN-VXLAN, so the classic virtual machine traffic optimization does not work with VXLAN. You can take advantage of the active-active Layer 2 functionality with VXLAN.

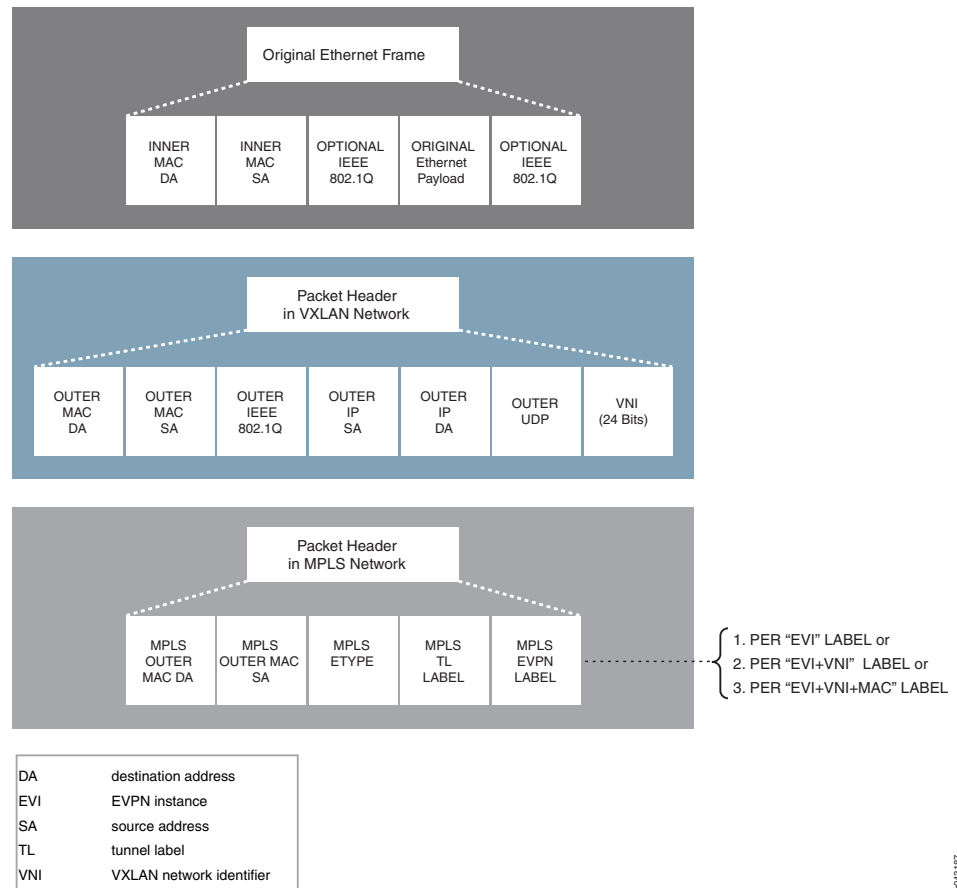

**NOTE:** MPLS core is not supported on switches—only MX Series routers support this feature.

You cannot simultaneously mix EVPN-VXLAN with Open vSwitch Database (OVSDB)-VXLAN on QFX Series switches. After a switch is set to OVSDB-managed, the controller treats all ports as managed by OVSDB.

## EVPN-VXLAN Packet Format

The EVPN-VXLAN packet format is shown in [Figure 49 on page 528](#).

Figure 49: EVPN-VXLAN Packet Format

## Q & A

Q: What is the difference between EVPN/VXLAN and MPLS/EVPN?

A: With EVPN/VxLAN the host entries are created by L2 and there is no existing infrastructure method to export to L3. In the MPLS/EVPN solution host entries are created by RPD, are in the RIB and can be exported into a VRF or inet.0. Therefore, the ability to advertise /32 host routes is not there with EVPN/VxLAN, so the classic VMTO does not work with VxLAN. You can take advantage of the A/A L2 functionality with VxLAN.

Q: Can I simultaneously use EVPN-VXLAN with OVSDb-VXLAN on QFX switches?

A: No, you cannot mix EVPN-VXLAN with OVSDb-VXLAN. Once a switch is set to OVSDb-managed, the controller expects all ports to be OVSDb managed.

**NOTE:** MPLS core is not supported on switches—only MX Series routers support this feature.

## EVPN-VXLAN Constraints on QFX Series Switches

QFX Series switches do not support the following features in an EVPN-VXLAN overlay network:

- Connectivity fault management (CFM)
- Internet Group Management Protocol (IGMP) snooping
- Multichassis link aggregation groups (MC-LAGs)
- Q-in-Q tunneling
- Spanning Tree Protocol (STP) (any variant)

- [Contrail vRouters and the L3-VRF Table on page 532](#)
- [Designated Forwarder Election on page 533](#)

## VXLAN Encapsulation

EVPN supports the VXLAN data plane encapsulation type within the same EVPN instance. To support the VXLAN encapsulation type, all EVPN PE devices specify the tunnel type as VXLAN in the BGP encapsulation extended community. The ingress PE determines which encapsulation types to use based on its own encapsulation capability and the one its EVPN remote PE device advertises.

When EVPN is used as overlay solution for the underlay IP network with VXLAN encapsulation, the data packet is encapsulated with a VXLAN header at the ingress PE device, and the data packet is de-encapsulated from the VXLAN header at the egress PE device. [Figure 50 on page 530](#) shows the packet format when a packet is forwarded in the core through the underlay IP network with VXLAN encapsulation:

Figure 50: Underlay IP Network with VXLAN Encapsulation

## EVPN BGP Routes and Attributes

EVPN BGP routes and attributes support EVPN-over-VXLAN data plane encapsulation and are affected as follows:

- By attaching the BGP encapsulation extended community attribute with tunnel encapsulation type VXLAN in the EVPN MAC routes, the egress PE device advertises the EVPN inclusive multicast route and EVPN per EVI route autodiscovery.
- The Ethernet tag fields for all EVPN BGP routes are set to zero to support VXLAN network identifier (VNI)-based mode only.
- The VNI, also referred to as the VNI field in the EVPN overlay, is placed in the MPLS fields for the EVPN MAC route, the EVPN inclusive multicast route, and per EVPN instance autodiscovery route.
- The Ethernet segment identifier label field is set to zero for the EVPN per Ethernet segment autodiscovery route because no Ethernet segment identifier label exists for the supported VXLAN encapsulation type.
- All corresponding EVPN routes from the remote PE device are resolved over the inet.0 or :vxlan.inet.0 table instead of the inet.3 table.

## EVPN Multihoming Procedure

When you configure a QFX5100 switch as a multihomed EVPN in active-active mode, you can configure a dual-homed bare-metal server (BMS) to a pair of QFX5100 switches at Layer 2 through a link aggregation group (LAG) interface. Because of the LAG interface, only one copy of BUM traffic is forwarded from a BMS to the core router. To prevent a Layer 2 loop and flooding of BUM traffic back to the same Ethernet segment to which the multihomed BMS is attached, the BUM traffic applies the multihomed active-active split-horizon filtering rule. To fully support the EVPN multihomed active-active mode feature, the QFX5100 switch also advertises the EVPN aliasing route to other EVPN PE devices.

The lack of MPLS label support for EVPN over IP with VXLAN data plane encapsulation causes impacts to the following EVPN multihomed active-active mode functions:

- [Local Bias and Split-Horizon Filtering Rule on page 531](#)
- [Aliasing on page 531](#)

**NOTE:** EVPN over VxLAN does not support active-standby mode of operation. You can only configure the active-active mode by using all-active option for the ESI interface configuration. Single-homing Ethernet segments with EVPN using VxLAN encapsulation using single-active is not supported.

### Local Bias and Split-Horizon Filtering Rule

---

Because of the missing MPLS label, the split-horizon filtering rule for the multihomed Ethernet segment is modified and based on the IP address of the EVPN PE device instead of the MPLS Ethernet segment label. For traffic coming from the access interface, any traffic forwarding to the multihomed Ethernet segment is based on the local bias for EVPN with VXLAN data plane encapsulation. Each EVPN PE device tracks the IP address of its peer multihomed EVPN PE device for which it shares the same Ethernet segment. This tracking provides the source VXLAN virtual tunnel endpoint (VTEP) IP address [outer Session Initiation Protocol (SIP)] for each VXLAN packet received from the other EVPN PE device. The split-horizon filtering rule is enforced on both ingress and egress PE devices for multi-destination traffic:

- Ingress PE—Responsible for forwarding multi-destination packets coming from any of its directly-attached access interfaces to its remaining associated multihomed Ethernet segments, regardless of the subject ingress PE device's DF election status.
- Egress PE—Allows no forwarding of any multi-destination packets to the same multihomed Ethernet segment to which an egress PE shares with its ingress PE device, regardless of the subject egress PE device's don't fragment (DF) bit election status.

### Aliasing

---

When you connect a BMS to a pair of QFX5100 switches through a LAG interface bundle, only one of the QFX5100 switches can learn the local MAC address. To support the load balance of known unicast traffic coming from the VXLAN to the BMS between the QFX5100 switches, the EVPN PE device on the QFX5100 switch must advertise EVPN per EVPN instance autodiscovery route. This advertisement signals to the remote EVPN PE devices that the MAC learned from the multihomed Ethernet segment from its peer multihomed PE device is also reachable. For VXLAN encapsulation, there is no change to the EVPN procedure when providing the EVPN aliasing function.

## Next-Hop Forwarding

The Layer 2 address learning daemon (l2ald) creates the VXLAN encapsulation composite next-hop at ingress, and the VXLAN de-encapsulation composite next-hop at the egress. The VXLAN encapsulation composite next-hop forwards Layer 2 unicast traffic to the remote PE device with the VXLAN encapsulation. If multiple paths are available to reach a remote MAC (as with the multihomed EVPN active-active case), the routing protocol daemon (rpd) informs the l2ald of all the remote VTEP IP addresses associated with the remote MAC. The l2ald is responsible for building an equal-cost multipath (ECMP) next hop for the remote MAC. The VXLAN de-encapsulation composite next-hop de-encapsulates the VXLAN tunnel header at the egress and then forwards the traffic to the BMS.

For known unicast traffic:

- At ingress, the rpd does not need to add a label route in the mpls.0 table.
- At egress, the rpd does not need to add a label route to point to the table next-hop in the mpls.0 table.

## Control Plane MAC Learning Method

A unique characteristic of EVPN is that MAC address learning between PE devices occurs in the control plane. The local PE router detects a new MAC address from a CE device and then, using MP-BGP, advertises the address to all the remote PE devices. This method differs from existing Layer 2 VPN solutions such as VPLS, which learn by flooding unknown unicast in the data plane. This control plane MAC learning method is a crucial component of the features and benefits that EVPN provides. Because MAC learning is handled in the control plane, EVPN has the flexibility to support different data plane encapsulation technologies between PE devices. This flexibility is important because not every backbone network may be running MPLS, especially in enterprise networks.

For control plane remote MAC learning, because the l2ald creates the VXLAN encapsulation composite next-hop and VXLAN de-encapsulation composite next-hop, the rpd no longer creates an indirect next-hop used in the MAC forwarding table. The rpd relies on the existing mechanism to inform the l2ald of the remote MAC addresses learned from the control plane. Instead of informing the l2ald about the VLAN ID and the indirect next-hop index used by the remote MAC in the MAC FIB table, the rpd informs the l2ald about the remote VTEP IP address and VXLAN network identifier. The control plane remote MAC learned route points to VXLAN encapsulation composite next-hop, or an ECMP next-hop created by the l2ald in the MAC forwarding table.

For the multihomed EVPN active-active, a pair of remote VTEP IP addresses are associated with the remote MAC address. The remote VTEP IP addresses are obtained from the MAC route received either from the remote PE device, or from the aliasing route from the remote PE device. When a remote PE device withdraws a MAC route or the aliasing route for the Ethernet segment from where the MAC learned, the rpd alerts the l2ald about the change to the pair of remote VTEP IP addresses accordingly. As a result, the l2ald updates the uni-list next-hop built for this MAC. When both remote MAC routes and its associated aliasing route are withdrawn or become unresolved, the rpd informs the l2ald about the deletion of this remote MAC and the l2ald withdraws this MAC from the MAC forwarding table.

## Contrail vRouters and the L3-VRF Table

The Contrail virtualization software creates virtual networks (VNs) associated with routes in a Layer 3 virtual routing and forwarding (L3-VRF) table.

The following are the associated routes:

- [Subnet Routes for an IRB Interface on page 532](#)
- [Virtual Machine Host Routes on page 533](#)
- [Bare-Metal Server Host Routes on page 533](#)

---

### Subnet Routes for an IRB Interface

For each pair of MAC-(virtual routing and forwarding) VRF and L3-VRF tables created for a virtual network on an MX Series router, a corresponding IRB interface is associated with the MAC-VRF and L3-VRF table pair. The L3-VRF table on the MX Series router has the subnet route from the IRB interface associated with its local virtual networks, as well

as, all subnet routes of the IRB interfaces associated with other virtual networks within a data center provided by the Junos OS routing leaking feature. The MX Series routers advertise these subnet routes through MP-BGP to the Contrail control nodes. As a result, the L3-VRF table in the Contrail vRouter contains the same set of subnet routes for the IRB interfaces in its IP FIB, and the subnet routes point their next hops to the MX Series routers.

---

### Virtual Machine Host Routes

The Contrail vRouters support proxy ARP and advertise the IP address with the EVPN MAC route for its virtual machine (VM). For both Contrail vRouters and MX Series routers, the L3-VRF table for a virtual network contains all of the VM host routes for those VMs that reside in the same virtual network, as well as, routes in all other virtual networks. intra- virtual network and inter- virtual network traffic between the VMs is forwarded directly at Layer 3 between the Contrail vRouters.

---

### Bare-Metal Server Host Routes

The QFX5100 switch does not advertise the IP address with the EVPN MAC route for the bare-metal server (BMS) to which it is attached. As a result of the EVPN MAC route advertisement from the QFX5100 switch, no BMS host route is installed in the L3-VRF table on Contrail vRouters and MX Series routers. However, ARP routes for the BMSs are installed in the kernel on the MX Series router if the MX Series router receives ARP responses from the BMSs.

## Designated Forwarder Election

To provide better load balance and more flexible topology, the election of the designated forwarder is determined by selecting the minimum VLAN ID or VXLAN network ID for each Ethernet segment instead of selecting based on the EVPN instance.

[Figure 51 on page 534](#) shows a sample designated forwarder election topology.

Figure 51: Designated Forwarder Election Topology

CE device (CE1) has an Ethernet segment identifier value configured equal to ES1 and is connected to both PE1 and PE2 devices, with configured VLANs 100 and 101. Router PE1 is elected as the designated forwarder for the two VLANs.

CE device (CE2) has an Ethernet segment identifier value configured equal to ES2 and is connected to both PE1 and PE3 devices, with configured VLAN 201. Router PE3 is elected as the designated forwarder for this VLAN.

The Ethernet tag ID can be either of the following:

- VLAN ID (for EVPN-MPLS)
- VXLAN network ID (for EVPN-VXLAN)

## EVPN Over VXLAN Encapsulation Configuration Overview for QFX5100 Series

To configure Ethernet VPN (EVPN) over Virtual Extensible Local Area Networks (VXLAN) data plane encapsulation, you configure switches.

You configure QFX5100 Series switches under the **switch-options** and **protocols evpn** hierarchies.

| CLI Statement                                                    | Description                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>route-distinguisher</code>                                 | Specifies an identifier attached to a route—this enables you to distinguish to which VPN or VPLS the route belongs. Each routing instance must have a unique route distinguisher associated with it. The route distinguisher is used to place bounds around a VPN so that the same IP address prefixes can be used in different VPNs without having them overlap. |
| <code>vrf-target</code>                                          | Specifies a VRF target community. In effect, this statement configures a single policy for import and a single policy for export to replace the per-VRF policies for every community. The <b>import</b> and <b>export</b> options apply on both routers and QFX5100 switches. The <b>auto</b> options applies to QFX5100 switches only.                           |
| <code>vrf-import</code>                                          | Specifies how routes are imported into the VRF table of the local provider edge (PE) router or switch from the remote PE.                                                                                                                                                                                                                                         |
| <code>vrf-export</code>                                          | Specifies how routes are exported from the local PE router's VRF table to the remote PE router.                                                                                                                                                                                                                                                                   |
| <code>designated-forwarder-election-hold-time</code>             | Establishes when a designated forwarder is required for customer edge (CE) devices that are multihomed to more than one provider edge (PE) device. Without a designated forwarder, multihomed hosts receive duplicate packets. Designated forwarders are chosen for an Ethernet segment identifier (ESI) based on type-4 route advertisements.                    |
| <code>encapsulation vxlan</code>                                 | Configures a VXLAN encapsulation type.                                                                                                                                                                                                                                                                                                                            |
| <code>extended-vni-list</code> and <code>extended-vni-all</code> | Establishes which VXLAN virtual network identifiers are designated as part of the virtual switch instance.                                                                                                                                                                                                                                                        |

## Understanding MX Series Router and Gateway Functionality Between Virtual Networks Traffic

MX Series routers provide a default gateway function for non-virtualized bare-metal servers (BMSs) for the traffic between end-hosts belonging to different virtual networks within the EVPN-over-VXLAN encapsulation. MX Series routers also provide failure protection of the MX Series default gateway through redundancy.

The following MX Series gateway functionality is supported for traffic between virtual networks:

- [MX Series Router as the Default Gateway on page 536](#)
- [MX Series Router as the Redundant Default Gateway on page 539](#)
- [MX Series Gateway and Dynamic ARP Processing on page 539](#)

### MX Series Router as the Default Gateway

MX Series routers provide Layer 3 a default gateway function for non-virtualized end hosts/VMs/servers for the traffic between end hosts belonging to different virtual networks or IP subnet through its integrated routing and bridging (IRB) interface. For EVPN-VXLAN deployments, configure the virtual gateway address when using a VXLAN overlay fabric in the data center and across the Data Center Interconnect (DCI) solution.

To provide the default gateway function, each IRB interface is assigned a pair of addresses: it's own unique IP address and its own unique media access control (MAC) address. In addition, each IRB interface is assigned a virtual gateway IP address and a MAC address associated with the virtual gateway IP address:

- When configuring the IP address for the IRB interface, one can think of the IRB IP address as having two separate parts:
  - A unique part
  - An anycast part

**NOTE:** One can consider the virtual gateway IP address as the anycast IP address. When using IPv4, the MAC address associated with the anycast IP address value is 00:00:5e:00:01:00, and when using IPv6, the MAC address for the anycast IP address value is 00:00:5e:00:02:00.

- A corresponding pair of MAC addresses (*VRRP MAC*, *IRB's MAC*). A Virtual Router Redundancy Protocol (VRRP) MAC is locally unique within the context of a virtual network. The VRRP MAC address used for the default gateway is auto-derived by default.

The anycast IP address with its VRRP MAC address provides the redundant default gateway function. The virtual gateway address is used as the default gateway IP address by either the end host or virtual machine attached to the bridge domain. You configure each end host or virtual machine to use the MX Series router's anycast IP address for the virtual network of which the end host or virtual machine belongs to as its default gateway address. By using the anycast IP and VRRP MAC addresses, you can enable the default gateway redundancy functionality. By using the anycast IP address as the default gateway address, when a virtual machine moves from one EVPN provider edge (PE) device to another PE device, the moved virtual machine can use the same default gateway and does not have to update its default gateway IP address for MAC binding.

The MX Series responds to the Address Resolution Protocol (ARP) requests for the virtual gateway IP and forwards the packets sent to the virtual gateway MAC address. The virtual gateway IP address is essentially the anycast IP address used by a pair of redundant MX Series routers.

**BEST PRACTICE:** We recommend that each IRB has its own unique IP and MAC addresses to avoid an asymmetric data path for the ARP request and response when the IRB sends ARP messages for an end-destination's MAC address.

**NOTE:** Ping to the virtual default gateway IP address is not currently supported. For the ARP request and ping initiated by the MX Series gateway, the IRB's unique interface IP address is used as the source IP address.

The MAC-VRF on the MX Series router advertises two MAC routes with its corresponding IP address associated with the IRB interface. However, no default gateway extended

community attribute is associated with the IRB's VRRP MAC route advertisement because all MX Series gateways have the same anycast IP address and VRRP MAC binding.

- [MX Series Router as the Default Gateway for Known Intersubnet Traffic Between Virtual Networks on page 538](#)
- [MX Series Router as the Default Gateway for Unknown Intersubnet Traffic Between Virtual Networks on page 539](#)

### MX Series Router as the Default Gateway for Known Intersubnet Traffic Between Virtual Networks

Whenever a BMS (end host or virtual machine) is involved in the configuration, known intersubnet traffic between virtual networks uses the IRB's anycast IP address and the MAC address associated with the anycast IP address. [Figure 52 on page 538](#) shows known intersubnet traffic between virtual networks.

**NOTE:** Within [Figure 52 on page 538](#), the IRB's anycast IP address and IRB's VRRP MAC address are referred to as IRB's IP address and IRB's MAC address.

**Figure 52: Known Intersubnet Traffic Between Virtual Networks**

For known intersubnet traffic between virtual networks that originated from the End Host1 in virtual network 1 (10.10.0.0/24), or End Host3 in virtual network 2 (10.20.0.0/24), End Host1 sends the packet with VXLAN encapsulation to the MX Series router's MAC-VRF with an inner destination MAC address of the IRB for virtual network 1, and inner Destination Internet Protocol (DIP) of VM2 or End Host3. After the MX Series router receives and de-encapsulates the packet, due to the IRB's MAC address, the packet is Layer 3 routed based on the L3-VRF routing table. Then depending on the ARP route entry, the packet is sent out with VXLAN encapsulation to the QFX5100 switch to which the destination BMS3 is connected. There is no host route for any end host in the L3-VRF table because the QFX5100 switch does not advertise the MAC address with an IP address.

### MX Series Router as the Default Gateway for Unknown Intersubnet Traffic Between Virtual Networks

For unknown intersubnet traffic between virtual networks initiated from the BMS (end host), an additional ARP request and response process is required at each stage. When the packet is received at the MX Series gateway, the gateway sends an ARP request for the destination BMS's IP address and the MAC address binding. After destination MAC plus IP binding for the end station is resolved, the traffic flows follow the same procedure as described for the known intersubnet forwarding process between virtual networks. See [“MX Series Router as the Default Gateway for Known Intersubnet Traffic Between Virtual Networks” on page 538](#).

### MX Series Router as the Redundant Default Gateway

The EVPN all-active multihoming feature provides gateway redundancy by associating all of the IRB interface's virtual gateway MAC and IP addresses for a given virtual network with the same Ethernet segment ID. A set of MX Series routers provides the redundant gateway functionality by protecting against gateway failures resulting in connectivity issues and halting traffic flow between the virtual network end-stations. You configure each MX Series gateway with an IRB interface for a given virtual network with the same virtual gateway IP address and MAC address.

For other EVPN provider edge (PE) devices, such as Contrail vRouters and QFX5100 switches, the VRRP MAC address for the IRB interfaces is multihomed to the MX Series routers using the same Ethernet segment. With the EVPN all-active process, a remote EVPN PE device builds an equal-cost multipath (ECMP) next hop to reach the IRB's VRRP MAC or anycast IP address based on the IRB's MAC route advertised by each MX Series gateway. Traffic destined to the IRB's virtual gateway MAC is load balanced in the core. If one of MX Series gateways fails, all of the remote EVPN PE devices are notified by the withdrawing or purging of the IRB MAC route. As a result, their next hops to the IRB's VRRP MAC or anycast IP address are updated to exclude the path to the failed gateway. Because the IRB's VRRP MAC and anycast IP addresses are still reachable through the updated next hop, no changes are made to the ARP entries on the BMS devices (end hosts) on the MX Series.

The Ethernet segment identifier value associated with the IRB's MAC address is auto-derived from an autonomous system (AS) and the VXLAN virtual network identifier associated with the virtual network so that the IRB MAC routes advertised by each MX Series gateway for a given virtual network have the same Ethernet segment identifier.

From the perspective of the remaining EVPN PE devices, the default gateway MAC address is reachable through a set of MX Series devices and is considered to be multihomed to an Ethernet segment. There is no master or backup MX Series gateway. All MX Series devices that participate in the default gateway function can forward the traffic sent to the default gateway MAC address.

### MX Series Gateway and Dynamic ARP Processing

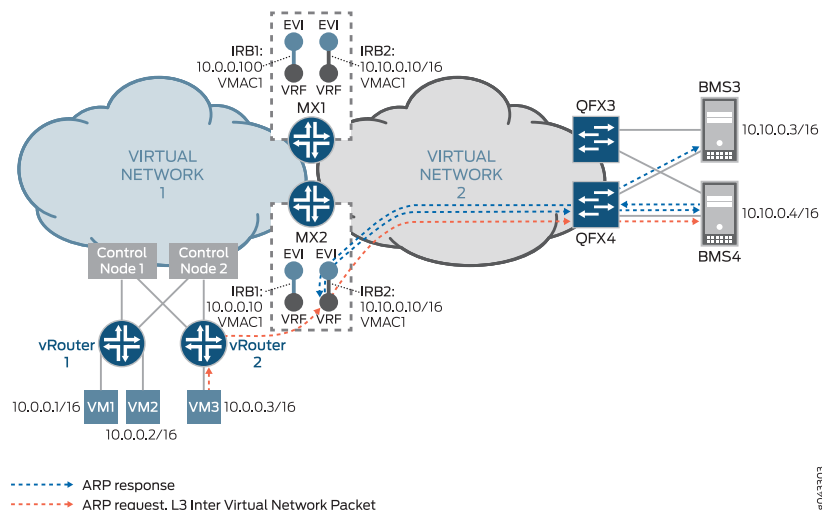

If an MX Series gateway receives an ARP packet from a remote PE device, the kernel creates a dynamic ARP route entry. The ARP entry points to a VXLAN ARP encapsulation next hop, and the kernel creates a VXLAN ARP encapsulation next hop with the target

next hop pointing to the remote VXLAN virtual tunnel endpoint (VTEP) IP address. When the remote VTEP IP address becomes unreachable, its corresponding remote VTEP logical interface is deleted, and the kernel also deletes its corresponding dynamic ARP entries.

When a BMS wants to use ARP to determine its default gateway's MAC address, the BMS initiates an ARP request for the IRB's anycast IP address. The ARP packet arrives at one of redundant MX Series gateways. The MX Series gateway that receives the ARP request learns the BMS device's IP and MAC binding, and creates an ARP entry. The MX Series gateway then replies with the VRRP's MAC address. The ARP request is sent back by unicast to the QFX5100 switch with the VXLAN encapsulation. The ARP packet is de-encapsulated at the QFX5100 switch and forwarded to the BMS.

For traffic between virtual networks destined to the BMS, when traffic is Layer 3 routed across the to virtual network to which the destination BMS belongs, the MX Series gateway searches for the BMS device's ARP entry. See [Figure 53 on page 540](#).

**Figure 53: MX Series Gateway and Dynamic ARP Processing**

For IP address 10.10.0.100, the MAC address VMAC1 is used by both MX1 and MX2. If the no ARP match is found, then the MX Series gateway initiates an ARP request with the IRB's own IP and MAC addresses. The BMS learns the IRB's IP and MAC binding, and adds or refreshes the ARP entry in the table based on the ARP request packet sent from the MX Series gateway. The ARP response from the BMS may arrive on any of the QFX5100 switches, and the ARP response has a destination MAC address equal to the IRB's own MAC address. The ARP request is sent back by unicast to the MX Series gateway that initiated the original ARP request.

## Example: Configuring an EVPN Control Plane and VXLAN Data Plane

---

This example shows how to configure EVPN and VXLAN on a network to support Data Center Interconnect (DCI), allow for optimal forwarding of Ethernet frames, provide network segmentation on a broad scale, enable control plane-based MAC learning, and many other advantages.

- [Requirements on page 541](#)
- [Overview on page 541](#)
- [Configuration on page 541](#)
- [Verification on page 567](#)

### Requirements

This example uses the following hardware and software components:

- Two Juniper Networks MX Series routers to act as IP gateways for the EVPN overlay
- Four Juniper Networks QFX5100 switches. Two of these switches act as PE devices in the EVPN topology, and the other two switches act as pure IP transport for the overlay.
- Junos OS Release 16.1 or later.

### Overview

Ethernet VPNs (EVPNs) enable you to connect groups of dispersed customer sites using Layer 2 virtual bridges, and Virtual Extensible LANs (VXLANs) enable you to stretch Layer 2 connection over an intervening Layer 3 network, while providing network segmentation like a VLAN, but without the scaling limitation of traditional VLANs. EVPN with VXLAN encapsulation handles Layer 2 connectivity at the scale required by cloud server providers and replaces limiting protocols like STP, freeing up your Layer 3 network to use more robust routing protocols.

This example configuration shows how to configure EVPN with VXLAN encapsulation. For the purposes of this example, the MX Series routers are named Core-1 and Core-2. The QFX5100 switches are named Leaf-1, Leaf-2, Spine-1, and Spine-2. The core routers act as IP gateways for the EVPN overlay, the leaf switches act as PE devices in the EVPN topology, and the spine switches act as pure IP transport for the overlay.

### Configuration

### Configuring Leaf-1

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

Configure the QFX5100 switch called Leaf-1:

1. Set the system hostname.  
  
[edit]  
user@leaf-1# set system host-name leaf-1
2. Configure routing options.  
  
[edit routing-options]  
user@leaf-1# set router-id 192.0.2.0  
user@leaf-1# set autonomous-system 65402

```
user@leaf-1# set forwarding-table export load-balance
user@leaf-1# set forwarding-table ecmp-fast-reroute
```

3. Configure load balancing.

```
[edit policy-options policy-statement load-balance]
user@leaf-1# set term 1 then load-balance per-packet
```

4. Make sure lo0 is exported and thus advertised into the underlay, then configure **family inet unicast loops 2**. Doing this is necessary because of the design choice to re-use the same autonomous system (AS) number within a tier.

```
[edit protocols bgp group underlay]
user@leaf-1# set type external
user@leaf-1# set advertise-peer-as
user@leaf-1# set family inet unicast loops 2
user@leaf-1# set export lo0
user@leaf-1# set peer-as 65401
user@leaf-1# set multipath
user@leaf-1# set neighbor 10.0.0.8 description spine-1
user@leaf-1# set neighbor 10.0.0.12 description spine-2
```

5. Configure policy options for the loopback address.

```
[edit policy-options policy-statement lo0]
user@leaf-1# set from family inet
user@leaf-1# set from protocol direct
user@leaf-1# set from route-filter 0.0.0.0/0 prefix-length-range /32-/32
user@leaf-1# set then accept
```

6. Configure switch options. At the **[switch-options]** hierarchy level, the virtual tunnel endpoint interface is lo0.0, which must be reachable through the underlay routing protocol. The route distinguisher must be unique across all switches in the network to ensure all route advertisements within MP-BGP are globally unique. The VRF table target on the QFX Series switch is, at a minimum, the community with which the switch sends all ESI (Type-1) routes. The **vrf-import vrf-imp** statement defines the target community list, which is imported into the default-switch.evpn.0 instance from bgp.evpn.0.

```
[edit switch-options]
user@leaf-1# set vtep-source-interface lo0.0
user@leaf-1# set route-distinguisher 192.0.2.0:1
user@leaf-1# set vrf-import vrf-imp
user@leaf-1# set vrf-target target:9999:9999
```

7. Configure the VRF table import policy.

```
[edit policy-options policy-statement vrf-imp]
user@leaf-1# set term t1 from community com100
user@leaf-1# set vrf-imp term t1 then accept
user@leaf-1# set vrf-imp term t2 from community com200
user@leaf-1# set vrf-imp term t2 then accept
user@leaf-1# set vrf-imp term t3 from community com300
user@leaf-1# set vrf-imp term t3 then accept
```

```

user@leaf-1# set vrf-imp term t4 from community com400
user@leaf-1# set vrf-imp term t4 then accept
user@leaf-1# set vrf-imp term t5 then reject

```

8. Configure the community policy options.

```

[edit policy-options community]

user@leaf-1# set com100 members target:1:100
user@leaf-1# set com200 members target:1:200
user@leaf-1# set com300 members target:1:300
user@leaf-1# set com400 members target:1:400

```

9. Configure the extended virtual network identifier list to establish which VXLAN network identifiers you want to be part of the EVPN and VXLAN MP-BGP domain. Next, set up the ingress replication; this EVPN and VXLAN ingress-replication is used instead of a multicast underlay. Then configure different route targets for each VXLAN network identifier instance under **vni-routing-options**.

```

[edit protocols evpn]

user@leaf-1# set encapsulation vxlan
user@leaf-1# set extended-vni-list 1100
user@leaf-1# set extended-vni-list 1200
user@leaf-1# set extended-vni-list 1300
user@leaf-1# set extended-vni-list 1400
user@leaf-1# set multicast-mode ingress-replication
user@leaf-1# set vni-routing-options vni 1100 vrf-target export target:1:100
user@leaf-1# set vni-routing-options vni 1200 vrf-target export target:1:200
user@leaf-1# set vni-routing-options vni 1300 vrf-target export target:1:300
user@leaf-1# set vni-routing-options vni 1400 vrf-target export target:1:400

```

10. Map locally significant VLAN IDs to globally significant VXLAN network identifiers.

```

[edit vlans]

user@leaf-1# set v100 vlan-id 100
user@leaf-1# set v100 vxlan vni 1100
user@leaf-1# set v100 vxlan ingress-node-replication
user@leaf-1# set v200 vlan-id 200
user@leaf-1# set v200 vxlan vni 1200
user@leaf-1# set v200 vxlan ingress-node-replication
user@leaf-1# set v300 vlan-id 300
user@leaf-1# set v300 vxlan vni 1300
user@leaf-1# set v300 vxlan ingress-node-replication
user@leaf-1# set v400 vlan-id 400
user@leaf-1# set v400 vxlan vni 1400
user@leaf-1# set v400 vxlan ingress-node-replication

```

11. Configure the EVPN MP-BGP sessions.

```

[edit protocols bgp group EVPN_VXLAN_CORE]

user@leaf-1# set type external
user@leaf-1# set multihop ttl 255
user@leaf-1# set multihop no-nexthop-change
user@leaf-1# set local-address 192.0.2.0
user@leaf-1# set family evpn signaling
user@leaf-1# set peer-as 65400
user@leaf-1# set local-as 65403

```

```

user@leaf-1# set neighbor 10.255.255.0 description core-1
user@leaf-1# set neighbor 10.255.255.1 description core-2
user@leaf-1# set type internal
user@leaf-1# set local-address 192.0.2.0
user@leaf-1# set family evpn signaling
user@leaf-1# set export LEAF-PREPEND
user@leaf-1# set neighbor 10.255.255.5 description leaf-2

```

12. Configure the Gigabit Ethernet interfaces.

```
[edit interfaces]
```

```

user@leaf-1# set xe-0/0/2 unit 0 family inet address 10.0.0.9/31
user@leaf-1# set xe-0/0/4 unit 0 family inet address 10.0.0.13/31
user@leaf-1# set xe-0/0/32 ether-options 802.3ad ae0
user@leaf-1# set xe-0/0/33 ether-options 802.3ad ae1
user@leaf-1# set xe-0/0/34 unit 0 family ethernet-switching interface-mode trunk
user@leaf-1# set xe-0/0/34 unit 0 family ethernet-switching vlan members v300
user@leaf-1# set xe-0/0/34 unit 0 family ethernet-switching vlan members v400

```

13. Configure two LACP-enabled LAG interfaces. The ESI value is globally unique across the entire EVPN domain. The **all-active** configuration statement ensures that all PE routers to which this multihomed tenant is attached to can forward traffic from the CE device, such that all CE links are actively used.

```
[edit interfaces]
```

```

user@leaf-1# set ae0 esi 00:01:01:01:01:01:01:01:01
user@leaf-1# set ae0 esi all-active
user@leaf-1# set e0 aggregated-ether-options lacp active
user@leaf-1# set ae0 aggregated-ether-options lacp system-id 00:00:00:01:01:01
user@leaf-1# set ae0 unit 0 family ethernet-switching interface-mode access
user@leaf-1# set ae0 unit 0 family ethernet-switching vlan members v100
user@leaf-1# set ae1 esi 00:02:02:02:02:02:02:02:02
user@leaf-1# set ae1 esi all-active
user@leaf-1# set ae1 aggregated-ether-options lacp active
user@leaf-1# set ae1 aggregated-ether-options lacp system-id 00:00:00:01:01:01
user@leaf-1# set ae1 unit 0 family ethernet-switching interface-mode access
user@leaf-1# set ae1 unit 0 family ethernet-switching vlan members v200

```

14. Configure the loopback interface address.

```
[edit interfaces]
```

```
user@leaf-1# set lo0 unit 0 family inet address 192.0.2.0/24
```

## Configuring Leaf-2

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

The configuration of Leaf-2 is very similar to the configuration of Leaf-1. Configure the QFX5100 switch called Leaf-2:

1. Set the system hostname.

```
[edit]
user@leaf-2# set system host-name leaf-2
```

2. Configure routing options.

```
[edit routing-options]
user@leaf-2# set router-id 10.255.255.5
user@leaf-2# set autonomous-system 65402
user@leaf-2# set forwarding-table export load-balance
user@leaf-2# set forwarding-table ecmp-fast-reroute
```

3. Configure load balancing.

```
[edit policy-options policy-statement load-balance]
user@leaf-2# set term 1 then load-balance per-packet
```

4. Make sure lo0 is exported and thus advertised into the underlay, then configure **family inet unicast loops 2**. Doing this is necessary because of the design choice to re-use the same autonomous system (AS) number within a tier.

```
[edit protocols bgp group underlay]
user@leaf-2# set type external
user@leaf-2# set advertise-peer-as
user@leaf-2# set family inet unicast loops 2
user@leaf-2# set export lo0
user@leaf-2# set peer-as 65401
user@leaf-2# set multipath
user@leaf-2# set neighbor 10.0.0.10 description spine-1
user@leaf-2# set neighbor 10.0.0.14 description spine-2
```

5. Configure policy options for the loopback address.

```
[edit policy-options policy-statement lo0]
user@leaf-2# set from family inet
user@leaf-2# set from protocol direct
user@leaf-2# set from route-filter 0.0.0.0/0 prefix-length-range /32-/32
user@leaf-2# set then accept
```

6. Configure switch options. At the **[switch-options]** hierarchy level, the virtual tunnel endpoint interface is lo0.0, which must be reachable through the underlay routing protocol. The route distinguisher must be unique across all switches in the network

to ensure all route advertisements within MP-BGP are globally unique. The VRF table target on the QFX Series switch is, at a minimum, the community with which the switch sends all ESI (Type-1) routes. The **vrf-import vrf-imp** statement defines the target community list, which is imported into the default-switch.evpn.0 instance from bgp.evpn.0.

```
[edit switch-options]
```

```
user@leaf-2# set vtep-source-interface lo0.0
user@leaf-2# set route-distinguisher 10.255.255.5:1
user@leaf-2# set vrf-import vrf-imp
user@leaf-2# set vrf-target target:9999:9999
```

7. Configure the VRF table import policy.

```
[edit policy-options policy-statement vrf-imp]
```

```
user@leaf-2# set term t1 from community com100
user@leaf-2# set vrf-imp term t1 then accept
user@leaf-2# set vrf-imp term t2 from community com200
user@leaf-2# set vrf-imp term t2 then accept
user@leaf-2# set vrf-imp term t3 from community com300
user@leaf-2# set vrf-imp term t3 then accept
user@leaf-2# set vrf-imp term t4 from community com400
user@leaf-2# set vrf-imp term t4 then accept
user@leaf-2# set vrf-imp term t5 then reject
```

8. Configure the community policy options.

```
[edit policy-options community]
```

```
user@leaf-2# set com100 members target:1:100
user@leaf-2# set com200 members target:1:200
user@leaf-2# set com300 members target:1:300
user@leaf-2# set com400 members target:1:400
```

9. Configure the extended virtual network identifier list to establish which VXLAN network identifiers you want to be part of the EVPN and VXLAN MP-BGP domain. Next, set up the ingress replication; this EVPN and VXLAN ingress-replication is used instead of a multicast underlay. Then configure different route targets for each VXLAN network identifier instance under **vni-routing-options**.

```
[edit protocols evpn]
```

```
user@leaf-2# set encapsulation vxlan
user@leaf-2# set extended-vni-list 1100
user@leaf-2# set extended-vni-list 1200
user@leaf-2# set extended-vni-list 1300
user@leaf-2# set extended-vni-list 1400
user@leaf-2# set multicast-mode ingress-replication
user@leaf-2# set vni-routing-options vni 1100 vrf-target export target:1:100
user@leaf-2# set vni-routing-options vni 1200 vrf-target export target:1:200
user@leaf-2# set vni-routing-options vni 1300 vrf-target export target:1:300
user@leaf-2# set vni-routing-options vni 1400 vrf-target export target:1:400
```

10. Map locally significant VLAN IDs to globally significant VXLAN network identifiers.

```
[edit vlans]
```

```

user@leaf-2# set v100 vlan-id 100
user@leaf-2# set v100 vxlan vni 1100
user@leaf-2# set v100 vxlan ingress-node-replication
user@leaf-2# set v200 vlan-id 200
user@leaf-2# set v200 vxlan vni 1200
user@leaf-2# set v200 vxlan ingress-node-replication
user@leaf-2# set v300 vlan-id 300
user@leaf-2# set v300 vxlan vni 1300
user@leaf-2# set v300 vxlan ingress-node-replication
user@leaf-2# set v400 vlan-id 400
user@leaf-2# set v400 vxlan vni 1400
user@leaf-2# set v400 vxlan ingress-node-replication

```

11. Configure the EVPN MP-BGP sessions.

```

[edit protocols bgp group EVPN_VXLAN_CORE]

user@leaf-2# set type external
user@leaf-2# set multihop ttl 255
user@leaf-2# set multihop no-nexthop-change
user@leaf-2# set local-address 10.255.255.5
user@leaf-2# set family evpn signaling
user@leaf-2# set peer-as 65400
user@leaf-2# set neighbor 10.255.255.0 description core-1
user@leaf-2# set neighbor 10.255.255.1 description core-2
user@leaf-2# set type internal
user@leaf-2# set local-address 10.255.255.5
user@leaf-2# set family evpn signaling
user@leaf-2# set export LEAF-PREPEND
user@leaf-2# set neighbor 192.0.2.0 description leaf-2

```

12. Configure the Gigabit Ethernet interfaces.

```

[edit interfaces]

user@leaf-2# set xe-0/0/3 unit 0 family inet address 10.0.0.11/31
user@leaf-2# set xe-0/0/5 unit 0 family inet address 10.0.0.15/31
user@leaf-2# set xe-0/0/36 ether-options 802.3ad ae0
user@leaf-2# set xe-0/0/37 ether-options 802.3ad ae1
user@leaf-2# set xe-0/0/38 unit 0 family ethernet-switching interface-mode trunk
user@leaf-2# set xe-0/0/38 unit 0 family ethernet-switching vlan members v300
user@leaf-2# set xe-0/0/38 unit 0 family ethernet-switching vlan members v100

```

13. Configure two LACP-enabled LAG interfaces. The ESI value is globally unique across the entire EVPN domain. The **all-active** configuration statement ensures that all PE routers to which this multihomed tenant is attached to can forward traffic from the CE device, such that all CE links are actively used.

```

[edit interfaces]

user@leaf-2# set ae0 esi 00:01:01:01:01:01:01:01:01
user@leaf-2# set ae0 esi all-active
user@leaf-2# set ae0 aggregated-ether-options lacp passive
user@leaf-2# set ae0 aggregated-ether-options lacp system-id 00:00:00:01:01:01
user@leaf-2# set ae0 unit 0 family ethernet-switching interface-mode access
user@leaf-2# set ae0 unit 0 family ethernet-switching vlan members v100
user@leaf-2# set ae1 esi 00:02:02:02:02:02:02:02:02

```

```
user@leaf-2# set ae1 esi all-active
user@leaf-2# set ae1 aggregated-ether-options lacp passive
user@leaf-2# set ae1 aggregated-ether-options lacp system-id 00:00:00:01:01:01
user@leaf-2# set ae1 unit 0 family ethernet-switching interface-mode access
user@leaf-2# set ae1 unit 0 family ethernet-switching vlan members v200
```

14. Configure the loopback interface address.

```
[edit interfaces]
user@leaf-2# set lo0 unit 0 family inet address 10.255.255.5/32
```

---

### Configuring Spine-1

---

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

The configuration of the spine switches is similar to the leaf switches. To configure Spine-1:

1. Set the system hostname.

```
[edit]
user@spine-1# set system host-name spine-1
```

2. Configure the routing options.

```
[edit routing-options]
user@spine-1# set router-id 10.255.255.2
user@spine-1# set autonomous-system 65401
user@spine-1# set forwarding-table export load-balance
user@spine-1# set forwarding-table ecmp-fast-reroute
```

3. Configure load balance policy options.

```
[edit policy-options policy-statement load-balance]
user@spine-1# set term 1 then load-balance per-packet
```

4. Configure the underlay Leaf group with the **advertise-peer-as** statement to enable Spine-1 to bypass EBGp rules and re-advertise a route to the same autonomous system (AS) number.

```
[edit protocols bgp group underlay-leaf]
user@spine-1# set type external
user@spine-1# set advertise-peer-as
user@spine-1# set family inet unicast loops 2
user@spine-1# set export lo0
user@spine-1# set peer-as 65402
user@spine-1# set multipath
user@spine-1# set neighbor 10.0.0.9 description leaf-1
user@spine-1# set neighbor 10.0.0.11 description leaf-2
```

5. Configure the underlay Core group. The MX Series Core routers are not EVPN peered, and do not require reachability to the other's loopback, so including the **advertise-peer-as** configuration statement is optional.

```
[edit protocols bgp group underlay-core]
user@spine-1# set type external
user@spine-1# set advertise-peer-as
user@spine-1# set family inet unicast loops 2
user@spine-1# set export lo0
user@spine-1# set peer-as 65400
user@spine-1# set multipath
user@spine-1# set neighbor 10.0.0.0 description core-1
user@spine-1# set neighbor 10.0.0.4 description core-2
```

6. Configure policy options for the loopback address.

```
[edit policy-options policy-statement lo0]
user@spine-1# set from family inet
user@spine-1# set from protocol direct
user@spine-1# set from route-filter 0.0.0.0/0 prefix-length-range /32-/32
user@spine-1# set then accept
```

## Configuring Spine-2

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

The configuration of the spine switches is similar to the leaf switches. To configure Spine-2:

1. Set the system hostname.

```
[edit]
user@spine-2# set system host-name spine-2
```

2. Configure the routing options.

```
[edit routing-options]
user@spine-2# set router-id 10.255.255.3
user@spine-2# set autonomous-system 65401
user@spine-2# set forwarding-table export load-balance
user@spine-2# set forwarding-table ecmp-fast-reroute
```

3. Configure load balance policy options.

```
[edit policy-options policy-statement load-balance]
user@spine-2# set term 1 then load-balance per-packet
```

4. Configure the underlay Leaf group with the **advertise-peer-as** statement to enable Spine-2 to bypass EBGp rules and re-advertise a route to the same autonomous system (AS) number.

```
[edit protocols bgp group underlay-leaf]

user@spine-2# set type external
user@spine-2# set advertise-peer-as
user@spine-2# set family inet unicast loops 2
user@spine-2# set export lo0
user@spine-2# set peer-as 65402
user@spine-2# set multipath
user@spine-2# set neighbor 10.0.0.13 description leaf-1
user@spine-2# set neighbor 10.0.0.15 description leaf-2
```

5. Configure the underlay Core group. The MX Series Core routers are not EVPN peered, and do not require reachability to the other's loopback, so including the **advertise-peer-as** configuration statement is optional.

```
[edit protocols bgp group underlay-core]

user@spine-2# set type external
user@spine-2# set advertise-peer-as
user@spine-2# set family inet unicast loops 2
user@spine-2# set export lo0
user@spine-2# set peer-as 65400
user@spine-2# set multipath
user@spine-2# set neighbor 10.0.0.2 description core-1
user@spine-2# set neighbor 10.0.0.6 description core-2
```

6. Configure policy options for the loopback address.

```
[edit policy-options policy-statement lo0]

user@spine-2# set from family inet
user@spine-2# set from protocol direct
user@spine-2# set from route-filter 0.0.0.0/0 prefix-length-range /32-/32
user@spine-2# set then accept
```

---

## Configuring Core-1

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Core-1:

1. Set the system hostname.

```
[edit]

user@core-1# set system host-name core-1
```

2. Configure the router ID and other routing options.

```
[edit routing-options]

user@core-1# set router-id 10.255.255.0
user@core-1# set autonomous-system 65400
user@core-1# set forwarding-table export load-balance
user@core-1# set forwarding-table ecmp-fast-reroute
```

3. Configure the load balance policy options.

```
[edit policy-options policy-statement load-balance]
user@core-1# set term 1 then load-balance per-packet
```

4. Configure the BGP underlay group.

```
[edit protocols bgp group underlay]
user@core-1# set type external
user@core-1# set advertise-peer-as
user@core-1# set family inet unicast loops 2
user@core-1# set export lo0
user@core-1# set peer-as 65401
user@core-1# set multipath
user@core-1# set neighbor 10.0.0.1 description spine-1
user@core-1# set neighbor 10.0.0.3 description spine-2
```

5. Configure the loopback address policy options.

```
[edit policy-options policy-statement lo0]
user@core-1# set from family inet
user@core-1# set from protocol direct
user@core-1# set lo0 from route-filter 0.0.0.0/0 prefix-length-range /32-/32
user@core-1# set lo0 then accept
```

6. A large portion of Core-1's configuration takes place in the **[routing-instance]** hierarchy. Configure the virtual routers and configure a unique VRF table import policy for each virtual switch.

```
[edit routing-instances]
user@core-1# set VRF_Tenant_A instance-type vrf
user@core-1# set VRF_Tenant_A interface irb.1100
user@core-1# set VRF_Tenant_A route-distinguisher 10.255.255.0:1100
user@core-1# set VRF_Tenant_A vrf-target target:10:100
user@core-1# set VRF_Tenant_A routing-options auto-export
user@core-1# set VRF_Tenant_B instance-type vrf
user@core-1# set VRF_Tenant_B interface irb.1200
user@core-1# set VRF_Tenant_B route-distinguisher 10.255.255.0:1200
user@core-1# set VRF_Tenant_B vrf-target target:10:200
user@core-1# set VRF_Tenant_C instance-type vrf
user@core-1# set VRF_Tenant_C interface irb.1300
user@core-1# set VRF_Tenant_C route-distinguisher 10.255.255.0:1300
user@core-1# set VRF_Tenant_C vrf-target target:10:300
user@core-1# set VRF_Tenant_D instance-type vrf
user@core-1# set VRF_Tenant_D interface irb.1400
user@core-1# set VRF_Tenant_D route-distinguisher 10.255.255.0:1400
user@core-1# set VRF_Tenant_D vrf-target target:10:400
user@core-1# set VS_VLAN100 vtep-source-interface lo0.0
user@core-1# set VS_VLAN100 instance-type virtual-switch
user@core-1# set VS_VLAN100 route-distinguisher 10.255.255.0:100
user@core-1# set VS_VLAN100 vrf-import VS_VLAN100_IMP
user@core-1# set VS_VLAN100 vrf-target target:1:100
user@core-1# set VS_VLAN100 protocols evpn encapsulation vxlan
user@core-1# set VS_VLAN100 protocols evpn extended-vni-list 1100
user@core-1# set VS_VLAN100 protocols evpn multicast-mode ingress-replication
user@core-1# set VS_VLAN100 bridge-domains bd1100 vlan-id 100
user@core-1# set VS_VLAN100 bridge-domains bd1100 routing-interface irb.1100
```

```

user@core-1# set VS_VLAN100 bridge-domains bd1100 vxlan vni 1100
user@core-1# set VS_VLAN100 bridge-domains bd1100 vxlan
ingress-node-replication
user@core-1# set VS_VLAN200 vtep-source-interface lo0.0
user@core-1# set VS_VLAN200 instance-type virtual-switch

ingress-node-replication

```

## 7. Configure the individual policy statements.

```
[edit policy-options policy-statement]
```

```

user@core-1# set VS_VLAN100_IMP term ESI from community comm-leaf_esi
user@core-1# set VS_VLAN100_IMP term ESI then accept
user@core-1# set VS_VLAN100_IMP term VS_VLAN100 from community comm-VS_VLAN100
user@core-1# set VS_VLAN100_IMP term VS_VLAN100 then accept
user@core-1# set VS_VLAN200_IMP term ESI from community comm-leaf_esi
user@core-1# set VS_VLAN200_IMP term ESI then accept
user@core-1# set VS_VLAN200_IMP term VS_VLAN200 from community comm-VS_VLAN200
user@core-1# set VS_VLAN200_IMP term VS_VLAN200 then accept
user@core-1# set VS_VLAN300_IMP term ESI from community comm-leaf_esi
user@core-1# set VS_VLAN300_IMP term ESI then accept
user@core-1# set VS_VLAN300_IMP term VS_VLAN300 from community comm-VS_VLAN300
user@core-1# set VS_VLAN300_IMP term VS_VLAN300 then accept
user@core-1# set VS_VLAN400_IMP term ESI from community comm-leaf_esi
user@core-1# set VS_VLAN400_IMP term ESI then accept

```

```

user@core-1# set VS_VLAN400_IMP term VS_VLAN400 from community comm-VS_VLAN400
user@core-1# set VS_VLAN400_IMP term VS_VLAN400 then accept
user@core-1# set lo0 from family inet
user@core-1# set lo0 from protocol direct
user@core-1# set lo0 from route-filter 0.0.0.0/0 prefix-length-range /32-/32
user@core-1# set lo0 then accept

```

8. Configure the community policy options. Make sure the **comm-leaf\_esi** policy option accepts target 9999:9999 to ensure that all virtual switches import the Type-1 ESI routes from all leafs.

```

[edit policy-options community]

user@core-1# set comm-VS_VLAN100 members target:1:100
user@core-1# set comm-VS_VLAN200 members target:1:200
user@core-1# set comm-VS_VLAN300 members target:1:300
user@core-1# set comm-VS_VLAN400 members target:1:400
user@core-1# set comm-leaf_esi members target:9999:9999

```

9. Configure the IRB interfaces. Every IRB has a virtual gateway address, which is a shared MAC address and IP address across Core-1 and Core-2.

```

[edit interfaces irb]

user@core-1# set unit 1100 family inet address 172.16.0.2/24
virtual-gateway-address 100.0.0.1
user@core-1# set unit 1200 family inet address 172.16.0.3/24
virtual-gateway-address 200.0.0.1
user@core-1# set unit 1300 family inet address 10.10.10.2/24
virtual-gateway-address 10.10.10.1
user@core-1# set unit 1400 family inet address 10.10.10.2/24
virtual-gateway-address 10.10.10.1

```

10. Configure MP-BGP sessions towards Leaf-1 and Leaf-2.

```

[edit protocols bgp group EVPN_VXLAN]

user@core-1# set type external
user@core-1# set local-address 10.255.255.0
user@core-1# set family evpn signaling
user@core-1# set peer-as 65402
user@core-1# set multipath
user@core-1# set neighbor 192.0.2.0 description leaf-1
user@core-1# set neighbor 192.0.2.0 multihop ttl 255
user@core-1# set neighbor 10.255.255.5 description leaf-2
user@core-1# set neighbor 10.255.255.5 multihop ttl 255

```

## Configuring Core-2

---

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Core-2:

1. Set the system hostname.

```
[edit]
```

```
user@core-2# set system host-name core-2
```

2. Configure the router ID and other routing options.

```
[edit routing-options]
```

```
user@core-2# set router-id 10.255.255.1
```

```
user@core-2# set autonomous-system 65400
```

```
user@core-2# set forwarding-table export load-balance
```

```
user@core-2# set forwarding-table ecmp-fast-reroute
```

3. Configure the load balance policy options.

```
[edit policy-options policy-statement load-balance]
```

```
user@core-2# set term 1 then load-balance per-packet
```

4. Configure the BGP underlay group.

```
[edit protocols bgp group underlay]
```

```
user@core-2# set type external
```

```
user@core-2# set advertise-peer-as
```

```
user@core-2# set family inet unicast loops 2
```

```
user@core-2# set export lo0
```

```
user@core-2# set peer-as 65401
```

```
user@core-2# set multipath
```

```
user@core-2# set neighbor 10.0.0.5 description spine-1
```

```
user@core-2# set neighbor 10.0.0.7 description spine-2
```

5. Configure the loopback address policy options.

```
[edit policy-options policy-statement lo0]
```

```
user@core-2# set from family inet
```

```
user@core-2# set from protocol direct
```

```
user@core-2# set lo0 from route-filter 0.0.0.0/0 prefix-length-range /32-/32
```

```
user@core-2# set lo0 then accept
```

6. A large portion of Core-1's configuration takes place in the **[routing-instance]** hierarchy. Configure the virtual routers and configure a unique VRF table import policy for each virtual switch.

```
[edit routing-instances]
```

```

user@core-2# set VRF_Tenant_A instance-type vrf
user@core-2# set VRF_Tenant_A interface irb.1100
user@core-2# set VRF_Tenant_A route-distinguisher 10.255.255.1:1100
user@core-2# set VRF_Tenant_A vrf-target target:10:100
user@core-2# set VRF_Tenant_A routing-options auto-export
user@core-2# set VRF_Tenant_B instance-type vrf
user@core-2# set VRF_Tenant_B interface irb.1200
user@core-2# set VRF_Tenant_B route-distinguisher 10.255.255.1:1200

user@core-2# set VS_VLAN400 bridge-domains bd1400 vxlan
ingress-node-replication

```

7. Configure the individual policy statements.

```

[edit policy-options policy-statement]

user@core-2# set VS_VLAN100_IMP term ESI from community comm-leaf_esi
user@core-2# set VS_VLAN100_IMP term ESI then accept
user@core-2# set VS_VLAN100_IMP term VS_VLAN100 from community comm-VS_VLAN100
user@core-2# set VS_VLAN100_IMP term VS_VLAN100 then accept
user@core-2# set VS_VLAN200_IMP term ESI from community comm-leaf_esi
user@core-2# set VS_VLAN200_IMP term ESI then accept
user@core-2# set VS_VLAN200_IMP term VS_VLAN200 from community comm-VS_VLAN200
user@core-2# set VS_VLAN200_IMP term VS_VLAN200 then accept
user@core-2# set VS_VLAN300_IMP term ESI from community comm-leaf_esi
user@core-2# set VS_VLAN300_IMP term ESI then accept
user@core-2# set VS_VLAN300_IMP term VS_VLAN300 from community comm-VS_VLAN300
user@core-2# set VS_VLAN300_IMP term VS_VLAN300 then accept
user@core-2# set VS_VLAN400_IMP term ESI from community comm-leaf_esi
user@core-2# set VS_VLAN400_IMP term ESI then accept
user@core-2# set VS_VLAN400_IMP term VS_VLAN400 from community comm-VS_VLAN400
user@core-2# set VS_VLAN400_IMP term VS_VLAN400 then accept
user@core-2# set lo0 from family inet
user@core-2# set lo0 from protocol direct
user@core-2# set lo0 from route-filter 0.0.0.0/0 prefix-length-range /32-/32
user@core-2# set lo0 then accept

```

8. Configure the community policy options. Make sure the **comm-leaf\_esi** policy option accepts target 9999:9999 to ensure that all virtual switches import the Type-1 ESI routes from all leaves.

```

[edit policy-options community]

user@core-2# set comm-VS_VLAN100 members target:1:100
user@core-2# set comm-VS_VLAN200 members target:1:200
user@core-2# set comm-VS_VLAN300 members target:1:300
user@core-2# set comm-VS_VLAN400 members target:1:400
user@core-2# set comm-leaf_esi members target:9999:9999

```

9. Configure the IRB interfaces. Every IRB has a virtual gateway address, which is a shared MAC address and IP address across Core-1 and Core-2.

```

[edit interfaces irb]

user@core-2# set unit 1100 family inet address 172.16.0.4/24
virtual-gateway-address 100.0.0.1
user@core-2# set unit 1200 family inet address 172.16.0.5/24
virtual-gateway-address 200.0.0.1
user@core-2# set unit 1300 family inet address 10.10.10.3/24
virtual-gateway-address 10.10.10.1

```

```
user@core-2# set unit 1400 family inet address 10.10.10.3/24
virtual-gateway-address 10.10.10.1
```

10. Configure MP-BGP sessions towards Leaf-1 and Leaf-2.

```
[edit protocols bgp group EVPN_VXLAN]

user@core-2# set type external
user@core-2# set local-address 10.255.255.1
user@core-2# set family evpn signaling
user@core-2# set peer-as 65402
user@core-2# set multipath
user@core-2# set neighbor 192.0.2.0 description leaf-1
user@core-2# set neighbor 192.0.2.0 multihop ttl 255
user@core-2# set neighbor 10.255.255.5 description leaf-2
user@core-2# set neighbor 10.255.255.5 multihop ttl 255
```

## Verification

After you configure both the underlay and EVPN overlay we recommend that you verify that the configurations work as you intended.

---

### Verifying Leaf-1 Configuration

**Purpose** Verify that Leaf-1 is properly configured.

**Action** Verify that the routing options are properly configured.

```
user@leaf-1> show configuration routing-options
router-id 192.0.2.0;
autonomous-system 65402;
forwarding-table {
 export load-balance;
}
```

Verify that the load-balance policy statement is properly configured.

```
user@leaf-1> show configuration policy-options policy-statement
load-balance
term 1 {
 then {
 load-balance per-packet;
 }
}
```

Verify the underlay BGP group configuration.

```
user@leaf-1> show configuration protocols bgp group underlay
type external;
advertise-peer-as;
family inet {
 unicast {
 loops 2;
 }
}
export lo0;
peer-as 65401;
multipath;
neighbor 10.0.0.8 {
 description spine-1;
}
neighbor 10.0.0.12 {
 description spine-2;
}
```

Verify that the loopback address is properly configured.

```
user@leaf-1> show configuration policy-options policy-statement lo0
from {
 family inet;
 protocol direct;
 route-filter 0.0.0.0/0 prefix-length-range /32-/32;
}
then accept;
```

Verify the configuration of the switch options.

```
user@leaf-1> show configuration switch-options
vtep-source-interface lo0.0;
route-distinguisher 192.0.2.0:1;
vrf-import vrf-imp;
vrf-target target:9999:9999;
```

Verify the configuration of the VRF table import policy statement.

```
user@leaf-1> show configuration policy-options policy-statement
vrf-imp
term t1 {
 from community com100;
 then accept;
}
term t2 {
 from community com200;
 then accept;
}
term t3 {
 from community com300;
 then accept;
}
term t4 {
 from community com400;
 then accept;
}
term t5 {
 then reject;
}
```

Verify the policy options for GREP.

```
user@leaf-1> show configuration policy-options | grep members
community com100 members target:1:100;
community com200 members target:1:200;
community com300 members target:1:300;
community com400 members target:1:400;
```

Verify that EVPN is properly configured with VXLAN details.

```
user@leaf-1> show configuration protocols evpn
encapsulation vxlan;
extended-vni-list [1100 1200 1300 1400];
multicast-mode ingress-replication;
vni-routing-options {
 vni 1100 {
 vrf-target export target:1:100;
 }
 vni 1200 {
 vrf-target export target:1:200;
 }
 vni 1300 {
 vrf-target export target:1:300;
 }
 vni 1400 {
 vrf-target export target:1:400;
 }
}
```

Verify the EVPN-VXLAN Core BGP group configuration.

```
user@leaf-1> show configuration protocols bgp group EVPN_VXLAN_CORE
type external;
multihop {
```

```
 ttl 255;
 no-nexthop-change;
 }
 local-address 192.0.2.0;
 family evpn {
 signaling;
 }
 peer-as 65400;
 neighbor 10.255.255.0 {
 description core-1;
 }
 neighbor 10.255.255.1 {
 description core-2;
 }
}
```

Verify the EVPN-VXLAN Leaf BGP group configuration.

```
user@leaf-1> show configuration protocols bgp group EVPN_VXLAN_LEAF
type internal;
local-address 192.0.2.0;
family evpn {
 signaling;
}
neighbor 10.255.255.5 {
 description leaf-2;
}
```

Verify the configuration for the xe-0/0/32 interface.

```
user@leaf-1> show configuration interfaces xe-0/0/32
ether-options {
 802.3ad ae0;
}
```

Verify the configuration for the xe-0/0/33 interface.

```
user@leaf-1> show configuration interfaces xe-0/0/33
ether-options {
 802.3ad ae1;
}
```

Verify the configuration for the ae0 interface.

```
user@leaf-1> show configuration interfaces ae0
esi {
 00:01:01:01:01:01:01:01;
 all-active;
}
aggregated-ether-options {
 lacp {
 active;
 system-id 00:00:00:01:01:01;
 }
}
unit 0 {
 family ethernet-switching {
 interface-mode access;
 vlan {
```

```
 members v100;
 }
}
```

Verify the configuration for the ae1 interface.

```
user@leaf-1> show configuration interfaces ae1
esi {
 00:02:02:02:02:02:02:02:02;
 all-active;
}
aggregated-ether-options {
 lacp {
 active;
 system-id 00:00:00:01:01:01;
 }
}
unit 0 {
 family ethernet-switching {
 interface-mode access;
 vlan {
 members v200;
 }
 }
}
```

---

### Verifying Leaf-2 Configuration

**Purpose** Verify that Leaf-2 is properly configured.

**Action** Verify that the routing options are properly configured.

```
user@leaf-2> show configuration routing-options
router-id 10.255.255.5;
autonomous-system 65402;
forwarding-table {
 export load-balance;
}
```

Verify that the load-balance policy statement is properly configured.

```
user@leaf-2> show configuration policy-options policy-statement
load-balance
term 1 {
 then {
 load-balance per-packet;
 }
}
```

Verify the underlay BGP group configuration.

```
user@leaf-2> show configuration protocols bgp group underlay
type external;
advertise-peer-as;
family inet {
 unicast {
 loops 2;
 }
}
export lo0;
peer-as 65401;

neighbor 10.0.0.10 {
 description spine-1;
}
neighbor 10.0.0.14 {
 description spine-2;
}
```

Verify that the loopback address is properly configured.

```
user@leaf-2> show configuration policy-options policy-statement lo0
from {
 family inet;
 protocol direct;
 route-filter 0.0.0.0/0 prefix-length-range /32-/32;
}
then accept;
```

Verify the configuration of the switch options.

```
user@leaf-2> show configuration switch-options
vtep-source-interface lo0.0;
route-distinguisher 10.255.255.5:1;
vrf-import vrf-imp;
vrf-target target:9999:9999;
```

Verify the configuration of the VRF table import policy statement.

```
user@leaf-2> show configuration policy-options policy-statement
vrf-imp
term t1 {
 from community com100;
 then accept;
}
term t2 {
 from community com200;
 then accept;
}
term t3 {
 from community com300;
 then accept;
}
term t4 {
 from community com400;
 then accept;
}
term t5 {
 then reject;
}
```

Verify the policy options for GREP.

```
user@leaf-2> show configuration policy-options | grep members
community com100 members target:1:100;
community com200 members target:1:200;
community com300 members target:1:300;
community com400 members target:1:400;
```

Verify that EVPN is properly configured with VXLAN details.

```
user@leaf-2> show configuration protocols evpn
encapsulation vxlan;
extended-vni-list [1100 1200 1300 1400];
multicast-mode ingress-replication;
vni-routing-options {
 vni 1100 {
 vrf-target export target:1:100;
 }
 vni 1200 {
 vrf-target export target:1:200;
 }
 vni 1300 {
 vrf-target export target:1:300;
 }
 vni 1400 {
 vrf-target export target:1:400;
 }
}
```

Verify the EVPN-VXLAN Core BGP group configuration.

```
user@leaf-2> show configuration protocols bgp group EVPN_VXLAN_CORE
type external;
multihop {
```

```
 ttl 255;
 no-nexthop-change;
 }
 local-address 10.255.255.5;

 }
}
```

Verify the EVPN-VXLAN Leaf BGP group configuration.

```
user@leaf-2> show configuration protocols bgp group EVPN_VXLAN_LEAF
type internal;
local-address 192.0.2.0;
family evpn {
 signaling;
}
neighbor 10.255.255.5 {
 description leaf-2;
}
```

Verify the configuration for the xe-0/0/36 interface.

```
user@leaf-2> show configuration interfaces xe-0/0/36
ether-options {
 802.3ad ae0;
}
```

Verify the configuration for the xe-0/0/37 interface.

```
user@leaf-2> show configuration interfaces xe-0/0/37
ether-options {
 802.3ad ae1;
}
```

Verify the configuration for the ae0 interface.

```
user@leaf-2> show configuration interfaces ae0
esi {
 00:01:01:01:01:01:01:01;
 all-active;
}
aggregated-ether-options {
 lacp {
 passive;

 members v200;
 }
 }
}
```

---

### Verifying Spine-1 Configuration

**Purpose** Verify that Spine-1 is properly configured.

**Action** Verify that the routing options are properly configured.

```
user@spine-1> show configuration routing-options
```

```
router-id 10.255.255.2;
autonomous-system 65401;
forwarding-table {
 export load-balance;
 ecmp-fast-reroute;
}
```

Verify that the load-balance policy statement is properly configured.

```
user@spine-1> show configuration policy-options policy-statement load-balance
```

```
term 1 {
 then {
 load-balance per-packet;
 }
}
```

Verify the underlay Leaf BGP group configuration.

```
user@spine-1> show configuration protocols bgp group underlay-leaf
```

```
type external;
advertise-peer-as;
family inet {
 unicast {
 loops 2;
 }
}
export lo0;
peer-as 65402;
multipath;
neighbor 10.0.0.9 {
 description leaf-1;
}
neighbor 10.0.0.11 {
 description leaf-2;
}
```

Verify the underlay Core BGP group configuration.

```
user@spine-1> show configuration protocols bgp group underlay-core
```

```
type external;
advertise-peer-as;
family inet {
 unicast {
 loops 2;
 }
}
export lo0;
peer-as 65400;
multipath;
neighbor 10.0.0.0 {
 description core-1;
}
```

```
}
neighbor 10.0.0.4 {
 description core-2;
}
```

Verify that the loopback address is properly configured.

```
user@spine-1> show configuration policy-options policy-statement lo0

from {
 family inet;
 protocol direct;
 route-filter 0.0.0.0/0 prefix-length-range /32-/32;
}
then accept;
```

---

### Verifying Spine-2 Configuration

**Purpose** Verify that Spine-2 is properly configured.

**Action** Verify that the routing options are properly configured.

```
user@spine-2> show configuration routing-options
```

```
router-id 10.255.255.3;
autonomous-system 65401;
forwarding-table {
 export load-balance;
 ecmp-fast-reroute;
}
```

Verify that the load-balance policy statement is properly configured.

```
user@spine-2> show configuration policy-options policy-statement load-balance
```

```
term 1 {
 then {
 load-balance per-packet;
 }
}
```

Verify the underlay Leaf BGP group configuration.

```
user@spine-2> show configuration protocols bgp group underlay-leaf
```

```
type external;
advertise-peer-as;
family inet {
 unicast {
 loops 2;
 }
}
export lo0;
peer-as 65402;
multipath;
neighbor 10.0.0.13 {
 description leaf-1;
}
neighbor 10.0.0.15 {
 description leaf-2;
}
```

Verify the underlay Core BGP group configuration.

```
user@spine-2> show configuration protocols bgp group underlay-core
```

```
type external;
advertise-peer-as;
family inet {
 unicast {
 loops 2;
 }
}
export lo0;
peer-as 65400;
multipath;
neighbor 10.0.0.2 {
 description core-1;
}
```

```
}
neighbor 10.0.0.6 {
 description core-2;
}
```

Verify that the loopback address is properly configured.

```
user@spine-2> show configuration policy-options policy-statement lo0
```

```
from {
 family inet;
 protocol direct;
 route-filter 0.0.0.0/0 prefix-length-range /32-/32;
}
then accept;
```

---

### Verifying Core-1 Configuration

**Purpose** Verify that Core-1 is properly configured.

**Action** Verify that the routing options are properly configured.

```
user@core-1> show configuration routing-options
router-id 10.255.255.0;
autonomous-system 65400;
forwarding-table {
 export load-balance;
 ecmp-fast-reroute;
}
```

Verify that the load-balance policy statement is properly configured.

```
user@core-1> show configuration policy-options policy-statement load-balance
term 1 {
 then {
 load-balance per-packet;
 }
}
```

Verify the underlay BGP group configuration.

```
user@core-1> show configuration protocols bgp
group underlay {
 type external;
 advertise-peer-as;
 family inet {
 unicast {
 loops 2;
 }
 }
 export lo0;
 peer-as 65401;
 multipath;
 neighbor 10.0.0.1 {
 description spine-1;
 }
 neighbor 10.0.0.3 {
 description spine-2;
 }
}
```

Verify that the loopback address is properly configured.

```
user@core-1> show configuration policy-options policy-statement lo0
from {
 family inet;
 protocol direct;
 route-filter 0.0.0.0/0 prefix-length-range /32-/32;
}
then accept;
```

Verify that the routing instances are properly configured.

```
user@core-1> show configuration routing-instances

---

### Verifying Core-2 Configuration

**Purpose** Verify that Core-2 is properly configured.

**Action** Verify that the routing options are properly configured.

```
user@core-2> show configuration routing-options
router-id 10.255.255.1;
autonomous-system 65400;
forwarding-table {
 export load-balance;
 ecmp-fast-reroute;
}
```

Verify that the load-balance policy statement is properly configured.

```
user@core-2> show configuration policy-options policy-statement load-balance
term 1 {
 then {
 load-balance per-packet;
 }
}
```

Verify the underlay BGP group configuration.

```
user@core-2> show configuration protocols bgp
group underlay {
 type external;
 advertise-peer-as;
 family inet {
 unicast {
 loops 2;
 }
 }
 export lo0;
 peer-as 65401;
 multipath;
 neighbor 10.0.0.5 {
 description spine-1;
 }
 neighbor 10.0.0.7 {
 description spine-2;
 }
}
```

Verify that the loopback address is properly configured.

```
user@core-2> show configuration policy-options policy-statement lo0
from {
 family inet;
 protocol direct;
 route-filter 0.0.0.0/0 prefix-length-range /32-/32;
}
then accept;
```

Verify that the routing instances are properly configured.

```
user@core-2> show configuration routing-instances
VRF_Tenant_A {

 multihop {
 ttl 255;
 }
}

```

### Verifying MAC Reachability to a Single-Homed CE Device (Leaf-1)

**Purpose** Verify MAC reachability to Tenant\_C single-homed to Leaf-1. First you need to verify that the MAC address is learned locally on Leaf-1. Leaf-1 generates the Type-2 route only after it has learned the MAC address.

**Action** Verify that the MAC address is learned locally on Leaf-1.

```
lab@leaf-1> show ethernet-switching table vlan-id 300
```

MAC flags (S - static MAC, D - dynamic MAC, L - locally learned, P - Persistent static  
SE - statistics enabled, NM - non configured MAC, R - remote PE MAC,  
O - ovsdb MAC)

Ethernet switching table : 5 entries, 5 learned

Routing instance : default-switch

| Vlan                          | MAC               | MAC   | Logical     | Active |
|-------------------------------|-------------------|-------|-------------|--------|
| name                          | address           | flags | interface   | source |
| v300                          | 00:00:5e:00:01:01 | DR    | esi.1726    |        |
| 05:00:00:ff:78:00:00:05:14:00 |                   |       |             |        |
| v300                          | 00:21:59:c8:24:65 | D     | xe-0/0/34.0 |        |
| v300                          | 00:21:59:c8:24:69 | D     | vtep.32771  |        |
| 10.255.255.5                  |                   |       |             |        |
| v300                          | 40:a6:77:9a:43:f0 | D     | vtep.32769  |        |
| 10.255.255.0                  |                   |       |             |        |
| v300                          | 40:a6:77:9a:47:f0 | D     | vtep.32770  |        |
| 10.255.255.1                  |                   |       |             |        |

**Meaning** The output shows that MAC 00:21:59:c8:24:65 is successfully learned towards the Tenant\_C CE device on xe-0/0/34.0, and from the output below, we can see that we generate the Type-2 route to Core-1.

## Verifying MAC Reachability to a Single-Homed CE Device (Type-2)

**Purpose** Verify MAC reachability to a single-homed CE device (Type-2)

**Action** Verify the generation of the Type-2 route to Core-1.

```
lab@leaf-1> show route advertising-protocol bgp 10.255.255.0 evpn-mac-address
00:21:59:c8:24:65

bgp.evpn.0: 77 destinations, 77 routes (77 active, 0 holddown, 0 hidden)
 Prefix Nexthop MED Lclpref AS path
 2:192.0.2.0:1::1300::00:21:59:c8:24:65/304
 * Self I
 2:192.0.2.0:1::1400::00:21:59:c8:24:65/304
 * Self I

default-switch.evpn.0: 67 destinations, 67 routes (67 active, 0 holddown, 0 hidden)

 Prefix Nexthop MED Lclpref AS path
 2:192.0.2.0:1::1300::00:21:59:c8:24:65/304
 * Self I
 2:192.0.2.0:1::1400::00:21:59:c8:24:65/304
 * Self I

__default_evpn__.evpn.0: 6 destinations, 6 routes (6 active, 0 holddown, 0 hidden)
```

**Meaning** The output shows that the same MAC address is advertised twice, with two different route targets. On xe-0/0/34, Tenant\_C and Tenant\_D are on the same physical server, running on different virtual machines. Tenant isolation is preserved by advertising these MACs on different VNIs and RTs.

On Core-1, the Type-2 route is received into bgp.evpn.0.

```
lab@core-1> show route receive-protocol bgp 192.0.2.0 evpn-mac-address
00:21:59:c8:24:65 extensive table bgp.evpn.0

[output omitted]
* 2:192.0.2.0:1::1300::00:21:59:c8:24:65/304 (2 entries, 0 announced)
 Import Accepted
 Route Distinguisher: 192.0.2.0:1
 Nexthop: 192.0.2.0
 AS path: 65402 I
 Communities: target:1:300 encapsulation0:0:0:0:vxlan

* 2:192.0.2.0:1::1400::00:21:59:c8:24:65/304 (2 entries, 0 announced)
 Import Accepted
 Route Distinguisher: 192.0.2.0:1
 Nexthop: 192.0.2.0
 AS path: 65402 I
 Communities: target:1:400 encapsulation0:0:0:0:vxlan
```

The output shows two Type-2 routes for 00:21:59:c8:24:65, but with different route targets. The route distinguisher is from Leaf-1, set as 192.0.2.0:1.

### Verifying the Imported Route

**Purpose** Verify that the Type-2 route is imported.

**Action** On Core-1, verify whether this Type-2 route is successfully imported from the bgp.evpn.0 table into the EVPN switch instance.

**Meaning** The output shows that, in Tenant\_C's virtual switch, the Type-2 route is advertised with the correct target, target:1:1300.

```
lab@core-1> show route table VS_VLAN300.evpn.0 evpn-mac-address 00:21:59:c8:24:65
| grep 00:21:59:c8:24:65
2:192.0.2.0:1::1300::00:21:59:c8:24:65/304
```

You can use the **extensive** option to review the Type-2 route in greater detail.

```
lab@core-1> show route table VS_VLAN300.evpn.0 evpn-mac-address 00:21:59:c8:24:65
extensive
```

[output omitted]

```

 Nexthop: 10.0.0.1 via ge-1/0/0.0

```

The output shows that Core-1 receives two copies. The first is the direct advertisement from Leaf-1 (Source: 192.0.2.0). The second is the indirect advertisement from Leaf-1 -> Leaf-2 -> Core-1 (Source: 10.255.255.5). Because we configured **no-nexthop-change** on Leaf-2, the protocol next hop of 192.0.2.0 is correct.

### Verifying the Layer 2 Address Learning Daemon Copy

- |                |                                                                                                          |
|----------------|----------------------------------------------------------------------------------------------------------|
| <b>Purpose</b> | Verify the Layer 2 address learning daemon copy.                                                         |
| <b>Action</b>  | Verify the Layer 2 address learning daemon copy by entering the <b>show bridge-mac table</b> command.    |
| <b>Meaning</b> | The output shows that 00:21:59:c8:24:65 is reachable through the vtep.32774 logical interface to Leaf-1. |

```
lab@core-1> show bridge mac-table instance VS_VLAN300
```

```

```

### Verifying the Kernel-Level Forwarding Table

- Purpose** Verify the kernel-level forwarding table, next hop identifier, and Layer 2 MAC table and hardware.
- Action** Query the kernel-level forwarding table, correlate the index next hop identifier with the correct virtual network identifier, and review the Layer 2 MAC table and hardware.
- Meaning** Tenant\_C's MAC, 00:21:59:c8:24:65, is reachable through index 699.

```

lab@core-1> show route forwarding-table family bridge vpn VS_VLAN300
Routing table: VS_VLAN300.evpn-vxlan

```

**Meaning** For the Tenant\_B CE device, four different routes are listed for ESI 00:02:02:02:02:02:02:02:02.

- 1:192.0.2.0:0::0202020202020202::FFFF:FFFF/304

This per-Ethernet Segment A-D Type-1 EVPN route originated from Leaf-1. The route distinguisher is taken from global-level **routing-options**. Core-1 receives this Type-1 route, originated from Leaf-1, from both Leaf-1 and Leaf-2.

- 1:192.0.2.0:1::0202020202020202::0/304

This is the per-EVI A-D Type-1 EVPN route. The route distinguisher is taken from the routing instance, or in the case of QFX5100, **switch-options**. Core-1 receives this Type-1 route, originated from Leaf-1, from both Leaf-1 and Leaf-2.

- 1:10.255.255.5:0::0202020202020202::FFFF:FFFF/304

This is the per-Ethernet Segment A-D Type-1 EVPN route originated from Leaf-2. The route distinguisher is taken from global-level **routing-options**. Core-1 receives this Type-1 route, originated from Leaf-2, from both Leaf-2 and Leaf-1.

- 1:10.255.255.5:1::0202020202020202::0/304

This is the per-EVI A-D Type-1 EVPN route. The route distinguisher is taken from the routing instance, or in the case of QFX5100, **switch-options**. Core-1 receives this Type-1 route, originated from Leaf-2, from both Leaf-2 and Leaf-1.

Type-2 routes for the two physical and one virtual MAC belonging to the Tenant\_B CE device originated as expected.

From the output we cannot yet determine what VTEPs are being used to forward to ESI 00:02:02:02:02:02:02:02:02. To determine the VTEPS, list the VXLAN tunnel endpoint ESIs.

```
lab@core-1> show l2-learning vxlan-tunnel-end-point esi
```

```

ESI RTT VLN BH INH ESI-IFL
LOC-IFL #RVTEPs
00:01:01:01:01:01:01:01:01 VS_VLAN200 704 1048580 esi.704
 2
 RVTEP-IP RVTEP-IFL VENH MASK-ID FLAGS
 10.255.255.5 vtep.32778 720 1 2
 192.0.2.0 vtep.32774 702 0 2
[output omitted]

```

The output shows active load-balancing on the VTEP interfaces to both Leaf-1 and Leaf-2 for MACs on this ESI, which validates the all-active configuration on Leaf-1 and Leaf-2.

The reference to esi.703 might be confusing. This is an internal unilist next hop that comprises multiple, valid, individual ECMP next hops. You can correlate these individual next hops to the unilist by executing this shell level command:

```
lab@core-1> start shell command "nhinfo -di 703"
[output omitted]
NHs in list: 720, 702,
[output omitted]
```

From the output we can reference index 720 with vtep.32778 to Leaf-2 and index 702 with vtep.32774 to Leaf-1.

### Verifying an EVPN Anycast Gateway

**Purpose** Verifying the EVPN anycast gateway is similar to the multihomed CE device scenario. For this example, verify from the leaf (QFX5100) perspective.

**Action** For this example, verify the anycast gateway on both Core-1 and Core-2 for VNI 1100 (Vlan 100 on both Leaf-1 and Leaf-2).

```

```

**Meaning** The output shows that Leaf-1 receives Type-1 advertisements for the autogenerated ESI's for the anycast gateway. The outputs also show the anycast and physical MACs (a.b.c.2) for each bridge domain.

Two unique advertisements are received for this ESI. One from Core-1, and the other from Core-2, with corresponding route distinguishers. Because Leaf-1 is iBGP peered with Leaf-2, the extra copy for each route from Leaf-2 displays with the original protocol-next hop preserved.

Leaf-1's Layer 2 address learning daemon table displays:

```
lab@leaf-1> show ethernet-switching table vlan-id 100
```

```

MAC flags (S - static MAC, D - dynamic MAC, L - locally learned, P - Persistent
static
 SE - statistics enabled, NM - non configured MAC, R - remote PE MAC,
O - ovsdb MAC)

```

Ethernet switching table : 5 entries, 5 learned

Routing instance : default-switch

| Vlan                          | MAC               | MAC   | Logical    | Active |

## PIM NSR and Unified ISSU Support for VXLAN Overview

---

Starting in Junos OS Release 16.2R1, Protocol Independent Multicast (PIM) nonstop active routing (NSR) support for Virtual Extensible LAN (VXLAN) is supported on MX Series routers.

The Layer 2 address learning daemon (l2ald) passes VXLAN parameters (VXLAN multicast group addresses and the source interface for a VXLAN tunnel [**vtep-source-interface**]) to the routing protocol process on the master Routing Engine. The routing protocol process forms PIM joins with the multicast routes through the pseudo-VXLAN interface based on these configuration details.

Because the l2ald daemon does not run on the backup Routing Engine, the configured parameters are not available to the routing protocol process in the backup Routing Engine when NSR is enabled. The PIM NSR mirroring mechanism provides the VXLAN configuration details to the backup Routing Engine, which enables creation of the required states. The routing protocol process matches the multicast routes on the backup Routing Engine with PIM states, which maintains the multicast routes in the Forwarding state.

In response to Routing Engine switchover, the multicast routes remain in the Forwarding state on the new master Routing Engine. This prevents traffic loss during Routing Engine switchover. When the l2ald process becomes active, it refreshes VXLAN configuration parameters to PIM.

**NOTE:** For this feature, NSR support is available for VXLAN in PIM sparse mode.

---

This feature does not introduce any new CLI commands. You can issue the following **show** commands on the backup Routing Engine to monitor the PIM joins and multicast routes on the backup Routing Engine:

- **show pim join extensive**
- **show multicast route extensive**

### Unified ISSU Support

Starting in Junos OS Release 17.2 R1, unified in-service software upgrade is supported for VXLAN using PIM on MX Series routers. ISSU enables you to upgrade your Junos OS software on your MX Series router with no disruption on the control plane and with minimal disruption of traffic. Unified ISSU is supported only on dual Routing Engine platforms. The graceful Routing Engine switchover (GRES) and nonstop active routing (NSR) features must both be enabled. Unified ISSU allows you to eliminate network downtime, reduce operating costs, and deliver higher levels of services. See *Getting Started with Unified In-Service Software Upgrade*.

**NOTE:** Unified ISSU is not supported on the QFX series switches.

---

To enable GRES, include the **graceful-switchover** statement at the **[edit chassis redundancy]** hierarchy level.

To enable NSR, include the **nonstop-routing** statement at the **[edit routing-options]** hierarchy level and the **commit synchronize** statement at the **[edit system]** hierarchy level.

**Release History Table**

## VXLAN Data Center Interconnect Using EVPN Overview

---

Starting in Junos OS Release 16.1, Ethernet VPN (EVPN) technology can be used to interconnect Virtual Extensible Local Area Network (VXLAN) networks over an MPLS/IP network to provide data center connectivity. This is done through Layer 2 intra-subnet connectivity and control-plane separation among the interconnected VXLAN networks.

The following sections describe the technology and implementation overview of integrating EVPN with VXLAN to be used as a data center interconnect (DCI) solution.

- [Technology Overview of VXLAN-EVPN Integration for DCI on page 611](#)
- [Implementation Overview of VXLAN-EVPN Integration for DCI on page 622](#)
- [Supported and Unsupported Features for VXLAN DCI Using EVPN on page 625](#)

## Technology Overview of VXLAN-EVPN Integration for DCI

The following sections provide a conceptual overview of VXLAN, EVPN, the need for their integration for DCI and the resulting benefits.

- [Understanding VXLAN on page 611](#)
- [Understanding EVPN on page 613](#)
- [VXLAN-EVPN Integration Overview on page 614](#)
- [VXLAN-EVPN Packet Format on page 616](#)
- [VXLAN-EVPN Packet Walkthrough on page 616](#)

### Understanding VXLAN

---

Virtual Extensible Local Area Network (VXLAN) is a Layer 3 encapsulation protocol that enables MX Series routers to push Layer 2 or Layer 3 packets through a VXLAN tunnel to a virtualized data center or the Internet. Communication is established between two virtual tunnel endpoints (VTEPs), which can be end hosts or network switches or routers,

that encapsulate and de-encapsulate the virtual machine (VM) traffic into a VXLAN header.

VXLAN is often described as an overlay technology because it allows you to stretch Layer 2 connections over an intervening Layer 3 network by encapsulating (tunneling) Ethernet frames in a VXLAN packet that includes IP addresses. This feature of VXLAN addresses the requirements of a multi-tenant datacenter, where each tenant's VM might be sharing the physical server with other tenants that are distributed across physical servers within or across different data centers, by meeting the growing need to provide seamless Layer 2 connectivity between all the VMs owned by a tenant, in addition to isolating each tenant's traffic for security and potential MAC address overlaps.

VXLAN tunnels are created between the physical servers by the hypervisors. Since a physical server can be hosting multiple tenants, each hypervisor creates multiple VXLAN tunnels.

Figure 54: VXLAN Overview

VXLAN is a technology that allows you to segment your networks (as VLANs do) but that also solves the scaling limitation of VLANs and provides benefits that VLANs cannot. Some of the important benefits of using VXLANs include:

- You can theoretically create as many as 16 million VXLANs in an administrative domain (as opposed to 4094 VLANs on a Juniper Networks device).

MX Series routers support as many as 32K VXLANs. This means that VXLANs provide network segmentation at the scale required by cloud builders to support very large numbers of tenants.

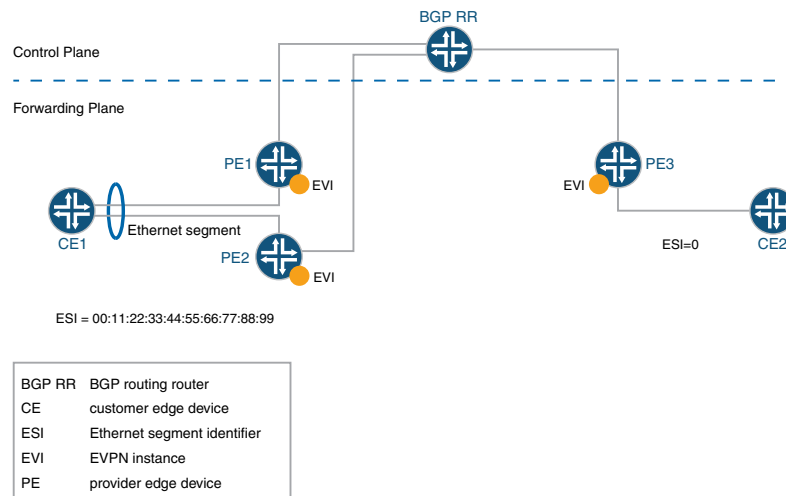

- You can enable migration of virtual machines between servers that exist in separate Layer 2 domains by tunneling the traffic over Layer 3 networks. This functionality allows you to dynamically allocate resources within or between data centers without being

constrained by Layer 2 boundaries or being forced to create large or geographically stretched Layer 2 domains.

### Understanding EVPN

EVPN is a new standards-based technology that provides virtual multi-point bridged connectivity between different Layer 2 domains over an IP or IP/MPLS backbone network. Similar to other VPN technologies, such as IPVPN and VPLS, EVPN instances (EVI) are configured on PE routers to maintain logical service separation between customers. The PEs connect to CE devices which can be a router, switch, or host. The PE routers then exchange reachability information using Multi-Protocol BGP (MP-BGP) and encapsulated traffic is forwarded between PEs. Because elements of the architecture are common with other VPN technologies, EVPN can be seamlessly introduced and integrated into existing service environments.

Figure 55: EVPN Overview

The EVPN technology provides mechanisms for next generation Data Center Interconnect (DCI) by adding extended control plane procedures to exchange the Layer 2 (MAC address) and Layer 3 (IP address) information among the participating Data Center Border Routers (DCBRs). These features help in addressing some of the DCI challenges, such as seamless VM mobility and optimal IP routing. Seamless VM mobility refers to the challenge of Layer 2 extension and maintaining connectivity in the face of VM mobility, and optimal IP routing refers to the challenge of supporting default gateway behavior for a VM's outbound traffic and triangular routing avoidance of a VM's inbound traffic.

The EVPN technology is used by the data center operator to offer multi-tenancy, flexible and resilient services that can be extended on demand. This flexibility and resiliency can require using compute resources among different physical data centers for a single service (Layer 2 extension), and VM motion.

EVPN supports all-active multihoming which allows a CE device to connect to two or more PE routers such that traffic is forwarded using all of the links between the devices. This enables the CE to load balance traffic to the multiple PE routers. More importantly

it allows a remote PE to load balance traffic to the multihomed PEs across the core network. This load balancing of traffic flows between data centers is known as aliasing. EVPN also has mechanisms that prevent the looping of broadcast, unknown unicast, and multicast (BUM) traffic in an all-active multi-homed topology.

Multihoming provides redundancy in the event that an access link or one of the PE routers fails. In either case traffic flows from the CE towards the PE use the remaining active links. For traffic in the other direction, the remote PE updates its forwarding table to send traffic to the remaining active PEs connected to the multihomed Ethernet segment. EVPN provides a fast convergence mechanism so that the time it takes to make this adjustment is independent of the number of MAC addresses learned by the PE.

EVPN's MP-BGP control plane allows live virtual machines to be dynamically moved from one data center to another, also known as VM motion. After a VM is moved to a destination server/hypervisor it transmits a Gratuitous ARP which updates the Layer 2 forwarding table of the PE at the destination data center. The PE then transmits a MAC route update to all remote PEs which in turn update their forwarding tables. In this manner, an EVPN tracks the movement of the VM, also known as MAC Mobility. EVPN also has mechanisms to detect and stop MAC flapping.

The EVPN technology, similar to Layer 3 MPLS VPN, is a technology that introduces the concept of routing MAC addresses using MP-BGP over MPLS core. Some of the important benefits of using EVPNs include:

- Ability to have a dual active multihomed edge device.
- Provides load balancing across dual-active links.
- Provides MAC address mobility.
- Provides multi-tenancy.
- Provides aliasing.
- Enables fast convergence.

---

### VXLAN-EVPN Integration Overview

---

VXLAN defines a tunneling scheme to overlay Layer 2 networks on top of Layer 3 networks. It allows for optimal forwarding of Ethernet frames with support for multipathing of unicast and multicast traffic with the use of UDP/IP encapsulation for tunneling, and is mainly used for the intra-datacenter site connectivity.

On the other hand, a unique characteristic of EVPN is that MAC address learning between PE devices occurs in the control plane. A new MAC address detected from a CE device is advertised by the local PE, using MP-BGP, to all the remote PE devices. This method differs from existing Layer 2 VPN solutions such as VPLS, which learn by flooding unknown unicast in the data plane. This control plane based MAC learning method is the key enabler of the many useful features provided by EVPN.

Because MAC learning is handled in the control plane, this leaves EVPN with the flexibility to support different data plane encapsulation technologies between PEs. This is important

because not every backbone network may be running MPLS, especially in Enterprise networks.

There is a lot of interest in EVPN today because it addresses many of the challenges faced by network operators that are building data centers to offer cloud and virtualization services. The main application of EVPN is Data Center Interconnect (DCI), the ability to extend Layer 2 connectivity between different data centers which are deployed to improve the performance of delivering application traffic to end users and for disaster recovery.

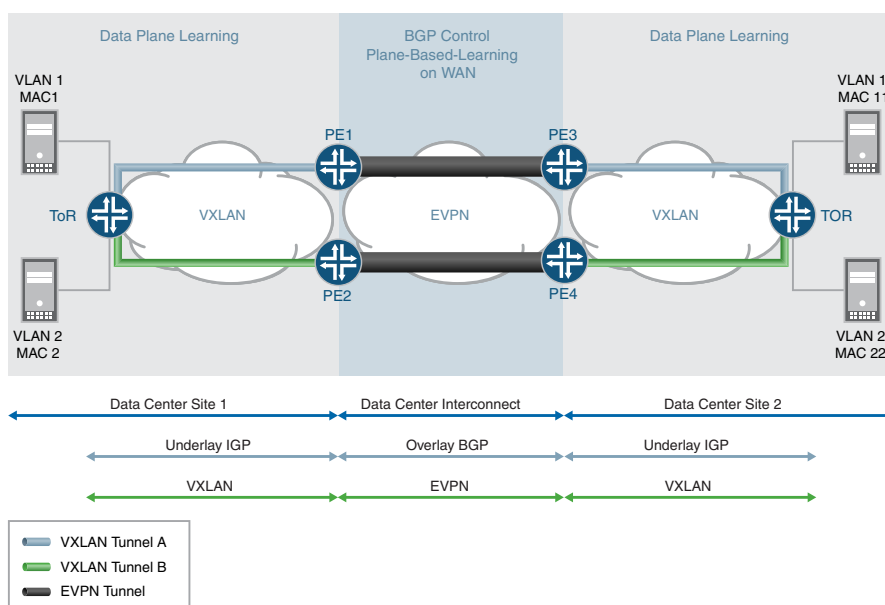

Although there are various DCI technologies available, EVPN has an added advantage over the other MPLS technologies because of its unique features, such as active-active redundancy, aliasing, and mass MAC withdrawal. As a result, to provide a solution for DCI, VXLAN is integrated with EVPN.

Every VXLAN network, which is connected to the MPLS or IP core, runs an independent instance of the IGP control plane. Each PE device participates in the IGP control plane instance of its VXLAN network. Here, each customer is a datacenter so it has its own virtual router for VXLAN underlay.

Each PE node may terminate the VXLAN data plane encapsulation where each VNI or VSID is mapped to a bridge domain. The PE router performs data plane learning on the traffic received from the VXLAN network.

Each PE node implements EVPN to distribute the client MAC addresses learnt over the VXLAN tunnel into BGP. Each PE node encapsulates the VXLAN or Ethernet frames with MPLS when sending the packets over the MPLS core and with the VXLAN tunnel header when sending the packets over the VXLAN network.

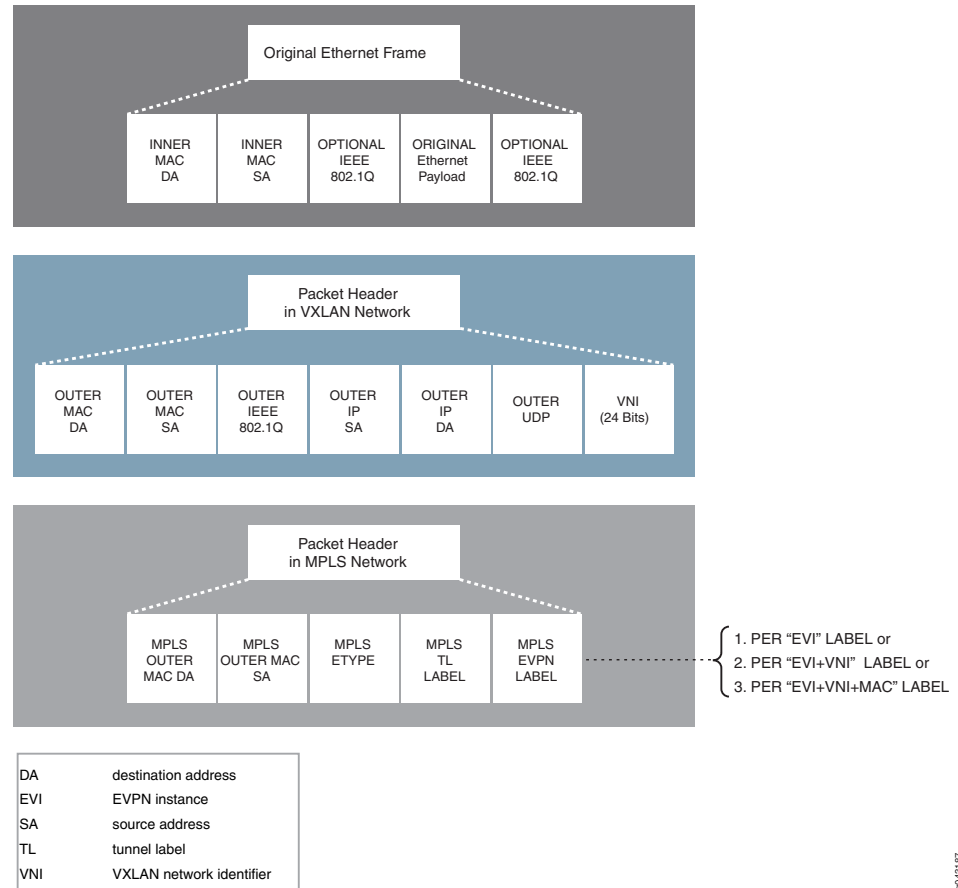

**Figure 56: VXLAN-EVPN Integration Overview**

## VXLAN-EVPN Packet Format

The VXLAN and EVPN packet format is as follows:

Figure 57: VXLAN-EVPN Packet Format

## VXLAN-EVPN Packet Walkthrough

The following sections describe the packet walkthrough for two types of traffic between the VXLAN and EVPN networks:

- [BUM Traffic Handling on page 617](#)
- [Unicast Traffic Handling on page 619](#)

**BUM Traffic Handling****Figure 58: VXLAN-EVPN BUM Traffic Handling**

The VXLAN to EVPN BUM traffic from VXLAN segment1 to VXLAN segment2 over the EVPN cloud is handled as follows:

1. **0**—On boot up, Server A wants to send traffic to Server B. Because Server A does not have an ARP binding for Server B in its ARP table, Server A builds an ARP broadcast request and sends it. and for ARP.

The contents of the ARP packets are as follows:

- VLAN ID = VLAN 10
- Source MAC= MACA (server A interface MAC)
- Destination MAC = ff.ff.ff.ff.ff
- Source IP address = IP address of Server A or VM IP address
- Destination IP address = IP address of Server B
- Ether type of packet = 0x0806

A Layer 2 frame is sent to top-of-rack (TOR) switch TOR A, which is VXLAN enabled.

2. **1**—The ARP request (broadcast) frame is received by switch TOR A. TOR A switch is the originator and terminator of the VXLAN VTEP for VNI 1000. The VTEP for VXLAN 1000 is part of the broadcast domain for Server A VLAN 100.

After receiving the frame, ingress processing that includes the ingress packet classification is performed by switch TOR A does. Based on the incoming VLAN in the packet, the packet gets classified into one of the IFL under a given port. The family of

this IFL is a bridge family. Based on the IFL bridge family, the bridge domain ID is identified.

After the bridge domain identification, the incoming frame source MAC is learned such that MAC A is reachable through this IFL. Because the frame is a broadcast frame, the frame needs to be sent over to all the members of the broadcast domain (other than the member on which the frame was received). One of the members is the VTEP for VNI 1000. For sending the frame on VXLAN segment, VXLAN BUM next hop processing on the frame is done. The next hop pushes VXLAN header.

The contents of the VXLAN header is as follows:

- Source MAC Address = MAC Address or source IP address interface
- Destination MAC address = Multicast MAC address
- Source IP address = 10.10.10.1
- Destination IP Address = Multicast group address (226.0.39.16)
- Source UDP port = Calculated based on the hash on the incoming frame header
- Destination UDP port = 4789 (well known port for VXLAN tunnel)

After building the VXLAN encapsulated frame, the frame is sent to Router PE2.

3. **2**—Router PE2 receives the VXLAN frame and identifies the frame as a VXLAN frame by looking at the well-known destination UDP port. This VXLAN frame's VNI ID is used for bridge domain identification. After the bridge domain is identified, MAC learning is done for the inner source MAC to the outer source IP address (MACA to 10.10.10.1 mapping). After the mapping is done, the VXLAN header is removed by VDNH.
4. **3A**—After MAC learning is done, the learnt source MAC (MAC1 to outer source IP) is sent to the L2ALD. This MAC route is sent by L2ALD to RPD for control plane learning of this MAC through BGP MAC route advertisement to BGP peers. After the BGP peer routers receive the MAC route advertisement, the routers install this MAC reachability (MACA, MPLS LABEL L1) in the bridge-domain table.
5. **3**—The given bridge domain points to the multicast next hop route for forwarding the packet over the EVPN cloud. This next hop pushes the service label (multicast MPLS label associated with VNI per peer ID, bridge domain, label is the per peer ID and VNI id). The MPLS packet is formed and sent over the MPLS cloud.
6. **4**—The frame is received by Router PE4 as an MPLS packet. Here the bridge domain identification is done by doing the MPLS label L1 lookup in the mpls.0 table. MPLS lookup points to the table next hop for the bridge domain next hop. After the bridge domain is identified and the packet is identified as a broadcast packet, the BUM composite flood next hop is executed. The BUM composite next hop also points to the VXLAN next hop (that is used for building the VXLAN multicast packet).
7. **5**—The VXLAN next hop contains information for building the VXLAN header.

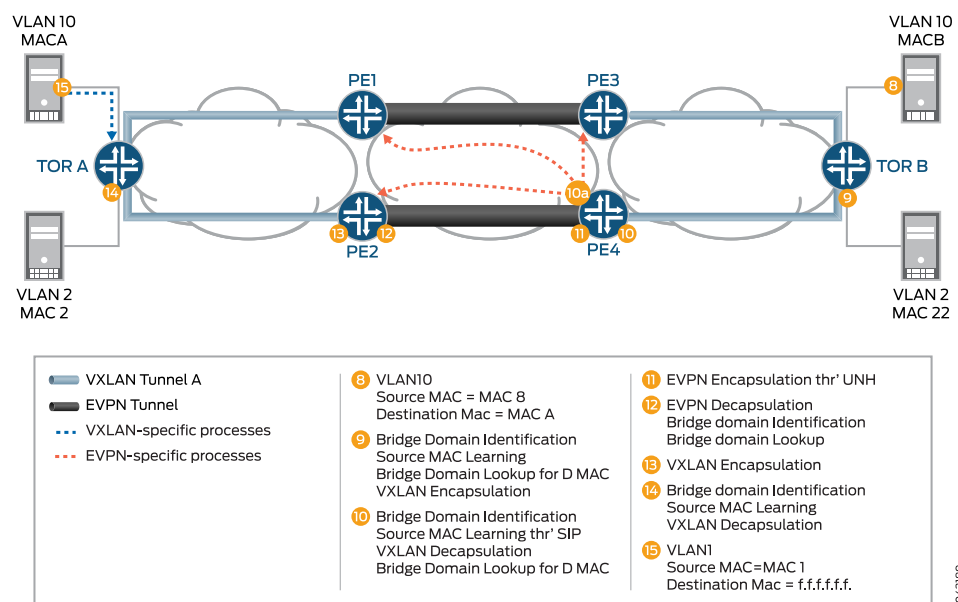

The VXLAN header information is as follows:

- Source MAC Address = MAC Address or the source IP address interface
  - Destination MAC address = Multicast MAC Address
  - Source IP address = 11.10.10.1
  - Destination IP Address = Multicast group address (226.0.39.16)
  - Source UDP port = Calculated based on the hash on the incoming frame header
  - Destination UDP port = 4789 (well known port for the VXLAN tunnel)
8. **6**—Frame handling for this step is same as step 1. After the VXLAN header is removed, the frame is forwarded to the CE flood route associated with the broadcast domain, and the packet is forwarded as a Layer 2 frame.
9. **7**—Server B receives an ARP request packet and sends an ARP reply to Server A.

### Unicast Traffic Handling

Figure 59: VXLAN-EVPN Unicast Traffic Handling

Assuming that both data and control plane MAC learning has already happened, the VXLAN to EVPN unicast traffic (ARP reply) from Server B is handled as follows:

1. **8**—Server B generates an ARP reply.

The contents of the ARP packets are as follows:

- VLAN ID = VLAN 10
- Source MAC = MACB (Server B interface MAC)
- Destination MAC = MACA
- Source IP address = IP address of Server B or VM IP address
- Destination IP address = IP address of Server A

The ARP packet is forwarded to switch TOR B.

2. **9**—After receiving the frame, the classification of the incoming frame is done by switch TOR B. The frame is classified in an IFL on the received interface. Based on the IFL family, bridge domain associated with IFL is identified. On the given bridge domain, the source MAC address learning is done. Now the bridge domain destination MAC (MACA) look up is done and this look up provides the VXLAN unicast next hop. This next hop contains all the information about forming the VXLAN header.

The content of the next hop that is required to form the packet is as follows:

- Source MAC Address = MAC Address of source IP address interface
- Destination MAC address = MAC address of the next hop
- Source IP address = 11.10.10.2
- Destination IP Address = 11.10.10.1 (as a result of the MAC learning process)
- Source UDP port = Calculated based on the hash on the incoming frame header
- Destination UDP port = 4789 (well known port for the VXLAN tunnel)

**NOTE:** Earlier version of the VXLAN draft was using 8472 as UDP port.

---

3. **10**—The VXLAN encapsulated frame is received by Router PE4. At PE4, the frame is identified by doing the lookup using the destination IP address and the destination UDP port. This lookup results in the VXLAN decapsulation. The decapsulation next hop also stores the outer source IP address.

The next lookup is done based on the VNI ID 1000. This lookup results into the bridge domain table.

4. **10A**—Source MAC to source IP address learning is done and the MAC learning notification is received by L2ALD. This MAC is sent to RPD for distribution to other PE routers through BGP-EVPN MAC advertisement route. BGP control plane distributes this MAC reachability information to all other PE routers.

The destination MAC (MAC1) lookup is done in the bridge domain MAC address table. This lookup results into an unicast next hop (EVPN NH).

5. **11**—EVPN unicast nexthop is executed here. This next hop contains an unicast MPLS service label. This label is distributed through MP-BGP control plane. The downstream peer allocates this MPLS service label. Allocation of this label can be per PE (PE, VLAN) or per MAC address basis. Based on the information in the next hop, MPLS packet is formed and forwarded on the MPLS network.

6. **12**—Router PE2 receives the frame. The frame is identified as an MPLS packet. An MPLS label lookup is done in the MPLS.0 table. This lookup results in the table next hop and in the bridge domain table.

The destination MAC (MAC1) lookup is done in the bridge domain MAC table. This lookup results in a VXLAN unicast next hop.

7. **13**—VXLAN unicast next hop contain all the information for building the VXLAN encapsulated header. The VXLAN header is imposed on the packet.

The contents of the VXLAN encapsulation next hop header are as follows:

- Source MAC Address = MAC Address of source IP address interface
- Destination MAC address = MAC address of the next hop
- Source IP address = 10.10.10.2
- Destination IP Address = 10.10.10.1 (as a result of the MAC learning process)
- Source UDP port = Calculated based on the hash on the incoming frame header
- Destination UDP port = 4789 (well known port for the VXLAN tunnel)

8. **14**—The VXLAN encapsulated frame is received by switch TOR A. At TOR A, the frame is identified by doing the lookup using the destination IP address and the destination UDP port. This lookup results in the VXLAN decapsulation. The decapsulated next hop also stores the outer source IP address.

The next lookup is done based on the VNI ID 1000. This lookup results into the bridge domain table. The source MAC (MAC2) to source IP address (10.10.10.2) learning is done. The destination MAC (MAC1) lookup is done in the bridge domain MAC address table. This lookup results into an unicast next hop that has the information about the egress interface.

9. **15**—The ARP reply is received by Server A, and Server A and Server B are ready to communicate.

## Implementation Overview of VXLAN-EVPN Integration for DCI

The following sections provide use case scenarios for VXLAN-EVPN integration for DCI.

- [VNI Base Service Use Case on page 622](#)
- [VNI Aware Service Use Case on page 622](#)
- [VXLAN-VLAN Interworking Use Case on page 623](#)
- [Inter VXLAN Routing Use Case on page 624](#)
- [Redundancy Use Case on page 625](#)

### VNI Base Service Use Case

In the case of the VNI base service, there is one-to-one mapping between a VNI and an EVI. In this case, there is no need to carry the VNI in the MAC advertisement route because the bridge domain ID can be derived from the route-target (RT) associated with this route. The MPLS label allocation is done per EVI basis.

[Figure 60 on page 622](#) provides an overview for VNI base use case scenarios. The VNI base service is used most commonly for achieving the VNI translation and VNI to VLAN interworking.

**Figure 60: VNI Base Service**

### VNI Aware Service Use Case

In the case of VNI aware bundle mode, there are multiple VNIs that can be mapped to the same EVI. The Ethernet tag ID must be set to the VNI ID in the BGP routes advertisements. The MPLS label allocation in this use case should be done per EVI, VNI basis so that the VXLAN can be terminated at the ingress PE router and recreated at the egress PE router.

[Figure 61 on page 623](#) provides details about the VNI aware service used case.

Figure 61: VNI Aware Service

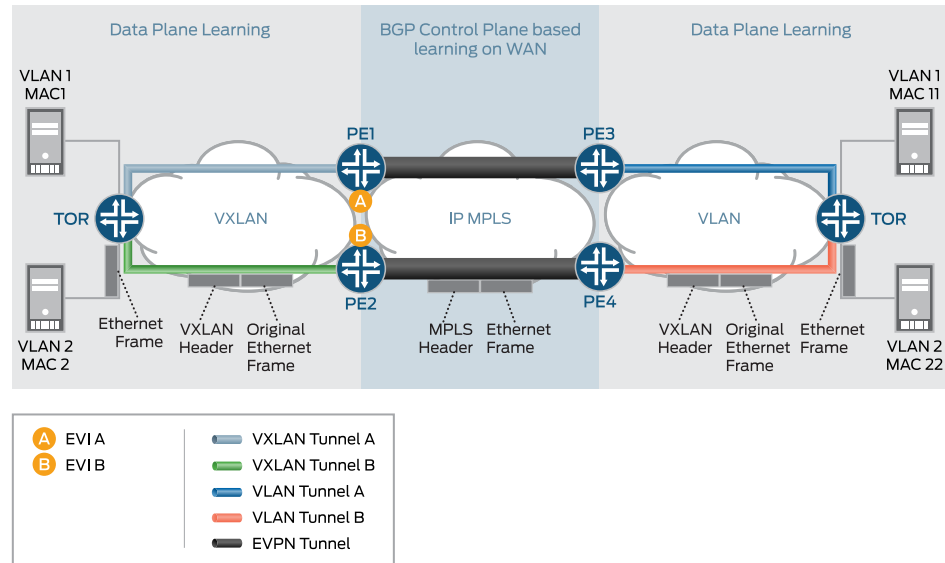

### VXLAN-VLAN Interworking Use Case

This use case scenario is required for heterogeneous datacenter sites. In this scenario, the new data center site is a VXLAN-based datacenter site, and the old datacenter sites are based on VLAN. In this scenario, there is a need to have VXLAN interworking with VLAN over EVPN.

Figure 62 on page 624 provides the detail packet walkthrough for the VXLAN-VLAN interworking use case scenario. There is a need to do the VLAN to VXLAN interworking and vice-versa from the control plane BGP route updates perspective. The label allocation needs to be done on a per EVI-basis.

Figure 62: VXLAN-VLAN Interworking

8043194

### Inter VXLAN Routing Use Case

In this use case, a VM or host in one subnet (VNI-A) want to send traffic to a VM or host in a different subnet (VNI-B). In order to provide this communication, the inter VXLAN routing should be supported.

Figure 63 on page 624 provides the use case scenarios for the inter VXLAN routing use case.

Figure 63: Inter-VXLAN Routing

8043195

## Redundancy Use Case

The two types of redundancy use case scenarios include:

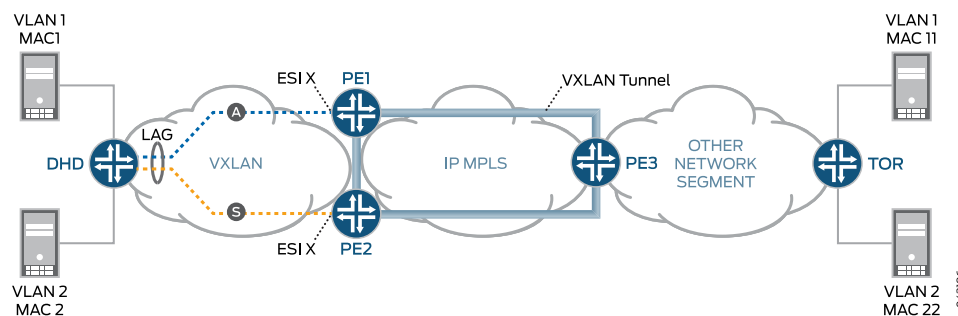

- [Active-Standby Redundancy Use Case on page 625](#)

### Active-Standby Redundancy Use Case

In this use case scenario, the TOR switch (VXLAN originating GW) or the VXLAN network originating the VXLAN tunnel, is dual homed to two PE devices for active-standby redundancy. If the active link or node fails, then a backup path takes over.

[Figure 64 on page 625](#) provides details of the active-standby redundancy use case scenario.

**Figure 64: Active-Standby Redundancy**

## Supported and Unsupported Features for VXLAN DCI Using EVPN

Junos OS supports the following features for VXLAN DCI using EVPN:

- One-to-one mapping of VXLAN tunnel and an EVPN instance. In other words, one-to-one mapping between a VNI and an EVI.
- Many-to-one mapping of VXLAN tunnels over one EVPN instance, where multiple VNIs can be mapped to the same EVI.
- VNI Translation

**NOTE:** VNI translation is supported by normalizing a VXLAN tag into a VLAN.

- VXLAN-to-VLAN interworking
- Inter-VXLAN routing
- Single active redundancy
- Active-active redundancy in the PIM BIDIR mode.
- VXLAN tunnel traffic protection using IPSec.

- Graceful Routing Engine switchover.
- ISSU

Junos OS does not support the following functionality for VXLAN DCI using EVPN:

- VXLAN uses IANA assigned UDP port 4789. Packets destined to the UDP port 4789 are processed only when the VXLAN configuration is enabled. The VXLAN packets are decapsulated by the forwarding plane and an inner Layer 2 packet is processed. MAC learnt packets are generated for the control plane processing for newly learnt MAC entries. These entries are throttled using existing infrastructure for MAC learning. VXLAN generates addition learn messages for the remote endpoints. These messages are also throttled using the existing infrastructure for the denial of service detection.
- Packets received on the VXLAN tunnel are processed only if the VXLAN identifier in the packet is a known entity to the device. Unknown entities are discarded by the forwarding plane.
- Using configurable firewall filters can be discarded before it reaches the VXLAN processing module in the forwarding plane of the MX series routers.
- Logical systems

**Release History Table**

| Release | Description                                                                                                                                                                                                       |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 16.1    | Starting in Junos OS Release 16.1, Ethernet VPN (EVPN) technology can be used to interconnect Virtual Extensible Local Area Network (VXLAN) networks over an MPLS/IP network to provide data center connectivity. |

## Example: Configuring VXLAN Data Center Interconnect Using EVPN

This example shows how to configure Virtual Extensible Local Area Network (VXLAN) data center connectivity using Ethernet VPN (EVPN) to leverage the benefits of EVPN as a data center interconnect (DCI) solution.

- [Requirements on page 626](#)
- [Overview on page 627](#)
- [Configuration on page 628](#)
- [Verification on page 636](#)

### Requirements

This example uses the following hardware and software components:

- Two provider edge (PE) devices in different data centers (DCs) acting as VXLAN tunnel endpoints (VTEPs).
- Two customer edge (CE) devices.
- Four host devices connected to each PE and CE device.

Before you begin:

- Configure the device interfaces.
- Configure an IGP, such as OSPF, on all the devices.
- Establish a BGP session between the PE devices.
- Configure MPLS and RSVP on the PE devices.
- Configure PIM on the CE devices and in the routing instance of the PE devices.

## Overview

VXLAN is a technology that provides intra data center connectivity using a tunneling scheme to stretch Layer 2 connections over an intervening Layer 3 network.

The Ethernet VPN (EVPN) technology, on the other hand, provides a solution for multipoint Layer 2 VPN services with advanced multihoming capabilities, using BGP control plane over MPLS/IP network.

Although several solutions are available for data center connectivity, the integration of EVPN with VXLAN in Junos OS Release 16.1 and later releases, provides an added advantage over the existing MPLS data center interconnect (DCI) technologies.

EVPN provides mechanisms for next generation DCI by adding extended control plane procedures to exchange Layer 2 MAC address and Layer 3 IP address information among the participating Data Center Border Routers (DCBRs). EVPN with its advanced features like active-active redundancy, aliasing, and mass MAC withdrawal helps in addressing the DCI challenges, such as seamless VM mobility and optimal IP routing, thus making it essential to provide VXLAN solutions over EVPN.

Figure 65 on page 627 illustrates VXLAN data center interconnect using EVPN between devices PE1 and PE2 that are located in different data centers (DC1 and DC2, respectively). Each PE device is connected to one CE device and one host. All the PE and CE devices are configured under VLAN 10, and with the same VXLAN Network Identifier (VNI) of 10. Devices CE1 and PE1 belong to the multicast group of 192.168.1.10, and devices CE2 and PE2 belong to the multicast group of 172.16.1.10.

## Topology

Figure 65: VXLAN Data Center Interconnect Using EVPN

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the [edit] hierarchy level, and then enter commit from configuration mode.

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure Device CE1:

**NOTE:** Repeat this procedure for Device CE2 after modifying the appropriate interface names, addresses, and other parameters.

1. Configure Device CE1 interfaces.

[edit interfaces]

```

user@CE1# set xe-0/0/0 vlan-tagging
user@CE1# set xe-0/0/0 encapsulation flexible-ethernet-services
user@CE1# set xe-0/0/0 unit 10 encapsulation vlan-bridge
user@CE1# set xe-0/0/0 unit 10 vlan-id 10

```

```

user@CE1# set ge-0/2/6 unit 0 family inet address 10.1.1.2/30
user@CE1# set ge-0/2/6 unit 0 family mpls

```

```

user@CE1# set lo0 unit 0 family inet address 10.255.181.43/32

```

2. Enable OSPF on Device CE1 interface, excluding the management interface.

[edit protocols]

```

user@CE1# set ospf area 0.0.0.0 interface ge-0/2/6.0
user@CE1# set ospf area 0.0.0.0 interface lo0.0 passive
user@CE1# set ospf area 0.0.0.0 interface fxp0.0 disable

```

3. Enable PIM on all the interfaces of Device CE1.

```
[edit protocols]
user@CE1# set pim rp local address 10.255.181.43
user@CE1# set pim interface all
```

4. Configure an EVPN bridge domain, and assign VLAN ID and interface.

```
[edit bridge-domains]
user@CE1# set evpn10 vlan-id 10
user@CE1# set evpn10 interface xe-0/0/0.10
```

5. Configure a VXLAN bridge domain, assign VXLAN ID, a multicast group address, and encapsulation and decapsulation parameters.

```
[edit bridge-domains]
user@CE1# set vxlan vni 10
user@CE1# set vxlan multicast-group 172.16.1.10
user@CE1# set vxlan encapsulate-inner-vlan
user@CE1# set vxlan decapsulate-accept-inner-vlan
```

#### Step-by-Step Procedure

To configure Device PE1:

**NOTE:** Repeat this procedure for Device PE2 after modifying the appropriate interface names, addresses, and other parameters.

1. Configure Device PE1 interfaces.

```
[edit interfaces]
user@PE1# set xe-0/0/2 vlan-tagging
user@PE1# set xe-0/0/2 encapsulation flexible-ethernet-services
user@PE1# set xe-0/0/2 unit 10 encapsulation vlan-bridge
user@PE1# set xe-0/0/2 unit 10 vlan-id 10
```

```
user@PE1# set ge-1/1/2 unit 0 family inet address 10.1.1.1/30
```

```
user@PE1# set ge-1/1/7 mtu 1600
user@PE1# set ge-1/1/7 unit 0 family inet address 198.51.100.5/30
user@PE1# set ge-1/1/7 unit 0 family mpls
```

```
user@PE1# set lo0 unit 1 family inet address 203.1.113.11/32
```

2. Enable MPLS and RSVP on all the interfaces of Device PE1.

```
[edit protocols]
user@PE1# set rsvp interface all
user@PE1# set mpls no-cspf
user@PE1# set mpls interface all
```

3. Configure a label-switched-path from Device PE1 to Device PE2.

**[edit protocols]**

```
user@PE1# set mpls label-switched-path to-PE2 to 10.255.181.72
```

4. Configure internal BGP peering between Devices PE1 and PE2, and enable EVPN signaling for the BGP session.

**[edit protocols]**

```
user@PE1# set bgp family evpn signaling
```

```
user@PE1# set bgp group ibgp type internal
```

```
user@PE1# set bgp group ibgp neighbor 10.255.181.72 local-address 10.255.181.13
```

5. Configure OSPF on Device PE1 interface, excluding the management interface.

**[edit protocols]**

```
user@PE1# set ospf area 0 interface ge-1/1/7.0
```

```
user@PE1# set ospf area 0 interface fxp0.0 disable
```

```
user@PE1# set ospf area 0 interface lo0.0 passive
```

6. Configure an EVPN routing instance, assign the VXLAN tunnel endpoint source interface, VLAN ID, assign route distinguisher and VRF target values, and assign Device PE1 interface to the routing instance.

**[edit routing-instances]**

```
user@PE1# set evpn10 vtep-source-interface lo0.1
```

```
user@PE1# set evpn10 instance-type evpn
```

```
user@PE1# set evpn10 vlan-id 10
```

```
user@PE1# set evpn10 interface xe-0/0/2.10
```

```
user@PE1# set evpn10 route-distinguisher 10.255.181.13:10
```

```
user@PE1# set evpn10 vrf-target target:10:10
```

```
user@PE1# set evpn10 protocols evpn
```

7. Assign the VXLAN ID, multicast group address, and encapsulation and decapsulation parameters for the EVPN routing instance.

**[edit routing-instances]**

```
user@PE1# set evpn10 vxlan vni 10
```

```
user@PE1# set evpn10 vxlan multicast-group 172.16.1.10
```

```
user@PE1# set evpn10 vxlan encapsulate-inner-vlan
```

```
user@PE1# set evpn10 vxlan decapsulate-accept-inner-vlan
```

8. Configure the first VPN routing and forwarding (VRF) routing instance, and assign route distinguisher and vrf-target values.

**[edit routing-instances]**

```
user@PE1# set evpna instance-type vrf
```

```
user@PE1# set evpna route-distinguisher 10.255.181.43:11
```

```
user@PE1# set evpna vrf-target target:65000:11
```

```
user@PE1# set evpna vrf-table-label
```

9. Configure the second VRF routing instance, and assign Device PE1 interfaces, route distinguisher and vrf-target values.

```
[edit routing-instances]
user@PE1# set vrf instance-type vrf
user@PE1# set vrf interface ge-1/1/2.0

## Verificatiton

Confirm that the configuration is working properly.

- [Verifying MAC Learning on page 636](#)
- [Verifying PIM Reachability on page 637](#)
- [Verifying VXLAN Reachability on page 638](#)

### Verifying MAC Learning

**Purpose** Verify the bridging and EVPN MAC table entries on CE and PE devices.

**Action** On Device CE1, determine the bridging MAC table entries.

From operational mode, run the **show bridge mac-table** command.

```
user@CE1> show bridge mac-table
```

```

MAC flags (S -static MAC, D -dynamic MAC, L -locally learned, C -Control
MAC 0 -OVSDB MAC, SE -Statistics enabled, NM -Non configured MAC, R -Remote PE
MAC)

```

```

Routing instance : default-switch
Bridging domain : evpn10, VLAN : 10
 MAC MAC Logical NH RTR
address flags interface Index ID
00:00:00:00:00:11 D xe-0/0/0.10
00:00:00:00:00:22 D vtep.32769

```

On Device PE1, determine the EVPN MAC table entries.

From operational mode, run the **show evpn mac-table** command.

```
user@PE1> show evpn mac-table

MAC flags (S -static MAC, D -dynamic MAC, L -locally learned, C -Control
MAC
 0 -OVSDB MAC, SE -Statistics enabled, NM -Non configured MAC, R -Remote PE
MAC)

Routing instance : evpn10
Bridging domain : __evpn10__, VLAN : 10
 MAC MAC Logical NH RTR
 address flags interface Index ID
00:00:00:00:00:11 D vtep.32769 1048576 1048576
00:00:00:00:00:22 DC
```

**Meaning** The bridging and EVPN MAC tables have learned the VLAN configurations.

### Verifying PIM Reachability

**Purpose** Verify that the PIM configuration is working properly on the CE and PE devices.

**Action** On Device CE1, verify PIM configuration.

From operational mode, run the **show pim rps extensive** command.

```
user@CE1> show pim rps extensive
Instance: PIM.master

address-family INET

user@PE1> show interfaces vtep
Physical interface: vtep, Enabled, Physical link is Up
Interface index: 133, SNMP ifIndex: 508
Type: Software-Pseudo, Link-level type: VxLAN-Tunnel-Endpoint, MTU: 1600,
Speed: Unlimited
Device flags : Present Running
Interface flags: SNMP-Traps
Link type : Full-Duplex
Link flags : None
Last flapped : Never
Input packets : 0
Output packets : 0

Logical interface vtep.32768 (Index 339) (SNMP ifIndex 560)
Flags: Up SNMP-Traps Encapsulation: ENET2
Ethernet segment value: 00:00:00:00:00:00:00:00:00:00:00:00:00:00:00:00, Mode: Single-homed,
Multi-homed status: Forwarding
VXLAN Endpoint Type: Source, VXLAN Endpoint Address: 203.1.113.11, L2 Routing
Instance: evpn10, L3 Routing Instance: vrf
Input packets : 0
Output packets : 0

Logical interface vtep.32769 (Index 341) (SNMP ifIndex 567)
Flags: Up SNMP-Traps Encapsulation: ENET2
VXLAN Endpoint Type: Remote, VXLAN Endpoint Address: 10.255.181.43, L2 Routing
Instance: evpn10, L3 Routing Instance: vrf

```

```
Input packets : 143746
Output packets: 95828
Protocol bridge, MTU: 1600
Flags: Trunk-Mode
```

**Meaning** The output shows the correct tunnel source IP address (assigned to the loopback interface), VLAN, and multicast group for the VXLAN. Device PE1 is reachable because its IP address (the address assigned to the loopback interface) appears in the output. The output also shows that the VXLAN (VNI 10) and corresponding multicast group are configured correctly on the remote VTEP, Device PE2.

## EVPN-VXLAN Data Center Interconnect Through EVPN-MPLS WAN Overview

You can interconnect different data center networks running Ethernet VPN (EVPN) with Virtual extensible LAN (VXLAN) encapsulation through a WAN running MPLS-based EVPN.

The following sections describe the technology and implementation overview of interconnecting data center networks running EVPN-VXLAN through a WAN running EVPN-MPLS to be used as a data center interconnect (DCI) solution.

## Interconnection of Data Center Networks Through WAN Overview

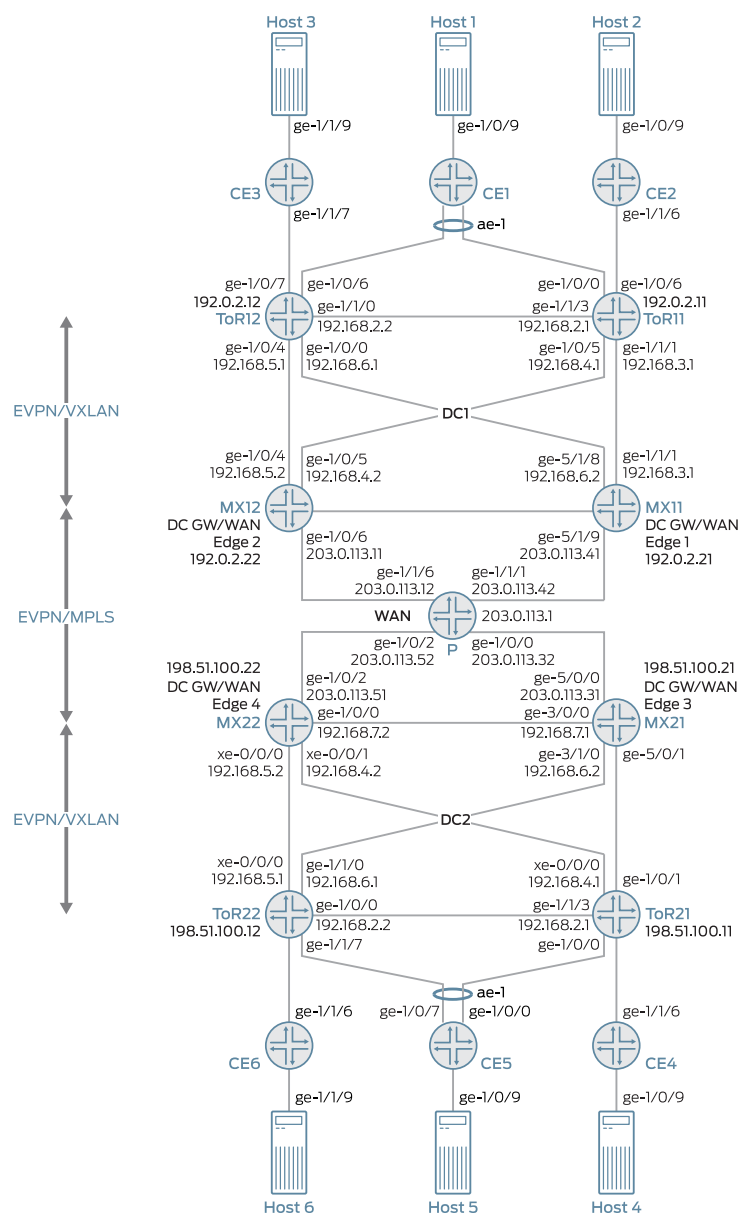

The following provides a conceptual overview of interconnecting different data center networks running Ethernet VPN (EVPN) with Virtual extensible LAN (VXLAN) encapsulation through a WAN running MPLS-based EVPN using the logical tunnel (It-) interface. You can:

- Connect data center edge routers over a WAN network running MPLS-based EVPN to achieve data center interconnection.

- Interconnect EVPN-VXLAN and EVPN-MPLS using the logical tunnel (lt-) interface configured on the data center edge routers.

Figure 66 on page 642 illustration shows the interconnection of two data center networks (DC1 and DC2) running EVPN-VXLAN encapsulation through a WAN running MPLS-based EVPN:

**Figure 66: EVPN-VXLAN Data Center Interconnect Through WAN Running EVPN-MPLS**

In this illustration,

- The following devices are a part of the data center EVPN-VXLAN overlay network 1 (DC1):
  - Customer edge devices (CE1, CE2, and CE3) connected to the data center network.
  - VLAN hosts connected to each CE device.
  - MX routers playing the role of top-of-rack (ToR11 and ToR12) routers.
  - MX routers playing the role of the data center gateway router in the EVPN-VXLAN network and as a WAN edge router running MPLS-based EVPN (MX11 and MX12).
- The following devices are a part of the data center EVPN-VXLAN overlay network 2 (DC2):
  - Customer edge devices (CE4, CE5, and CE6) connected to the data center network.
  - VLAN hosts connected to each CE device.
  - MX routers playing the role of top-of-rack (ToR21 and ToR22) routers.
  - MX routers playing the role of the data center gateway router in the EVPN-VXLAN network and as a WAN edge router running MPLS-based EVPN (MX21 and MX22).

The interconnection of the data center network is realized on the data center gateway router through a pair of logical tunnel (lt-) interface.

On the data center gateway router, you need to configure a pair of logical tunnel (lt-) interface to interconnect the data center EVPN-VXLAN instance and the WAN MPLS-based EVPN instance: one logical tunnel (lt-) interface is configured as the access interface for EVPN-VXLAN network and the other logical tunnel (lt-) interface as the access interface for MPLS-based EVPN network as shown in the [Figure 67 on page 643](#).

The support for active-active multi-homing is provided at the data center gateway routers for interconnection.

**Figure 67: Logical Tunnel (lt-) Interface of DC GW/WAN Edge Router Configured to Interconnect EVPN-VXLAN and EVPN-MPLS Instances**

To configure EVPN-VXLAN and MPLS-based EVPN instances on the logical tunnel (lt-) interface of the data center gateway router, see [“Example: Interconnecting EVPN-VXLAN Data Center Networks Through a WAN Running EVPN-based MPLS” on page 649](#).

## Multi-homing on Data Center Gateways

You can configure redundant data center gateways and active-active multi-homing of EVPN-VXLAN network to a WAN running MPLS-based EVPN and active-active multi-homing of MPLS-based EVPN network to EVPN-VXLAN. This allows redundancy between the interconnection of EVPN-VXLAN network and MPLS-based EVPN WAN network. This also enables load-balancing of unicast traffic among the redundant data center gateways in both directions (from EVPN-VXLAN to EVPN-MPLS, as well as from EVPN-MPLS to EVPN-VXLAN). Broadcast, unknown unicast, and multicast (BUM) traffic is forwarded out of the data center by one of the data center gateways.

## EVPN Designated Forwarder (DF) Election

To achieve active-active EVPN-VXLAN to EVPN-MPLS interconnect instance and active-active EVPN-MPLS to EVPN-VXLAN instance, the logical tunnel (lt-) interface on the data center gateway router is configured with a non-zero Ethernet Segment Identifier (ESI). The ESI, a 10-octet value that must be unique across the entire network, is configured on a per port basis for the logical tunnel (lt-) interface. As per the EVPN multi-homing procedure defined in the RFC7432, the following routes are advertised for an EVPN instance (EVI):

- Advertise an Ethernet segment route
- Advertise an ESI auto-discovery route with a valid split-horizon label and mode set to multi-homing

The standard EVPN DF election procedure described in RFC7432 is considered. The DF election is based on per Ethernet segment for each EVI. The EVPN-VXLAN and EVPN-MPLS run its DF election process independently.

## Split Horizon

Split horizon prevents the looping of BUM traffic in a network, see RFC7432. For BUM traffic from core to the data center gateway (EVPN PE) direction, DF floods the BUM traffic to the access (lt- interface) router and non-DF blocks the BUM traffic. When a DF or non-DF receives the BUM traffic coming from access (lt- interface) router, it gets flooded to the core, but DF does not flood BUM traffic received from its non-DF to the access router based on split horizon rules. For a given BUM packet, only one copy is flooded to the access router (lt- interface) and then to the EVPN core through one of the data center gateway routers because EVPN is multi-homed to another EVPN network. The DF filter rule from the first EVPN instance guarantees that only one copy of BUM traffic is forwarded from the DF to the lt-interface before it re-enters the second EVPN instance.

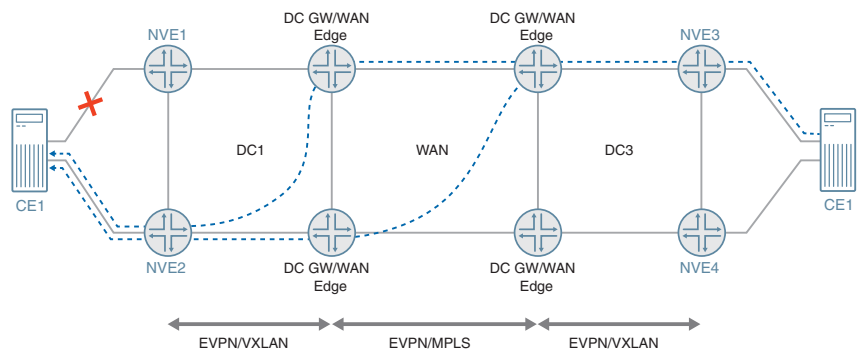

## Aliasing

When redundancy is configured in data center gateways, the traffic is load-balanced among redundant data center gateway routers on a per flow basis. MAC address is learned through the data plane using a pair of logical tunnel (lt-) interfaces configured for EVPN-VXLAN instance and EVPN-MPLS instance for data center interconnect. However, the MAC owned by a host is always accessible by all the redundant data center

gateways due to the nature of active-active multi-homing and full-mesh of EVPN PEs in both EVPN-VXLAN network and in WAN running EVPN-MPLS. Each EVPN instance on the data center gateway router declares the support of aliasing function for the ESI configured on the logical tunnel (lt-) interface by advertising per EVI auto-discovery route. The aliasing functionality support is defined in the RFC7432.

Figure 68 on page 645 illustrates a link failure between CE1 and NVE1 but CE1 is still reachable by both data center gateway routers within the data center network (DC1).

**Figure 68: Load Balancing Among Redundant DC GW/WAN Edge Routers**

A link failure between a host and its top-of-rack (TOR) devices does not impact the aliasing functionality declared by the data center gateway router as the data center network itself is active-active to the WAN running EVPN-MPLS. As long as the host is connected to another ToR device in the data center network, the host is still accessible by all the other redundant data center gateway routers, so the aliasing functionality applies.

## VLAN-Aware Bundle Service

In Junos OS for MX Series, both EVPN-VXLAN and EVPN-MPLS instances support VLAN-aware bundle service with one or more bridge domains. To connect two EVIs with VLAN-aware bundle service through a pair of logical tunnel (lt-) interface, it needs trunk interface support on the logical tunnel (lt-) interface, as well as trunk interface support for both EVPN-VXLAN and EVPN-MPLS instances. A trunk interface on Junos OS MX Series allows a logical interface to accept packets tagged with any VLAN ID specified in a VLAN ID list.

When the trunk mode is used for the logical tunnel (lt-) interface, the frames going out of the logical tunnel (lt-) interface trunk port from the first EVPN virtual switch are tagged with the appropriate VLAN tag; going through its peer logical tunnel (lt-) interface, the incoming frames to the second virtual switch are inspected and forwarded based on the VLAN tag found within the frame.

The following is a sample configuration to use trunk mode on logical tunnel (lt-) interface to support VLAN-aware bundle service for interconnection of EVPN-VXLAN with a WAN running MPLS-based EVPN:

```
interfaces lt-1/0/10 {
esi {
```

```
36:36:36:36:36:36:36:36:36:36;
all-active;
}
unit 3 {
 encapsulation ethernet-bridge;
 peer-unit 4;
 family bridge {
 interface-mode trunk;
 vlan-id-list [51 52];
 }
}
unit 4 {
 encapsulation ethernet-bridge;
 peer-unit 3;
 family bridge {
 interface-mode trunk;
 vlan-id-list [51 52];
 }
}
}
```

The following is a sample configuration of trunk port support for EVPN-VXLAN and EVPN-MPLS:

```
routing-instances evpn-mpls {
 vtep-source-interface lo0.0;
 instance-type virtual-switch;
 interface lt-1/0/10.4;
 route-distinguisher 101:2;
 vrf-target target:2:2;
 protocols {
 evpn {
 extended-vlan-list 51-52;
 }
 }
}
bridge-domains {
 bd1 {
 domain-type bridge;
 vlan-id 51;
 }
 bd2 {
 domain-type bridge;
 vlan-id 52;
 }
}
}
routing-instances red {
 vtep-source-interface lo0.0;
 instance-type virtual-switch;
 interface lt-1/0/10.4;
 route-distinguisher 101:1;
 vrf-target target:1:1;
 protocols {
 evpn {
 encapsulation vxlan;
 extended-vni-list all;
 }
 }
}
```

```

 }
 }
 bridge-domains {
 bd1 {
 domain-type bridge;
 vlan-id 51;
 routing-interface irb.0;
 vxlan {
 vni 51;
 encapsulate-inner-vlan;
 decapsulate-accept-inner-vlan;
 ingress-node-replication;
 }
 }
 bd2 {
 domain-type bridge;
 vlan-id 52;
 routing-interface irb.1;
 vxlan {
 vni 52;
 encapsulate-inner-vlan;
 decapsulate-accept-inner-vlan;
 ingress-node-replication;
 }
 }
 }
}
}

```

### Data Center Network Design and Considerations

Before designing a data center network, you need to decide whether to use IGP, or iBGP, or eBGP protocols in the data center network for IP underlay. Another important factor to consider is the AS assignment. The ToR device in the data center network is required to have an AS number that is different than the AS number used in the WAN edge router.

For the overlay network, you need to decide whether to use iBGP, or eBGP, or a combination of both iBGP and eBGP.

**Figure 69: Data Center Network Design**

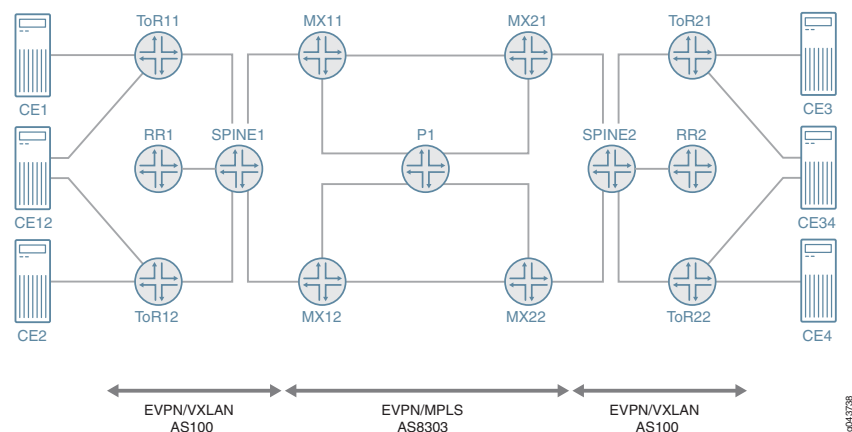

Figure 69 on page 647 illustrates the MX routers (MX11, MX12, MX21 and MX22) as the data center gateway and WAN edge routers that interconnects EVPN-VXLAN to EVPN-MPLS. Spine switches provide connection for east and west traffic among ToRs so that traffic that does not need to be Layer 3 routed does not go through the MX routers. From a network design perspective, to provide an end-to-end EVPN solution, the following requirements must be met:

- [Isolate IGP Between EVPN-VXLAN and EVPN-MPLS Segments on page 648](#)
- [Different Autonomous Systems \(AS\) in EVPN-VXLAN and EVPN-MPLS Network on page 648](#)

#### ***Isolate IGP Between EVPN-VXLAN and EVPN-MPLS Segments***

When IGP is used in the data center network, you need to isolate the IP network in EVPN-VXLAN from the IP network in the WAN. When IGP is used in the data center, one option is not to run IGP protocol on the interfaces that connects spine switches and MX routers. Instead, an eBGP session with address family inet unicast is used between spine switches and MX routers such that through IGP/eBGP/policy you can leak loopback addresses of ToR and MX routers to each other and still maintain the isolation of IP network in the data center from WAN. In the EVPN-VXLAN segment, IGP is between spine switches and ToRs only. In the EVPN-MPLS segment, IGP is between all the MX routers.

- [Using iBGP for IP Underlay in the Data Center Network on page 648](#)
- [Using eBGP for the IP Underlay in the Data Center Network on page 648](#)

#### ***Using iBGP for IP Underlay in the Data Center Network***

If the requirement is to not use IGP in the IP underlay in the data center, iBGP with address family inet unicast can be used to replace OSPF between spine switches and ToRs. Between spine switches and data center gateways, you still need to use eBGP for advertising loopback IP.

#### ***Using eBGP for the IP Underlay in the Data Center Network***

If the requirement is to use eBGP only in the data center, you need to use eBGP with address family inet unicast for the IP underlay. In this case, it is a typical 2 stage CLOS network without spine aggregation layer. Each ToR and data center gateway is assigned a unique AS number. ToR establishes eBGP session with data center gateway routers directly.

#### ***Different Autonomous Systems (AS) in EVPN-VXLAN and EVPN-MPLS Network***

The following is support for different AS in EVPN-VXLAN and EVPN-MPLS network running iBGP, or eBGP for the IP overlay.

- [Running iBGP/eBGP for the Overlay on page 648](#)
- [Running eBGP only for the Overlay on page 649](#)

#### ***Running iBGP/eBGP for the Overlay***

ToRs and spine switches are in the same AS100 and all MX Series routers are in AS8303. Among ToRs, its EVPN Network Layer Reachability Information (NLRI) is exchanged through iBGP session. A BGP route reflector (RR) is used and each ToR establishes iBGP

session with the RR. Data traffic between ToRs that belongs to the same bridge domain goes through spine switch only and it is always 2 hops away. Since the ToRs and spine switches are in the same AS and the MX edge routers are in the different AS, the MX edge router establishes eBGP session to either RR or each ToR directly. By default, route learned from iBGP session (ToRs) are re-advertised to the eBGP (MX routers) and vice versa. BGP next-hop unchanged is enforced when BGP re-advertises EVPN NLRI among iBGP and eBGP session.

#### ***Running eBGP only for the Overlay***

If the requirement is to run eBGP only in the data center, each ToR is assigned a unique AS number. Each data center gateway router uses a unique AS number on the data center facing side. For the WAN facing side, the same AS number is used, but the AS number would be different from the AS number used for the data center facing side. The AS number may also be reused in each data center.

To prevent an EVPN route in the data center to be advertised to the data center gateway routers in another data center, you must turn on the route constrain in the EVPN-MPLS network. To make BGP route constrain to work, different route target is used for EVPN-VXLAN and EVPN-MPLS network, respectively.

## **Example: Interconnecting EVPN-VXLAN Data Center Networks Through a WAN Running EVPN-based MPLS**

---

This example shows how to interconnect EVPN-VXLAN data center networks through a WAN running EVPN-MPLS to leverage the benefits of EVPN as a Data Center Interconnect (DCI) solution.

- [Requirements on page 649](#)
- [Overview on page 650](#)
- [Configuration on page 652](#)
- [Verification on page 727](#)

### **Requirements**

This example uses the following hardware and software components:

- Four Juniper Networks MX Series routers to be configured as data center gateways and WAN edge routers.
- Four Juniper Networks MX Series routers to be configured as top-of-rack (ToR) routers.
- Six customer edge (CE) devices.
- Six host devices connected to each CE device that has the capability to configure multiple VLANs.

- One provider (P) router part of the EVPN-MPLS WAN network.
- Junos OS Release 17.2, or later.

## Overview

You can interconnect different data center networks running Ethernet VPN (EVPN) with Virtual extensible LAN (VXLAN) encapsulation through a WAN running MPLS-based EVPN using the logical tunnel (lt-) interface.

[Figure 70 on page 651](#) illustrates the interconnection of data center networks running EVPN with VXLAN encapsulation through a WAN running MPLS-based EVPN. For the purposes of this example, the MX Series routers acting as data center gateways and as WAN edge routers are named MX11, MX12, MX21, and MX22. The MX Series routers acting as top-of-rack (ToR) routers are named ToR11, ToR12, ToR21, and ToR22. The customer edge (CE) devices connected to the data center network 1 (DC1) are named CE1, CE2, and CE3. The customer edge (CE) devices connected to the data center network 2 (DC2) are named CE4, CE5, and CE6. The host devices connected to each CE device should be able to configure multiple host VLANs. The WAN provider router is named as P.

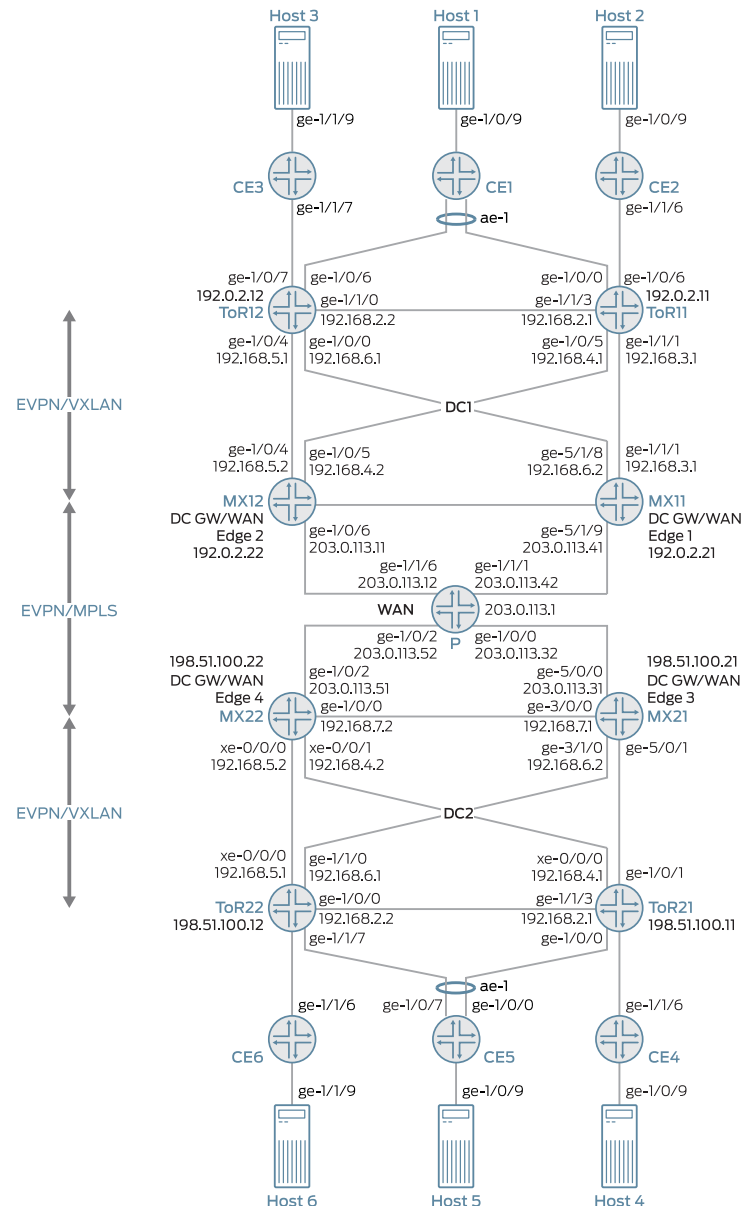

**NOTE:** CE devices are part of the logical system of ToR devices.

---

**Figure 70: EVPN-VXLAN Data Center Interconnect Through WAN Running EVPN-MPLS**

For the MX Series routers acting as data center gateways and WAN edge routers, configure the following information:

- IRB interfaces, virtual gateway addresses, and loopback logical interfaces.
- Multiprotocol external BGP (MP-EBGP) underlay connectivity between gateway and ToR routers, EVPN as the signaling protocol.
- Routing policies to allow specific routes into the virtual-switch tables.

- Routing instances (Layer 3 VRFs) for each virtual network, including a unique route distinguisher, and a vrf-target value.
- Virtual-switch instances (Layer 2 MAC-VRFs) for each virtual network, the VTEP source interface (always lo0.0), route distinguisher, and vrf-import policy.
- EVPN protocol, encapsulation method, VNI list, and BUM traffic forwarding method for each virtual switch.
- Bridge domain within each virtual switch that maps VNIDs to VLAN IDs, an IRB (Layer 3) interface, and the BUM forwarding method.

For the MX Series routers acting as top-of-rack (ToR) routers, configure the following information:

- Host facing interfaces with VLANs, VLAN IDs, and loopback logical interfaces.
- Link Aggregation Control Protocol (LACP)-enabled link aggregation group (LAG), Ethernet Segment ID (ESI), and all-active mode.
- Multiprotocol external BGP (MP-EBGP) overlays between ToR and gateway routers using EVPN as the signaling protocol.
- EVPN with VXLAN as the encapsulation method, extended-vni-list, multicast mode, and route targets for each VNI.
- Vrf-imp policy, vtep-source-interface, route-distinguisher, and vrf import and target information.
- VLANs, with VLAN IDs mapped to globally significant VNIs, and VXLAN ingress node replication.

**NOTE:** You can set the virtual gateway address as the default IPv4 or IPv6 gateway address for end hosts (virtual machines or servers).

---

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

## Configuring ToR11

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

Configure the MX router as ToR11:

1. Set the system hostname.

[edit]

```
user@ToR11# set system host-name ToR11
```

2. Configure the interfaces and bridge domains on the CE2 device to enable Layer 2 connectivity.

[edit]

```
user@ce2# set logical-systems CE-2 interfaces ge-1/0/9 unit 0 description
"CONNECTED TO Host 2"
user@ce2# set logical-systems CE-2 interfaces ge-1/0/9 unit 0 family bridge
interface-mode trunk
user@ce2# set logical-systems CE-2 interfaces ge-1/0/9 unit 0 family bridge
vlan-id-list 1-5
user@ce2# set logical-systems CE-2 interfaces ge-1/1/6 unit 0 description
"CONNECTED TO ToR11"
user@ce2# set logical-systems CE-2 interfaces ge-1/1/6 unit 0 family bridge
interface-mode trunk
user@ce2# set logical-systems CE-2 interfaces ge-1/1/6 unit 0 family bridge
vlan-id-list 1-5
user@ce2# set logical-systems CE-2 bridge-domains BD-1 domain-type bridge
user@ce2# set logical-systems CE-2 bridge-domains BD-1 vlan-id 1
user@ce2# set logical-systems CE-2 bridge-domains BD-2 domain-type bridge
user@ce2# set logical-systems CE-2 bridge-domains BD-2 vlan-id 2
user@ce2# set logical-systems CE-2 bridge-domains BD-3 domain-type bridge
user@ce2# set logical-systems CE-2 bridge-domains BD-3 vlan-id 3
user@ce2# set logical-systems CE-2 bridge-domains BD-4 domain-type bridge
user@ce2# set logical-systems CE-2 bridge-domains BD-4 vlan-id 4
user@ce2# set logical-systems CE-2 bridge-domains BD-5 domain-type bridge
user@ce2# set logical-systems CE-2 bridge-domains BD-5 vlan-id 5
```

3. Configure trace options for the interfaces to enable trace logs.

[edit]

```
user@ce2# set interfaces traceoptions file R0-DCD.log
user@ce2# set interfaces traceoptions file size 10m
user@ce2# set interfaces traceoptions flag all
```

4. Set the number of aggregated Ethernet interfaces.

[edit]

```
user@ToR11# set chassis aggregated-devices ethernet device-count 1
```

5. Configure the interfaces on the ToR11 device to connect to the MX12, CE-2, CE-1, ToR12, and MX11 devices to enable underlay connectivity.

[edit]

```
user@ToR11# set interfaces ge-1/0/5 unit 0 description "CONNECTED TO MX12"
user@ToR11# set interfaces ge-1/0/5 unit 0 family inet address 192.168.4.1/24
user@ToR11# set interfaces ge-1/0/6 unit 0 description "CONNECTED TO CE-2"
user@ToR11# set interfaces ge-1/0/6 unit 0 family bridge interface-mode trunk
user@ToR11# set interfaces ge-1/0/6 unit 0 family bridge vlan-id-list 1-5
user@ToR11# set interfaces ge-1/1/0 description "CONNECTED TO CE-1"
user@ToR11# set interfaces ge-1/1/0 gigether-options 802.3ad ae0
user@ToR11# set interfaces ge-1/1/1 unit 0 description "CONNECTED TO MX11"
user@ToR11# set interfaces ge-1/1/1 unit 0 family inet address 192.168.3.1/24
user@ToR11# set interfaces ge-1/1/3 unit 0 description "CONNECTED TO ToR12"
user@ToR11# set interfaces ge-1/1/3 unit 0 family inet address 192.168.2.1/24
```

6. Configure a Link Aggregation Control Protocol (LACP)-enabled link aggregation group (LAG) interface towards the CE-1 end host device. The ESI value is globally unique across the entire EVPN domain. The all-active configuration enables ToR11 and ToR12 to forward traffic to, and from the CE devices, such that all CE links are actively used.

[edit]

```
user@ToR11# set interfaces ae0 esi 00:11:11:11:11:11:11:11:11:11
user@ToR11# set interfaces ae0 esi all-active
user@ToR11# set interfaces ae0 aggregated-ether-options lacp active
user@ToR11# set interfaces ae0 aggregated-ether-options lacp periodic fast
user@ToR11# set interfaces ae0 aggregated-ether-options lacp system-id
11:11:11:11:11:11
user@ToR11# set interfaces ae0 unit 0 family bridge interface-mode trunk
user@ToR11# set interfaces ae0 unit 0 family bridge vlan-id-list 1-5
```

7. Configure the loopback interface address and routing options.

[edit]

```
user@ToR11# set interfaces lo0 unit 81 family inet address 192.0.2.11/32
user@ToR11# set routing-options router-id 192.0.2.11
user@ToR11# set routing-options autonomous-system 100
```

8. Configure load balancing on ToR11.

[edit]

```
user@ToR11# set routing-options forwarding-table export evpn-pplb
```

9. Configure a multiprotocol external BGP (MP-EBGP) underlay connectivity between the ToR (ToR11 and ToR12) and gateway routers (MX11 and MX12).

[edit]

```
user@ToR11# set protocols bgp local-as 100

```

user@ToR11# set protocols bgp group ToR12 local-as 100
user@ToR11# set protocols bgp group ToR12 neighbor 192.168.2.2 family inet
unicast

```

10. Configure a multiprotocol external BGP (MP-EBGP) overlay between the ToR (ToR11 and ToR12) and gateway routers (MX11 and MX12) and set EVPN as the signaling protocol.
  - a. Configure a MP-EBGP overlay to connect between ToR11 and MX11 using EVPN signaling.

[edit]

```

user@ToR11# set protocols bgp group MX11-EVPN type external
user@ToR11# set protocols bgp group MX11-EVPN multihop ttl 2
user@ToR11# set protocols bgp group MX11-EVPN multihop no-nexthop-change
user@ToR11# set protocols bgp group MX11-EVPN local-address 192.0.2.11
user@ToR11# set protocols bgp group MX11-EVPN export TEST
user@ToR11# set protocols bgp group MX11-EVPN peer-as 400
user@ToR11# set protocols bgp group MX11-EVPN local-as 100
user@ToR11# set protocols bgp group MX11-EVPN neighbor 192.0.2.21 family
evpn signaling

```

- b. Configure a MP-EBGP overlay to connect between ToR11 and MX12 using EVPN signaling.

[edit]

```

user@ToR11# set protocols bgp group MX12-EVPN type external
user@ToR11# set protocols bgp group MX12-EVPN multihop ttl 2
user@ToR11# set protocols bgp group MX12-EVPN multihop no-nexthop-change
user@ToR11# set protocols bgp group MX12-EVPN local-address 192.0.2.11
user@ToR11# set protocols bgp group MX12-EVPN export TEST
user@ToR11# set protocols bgp group MX12-EVPN peer-as 500
user@ToR11# set protocols bgp group MX12-EVPN local-as 100
user@ToR11# set protocols bgp group MX12-EVPN neighbor 192.0.2.22 family
evpn signaling

```

- c. Configure a MP-EBGP overlay to connect between ToR11 and ToR12 using EVPN signaling.

[edit]

```

user@ToR11# set protocols bgp group ToR12-EVPN type external
user@ToR11# set protocols bgp group ToR12-EVPN multihop ttl 2
user@ToR11# set protocols bgp group ToR12-EVPN multihop no-nexthop-change
user@ToR11# set protocols bgp group ToR12-EVPN local-address 192.0.2.11
user@ToR11# set protocols bgp group ToR12-EVPN export TEST
user@ToR11# set protocols bgp group ToR12-EVPN peer-as 200
user@ToR11# set protocols bgp group ToR12-EVPN local-as 100
user@ToR11# set protocols bgp group ToR12-EVPN neighbor 192.0.2.12 family
evpn signaling

```

11. Configure trace operations to track all Layer 2 address learning and forwarding properties.

[edit]

```
user@ToR11# set protocols l2-learning traceoptions file TOR11-L2ALD.log
user@ToR11# set protocols l2-learning traceoptions file size 10m
user@ToR11# set protocols l2-learning traceoptions level all
user@ToR11# set protocols l2-learning traceoptions flag all
```

12. Configure routing policies to accept the direct loopback address route and redirect it into BGP.

[edit]

```
user@ToR11# set policy-options policy-statement L0 term 1 from protocol
direct
user@ToR11# set policy-options policy-statement L0 term 1 from route-filter
192.0.2.11/32 exact
user@ToR11# set policy-options policy-statement L0 term 1 then accept
```

13. Configure community policy options.

[edit]

```
user@ToR11# set policy-options community NO-EXPORT members no-advertise
user@ToR11# set policy-options community NO-EXPORT members no-export
user@ToR11# set policy-options community NO-EXPORT members no-export-subconfed
```

14. Apply load balance.

[edit]

```
user@ToR11# set policy-options policy-statement TEST then community add
NO-EXPORT
user@ToR11# set policy-options policy-statement evpn-pp1b from protocol evpn
user@ToR11# set policy-options policy-statement evpn-pp1b then load-balance
per-packet
```

15. Configure EVPN routing instances for each virtual network. Define the VTEP source interface, route distinguisher (used to identify and advertise EVPN routes), and vrf-target (exports and tags all routes for that local VRF using the defined route target). Configure the EVPN protocol, encapsulation method, VNI list, and BUM traffic forwarding method. Finally, configure a bridge domain for each virtual router that maps VNIDs to VLAN IDs, and identify the BUM forwarding method.

[edit]

```
user@ToR11# set routing-instances EVPN-VXLAN-1 vtep-source-interface lo0.81
user@ToR11# set routing-instances EVPN-VXLAN-1 instance-type virtual-switch
user@ToR11# set routing-instances EVPN-VXLAN-1 interface ge-1/0/6.0

```

## Configuring ToR12

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

Configure the MX router ToR12:

1. Set the system hostname.

[edit]

```
user@ToR12# set system host-name ToR12
```

2. Configure the interfaces and bridge domains on the CE-1 device to enable Layer 2 connectivity.

[edit]

```

user@ce1# set logical-systems CE-1 interfaces ge-1/0/9 unit 0 description
"CONNECTED TO Host 1"
user@ce1# set logical-systems CE-1 interfaces ge-1/0/9 unit 0 family bridge
interface-mode trunk
user@ce1# set logical-systems CE-1 interfaces ge-1/0/9 unit 0 family bridge
vlan-id-list 1-5
user@ce1# set logical-systems CE-1 interfaces ae1 unit 0 description
"CONNECTED TO ToR12"
user@ce1# set logical-systems CE-1 interfaces ae1 unit 0 family bridge
interface-mode trunk
user@ce1# set logical-systems CE-1 interfaces ae1 unit 0 family bridge
vlan-id-list 1-5
user@ce1# set logical-systems CE-1 bridge-domains BD-1 domain-type bridge
user@ce1# set logical-systems CE-1 bridge-domains BD-1 vlan-id 1
user@ce1# set logical-systems CE-1 bridge-domains BD-2 domain-type bridge
user@ce1# set logical-systems CE-1 bridge-domains BD-2 vlan-id 2
user@ce1# set logical-systems CE-1 bridge-domains BD-3 domain-type bridge
user@ce1# set logical-systems CE-1 bridge-domains BD-3 vlan-id 3
user@ce1# set logical-systems CE-1 bridge-domains BD-4 domain-type bridge
user@ce1# set logical-systems CE-1 bridge-domains BD-4 vlan-id 4
user@ce1# set logical-systems CE-1 bridge-domains BD-5 domain-type bridge
user@ce1# set logical-systems CE-1 bridge-domains BD-5 vlan-id 5

```

3. Configure the interfaces and bridge domains on the CE-3 device to enable Layer 2 connectivity.

[edit]

```

user@ce3# set logical-systems CE-3 interfaces ge-1/1/7 unit 0 description
"CONNECTED TO ToR12"
user@ce3# set logical-systems CE-3 interfaces ge-1/1/7 unit 0 family bridge
interface-mode trunk
user@ce3# set logical-systems CE-3 interfaces ge-1/1/7 unit 0 family bridge
vlan-id-list 1-5
user@ce3# set logical-systems CE-3 interfaces ge-1/1/9 unit 0 description
"CONNECTED TO Host 3"
user@ce3# set logical-systems CE-3 interfaces ge-1/1/9 unit 0 family bridge
interface-mode trunk
user@ce3# set logical-systems CE-3 interfaces ge-1/1/9 unit 0 family bridge
vlan-id-list 1-5
user@ce3# set logical-systems CE-3 bridge-domains BD-1 domain-type bridge
user@ce3# set logical-systems CE-3 bridge-domains BD-1 vlan-id 1
user@ce3# set logical-systems CE-3 bridge-domains BD-2 domain-type bridge
user@ce3# set logical-systems CE-3 bridge-domains BD-2 vlan-id 2
user@ce3# set logical-systems CE-3 bridge-domains BD-3 domain-type bridge
user@ce3# set logical-systems CE-3 bridge-domains BD-3 vlan-id 3
user@ce3# set logical-systems CE-3 bridge-domains BD-4 domain-type bridge
user@ce3# set logical-systems CE-3 bridge-domains BD-4 vlan-id 4
user@ce3# set logical-systems CE-3 bridge-domains BD-5 domain-type bridge
user@ce3# set logical-systems CE-3 bridge-domains BD-5 vlan-id 5

```

4. Configure trace options for the interfaces to enable trace logs.

[edit]

```

user@ce3# set interfaces traceoptions file R1-DCD.log
user@ce3# set interfaces traceoptions file size 10m
user@ce3# set interfaces traceoptions flag all

```

5. Set the number of aggregated Ethernet interfaces.

[edit]

```
user@ToR12# set chassis aggregated-devices ethernet device-count 2
```

6. Configure the interfaces on the ToR12 device to connect to the MX12, CE-2, CE-3, ToR11, and MX11 devices to enable underlay connectivity.

[edit]

```
user@ToR12# set interfaces ge-1/0/0 unit 0 description "CONNECTED TO MX11"
user@ToR12# set interfaces ge-1/0/0 unit 0 family inet address 192.168.6.1/24
user@ToR12# set interfaces ge-1/0/4 unit 0 description "CONNECTED TO MX12"
user@ToR12# set interfaces ge-1/0/4 unit 0 family inet address 192.168.5.1/24
user@ToR12# set interfaces ge-1/0/6 description "CONNECTED TO CE-1"
user@ToR12# set interfaces ge-1/0/6 gigether-options 802.3ad ae0
user@ToR12# set interfaces ge-1/0/7 unit 0 description "CONNECTED TO CE-3"
user@ToR12# set interfaces ge-1/0/7 unit 0 family bridge interface-mode trunk
user@ToR12# set interfaces ge-1/0/7 unit 0 family bridge vlan-id-list 1-5
user@ToR12# set interfaces ge-1/1/0 description "CONNECTED TO ToR11"
user@ToR12# set interfaces ge-1/1/0 gigether-options 802.3ad ae1
user@ToR12# set interfaces ge-1/1/3 unit 0 description "CONNECTED TO ToR11"
user@ToR12# set interfaces ge-1/1/3 unit 0 family inet address 192.168.2.2/24
user@ToR12# set interfaces ge-1/1/6 description "CONNECTED TO ToR12"
user@ToR12# set interfaces ge-1/1/6 gigether-options 802.3ad ae1
```

7. Configure a Link Aggregation Control Protocol (LACP)-enabled link aggregation group (LAG) interface towards the CE-1 end host device. The ESI value is globally unique across the entire EVPN domain. The all-active configuration enables ToR11 and ToR12 to forward traffic to, and from the CE devices, such that all CE links are actively used.

[edit]

```
user@ToR12# set interfaces ae0 esi 00:11:11:11:11:11:11:11:11:11
user@ToR12# set interfaces ae0 esi all-active
user@ToR12# set interfaces ae0 aggregated-ether-options lacp system-id
11:11:11:11:11:11
user@ToR12# set interfaces ae0 unit 0 family bridge interface-mode trunk
user@ToR12# set interfaces ae0 unit 0 family bridge vlan-id-list 1-5
user@ToR12# set interfaces ae1 aggregated-ether-options lacp active
user@ToR12# set interfaces ae1 aggregated-ether-options lacp periodic fast
```

8. Configure the loopback interface address and routing options.

[edit]

```
user@ToR12# set interfaces lo0 unit 82 family inet address 192.0.2.12/32
user@ToR12# set routing-options router-id 192.0.2.12
user@ToR12# set routing-options autonomous-system 200
```

9. Configure load balancing on ToR12.

[edit]

```
user@ToR12# set routing-options forwarding-table export evpn-pp1b
```

10. Configure a multiprotocol external BGP (MP-EBGP) underlay connectivity between the ToR (ToR12 and ToR11) and gateway routers (MX11 and MX12).

[edit]

```
user@ToR12# set protocols bgp local-as 200
user@ToR12# set protocols bgp group MX11 type external
user@ToR12# set protocols bgp group MX11 local-address 192.168.6.1
user@ToR12# set protocols bgp group MX11 export L0
user@ToR12# set protocols bgp group MX11 export TEST
user@ToR12# set protocols bgp group MX11 peer-as 400
user@ToR12# set protocols bgp group MX11 local-as 200
user@ToR12# set protocols bgp group MX11 neighbor 192.168.6.2 family inet
unicast
user@ToR12# set protocols bgp group MX12 type external
user@ToR12# set protocols bgp group MX12 local-address 192.168.5.1
user@ToR12# set protocols bgp group MX12 export L0
user@ToR12# set protocols bgp group MX12 export TEST
user@ToR12# set protocols bgp group MX12 peer-as 500
user@ToR12# set protocols bgp group MX12 local-as 200
user@ToR12# set protocols bgp group MX12 neighbor 192.168.5.2 family inet
unicast
user@ToR12# set protocols bgp group ToR11 type external
user@ToR12# set protocols bgp group ToR11 local-address 192.168.2.2
user@ToR12# set protocols bgp group ToR11 export L0
user@ToR12# set protocols bgp group ToR11 export TEST
user@ToR12# set protocols bgp group ToR11 peer-as 100
user@ToR12# set protocols bgp group ToR11 local-as 200
user@ToR12# set protocols bgp group ToR11 neighbor 192.168.2.1 family inet
unicast
```

11. Configure a multiprotocol external BGP (MP-EBGP) overlay between the ToR (ToR12 and ToR11) and gateway routers (MX11 and MX12) and set EVPN as the signaling protocol.
  - a. Configure a MP-EBGP overlay to connect between ToR12 and MX11 using EVPN signaling.

[edit]

```
user@ToR12# set protocols bgp group MX11-EVPN type external
user@ToR12# set protocols bgp group MX11-EVPN multihop ttl 2
user@ToR12# set protocols bgp group MX11-EVPN multihop no-nexthop-change
user@ToR12# set protocols bgp group MX11-EVPN local-address 192.0.2.12
user@ToR12# set protocols bgp group MX11-EVPN export TEST
user@ToR12# set protocols bgp group MX11-EVPN peer-as 400
user@ToR12# set protocols bgp group MX11-EVPN local-as 200
user@ToR12# set protocols bgp group MX11-EVPN neighbor 192.0.2.21 family
evpn signaling
```

- b. Configure a MP-EBGP overlay to connect between ToR12 and MX12 using EVPN signaling.

[edit]

```

user@ToR12# set protocols bgp group MX12-EVPN type external
user@ToR12# set protocols bgp group MX12-EVPN multihop ttl 2
user@ToR12# set protocols bgp group MX12-EVPN multihop no-nexthop-change
user@ToR12# set protocols bgp group MX12-EVPN local-address 192.0.2.12
user@ToR12# set protocols bgp group MX12-EVPN export TEST
user@ToR12# set protocols bgp group MX12-EVPN peer-as 500
user@ToR12# set protocols bgp group MX12-EVPN local-as 200
user@ToR12# set protocols bgp group MX12-EVPN neighbor 192.0.2.22 family
evpn signaling

```

- c. Configure a MP-EBGP overlay to connect between ToR12 and ToR11 using EVPN signaling.

[edit]

```

user@ToR12# set protocols bgp group ToR11-EVPN type external
user@ToR12# set protocols bgp group ToR11-EVPN multihop ttl 2
user@ToR12# set protocols bgp group ToR11-EVPN multihop no-nexthop-change
user@ToR12# set protocols bgp group ToR11-EVPN local-address 192.0.2.12
user@ToR12# set protocols bgp group ToR11-EVPN export TEST
user@ToR12# set protocols bgp group ToR11-EVPN peer-as 100
user@ToR12# set protocols bgp group ToR11-EVPN local-as 200
user@ToR12# set protocols bgp group ToR11-EVPN neighbor 192.0.2.11 family
evpn signaling
user@ToR12# set protocols bgp group ToR12-EVPN export TEST

```

12. Configure trace operations to track all Layer 2 address learning and forwarding properties.

[edit]

```

user@ToR12# set protocols l2-learning traceoptions file TOR12-L2ALD.log
user@ToR12# set protocols l2-learning traceoptions file size 10m
user@ToR12# set protocols l2-learning traceoptions level all
user@ToR12# set protocols l2-learning traceoptions flag all

```

13. Configure routing policies to accept the direct loopback address route and redirect it into BGP.

[edit]

```

user@ToR12# set policy-options policy-statement L0 term 1 from protocol
direct
user@ToR12# set policy-options policy-statement L0 term 1 from route-filter
192.0.2.12/32 exact
user@ToR12# set policy-options policy-statement L0 term 1 then accept

```

14. Configure community policy options.

[edit]

```

user@ToR12# set policy-options community NO-EXPORT members no-advertise
user@ToR12# set policy-options community NO-EXPORT members no-export
user@ToR12# set policy-options community NO-EXPORT members no-export-subconfed

```

15. Apply load balance.

[edit]

```
user@ToR12# set policy-options policy-statement TEST then community add
NO-EXPORT
user@ToR12# set policy-options policy-statement evpn-pplb from protocol evpn
user@ToR12# set policy-options policy-statement evpn-pplb then load-balance
per-packet
```

16. Configure EVPN routing instances for each virtual network. Define the VTEP source interface, route distinguisher (used to identify and advertise EVPN routes), and vrf-target (exports and tags all routes for that local VRF using the defined route target). Configure the EVPN protocol, encapsulation method, VNI list, and BUM traffic forwarding method. Finally, configure a bridge domain for each virtual router that maps VNIDs to VLAN IDs, and identify the BUM forwarding method.

[edit]

```
user@ToR12# set routing-instances EVPN-VXLAN-1 vtep-source-interface lo0.82
user@ToR12# set routing-instances EVPN-VXLAN-1 instance-type virtual-switch
user@ToR12# set routing-instances EVPN-VXLAN-1 interface ge-1/0/7.0
user@ToR12# set routing-instances EVPN-VXLAN-1 interface ae0.0
user@ToR12# set routing-instances EVPN-VXLAN-1 route-distinguisher

```

### Configuring Data Center Gateway and WAN Edge 1 Router (MX11)

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

Configure an MX Series router as the data center gateway and WAN edge router and name it as MX11:

1. Set the system hostname.

[edit]

```
user@MX11# set system host-name MX11
```

2. Configure the interfaces on the MX11 router (DC GW/WAN Edge1) to enable the underlay connectivity to the MX12, ToR11, ToR12, and P devices, which is the EVPN-VXLAN part of DC1 network.

[edit]

```

user@MX11# set interfaces ge-5/1/0 unit 0 description "CONNECTED TO MX12"
user@MX11# set interfaces ge-5/1/0 unit 0 family inet address 192.168.7.1/24
user@MX11# set interfaces ge-5/1/1 unit 0 description "CONNECTED TO ToR11"
user@MX11# set interfaces ge-5/1/1 unit 0 family inet address 192.168.3.2/24
user@MX11# set interfaces ge-5/1/8 unit 0 description "CONNECTED TO ToR12"
user@MX11# set interfaces ge-5/1/8 unit 0 family inet address 192.168.6.2/24
user@MX11# set interfaces ge-5/1/9 unit 0 description "CONNECTED TO P"
user@MX11# set interfaces ge-5/1/9 unit 0 family inet address 203.0.1.1/24
user@MX11# set interfaces ge-5/1/9 unit 0 family mpls

```

3. Configure a multiprotocol external BGP (MP-EBGP) underlay connectivity between the gateway routers (MX11 and MX12) and ToR (ToR11 and ToR12).

[edit]

```

user@MX11# set protocols bgp group ToR11 type external
user@MX11# set protocols bgp group ToR11 local-address 192.168.3.2
user@MX11# set protocols bgp group ToR11 import TEST
user@MX11# set protocols bgp group ToR11 export TEST
user@MX11# set protocols bgp group ToR11 export LO
user@MX11# set protocols bgp group ToR11 peer-as 100
user@MX11# set protocols bgp group ToR11 local-as 400
user@MX11# set protocols bgp group ToR11 neighbor 192.168.3.1 family inet
unicast
user@MX11# set protocols bgp group ToR12 type external
user@MX11# set protocols bgp group ToR12 local-address 192.168.6.2

```

```

user@MX11# set protocols bgp group ToR12 export TEST
user@MX11# set protocols bgp group ToR12 export L0
user@MX11# set protocols bgp group ToR12 peer-as 200
user@MX11# set protocols bgp group ToR12 local-as 400
user@MX11# set protocols bgp group ToR12 neighbor 192.168.6.1 family inet
unicast
user@MX11# set protocols bgp group MX12 type external
user@MX11# set protocols bgp group MX12 local-address 192.168.7.1
user@MX11# set protocols bgp group MX12 export TEST
user@MX11# set protocols bgp group MX12 export L0

signaling

```

5. Configure integrated routing and bridging (IRB) interfaces that advertises the MAC and IP routes (MAC+IP type 2 routes) for hosts in the topology. The IRB configuration is the gateway for the VLANs on the hosts.

- a. The following is the IRB gateway configuration for the VLAN-1 on Host (which is the host part of VLAN-1):

[edit]

```
user@MX11# set interfaces irb unit 1 proxy-macip-advertisement
user@MX11# set interfaces irb unit 1 virtual-gateway-esi
00:11:aa:aa:aa:aa:aa:aa:aa
user@MX11# set interfaces irb unit 1 virtual-gateway-esi all-active
user@MX11# set interfaces irb unit 1 family inet address 10.11.1.12/24
virtual-gateway-address 10.11.1.10
```

- b. The following is the IRB gateway configuration for the VLAN-2 on Host (which is the host part of VLAN-2):

[edit]

```
user@MX11# set interfaces irb unit 2 proxy-macip-advertisement
user@MX11# set interfaces irb unit 2 virtual-gateway-esi
00:11:bb:bb:bb:bb:bb:bb:bb
user@MX11# set interfaces irb unit 2 virtual-gateway-esi all-active
user@MX11# set interfaces irb unit 2 family inet address 10.12.1.12/24
virtual-gateway-address 10.12.1.10
```

- c. The following is the IRB gateway configuration for the VLAN-3 on Host (which is the host part of VLAN-3):

[edit]

```
user@MX11# set interfaces irb unit 3 proxy-macip-advertisement
user@MX11# set interfaces irb unit 3 virtual-gateway-esi
00:11:cc:cc:cc:cc:cc:cc:cc
user@MX11# set interfaces irb unit 3 virtual-gateway-esi all-active
user@MX11# set interfaces irb unit 3 family inet address 10.13.1.12/24
virtual-gateway-address 10.13.1.10
```

- d. The following is the IRB gateway configuration for the VLAN-4 on Host (which is the host part of VLAN-4):

[edit]

```
user@MX11# set interfaces irb unit 4 proxy-macip-advertisement
user@MX11# set interfaces irb unit 4 virtual-gateway-esi
00:11:dd:dd:dd:dd:dd:dd:dd
user@MX11# set interfaces irb unit 4 virtual-gateway-esi all-active
user@MX11# set interfaces irb unit 4 family inet address 10.14.1.12/24
virtual-gateway-address 10.14.1.10
```

- e. The following is the IRB gateway configuration for the VLAN-5 on Host (which is the host part of VLAN-5):

[edit]

```
user@MX11# set interfaces irb unit 5 proxy-macip-advertisement
user@MX11# set interfaces irb unit 5 virtual-gateway-esi
00:11:ee:ee:ee:ee:ee:ee:ee
user@MX11# set interfaces irb unit 5 virtual-gateway-esi all-active
user@MX11# set interfaces irb unit 5 family inet address 10.15.1.12/24
virtual-gateway-address 10.15.1.10
```

6. Configure trace operations to track all Layer 2 address learning and forwarding properties.

[edit]

```
user@MX11# set protocols l2-learning traceoptions file MX11-L2ALD.log
user@MX11# set protocols l2-learning traceoptions file size 10m
user@MX11# set protocols l2-learning traceoptions level all
user@MX11# set protocols l2-learning traceoptions flag all
```

7. Configure routing policies to accept the direct loopback address route and redirect it into BGP.

[edit]

```
user@MX11# set policy-options policy-statement L0 term 1 from protocol direct
user@MX11# set policy-options policy-statement L0 term 1 from route-filter
192.0.2.21/32 exact
user@MX11# set policy-options policy-statement L0 term 1 then accept
user@MX11# set policy-options policy-statement L0 from protocol direct
user@MX11# set policy-options policy-statement L0 from route-filter
192.0.2.21/32 exact
user@MX11# set policy-options policy-statement L0 then accept
```

8. Configure community policy options.

[edit]

```
user@MX11# set policy-options community NO-EXPORT members no-advertise
user@MX11# set policy-options community NO-EXPORT members no-export
user@MX11# set policy-options community NO-EXPORT members no-export-subconfed
```

9. Apply load balance.

[edit]

```
user@MX11# set policy-options policy-statement TEST then community add
NO-EXPORT
user@MX11# set policy-options policy-statement evpn-pplb from protocol evpn
user@MX11# set policy-options policy-statement evpn-pplb then load-balance
per-packet
```

10. Configure an ESI value on the logical tunnel interface. Use the same ESI value on all other gateway/WAN edge routers in the DC1 network.

[edit]

```
user@MX11# set interfaces lt-5/1/0 esi 00:22:22:22:22:22:22:22
```

11. Configure active-active multihoming on the logical tunnel interface by including the all-active statement.

```
[edit]
```

```
user@MX11# set interfaces lt-5/1/0 esi all-active
```

12. Configure a pair of logical tunnel (lt-) interface on the MX11 gateway router to interconnect the EVPN-VXLAN instance of the data center network with the MPLS-based EVPN instance of the WAN. One logical tunnel (lt-) interface is configured as the access interface for EVPN-VXLAN and the other logical tunnel (lt-) interface is configured as the access interface for MPLS-based EVPN.

```
[edit]
```

```
user@MX11# set interfaces lt-5/1/0 unit 0 peer-unit 1
user@MX11# set interfaces lt-5/1/0 unit 0 family bridge interface-mode trunk
user@MX11# set interfaces lt-5/1/0 unit 0 family bridge vlan-id-list 1-5
user@MX11# set interfaces lt-5/1/0 unit 1 peer-unit 0
user@MX11# set interfaces lt-5/1/0 unit 1 family bridge interface-mode trunk
user@MX11# set interfaces lt-5/1/0 unit 1 family bridge vlan-id-list 1-5
```

13. Configure the loopback interface address and routing options.

```
[edit]
```

```
user@MX11# set interfaces lo0 unit 84 family inet address 192.0.2.21/32
user@MX11# set interfaces lo0 unit 84 family mpls
user@MX11# set routing-options router-id 192.0.2.21
user@MX11# set routing-options autonomous-system 300
```

14. Configure load balancing on MX11.

```
[edit]
```

```
user@MX11# set routing-options forwarding-table export evpn-pplb
```

15. Enable RSVP, MPLS, BGP, and OSPF protocols on the core interfaces. Create MPLS LSPs and specify the address of the other gateway and WAN edge routers (MX12, P, MX21, MX22).

```
[edit]
```

```
user@MX11# set protocols rsvp interface all
user@MX11# set protocols rsvp interface fxp0.0 disable
user@MX11# set protocols mpls label-switched-path MX11-T0-MX12 to 192.0.2.22
user@MX11# set protocols mpls label-switched-path MX11-T0-P to 203.0.113.1
user@MX11# set protocols mpls label-switched-path MX11-T0-MX21 to
198.51.100.21
user@MX11# set protocols mpls label-switched-path MX11-T0-MX22 to
198.51.100.22
```

```

user@MX11# set protocols mpls interface all
user@MX11# set protocols mpls interface fxp0.0 disable
user@MX11# set protocols bgp local-address 192.0.2.21
user@MX11# set protocols bgp local-as 300
user@MX11# set protocols bgp group INT type internal
user@MX11# set protocols bgp group INT local-address 192.0.2.21
user@MX11# set protocols bgp group INT family evpn signaling
user@MX11# set protocols bgp group INT export TEST
user@MX11# set protocols bgp group INT neighbor 203.0.113.1
user@MX11# set protocols ospf traffic-engineering
user@MX11# set protocols ospf area 0.0.0.0 interface ge-5/1/9.0
user@MX11# set protocols ospf area 0.0.0.0 interface lo0.84 passive

```

16. Configure EVPN-based MPLS routing instances on the MX11 router for each virtual network. Define the route distinguisher (used to identify and advertise EVPN-MPLS routes) and vrf-target (exports and tags all routes for that local VRF using the defined route target). Configure a bridge domain for each virtual router that maps VLAN IDs.

[edit]

```

user@MX11# set routing-instances EVPN-MPLS-1 instance-type virtual-switch
user@MX11# set routing-instances EVPN-MPLS-1 interface lt-5/1/0.0
user@MX11# set routing-instances EVPN-MPLS-1 route-distinguisher
192.0.2.21:100
user@MX11# set routing-instances EVPN-MPLS-1 vrf-target target:1:2
user@MX11# set routing-instances EVPN-MPLS-1 protocols evpn traceoptions
file MX11-EVPN-MPLS-1.log
user@MX11# set routing-instances EVPN-MPLS-1 protocols evpn traceoptions
file size 10m
user@MX11# set routing-instances EVPN-MPLS-1 protocols evpn traceoptions
flag all
user@MX11# set routing-instances EVPN-MPLS-1 protocols evpn extended-vlan-list
1-5
user@MX11# set routing-instances EVPN-MPLS-1 protocols evpn default-gateway
no-gateway-community
user@MX11# set routing-instances EVPN-MPLS-1 bridge-domains BD-1 domain-type
bridge
user@MX11# set routing-instances EVPN-MPLS-1 bridge-domains BD-1 vlan-id 1
user@MX11# set routing-instances EVPN-MPLS-1 bridge-domains BD-2 domain-type
bridge
user@MX11# set routing-instances EVPN-MPLS-1 bridge-domains BD-2 vlan-id 2
user@MX11# set routing-instances EVPN-MPLS-1 bridge-domains BD-3 domain-type
bridge
user@MX11# set routing-instances EVPN-MPLS-1 bridge-domains BD-3 vlan-id 3
user@MX11# set routing-instances EVPN-MPLS-1 bridge-domains BD-4 domain-type
bridge
user@MX11# set routing-instances EVPN-MPLS-1 bridge-domains BD-4 vlan-id 4
user@MX11# set routing-instances EVPN-MPLS-1 bridge-domains BD-5 domain-type
bridge
user@MX11# set routing-instances EVPN-MPLS-1 bridge-domains BD-5 vlan-id 5

```

17. Configure EVPN-VXLAN routing instances on the MX11 router for each virtual network. Define the VTEP source interface, route distinguisher (used to identify and advertise EVPN routes), and vrf-target (exports and tags all routes for that local VRF using the defined route target). Configure the EVPN protocol, encapsulation method, VNI list, and BUM traffic forwarding method. Finally, configure a bridge domain for each virtual router that maps VNIDs to VLAN IDs, and identify the BUM forwarding method.

[edit]

```
user@MX11# set routing-instances EVPN-VXLAN-1 vtep-source-interface lo0.84
user@MX11# set routing-instances EVPN-VXLAN-1 instance-type virtual-switch

```

## Configuring Data Center Gateway and WAN Edge 2 Router (MX12)

### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

Configure an MX Series router as the data center gateway and WAN edge router and name it as MX12:

1. Set the system hostname.

```
[edit]
```

```
user@MX12# set system host-name MX12
```

2. Configure the P device as the logical system of MX12 data center gateway and WAN edge router.
  - a. Configure the P device to operate in the enhanced-ip mode because the EVPN active-active functionality is supported on routers with MPCs and MIC interfaces only. A system reboot is required on committing this configuration.

```
[edit chassis]
```

```
user@P# set network-services enhanced-ip
```

- b. Configure the interfaces of the P device.

```
[edit]
```

```
user@P# set interfaces ge-1/0/4 unit 0 description "CONNECTED TO ToR12"
user@P# set interfaces ge-1/0/4 unit 0 family inet address 192.168.5.2/24
user@P# set interfaces ge-1/0/5 unit 0 description "CONNECTED TO TOR11"
user@P# set interfaces ge-1/0/5 unit 0 family inet address 192.168.4.2/24
user@P# set interfaces ge-1/0/6 unit 0 description "CONNECTED TO P"
user@P# set interfaces ge-1/0/6 unit 0 family inet address 203.0.2.1/24
user@P# set interfaces ge-1/0/6 unit 0 family mpls
user@P# set interfaces ge-1/1/0 unit 0 description "CONNECTED TO MX11"
user@P# set interfaces ge-1/1/0 unit 0 family inet address 192.168.7.2/24
```

- c. Enable RSVP, MPLS, BGP, and OSPF protocols on the core interfaces of the P device. Create MPLS LSPs and specify the address of the other gateway and WAN edge routers (MX11, MX12, MX21, MX22).

```
[edit]
```

```
user@P# set logical-systems P protocols rsvp interface all
user@P# set logical-systems P protocols mpls label-switched-path P-T0-MX11
 from 203.0.113.1
user@P# set logical-systems P protocols mpls label-switched-path P-T0-MX11
 to 192.0.2.21
user@P# set logical-systems P protocols mpls label-switched-path P-T0-MX12
```

```

to 192.0.2.22
user@P# set logical-systems P protocols mpls label-switched-path P-T0-MX21
to 198.51.100.21
user@P# set logical-systems P protocols mpls label-switched-path P-T0-MX22
to 198.51.100.22
user@P# set logical-systems P protocols mpls interface all
user@P# set logical-systems P protocols bgp local-address 203.0.113.1
user@P# set logical-systems P protocols bgp local-as 300
user@P# set logical-systems P protocols bgp group INT type internal
user@P# set logical-systems P protocols bgp group INT import
BLOCK-VXLAN-ROUTES-FROM-CORE
user@P# set logical-systems P protocols bgp group INT family evpn signaling
user@P# set logical-systems P protocols bgp group INT cluster 203.0.113.1
user@P# set logical-systems P protocols bgp group INT neighbor 192.0.2.21
user@P# set logical-systems P protocols bgp group INT neighbor 192.0.2.22
user@P# set logical-systems P protocols bgp group INT neighbor
198.51.100.21
user@P# set logical-systems P protocols bgp group INT neighbor
198.51.100.22
user@P# set logical-systems P protocols ospf traffic-engineering
user@P# set logical-systems P protocols ospf area 0.0.0.0 interface all
user@P# set logical-systems P protocols ospf area 0.0.0.0 interface lo0.86

```

- d. Configure the loopback interface address and routing options.

[edit]

```

user@P# set logical-systems P interfaces lo0 unit 86 family inet address
203.0.113.1/32
user@P# set logical-systems P interfaces lo0 unit 86 family mpls
user@P# set logical-systems P routing-options router-id 203.0.113.1
user@P# set logical-systems P routing-options autonomous-system 300

```

- e. Configure routing policies to accept the direct loopback address route and redirect it into BGP.

[edit]

```

user@P# set logical-systems P policy-options policy-statement
BLOCK-VXLAN-ROUTES-FROM-CORE term 1 from protocol bgp
user@P# set logical-systems P policy-options policy-statement
BLOCK-VXLAN-ROUTES-FROM-CORE term 1 from community RT-CORE
user@P# set logical-systems P policy-options policy-statement
BLOCK-VXLAN-ROUTES-FROM-CORE term 1 then accept
user@P# set logical-systems P policy-options policy-statement
BLOCK-VXLAN-ROUTES-FROM-CORE term 2 from protocol bgp
user@P# set logical-systems P policy-options policy-statement
BLOCK-VXLAN-ROUTES-FROM-CORE term 2 from community RT-DC1
user@P# set logical-systems P policy-options policy-statement
BLOCK-VXLAN-ROUTES-FROM-CORE term 2 then reject
user@P# set logical-systems P policy-options policy-statement
BLOCK-VXLAN-ROUTES-FROM-CORE term 3 from protocol bgp
user@P# set logical-systems P policy-options policy-statement
BLOCK-VXLAN-ROUTES-FROM-CORE term 3 from community RT-DC2
user@P# set logical-systems P policy-options policy-statement
BLOCK-VXLAN-ROUTES-FROM-CORE term 3 then reject

```

- f. Configure community policy options.

[edit]

```
user@P# set logical-systems P policy-options community RT-CORE members
target:1:2
user@P# set logical-systems P policy-options community RT-DC1 members
target:1:1
user@P# set logical-systems P policy-options community RT-DC2 members
target:1:3
```

- g. Configure trace options for the interfaces to enable trace logs.

[edit]

```
user@P# set interfaces traceoptions file R3-DCD.log
user@P# set interfaces traceoptions file size 10m
user@P# set interfaces traceoptions flag all
```

3. Configure the interfaces on the MX12 router (DC GW/WAN Edge 2) to enable the underlay connectivity to the MX11, ToR12, ToR11, and P devices, which is the EVPN-VXLAN part of DC1 network.

[edit]

```
user@MX12# set interfaces ge-1/0/4 unit 0 description "CONNECTED TO ToR12"
user@MX12# set interfaces ge-1/0/4 unit 0 family inet address 192.168.5.2/24
user@MX12# set interfaces ge-1/0/5 unit 0 description "CONNECTED TO ToR11"
user@MX12# set interfaces ge-1/0/5 unit 0 family inet address 192.168.4.2/24
user@MX12# set interfaces ge-1/0/6 unit 0 description "CONNECTED TO P"
user@MX12# set interfaces ge-1/0/6 unit 0 family inet address 203.0.2.1/24
user@MX12# set interfaces ge-1/0/6 unit 0 family mpls
user@MX12# set interfaces ge-1/1/0 unit 0 description "CONNECTED TO MX11"
user@MX12# set interfaces ge-1/1/0 unit 0 family inet address 192.168.7.2/24
```

4. Configure a multiprotocol external BGP (MP-EBGP) underlay connectivity between the gateway routers (MX11 and MX12) and ToR (ToR11 and ToR12).

[edit]

```
user@MX12# set protocols bgp group ToR11 type external
user@MX12# set protocols bgp group ToR11 local-address 192.168.4.2
user@MX12# set protocols bgp group ToR11 export TEST
user@MX12# set protocols bgp group ToR11 export L0
user@MX12# set protocols bgp group ToR11 peer-as 100
user@MX12# set protocols bgp group ToR11 local-as 500
user@MX12# set protocols bgp group ToR11 neighbor 192.168.4.1 family inet
unicast
user@MX12# set protocols bgp group ToR12 type external
user@MX12# set protocols bgp group ToR12 local-address 192.168.5.2
user@MX12# set protocols bgp group ToR12 export TEST
user@MX12# set protocols bgp group ToR12 export L0
user@MX12# set protocols bgp group ToR12 peer-as 200
user@MX12# set protocols bgp group ToR12 local-as 500
user@MX12# set protocols bgp group ToR12 neighbor 192.168.5.1 family inet
unicast
user@MX12# set protocols bgp group MX11 type external
user@MX12# set protocols bgp group MX11 local-address 192.168.7.2
user@MX12# set protocols bgp group MX11 export TEST
```

```

user@MX12# set protocols bgp group MX11 export LO
user@MX12# set protocols bgp group MX11 peer-as 400
user@MX12# set protocols bgp group MX11 local-as 500
user@MX12# set protocols bgp group MX11 neighbor 192.168.7.1 family inet
unicast

```

5. Configure a multiprotocol external BGP (MP-EBGP) overlay connectivity between the gateway routers (MX11 and MX12) and ToR (ToR11 and ToR12) and set EVPN as the signaling protocol.

[edit]

```

user@MX12# set protocols bgp group ToR11-EVPN type external
user@MX12# set protocols bgp group ToR11-EVPN multihop ttl 2
user@MX12# set protocols bgp group ToR11-EVPN multihop no-nexthop-change
user@MX12# set protocols bgp group ToR11-EVPN local-address 192.0.2.22

signaling
user@MX12# set protocols bgp group MX12-EVPN export TEST

```

6. Configure integrated routing and bridging (IRB) interfaces that advertises the MAC and IP routes (MAC+IP type 2 routes) for hosts in the topology. The IRB configuration is the gateway for the VLANs on the hosts.

- a. The following is the IRB gateway configuration for the VLAN-1 on Host (which is the host part of VLAN-1):

[edit]

```
user@MX12# set interfaces irb unit 1 proxy-macip-advertisement
user@MX12# set interfaces irb unit 1 virtual-gateway-esi
00:11:aa:aa:aa:aa:aa:aa:aa
user@MX12# set interfaces irb unit 1 virtual-gateway-esi all-active
user@MX12# set interfaces irb unit 1 family inet address 10.11.1.13/24
virtual-gateway-address 10.11.1.10
```

- b. The following is the IRB gateway configuration for the VLAN-2 on Host (which is the host part of VLAN-2):

[edit]

```
user@MX12# set interfaces irb unit 2 proxy-macip-advertisement
user@MX12# set interfaces irb unit 2 virtual-gateway-esi
00:11:bb:bb:bb:bb:bb:bb:bb
user@MX12# set interfaces irb unit 2 virtual-gateway-esi all-active
user@MX12# set interfaces irb unit 2 family inet address 10.12.1.13/24
virtual-gateway-address 10.12.1.10
```

- c. The following is the IRB gateway configuration for the VLAN-3 on Host (which is the host part of VLAN-3):

[edit]

```
user@MX12# set interfaces irb unit 3 proxy-macip-advertisement
user@MX12# set interfaces irb unit 3 virtual-gateway-esi
00:11:cc:cc:cc:cc:cc:cc:cc
user@MX12# set interfaces irb unit 3 virtual-gateway-esi all-active
user@MX12# set interfaces irb unit 3 family inet address 10.13.1.13/24
virtual-gateway-address 10.13.1.10
```

- d. The following is the IRB gateway configuration for the VLAN-4 on Host (which is the host part of VLAN-4):

[edit]

```
user@MX12# set interfaces irb unit 4 proxy-macip-advertisement
user@MX12# set interfaces irb unit 4 virtual-gateway-esi
00:11:dd:dd:dd:dd:dd:dd:dd
user@MX12# set interfaces irb unit 4 virtual-gateway-esi all-active
user@MX12# set interfaces irb unit 4 family inet address 10.14.1.13/24
virtual-gateway-address 10.14.1.10
```

- e. The following is the IRB gateway configuration for the VLAN-5 on Host (which is the host part of VLAN-5):

[edit]

```
user@MX12# set interfaces irb unit 5 proxy-macip-advertisement
user@MX12# set interfaces irb unit 5 virtual-gateway-esi
00:11:ee:ee:ee:ee:ee:ee:ee
user@MX12# set interfaces irb unit 5 virtual-gateway-esi all-active
user@MX12# set interfaces irb unit 5 family inet address 10.15.1.13/24
virtual-gateway-address 10.15.1.10
```

7. Configure trace operations to track all Layer 2 address learning and forwarding properties.

[edit]

```
user@MX12# set protocols l2-learning traceoptions file MX12-L2ALD.log
user@MX12# set protocols l2-learning traceoptions file size 10m
user@MX12# set protocols l2-learning traceoptions level all
user@MX12# set protocols l2-learning traceoptions flag all
```

8. Configure routing policies to accept the direct loopback address route and redirect it into BGP.

[edit]

```
user@MX12# set policy-options policy-statement L0 from protocol direct
user@MX12# set policy-options policy-statement L0 from route-filter
192.0.2.22/32 exact
user@MX12# set policy-options policy-statement L0 then accept
user@MX12# set policy-options policy-statement L0 term 1 from protocol direct
user@MX12# set policy-options policy-statement L0 term 1 from route-filter
192.0.2.22/32 exact
user@MX12# set policy-options policy-statement L0 term 1 then accept
user@MX12# set policy-options policy-statement TEST from protocol bgp
user@MX12# set policy-options policy-statement TEST from protocol evpn
```

9. Configure community policy options.

[edit]

```
user@MX12# set policy-options community NO-EXPORT members no-advertise
user@MX12# set policy-options community NO-EXPORT members no-export
user@MX12# set policy-options community NO-EXPORT members no-export-subconfed
```

10. Apply load balance.

[edit]

```
user@MX12# set policy-options policy-statement TEST then community add
NO-EXPORT
user@MX12# set policy-options policy-statement evpn-pplb from protocol evpn
user@MX12# set policy-options policy-statement evpn-pplb then load-balance
per-packet
```

11. Configure an ESI value on the logical tunnel interface. Use the same ESI value on all other gateway/WAN edge routers in the DC1 network.

[edit]

```
user@MX12# set interfaces lt-1/0/0 esi 00:22:22:22:22:22:22:22
```

12. Configure active-active multihoming on the logical tunnel interface by including the all-active statement.

[edit]

```
user@MX12# set interfaces lt-1/0/0 esi all-active
```

13. Configure a pair of logical tunnel (lt-) interface on the MX12 gateway router to interconnect the EVPN-VXLAN instance of the data center network with the MPLS-based EVPN instance of the WAN. One logical tunnel (lt-) interface is configured as the access interface for EVPN-VXLAN and the other logical tunnel (lt-) interface is configured as the access interface for MPLS-based EVPN.

[edit]

```
user@MX12# set interfaces lt-1/0/0 unit 0 peer-unit 1
user@MX12# set interfaces lt-1/0/0 unit 0 family bridge interface-mode trunk
user@MX12# set interfaces lt-1/0/0 unit 0 family bridge vlan-id-list 1-5
user@MX12# set interfaces lt-1/0/0 unit 1 peer-unit 0
user@MX12# set interfaces lt-1/0/0 unit 1 family bridge interface-mode trunk
user@MX12# set interfaces lt-1/0/0 unit 1 family bridge vlan-id-list 1-5
```

14. Configure the loopback interface address and routing options.

[edit]

```
user@MX12# set interfaces lo0 unit 85 family inet address 192.0.2.22/32
user@MX12# set interfaces lo0 unit 85 family mpls
user@MX12# set routing-options router-id 192.0.2.22
user@MX12# set routing-options autonomous-system 300
```

15. Configure load balancing on MX12.

[edit]

```
user@MX12# set routing-options forwarding-table export evpn-pplb
```

16. Enable RSVP, MPLS, BGP, and OSPF protocols on the core interfaces. Create MPLS LSPs and specify the address of the other gateway and WAN edge routers (MX11, MX21, P, MX22).

[edit]

```
user@MX12# set protocols rsvp interface all
user@MX12# set protocols rsvp interface fxp0.0 disable
user@MX12# set protocols mpls label-switched-path MX12-T0-MX11 to 192.0.2.21
user@MX12# set protocols mpls label-switched-path MX12-T0-P to 203.0.113.1
user@MX12# set protocols mpls label-switched-path MX12-T0-MX21 to
198.51.100.21
user@MX12# set protocols mpls label-switched-path MX12-T0-MX22 to
```

```

198.51.100.22
user@MX12# set protocols mpls interface all
user@MX12# set protocols mpls interface fxp0.0 disable
user@MX12# set protocols bgp local-address 192.0.2.22
user@MX12# set protocols bgp local-as 300
user@MX12# set protocols bgp group INT type internal
user@MX12# set protocols bgp group INT family evpn signaling
user@MX12# set protocols bgp group INT export TEST
user@MX12# set protocols bgp group INT neighbor 203.0.113.1
user@MX12# set protocols ospf traffic-engineering
user@MX12# set protocols ospf area 0.0.0.0 interface ge-1/0/6.0
user@MX12# set protocols ospf area 0.0.0.0 interface lo0.85 passive

```

17. Configure EVPN-based MPLS routing instances on the MX12 router for each virtual network. Define the route distinguisher (used to identify and advertise EVPN-MPLS routes) and vrf-target (exports and tags all routes for that local VRF using the defined route target). Configure a bridge domain for each virtual router that maps VLAN IDs.

[edit]

```

user@MX12# set routing-instances EVPN-MPLS-1 instance-type virtual-switch
user@MX12# set routing-instances EVPN-MPLS-1 interface lt-1/0/0.0
user@MX12# set routing-instances EVPN-MPLS-1 route-distinguisher
192.0.2.22:100
user@MX12# set routing-instances EVPN-MPLS-1 vrf-target target:1:2
user@MX12# set routing-instances EVPN-MPLS-1 protocols evpn traceoptions
file MX12-EVPN-MPLS-1.log
user@MX12# set routing-instances EVPN-MPLS-1 protocols evpn traceoptions
file size 10m
user@MX12# set routing-instances EVPN-MPLS-1 protocols evpn traceoptions
flag all
user@MX12# set routing-instances EVPN-MPLS-1 protocols evpn extended-vlan-list
1-5
user@MX12# set routing-instances EVPN-MPLS-1 protocols evpn default-gateway
no-gateway-community
user@MX12# set routing-instances EVPN-MPLS-1 bridge-domains BD-1 domain-type
bridge
user@MX12# set routing-instances EVPN-MPLS-1 bridge-domains BD-1 vlan-id 1
user@MX12# set routing-instances EVPN-MPLS-1 bridge-domains BD-2 domain-type
bridge
user@MX12# set routing-instances EVPN-MPLS-1 bridge-domains BD-2 vlan-id 2
user@MX12# set routing-instances EVPN-MPLS-1 bridge-domains BD-3 domain-type
bridge
user@MX12# set routing-instances EVPN-MPLS-1 bridge-domains BD-3 vlan-id 3
user@MX12# set routing-instances EVPN-MPLS-1 bridge-domains BD-4 domain-type
bridge
user@MX12# set routing-instances EVPN-MPLS-1 bridge-domains BD-4 vlan-id 4
user@MX12# set routing-instances EVPN-MPLS-1 bridge-domains BD-5 domain-type
bridge
user@MX12# set routing-instances EVPN-MPLS-1 bridge-domains BD-5 vlan-id 5

```

18. Configure EVPN-VXLAN routing instances on the MX12 router for each virtual network. Define the VTEP source interface, route distinguisher (used to identify and advertise EVPN routes), and vrf-target (exports and tags all routes for that local VRF using the defined route target). Configure the EVPN protocol, encapsulation method, VNI list, and BUM traffic forwarding method. Finally, configure a bridge

domain for each virtual router that maps VNIDs to VLAN IDs, and identify the BUM forwarding method.

[edit]

```

user@MX12# set routing-instances EVPN-VXLAN-1 vtep-source-interface lo0.85

### Configuring Data Center Gateway and WAN Edge 3 Router (MX21)

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

Configure an MX Series router as the data center gateway and WAN edge router and name it as MX21:

1. Set the system hostname.

[edit]

```
user@MX21# set system host-name MX21
```

2. Configure the interfaces on the MX21 router (DC GW/WAN Edge 3) to enable the underlay connectivity to the MX22, ToR22, ToR21, and P devices, which is the EVPN-VXLAN part of DC2 network.

[edit]

```

user@MX21# set interfaces ge-3/0/0 unit 0 description "CONNECTED TO MX22"
user@MX21# set interfaces ge-3/0/0 unit 0 family inet address 192.168.13.1/24
user@MX21# set interfaces ge-3/1/0 unit 0 description "CONNECTED TO ToR22"
user@MX21# set interfaces ge-3/1/0 unit 0 family inet address 192.168.8.1/24
user@MX21# set interfaces ge-5/0/0 unit 0 description "CONNECTED TO P"
user@MX21# set interfaces ge-5/0/0 unit 0 family inet address 203.0.4.1/24
user@MX21# set interfaces ge-5/0/0 unit 0 family mpls
user@MX21# set interfaces ge-5/0/1 unit 0 description "CONNECTED TO ToR21"
user@MX21# set interfaces ge-5/0/1 unit 0 family inet address 192.168.9.1/24

```

3. Configure a multiprotocol external BGP (MP-EBGP) underlay connectivity between the gateway routers (MX21 and MX22) and ToR (ToR21 and ToR22).

[edit]

```

user@MX21# set protocols bgp group ToR21 type external
user@MX21# set protocols bgp group ToR21 local-address 192.168.9.1
user@MX21# set protocols bgp group ToR21 export TEST
user@MX21# set protocols bgp group ToR21 export L0
user@MX21# set protocols bgp group ToR21 peer-as 600
user@MX21# set protocols bgp group ToR21 local-as 800
user@MX21# set protocols bgp group ToR21 neighbor 192.168.9.2 family inet
unicast
user@MX21# set protocols bgp group ToR22 type external
user@MX21# set protocols bgp group ToR22 local-address 192.168.8.1
user@MX21# set protocols bgp group ToR22 export TEST
user@MX21# set protocols bgp group ToR22 export L0

```

```

user@MX21# set protocols bgp group ToR22 peer-as 700
user@MX21# set protocols bgp group ToR22 local-as 800
user@MX21# set protocols bgp group ToR22 neighbor 192.168.8.2 family inet
unicast
user@MX21# set protocols bgp group MX22 type external
user@MX21# set protocols bgp group MX22 local-address 192.168.13.1
user@MX21# set protocols bgp group MX22 export TEST
user@MX21# set protocols bgp group MX22 export LO
user@MX21# set protocols bgp group MX22 peer-as 900
user@MX21# set protocols bgp group MX22 local-as 800
user@MX21# set protocols bgp group MX22 neighbor 10.115.15.2 family inet
unicast

```

4. Configure a multiprotocol external BGP (MP-EBGP) overlay connectivity between the gateway routers (MX21 and MX22) and ToR (ToR21 and ToR22) and set EVPN as the signaling protocol.

[edit]

```

user@MX21# set protocols bgp group ToR21-EVPN type external
user@MX21# set protocols bgp group ToR21-EVPN multihop ttl 2
user@MX21# set protocols bgp group ToR21-EVPN multihop no-nexthop-change
user@MX21# set protocols bgp group ToR21-EVPN local-address 198.51.100.21
user@MX21# set protocols bgp group ToR21-EVPN peer-as 600
user@MX21# set protocols bgp group ToR21-EVPN local-as 800
user@MX21# set protocols bgp group ToR21-EVPN neighbor 198.51.100.11 family
evpn signaling
user@MX21# set protocols bgp group ToR22-EVPN type external
user@MX21# set protocols bgp group ToR22-EVPN multihop ttl 2
user@MX21# set protocols bgp group ToR22-EVPN multihop no-nexthop-change
user@MX21# set protocols bgp group ToR22-EVPN local-address 198.51.100.21
user@MX21# set protocols bgp group ToR22-EVPN peer-as 700
user@MX21# set protocols bgp group ToR22-EVPN local-as 800
user@MX21# set protocols bgp group ToR22-EVPN neighbor 198.51.100.12 family
evpn signaling
user@MX21# set protocols bgp group MX22-EVPN type external
user@MX21# set protocols bgp group MX22-EVPN multihop ttl 2
user@MX21# set protocols bgp group MX22-EVPN multihop no-nexthop-change
user@MX21# set protocols bgp group MX22-EVPN local-address 198.51.100.21
user@MX21# set protocols bgp group MX22-EVPN peer-as 900
user@MX21# set protocols bgp group MX22-EVPN local-as 800
user@MX21# set protocols bgp group MX22-EVPN neighbor 198.51.100.22 family
evpn signaling

```

5. Configure integrated routing and bridging (IRB) interfaces that advertises the MAC and IP routes (MAC+IP type 2 routes) for hosts in the topology. The IRB configuration is the gateway for the VLANs on the hosts.

- a. The following is the IRB gateway configuration for the VLAN-1 on Host (which is the host part of VLAN-1):

[edit]

```
user@MX21# set interfaces irb unit 1 proxy-macip-advertisement
user@MX21# set interfaces irb unit 1 virtual-gateway-esi
00:22:aa:aa:aa:aa:aa:aa:aa
user@MX21# set interfaces irb unit 1 virtual-gateway-esi all-active
user@MX21# set interfaces irb unit 1 family inet address 10.11.1.14/24
virtual-gateway-address 10.11.1.11
```

- b. The following is the IRB gateway configuration for the VLAN-2 on Host (which is the host part of VLAN-2):

[edit]

```
user@MX21# set interfaces irb unit 2 proxy-macip-advertisement
user@MX21# set interfaces irb unit 2 virtual-gateway-esi
00:22:bb:bb:bb:bb:bb:bb:bb
user@MX21# set interfaces irb unit 2 virtual-gateway-esi all-active
user@MX21# set interfaces irb unit 2 family inet address 10.12.1.14/24
virtual-gateway-address 10.12.1.11
```

- c. The following is the IRB gateway configuration for the VLAN-3 on Host (which is the host part of VLAN-3):

[edit]

```
user@MX21# set interfaces irb unit 3 proxy-macip-advertisement
user@MX21# set interfaces irb unit 3 virtual-gateway-esi
00:22:cc:cc:cc:cc:cc:cc:cc
user@MX21# set interfaces irb unit 3 virtual-gateway-esi all-active
user@MX21# set interfaces irb unit 3 family inet address 10.13.1.14/24
virtual-gateway-address 10.13.1.11
```

- d. The following is the IRB gateway configuration for the VLAN-4 on Host (which is the host part of VLAN-4):

[edit]

```
user@MX21# set interfaces irb unit 4 proxy-macip-advertisement
user@MX21# set interfaces irb unit 4 virtual-gateway-esi
00:22:dd:dd:dd:dd:dd:dd:dd
user@MX21# set interfaces irb unit 4 virtual-gateway-esi all-active
user@MX21# set interfaces irb unit 4 family inet address 10.14.1.14/24
virtual-gateway-address 10.14.1.11
```

- e. The following is the IRB gateway configuration for the VLAN-5 on Host (which is the host part of VLAN-5):

[edit]

```
user@MX21# set interfaces irb unit 5 proxy-macip-advertisement
user@MX21# set interfaces irb unit 5 virtual-gateway-esi
00:22:ee:ee:ee:ee:ee:ee:ee
user@MX21# set interfaces irb unit 5 virtual-gateway-esi all-active
user@MX21# set interfaces irb unit 5 family inet address 10.15.1.14/24
virtual-gateway-address 10.15.1.11
```

6. Configure trace operations to track all Layer 2 address learning and forwarding properties.

[edit]

```
user@MX21# set protocols l2-learning traceoptions file MX21-L2ALD.log
user@MX21# set protocols l2-learning traceoptions file size 10m
user@MX21# set protocols l2-learning traceoptions level all
user@MX21# set protocols l2-learning traceoptions flag all
```

7. Configure routing policies to accept the direct loopback address route and redirect it into BGP.

[edit]

```
user@MX21# set policy-options policy-statement L0 from protocol direct
user@MX21# set policy-options policy-statement L0 from route-filter
198.51.100.21/32 exact
user@MX21# set policy-options policy-statement L0 then accept
user@MX21# set policy-options policy-statement TEST1 term 1 from protocol
bgp
user@MX21# set policy-options policy-statement TEST1 term 1 from external
user@MX21# set policy-options policy-statement TEST1 term 1 then reject
```

8. Configure community policy options.

[edit]

```
user@MX21# set policy-options community NO-EXPORT members no-advertise
user@MX21# set policy-options community NO-EXPORT members no-export
user@MX21# set policy-options community NO-EXPORT members no-export-subconfed
```

9. Apply load balance.

[edit]

```
user@MX21# set policy-options policy-statement TEST then community add
NO-EXPORT
user@MX21# set policy-options policy-statement evpn-pplb from protocol evpn
user@MX21# set policy-options policy-statement evpn-pplb then load-balance
per-packet
```

10. Configure an ESI value on the logical tunnel interface. Use the same ESI value on all other gateway/WAN edge routers in the DC2 network.

[edit]

```
user@MX21# set interfaces lt-5/0/0 esi 00:33:33:33:33:33:33:33:33:33
```

11. Configure active-active multihoming on the logical tunnel interface by including the all-active statement.

```
[edit]
```

```
user@MX21# set interfaces lt-5/0/0 esi all-active
```

12. Configure a pair of logical tunnel (lt-) interface on the MX21 gateway router to interconnect the EVPN-VXLAN instance of the data center network with the MPLS-based EVPN instance of the WAN. One logical tunnel (lt-) interface is configured as the access interface for EVPN-VXLAN and the other logical tunnel (lt-) interface is configured as the access interface for MPLS-based EVPN.

```
[edit]
```

```
user@MX21# set interfaces lt-5/0/0 unit 0 peer-unit 1
user@MX21# set interfaces lt-5/0/0 unit 0 family bridge interface-mode trunk
user@MX21# set interfaces lt-5/0/0 unit 0 family bridge vlan-id-list 1-5
user@MX21# set interfaces lt-5/0/0 unit 1 peer-unit 0
user@MX21# set interfaces lt-5/0/0 unit 1 family bridge interface-mode trunk
user@MX21# set interfaces lt-5/0/0 unit 1 family bridge vlan-id-list 1-5
```

13. Configure the loopback interface address and routing options.

```
[edit]
```

```
user@MX21# set interfaces lo0 unit 87 family inet address 198.51.100.21/32
user@MX21# set interfaces lo0 unit 87 family mpls
user@MX21# set routing-options router-id 198.51.100.21
user@MX21# set routing-options autonomous-system 300
```

14. Configure load balancing on MX21.

```
[edit]
```

```
user@MX21# set routing-options forwarding-table export evpn-pplb
```

15. Enable RSVP, MPLS, BGP, and OSPF protocols on the core interfaces. Create MPLS LSPs and specify the address of the other gateway and WAN edge routers (MX11, MX12, P, MX22).

```
[edit]
```

```
user@MX21# set protocols rsvp interface all
user@MX21# set protocols rsvp interface fxp0.0 disable
user@MX21# set protocols mpls label-switched-path MX21-T0-MX11 to 192.0.2.21
user@MX21# set protocols mpls label-switched-path MX21-T0-MX12 to 192.0.2.22
user@MX21# set protocols mpls label-switched-path MX21-T0-P to 203.0.113.1
user@MX21# set protocols mpls label-switched-path MX21-T0-MX22 to
198.51.100.22
user@MX21# set protocols mpls interface all
```

```

user@MX21# set protocols mpls interface fxp0.0 disable
user@MX21# set protocols bgp local-address 198.51.100.21
user@MX21# set protocols bgp export TEST
user@MX21# set protocols bgp local-as 300
user@MX21# set protocols bgp group INT type internal
user@MX21# set protocols bgp group INT local-address 198.51.100.21
user@MX21# set protocols bgp group INT family evpn signaling
user@MX21# set protocols bgp group INT export TEST1
user@MX21# set protocols bgp group INT neighbor 203.0.113.1
user@MX21# set protocols ospf traffic-engineering
user@MX21# set protocols ospf area 0.0.0.0 interface ge-5/0/0.0
user@MX21# set protocols ospf area 0.0.0.0 interface lo0.87 passive

```

16. Configure EVPN-based MPLS routing instances on the MX21 router for each virtual network. Define the route distinguisher (used to identify and advertise EVPN-MPLS routes) and vrf-target (exports and tags all routes for that local VRF using the defined route target). Configure a bridge domain for each virtual router that maps VLAN IDs.

[edit]

```

user@MX21# set routing-instances EVPN-MPLS-1 instance-type virtual-switch
user@MX21# set routing-instances EVPN-MPLS-1 interface lt-5/0/0.0
user@MX21# set routing-instances EVPN-MPLS-1 route-distinguisher
198.51.100.21:100
user@MX21# set routing-instances EVPN-MPLS-1 vrf-target target:1:2
user@MX21# set routing-instances EVPN-MPLS-1 protocols evpn traceoptions
file MX21-EVPN-MPLS-1.log
user@MX21# set routing-instances EVPN-MPLS-1 protocols evpn traceoptions
file size 10m
user@MX21# set routing-instances EVPN-MPLS-1 protocols evpn traceoptions
flag all
user@MX21# set routing-instances EVPN-MPLS-1 protocols evpn extended-vlan-list

user@MX21# set routing-instances EVPN-MPLS-1 bridge-domains BD-1 vlan-id 1
user@MX21# set routing-instances EVPN-MPLS-1 bridge-domains BD-2 domain-type
bridge
user@MX21# set routing-instances EVPN-MPLS-1 bridge-domains BD-2 vlan-id 2
user@MX21# set routing-instances EVPN-MPLS-1 bridge-domains BD-3 domain-type
bridge
user@MX21# set routing-instances EVPN-MPLS-1 bridge-domains BD-3 vlan-id 3
user@MX21# set routing-instances EVPN-MPLS-1 bridge-domains BD-4 domain-type
bridge
user@MX21# set routing-instances EVPN-MPLS-1 bridge-domains BD-4 vlan-id 4
user@MX21# set routing-instances EVPN-MPLS-1 bridge-domains BD-5 domain-type
bridge
user@MX21# set routing-instances EVPN-MPLS-1 bridge-domains BD-5 vlan-id 5

```

17. Configure EVPN-VXLAN routing instances on the MX21 router for each virtual network. Define the VTEP source interface, route distinguisher (used to identify and advertise EVPN routes), and vrf-target (exports and tags all routes for that local VRF using the defined route target). Configure the EVPN protocol, encapsulation method, VNI list, and BUM traffic forwarding method. Finally, configure a bridge

domain for each virtual router that maps VNIDs to VLAN IDs, and identify the BUM forwarding method.

[edit]

```

## Configuring Data Center Gateway and WAN Edge 4 Router (MX22)

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

Configure an MX Series router as the data center gateway and WAN edge router and name it as MX22:

1. Set the system hostname.

[edit]

```
user@MX22# set system host-name MX22
```

2. Configure the interfaces on the MX22 router (DC GW/WAN Edge 4) to enable the underlay connectivity to the MX22, ToR21, MX21, and P devices, which is the EVPN-VXLAN part of DC2 network.

[edit]

```

user@MX22# set interfaces xe-0/0/0 unit 0 description "CONNECTED TO ToR22"
user@MX22# set interfaces xe-0/0/0 unit 0 family inet address 192.168.11.1/24
user@MX22# set interfaces xe-0/0/1 unit 0 description "CONNECTED TO ToR21"
user@MX22# set interfaces xe-0/0/1 unit 0 family inet address 192.168.10.1/24
user@MX22# set interfaces ge-1/0/0 unit 0 description "CONNECTED TO MX21"
user@MX22# set interfaces ge-1/0/0 unit 0 family inet address 10.115.15.2/24
user@MX22# set interfaces ge-1/0/2 unit 0 description "CONNECTED TO P"
user@MX22# set interfaces ge-1/0/2 unit 0 family inet address 203.0.3.1/24
user@MX22# set interfaces ge-1/0/2 unit 0 family mpls

```

3. Configure a multiprotocol external BGP (MP-EBGP) underlay connectivity between the gateway routers (MX21 and MX22) and ToR (ToR21 and ToR22).

[edit]

```

user@MX22# set protocols bgp group ToR21 type external
user@MX22# set protocols bgp group ToR21 local-address 192.168.10.1
user@MX22# set protocols bgp group ToR21 export TEST
user@MX22# set protocols bgp group ToR21 export L0
user@MX22# set protocols bgp group ToR21 peer-as 600
user@MX22# set protocols bgp group ToR21 local-as 900
user@MX22# set protocols bgp group ToR21 neighbor 10.102.2.1 family inet
unicast
user@MX22# set protocols bgp group ToR22 type external
user@MX22# set protocols bgp group ToR22 local-address 192.168.11.1
user@MX22# set protocols bgp group ToR22 export TEST
user@MX22# set protocols bgp group ToR22 export L0
user@MX22# set protocols bgp group ToR22 peer-as 700

```

```

user@MX22# set protocols bgp group ToR22 local-as 900
user@MX22# set protocols bgp group ToR22 neighbor 192.168.11.2 family inet
unicast
user@MX22# set protocols bgp group MX21 type external
user@MX22# set protocols bgp group MX21 local-address 10.115.15.2
user@MX22# set protocols bgp group MX21 export TEST
user@MX22# set protocols bgp group MX21 export L0
user@MX22# set protocols bgp group MX21 peer-as 800
user@MX22# set protocols bgp group MX21 local-as 900
user@MX22# set protocols bgp group MX21 neighbor 192.168.13.1 family inet
unicast

```

4. Configure a multiprotocol external BGP (MP-EBGP) overlay connectivity between the gateway routers (MX21 and MX22) and ToR (ToR21 and ToR22) and set EVPN as the signaling protocol.

[edit]

```

user@MX22# set protocols bgp group ToR21-EVPN type external
user@MX22# set protocols bgp group ToR21-EVPN multihop ttl 2
user@MX22# set protocols bgp group ToR21-EVPN multihop no-nexthop-change
user@MX22# set protocols bgp group ToR21-EVPN local-address 198.51.100.22
user@MX22# set protocols bgp group ToR21-EVPN peer-as 600
user@MX22# set protocols bgp group ToR21-EVPN local-as 900
user@MX22# set protocols bgp group ToR21-EVPN neighbor 198.51.100.11 family
evpn signaling
user@MX22# set protocols bgp group ToR22-EVPN type external
user@MX22# set protocols bgp group ToR22-EVPN multihop ttl 2
user@MX22# set protocols bgp group ToR22-EVPN multihop no-nexthop-change
user@MX22# set protocols bgp group ToR22-EVPN local-address 198.51.100.22
user@MX22# set protocols bgp group ToR22-EVPN peer-as 700
user@MX22# set protocols bgp group ToR22-EVPN local-as 900
user@MX22# set protocols bgp group ToR22-EVPN neighbor 198.51.100.12 family
evpn signaling
user@MX22# set protocols bgp group MX21-EVPN type external
user@MX22# set protocols bgp group MX21-EVPN multihop ttl 2
user@MX22# set protocols bgp group MX21-EVPN multihop no-nexthop-change
user@MX22# set protocols bgp group MX21-EVPN local-address 198.51.100.22
user@MX22# set protocols bgp group MX21-EVPN peer-as 800
user@MX22# set protocols bgp group MX21-EVPN local-as 900
user@MX22# set protocols bgp group MX21-EVPN neighbor 198.51.100.21 family
evpn signaling

```

5. Configure integrated routing and bridging (IRB) interfaces that advertises the MAC and IP routes (MAC+IP type 2 routes) for hosts in the topology. The IRB configuration is the gateway for the VLANs on the hosts.

- a. The following is the IRB gateway configuration for the VLAN-1 on Host (which is the host part of VLAN-1):

[edit]

```
user@MX22# set interfaces irb unit 1 proxy-macip-advertisement
user@MX22# set interfaces irb unit 1 virtual-gateway-esi
00:22:aa:aa:aa:aa:aa:aa:aa
user@MX22# set interfaces irb unit 1 virtual-gateway-esi all-active
user@MX22# set interfaces irb unit 1 family inet address 10.11.1.15/24
virtual-gateway-address 10.11.1.11
```

- b. The following is the IRB gateway configuration for the VLAN-2 on Host (which is the host part of VLAN-2):

[edit]

```
user@MX22# set interfaces irb unit 2 proxy-macip-advertisement
user@MX22# set interfaces irb unit 2 virtual-gateway-esi
00:22:bb:bb:bb:bb:bb:bb:bb
user@MX22# set interfaces irb unit 2 virtual-gateway-esi all-active
user@MX22# set interfaces irb unit 2 family inet address 10.12.1.15/24
virtual-gateway-address 10.12.1.11
```

- c. The following is the IRB gateway configuration for the VLAN-3 on Host (which is the host part of VLAN-3):

[edit]

```
user@MX22# set interfaces irb unit 3 proxy-macip-advertisement
user@MX22# set interfaces irb unit 3 virtual-gateway-esi
00:22:cc:cc:cc:cc:cc:cc:cc
user@MX22# set interfaces irb unit 3 virtual-gateway-esi all-active
user@MX22# set interfaces irb unit 3 family inet address 10.13.1.15/24
virtual-gateway-address 10.13.1.11
```

- d. The following is the IRB gateway configuration for the VLAN-4 on Host (which is the host part of VLAN-4):

[edit]

```
user@MX22# set interfaces irb unit 4 proxy-macip-advertisement
user@MX22# set interfaces irb unit 4 virtual-gateway-esi
00:22:dd:dd:dd:dd:dd:dd:dd
user@MX22# set interfaces irb unit 4 virtual-gateway-esi all-active
user@MX22# set interfaces irb unit 4 family inet address 10.14.1.15/24
virtual-gateway-address 10.14.1.11
```

- e. The following is the IRB gateway configuration for the VLAN-5 on Host (which is the host part of VLAN-5):

[edit]

```
user@MX22# set interfaces irb unit 5 proxy-macip-advertisement
user@MX22# set interfaces irb unit 5 virtual-gateway-esi
00:22:ee:ee:ee:ee:ee:ee:ee
user@MX22# set interfaces irb unit 5 virtual-gateway-esi all-active
user@MX22# set interfaces irb unit 5 family inet address 10.15.1.15/24
virtual-gateway-address 10.15.1.11
```

6. Configure trace operations to track all Layer 2 address learning and forwarding properties.

[edit]

```
user@MX22# set protocols l2-learning traceoptions file MX22-L2ALD.log
user@MX22# set protocols l2-learning traceoptions file size 10m
user@MX22# set protocols l2-learning traceoptions level all
user@MX22# set protocols l2-learning traceoptions flag all
```

7. Configure routing policies to accept the direct loopback address route and redirect it into BGP.

[edit]

```
user@MX22# set policy-options policy-statement L0 from protocol direct
user@MX22# set policy-options policy-statement L0 from route-filter
198.51.100.22/32 exact
user@MX22# set policy-options policy-statement L0 then accept
user@MX22# set policy-options policy-statement TEST1 term 1 from protocol
bgp
user@MX22# set policy-options policy-statement TEST1 term 1 from external
user@MX22# set policy-options policy-statement TEST1 term 1 then reject
```

8. Configure community policy options.

[edit]

```
user@MX22# set policy-options community NO-EXPORT members no-advertise
user@MX22# set policy-options community NO-EXPORT members no-export
user@MX22# set policy-options community NO-EXPORT members no-export-subconfed
```

9. Apply load balance.

[edit]

```
user@MX22# set policy-options policy-statement TEST then community add
NO-EXPORT
user@MX22# set policy-options policy-statement evpn-pplb from protocol evpn
user@MX22# set policy-options policy-statement evpn-pplb then load-balance
per-packet
```

10. Configure an ESI value on the logical tunnel interface. Use the same ESI value on all other gateway/WAN edge routers in the DC2 network.

[edit]

```
user@MX22# set interfaces lt-1/0/0 esi 00:33:33:33:33:33:33:33
```

11. Configure active-active multihoming on the logical tunnel interface by including the all-active statement.

```
[edit]
```

```
user@MX22# set interfaces lt-1/0/0 esi all-active
```

12. Configure a pair of logical tunnel (lt-) interface on the MX22 gateway router to interconnect the EVPN-VXLAN instance of the data center network with the MPLS-based EVPN instance of the WAN. One logical tunnel (lt-) interface is configured as the access interface for EVPN-VXLAN and the other logical tunnel (lt-) interface is configured as the access interface for MPLS-based EVPN.

```
[edit]
```

```
user@MX22# set interfaces lt-1/0/0 unit 0 peer-unit 1
user@MX22# set interfaces lt-1/0/0 unit 0 family bridge interface-mode trunk
user@MX22# set interfaces lt-1/0/0 unit 0 family bridge vlan-id-list 1-5
user@MX22# set interfaces lt-1/0/0 unit 1 peer-unit 0
user@MX22# set interfaces lt-1/0/0 unit 1 family bridge interface-mode trunk
user@MX22# set interfaces lt-1/0/0 unit 1 family bridge vlan-id-list 1-5
```

13. Configure the loopback interface address and routing options.

```
[edit]
```

```
user@MX22# set interfaces lo0 unit 88 family inet address 198.51.100.22/32
user@MX22# set routing-options router-id 198.51.100.22
user@MX22# set routing-options autonomous-system 300
```

14. Configure load balancing on MX22.

```
[edit]
```

```
user@MX22# set routing-options forwarding-table export evpn-pplb
```

15. Enable RSVP, MPLS, BGP, and OSPF protocols on the core interfaces. Create MPLS LSPs and specify the address of the other gateway and WAN edge routers (MX11, MX12, P, MX21).

```
[edit]
```

```
user@MX22# set protocols rsvp interface all
user@MX22# set protocols rsvp interface fxp0.0 disable
user@MX22# set protocols mpls label-switched-path MX22-T0-MX11 to 192.0.2.21
user@MX22# set protocols mpls label-switched-path MX22-T0-MX12 to 192.0.2.22
user@MX22# set protocols mpls label-switched-path MX22-T0-P to 203.0.113.1
user@MX22# set protocols mpls label-switched-path MX22-T0-MX21 to
198.51.100.21
user@MX22# set protocols mpls interface all
user@MX22# set protocols mpls interface fxp0.0 disable
```

```

user@MX22# set protocols bgp local-address 198.51.100.22
user@MX22# set protocols bgp export TEST
user@MX22# set protocols bgp local-as 300
user@MX22# set protocols bgp group INT type internal
user@MX22# set protocols bgp group INT family evpn signaling
user@MX22# set protocols bgp group INT export TEST1
user@MX22# set protocols bgp group INT neighbor 203.0.113.1
user@MX22# set protocols ospf traffic-engineering
user@MX22# set protocols ospf area 0.0.0.0 interface ge-1/0/2.0
user@MX22# set protocols ospf area 0.0.0.0 interface lo0.88 passive

```

16. Configure EVPN-based MPLS routing instances on the MX22 router for each virtual network. Define the route distinguisher (used to identify and advertise EVPN-MPLS routes) and vrf-target (exports and tags all routes for that local VRF using the defined route target). Configure a bridge domain for each virtual router that maps VLAN IDs.

[edit]

```

user@MX22# set routing-instances EVPN-MPLS-1 instance-type virtual-switch
user@MX22# set routing-instances EVPN-MPLS-1 interface lt-1/0/0.0

user@MX22# set routing-instances EVPN-MPLS-1 bridge-domains BD-5 vlan-id 5

```

17. Configure EVPN-VXLAN routing instances on the MX22 router for each virtual network. Define the VTEP source interface, route distinguisher (used to identify and advertise EVPN routes), and vrf-target (exports and tags all routes for that local VRF using the defined route target). Configure the EVPN protocol, encapsulation method, VNI list, and BUM traffic forwarding method. Finally, configure a bridge domain for each virtual router that maps VNIDs to VLAN IDs, and identify the BUM forwarding method.

[edit]

## Configuring ToR21

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

Configure the MX router as ToR21:

1. Set the system hostname.

```
[edit]
user@ToR21# set system host-name ToR21
```

2. Configure the interfaces and bridge domains on the CE4 device to enable Layer 2 connectivity.

```
[edit]

user@ce4# set logical-systems CE-4 interfaces ge-1/0/9 unit 0 description
"CONNECTED TO Host 4"
user@ce4# set logical-systems CE-4 interfaces ge-1/0/9 unit 0 family bridge
interface-mode trunk
user@ce4# set logical-systems CE-4 interfaces ge-1/0/9 unit 0 family bridge
vlan-id-list 1-5
user@ce4# set logical-systems CE-4 interfaces ge-1/1/6 unit 0 description
"CONNECTED TO ToR21"
user@ce4# set logical-systems CE-4 interfaces ge-1/1/6 unit 0 family bridge
interface-mode trunk
user@ce4# set logical-systems CE-4 interfaces ge-1/1/6 unit 0 family bridge
vlan-id-list 1-5
user@ce4# set logical-systems CE-4 bridge-domains BD-1 domain-type bridge
user@ce4# set logical-systems CE-4 bridge-domains BD-1 vlan-id 1
user@ce4# set logical-systems CE-4 bridge-domains BD-2 domain-type bridge
user@ce4# set logical-systems CE-4 bridge-domains BD-2 vlan-id 2
user@ce4# set logical-systems CE-4 bridge-domains BD-3 domain-type bridge
user@ce4# set logical-systems CE-4 bridge-domains BD-3 vlan-id 3
user@ce4# set logical-systems CE-4 bridge-domains BD-4 domain-type bridge
user@ce4# set logical-systems CE-4 bridge-domains BD-4 vlan-id 4
user@ce4# set logical-systems CE-4 bridge-domains BD-5 domain-type bridge
user@ce4# set logical-systems CE-4 bridge-domains BD-5 vlan-id 5
```

3. Configure trace options for the interfaces to enable trace logs.

```
[edit]

user@ce4# set interfaces traceoptions file R6-DCD.log
user@ce4# set interfaces traceoptions file size 10m
user@ce4# set interfaces traceoptions flag all
```

4. Set the number of aggregated Ethernet interfaces.

```
[edit]
```

```
user@ToR21# set chassis aggregated-devices ethernet device-count 1
```

5. Configure the interfaces on the ToR21 device to connect to the MX22, CE-5, CE-4, ToR22, and MX21 devices to enable underlay connectivity.

[edit]

```
user@ToR21# set interfaces xe-0/0/0 unit 0 description "CONNECTED TO MX22"
user@ToR21# set interfaces xe-0/0/0 unit 0 family inet address 192.168.10.2/24
user@ToR21# set interfaces ge-1/0/0 description "CONNECTED TO CE-5"
user@ToR21# set interfaces ge-1/0/0 gigether-options 802.3ad ae0
user@ToR21# set interfaces ge-1/0/1 unit 0 description "CONNECTED TO MX21"
user@ToR21# set interfaces ge-1/0/1 unit 0 family inet address
192.168.101.1/24
user@ToR21# set interfaces ge-1/0/6 unit 0 description "CONNECTED TO CE-4"
user@ToR21# set interfaces ge-1/0/6 unit 0 family bridge interface-mode trunk
user@ToR21# set interfaces ge-1/0/6 unit 0 family bridge vlan-id-list 1-5
user@ToR21# set interfaces ge-1/1/3 unit 0 description "CONNECTED TO ToR22"
user@ToR21# set interfaces ge-1/1/3 unit 0 family inet address 192.168.12.1/24
```

6. Configure a Link Aggregation Control Protocol (LACP)-enabled link aggregation group (LAG) interface towards the CE-5 end host device. The ESI value is globally unique across the entire EVPN domain. The all-active configuration enables ToR21 and ToR22 to forward traffic to, and from the CE devices, such that all CE links are actively used.

[edit]

```
user@ToR21# set interfaces ae0 esi 00:44:44:44:44:44:44:44:44:44
user@ToR21# set interfaces ae0 esi all-active
user@ToR21# set interfaces ae0 aggregated-ether-options lacp active
user@ToR21# set interfaces ae0 aggregated-ether-options lacp periodic fast
user@ToR21# set interfaces ae0 aggregated-ether-options lacp system-id
22:22:22:22:22:22
user@ToR21# set interfaces ae0 unit 0 family bridge interface-mode trunk
user@ToR21# set interfaces ae0 unit 0 family bridge vlan-id-list 1-5
```

7. Configure the loopback interface address and routing options.

[edit]

```
user@ToR21# set interfaces lo0 unit 90 family inet address 198.51.100.11/32
user@ToR21# set routing-options router-id 198.51.100.11
user@ToR21# set routing-options autonomous-system 600
```

8. Configure load balancing on ToR21.

[edit]

```
user@ToR21# set routing-options forwarding-table export evpn-pplb
```

9. Configure a multiprotocol external BGP (MP-EBGP) underlay connectivity between the ToR (ToR21 and ToR22) and gateway routers (MX21 and MX22).

[edit]

```

user@ToR21# set protocols bgp export TEST
user@ToR21# set protocols bgp local-as 600
user@ToR21# set protocols bgp group MX21 type external
user@ToR21# set protocols bgp group MX21 local-address 192.168.9.2
user@ToR21# set protocols bgp group MX21 export LO
user@ToR21# set protocols bgp group MX21 export TEST
user@ToR21# set protocols bgp group MX21 peer-as 800
user@ToR21# set protocols bgp group MX21 local-as 600
user@ToR21# set protocols bgp group MX21 neighbor 192.168.9.1 family inet
unicast
user@ToR21# set protocols bgp group MX22 type external
user@ToR21# set protocols bgp group MX22 local-address 10.102.2.1
user@ToR21# set protocols bgp group MX22 export LO
user@ToR21# set protocols bgp group MX22 export TEST
user@ToR21# set protocols bgp group MX22 peer-as 900
user@ToR21# set protocols bgp group MX22 local-as 600
user@ToR21# set protocols bgp group MX22 neighbor 192.168.10.1 family inet
unicast
user@ToR21# set protocols bgp group ToR22 type external
user@ToR21# set protocols bgp group ToR22 local-address 10.105.5.1
user@ToR21# set protocols bgp group ToR22 export LO
user@ToR21# set protocols bgp group ToR22 export TEST
user@ToR21# set protocols bgp group ToR22 peer-as 700
user@ToR21# set protocols bgp group ToR22 local-as 600
user@ToR21# set protocols bgp group ToR22 neighbor 192.168.12.2 family inet
unicast

```

10. Configure a multiprotocol external BGP (MP-EBGP) overlay between the ToR (ToR21 and ToR22) and gateway routers (MX21 and MX22) and set EVPN as the signaling protocol.
  - a. Configure a MP-EBGP overlay to connect between ToR21 and MX21 using EVPN signaling.

[edit]

```

user@ToR21# set protocols bgp group MX21-EVPN type external
user@ToR21# set protocols bgp group MX21-EVPN multihop ttl 2
user@ToR21# set protocols bgp group MX21-EVPN multihop no-nexthop-change
user@ToR21# set protocols bgp group MX21-EVPN local-address 198.51.100.11
user@ToR21# set protocols bgp group MX21-EVPN peer-as 800
user@ToR21# set protocols bgp group MX21-EVPN local-as 600
user@ToR21# set protocols bgp group MX21-EVPN neighbor 198.51.100.21 family
evpn signaling

```

- b. Configure a MP-EBGP overlay to connect between ToR21 and MX22 using EVPN signaling.

[edit]

```

user@ToR21# set protocols bgp group MX22-EVPN type external
user@ToR21# set protocols bgp group MX22-EVPN multihop ttl 2
user@ToR21# set protocols bgp group MX22-EVPN multihop no-nexthop-change
user@ToR21# set protocols bgp group MX22-EVPN local-address 198.51.100.11
user@ToR21# set protocols bgp group MX22-EVPN peer-as 900
user@ToR21# set protocols bgp group MX22-EVPN local-as 600

```

```
user@ToR21# set protocols bgp group MX22-EVPN neighbor 198.51.100.22 family
evpn signaling
```

- c. Configure a MP-EBGP overlay to connect between ToR21 and ToR22 using EVPN signaling.

[edit]

```
user@ToR21# set protocols bgp group ToR22-EVPN type external
user@ToR21# set protocols bgp group ToR22-EVPN multihop ttl 2
user@ToR21# set protocols bgp group ToR22-EVPN multihop no-nexthop-change
user@ToR21# set protocols bgp group ToR22-EVPN local-address 198.51.100.11
user@ToR21# set protocols bgp group ToR22-EVPN peer-as 700
user@ToR21# set protocols bgp group ToR22-EVPN local-as 600
user@ToR21# set protocols bgp group ToR22-EVPN neighbor 198.51.100.12
family evpn signaling
```

11. Configure trace operations to track all Layer 2 address learning and forwarding properties.

[edit]

```
user@ToR21# set protocols l2-learning traceoptions file TOR21-L2ALD.log
user@ToR21# set protocols l2-learning traceoptions file size 10m
user@ToR21# set protocols l2-learning traceoptions level all
user@ToR21# set protocols l2-learning traceoptions flag all
```

12. Configure routing policies to accept the direct loopback address route and redirect it into BGP.

[edit]

```
user@ToR21# set policy-options policy-statement L0 term 1 from protocol
direct
user@ToR21# set policy-options policy-statement L0 term 1 from route-filter
198.51.100.11/32 exact
user@ToR21# set policy-options policy-statement L0 term 1 then accept
```

13. Configure community policy options.

[edit]

```
user@ToR21# set policy-options community NO-EXPORT members no-advertise
user@ToR21# set policy-options community NO-EXPORT members no-export
user@ToR21# set policy-options community NO-EXPORT members no-export-subconfed
```

14. Apply load balance.

[edit]

```
user@ToR21# set policy-options policy-statement TEST then community add
NO-EXPORT
user@ToR21# set policy-options policy-statement evpn-pplb from protocol evpn
```

```
user@ToR21# set policy-options policy-statement evpn-pplb then load-balance
per-packet
```

15. Configure EVPN routing instances for each virtual network. Define the VTEP source interface, route distinguisher (used to identify and advertise EVPN routes), and vrf-target (exports and tags all routes for that local VRF using the defined route target). Configure the EVPN protocol, encapsulation method, VNI list, and BUM traffic forwarding method. Finally, configure a bridge domain for each virtual router that maps VNIDs to VLAN IDs, and identify the BUM forwarding method.

[edit]

```
user@ToR21# set routing-instances EVPN-VXLAN-1 vtep-source-interface lo0.90
user@ToR21# set routing-instances EVPN-VXLAN-1 instance-type virtual-switch
user@ToR21# set routing-instances EVPN-VXLAN-1 interface ge-1/0/6.0

```

## Configuring ToR22

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

Configure the MX router ToR22:

1. Set the system hostname.

[edit]

```
user@ToR22# set system host-name ToR22
```

2. Configure the interfaces and bridge domains on the CE-5 device to enable Layer 2 connectivity.

[edit]

```
user@ce5# set logical-systems CE-5 interfaces ge-1/0/9 unit 0 description
"CONNECTED TO Host 5"
user@ce5# set logical-systems CE-5 interfaces ge-1/0/9 unit 0 family bridge
interface-mode trunk
user@ce5# set logical-systems CE-5 interfaces ge-1/0/9 unit 0 family bridge
vlan-id-list 1-5
user@ce5# set logical-systems CE-5 interfaces ae1 unit 0 description
"CONNECTED TO ToR21"
user@ce5# set logical-systems CE-5 interfaces ae1 unit 0 family bridge
interface-mode trunk
user@ce5# set logical-systems CE-5 interfaces ae1 unit 0 family bridge
vlan-id-list 1-5
user@ce5# set logical-systems CE-5 bridge-domains BD-1 domain-type bridge
user@ce5# set logical-systems CE-5 bridge-domains BD-1 vlan-id 1
user@ce5# set logical-systems CE-5 bridge-domains BD-2 domain-type bridge
user@ce5# set logical-systems CE-5 bridge-domains BD-2 vlan-id 2
user@ce5# set logical-systems CE-5 bridge-domains BD-3 domain-type bridge
user@ce5# set logical-systems CE-5 bridge-domains BD-3 vlan-id 3
user@ce5# set logical-systems CE-5 bridge-domains BD-4 domain-type bridge
user@ce5# set logical-systems CE-5 bridge-domains BD-4 vlan-id 4
user@ce5# set logical-systems CE-5 bridge-domains BD-5 domain-type bridge
user@ce5# set logical-systems CE-5 bridge-domains BD-5 vlan-id 5
```

3. Configure the interfaces and bridge domains on the CE-3 device to enable Layer 2 connectivity.

[edit]

```
user@ce3# set logical-systems CE-3 interfaces ge-1/1/7 unit 0 description
"CONNECTED TO ToR12"
user@ce3# set logical-systems CE-3 interfaces ge-1/1/7 unit 0 family bridge
interface-mode trunk
user@ce3# set logical-systems CE-3 interfaces ge-1/1/7 unit 0 family bridge
vlan-id-list 1-5
user@ce3# set logical-systems CE-3 interfaces ge-1/1/9 unit 0 description
"CONNECTED TO Host 3"
user@ce3# set logical-systems CE-3 interfaces ge-1/1/9 unit 0 family bridge
interface-mode trunk
```

```

user@ce3# set logical-systems CE-3 interfaces ge-1/1/9 unit 0 family bridge
vlan-id-list 1-5
user@ce3# set logical-systems CE-3 bridge-domains BD-1 domain-type bridge
user@ce3# set logical-systems CE-3 bridge-domains BD-1 vlan-id 1
user@ce3# set logical-systems CE-3 bridge-domains BD-2 domain-type bridge
user@ce3# set logical-systems CE-3 bridge-domains BD-2 vlan-id 2
user@ce3# set logical-systems CE-3 bridge-domains BD-3 domain-type bridge
user@ce3# set logical-systems CE-3 bridge-domains BD-3 vlan-id 3
user@ce3# set logical-systems CE-3 bridge-domains BD-4 domain-type bridge
user@ce3# set logical-systems CE-3 bridge-domains BD-4 vlan-id 4
user@ce3# set logical-systems CE-3 bridge-domains BD-5 domain-type bridge
user@ce3# set logical-systems CE-3 bridge-domains BD-5 vlan-id 5

```

4. Configure trace options for the interfaces to enable trace logs.

[edit]

```

user@ce3# set interfaces traceoptions file R1-DCD.log
user@ce3# set interfaces traceoptions file size 10m
user@ce3# set interfaces traceoptions flag all

```

5. Set the number of aggregated Ethernet interfaces.

[edit]

```

user@ToR12# set chassis aggregated-devices ethernet device-count 2

```

6. Configure the interfaces on the ToR12 device to connect to the MX12, CE-2, CE-3, ToR11, and MX11 devices to enable underlay connectivity.

[edit]

```

user@ToR12# set interfaces ge-1/0/0 unit 0 description "CONNECTED TO MX11"
user@ToR12# set interfaces ge-1/0/0 unit 0 family inet address 192.168.6.1/24
user@ToR12# set interfaces ge-1/0/4 unit 0 description "CONNECTED TO MX12"
user@ToR12# set interfaces ge-1/0/4 unit 0 family inet address 192.168.5.1/24
user@ToR12# set interfaces ge-1/0/6 description "CONNECTED TO CE-1"
user@ToR12# set interfaces ge-1/0/6 gigether-options 802.3ad ae0
user@ToR12# set interfaces ge-1/0/7 unit 0 description "CONNECTED TO CE-3"
user@ToR12# set interfaces ge-1/0/7 unit 0 family bridge interface-mode trunk
user@ToR12# set interfaces ge-1/0/7 unit 0 family bridge vlan-id-list 1-5
user@ToR12# set interfaces ge-1/1/0 description "CONNECTED TO ToR11"
user@ToR12# set interfaces ge-1/1/0 gigether-options 802.3ad ae1
user@ToR12# set interfaces ge-1/1/3 unit 0 description "CONNECTED TO ToR11"
user@ToR12# set interfaces ge-1/1/3 unit 0 family inet address 192.168.2.2/24
user@ToR12# set interfaces ge-1/1/6 description "CONNECTED TO ToR12"
user@ToR12# set interfaces ge-1/1/6 gigether-options 802.3ad ae1

```

7. Configure a Link Aggregation Control Protocol (LACP)-enabled link aggregation group (LAG) interface towards the CE-1 end host device. The ESI value is globally unique across the entire EVPN domain. The all-active configuration enables ToR11 and ToR12 to forward traffic to, and from the CE devices, such that all CE links are actively used.

[edit]

```

user@ToR12# set interfaces ae0 esi 00:11:11:11:11:11:11:11:11:11
user@ToR12# set interfaces ae0 esi all-active
user@ToR12# set interfaces ae0 aggregated-ether-options lacp system-id
11:11:11:11:11:11
user@ToR12# set interfaces ae0 unit 0 family bridge interface-mode trunk
user@ToR12# set interfaces ae0 unit 0 family bridge vlan-id-list 1-5
user@ToR12# set interfaces ae1 aggregated-ether-options lacp active
user@ToR12# set interfaces ae1 aggregated-ether-options lacp periodic fast

```

8. Configure the loopback interface address and routing options.

[edit]

```

user@ToR12# set interfaces lo0 unit 82 family inet address 192.0.2.12/32
user@ToR12# set routing-options router-id 192.0.2.12
user@ToR12# set routing-options autonomous-system 200

```

9. Configure load balancing on ToR12.

[edit]

```

user@ToR12# set routing-options forwarding-table export evpn-pplb

```

10. Configure a multiprotocol external BGP (MP-EBGP) underlay connectivity between the ToR (ToR12 and ToR11) and gateway routers (MX11 and MX12).

[edit]

```

user@ToR12# set protocols bgp local-as 200
user@ToR12# set protocols bgp group MX11 type external
user@ToR12# set protocols bgp group MX11 local-address 192.168.6.1
user@ToR12# set protocols bgp group MX11 export L0
user@ToR12# set protocols bgp group MX11 export TEST
user@ToR12# set protocols bgp group MX11 peer-as 400
user@ToR12# set protocols bgp group MX11 local-as 200
user@ToR12# set protocols bgp group MX11 neighbor 192.168.6.2 family inet
unicast
user@ToR12# set protocols bgp group MX12 type external
user@ToR12# set protocols bgp group MX12 local-address 192.168.5.1
user@ToR12# set protocols bgp group MX12 export L0
user@ToR12# set protocols bgp group MX12 export TEST
user@ToR12# set protocols bgp group MX12 peer-as 500

user@ToR12# set protocols bgp group ToR11 local-as 200
user@ToR12# set protocols bgp group ToR11 neighbor 192.168.2.1 family inet
unicast

```

11. Configure a multiprotocol external BGP (MP-EBGP) overlay between the ToR (ToR12 and ToR11) and gateway routers (MX11 and MX12) and set EVPN as the signaling protocol.

- a. Configure a MP-EBGP overlay to connect between ToR12 and MX11 using EVPN signaling.

[edit]

```
user@ToR12# set protocols bgp group MX11-EVPN type external
user@ToR12# set protocols bgp group MX11-EVPN multihop ttl 2
user@ToR12# set protocols bgp group MX11-EVPN multihop no-nexthop-change
user@ToR12# set protocols bgp group MX11-EVPN local-address 192.0.2.12
user@ToR12# set protocols bgp group MX11-EVPN export TEST
user@ToR12# set protocols bgp group MX11-EVPN peer-as 400
user@ToR12# set protocols bgp group MX11-EVPN local-as 200
user@ToR12# set protocols bgp group MX11-EVPN neighbor 192.0.2.21 family
evpn signaling
```

- b. Configure a MP-EBGP overlay to connect between ToR12 and MX12 using EVPN signaling.

[edit]

```
user@ToR12# set protocols bgp group MX12-EVPN type external
user@ToR12# set protocols bgp group MX12-EVPN multihop ttl 2
user@ToR12# set protocols bgp group MX12-EVPN multihop no-nexthop-change
user@ToR12# set protocols bgp group MX12-EVPN local-address 192.0.2.12
user@ToR12# set protocols bgp group MX12-EVPN export TEST
user@ToR12# set protocols bgp group MX12-EVPN peer-as 500
user@ToR12# set protocols bgp group MX12-EVPN local-as 200
user@ToR12# set protocols bgp group MX12-EVPN neighbor 192.0.2.22 family
evpn signaling
```

- c. Configure a MP-EBGP overlay to connect between ToR12 and ToR11 using EVPN signaling.

[edit]

```
user@ToR12# set protocols bgp group ToR11-EVPN type external
user@ToR12# set protocols bgp group ToR11-EVPN multihop ttl 2
user@ToR12# set protocols bgp group ToR11-EVPN multihop no-nexthop-change
user@ToR12# set protocols bgp group ToR11-EVPN local-address 192.0.2.12
user@ToR12# set protocols bgp group ToR11-EVPN export TEST
user@ToR12# set protocols bgp group ToR11-EVPN peer-as 100
user@ToR12# set protocols bgp group ToR11-EVPN local-as 200
user@ToR12# set protocols bgp group ToR11-EVPN neighbor 192.0.2.11 family
evpn signaling
user@ToR12# set protocols bgp group ToR12-EVPN export TEST
```

12. Configure trace operations to track all Layer 2 address learning and forwarding properties.

[edit]

```
user@ToR12# set protocols l2-learning traceoptions file TOR12-L2ALD.log
```

```

user@ToR12# set protocols l2-learning traceoptions file size 10m
user@ToR12# set protocols l2-learning traceoptions level all
user@ToR12# set protocols l2-learning traceoptions flag all

```

13. Configure routing policies to accept the direct loopback address route and redirect it into BGP.

[edit]

```

user@ToR12# set policy-options policy-statement L0 term 1 from protocol
direct
user@ToR12# set policy-options policy-statement L0 term 1 from route-filter
192.0.2.12/32 exact
user@ToR12# set policy-options policy-statement L0 term 1 then accept

```

14. Configure community policy options.

[edit]

```

user@ToR12# set policy-options community NO-EXPORT members no-advertise
user@ToR12# set policy-options community NO-EXPORT members no-export
user@ToR12# set policy-options community NO-EXPORT members no-export-subconfed

```

15. Apply load balance.

[edit]

```

user@ToR12# set policy-options policy-statement TEST then community add
NO-EXPORT
user@ToR12# set policy-options policy-statement evpn-pplb from protocol evpn
user@ToR12# set policy-options policy-statement evpn-pplb then load-balance
per-packet

```

16. Configure EVPN routing instances for each virtual network. Define the VTEP source interface, route distinguisher (used to identify and advertise EVPN routes), and vrf-target (exports and tags all routes for that local VRF using the defined route target). Configure the EVPN protocol, encapsulation method, VNI list, and BUM traffic forwarding method. Finally, configure a bridge domain for each virtual router that maps VNIDs to VLAN IDs, and identify the BUM forwarding method.

[edit]

```

user@ToR12# set routing-instances EVPN-VXLAN-1 vtep-source-interface lo0.82
user@ToR12# set routing-instances EVPN-VXLAN-1 instance-type virtual-switch

```

## Verification

After you configure both the underlay and EVPN overlay we recommend that you verify that the configurations work as you intended.

### Verifying ToR11 Configuration

---

**Purpose** Verify that ToR11 is properly configured.

**Action** Verify that the logical system interfaces and bridge domains on the CE2 device are properly configured to enable Layer 2 connectivity.

```
user@ce2> show configuration logical-systems

CE-2 {
 interfaces {
 ge-1/0/9 {
 unit 0 {
 description "CONNECTED TO Host 2";
 family bridge {
 interface-mode trunk;
 vlan-id-list 1-5;
 }
 }
 }
 ge-1/1/6 {
 unit 0 {
 description "CONNECTED TO ToR11";
 family bridge {
 interface-mode trunk;
 vlan-id-list 1-5;
 }
 }
 }
 }
 bridge-domains {
 BD-1 {
 domain-type bridge;
 vlan-id 1;
 }
 BD-2 {
 domain-type bridge;
 vlan-id 2;
 }
 BD-3 {
 domain-type bridge;
 vlan-id 3;
 }
 BD-4 {
 domain-type bridge;
 vlan-id 4;
 }
 BD-5 {
 domain-type bridge;
 vlan-id 5;
 }
 }
}
```

Verify that the interfaces and trace options on ToR11 are configured properly to enable underlay connectivity to other ToR and gateway and WAN edge devices.

```
user@ToR11>show configuration interfaces

traceoptions {
 file R0-DCD.log size 10m;
 flag all;
}
ge-1/0/5 {
 unit 0 {
 description "CONNECTED TO MX12";
 family inet {
 address 192.168.4.1/24;
 }
 }
}
ge-1/0/6 {
 unit 0 {
 description "CONNECTED TO CE-2";
 family bridge {
 interface-mode trunk;
 vlan-id-list 1-5;
 }
 }

---

### Verifying ToR12 Configuration

**Purpose** Verify that ToR12 is properly configured.

**Action** Verify that the logical system interfaces and bridge domains on the CE1 and CE3 devices are properly configured to enable Layer 2 connectivity.

```
user@ce1> show configuration logical-systems
```

```
CE-1 {
 interfaces {
 ge-1/0/9 {
 unit 0 {
 description "CONNECTED TO Host 1";
 family bridge {
 interface-mode trunk;
 vlan-id-list 1-5;
 }
 }
 }
 }
 ae1 {
 unit 0 {
 description "CONNECTED TO ToR12";
 family bridge {
 interface-mode trunk;
 vlan-id-list 1-5;
 }
 }
 }
 bridge-domains {
 BD-1 {
 domain-type bridge;
 vlan-id 1;
 }
 BD-2 {
 domain-type bridge;
 vlan-id 2;
 }
 BD-3 {
 domain-type bridge;
 vlan-id 3;
 }
 BD-4 {
 domain-type bridge;
 vlan-id 4;
 }
 BD-5 {
 domain-type bridge;
 vlan-id 5;
 }
 }
}
```

```
user@ce3> show configuration logical-systems
```

```
CE-3 {
 interfaces {
```

```

ge-1/1/7 {
 unit 0 {
 description "CONNECTED TO ToR12";
 family bridge {
 interface-mode trunk;
 vlan-id-list 1-5;
 }
 }
}
ge-1/1/9 {
 unit 0 {
 description "CONNECTED TO Host 3";
 family bridge {
 interface-mode trunk;
 vlan-id-list 1-5;
 }
 }
}
}
bridge-domains {
 BD-1 {

### Verifying Data Center Gateway and WAN Edge 1 Router (MX11) Configuration

**Purpose** Verify that MX11 is properly configured.

**Action** Verify that the interfaces on the MX11 router (DC GW/WAN Edge1) are configured for the following:

Underlay connectivity to the MX12, ToR11, ToR12, and P devices, which is the EVPN-VXLAN part of DC1 network.

```
user@MX11> show configuration interfaces
```

```
traceoptions {
 file R2-DCD.log size 10m;
 flag all;
}
ge-5/1/0 {
 unit 0 {
 description "CONNECTED TO MX-21";
 family inet {
 address 192.168.7.1/24;
 }
 }
}
ge-5/1/1 {
 unit 0 {
 description "CONNECTED TO TOR-11";
 family inet {
 address 192.168.3.2/24;
 }
 }
}
ge-5/1/8 {
 unit 0 {
 description "CONNECTED TO TOR-12";
 family inet {
 address 192.168.6.2/24;
 }
 }
}
ge-5/1/9 {
 unit 0 {
 description "CONNECTED TO P";
 family inet {
 address 203.0.1.1/24;
 }
 family mpls;
 }
}
```

Integrated routing and bridging (IRB) interfaces that advertises the MAC and IP routes (MAC+IP type 2 routes) for hosts in the topology. The IRB configuration is the gateway for the VLANs on the hosts.

```
user@MX11> show configuration interfaces
```

```
irb {
 unit 1 {
 proxy-macip-advertisement;
 virtual-gateway-esi {
 00:11:aa:aa:aa:aa:aa:aa:aa;
 all-active;
 }
 }
}
```

```

 family inet {

### Verifying Data Center Gateway and WAN Edge 4 Router (MX22) Configuration

**Purpose** Verify that MX22 is properly configured.

**Action** Verify that the interfaces on the MX11 router (DC GW/WAN Edge1) are configured for the following:

Underlay connectivity to the MX12, ToR11, ToR12, and P devices, which is the EVPN-VXLAN part of DC1 network.

```
user@MX11> show configuration interfaces
```

```
traceoptions {
 file R2-DCD.log size 10m;
 flag all;
}
ge-5/1/0 {
 unit 0 {
 description "CONNECTED TO MX-21";
 family inet {
 address 192.168.7.1/24;
 }
 }
}

### Verifying ToR21 Configuration

**Purpose** Verify that ToR21 is properly configured.

**Action** Verify that the logical system interfaces and bridge domains on the CE4 device are properly configured to enable Layer 2 connectivity and to handle inter-VXLAN traffic.

```
user@ce4> show configuration logical-systems

CE-4 {
 interfaces {
 ge-1/0/9 {
 unit 0 {
 description "CONNECTED TO Host 4";
 family bridge {
 interface-mode trunk;
 vlan-id-list 1-5;
 }
 }
 }
 ge-1/1/6 {
 unit 0 {
 description "CONNECTED TO ToR21";
 family bridge {
 interface-mode trunk;
 vlan-id-list 1-5;
 }
 }
 }
 }
 bridge-domains {
 BD-1 {
 domain-type bridge;
 vlan-id 1;
 }
 BD-2 {
 domain-type bridge;
 vlan-id 2;
 }
 BD-3 {
 domain-type bridge;
 vlan-id 3;
 }
 BD-4 {
 domain-type bridge;
 vlan-id 4;
 }
 BD-5 {
 domain-type bridge;
 vlan-id 5;
 }
 }
}
```

Verify that the interfaces and trace options on ToR21 are configured properly to enable underlay connectivity to other ToR and gateway and WAN edge devices.

```
user@ToR21>show configuration interfaces
```

```

## EVPN MAC Pinning Overview

---

Starting in Release 16.2, Junos OS enables MAC address pinning for Ethernet VPN (EVPN), including customer edge (CE) interfaces and EVPN over MPLS core interfaces, in both all-active mode or active-standby mode.

When you configure an interface with MAC pinning, the l2ald process adds an 8-octet extension to the address (which implements aspects of Section 7.7 of RFC-7432: MAC Mobility Extended Community). The low-order bit in the flag octet of this structure is the Sticky/static flag. Configuring MAC pinning sets the flag to 1 and designates the address is static.

If you configure MAC pinning on a CE/VPLS interface, that MAC address cannot be moved to any other CE/VPLS interface. Similarly, if you configure MAC pinning on an MPLS core interface on a PE device, that MAC address cannot be moved to a different interface on the MPLS core.

CE devices advertise MAC pinned addresses through the l2ald process to remote PE devices. When a PE device learns a MAC-pinned interface address from a CE device, the PE device synchronizes the address, through the control plane, with remote peer PE devices in the EVPN network. Thereafter, if the PE device receives traffic, or an advertised route, from any CE device in the EVPN network that bears the same source MAC address, the receiving device drops the traffic.

A PE device that learns a MAC pinned address via its control plane prefers that address over an address bearing the identical MAC address that is learned from a remote peer PE device, or locally by way of its l2ald from a CE/VPLS interface.

Before the introduction of MAC address pinning for EVPN, a MAC address on a remote PE device that was learned locally could be aged out. For EVPN MAC pinning, a pinned MAC address does not age out on the remote PE device unless the routing protocol process removes it from the routing table. Similarly, a pinned MAC address persists for the control plane of the remote PE device.

This static interface address cannot be moved unless it is deleted from the routing table of the device on which it is configured.

A MAC address might be considered moved as a result of:

- Misconfiguration
- Configuration on a different Ethernet segment
- Physical movement of a device within a network topology

**NOTE:** If EVPN is configured in all-active multihoming mode, you must either enable or disable MAC pinning on the multihoming PE device interfaces in the broadcast domain. Also, either enable or disable MAC pinning on all CE device interfaces to avoid inconsistent MAC learning in the EVPN broadcast domain.

If EVPN is configured in active-standby multihoming mode, a MAC pinned address received by the active PE device can be moved to a CE interface on the standby PE device in response to a switchover, if traffic has been running continuously on the CE interface.

**CAUTION:** Do not enable or disable MAC pinning on an interface while traffic is running.

#### Release History Table

## Configuring EVPN MAC Pinning

---

The EVPN MAC pinning feature enables you to apply MAC pinning to CE/VPLS interfaces in a bridge domain and to PE interfaces in the core of a service-provider network.

The EVPN MAC pinning feature enables you to make the MAC address associated with a specific interface static. That is, the MAC-pinned address cannot be moved to any other interface in the bridge domain. The MAC-pinned address on the interface will not age out.

Traffic transmitted with pinned MAC address as source MAC, from any interface in the EVPN domain other than the one on which the MAC address is pinned, will be discarded.

Pinning a MAC address to an interface for EVPN does not require new CLI. Existing CLI enables pinning MAC addresses to CE-device and PE-device interfaces. You can enable MAC Pinning on an interface in an EVPN network with the following command:

```
User@CE1# set switch-options interface interface-name mac-pinning
```

## Provider Backbone Bridging (PBB) and EVPN Integration Overview

---

Ethernet VPN (EVPN) provides a solution for multipoint Layer 2 VPN services with advanced multihoming capabilities using BGP for distributing MAC address reachability information over the core MPLS or IP network. However, with EVPN, several thousands of MAC addresses are carried from each virtual routing and forwarding (VRF) instance, requiring frequent updates on newly learned MAC routes and withdrawn routes. This increases the overhead on the provider network.

Provider backbone bridging (PBB) extends Layer 2 Ethernet switching to provide enhanced scalability, quality-of-service (QoS) features, and carrier-class reliability. With the integration of PBB with EVPN, instead of sending the customer MAC (C-MAC) addresses as control plane learning, the backbone MAC (B-MAC) addresses are distributed in the EVPN core. This simplifies the control plane learning across the core and allows a huge number of Layer 2 services, such as data center connectivity, to transit the network in a simple manner.

The following sections describe the technology and implementation overview of PBB-EVPN integration:

## Understanding Provider Backbone Bridging (PBB)

Provider backbone bridging (PBB) was originally defined as IEEE 802.1ah standard, and operates in exactly the same manner as IEEE 802.1ad standard. However, instead of multiplexing VLANs, PBB duplicates the MAC layer of the customer frame and separates it from the provider domain, by encapsulating it in a 24 bit instance service identifier (I-SID). This allows for complete transparency between the customer network and the provider network.

When operating on customer MAC (C-MAC) and service MAC (S-MAC) addresses, PBB uses a new backbone MAC (B-MAC) address. The B-MAC address is added at the edge of the PBB network, that is administered by a carrier VPN or a carrier-of-carriers VPN. With the use of an I-SID for the customer routing instance (I-component) service group, PBB improves the scalability of Ethernet services.

Figure 71 on page 794 illustrates a PBB network, describing the PBB network elements and MAC address spaces.

Figure 71: PBB Network Elements

The PBB terms are:

- **PB**—Provider bridge (802.1ad)
- **PEB**—Provider edge bridge (802.1ad)
- **BEB**—Backbone edge bridge (802.1ah)
- **BCB**—Backbone core bridge (802.1ah)

The BEB device is the first immediate point of interest within PBB, and forms the boundary between the access network and the core. This introduces two key components—the I-component and B-component in PBB.

- **I-component**

The I-component forms the customer or access facing interface or routing instance. The I-component is responsible for mapping customer Ethernet traffic to the appropriate I-SID. At first, the customer Ethernet traffic is mapped to a customer bridge domain. Then each customer bridge domain is mapped to an I-SID. This service mapping

can be per port, per port with service VLAN (S-VLAN), or per port with S-VLAN and customer VLAN (C-VLAN). The I-component is used to learn and forward frames based on the C-MAC addresses, and maintains a C-MAC-to-B-MAC mapping table that is based on instance tag (I-TAG).

Within the I-component there are two ports:

- Customer Instance Port (CIP)

These ports are customer service instances at the customer-facing interfaces. Service definitions can be per port, per port with S-VLAN, or per port with S-VLAN and C-VLAN.

- Provider Instance Port (PIP)

This port performs PBB encapsulation, such as pushing the I-TAG, source and destination B-MAC addresses, and PBB decapsulation, such as popping the I-SID, learning source B-MAC-to-C-MAC mapping, in the ingress direction.

- **B-component**

the B-component is the backbone-facing PBB core instance. The B-component is used to learn and forward packets based on the B-MAC addresses. The B-component is then responsible for mapping the I-SIDs to the appropriate B-VLANs (in the case of PBB networks) or pushing and popping service MPLS labels for MPLS-based networks.

Within the B-component there are two ports:

- Customer Backbone Port (CBP)

These ports are backbone edge ports that can receive and transmit instance-tagged frames from multiple customers, and assign backbone VLAN IDs (B-VIDs) and translate the I-SID on the basis of the received I-SID.

- Provider Backbone Port (PBP)

These ports provide connectivity to the other bridges within and attached to the backbone. These are provider-facing ports. These ports support the S-VLAN component.

[Figure 72 on page 796](#) illustrates the key components of PBB. [Figure 73 on page 796](#) illustrates the PBB packet format.

Figure 72: PBB Key Components

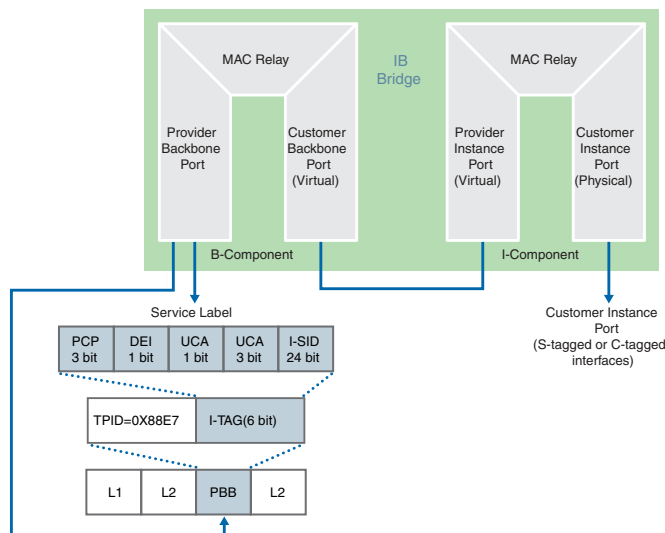

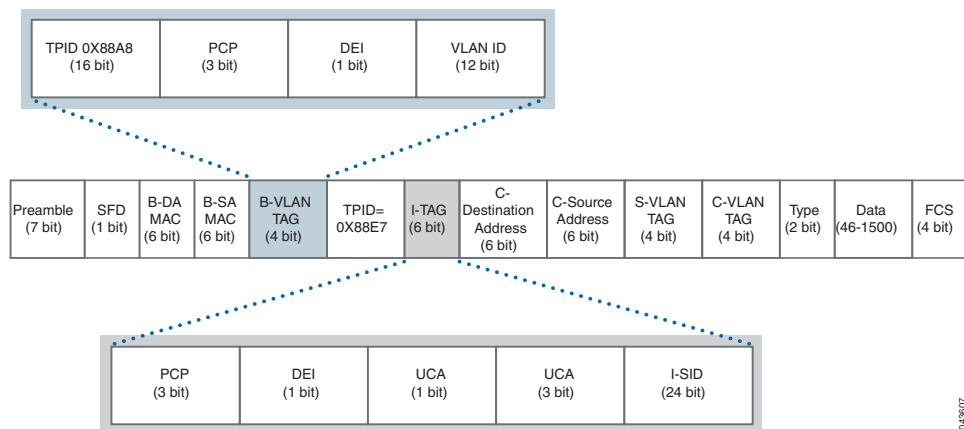

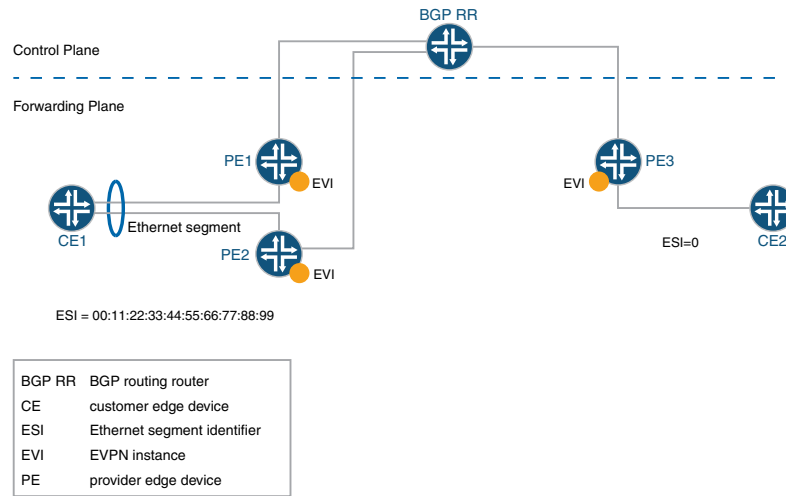

Figure 73: PBB Packet Format

## Understanding EVPN

EVPN is a new standards-based technology that provides virtual multipoint bridged connectivity between different Layer 2 domains over an IP or IP/MPLS backbone network. Similar to other VPN technologies, such as IPVPN and VPLS, EVPN instances (EVIs) are configured on PE routers to maintain logical service separation between customers. The provider edge (PE) devices connect to customer edge (CE) devices, which can be a router, switch, or host. The PE devices then exchange reachability information using MultiProtocol BGP (MP-BGP) and encapsulated traffic is forwarded between them. Because elements of the architecture are common with other VPN technologies, EVPN can be seamlessly introduced and integrated into existing service environments.

Figure 74: EVPN Overview

The EVPN technology provides mechanisms for next-generation DCI by adding extended control plane procedures to exchange the Layer 2 (MAC address) and Layer 3 (IP address) information among the participating Data Center Border Routers (DCBRs). These features help address some of the DCI challenges, such as seamless VM mobility and optimal IP routing. Seamless VM mobility refers to the challenge of Layer 2 extension and maintaining connectivity in the face of VM mobility, and optimal IP routing refers to the challenge of supporting default gateway behavior for a VM's outbound traffic and triangular routing avoidance of a VM's inbound traffic.

The EVPN technology is used by the data center operator to offer multi-tenancy, flexible, and resilient services that can be extended on demand. This flexibility and resiliency can require using compute resources among different physical data centers for a single service (Layer 2 extension) and VM motion.

EVPN supports all-active multihoming, which allows a CE device to connect to two or more PE devices such that traffic is forwarded using all of the links between the devices. This enables the CE device to load-balance traffic to the multiple PE devices. More importantly it allows a remote PE device to load-balance traffic to the multihomed PEs across the core network. This load balancing of traffic flows between data centers is known as aliasing. EVPN also has mechanisms that prevent the looping of broadcast, unknown unicast, and multicast (BUM) traffic in an all-active multihomed topology.

Multihoming provides redundancy in the event that an access link or a PE device fails. In either case, traffic flows from the CE device toward the PE device use the remaining active links. For traffic in the other direction, the remote PE device updates its forwarding table to send traffic to the remaining active PE devices connected to the multihomed Ethernet segment. EVPN provides a fast convergence mechanism so that the time it takes to make this adjustment is independent of the number of MAC addresses learned by the PE device.

EVPN's MP-BGP control plane allows live virtual machines to be dynamically moved from one data center to another, also known as VM motion. After a VM is moved to a

destination server/hypervisor, it transmits a gratuitous ARP that updates the Layer 2 forwarding table of the PE device at the destination data center. The PE device then transmits a MAC route update to all remote PE devices which in turn update their forwarding tables. In this manner, an EVPN tracks the movement of the VM, also known as MAC Mobility. EVPN also has mechanisms to detect and stop MAC flapping.

The EVPN technology, similar to Layer 3 MPLS VPN, introduces the concept of routing MAC addresses using MP-BGP over the MPLS core. Some of the important benefits of using EVPNs include:

- Ability to have a dual-active multihomed edge device
- Provides load balancing across dual-active links
- Provides MAC address mobility
- Provides multi-tenancy
- Provides aliasing
- Enables fast convergence

---

### PBB-EVPN Integration

---

The integration of PBB with EVPN is described in the following sections:

- [Integrating the PBB and EVPN Network Elements on page 798](#)
- [PBB-EVPN Control Plane Initialization on page 799](#)
- [Discovery of EVPN Routes in PBB-EVPN on page 800](#)

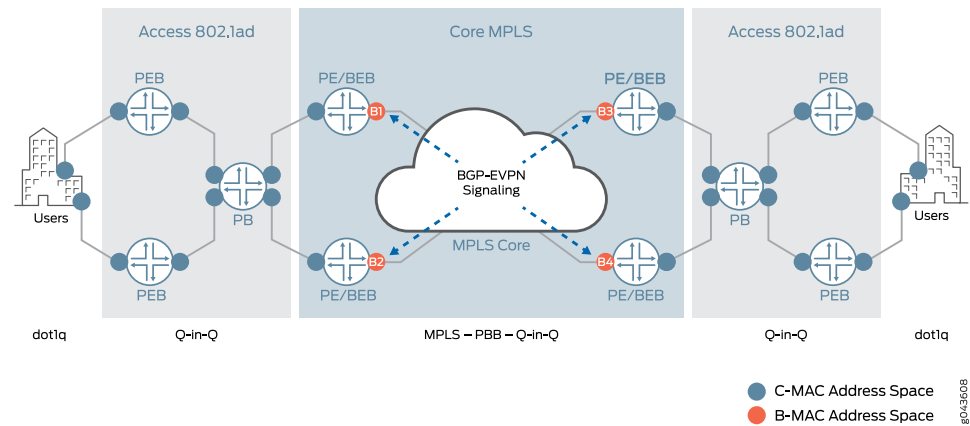

#### ***Integrating the PBB and EVPN Network Elements***

In a PBB network, a huge amount of customer MAC (C-MAC) addresses are hid behind a drastically smaller number of backbone MAC (B-MAC) addresses, without the devices in the core having to learn and process all the individual customer states. The I-SID creates an encapsulation that enables a large number of services to be deployed. However, unlike modern networks that have a simple MPLS core composed of PE and provider devices, the devices in the PBB core need to act as switches, called the backbone core bridge (BCB), performing forwarding decisions based on B-MAC addresses. This causes incompatibility issues with modern MPLS networks, where packets are switched between edge loopback addresses using MPLS labels and recursion.

With the integration of PBB with EVPN, the BCB element in the PBB core is replaced with MPLS, while retaining the service scaling properties of the BEB PBB edge device. The B-component is signaled using EVPN BGP signaling and encapsulated inside MPLS using PE and provider devices. As a result, the vast scale of PBB is combined with the simplicity of a traditional basic MPLS core network and the amount of network-wide state information is significantly reduced, as opposed to regular PBB.

[Figure 75 on page 799](#) illustrates the PBB-EVPN integration using the different elements of a PBB and EVPN network.

Figure 75: PBB-EVPN Integration

### PBB-EVPN Control Plane Initialization

In a PBB-EVPN network, B-MAC addresses are distributed over the EVPN core and C-MAC addresses are learned in the data plane and aggregated behind the B-MAC addresses.

Figure 76 on page 799 illustrates the control plane handling in a sample PBB-EVPN network with four PE devices and two top-of-rack devices across two data centers.

Figure 76: PBB-EVPN Control Plane Handling

The control plane handling at the Data Center Site 1 is as follows:

1. The C-MAC address lookup occurs and the C-MAC address is learned.
2. The B-MAC source address and I-SID are pushed on the packet.

3. Destination address lookup of C-MAC to B-MAC is done in the I-SID table. If the MAC address is present, the packet is routed using an EVPN MAC route; otherwise a multicast route is used.
4. This route gives the service label for the packet, which has PBB and also the original frame.

The control plane handling at the Data Center Site 2 is as follows:

1. At the disposition PE device, the packet is received with a single service label, indicating that it is a PBB frame.
2. The source address allocation of C-MAC to B-MAC is learned in the I-SID table.
3. The source address of the C-MAC is learned in the customer bridge domain (C-BD) MAC table.

#### ***Discovery of EVPN Routes in PBB-EVPN***

PBB with Dot1ah functionality is implemented at the PE devices. In the case of PBB-EVPN, the PE devices implement the instance and backbone bridge functionality. Only B-MAC addresses are distributed in the control plane, the C-MAC addresses are learned in the data plane. The following EVPN routes are discovered on the different PE devices:

- [VPN Autodiscovery on page 800](#)
- [Ethernet Segment Discovery on page 801](#)
- [Ethernet MAC Routes Discovery on page 802](#)
- [Differences Between PBB-EVPN and EVPN on page 803](#)

#### ***VPN Autodiscovery***

When an EVPN instance (EVI) is configured on different PE devices, autodiscovery of the VPN happens first for discovering the EVPN endpoints. Each PE device that is configured with an EVI sends the inclusive multicast route.

The inclusive multicast route fields are as follows:

- **RD**—Unique route distinguisher value per advertising PE device per EVI. The significance of the RD is local to a PE device.
- **TAG ID**—Service ID equivalent to the I-SID value. One I-SID is assigned to one bridge domain under an EVI when service is supported. The TAG ID is set to 0 for the I-SID bundle service, where multiple I-SIDs are mapped to one bridge domain.
- **Originating IP addr**—Loopback IP address.
- **P-Multicast Service Interface (PMSI) Attributes**—Attributes required for transmitting the BUM traffic. There are two type of tunnels—point-to-multipoint LSP and ingress replication. In the case of ingress replication, the multicast label for BUM traffic is downstream assigned. In the case of point-to-multipoint LSP, the PMSI attribute includes the point-to-multipoint LSP identifier. If the multicast tree is shared or

aggregated among multiple EVIs, the PE device uses the upstream assigned label to associate or bind to the EVI.

- **RT Extended Community**—Route target associated with an EVI. This attribute is of global significance in EVPN.

In [Figure 77 on page 801](#), each PE device sends the inclusive multicast route to each BGP neighbor. Device PE1 sends an inclusive multicast route to Devices PE2, PE3, and PE4 for VPN autodiscovery. The handling of BUM traffic is also illustrated in the figure. During the startup sequence, Devices PE1, PE2, PE3, and PE4 send inclusive multicast route that include the multicast label.

### Figure 77: VPN Autodiscovery

### Ethernet Segment Discovery

The Ethernet segment route is encoded in the EVPN NLRI using the Route Type of value 4. This NLRI is used for discovering the multihomed Ethernet segment and for DF election.

ES-import route target, a transitive route target extended community, is also carried with the Ethernet segment route. ES-import extended community enables all the PE devices connected to the same multihomed site to import the Ethernet segment routes. The import of this route is done by the PE device that has the ESI configured. All other PE devices discard this Ethernet segment route.

Figure 78 on page 802 provide details about the procedure of Ethernet segment route for multihomed Ethernet segment autodiscovery.

Figure 78: Ethernet Segment Discovery

In this figure, Devices PE1 and PE2 are connected to a multihomed segment with ESI value of ESI1 and B-MAC address of B-MAC1. In the case of an active-active multihomed segment, this B-MAC should be the on Devices PE1 and PE2. Similarly, Devices PE3 and PE4 are active/active multihomed for ESI2 with B-MAC address of B-MAC2. Devices PE1 and PE2 send the Ethernet segment route for ESI1, which is received by Devices PE3 and PE4, but is ignored because the devices are not configured for ESI1. Only Devices PE1 and PE2 are in one redundant group and the DF election is performed in this group. Similarly, Devices PE3 and PE4 are in another redundant group and either Device PE3 or PE4 is selected as the DF.

### Ethernet MAC Routes Discovery

Ethernet MAC Advertisement route is used for distributing B-MAC addresses of PE nodes. The MAC advertisement route is encoded with following fields:

- MAC address field contains B-MAC address.
- Ethernet Tag field is set to 0.
- Ethernet segment identifier field must be set to 0 (for single-homed segments or multihomed segments with per-I-SID load balancing) or to MAX-ESI (for multihomed segment with per-flow load balancing).
- Label is associated with unicast forwarding of traffic from different PE devices.
- RT (route target) extended community associated with its EVI.

Figure 79 on page 803 illustrates the MAC route advertisement in PBB-EVPN.

Figure 79: Ethernet MAC Routes Discovery

**Differences Between PBB-EVPN and EVPN**

Table 19 on page 803 and Table 20 on page 804 list the differences between PBB-EVPN and pure EVPN for Layer 2 networks in the context of different route types and route attributes, respectively.

Table 19: Route Differences Between PBB-EVPN and EVPN

| Route                        | Usage                                                                                                                             | Applicability    |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|------------------|
| Ethernet autodiscovery route | <ul style="list-style-type: none"> <li>MAC mass withdrawal</li> <li>Aliasing</li> <li>Advertising split horizon labels</li> </ul> | EVPN only        |

| Inclusive multicast route    | Multicast tunnel endpoint discovery                                                                                               | EVPN<br>PBB-EVPN |
| Ethernet segment route       | <ul style="list-style-type: none"> <li>Redundancy</li> <li>Designated forwarder (DF) election</li> </ul>                          | EVPN<br>PBB-EVPN |

Table 20: Route Attributes and Route Usage Differences Between PBB-EVPN and EVPN

| Attribute                          | Usage                                                                                                                                                                                                     | Applicability                |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| ESI MPLS lable extended community  | <ul style="list-style-type: none"> <li>Encode split horizon label for the Ethernet segment.</li> <li>Indicate redundancy mode (active/standby or active/active).</li> </ul>                               | Ethernet autodiscovery route |
| ES-import extended community       | Limit the import scope of the Ethernet segment routes.                                                                                                                                                    | Ethernet segment route       |
| MAC mobility extended community    | <ul style="list-style-type: none"> <li>EVPN: Indicates that a MAC address has moved from one segment to another across PE devices.</li> <li>PBB-EVPN: Signal C-MAC address flush notification.</li> </ul> | MAC advertisement route      |
| Default gateway extended community | Indicate the MAC or IP bindings of a gateway.                                                                                                                                                             | MAC advertisement route      |

### PBB-EVPN Packet Walkthrough

Based on the PBB and EVPN configuration on different PE devices of the network, the Ethernet segment, B-MAC address reachability, and multicast routes are already programmed on different PE devices in the EVPN cloud. The packet walkthrough of PBB-EVPN includes the handling of the following traffic types:

- [Handling BUM Traffic in PBB-EVPN on page 804](#)
- [Handling Unicast Traffic in PBB-EVPN on page 807](#)
- [Handling Path Forwarding in PBB-EVPN on page 809](#)
- [Handling MAC Mobility in PBB-EVPN on page 810](#)
- [Handling End-to-End OAM for PBB-EVPN on page 811](#)
- [Handling QoS and Firewall Policer Support for PBB-EVPN on page 811](#)

#### **Handling BUM Traffic in PBB-EVPN**

[Figure 80 on page 805](#) illustrates the PBB-EVPN control plane and BUM traffic handling.

Figure 80: PBB-EVPN BUM Traffic Handling

The PBB-EVPN handling of BUM traffic over the EVPN cloud is as follows:

1. After Server A boots up, Server A attempts to send traffic to Server B. Server A does not have the ARP binding in the ARP table for Server B, so Server A builds an ARP broadcast request and sends it. The contents of the ARP packets are VLAN 10, S-MAC=M2 (server A interface MAC), Destination MAC=ff.ff.ff.ff.ff, source IP address=IP address of Server A or VM IP address, and destination IP address=IP address of Server B. Ether type of packet for ARP is 0x0806. Layer 2 frame is sent to Device CE1.
2. Device CE1 does the Layer 2 switching operation on this frame. Because this is a Layer 2 broadcast frame, the frame is classified to an interface and based on the bridge domain configuration for this service and broadcast behavior. The packet is forwarded to all the members of the bridge domain except to the one on which it was received. There might be VLAN translation, such as push, pop, or translate, done on this frame. This frame is sent over to Device PE2. This frame might be untagged, single tagged, or Q-in-Q.
3. After Device PE2 receives this frame, at first it goes through the classification engine to classify the frame into a service. Based on the classification result interface (that is, the Customer Instance Port [CIP]) the service is identified. The source MAC address is learned (if it is not present in the MAC table). This classification results in the C-BD. Because this frame is a broadcast frame, it is sent to all the member interfaces of this

bridge domain. One of the member interfaces of this bridge domain is the Provider Instance Port (PIP) interface. Now the packet is formed based on the I-SID configured for this PIP interface. The outer header of the packet at the PIP egress interface is formed based on the following information:

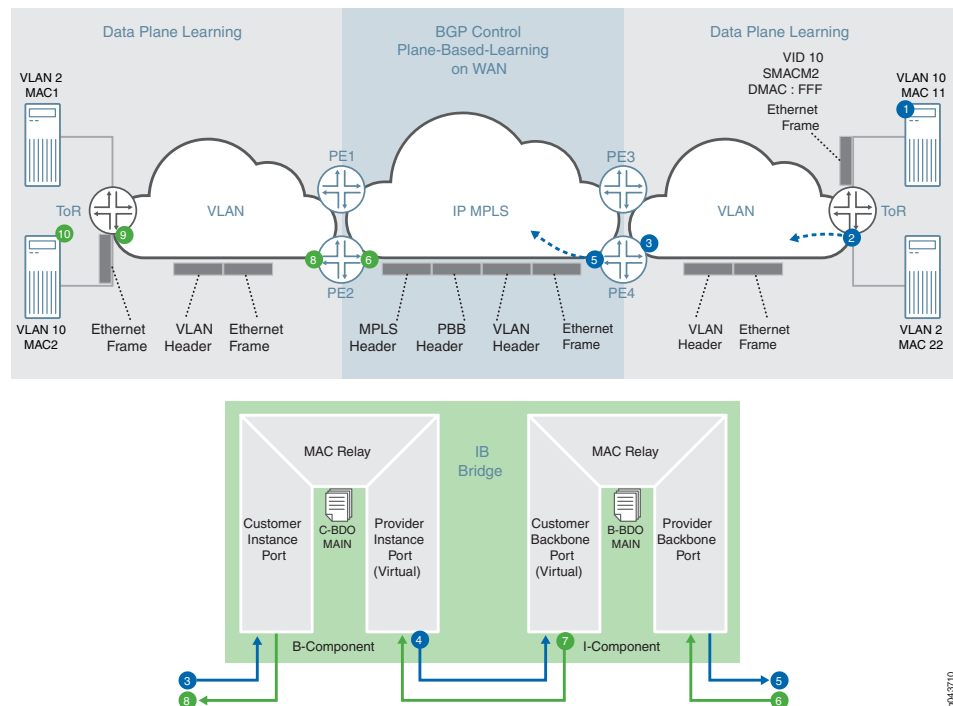

- I-SID—Configured I-SID value on this PIP interface.
  - Source MAC address—B-MAC address configured or autogenerated for this frame.
  - Destination MAC address—Based on the per-I-SID mapping table that is built based on the source C-MAC-to-B-MAC address learning and the destination C-MAC-to-B-MAC address. For BUM traffic, the default value of the bridge destination address (B-DA) is the Backbone Service Instance Group address. When the B-DA of a frame is a Backbone Service Instance Group address, the normal behavior is to deliver the frame to all Customer Backbone Ports (CBPs) reachable within the backbone VLAN (B-VLAN) to which the backbone service instance is mapped. Filtering based on I-SID by the egress CBP ensures that frames are not transmitted by CBPs that are not part of the backbone service instance.
  - Layer 2 Ethernet type—0x88E7.
  - Payload—Customer frame.
4. The I-SID-formed packet is sent to the CBP for identifying the backbone bridge domain (B-BD) associated with the I-SID.
  5. Lookup in the B-BD is done to send the packet to the right destination. Because this frame is a broadcast frame and the destination B-MAC is a multicast address (00-1E-83-<ISID value>), the packet needs to be handled as the ingress replication (that is, VPLS edge flood next hop) for EVPN. This next hop pushes the service label (multicast MPLS label associated with B-VLAN per peer ID and bridge VLAN ID). The MPLS packet is formed and sent over the MPLS cloud for Devices PE1, PE3 and PE4.
  6. The frame is received by Device PE4 as a MPLS packet. The bridge domain identification is accomplished by doing an MPLS label L1 lookup in the mpls.0 routing table. The MPLS lookup points to the table next hop for the bridge domain next hop. After the bridge domain is identified, the packet is identified as a broadcast packet. The BUM composite flood next hop is executed, and this next hop points to the CBP.
  7. The egress interfaces are identified. One of the egress interfaces is a PIP interface where the I-SID is configured, and I-SID based filtering (MAC filtering) is applied for filtering the frame. The source C-MAC-to-B-MAC address is learned for the I-SID MAC mapping table. This table is used for building the destination B-MAC address for unicast traffic. The outer I-SID header is popped from the customer Layer 2 frame. The customer bridge domain (C-BD) is found based on the I-SID classification to the PIP interface.
  8. The source C-MAC address is learned. The destination C-MAC lookup is done. This is a broadcast frame, and based on the BUM handling (flood next hop), the frame is forwarded to all the member of the C-BD, except the member interface on which this frame was received.

9. Device CE2 receives this frame. Service classification is done based on the frame VLAN. Based on the classification, the bridge domain forwarding service is found and MAC learning is done. Because the frame is a broadcast frame, it is handled by flood next hop.
10. Server B receives the ARP request packet and sends the ARP reply to Server A.

### Handling Unicast Traffic in PBB-EVPN

Figure 81 on page 807 illustrates the PBB-EVPN control plane and unicast traffic handling in the form of an ARP reply from Server B.

Figure 81: PBB-EVPN Unicast Traffic Handling

For the unicast traffic flow, it is assumed that both the data and control plane MAC learning has already happened.

1. Server B generates an ARP reply. The contents of the ARP packets are VLAN 10, S-MAC=MAC11 (Server B interface MAC), destination MAC=MACA, source IP address=IP address of Server B or VM IP address, and destination IP address=IP address of Server A. This frame is forwarded to top-of-rack B.
2. After receiving the frame, the CE device classifies the incoming frame. Based on the interface family, the bridge domain associated with the interface is identified. Source MAC address learning takes place on the bridge domain. Next the bridge domain destination MAC (MACA) lookup is done, and the lookup provides the Layer 2 egress

interface. The output feature of the egress interface is applied before the CE device sends the frame to the egress interface.

3. Layer 2 encapsulated frame is received by Device PE4. The Layer 2 service classification is done to identify the customer bridge domain (C-BD) associated with this frame. The source MAC address (MAC11) learning is done in the context of the C-BD on the CIP interface.
4. Destination MAC lookup in the context of C-BD points to the PIP interface. At this point, the PIP interface egress feature list is executed. Based on the feature list, the outer I-SID header is pushed on the original Ethernet frame.
  - Source MAC—B-MAC of Device PE4
  - Destination MAC—B-MAC of Device PE2 (lookup result in I-SID C-MAC-to-B-MAC table)
  - I-SID—Configured value of I-SID
  - Layer 2 Ether typ—0x88E7
5. The destination MAC address (B-MAC of Device PE2) lookup is done in the B-BD MAC address table. This lookup results in a unicast next hop (that is, an EVPN next hop). This next hop contains a unicast MPLS service label. This label is distributed through the multiprotocol BGP (MP-BGP) control plane. The downstream peer allocates this MPLS service label. Allocation of this label can be per EVI; per EVI and VLAN; per EVI, VLAN, and attachment circuit; or per MAC address. Based on the information in the next hop, the MPLS packet is formed and forwarded on the MPLS network.
6. Device PE2 receives the frame. It is identified as an MPLS packet. The MPLS label lookup is done in the mpls.0 routing table. This lookup results in the table next hop. This lookup results in the B-BD table. The B-MAC rule (that is, source B-MAC is destination B-MAC) and I-SID filtering (CBP configured ISID=packet ISID) rules are applied. Based on the received frame I-SID, CBP is identified and B-VLAN is popped.
7. The frame header is passed to the PIP interface for further processing. The C-MAC address (M11 to B-MAC-PE2) to B-MAC mapping is learned in the I-SID table. The outer I-SID header is popped.
8. The inner source MAC address is learned on the PIP interface in the context of C-BD. The inner destination MAC address lookup is done, resulting in the egress CIP interface.
9. The CE device receives the Layer 2 frame, and Layer 2 forwarding is done.
10. Server A receives the unicast ARP reply packet from Server B.

***Handling Path Forwarding in PBB-EVPN***

In a PBB-EVPN network, a frame can come from either the customer edge (CE) side (bridge interface) or the MPLS-enabled interface (core-facing interface).

The packet flow for packets received from the CE side is as follows:

1. If the frame is received from a CE interface, the interface belongs to the bridge family, and the MAC address lookup and learning are done in the customer bridge domain (C-BD) context. The result of the lookup is a unicast MAC route or a flood MAC route.
2. The next lookup is done in the I-SID MAC table to determine the destination B-MAC associated with the destination C-MAC.
3. The I-SID header is prepended to the packet.
4. The next lookup is done in the B-BD because the PIP interface belongs to the bridge family.
5. The B-BD lookup points to either the unicast MAC route or the flood MAC route and this route points to either the EVPN indirect multicast next hop or the unicast indirect next hop.

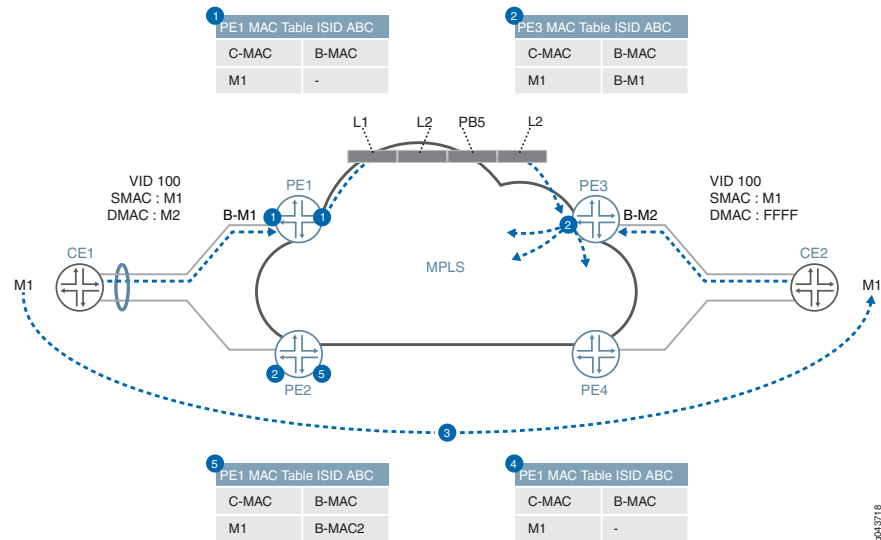

The packet flow for packets received from the core side is as follows:

1. If the frame is received from the core-facing interface, the interface belongs to the MPLS family, and the MPLS label lookup is done in the mpls.0 routing table next hop. The result of this lookup is the routing instance context.
2. The next lookup is done based on the I-SID from the packet to the BBD lookup.
3. If the BBD is found, then I-SID based filtering rules are applied, where the I-SID configured MAC should match the packet source B-MAC, then the frame is dropped.
4. The I-SID MAC table is updated for the destination B-MAC associated with the destination C-MAC for building the C-MAC-to-B-MAC association.
5. The I-SID header is removed and C-BD is found based on the PIP interface.
6. The next lookup is done in the C-BD because the PIP interface belongs to the bridge family.
7. The C-BD lookup points to either a unicast MAC route or a flood MAC route, and this route points to a CE interface or flood route.

### Handling MAC Mobility in PBB-EVPN

Figure 82 on page 810 illustrates PBB-EVPN MAC mobility from the point of the forwarding and control plane.

Figure 82: PBB-EVPN MAC Mobility Handling

MAC mobility from the point of the forwarding and control plane is handled as follows:

1. Device PE1 learns the C-MAC address, M1, on the local port and forwards it across the core according to the destination-C-MAC-to-remote-B-MAC mapping. This mapping is either statically configured or learned through the data plane. If the destination-C-MAC-to-remote-B-MAC mapping is not found in the I-SID mapping table, then the remote B-MAC is derived by using the I-SID.
2. Device PE3 learns the C-MAC address, M1, through the B-MAC address, B-M1, from the dataplane.
3. Customer M1 is moved from Device CE1 to behind Device CE2.
4. When Customer M1 wants to communicate with a customer behind Device CE1, a broadcast traffic with VID: 100, Source MAC: M1, and destination MAC: ff.ff.ff.ff.ff is sent. Device PE3 learns the MAC M1 in the C-BD MAC table and updates the M1 location in the I-SID mapping table.
5. Device PE1 receives the packet and M1 is learned and updated in the I-SID mapping table as reachable through the remote MAC is B-M2.

### Handling End-to-End OAM for PBB-EVPN

You can run provider-level Operation, Administration, and Maintenance (OAM) by running connectivity fault management (CFM) on the inward or outward facing maintenance endpoints (MEPs) either on the PIP interface or over the EVPN service.

Currently, the designated forwarder (DF) election is decided based on the DF election algorithm and it is the local decision of the PE devices. This is useful in an end-to-end service handling scenario, where the decision of DF election can be done with operator's consent as well and vice versa. Another scenario in which it might be useful to influence the DF role per service basis or propagating the DF to a CE device is for multihomed networks, where there is no direct link between the CE and PE devices.

### Handling QoS and Firewall Policer Support for PBB-EVPN

[Table 21 on page 811](#) provides details about the QoS and firewall features that are supported in the context of PBB-EVPN integration.

**Table 21: Firewall and QoS Feature Support in PBB-EVPN**

| Feature        | Description                                                                                         | Support on round-trip time (RTT) | Support on CE Interface                   | Support on Core Interface |
|----------------|-----------------------------------------------------------------------------------------------------|----------------------------------|-------------------------------------------|---------------------------|
| Classification | Fixed classification to one FC                                                                      | Yes                              | Yes                                       | Yes                       |
|                | Behavior aggregate (BA) and multifield classifier (MF) classification for inner output vlan .1p bit | Yes                              | Yes                                       | Yes                       |
|                | BA and MF classification based on DEI and PCP                                                       | No                               | Not required                              | No                        |
|                | BA and MF classification based on Exp                                                               | No                               | No                                        | Yes                       |
| CoS Marking    | .1P to I-SID PCP and DEI: Customer VLAN .1p                                                         | No                               | By default, .1P is mapped to PCP and DEI. | Yes                       |
|                | .1P to Exp: Customer VLAN .1p                                                                       | No                               | No                                        | Yes                       |

## Implementation Overview of PBB-EVPN Integration

The following sections provide use case scenarios for PBB-EVPN integration for DCI.

- [PBB-EVPN Failure Scenarios on page 812](#)
- [PBB-EVPN I-SID Use Case Scenarios on page 815](#)
- [VPLS Integration with PBB-EVPN Use Case Scenario on page 816](#)
- [PBB-EVPN Redundancy Use Case Scenarios on page 817](#)

### PBB-EVPN Failure Scenarios

There are different PBB-EVPN failure scenarios that should be taken care of while providing an end-to-end solution. These failure scenarios can be of the following types:

- [Segment Failure on page 812](#)
- [Node Failure on page 813](#)
- [Core Failure on page 814](#)

#### **Segment Failure**

A segment, or CE-facing link, failure is handled in the active/active and active/standby multihoming redundancy modes.

[Figure 83 on page 813](#) shows the handling of segment failure for flow-based load balancing at Device CE1.

Figure 83: PBB-EVPN Segment Failure

A segment failure in PBB-EVPN is handled as follows:

1. Ethernet link between Devices CE1 and PE1 failed due to fiber cut or the interface is down. Device PE1 detects the failed segment.
2. Device PE1 withdraws the B-MAC address that is advertised for the failed segment (B-M1).
3. The CE1-facing link goes down. If the link failure happens in the single-active redundancy mode or no redundancy case, the C-MAC flush is also done.

The C-MAC address flushing happens in two ways:

- If Device PE2 uses the shared B-MAC address for multiple I-SIDs, it notifies the remote PE device by readvertising the B-MAC address with the MAC mobility extended community attribute by incrementing the value of counter. This causes the remote PE device to flush all C-MAC addresses associated with the B-MAC address for Device PE1.
  - If Device PE2 uses the dedicated B-MAC address, then it withdraws the B-MAC address associated with the failed segment and sends it to Devices PE2, PE3, and PE4.
4. After receiving the B-MAC withdraw from Device PE1, Device PE3 removes PE1 reachability for B-MAC1 from its forwarding table. Reachability of B-MAC1 through Device PE2 still exists.
  5. The DF election is rerun on Device PE2 for all the I-SIDs for the Ethernet segment ESI.

### Node Failure

A node, or PE device, failure scenario is similar to a segment failure from the point of view of CE side failure handling, but it is different from core side failure handling. In the case of core side failure handling, EVPN depends on the BGP session timeout for clearing the state of the EVPN sessions on affected PE devices.

Figure 84 on page 814 illustrates a node failure scenario for node failure handling.

**Figure 84: PBB-EVPN Node Failure**

1. Device PE1 failed and the CE side switchover to Device PE2 is done by an interface down event.
2. Devices PE2, PE3, and PE4, or BGP route reflector, detect the BGP session timeout with Device PE1.
3. As soon as the BGP session timeout happens, Devices PE3 and PE4 remove Device PE1 from the forwarding table by marking the Device PE1 next hop as unreachable or deleted. In the case of single-active redundancy mode, the I-SID table for C-MAC-to-B-MAC mapping table has to be flushed or updated. In the case of active/active redundancy mode, it is not required to flush the I-SID table, because the same B-MAC address is used for both Devices PE1 and PE2 for a given EVI.
4. At Device PE2, after a BGP timeout, the DF election algorithm is rerun and Device PE2 becomes the DF for all I-SIDs on an affected Ethernet segment.

### Core Failure

The handling of core side isolation in the EVPN network is similar to the PE side failure, with some differences in handling of the CE device or Ethernet segment.

Figure 85 on page 815 provides details about the handling of core isolation.

Figure 85: PBB-EVPN Core Failure

Core isolation in PBB-EVPN is handled as follows:

1. Device PE1 loses connectivity to the core.
2. Devices PE2, PE3, and PE4, or BGP route reflector, detect the BGP session timeout with Device PE1.
3. Device PE1 sends an LACP OUT\_OF\_SYNC message to Device CE1 to take the port out of the bundle.
4. Device PE2, or BGP route reflector, detects the BGP session timeout with Device PE1.
5. Device PE2 reruns the DF election and is selected as the DF for all the I-SIDs on the segment.

### PBB-EVPN I-SID Use Case Scenarios

- [I-SID Base Service on page 815](#)
- [I-SID-Aware Service on page 816](#)

#### **I-SID Base Service**

In the case of the I-SID base service, there is one-to-one mapping between a bridge domain and an EVI. In this case, there is no need to carry the I-SID in the MAC advertisement route, because the bridge domain ID can be derived from the route target (RT) associated with this route. The MPLS label allocation is done on a per-EVI basis.

[Figure 86 on page 816](#) provides an overview of the I-SID base use case scenario.

Figure 86: I-SID Base Service Use Case

In the case of I-SID load balancing, where load balancing of traffic is done on a per-service basis from the originating CE link aggregation group (LAG) configuration, there are two models for B-MAC addresses:

- Shared source B-MAC

In this model, all I-SIDs from an Ethernet segment share one source B-MAC address. This model has limitations from the point of view of B-MAC withdrawal because of service failure. The remote PE device needs to flush B-MAC-to-C-MAC mapping for all I-SIDs. This creates problem for convergence because MAC flush is done for all I-SIDs.

- Unique source B-MAC per I-SID

Unique unicast B-MAC addresses (one per I-SID) are allocated per multihomed Ethernet segment. The DF filtering is applied to unicast and multicast traffic, in both the core-to-segment and segment-to-core directions.

### ***I-SID-Aware Service***

In the case of I-SID-aware service, multiple I-SIDs can be mapped to the same EVI. But there is one-to-one mapping between a bridge domain and an I-SID. The Ethernet Tag ID must be set to the I-SID in the BGP routes advertisements. The MPLS label allocation is done on a per-EVI or per-EVI/I-SID basis so that the PBB can be terminated at the ingress PE device and recreated at the egress PE device.

### **VPLS Integration with PBB-EVPN Use Case Scenario**

In this use case scenario, VPLS is one cloud that is getting integrated with PBB-EVPN by using logical tunnel interfaces. The logical tunnel interface is being terminated into the customer bridge domain (C-BD). MAC address learning from the VPLS cloud is happening in the context of the C-BD. The C-bridge domain gets mapped to the backbone bridge domain and going to the EVPN cloud.

**NOTE:** PBB-VPLS interworking with PBB-EVPN under an EVI is not supported in Junos OS Release 17.2R1.

### PBB-EVPN Redundancy Use Case Scenarios

- [Single Active Redundancy Use Case Scenario on page 817](#)
- [Active/Standby Redundancy Use Case Scenario on page 817](#)

#### Single Active Redundancy Use Case Scenario

In this use case scenario, a CE device is multihomed to multiple PE devices. The Ethernet segment for this scenario is defined by configuring the same ESI ID on multiple physical interfaces or aggregated Ethernet interfaces on the PE devices along with the mode of operation. In this mode of operation, only one PE device (that is, the DF) is allowed to forward the traffic to and from this Ethernet segment for BUM traffic. The DF election is done based on each ESI in an EVI and by taking the lowest configured I-SID into consideration. This also depends on this number of PE devices to which a segment is multihomed. The service carving is achieved by putting different I-SIDs in different EVIs. The DF election is similar to the DF election in the VLAN-based EVPN. A default timer of 3 seconds is used for reception of Ethernet segment routes from other PE nodes, and this timer can be configured with the same command as used in EVPN—the **designated-forwarder-election hold-time** statement.

In case of PBB-EVPN, the Ethernet autodiscovery route is not used. This mode is specified in the B-MAC advertisement route. In a single-homed or multihomed setup, with the single-active mode, the ESI field must be set to 0 in the B-MAC route advertisement. If ESI 0 is used in the MAC advertisement route, then I-SID-based load balancing is performed. An I-SID value can serve as a single home, an active/standby scenario, or an active/active scenario. It cannot, however, be used in a mixed mode of operation.

[Figure 87 on page 817](#) provides the use case scenario for active/standby multihoming along with DF election.

**Figure 87: PBB-EVPN Redundancy Use Case**

#### Active/Standby Redundancy Use Case Scenario

In the case of the active/active redundancy use case scenario, the DF election is used for handling the BUM traffic. In the case of PBB-EVPN, split horizon of EVPN is not used for filtering the BUM traffic. Instead, BUM traffic is filtered by filtering the destination B-MAC, where the configured B-MAC is the same as the received packet B-MAC; therefore that packet is from the same segment.

The aliasing approach is the same as the EVPN, but the B-MAC route is advertised by setting the ESI field to MAX-ESI. When the remote PE device receives the B-MAC route

with the MAX-ESI value, then the remote PE device does the load balancing between Devices PE1 and PE2.

## Configuration Overview of PBB-EVPN Integration

The PBB-EVPN configuration is done using the following models:

- One-to-one mapping between the I-SID and the bridge domain

In this configuration model, there is a shared EVPN instance (EVI) between different services, although there is one-to-one mapping between the bridge domain and the I-SID.

- Many-to-one mapping between the I-SID and the bridge domain

In this configuration model, virtual switch configuration is used to allow multiple I-SIDs to be mapped to one bridge domain. This model allows only one bridge domain in a given EVI, and all other bridge domains are mapped to the other Layer 2 services.

### Sample PBB-EVPN Port Configuration:

- Provider Backbone Port (PBP) Configuration:

```
routing-instances {
 evpnA {
 instance-type virtual-switch;
 route-distinguisher 192.0.2.1;
 vrf-target target:65221:111;
 protocols {
 evpn {
 label-allocation per-instance;
 extended-isid-list [10000 10401 20000-20001]
 }
 }
 }
}
```

- Customer Backbone Port (CBP) Configuration:

```
interfaces {
 cbp {
 flexible-valn-tagging;
 unit 0 {
 family bridge {
 interface-mode trunk;
 isid-list [10000 10401 20000-20001] [all];
 }
 }
 }
}
```

- Provider Instance Port (PIP) Configuration:

```
interfaces {
 pip {
 flexible-valn-tagging;
 unit 0 {
 family bridge {
```

```

 interface-mode trunk;
 isid-list [20000 20001];
 }
}
unit 1 {
 family bridge {
 interface-mode trunk;
 isid-list [10000 10401];
 }
}
}
}

```

- Customer Instance Port (CIP) Configuration:

```

interfaces {
 ge-4/0/0 {
 flexible-vlan-tagging;
 esi 1 primary;
 unit 0 {
 family bridge {
 interface-mode trunk;
 vlan-id-list [1-399 500 800];
 }
 }
 }
 ge-7/0/0 {
 flexible-vlan-tagging;
 unit 0 {
 family bridge {
 interface-mode trunk;
 vlan-id-list [1-401];
 }
 }
 }
 ge-8/0/0 {
 flexible-vlan-tagging;
 unit 0 {
 family bridge {
 interface-mode trunk;
 vlan-id-list [500-501];
 }
 }
 }
}

```

#### Sample PBB-EVPN Routing Instance Configuration:

- Provider Routing Instance Configuration:

```

routing-instances {
 EVPN A {
 instance-type virtual-switch;
 route-distinguisher 192.0.2.1;
 vrf-target target:65221:111;
 protocols {
 pbb-evpn {
 label-allocation per-instance;
 }
 }
 }
}

```

```

 extended-isid-list [10000 10401 20000] [all];
 }
 evpn {
 label-allocation per-instance;
 extended-vlan-list 1000;
 }
}
interface cbp.0;
bridge-domains {
 B-BD1 {
 isid-list 10000;
 }
 B-BD2 {
 isid-list 10401;
 }
 B-BD3 {
 isid-list 20000;
 }
 B-BD4 {
 isid-list 1000;
 }
}
pbb-options {
 vlan-id 1000 isid-list [20001];
 default-bvlan 22;
}
}
}

```

- Customer Routing Instance Configuration:

```

routing-instances {
 PBN-1 {
 instance-type virtual-switch;
 interface ge-4/0/0.0;
 interface pip.0;
 bridge-domains {
 customer-BDs {
 vlan-id-list [1-399 500 800];
 }
 }
 pbb-options {
 peer-instance EVPN A;
 source-bmac <mac-address>;
 service-groups {
 pbb-1-isid {
 source-bmac <mac-address>;
 isid {
 isid-1 {
 isid 20000 vlan-id-list [1-399 500] [all];
 source-bmac <mac-address>;
 map-dest-bmac-to-dest-cmac <b-mac> <c-mac>;
 }
 isid-2 {
 isid 20001 vlan-id-list [800] [all];
 }
 }
 }
 }
 }
 }
}

```

```

 }
 }
}
PBN-2 {
 instance-type virtual-switch;
 interface ge-7/0/0.0;
 interface pip.1;
 bridge-domains {
 customer-BDs {
 vlan-id-list [1-401];
 }
 }
 pbb-options {
 peer-instance EVPN A;
 default-isid <i-sid>;
 service-groups {
 pbb-2-isid-1 {
 isid {
 isid-1 {
 isid 10000 vlan-id-list [1-400];
 }
 }
 }
 pbb-2-isid-2 {
 isid {
 isid-1 {
 isid 10401 vlan-id-list [401];
 }
 }
 }
 }
 }
}
}

```

## Supported and Unsupported Features on PBB-EVPN

Junos OS supports the following features with PBB-EVPN:

- Graceful Routing Engine switchover (GRES), unified in-service software upgrade (ISSU), and nonstop software upgrade (NSSU).
- Nonstop active routing (NSR) for BGP peers configured with EVPN family.

NSR on PBB-EVPN replicates and recreates backbone MAC (B-MAC) routes, inclusive multicast routes, and Ethernet segment identifier (ESI) routes.

- Feature support on 64-bit platforms.
- IEEE assigned standard ether type as 0x88E7 for I-SID frames. In addition to this, 802.1x can be used.

The following security considerations are supported:

- Packet destined to the Layer 2 ether type as 0x88E7 is processed only if PBB is enabled on the ingress core PE device.
- Packet received from the core is processed only if the I-SID is known and configured on the ingress PE device; otherwise, the frame is dropped.

Junos OS does not support the following features for PBB-EVPN integration:

- Complete support of EVPN NSR
- Integrated routing and bridging (IRB) interfaces
- IPv6 IP addresses
- Logical systems

## Example: Configuring PBB with Single-Homed EVPN

This example shows how to integrate provider backbone bridging (PBB) with Ethernet VPN (EVPN). With this integration, the control plane operations in the core are simplified, providing faster convergence and scalability enhancements than regular EVPN. The PBB-EVPN applications include Data Center Interconnect (DCI) and carrier Ethernet E-LAN services.

- [Requirements on page 822](#)
- [Overview and Topology on page 823](#)
- [Configuration on page 823](#)
- [Verification on page 837](#)

### Requirements

This example uses the following hardware and software components:

- Three provider edge (PE) devices each connected to single-homed customer sites.
- Four customer edge (CE) devices that are single-homed to the PE devices.
- Junos OS Release 17.2R1 or later running on all the PE routers.

Before you begin:

- Configure the device interfaces.
- Configure an IGP, such as OSPF, on all the PE devices.
- Establish an internal BGP session between the PE devices.

- Enable RSVP on the PE devices.
- Configure MPLS and label-switched paths (LSPs) between the PE devices.

## Overview and Topology

Starting in Junos OS Release 17.2R1, PBB is integrated with Ethernet VPN (EVPN) to enable significant reduction in the control plane learning across the core, allowing a huge number of Layer 2 services, such as data center connectivity, to transit the network in a simplified manner.

In a PBB-EVPN network, the backbone core bridge (BCB) device in the PBB core is replaced with MPLS, while retaining the service scaling properties of the PBB backbone edge bridge (BEB). The B-component (provider routing instance) is signalled using EVPN BGP signaling and encapsulated inside MPLS using provider edge (PE) and provider (P) devices. Thus, PBB-EVPN combines the vast scaling property of PBB with the simplicity of a traditional basic MPLS core network, resulting in significant reduction in the amount of network-wide state information, as opposed to regular PBB.

Figure 88: PBB with Single-Homed EVPN

In Figure 88 on page 823, PBB is integrated with EVPN, where the CE devices are single-homed to Devices PE1, PE2, and PE3.

## Configuration

### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

PE1 set chassis aggregated-devices ethernet device-count 16
 set chassis network-services enhanced-ip
 set interfaces xe-1/0/0 flexible-vlan-tagging
 set interfaces xe-1/0/0 encapsulation flexible-ethernet-services
 set interfaces xe-1/0/0 unit 0 encapsulation vlan-bridge
 set interfaces xe-1/0/0 unit 0 vlan-id 10
 set interfaces xe-1/0/0 unit 1 encapsulation vlan-bridge
 set interfaces xe-1/0/0 unit 1 vlan-id 20

```

```
set interfaces xe-1/2/2 flexible-vlan-tagging
set interfaces xe-1/2/2 encapsulation flexible-ethernet-services

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Set the number of aggregated Ethernet interfaces on Device PE1.

```

[edit chassis]
user@PE1# set aggregated-devices ethernet device-count 16

```

2. Set Device PE1's network services to enhanced Internet Protocol and use enhanced mode capabilities.

```

[edit chassis]
user@PE1# set chassis network-services enhanced-ip

```

3. Configure the CE-facing interfaces of Device PE1.

```

[edit interfaces]
user@PE1# set xe-1/0/0 flexible-vlan-tagging
user@PE1# set xe-1/0/0 encapsulation flexible-ethernet-services
user@PE1# set xe-1/0/0 unit 0 encapsulation vlan-bridge
user@PE1# set xe-1/0/0 unit 0 vlan-id 10
user@PE1# set xe-1/0/0 unit 1 encapsulation vlan-bridge
user@PE1# set xe-1/0/0 unit 1 vlan-id 20

```

```

user@PE1# set xe-1/2/2 flexible-vlan-tagging
user@PE1# set xe-1/2/2 encapsulation flexible-ethernet-services
user@PE1# set xe-1/2/2 unit 0 encapsulation vlan-bridge
user@PE1# set xe-1/2/2 unit 0 vlan-id 10
user@PE1# set xe-1/2/2 unit 0 family bridge filter input BRI
user@PE1# set xe-1/2/2 unit 1 encapsulation vlan-bridge
user@PE1# set xe-1/2/2 unit 1 vlan-id 20
user@PE1# set xe-1/2/2 unit 2 encapsulation vlan-bridge
user@PE1# set xe-1/2/2 unit 2 vlan-id 11
user@PE1# set xe-1/2/2 unit 2 family bridge
user@PE1# set xe-1/2/2 unit 3 encapsulation vlan-bridge
user@PE1# set xe-1/2/2 unit 3 vlan-id 21
user@PE1# set xe-1/2/2 unit 3 family bridge

```

4. Configure the interfaces connecting Device PE1 with the other PE devices.

```

[edit interfaces]
user@PE1# set ge-2/1/0 gigether-options 802.3ad ae6

```

```
user@PE1# set ge-2/1/1 unit 0 family inet address 10.0.0.1/8
user@PE1# set ge-2/1/1 unit 0 family iso
user@PE1# set ge-2/1/1 unit 0 family mpls
```

5. Configure the aggregated Ethernet bundle ae6.

```
[edit interfaces]
user@PE1# set ae6 encapsulation ethernet-bridge
user@PE1# set ae6 unit 0 family bridge
```

6. Configure the loopback interface of Device PE1.

```
[edit interfaces]
user@PE1# set interfaces lo0 unit 0 family inet address 127.0.0.1/8 primary
```

7. Configure the integrated routing and bridging (IRB) interfaces for Device PE1.

```
[edit interfaces]
user@PE1# set interfaces irb unit 0 family inet address 10.0.0.1/8
user@PE1# set interfaces irb unit 0 family iso
user@PE1# set interfaces irb unit 0 family mpls
```

8. Configure the customer backbone port (CBP) interfaces on Device PE1.

```
[edit interfaces]
user@PE1# set cbp0 unit 0 family bridge interface-mode trunk
user@PE1# set cbp0 unit 0 family bridge bridge-domain-type bvlan
user@PE1# set cbp0 unit 0 family bridge isid-list all
```

```
user@PE1# set cbp0 unit 1 family bridge interface-mode trunk
user@PE1# set cbp0 unit 1 family bridge bridge-domain-type bvlan
user@PE1# set cbp0 unit 1 family bridge isid-list all
```

9. Configure the Provider Instance Port (PIP) on Device PE1.

```
[edit interfaces]
user@PE1# set pip0 unit 0 family bridge interface-mode trunk
user@PE1# set pip0 unit 0 family bridge bridge-domain-type svlan
user@PE1# set pip0 unit 0 family bridge isid-list all-service-groups
```

```
user@PE1# set pip0 unit 1 family bridge interface-mode trunk
user@PE1# set pip0 unit 1 family bridge bridge-domain-type svlan
user@PE1# set pip0 unit 1 family bridge isid-list all-service-groups
```

10. Configure the router ID and autonomous system number for Device PE1.

```
[edit routing-options]
user@PE1# set router-id 127.0.0.1
user@PE1# set autonomous-system 65221
```

11. Configure RSVP on all the interfaces of Device PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set rsvp interface all
user@PE1# set rsvp interface fxp0.0 disable
```

12. Configure MPLS on all the interfaces of Device PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```

13. Configure LSPs from Device PE1 to all other PE devices.

```
[edit protocols]
user@PE1# set mpls label-switched-path PE1toPE2 from 127.0.0.1
user@PE1# set mpls label-switched-path PE1toPE2 to 127.0.0.2
```

```
user@PE1# set mpls label-switched-path PE1toPE3 from 127.0.0.1
user@PE1# set mpls label-switched-path PE1toPE3 to 127.0.0.3
```

14. Configure an internal BGP session under family EVPN from Device PE1 to all other PE devices.

```
[edit protocols]
user@PE1# set bgp group ibgp type internal
user@PE1# set bgp group ibgp local-address 127.0.0.1
user@PE1# set bgp group ibgp family evpn signaling
user@PE1# set bgp group ibgp neighbor 127.0.0.2
user@PE1# set bgp group ibgp neighbor 127.0.0.3
```

15. Configure OSPF on all the interfaces of Device of PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set ospf traffic-engineering
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

16. Configure a customer routing instance (I-component) on Device PE1 with type virtual switch. Assign the CBP interface, route-distinguisher, and virtual routing and forwarding (VRF) target values to the PBBN routing instance.

```
[edit routing-instances]
user@PE1# set pbbn1 instance-type virtual-switch
user@PE1# set pbbn1 interface cbp0.0

user@PE1# set pbbn1 route-distinguisher 127.0.0.1:100

user@PE1# set pbbn1 vrf-target target:100:100
```

17. Configure PBB-EVPN integration from the customer routing instance. Assign the extended I-SID list and bridge domains to the routing instance.

```
[edit routing-instances]
user@PE1# set pbbn1 protocols evpn pbb-evpn-core

user@PE1# set pbbn1 protocols evpn extended-isid-list 1000
user@PE1# set pbbn1 protocols evpn extended-isid-list 2000

user@PE1# set pbbn1 bridge-domains bda vlan-id 100
user@PE1# set pbbn1 bridge-domains bda isid-list 1000
user@PE1# set pbbn1 bridge-domains bda vlan-id-scope-local

user@PE1# set pbbn1 bridge-domains bdb vlan-id 200
user@PE1# set pbbn1 bridge-domains bdb isid-list 2000
user@PE1# set pbbn1 bridge-domains bdb vlan-id-scope-local
```

18. Configure a provider routing instance on Device PE1 with type virtual switch. Assign the PBP interface and bridge domains to the routing instance.

```
[edit routing-instances]
user@PE1# set pbn1 instance-type virtual-switch
user@PE1# set pbn1 interface pip0.0

user@PE1# set pbn1 bridge-domains bda domain-type bridge
user@PE1# set pbn1 bridge-domains bda vlan-id 10
user@PE1# set pbn1 bridge-domains bda interface xe-1/2/2.0
user@PE1# set pbn1 bridge-domains bda interface xe-1/0/0.0

user@PE1# set pbn1 bridge-domains bdb domain-type bridge
user@PE1# set pbn1 bridge-domains bdb vlan-id 20
user@PE1# set pbn1 bridge-domains bdb interface xe-1/2/2.1
user@PE1# set pbn1 bridge-domains bdb interface xe-1/0/0.1

user@PE1# set pbn1 bridge-domains bdc domain-type bridge
user@PE1# set pbn1 bridge-domains bdc vlan-id 11
user@PE1# set pbn1 bridge-domains bdc interface xe-1/2/2.2

user@PE1# set pbn1 bridge-domains bdd domain-type bridge
user@PE1# set pbn1 bridge-domains bdd vlan-id 21
user@PE1# set pbn1 bridge-domains bdd interface xe-1/2/2.3
```

19. Configure the peer PBBN routing instance in the customer routing instance.

```
[edit routing-instances]
user@PE1# set pbn1 pbb-options peer-instance pbbn1
```

20. Configure the service groups to be supported in the customer routing instance.

```
[edit routing-instances]
user@PE1# set pbn1 service-groups sga service-type elan
user@PE1# set pbn1 service-groups sga pbb-service-options isid 1000 vlan-id-list
10
user@PE1# set pbn1 service-groups sga pbb-service-options isid 1000 vlan-id-list
11
```

```

user@PE1# set pbn1 service-groups sga pbb-service-options source-bmac
00:50:50:50:50:50
user@PE1# set pbn1 service-groups sgb service-type elan
user@PE1# set pbn1 service-groups sgb pbb-service-options isid 2000 vlan-id-list
20
user@PE1# set pbn1 service-groups sgb pbb-service-options isid 2000 vlan-id-list
21

```

21. Configure the bridge domains on Device PE1.

```

[edit bridge-domains]
user@PE1# set bd vlan-id none
user@PE1# set bd interface ae6.0
user@PE1# set bd routing-interface irb.0

```

## Results

From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show routing-options**, **show protocols**, **show routing-instances**, and **show bridge-domains** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

user@PE1# show chassis

- [Verifying the MAC Table Entries on page 842](#)
- [Verifying the inet.3 Routing Table Entries on page 844](#)

### Verifying BGP Peering Status

---

**Purpose** Verify that the BGP session is established between the PE devices.

**Action** From operational mode, run the **show bgp summary** command.

```
user@PE1> show bgp summary
Groups: 1 Peers: 2 Down peers: 0
Table Tot Paths Act Paths Suppressed History Damp State Pending
bgp.evpn.0
8 8 0 0 0 0
Peer AS InPkt OutPkt OutQ Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
127.0.0.2 65221 9 7 0 0 2:09 Establ

 bgp.evpn.0: 4/4/4/0
 pbbn1.evpn.0: 4/4/4/0
 __default_evpn__.evpn.0: 0/0/0/0
127.0.0.3 65221 7 7 0 0 1:25 Establ

 bgp.evpn.0: 4/4/4/0
 pbbn1.evpn.0: 4/4/4/0
 __default_evpn__.evpn.0: 0/0/0/0
```

**Meaning** A BGP session is established between the PE devices.

### Verifying MPLS LSPs

---

**Purpose** Verify the MPLS LSP status on Device PE1.

**Action** From operational mode, run the **show mpls lsp** command.

```
user@PE1> show mpls lsp
Ingress LSP: 2 sessions
To From State Rt P ActivePath LSPname
127.0.0.2 127.0.0.1 Up 0 * PE1toPE2
127.0.0.3 127.0.0.1 Up 0 * PE1toPE3
Total 2 displayed, Up 2, Down 0

Egress LSP: 2 sessions

Total 2 displayed, Up 2, Down 0

Transit LSP: 0 sessions

Total 0 displayed, Up 0, Down 0
```

### Verifying the EVPN Routing Instance

**Purpose** Verify the EVPN routing instance information.

**Action** From operational mode, run the **show evpn instance extensive** command.

```

user@PE1> show evpn instance extensive
Instance: __default_evpn__
 Route Distinguisher: 127.0.0.1:0
 Number of bridge domains: 0
 Number of neighbors: 0

```

**Meaning** The output displays the **pbbn1** routing instance information, such as the integration of PBB with EVPN, the single-homed EVPN mode of operation, and the IP address of Devices PE2 and PE3 as the neighbors.

### Verifying Routing Table Entries of the EVPN Routing Instance

**Purpose** Verify the routing table entries of the EVPN routing instance.

**Action** From operational mode, run the `show route table pbbn1.evpn.0` command.

```

user@PE1> show route table pbbn1.evpn.0
pbbn1.evpn.0: 12 destinations, 12 routes (12 active, 0 holddown, 0 hidden)

 00:00:00:00:0a:09 D xe-1/0/0.0

```

**Meaning** The output displays the MAC addresses associated with the **ae6** aggregated Ethernet bundle.

---

### Verifying the inet.3 Routing Table Entries

---

**Purpose** Verify the inet.3 routing table entries on Device PE1.

**Action** From operational mode, run the **show route table inet.3** command.

```
user@PE1> show route table inet.3
inet.3: 2 destinations, 2 routes (2 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

127.0.0.2/8 *[RSVP/7/1] 00:11:15, metric 1
 > to 10.0.0.2 via irb.0, label-switched-path PE1toPE2
127.0.0.3/8 *[RSVP/7/1] 00:09:48, metric 1
 > to 172.17.0.1 via ge-2/1/1.0, label-switched-path PE1toPE3
```

**Meaning** The LSPs to Device PE2 and PE3 are routed using the IRB interface.

## Example: Configuring PBB with Multihomed EVPN

---

This example shows how to integrate provider backbone bridging (PBB) with Ethernet VPN (EVPN). With this integration, the control plane operations in the core are simplified, providing faster convergence and scalability enhancements than regular EVPN. The PBB-EVPN applications include Data Center Interconnect (DCI) and carrier Ethernet E-LAN services.

- [Requirements on page 844](#)
- [Overview and Topology on page 845](#)
- [Configuration on page 846](#)
- [Verification on page 870](#)

### Requirements

This example uses the following hardware and software components:

- Four provider edge (PE) devices connected to two common multihomed customer sites, and each PE device is connected to a host.
- Two multihomed customer edge (CE) devices.

- Junos OS Release 17.2R1 or later running on all the PE routers.

Before you begin:

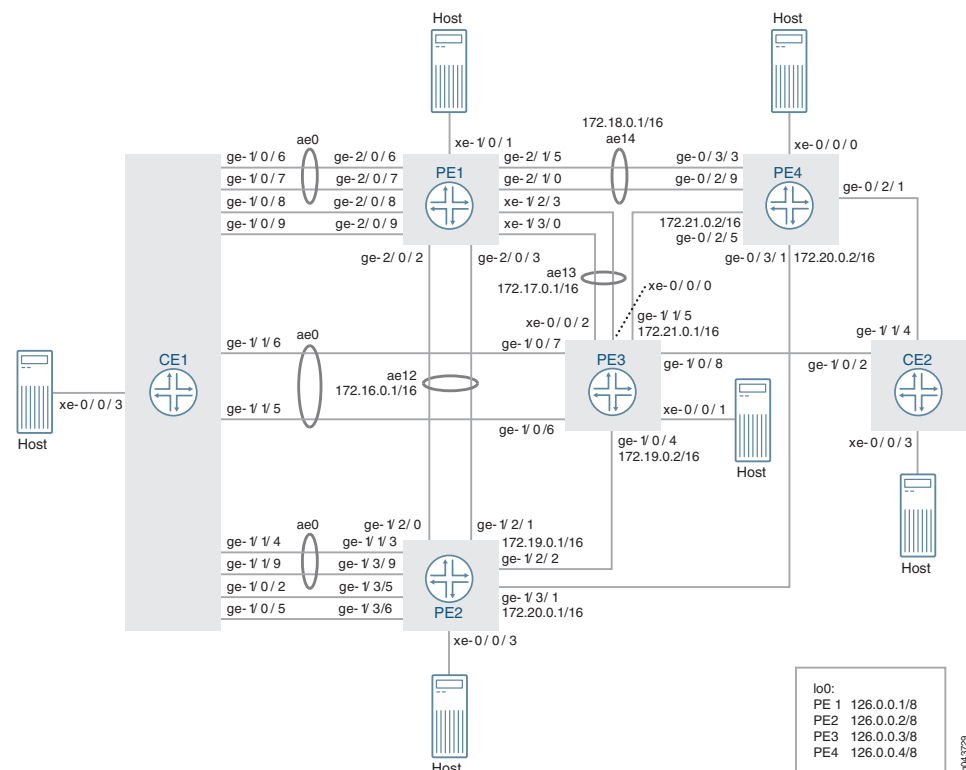

- Configure the device interfaces.
- Configure an IGP, such as OSPF, on all the PE devices.
- Establish an internal BGP session between the PE devices.
- Enable RSVP on the PE devices.
- Configure MPLS and label-switched paths (LSPs) between the PE devices.

## Overview and Topology

Starting in Junos OS Release 17.2R1, PBB is integrated with Ethernet VPN (EVPN) to enable significant reduction in the control plane learning across the core, allowing a huge number of Layer 2 services, such as data center connectivity, to transit the network in a simplified manner.

In a PBB-EVPN network, the backbone core bridge (BCB) device in the PBB core is replaced with MPLS, while retaining the service scaling properties of the PBB backbone edge bridge (BEB). The B-component (provider routing instance) is signaled using EVPN BGP signaling and encapsulated inside MPLS using provider edge (PE) and provider (P) devices. Thus, PBB-EVPN combines the vast scaling property of PBB with the simplicity of a traditional basic MPLS core network, resulting in significant reduction in the amount of network-wide state information, as opposed to regular PBB.

Figure 89: PBB with Active/Standby EVPN Multihoming

In Figure 89 on page 846, PBB is integrated with EVPN, where the CE devices are multihomed in the active/standby mode. Device CE1 is multihomed to Devices PE1, PE2, and PE3, and Device CE2 is multihomed to Device PE3 and PE4.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

## Configuring Device CE1

---

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device CE1:

1. Set the number of aggregated Ethernet interfaces on Device CE1.

```
[edit chassis]
user@CE1# set aggregated-devices ethernet device-count 50
```

2. Set Device CE1's network services to enhanced Internet Protocol and use enhanced mode capabilities.

```
[edit chassis]
user@CE1# set chassis network-services enhanced-ip
```

3. Configure Device CE1's interfaces.

```
[edit interfaces]
user@CE1# set interfaces xe-0/0/3 flexible-vlan-tagging
user@CE1# set interfaces xe-0/0/3 encapsulation flexible-ethernet-services
user@CE1# set interfaces xe-0/0/3 unit 0 encapsulation vlan-bridge
user@CE1# set interfaces xe-0/0/3 unit 0 vlan-id 10
user@CE1# set interfaces xe-0/0/3 unit 1 encapsulation vlan-bridge
user@CE1# set interfaces xe-0/0/3 unit 1 vlan-id 20
user@CE1# set interfaces xe-0/0/3 unit 2 encapsulation vlan-bridge
user@CE1# set interfaces xe-0/0/3 unit 2 vlan-id 30
```

```
user@CE1# set interfaces ge-1/0/2 flexible-vlan-tagging
user@CE1# set interfaces ge-1/0/2 encapsulation flexible-ethernet-services
user@CE1# set interfaces ge-1/0/2 unit 1 encapsulation vlan-bridge
user@CE1# set interfaces ge-1/0/2 unit 1 vlan-id 20
```

```
user@CE1# set interfaces ge-1/0/5 flexible-vlan-tagging
user@CE1# set interfaces ge-1/0/5 encapsulation flexible-ethernet-services
user@CE1# set interfaces ge-1/0/5 unit 2 encapsulation vlan-bridge
user@CE1# set interfaces ge-1/0/5 unit 2 vlan-id 30
```

```
user@CE1# set interfaces ge-1/0/6 gigether-options 802.3ad ae0
```

```
user@CE1# set interfaces ge-1/0/7 gigether-options 802.3ad ae0
```

```
user@CE1# set interfaces ge-1/0/8 flexible-vlan-tagging
user@CE1# set interfaces ge-1/0/8 encapsulation flexible-ethernet-services
user@CE1# set interfaces ge-1/0/8 unit 1 encapsulation vlan-bridge
user@CE1# set interfaces ge-1/0/8 unit 1 vlan-id 20
```

```
user@CE1# set interfaces ge-1/0/9 flexible-vlan-tagging
user@CE1# set interfaces ge-1/0/9 encapsulation flexible-ethernet-services
```

```
user@CE1# set interfaces ge-1/0/9 unit 2 encapsulation vlan-bridge
user@CE1# set interfaces ge-1/0/9 unit 2 vlan-id 30
```

```
user@CE1# set interfaces ge-1/1/4 gigether-options 802.3ad ae0
```

```
user@CE1# set interfaces ge-1/1/5 gigether-options 802.3ad ae0
```

```
user@CE1# set interfaces ge-1/1/6 gigether-options 802.3ad ae0
```

```
user@CE1# set interfaces ge-1/1/9 gigether-options 802.3ad ae0
```

4. Configure the aggregated Ethernet bundle on Device CE1.

```
[edit interfaces]
user@CE1# set interfaces ae0 flexible-vlan-tagging
user@CE1# set interfaces ae0 encapsulation flexible-ethernet-services
user@CE1# set interfaces ae0 aggregated-ether-options minimum-links 1
user@CE1# set interfaces ae0 unit 0 encapsulation vlan-bridge
user@CE1# set interfaces ae0 unit 0 vlan-id 10
```

5. Configure the bridge domains on Device CE1.

```
[edit bridge-domains]
user@CE1# set bd10 domain-type bridge
user@CE1# set bd10 vlan-id 10
user@CE1# set bd10 interface ae0.0
user@CE1# set bd10 interface xe-0/0/3.0
```

```
user@CE1# set bd20 domain-type bridge
user@CE1# set bd20 vlan-id 20
user@CE1# set bd20 interface xe-0/0/3.1
user@CE1# set bd20 interface ge-1/0/8.1
user@CE1# set bd20 interface ge-1/0/2.1
```

```
user@CE1# set bd30 domain-type bridge
user@CE1# set bd30 vlan-id 30
user@CE1# set bd30 interface xe-0/0/3.2
user@CE1# set bd30 interface ge-1/0/9.2
user@CE1# set bd30 interface ge-1/0/5.2
```

**Results** From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, and **show bridge-domains** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@CE1# show chassis
aggregated-devices {
 ethernet {
 device-count 50;
 }
}
network-services enhanced-ip;
```

```
user@CE1# show interfaces

```

If you are done configuring the device, enter **commit** from configuration mode.

### Configuring Device PE1

---

**Step-by-Step Procedure** The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Set the number of aggregated Ethernet interfaces on Device PE1.  

```
[edit chassis]
user@PE1# set aggregated-devices ethernet device-count 50
```
2. Set Device PE1's network services to enhanced Internet Protocol and use enhanced mode capabilities.  

```
[edit chassis]
user@PE1# set network-services enhanced-ip
```
3. Configure the CE-facing interfaces of Device PE1.  

```
[edit interfaces]
user@PE1# set ge-2/0/6 gigether-options 802.3ad ae0

user@PE1# set ge-2/0/7 gigether-options 802.3ad ae0

user@PE1# set ge-2/0/8 flexible-vlan-tagging
user@PE1# set ge-2/0/8 encapsulation flexible-ethernet-services
user@PE1# set ge-2/0/8 unit 0 encapsulation vlan-bridge
user@PE1# set ge-2/0/8 unit 0 vlan-id 20

user@PE1# set ge-2/0/9 flexible-vlan-tagging
user@PE1# set ge-2/0/9 encapsulation flexible-ethernet-services
user@PE1# set ge-2/0/9 unit 0 encapsulation vlan-bridge
user@PE1# set ge-2/0/9 unit 0 vlan-id 30
```
4. Configure the aggregate Ethernet bundle on Device PE1 that connects to Device CE1.  

```
[edit interfaces]
user@PE1# set ae0 flexible-vlan-tagging
user@PE1# set ae0 encapsulation flexible-ethernet-services
user@PE1# set ae0 unit 0 encapsulation vlan-bridge
user@PE1# set ae0 unit 0 vlan-id 10
```
5. Configure the EVPN multihoming parameters for the CE-facing interfaces and aggregate Ethernet bundle that connect to the multihomed customer site.  

```
[edit interfaces]
user@PE1# set ge-2/0/8 esi 00:22:22:22:22:22:22:22:22:22
```

```
user@PE1# set ge-2/0/8 esi single-active
user@PE1# set ge-2/0/8 esi source-bmac 00:22:22:22:22:22
```

```
user@PE1# set ge-2/0/9 esi 00:33:33:33:33:33:33:33
user@PE1# set ge-2/0/9 esi single-active
user@PE1# set ge-2/0/9 esi source-bmac 00:33:33:33:33:33
```

```
user@PE1# set ae0 esi 00:11:11:11:11:11:11:11
user@PE1# set ae0 esi single-active
user@PE1# set ae0 esi source-bmac 00:11:11:11:11:11
```

**NOTE:** In this example, the EVPN multihoming is operating in the active/standby mode. To configure active/active EVPN multihoming, include the `active-active` statement at the `[edit interfaces interface-name esi]` hierarchy level instead of the `single-active` statement.

6. Configure the interface of Device PE1 that connects to Devices PE2, PE3, and PE4.

```
[edit interfaces]
user@PE1# set ge-2/0/2 gigether-options 802.3ad ae12
user@PE1# set ge-2/0/3 gigether-options 802.3ad ae12

user@PE1# set xe-1/2/3 gigether-options 802.3ad ae13
user@PE1# set xe-1/3/0 gigether-options 802.3ad ae13

user@PE1# set ge-2/1/0 gigether-options 802.3ad ae14
user@PE1# set ge-2/1/5 gigether-options 802.3ad ae14
```

7. Configure the aggregate Ethernet bundle on Device PE1 that connect to Devices PE2, PE3, and PE4.

```
[edit interfaces]
user@PE1# set ae12 flexible-vlan-tagging
user@PE1# set ae12 encapsulation flexible-ethernet-services
user@PE1# set ae12 aggregated-ether-options minimum-links 1
user@PE1# set ae12 unit 0 vlan-id 1200
user@PE1# set ae12 unit 0 family inet address 172.16.0.1/16
user@PE1# set ae12 unit 0 family iso
user@PE1# set ae12 unit 0 family mpls

user@PE1# set ae13 flexible-vlan-tagging
user@PE1# set ae13 encapsulation flexible-ethernet-services
user@PE1# set ae13 aggregated-ether-options minimum-links 1
user@PE1# set ae13 unit 0 vlan-tags outer 1300
user@PE1# set ae13 unit 0 vlan-tags inner 13
user@PE1# set ae13 unit 0 family inet address 172.17.0.1/16
user@PE1# set ae13 unit 0 family iso
user@PE1# set ae13 unit 0 family mpls
```

```
user@PE1# set ae14 aggregated-ether-options minimum-links 1
user@PE1# set ae14 unit 0 family inet address 172.18.0.1/16
user@PE1# set ae14 unit 0 family iso
user@PE1# set ae14 unit 0 family mpls
```

8. Configure the interface of Device PE1 that connects to the host.

```
[edit interfaces]
user@PE1# set xe-1/0/1 flexible-vlan-tagging
user@PE1# set xe-1/0/1 encapsulation flexible-ethernet-services
user@PE1# set xe-1/0/1 unit 0 encapsulation vlan-bridge
user@PE1# set xe-1/0/1 unit 0 vlan-id 10
```

9. Configure the loopback interface of Device PE1.

```
[edit interfaces]
user@PE1# set lo0 unit 0 family inet address 127.0.0.1/8 primary
user@PE1# set lo0 unit 0 family iso
```

10. Configure the customer backbone port (CBP) interfaces on Device PE1.

```
[edit interfaces]
user@PE1# set cbp0 unit 0 family bridge interface-mode trunk
user@PE1# set cbp0 unit 0 family bridge bridge-domain-type bvlan
user@PE1# set cbp0 unit 0 family bridge isid-list all
```

```
user@PE1# set cbp0 unit 1 family bridge interface-mode trunk
user@PE1# set cbp0 unit 1 family bridge bridge-domain-type bvlan
user@PE1# set cbp0 unit 1 family bridge isid-list all
```

11. Configure the Provider Instance Port (PIP) on Device PE1.

```
[edit interfaces]
user@PE1# set pip0 unit 0 family bridge interface-mode trunk
user@PE1# set pip0 unit 0 family bridge bridge-domain-type svlan
user@PE1# set pip0 unit 0 family bridge isid-list all-service-groups
```

```
user@PE1# set pip0 unit 1 family bridge interface-mode trunk
user@PE1# set pip0 unit 1 family bridge bridge-domain-type svlan
user@PE1# set pip0 unit 1 family bridge isid-list all-service-groups
```

12. Configure the router ID and autonomous system number for Device PE1.

```
[edit routing-options]
user@PE1# set router-id 127.0.0.1
user@PE1# set autonomous-system 65221
```

13. Configure RSVP on all the interfaces of Device PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set rsvp interface all
user@PE1# set rsvp interface fxp0.0 disable
```

14. Configure MPLS on all the interfaces of Device PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
```

15. Configure LSPs from Device PE1 to all other PE devices.

```
[edit protocols]
user@PE1# set mpls label-switched-path pe1tope2 from 127.0.0.1
user@PE1# set mpls label-switched-path pe1tope2 to 127.0.0.2
user@PE1# set mpls label-switched-path pe1tope2 primary direct_to_pe2
```

```
user@PE1# set mpls label-switched-path pe1tope3 from 127.0.0.1
user@PE1# set mpls label-switched-path pe1tope3 to 127.0.0.3
user@PE1# set mpls label-switched-path pe1tope3 primary direct_to_pe3
```

```
user@PE1# set mpls label-switched-path pe1tope4 from 127.0.0.1
user@PE1# set mpls label-switched-path pe1tope4 to 127.0.0.4
user@PE1# set mpls label-switched-path pe1tope4 primary direct_to_pe4
```

16. Configure MPLS paths from Device PE1 to all other PE devices.

```
[edit protocols]
user@PE1# set mpls path direct_to_pe2 100.12.1.2 strict
user@PE1# set mpls path direct_to_pe3 100.13.1.3 strict
user@PE1# set mpls path direct_to_pe4 100.14.1.4 strict
```

17. Configure an internal BGP session under family EVPN from Device PE1 to all other PE devices.

```
[edit protocols]
user@PE1# set bgp group ibgp type internal
user@PE1# set bgp group ibgp local-address 127.0.0.1
user@PE1# set bgp group ibgp family evpn signaling
user@PE1# set bgp group ibgp neighbor 127.0.0.2
user@PE1# set bgp group ibgp neighbor 127.0.0.3
user@PE1# set bgp group ibgp neighbor 127.0.0.4
```

18. Configure OSPF on all the interfaces of Device of PE1, excluding the management interface.

```
[edit protocols]
user@PE1# set ospf traffic-engineering
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

19. Configure a customer routing instance (I-component) on Device PE1 with type virtual switch. Assign the CBP interface, route-distinguisher, and virtual routing and forwarding (VRF) target values to the PBBN routing instance.

```
[edit routing-instances]
```

```
user@PE1# set pbbn1 instance-type virtual-switch
user@PE1# set pbbn1 interface cbp0.0
```

```
user@PE1# set pbbn1 route-distinguisher 127.0.0.1:1
```

```
user@PE1# set pbbn1 vrf-target target:100:1
```

20. Configure PBB-EVPN integration from the customer routing instance. Assign the extended I-SID list and bridge domains to the routing instance.

```
[edit routing-instances]
user@PE1# set pbbn1 protocols evpn pbb-evpn-core
user@PE1# set pbbn1 protocols evpn extended-isid-list 1000

user@PE1# set pbbn1 bridge-domains bda vlan-id 100
user@PE1# set pbbn1 bridge-domains bda isid-list 1000
user@PE1# set pbbn1 bridge-domains bda vlan-id-scope-local
```

21. Configure a provider routing instance on Device PE1 with type virtual switch. Assign the PBP interface and bridge domains to the routing instance.

```
[edit routing-instances]
user@PE1# set pbn1 instance-type virtual-switch
user@PE1# set pbn1 interface pip0.0

user@PE1# set pbn1 bridge-domains bda domain-type bridge
user@PE1# set pbn1 bridge-domains bda vlan-id 10
user@PE1# set pbn1 bridge-domains bda interface ae0.0
user@PE1# set pbn1 bridge-domains bda interface xe-1/0/1.0
user@PE1# set pbn1 bridge-domains bda interface ge-2/0/9.0
user@PE1# set pbn1 bridge-domains bda interface ge-2/0/8.0
```

22. Configure the peer PBBN routing instance in the customer routing instance.

```
[edit routing-instances]
user@PE1# set pbn1 pbb-options peer-instance pbbn1
```

23. Configure the service groups to be supported in the customer routing instance.

```
[edit routing-instances]
user@PE1# set pbn1 service-groups sga service-type elan
user@PE1# set pbn1 service-groups sga pbb-service-options isid 1000 vlan-id-list
10
```

**Results** From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **routing-options**, **show protocols** and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Verifying BGP Peering Status on page 870](#)
- [Verify MAC Table Entries on page 871](#)
- [Verifying the EVPN Database on page 871](#)
- [Verifying EVPN Routing Instances on page 871](#)

### Verifying BGP Peering Status

**Purpose** Verify that the BGP session is established between the PE devices.

**Action** From operational mode, run the **show bgp summary** command.

```

user@PE1> show bgp summary
Groups: 1 Peers: 3 Down peers: 0
Table Tot Paths Act Paths Suppressed History Damp State Pending
bgp.evpn.0
13 13 0 0 0 0
Peer AS InPkt OutPkt OutQ Flaps Last Up/Dwn
State|#Active/Received/Accepted/Damped...
127.0.0.2 65221 10 8 0 0 42 Establ

 bgp.evpn.0: 6/6/6/0
 pbbn1.evpn.0: 3/3/3/0
 __default_evpn__.evpn.0: 3/3/3/0
127.0.0.3 65221 8 8 0 0 40 Establ

 bgp.evpn.0: 4/4/4/0
 pbbn1.evpn.0: 3/3/3/0
 __default_evpn__.evpn.0: 1/1/1/0
127.0.0.4 65221 9 11 0 0 1:04 Establ

 bgp.evpn.0: 3/3/3/0
 pbbn1.evpn.0: 3/3/3/0
 __default_evpn__.evpn.0: 0/0/0/0

```

**Meaning** A BGP session is established between the PE devices.

### Verify MAC Table Entries

**Purpose** Verify the number of **rbeb** interfaces learned in the MAC table on all PEs.

**Action** From operational mode, run the **show bgp summary** command.

```
user@PE1> show bridge mac-table count instance pbn1 bridge-domain bda
10 MAC address learned in routing instance pbn1 bridge domain bda
```

MAC address count per interface within routing instance:

| Logical interface | MAC count |
|-------------------|-----------|
| ae0.0:10          | 0         |
| ge-2/0/8.0:10     | 10        |
| ge-2/0/9.0:10     | 0         |
| rbeb.32772        | 0         |
| rbeb.32771        | 0         |
| xe-1/0/0.0:10     | 0         |

MAC address count per learn VLAN within routing instance:

| Learn VLAN ID | MAC count |
|---------------|-----------|
| 10            | 10        |

**Meaning** For VLAN ID 10, 10 MAC addresses have been learned in the MAC table of Device PE1.

### Verifying the EVPN Database

**Purpose** Verify the EVPN database information on Device PE4.

**Action** From operational mode, run the **show evpn database** command.

```
user@PE1> show evpn database
```

Instance: pbbn1

| VLAN       | DomainId | MAC address       | Active source | Timestamp       |

```

**Meaning** The command output displays PBB-EVPN integration, where EVPN is in the active/standby multihoming mode. If EVPN multihoming was configured in the active/active mode, the status of all the ESIs would be **Up/Forwarding**. In the active/standby multihoming mode, one ESI is in the **Up/Forwarding** state and all other ESIs remain in the **Up/Blocking** state.

## PBB-EVPN MAC Pinning Overview

---

Starting in Junos OS Release 17.2, the MAC pinning feature is enabled on provider backbone bridging (PBB) and Ethernet VPN (EVPN) integration, including customer edge (CE) interfaces and EVPN over PBB core in both all-active or single-active mode.

The MAC pinning feature is used to avoid loops in a network and is also used for MAC security restriction by avoiding MAC move on duplicate MAC detection. When MAC pinning is enabled, the dynamically learned MAC addresses are not allowed to move to any other interface in a bridge domain until it is aged out and traffic received with the same source MAC address on other bridge interfaces are discarded. This feature is an advantage over blocking of the complete interface on duplicate MAC detection or loop, as MAC pinning works at the MAC label. This feature is local to a provider edge (PE) device and does not require any interoperability.

PBB has I-component and B-Component, where I-component (customer routing instance) is responsible for mapping the CE port traffic to the instance source ID (I-SID), and the B-component learns and forwards traffic on the backbone port. Traffic received from the MPLS core or from the PBB port is classified and based on the I-SID and PBB MAC, and gets mapped to the correct I-component. Remote customer MAC addresses are learned over remote backbone edge port (BEB) interface in the I-component bridge domain. This interface is created dynamically on PBB neighbor detection. MAC addresses learned over the remote BEB interface in I-component are pinned when MAC pinning is enabled for PBB-EVPN.

To configure MAC pinning for PBB-EVPN, include the **mac-pinning** statement at the **[edit routing-instances *pbbn* protocols evpn]**, where **pbbn** is the PBB routing instance over backbone port (B-component). With this configuration, the dynamically learned MAC addresses in the PBB I-component bridge domain over CE interfaces, as well as PBB-MPLS core interfaces are pinned.

When configuring the PBB-EVPN MAC pinning feature, take the following into consideration:

- PBB-EVPN MAC pinning is supported on MX Series routers with MPC and MIC interfaces only.
- PBB-EVPN MAC pinning is supported on Ethernet Layer 2 bridge interfaces only.
- When there is a MAC move between the I-component and an access interface, the MAC address is learned locally over the PBB-EVPN MPLS core over a remote BEB interface in the I-component bridge domain. The MAC moves between the CE or core interfaces for this MAC is not allowed.
- In MAC pinning for PBB with EVPN active-active and single-active multihoming, MAC pinning must be enabled or disabled on all the multihomed PE devices in the broadcast domain. This is because MAC pinning at a multihomed PE device is local to the PE, and it is possible that a MAC address that is pinned towards a multihomed CE device and PE device is also pinned toward a single-homed customer site or toward any other Ethernet segment identifier (ESI) at another multihomed PE device.
- A next hop bridge domain is created in PBB-EVPN I-component bridge domain toward the B-component when there is an unresolved source MAC notification when the first remote MAC address is received. As a result, the first MAC address learned over PBB back bone core interface can be delayed on pinning, and may result moving to other single-homed or ESI interface if the same MAC traffic is received.
- Static MAC addresses are given preference over dynamic pin MACs.
- MAC pinning is enabled for all neighbors of a PBB routing instance and cannot be enabled for a specific neighbor.
- PBB-EVPN MAC pin discard notification is not generated for a remote BEB interface when traffic is discarded due to MAC pinning until a MAC is learned locally over the remote BEB interface.

## Configuring PBB-EVPN MAC Pinning

Starting in Junos OS Release 17.2, the MAC pinning feature is enabled on provider backbone bridging (PBB) and Ethernet VPN (EVPN) integration, including customer edge (CE) interfaces and EVPN over PBB core in both all-active or single-active mode.

When MAC pinning is enabled, the dynamically learned MAC addresses are not allowed to move to any other interface in a bridge domain until it is aged out and traffic received with the same source MAC address on other bridge interfaces are discarded. This feature is an advantage over blocking of the complete interface on duplicate MAC detection or loop detection, as MAC pinning works at the MAC label. This feature is local to a provider edge (PE) device and does not require any interoperability.

Before you begin:

- Configure the device interfaces, including the customer backbone port (CBP) interface, the provider instance port (PIP) interfaces, and the loopback interface. Assign the bridge family to the interfaces.
- Assign the router ID and autonomous system ID to the device.
- Configure an internal BGP group with EVPN signaling.
- Enable the following protocols on the device:
  - MPLS
  - LDP
  - OSPF

To enable MAC pinning on PBB-EVPN:

1. Configure the B-component routing instance.

Assign the virtual switch instance type and the CBP interface to it. Configure other routing instance attributes like route distinguisher and virtual routing and forwarding (VRF) target to the routing instance.

**NOTE:** Configure B-component routing instances for other CBP interface units on the device, and assign different VLAN IDs and I-SID lists for the different interface units.

```
[edit routing-instances]
user@R1# set pbbn instance-type virtual-switch
user@R1# set pbbn interface cbp-interface
user@R1# set pbbn route-distinguisher route-distinguisher-value
user@R1# set pbbn vrf-target vrf-target
```

2. Enable PBB- EVPN integration for the B-component routing instance.

```
[edit routing-instances]
```

```
user@R1# set pbbn protocols evpn pbb-evpn-core
```

3. Enable MAC pinning for the B-component routing instance.

```
[edit routing-instances]
user@R1# set pbbn protocols evpn mac-pinning
```

4. Assign instance source IDs (I-SID) list to the B-component routing instance.

```
[edit routing-instances]
user@R1# set pbbn protocols evpn extended-isid-list extended-isid-list
```

5. Configure a bridge domain for the B-component routing instance and assign a VLAN and I-SID list to the bridge domain.

```
[edit routing-instances]
user@R1# set pbbn bridge-domains bridge-domain vlan-id vlan-id
user@R1# set pbbn bridge-domains bridge-domain isid-list isid-list
```

6. Configure the I-component routing instance.

Assign the virtual switch instance type and the PIP interface to it.

**NOTE:** Configure I-component routing instances for other PIP interface units on the device, and assign different bridge domains, VLAN IDs and I-SID lists for the different interface units.

```
[edit routing-instances]
user@R1# set pbn instance-type virtual-switch
user@R1# set pbn interface pip-interface
```

7. Configure bridge domain for the I-component routing instance and assign interfaces and VLANs to the bridge domain.

```
[edit routing-instances]
user@R1# set pbn bridge-domains bridge-domain domain-type bridge
user@R1# set pbn bridge-domains bridge-domain vlan-id vlan-id
user@R1# set pbn bridge-domains bridge-domain interface interface-name
```

8. Enable MAC pinning for the interface in the I-component routing instance.

```
[edit routing-instances]
user@R1# set pbn bridge-domains bridge-domain bridge-options interface
interface-name mac-pinning
```

9. Configure peering between the B-component and the I-component routing instances.

```
[edit routing-instances]
user@R1# set pbn bridge-domains bridge-domain pbb-options peer-instance pbbn
```

10. Configure PBB service group and assign I-SID and VLAN ID list.

```
[edit routing-instances]
```

```
user@R1# set pbn service-groups service-group pbb-service-options isid isid vlan-id-list
valn-id-list
```

- [Layer 2 Circuit Overview on page 885](#)

## Layer 2 Circuit Overview

A Layer 2 circuit is a point-to-point Layer 2 connection transported using Multiprotocol Label Switching (MPLS) or other tunneling technology on the service provider's network. A Layer 2 circuit is similar to a circuit cross-connect (CCC), except that multiple virtual circuits (VCs) are transported over a single shared label-switched path (LSP) tunnel between two provider edge (PE) routers. In contrast, each CCC requires a separate dedicated LSP.

The Junos OS implementation of Layer 2 circuits supports only the remote form of a Layer 2 circuit; that is, a connection from a local customer edge (CE) router to a remote CE router. [Figure 90 on page 885](#) illustrates the components of a Layer 2 circuit.

**Figure 90: Components of a Layer 2 Circuit**

To establish a Layer 2 circuit, the Link Integrity Protocol (LIP) is used as the signaling protocol to advertise the ingress label to the remote PE routers. For this purpose, a targeted remote LDP neighbor session is established using the extended discovery mechanism described in LDP, and the session is brought up to the remote PE loopback IP address. Because LDP looks at the Layer 2 circuit configuration and initiates extended neighbor discovery for all the Layer 2 circuit neighbors (the remote PEs), no new configuration is necessary in LDP. Each Layer 2 circuit is represented by the logical interface connecting the local PE router to the local customer edge (CE) router. Note that LDP

must be enabled on the lo0.0 interface for extended neighbor discovery to function correctly.

Packets are sent to remote CE routers over an egress VPN label advertised by the remote PE router, using a targeted LDP session. The VPN label is sent over an LDP LSP to the remote PE router connected to the remote CE router. Return traffic from the remote CE router destined to the local CE router is sent using an ingress VPN label advertised by the local PE router, which is also sent over the LDP LSP to the local PE router from the remote PE router.

# Layer 2 Circuits Configuration Overview

- [Configuring Static Layer 2 Circuits on page 887](#)
- [Configuring Local Interface Switching in Layer 2 Circuits on page 888](#)
- [Configuring Interfaces for Layer 2 Circuits on page 890](#)
- [Configuring Policies for Layer 2 Circuits on page 898](#)
- [Configuring LDP for Layer 2 Circuits on page 901](#)

## Configuring Static Layer 2 Circuits

---

You can configure static Layer 2 circuit pseudowires. Static pseudowires are designed for networks that do not support LDP or do not have LDP enabled. You configure a static pseudowire by configuring static values for the in and out labels needed to enable a pseudowire connection. The **ignore-mtu-mismatch**, **ignore-vlan-id**, and **ignore-encapsulation-mismatch** statements are not relevant for static pseudowire configurations since the peer router cannot forward this information.

When you configure static pseudowires, you need to manually compare the encapsulation, TDM bit rate, and control word of the router with the remote peer router and ensure that they match, otherwise the static pseudowire might not work.

To configure static Layer 2 circuit pseudowires, include the **static** statement:

```
static {
 incoming-label label;
 outgoing-label label;
 send-oam;
}
```

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

You can configure a static pseudowire as a standalone Layer 2 circuit or in conjunction with a redundant pseudowire. You configure the static pseudowire statement at the **[edit protocols l2circuit neighbor address interface *interface-name*]** hierarchy level. You configure the redundant pseudowire at the **[edit protocols l2circuit neighbor address interface *interface-name* backup-neighbor *neighbor*]** hierarchy level. If you configure a static pseudowire to a neighbor and also configure a redundant pseudowire, the redundant pseudowire must also be static.

You can enable the ability to ping a static pseudowire by configuring the **send-oam** statement. This functionality applies to the backup neighbor as well. Once you have configured this statement, you can ping the static pseudowire by issuing the **ping mpls l2circuit** command.

For information about how to configure redundant pseudowires, see “[Configuring Redundant Pseudowires for Layer 2 Circuits and VPLS](#)” on page 185.

---

## Configuring Local Interface Switching in Layer 2 Circuits

You can configure a virtual circuit entirely on the local router, terminating the circuit on a local interface. Possible uses for this feature include being able to enable switching between Frame Relay DLCIs.

To configure a virtual circuit to terminate locally, include the **local-switching** statement:

```
local-switching {
 interface interface-name {
 description text;
 end-interface {
 interface interface-name;
 no-revert;
 protect-interface interface-name;
 }
 ignore-mtu-mismatch;
 no-revert;
 protect-interface interface-name;
 }
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols l2circuit]**
- **[edit logical-systems *logical-system-name* protocols l2circuit]**

**NOTE:** ACX Series routers do not support the **[edit logical-systems]** hierarchy level.

---

The following sections describe how to configure local interface switching:

- [Configuring the Interfaces for the Local Interface Switch on page 889](#)
- [Enabling Local Interface Switching When the MTU Does Not Match on page 890](#)

## Configuring the Interfaces for the Local Interface Switch

Local interface switching requires you to configure at least two interfaces:

- Starting interface—Include the **interface** statement at the **[edit protocols l2circuit local-switching]** hierarchy level.
- Ending interface—Include the **end-interface** statement at the **[edit protocols l2circuit local-switching interface *interface-name*]** hierarchy level.

You can also configure virtual circuit interface protection for each local interface:

- Protect interface for the starting interface—Include the **protect-interface** statement at the **[edit protocols l2circuit local-switching interface *interface-name*]** hierarchy level.
- Protect interface for the ending interface—Include the **protect-interface** statement at the **[edit protocols l2circuit local-switching interface *interface-name* end-interface]** hierarchy level.

For more information about how to configure protect interfaces, see [“Configuring the Protect Interface” on page 894](#).

Typically, when the primary interface goes down, the pseudowire starts using the protect interface. By default, when the primary interface comes back online, the interface is switched-over back from the protect interface to the primary interface. To prevent the switchover back to the primary interface, unless the primary interface goes down, include the **no-revert** statement. This prevents loss of traffic during the switchover.

**NOTE:** If the protect interface fails, the interface is switched-over back to the primary interface, irrespective of whether or not the **no-revert** statement is included in the configuration.

You can configure the **no-revert** statement both for the starting interface and the ending interface.

```
[edit protocols l2circuit local-switching interface interface-name]
no-revert;
end-interface {
 interface interface-name;
 no-revert;
}
```

**NOTE:** The protect interface must be configured prior to configuring the **no-revert** statement.

## Enabling Local Interface Switching When the MTU Does Not Match

You can configure a local switching interface to ignore the MTU configuration set for the associated physical interface. This enables you to bring up a circuit between two logical interfaces that are defined on physical interfaces with different MTU values.

To configure the local switching interface to ignore the MTU configured for the physical interface, include the **ignore-mtu-mismatch** statement:

```
ignore-mtu-mismatch;
```

You can include this statement at the following hierarchy levels:

- [edit protocols l2circuit local-switching interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols l2circuit local-switching interface *interface-name*]

**NOTE:** ACX Series routers do not support the [edit logical-systems] hierarchy level.

---

## Configuring Interfaces for Layer 2 Circuits

The following sections describe how to configure interfaces for Layer 2 circuits:

**NOTE:** Not all subtasks are supported on all platforms; check the CLI on your device.

- [Configuring the Address for the Neighbor of the Layer 2 Circuit on page 890](#)
- [Configuring the Neighbor Interface for the Layer 2 Circuit on page 891](#)
- [Configuring the Interface Encapsulation Type for Layer 2 Circuits on page 897](#)
- [Configuring ATM2 IQ Interfaces for Layer 2 Circuits on page 897](#)

## Configuring the Address for the Neighbor of the Layer 2 Circuit

All the Layer 2 circuits using a particular remote PE router designated for remote CE routers are listed under the **neighbor** statement (“neighbor” designates the PE router). Each neighbor is identified by its IP address and is usually the end-point destination for the label-switched path (LSP) tunnel transporting the Layer 2 circuit.

To configure a PE router as a neighbor for a Layer 2 circuit, specify the neighbor address using the **neighbor** statement:

```
neighbor address {
 ...
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols l2circuit]

- [edit logical-systems *logical-system-name* protocols l2circuit]

## Configuring the Neighbor Interface for the Layer 2 Circuit

Each Layer 2 circuit is represented by the logical interencapsulationface connecting the local provider edge (PE) router to the local customer edge (CE) router. This interface is tied to the Layer 2 circuit neighbor configured in “Configuring the Address for the Neighbor of the Layer 2 Circuit” on page 890.

To configure the interface for a Layer 2 circuit neighbor, include the **interface** statement:

**NOTE:** The commit operation fails, if the same logical interface is configured for both Layer 2 circuit and ccc connection.

**NOTE:** On the EX9200 switches, replace encapsulation-type with the **encapsulation** statement.

```
interface interface-name {
 bandwidth (bandwidth | ctnumber bandwidth);
 community community-name;
 (control-word | no-control-word);
 description text;
 encapsulation-type type;
 ignore-encapsulation-mismatch;
 ignore-mtu-mismatch;
 mtu mtu-number;
 no-revert;
 protect-interface interface-name;
 pseudowire-status-tlv;
 psn-tunnel-endpoint address;
 virtual-circuit-id identifier;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols l2circuit neighbor *address*]
- [edit logical-systems *logical-system-name* protocols l2circuit neighbor *address*]

The following sections describe how to configure the interface for the Layer 2 circuit neighbor:

- Configuring a Community for the Layer 2 Circuit on page 892
- Configuring the Control Word for Layer 2 Circuits on page 892
- Configuring the Encapsulation Type for the Layer 2 Circuit Neighbor Interface on page 893
- Enabling the Layer 2 Circuit When the Encapsulation Does Not Match on page 894
- Configuring the Protect Interface on page 894
- Configuring the Protect Interface From Switching Over to the Primary Interface on page 894

- [Configuring the Pseudowire Status TLV on page 895](#)
- [Configuring Layer 2 Circuits over Both RSVP and LDP LSPs on page 895](#)
- [Configuring the Virtual Circuit ID on page 896](#)

---

### Configuring a Community for the Layer 2 Circuit

---

To configure a community for a Layer 2 circuit, include the **community** statement:

```
community community-name;
```

You can include this statement at the following hierarchy levels:

- **[edit protocols l2circuit neighbor *address* interface *interface-name*]**
- **[edit logical-systems *logical-system-name* protocols l2circuit neighbor *address* interface *interface-name*]**

For information about how to configure a routing policy for a Layer 2 circuit, see [“Configuring Policies for Layer 2 Circuits” on page 898](#).

---

### Configuring the Control Word for Layer 2 Circuits

---

To emulate the virtual circuit (VC) encapsulation for Layer 2 circuits, a 4-byte control word is added between the Layer 2 protocol data unit (PDU) being transported and the VC label that is used for demultiplexing. For most protocols, a null control word consisting of all zeroes is sent between Layer 2 circuit neighbors.

However, individual bits are available in a control word that can carry Layer 2 protocol control information. The control information is mapped into the control word, which allows the header of a Layer 2 protocol to be stripped from the frame. The remaining data and control word can be sent over the Layer 2 circuit, and the frame can be reassembled with the proper control information at the egress point of the circuit.

The following Layer 2 protocols map Layer 2 control information into special bit fields in the control word:

- **Frame Relay**—The control word supports the transport of discard eligible (DE), forward explicit congestion notification (FECN), and backward explicit congestion notification (BECN) information. For configuration information, see [“Configuring the Control Word for Frame Relay Interfaces” on page 893](#).

**NOTE:** Frame Relay is not supported on the ACX Series routers.

---

- **ATM AAL5 mode**—The control word supports the transport of sequence number processing, ATM cell loss priority (CLP), and explicit forward congestion indication (EFCI) information. When you configure an AAL5 mode Layer 2 circuit, the control information is carried by default and no additional configuration is needed.
- **ATM cell-relay mode**—The control word supports sequence number processing only. When you configure a cell-relay mode Layer 2 circuit, the sequence number information is carried by default and no additional configuration is needed.

The Junos OS implementation of sequence number processing for ATM cell-relay mode and AAL5 mode is not the same as that described in Sec. 3.1.2 of the IETF draft *Encapsulation Methods for Transport of Layer 2 Frames Over IP and MPLS Networks*. The differences are as follows:

- A packet with a sequence number of 0 is considered as out of sequence.
- A packet that does not have the next incremental sequence number is considered out of sequence.
- When out-of-sequence packets arrive, the sequence number in the Layer 2 circuit control word increments by one and becomes the expected sequence number for the neighbor.

The following sections discuss how to configure the control word for Layer 2 circuits:

- [Configuring the Control Word for Frame Relay Interfaces on page 893](#)
- [Disabling the Control Word for Layer 2 Circuits on page 893](#)

#### ***Configuring the Control Word for Frame Relay Interfaces***

On interfaces with Frame Relay CCC encapsulation, you can configure Frame Relay control bit translation to support Frame Relay services over IP and MPLS backbones by using CCC, Layer 2 VPNs, and Layer 2 circuits. When you configure translation of Frame Relay control bits, the bits are mapped into the Layer 2 circuit control word and preserved across the IP or MPLS backbone.

For information about how to configure the control bits, see the *Configuring Frame Relay Control Bit Translation*.

#### ***Disabling the Control Word for Layer 2 Circuits***

The Junos OS can typically determine whether a neighboring router supports the control word. However, if you want to explicitly disable its use on a specific interface, include the **no-control-word** statement:

```
no-control-word;
```

For a list of hierarchy levels at which you can configure this statement, see the statement summary section for this statement.

#### ***Configuring the Encapsulation Type for the Layer 2 Circuit Neighbor Interface***

You can specify the Layer 2 circuit encapsulation type for the interface receiving traffic from a Layer 2 circuit neighbor. The encapsulation type is carried in the LDP-signaling messages exchanged between Layer 2 circuit neighbors when pseudowires are created. The encapsulation type you configure for each Layer 2 circuit neighbor varies depending on the type of networking equipment or the type of Layer 2 protocol you have deployed in your network. If you do not specify an encapsulation type for the Layer 2 circuit, the encapsulation of the CE device interface is used by default.

Specify the encapsulation type for the Layer 2 circuit neighbor interface by including the **encapsulation-type** statement:

**encapsulation-type** (atm-aal5 | atm-cell | atm-cell-port-mode | atm-cell-vc-mode | atm-cell-vp-mode | cesop | cisco-hdlc | ethernet | ethernet-vlan | frame-relay | frame-relay-port-mode | interworking | ppp | satop-e1 | satop-e3 | satop-t1 | satop-t3);

You can include this statement at the following hierarchy levels:

- [edit protocols l2circuit neighbor *address* interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols l2circuit neighbor *address* interface *interface-name*]

### Enabling the Layer 2 Circuit When the Encapsulation Does Not Match

You can configure the Junos OS to allow a Layer 2 circuit to be established even though the encapsulation configured on the CE device interface does not match the encapsulation configured on the Layer 2 circuit interface by including the **ignore-encapsulation-mismatch** statement. You can configure the **ignore-encapsulation-mismatch** statement for the connection to the remote connection by including the statement at the [edit protocols l2circuit neighbor *address* interface *interface-name*] hierarchy level or for the local connection by including this statement at the [edit protocols l2circuit local-switching interface *interface-name*] hierarchy level.

**ignore-encapsulation-mismatch**;

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

### Configuring the Protect Interface

You can configure a protect interface for the logical interface linking a virtual circuit to its destination, whether the destination is remote or local. A protect interface provides a backup for the protected interface in case of failure. Network traffic uses the primary interface only so long as the primary interface functions. If the primary interface fails, traffic is switched to the protect interface. The protect interface is optional.

To configure the protect interface, include the **protect-interface** statement:

**protect-interface** *interface-name*;

**NOTE:** The protect interface must be configured prior to configuring the **no-revert** statement.

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

For an example of how to configure a protect interface for a Layer 2 circuit, see “[Example: Configuring Layer 2 Circuit Protect Interfaces](#)” on page 962.

### Configuring the Protect Interface From Switching Over to the Primary Interface

Typically, when the primary interface goes down, the pseudowire starts using the protect interface. By default, when the primary interface comes back online, the interface is switched-over back from the protect interface to the primary interface. To prevent the

switchover back to the primary interface, unless the protect interface goes down, include the **no-revert** statement. This prevents loss of traffic during the switchover.

**NOTE:** If the protect interface fails, the interface is switched-over back to the primary interface, irrespective of whether or not the **no-revert** statement is included in the configuration.

You can configure the **no-revert** statement at the **[edit protocols l2circuit neighbor address interface *interface-name*]** hierarchy level:

```
[edit protocols l2circuit neighbor address interface interface-name]
no-revert;
```

### Configuring the Pseudowire Status TLV

The pseudowire status type length variable (TLV) is used to communicate the status of a pseudowire back and forth between two PE routers. For Layer 2 circuit configurations, you can configure the PE router to negotiate the pseudowire with its neighbor using the pseudowire status TLV. This same functionality is also available for LDP VPLS neighbor configurations. The pseudowire status TLV is configurable for each pseudowire connection and is disabled by default. The pseudowire status negotiation process assures that a PE router reverts back to the label withdraw method for pseudowire status if its remote PE router neighbor does not support the pseudowire status TLV.

Unlike the control word, a PE router's ability to support the pseudowire status TLV is communicated when the initial label mapping message is sent to its remote PE router. Once the PE router transmits its support for the pseudowire status TLV to its remote PE router, it includes the pseudowire status TLV in every label mapping message sent to the remote PE router. If you disable support for the pseudowire status TLV on the PE router, a label withdraw message is sent to the remote PE router and then a new label mapping message without the pseudowire status TLV follows.

To configure the pseudowire status TLV for the pseudowire to the neighbor PE router, include the **pseudowire-status-tlv** statement:

```
pseudowire-status-tlv;
```

For a list of the hierarchy levels at which you can include this statement, see the statement summary section for this statement.

### Configuring Layer 2 Circuits over Both RSVP and LDP LSPs

You can configure two Layer 2 circuits between the same two routers, and have one Layer 2 circuit traverse an RSVP LSP and the other traverse an LDP LSP. To accomplish this, you need to configure two loopback addresses on the local router. You configure one of the loopback address for the Layer 2 circuit traversing the RSVP LSP. You configure the other loopback address to handle the Layer 2 circuit traversing the LDP LSP. For information about how to configure multiple loop back interfaces, see *Configuring Logical Units on the Loopback Interface for Routing Instances in Layer 3 VPNs*.

You also need to configure a packet switched network (PSN) tunnel endpoint for one of the Layer 2 circuits. It can be either the Layer 2 circuit traversing the RSVP LSP or the one traversing the LDP LSP. The PSN tunnel endpoint address is the destination address for the LSP on the remote router.

To configure the address for the PSN tunnel endpoint, include the **psn-tunnel-endpoint** statement:

```
psn-tunnel-endpoint address;
```

You can include this statement at the following hierarchy levels:

- **[edit logical-systems *logical-system-name* protocols l2circuit neighbor *address* interface *interface-name*]**
- **[edit protocols l2circuit neighbor *address* interface *interface-name*]**

By default, the PSN tunnel endpoint for a Layer 2 circuit is identical to the neighbor address, which is also the same as the LDP neighbor address.

The tunnel endpoints on the remote router do not need to be loopback addresses.

#### ***Example: PSN Tunnel Endpoint***

The following example illustrates how you might configure a PSN tunnel endpoint:

```
[edit protocols l2circuit]
neighbor 10.255.0.6 {
 interface t1-0/2/2.0 {
 psn-tunnel-endpoint 192.0.2.0;
 virtual-circuit-id 1;
 }
 interface t1-0/2/1.0 {
 virtual-circuit-id 10;
 }
}
```

The Layer 2 circuit configured for the **t1-0/2/2.0** interface resolves in the inet3 routing table to **192.0.2.0**. This could be either an RSVP route or a static route with an LSP next hop.

---

#### **Configuring the Virtual Circuit ID**

You configure a virtual circuit ID on each interface. Each virtual circuit ID uniquely identifies the Layer 2 circuit among all the Layer 2 circuits to a specific neighbor. The key to identifying a particular Layer 2 circuit on a PE router is the neighbor address and the virtual circuit ID. An LDP-FEC-to-label binding is associated with a Layer 2 circuit based on the virtual circuit ID in the FEC and the neighbor that sent this binding. The LDP-FEC-to-label binding enables the dissemination of the VPN label used for sending traffic on that Layer 2 circuit to the remote CE device.

You also configure a virtual circuit ID for each redundant pseudowire. A redundant pseudowire is identified by the backup neighbor address and the virtual circuit ID. For more information, see [“Configuring Pseudowire Redundancy on the PE Router” on page 186](#).

To configure the virtual circuit ID, include the **virtual-circuit-id** statement:

**virtual-circuit-id** *identifier*;

For a list of hierarchy levels at which you can include this statement, see the statement summary section for this statement.

## Configuring the Interface Encapsulation Type for Layer 2 Circuits

The Layer 2 encapsulation type is carried in the LDP forwarding equivalence class (FEC). You can configure either circuit cross-connect (CCC) or translational cross-connect (TCC) encapsulation types for Layer 2 circuits. For more information, see the *MPLS Applications Feature Guide* and *Junos OS Network Interfaces Library for Routing Devices*.

**NOTE:** Some platform and FPC combinations can not pass TCC encapsulated ISO traffic. See *Platforms/FPCs That Cannot Forward TCC Encapsulated ISO Traffic* for details.

To configure the interface encapsulation for a Layer 2 circuit, include the **encapsulation** statement:

**encapsulation** *encapsulation*;

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name*]
- [edit logical-systems *logical-system-name* interfaces *interface-name*]

## Configuring ATM2 IQ Interfaces for Layer 2 Circuits

You can configure Asynchronous Transfer Mode 2 (ATM2) intelligent queuing (IQ) interfaces for Layer 2 circuits by using Layer 2 circuit ATM Adaptation Layer 5 (AAL5) transport mode, Layer 2 circuit ATM cell relay mode, and the Layer 2 circuit ATM trunk mode.

The configuration statements are as follows:

- **atm-l2circuit-mode aal5**
- **atm-l2circuit-mode cell**
- **atm-l2circuit-mode trunk**

For more information about these statements, see the *Junos OS Administration Library*. For more information about how to configure ATM2 IQ interfaces, see the *Junos OS Network Interfaces Library for Routing Devices*.

The Junos OS implementation of sequence number processing for Layer 2 circuit ATM cell relay mode and Layer 2 circuit AAL5 mode differs from that described in the Internet draft draft-martini-l2circuit-encap-mpls-11.txt, *Encapsulation Methods for Transport of Layer 2 Frames over MPLS Networks* (expires August 2006).

The Junos OS implementation has the following differences:

1. A packet with a sequence number of 0 is treated as out of sequence.
2. A packet that does not have the next incremental sequence number is considered out of sequence.

When out-of-sequence packets arrive, the expected sequence number for the neighbor is set to the sequence number in the Layer 2 circuit control word.

## Configuring Policies for Layer 2 Circuits

---

You can configure Junos routing policies to control the flow of packets over Layer 2 circuits. This capability allows you to provide different level of service over a set of equal-cost Layer 2 circuits. For example, you can configure a circuit for high-priority traffic, a circuit for average-priority traffic, and a circuit for low-priority traffic. By configuring Layer 2 circuit policies, you can ensure that higher-value traffic has a greater likelihood of reaching its destination.

The following sections explain how to configure Layer 2 circuit policies:

- [Configuring the Layer 2 Circuit Community on page 898](#)
- [Configuring the Policy Statement for the Layer 2 Circuit Community on page 899](#)
- [Verifying the Layer 2 Circuit Policy Configuration on page 900](#)

### Configuring the Layer 2 Circuit Community

To configure a community for Layer 2 circuits, include the **community** statement.

```
community community-name {
 members [community-ids];
}
```

You can include this statement at the following hierarchy levels:

- **[edit policy-options]**
- **[edit logical-systems *logical-system-name* policy-options]**

***name*** identifies the community or communities.

***community-ids*** identifies the type of community or extended community:

- A normal community uses the following community ID format:

***as-number:community-value***

***as-number*** is the autonomous system (AS) number of the community member.

***community-value*** is the identifier of the community member. It can be a number from 0 through 65,535.

- An extended community uses the following community ID format:

***type:administrator:assigned-number***

***type*** is the type of target community. The target community identifies the route's destination.

**administrator** is either an AS number or an IP version 4 (IPv4) address prefix, depending on the type of community.

**assigned-number** identifies the local provider.

You also need to configure the community for the Layer 2 circuit interface; see [“Configuring a Community for the Layer 2 Circuit” on page 892](#).

## Configuring the Policy Statement for the Layer 2 Circuit Community

To configure a policy to send community traffic over a specific LSP, include the **policy-statement** statement:

```
policy-statement policy-name {
 term term-name {
 from community community-name;
 then {
 install-nexthop (except | lsp lsp-name | lsp-regex lsp-regular-expression);
 accept;
 }
 }
}
```

You can include this statement at the following hierarchy levels:

- [edit policy-options]
- [edit logical-systems *logical-system-name* policy-options]

To prevent the installation of any matching next hops, include the **install-nexthop** statement with the **except** option:

```
install-nexthop except;
```

You can include this statement at the following hierarchy levels:

- [edit policy-options policy-statement *policy-name* term *term-name* then]
- [edit logical-systems *logical-system-name* policy-options policy-statement *policy-name* term *term-name* then]

To assign traffic from a community to a specific LSP, include the **install-nexthop** statement with the **lsp** *lsp-name* option and the **accept** statement:

```
install-nexthop lsp lsp-name;
accept;
```

You can include these statements at the following hierarchy levels:

- [edit policy-options policy-statement *policy-name* term *term-name* then]
- [edit logical-systems *logical-system-name* policy-options policy-statement *policy-name* term *term-name* then]

You can also use a regular expression to select an LSP from a set of similarly named LSPs for the **install-nexthop** statement. To configure a regular expression, include the **install-nexthop** statement with the **lsp-regex** option and the **accept** statement:

```
install-nexthop lsp-regex lsp-regular-expression;
accept;
```

You can include these statements at the following hierarchy levels:

- [edit policy-options policy-statement *policy-name* term *term-name* then]
- [edit logical-systems *logical-system-name* policy-options policy-statement *policy-name* term *term-name* then]

---

### Example: Configuring a Policy for a Layer 2 Circuit Community

The following example illustrates how you might configure a regular expression in a Layer 2 circuit policy. You create three LSPs to handle gold-tier traffic from a Layer 2 circuit. The LSPs are named **alpha-gold**, **beta-gold**, and **delta-gold**. You then include the **install-nexthop** statement with the **lsp-regex** option with the LSP regular expression **.\*-gold** at the [edit policy-options policy-statement *policy-name* term *term-name* then] hierarchy level:

```
[edit policy-options]
policy-statement gold-traffic {
 term to-gold-LSPs {
 from community gold;
 then {
 install-nexthop lsp-regex .*-gold;
 accept;
 }
 }
}
```

The community **gold** Layer 2 circuits can now use any of the **-gold** LSPs. Given equal utilization across the three **-gold** LSPs, LSP selection is made at random.

You need to apply the policy to the forwarding table. To apply a policy to the forwarding table, configure the **export** statement at the [edit routing-options forwarding-table] hierarchy level:

```
[edit routing-options forwarding-table]
export policy-name;
```

### Verifying the Layer 2 Circuit Policy Configuration

To verify that you have configured a policy for the Layer 2 circuit, issue the **show route table mpls detail** command. It should display the community for ingress routes that corresponds to the Layer 2 circuits, as shown by the following example:

```
user@host> show route table mpls detail
so-1/0/1.0 (1 entry, 1 announced)
*L2VPN Preference: 7
Next hop: via so-1/0/0.0 weight 1, selected
Label-switched-path to-community-gold
Label operation: Push 100000 Offset: -4
Next hop: via so-1/0/0.0 weight 1
Label-switched-path to-community-silver
Label operation: Push 100000 Offset: -4
Protocol next hop: 10.255.245.45
```

```
Push 100000 Offset: -4
Indirect next hop: 85333f0 314
State: <Active Int>
Local AS: 100
Age: 22
Task: Common L2 VC
Announcement bits (2): 0-KRT 1-Common L2 VC
AS path: I
Communities: 100:1
```

For more information about how to configure routing policies, see *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

---

## Configuring LDP for Layer 2 Circuits

Use LDP as the signaling protocol to advertise ingress labels to the remote PE routers. When configured, LDP examines the Layer 2 circuit configuration and initiates extended neighbor discovery for all the Layer 2 circuit neighbors (for example, remote PEs). This process is similar to how LDP works when tunneled over RSVP. You must run LDP on the **lo0.0** interface for extended neighbor discovery to function correctly.

For detailed information about how to configure LDP, see the *MPLS Applications Feature Guide*.

# Configuring Class of Service with Layer 2 Circuits

- [Configuring ATM Trunking on Layer 2 Circuits on page 903](#)
- [Layer 2 Circuit Bandwidth Accounting and Call Admission Control on page 905](#)
- [Configuring Bandwidth Allocation and Call Admission Control in Layer 2 Circuits on page 908](#)

## Configuring ATM Trunking on Layer 2 Circuits

You can configure Layer 2 circuits to transport ATM traffic from directly connected ATM switches across an MPLS core network. Traffic from an ATM switch is received on the local PE router. The ATM cells are given an MPLS label and then sent across the MPLS network to the remote PE router. The receiving router removes the MPLS label from the ATM cell and then forwards the cell the receiving ATM switch.

**NOTE:** ATM trunking on Layer 2 circuits is supported only on T Series and M320 routers and ATM2 IQ PICs.

**Figure 91: ATM Trunking on Layer 2 Circuits**

Figure 91 on page 903 illustrates how ATM switches could be linked together by a Layer 2 circuit. The PE1 Router is configured to receive ATM trunk traffic from ATM Switch 1. As each ATM cell is received on the PE1 Router, it is classified by means of the class-of-service (CoS) information in the cell header and then encapsulated as a labeled packet. The CoS information and cell loss priority (CLP) of the ATM cell are copied into the experimental (EXP) bits of the MPLS label. The labeled packet is then transported across the service provider network to the PE2 Router by means of a Layer 2 circuit.

On the PE2 Router, the label is removed and the plain ATM cell is forwarded to ATM Switch 2. The CoS and CLP are extracted from the EXP bits and are then used to select the correct output queue and determine whether the ATM cell should be dropped.

The ATM physical port on the router can support 32 logical trunks when network-to-network interface (NNI) is used and 8 logical trunks when user-to-network interface (UNI) is used. A trunk can carry traffic on 32 virtual path identifiers (VPIs), numbered 0 through 31. Each ATM trunk is associated with an MPLS label and a logical interface. On the ingress router, one or more of these trunks are mapped to a Layer 2 circuit.

The configuration for the Layer 2 circuit between PE routers is conventional. Follow the procedures outlined in this chapter for configuring the circuit. However, there is some specific configuration you need to complete for the Layer 2 circuit to carry traffic from an ATM trunk.

First, enable ATM trunking for Layer 2 circuits. To enable ATM trunking for Layer 2 circuits, specify the **trunk** option for the **atm-l2circuit-mode** statement at the **[edit chassis fpc number pic number]** hierarchy level:

```
[edit chassis fpc number pic number]
 atm-l2circuit-mode trunk (uni | nni);
```

Specify the **uni** option for UNI trunks and the **nni** option for NNI trunks. The default option is **uni**.

You also need to configure each ATM trunk for a specific logical interface. Each ATM trunk has a trunk identifier in the range from 0 to 31. This configuration step is in addition to the typical configuration steps you follow related to configuring interfaces for Layer 2 circuits, as described in [“Configuring Interfaces for Layer 2 Circuits” on page 890](#).

To associate a specific trunk identifier with a logical interface, include the **trunk-id** statement:

```
trunk-id number;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces interface-name unit number]**
- **[edit logical-systems logical-system-name interfaces interface-name unit number]**

Since ATM trunking is supported on ATM2 IQ PICs only, the only value you can configure for the **pic-type** statement is **atm2**. If you do not configure the **pic-type** statement but you do configure the **trunk** option for the **atm-l2circuit-mode** statement (at the **[chassis fpc number pic number]** hierarchy level), the **pic-type** statement defaults to **atm2**.

## Layer 2 Circuit Bandwidth Accounting and Call Admission Control

---

The sections that follow discuss Layer 2 circuit bandwidth accounting and call admission control (CAC):

- [Bandwidth Accounting and Call Admission Control Overview on page 905](#)
- [Selecting an LSP Based on the Bandwidth Constraint on page 905](#)
- [LSP Path Protection and CAC on page 906](#)
- [Layer 2 Circuits Trunk Mode on page 907](#)

### Bandwidth Accounting and Call Admission Control Overview

Some network environments require that a certain level of service be guaranteed across the entire length of a path transiting a service provider's network. For Layer 2 circuits transiting an MPLS core network, a customer requirement might be to assure that guarantees for bandwidth and class of service (CoS) be maintained across the core network. For example, an Asynchronous Transfer Mode (ATM) circuit can provide service guarantees for each traffic class. A Layer 2 circuit configured to transport that ATM circuit across the network could be expected to provide the same service guarantees.

Providing this type of service guarantee requires the following:

- The LSPs in the MPLS core network must be able to provide service guarantees for bandwidth, rerouting, and route failures. You accomplish these guarantees by configuring multiclass LSPs. For more information about multiclass LSPs, see *Configuring Multiclass LSPs*.
- The service guarantee must be maintained across the entire length of the link as it transits the service provider's network. Different Layer 2 circuits could have different bandwidth requirements. However, many Layer 2 circuits could be transported over the same E-LSP in the MPLS core network.
- CAC ensures that the LSP has sufficient bandwidth to accommodate the Layer 2 circuit. If there is not enough bandwidth over a particular LSP, the Layer 2 circuit is prevented from using that LSP.

### Selecting an LSP Based on the Bandwidth Constraint

CAC of Layer 2 circuits is based on the bandwidth constraint. You must configure this constraint for each Layer 2 circuit interface. If there is a bandwidth constraint configured for a Layer 2 circuit, CAC bases the final selection of which LSP-forwarding next hop to use on the following:

- If multiple LSPs meet the bandwidth requirements, the first LSP found that can satisfy the bandwidth requirements for the Layer 2 circuit is selected.
- If there is more than one next hop mapped to the same LSP, then all the next hops that map to that LSP and pass CAC constraints are installed. This allows the Layer 2 circuit routes to restore themselves quickly in case of failure.

- The available bandwidth on the selected LSP is decremented by the bandwidth required for each Layer 2 circuit. Similarly, when the Layer 2 circuit route is changed or deleted (for example, when the route is disassociated from that particular LSP), the bandwidth on the corresponding LSP is incremented.
- There are no priorities among different Layer 2 circuits competing for the same LSP next hop in the core network.
- When an LSP's bandwidth changes, the Layer 2 circuits using that LSP repeat the CAC process again.

If the LSP bandwidth increases, some Layer 2 circuits that were not established might now successfully resolve over the LSP. Similarly, if the bandwidth of the LSP decreases, some Layer 2 circuits that were previously up might now be declared down because of insufficient bandwidth on the LSP.

- When no LSP is found to meet the bandwidth requirements of the Layer 2 circuit, it is considered to be a CAC failure, and an error is reported.

## LSP Path Protection and CAC

CAC can take into account LSPs that have been configured with an MPLS path protection feature, such as secondary paths, fast reroute, or node and link protection. CAC can consider the bandwidth available on these auxiliary links and can accept the backup connection as valid if the main connection fails. However, there are limitations on how the path protection feature must be configured to prevent CAC from taking down the Layer 2 circuit when the LSP it is using is switched to a backup route.

For more information about MPLS path protection features, see the *MPLS and Traffic Protection*.

The sections that follow discuss the path protection features that can be used in conjunction with CAC and how they must be configured:

- [Secondary Paths and CAC on page 906](#)
- [Fast Reroute and CAC on page 907](#)
- [Link and Node Protection and CAC on page 907](#)

---

### Secondary Paths and CAC

The following describes the ways in which secondary paths would interact with Layer 2 circuit CAC:

- If an LSP is configured with both primary and secondary paths, if the paths have the same bandwidth, and if this bandwidth is enough to accommodate the Layer 2 circuit, the Layer 2 circuit route installs both next hops in the forwarding table.

CAC allows the Layer 2 circuit to be switched to the secondary path if the primary path fails.

- If the LSP has primary and secondary paths configured with different bandwidths, each path must run through CAC independently. If the active path for that LSP passes CAC constraints successfully, then that next hop is installed and the corresponding LSP is

selected to transport the Layer 2 circuit traffic. The LSP's secondary paths are then checked for CAC, and installed if there is sufficient bandwidth.

However, if the active path for the LSP fails to meet the CAC constraints, then that LSP is not selected and the system looks for a different LSP to transport the Layer 2 circuit.

For example, an LSP has an active primary path with 30 megabits of bandwidth and a secondary path with 10 megabits of bandwidth. The Layer 2 circuit requires 15 megabits of bandwidth. The secondary path fails CAC, and only the next hop corresponding to the primary path is installed for the Layer 2 circuit route. The path protection originally provided by the secondary path is no longer available.

---

### Fast Reroute and CAC

No CAC is done for fast reroute detours. However, as long as the protected path satisfies the CAC bandwidth constraints, the detour next hop is also selected and installed.

---

### Link and Node Protection and CAC

You can configure CAC on Layer 2 circuit-based LSPs with bandwidth constraints and also enable link and node protection. However, if the primary LSP fails, CAC might not be applied to the bypass LSP, meaning the bypass LSP might not meet the bandwidth constraint for the Layer 2 circuit. To minimize the risk of losing traffic, the Layer 2 circuit continues to use the non-CAC bypass LSP while an attempt is made to establish a new Layer 2 circuit route over an LSP that does support CAC.

## Layer 2 Circuits Trunk Mode

Using Layer 2 circuit trunk mode, you can configure Layer 2 circuits to carry ATM trunks, providing a way to link ATM switches over an MPLS core network.

Layer 2 circuit trunk mode allows you to configure the following CoS features:

- CoS queues in Layer 2 circuit trunk mode—For ATM2 IQ interfaces, you can configure ATM CoS queues for Layer 2 circuit trunk mode.
- Layer 2 circuit trunk mode scheduling—For ATM2 IQ interfaces configured to use Layer 2 circuit trunk mode, you can share a scheduler among 32 trunks on an ATM port.
- Two early packet discard (EPD) thresholds per queue—For ATM2 IQ interfaces configured to use Layer 2 circuit trunk mode, you can set two EPD thresholds that depend on the packet-loss priorities (PLPs) of the packets.

For a detailed overview and configuration documentation, see the *ATM Interfaces Feature Guide for Routing Devices* and *Class of Service Feature Guide for Routing Devices*.

**Related Documentation**

- *MPLS and Traffic Protection*

## Configuring Bandwidth Allocation and Call Admission Control in Layer 2 Circuits

You can configure bandwidth allocation and call admission control (CAC) on Layer 2 circuits. This feature is available for RSVP-signaled LSPs traversing an MPLS network.

When you enable bandwidth allocation on a Layer 2 circuit, attempts to establish an RSVP-signaled LSP are preceded by a check of the available bandwidth on the network. This check is the CAC. The available bandwidth is compared to the bandwidth requested by the LSP. If there is insufficient bandwidth, the Layer 2 circuit is not established and an error message is generated. To apply CAC to a Layer 2 circuit, a bandwidth constraint must be configured.

You can specify the bandwidth for a Layer 2 circuit without configuring a bandwidth for each class type (queue). To specify the bandwidth allocation for a Layer 2 circuit, include the **bandwidth** statement:

```
bandwidth bandwidth;
```

Specify the bandwidth in bits per second.

You can include this statement at the following hierarchy levels:

- [edit protocols l2circuit neighbor *address* interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols l2circuit neighbor *address* interface *interface-name*]

Alternatively, you can configure the bandwidth for each class type on a Layer 2 circuit. If you use this type of configuration, you cannot simultaneously configure the nonclass type of bandwidth configuration for the Layer 2 circuit (the commit operation fails).

To configure the bandwidth for each class type on an Layer 2 circuit, include the **bandwidth** statement:

```
bandwidth {
 ct0 bandwidth;
 ct1 bandwidth;
 ct2 bandwidth;
 ct3 bandwidth;
}
```

You can include this statement at the following hierarchy levels:

- [edit protocols l2circuit neighbor *address* interface *interface-name*]
- [edit logical-systems *logical-system-name* protocols l2circuit neighbor *address* interface *interface-name*]

Specify the bandwidth for each class type in bits per second. It is not necessary to specify a bandwidth for all four class types.

# Configuring Pseudowire Redundancy for Layer 2 Circuits

- [Understanding Pseudowire Redundancy Mobile Backhaul Scenarios on page 909](#)
- [Example: Configuring Pseudowire Redundancy in a Mobile Backhaul Scenario on page 913](#)
- [Extension of Pseudowire Redundancy Condition Logic to Pseudowire Service Logical Interface Overview on page 936](#)

## Understanding Pseudowire Redundancy Mobile Backhaul Scenarios

With the rising demand for mobile broadband services, telecommunication providers are seeing a sharp increase in bandwidth requirements. To keep pace with demand, operators are deploying packet-based backhaul networks that offer increased capacity at a lower cost, while providing the necessary service reliability and quality of experience that users expect.

Most of the legacy backhaul infrastructure has been traditionally built over PDH microwave, TDM T1/E1, or ATM-over-DSL links. Service providers have traditionally added subsequent TDM links to their base stations when needed to deal with bandwidth constraint scenarios. This expansion model has proven to be inefficient for the unprecedented traffic demands required by 3G and Long Term Evolution (LTE) services. As a direct consequence, operators are gradually migrating to an Ethernet-based higher capacity infrastructure in the backhaul portion of 3G and LTE topologies. Modern base stations now provide Ethernet backhaul connectivity, allowing pseudowire technologies to transport end-user content to the desired destination. As part of this Ethernet transition, service providers are increasingly demanding better resiliency mechanisms to cover the existence gap with those features provided by previous legacy technologies. With that goal in mind, Junos OS provides efficient pseudowire redundancy capabilities to those topologies where Layer 2 and Layer 3 segments are interconnected.

- [Sample Topology on page 910](#)
- [Benefits of Pseudowire Redundancy Mobile Backhaul on page 910](#)
- [Layer 2 Virtual Circuit Status TLV Extension on page 910](#)
- [How It Works on page 911](#)

## Sample Topology

Figure 92 on page 910 shows a sample topology.

**Figure 92: Pseudowire Redundancy Mobile Backhaul Sample Topology**

## Benefits of Pseudowire Redundancy Mobile Backhaul

Junos OS pseudowire redundancy capabilities are as follows:

- Redundant loop-free paths to interconnect Layer 2 and Layer 3 domains.
- Layer 2 and Layer 3 domains are synchronized with regard to the elected data path.
- Traffic disruption is minimal for the following possible scenarios:
  - Access link failures
  - Node failures
  - Control-plane failures
- Traffic interruption is minimal after the failure's restoration is completed.

## Layer 2 Virtual Circuit Status TLV Extension

The pseudowire status TLV is used to communicate the status of a pseudowire between provider edge (PE) routers. To avoid potential primary-path discrepancies, there must be a mechanism that allows all network elements to be synchronized with respect to the primary path over which traffic needs to be sent. With this goal in mind, the status TLV is extended to address this requirement.

**NOTE:** The pseudowire status TLV is not supported by ACX5000 line of routers.

By having the active and standby states being defined by the access routers, Junos OS mitigates potential primary path collisions, as there is a unique network element dictating

the preferable forwarding path to be elected. As an added value, this allows network operators to switch forwarding paths on demand, which is quite useful for troubleshooting and network maintenance purposes.

The active and standby states are communicated to the aggregation routers by making use of an additional pseudowire state flag.

[Table 22 on page 911](#) includes a list of the pseudowire state flags.

**Table 22: Pseudowire Status Code for the Pseudowire Status TLV**

| Flag                         | Code                         |
|------------------------------|------------------------------|
| L2CKT_PW_STATUS_PW_FWD       | 0x00000000                   |
| L2CKT_PW_STATUS_PW_NOT_FWD   | 0x00000001                   |
| L2CKT_PW_STATUS_AC_RX_FAULT  | 0x00000002                   |
| L2CKT_PW_STATUS_AC_TX_FAULT  | 0x00000004                   |
| L2CKT_PW_STATUS_PSN_RX_FAULT | 0x00000008                   |
| L2CKT_PW_STATUS_PSN_TX_FAULT | 0x00000010                   |
| L2CKT_PW_STATUS_PW_FWD_STDBY | 0x00000020                   |
|                              | Indicates the standby state. |
| L2CKT_PW_STATUS_SWITCH_OVER  | 0x00000040                   |

In multichassis LAG (MC-LAG)-based scenarios, this same PW\_FWD\_STDBY flag is used to advertise to remote PE devices which attachment circuit (AC) is being used as the active one. Upon arrival of this flag, the receiving PE device drops any pseudowire built toward the router originating this state. As we can see, this behavior denotes a slightly different semantic for the PW\_FWD\_STDBY flag. As a consequence, you can configure the **hot-standby-vc-on** statement to control whether the pseudowire must be constructed upon arrival of the PW\_FWD\_STDBY flag (in the hot-standby pseudowire scenario), or simply destroy it (in the MC-LAG scenario).

## How It Works

The solution uses logical tunnel (lt-) paired interfaces for stitching the Layer 2 and Layer 3 domains.

[Figure 93 on page 912](#) shows a diagram depicting how pseudowire redundancy in a mobile backhaul scenario works.

Figure 93: Pseudowire Redundancy Mobile Backhaul Solution

A Layer 2 pseudowire terminates on one of the logical tunnel interfaces (x), defined with the circuit cross-connect (CCC) address family configured. A Layer 3 VPN (RFC 2547) terminates the second logical tunnel interface (y), defined with the IPv4 (inet) address family. Logical tunnel interface (x) and (y) are paired. Layer 2 pseudowires established between each access router and its corresponding aggregation PE devices terminate on the logical tunnel interface defined within each PE device. This logical tunnel interface is used to establish a Layer 2 virtual circuit (VC) toward the remote end. In consequence, the CCC address family needs to be configured on it. The same applies to the remote end, where an equivalent interface needs to be defined with CCC capabilities.

This CCC logical tunnel interface created in the aggregation PE devices is paired with a second logical tunnel interface on which the INET address family is enabled. This second logical tunnel interface is configured within the context of an RFC 2547 Layer 3 VPN.

Within the scope of this document, we refer to the CCC and INET logical tunnel interfaces as LT(x) and LT(y), respectively.

The Junos OS routing protocol process (rpd) enables the stitching required to interconnect the Layer 2 VC ending in LT(x) and the associated LT(y).

In the aggregation PE routers, the routing process builds a pseudowire toward access routers, and this happens regardless of the active or standby state of the pseudowire. The same occurs in access routers, where the control and forwarding state is preestablished in both the Routing Engine and the Packet Forwarding Engine to mitigate traffic disruption during convergence periods.

An attachment circuit (AC) is a physical or virtual circuit (VC) that attaches a CE device to a PE device. Local preference is used to provide better information than the multiple exit discriminator (MED) value provides for a packet's path selection. You can configure the local preference attribute so that it has a higher value for prefixes received from a router that provides a desired path than prefixes received from a router that provides a less desirable path. The higher the value, the more preferred the route. The local

preference attribute is the metric most often used in practice to express preferences for one set of paths over another.

If the Layer 2 circuit is primary, the corresponding PE device advertises the AC's subnet with the higher local preference. All aggregation PE devices initially advertise the AC's subnet with the same local preference. You can configure a routing policy to allow a higher local preference value to be advertised if the Layer 2 VC is active.

If a pseudowire is down, LT(x) is tagged with the CCC\_Down flag. When this happens, the corresponding PE device withdraws the AC subnet that was initially advertised. The LT(y) address is shared between the aggregation PE devices as a virtual instance port (VIP). No VRRP hello messages are exchanged. Both PE devices assume mastership.

Both primary and standby Layer 2 VCs are kept open to reduce traffic disruption in backup-to-primary transitions. The **hot-standby-vc-on** configuration statement allows manual activation.

Resiliency in the Layer 2 domain is provided through plain pseudowire redundancy for back-to-back connections. For other topologies, pseudowire virtual circuit connectivity verification (VCCV) is used.

Resiliency in the Layer 3 domain is provided by MPLS fast reroute and end-to-end service restoration. A restoration timer prevents having VCs in the secondary path from being switched back to the primary path immediately after the master PE device is restored.

Access routers can indicate to the aggregation routers which Layer 2 VC is considered to be active. Upon arrival at LT(x) of a status TLV message communicating a standby state, the routing process decreases the BGP's local preference value of the direct subnet represented by the LT(y) IPv4 address. At this point, BGP proceeds to advertise this local preference change to the rest of the members within the Layer 3 domain, which will then reelect the designated forwarder PE device by relying on BGP's path selection mechanisms.

A similar behavior occurs upon arrival of a status TLV message indicating a Layer 2 VC active state. In this case, the receiving PE device changes the local preference corresponding to the LT(y)'s subnet. The value to be used to either decrease or increase the subnet's local preference value is manually configured using a policy.

## Example: Configuring Pseudowire Redundancy in a Mobile Backhaul Scenario

---

This example shows how to configure pseudowire redundancy where Layer 2 and Layer 3 segments are interconnected in a mobile backhaul scenario.

- [Requirements on page 914](#)
- [Overview on page 914](#)

- [Configuration on page 915](#)
- [Verification on page 933](#)

## Requirements

This example can be configured using the following hardware and software components:

- Junos OS Release 13.2 or later
- MX Series 3D Universal Edge Routers or M Series Multiservice Edge Routers for the Provider Edge (PE) Routers
- PTX Series Packet Transport Routers acting as transit label-switched routers
- T Series Core Routers for the Core Routers

**NOTE:** The PE routers could also be T Series Core Routers but that is not typical. Depending on your scaling requirements, the core routers could also be MX Series 3D Universal Edge Routers or M Series Multiservice Edge Routers. The Customer Edge (CE) devices could be other routers or switches from Juniper Networks or another vendor.

No special configuration beyond device initialization is required before configuring this example.

## Overview

Device CE1 is a simple edge router with an IPv4 interface and a static route pointing to the PE devices. Device A1 establishes two virtual circuits (VCs) toward Device PE1 and Device PE2 by making use of the **hot-standby** statement. Device PE1 and Device PE2 terminate these VCs and enforce a policy condition over the logical tunnel IPv4 subnet. Device PE3 performs as a Layer 3 VPN provider edge device by having an IPv4 interface in a Layer 3 VPN shared with Device PE1 and Device PE2.

[“CLI Quick Configuration” on page 915](#) shows the configuration for all of the devices in [Figure 94 on page 915](#).

The section [“Step-by-Step Procedure” on page 920](#) describes the steps on Device A1 and Device PE1.

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device A1:

1. Configure the interfaces.

Enable MPLS on the core-facing interfaces. The ISO address family is also enabled, because IS-IS is used as the interior gateway protocol (IGP) in the provider network.

On the customer-facing interface, you do not need to enable MPLS. On this interface, enable CCC encapsulation and address family CCC.

```
[edit interfaces]
user@A1# set ge-1/3/0 unit 0 family inet address 10.20.0.100/24
user@A1# set ge-1/3/0 unit 0 family iso
user@A1# set ge-1/3/0 unit 0 family mpls

user@A1# set ge-1/3/1 unit 0 family inet address 10.10.0.100/24
user@A1# set ge-1/3/1 unit 0 family iso
user@A1# set ge-1/3/1 unit 0 family mpls

user@A1# set ge-1/3/2 vlan-tagging
user@A1# set ge-1/3/2 encapsulation vlan-ccc
user@A1# set ge-1/3/2 unit 600 encapsulation vlan-ccc
user@A1# set ge-1/3/2 unit 600 vlan-id 600
user@A1# set ge-1/3/2 unit 600 family ccc

user@A1# set lo0 unit 0 family inet address 192.168.0.100/32 primary
user@A1# set lo0 unit 0 family iso address 49.0002.0192.0168.0100.00
```

2. Configure the RSVP on the core-facing interfaces and on the loopback interface.

RSVP is used in the Layer 3 domain.

```
[edit protocols rsvp]
user@A1# set interface ge-1/3/0.0
user@A1# set interface ge-1/3/1.0
user@A1# set interface lo0.0
```

3. Configure LDP on the core-facing interfaces and on the loopback interface.

LDP is used in Layer 2 domain.

```
[edit protocols ldp]
user@A1# set interface ge-1/3/0.0
user@A1# set interface ge-1/3/1.0
user@A1# set interface lo0.0
```

4. Configure MPLS on the core-facing interfaces.

```
[edit protocols mpls]
user@A1# set interface ge-1/3/0.0
user@A1# set interface ge-1/3/1.0
```

5. Configure an interior gateway protocol, such as IS-IS or OSPF, on the core-facing interfaces and on the loopback interface.

```
[edit protocols isis]
user@A1# set interface ge-1/3/0.0
user@A1# set interface ge-1/3/1.0
```

```
user@A1# set interface lo0.0
```

6. On the interface that faces the customer edge, configure the Layer 2 circuit.

Configure the **hot-standby** statement on those routers with both active and standby virtual circuits (VCs) (Device A1 in our topology). You must include the **pseudowire-status-tlv** statement on access routers. Without the status TLV signaling, the standby flag cannot be advertised to remote provider edge (PE) devices.

The **revert-time** statement and the **maximum** option should also be configured on access routers. Without the **revert-time** statement, traffic of all the VCs will not be transitioned to the primary path upon completion of the restoration. If a **revert-time** delay is defined but a **maximum** delay is not, then VCs are restored immediately upon the revert timer's expiration. The maximum option allows the VCs to be restored in a scattered fashion rather than all at once.

```
[edit protocols l2circuit neighbor 192.168.0.101 interface ge-1/3/2.600]
user@A1# set virtual-circuit-id 1
user@A1# set pseudowire-status-tlv
user@A1# set revert-time 10 maximum 60
user@A1# set backup-neighbor 192.168.0.102 virtual-circuit-id 2
user@A1# set backup-neighbor 192.168.0.102 hot-standby
```

7. To have the unicast next hop get pushed to other access routers, configure per-packet load balancing.

```
[edit policy-options policy-statement pplb]
user@A1# set then load-balance per-packet
```

8. Apply the per-packet load balancing policy.

```
[edit routing-options forwarding-table]
user@A1# set export pplb
```

9. Configure the autonomous system (AS) ID and the router ID.

```
[edit routing-options]
user@A1# set router-id 192.168.0.100
user@A1# set autonomous-system 64510
```

Similarly, configure any other access devices.

#### Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device PE1:

1. Configure the interfaces.

Enable MPLS on the core-facing interfaces.

```
[edit interfaces]
```

```

user@PE1# set ge-0/1/1 unit 0 family inet address 10.21.0.101/24
user@PE1# set ge-0/1/1 unit 0 family iso
user@PE1# set ge-0/1/1 unit 0 family mpls

```

```

user@PE1# set ge-0/1/2 unit 0 family inet address 10.31.0.101/24
user@PE1# set ge-0/1/2 unit 0 family iso
user@PE1# set ge-0/1/2 unit 0 family mpls

```

```

user@PE1# set ge-0/1/3 unit 0 family inet address 10.10.0.101/24
user@PE1# set ge-0/1/3 unit 0 family iso
user@PE1# set ge-0/1/3 unit 0 family mpls

```

```

user@PE1# set lo0 unit 0 family inet address 192.168.0.101/32 primary
user@PE1# set lo0 unit 0 family iso address 49.0002.0192.0168.0003.00
user@PE1# set lo0 unit 1 family inet address 192.168.1.101/32

```

2. On Device PE1 and Device PE2, which are aggregation routers, configure a pair of logical tunnel interfaces to represent LT(x) and LT(y).

The solution uses logical tunnel (lt-) paired interfaces for stitching the Layer 2 and Layer 3 domains.

A Layer 2 pseudowire terminates on one of the logical tunnel interfaces, LT(x), defined with the circuit cross-connect (CCC) address family. A Layer 3 VPN terminates the second logical tunnel interface, LT(y), defined with the IPv4 (inet) address family. LT(x) and LT(y) are paired.

```

[edit interfaces]
user@PE1# set lt-1/2/0 unit 600 encapsulation vlan-ccc
user@PE1# set lt-1/2/0 unit 600 vlan-id 600
user@PE1# set lt-1/2/0 unit 600 peer-unit 601

user@PE1# set lt-1/2/0 unit 601 encapsulation vlan
user@PE1# set lt-1/2/0 unit 601 vlan-id 600
user@PE1# set lt-1/2/0 unit 601 peer-unit 600
user@PE1# set lt-1/2/0 unit 601 family inet filter input icmp_inet
user@PE1# set lt-1/2/0 unit 601 family inet filter output icmp_inet

```

3. (Optional) Associate a unique VRRP address with both Device PE1 and Device PE2.

In this case, both Device PE1 and Device PE2 assume the mastership state for the defined VIP IPv4 address, so no VRRP hello message are exchanged between the routers.

```

[edit interfaces lt-1/2/0 unit 601 family inet address 10.41.0.101/24]
user@PE1# set vrrp-group 0 virtual-address 10.41.0.1
user@PE1# set vrrp-group 0 accept-data

```

4. Configure IS-IS or another IGP.

```

[edit protocols isis]
user@PE1# set interface ge-0/1/1.0
user@PE1# set interface ge-0/1/2.0

```

```
user@PE1# set interface ge-0/1/3.0
user@PE1# set interface lo0.0
```

5. Configure the MPLS on the core-facing interfaces.

```
[edit protocols mpls]
user@PE1# set interface ge-0/1/1.0
user@PE1# set interface ge-0/1/2.0
user@PE1# set interface ge-0/1/3.0
```

6. Configure label-switched paths to the other PE devices.

BGP is a policy-driven protocol, so also configure and apply any needed routing policies. For example, you might want to export static routes into BGP.

```
[edit protocols mpls]
user@PE1# set label-switched-path to_PE3 to 192.168.0.103
user@PE1# set label-switched-path to_PE2 to 192.168.0.102
```

7. Configure LDP on the core-facing interfaces and on the loopback interface.

```
[edit protocols ldp]
user@PE1# set interface ge-0/1/1.0
user@PE1# set interface ge-0/1/2.0
user@PE1# set interface ge-0/1/3.0
user@PE1# set interface lo0.0
```

8. Configure RSVP on the core-facing interfaces and on the loopback interface.

```
[edit protocols rsvp]
user@PE1# set interface ge-0/1/1.0
user@PE1# set interface ge-0/1/2.0
user@PE1# set interface ge-0/1/3.0
user@PE1# set interface lo0.0
```

9. Configure internal BGP (IBGP).

```
[edit protocols bgp]
user@PE1# set local-address 192.168.0.101
user@PE1# set group ibgp family inet-vpn any
user@PE1# set group ibgp peer-as 64511
user@PE1# set group ibgp neighbor 192.168.0.102
user@PE1# set group ibgp neighbor 192.168.0.103
```

10. Configure the Layer 2 circuit on the logical tunnel interface.

Configure the **hot-standby-vc-on** statement if you want a hot standby pseudowire to be established upon arrival of PW\_FWD\_STDBY status TLV.

```
[edit protocols l2circuit neighbor 192.168.0.100 interface lt-1/2/0.600]
user@PE1# set virtual-circuit-id 1
user@PE1# set pseudowire-status-tlv hot-standby-vc-on
```

11. Define a pair of conditions to be applied to the egress policy defined within the Layer 3 VPN instance.

In both condition **primary** and condition **standby**, the matching route corresponds to the interface `lt-1/2/0.600 (y)`, as this is the format in which egress routes appear in routing table `mpls.0` to represent any given pseudowire.

The difference between these conditions is in the **standby** attribute. Upon arrival of the `PW_FWD_STDBY` status TLV to Device PE1 or Device PE2, Junos OS matches condition **standby**, and in consequence, only term **standby** within the **l3vpn** policy will be executed. On the other hand, if the `PW_FWD_STDBY` status TLV is not present, the policy only matches condition **primary**, which then executes term **primary** in the **l3vpn** policy. Also, for logical tunnel-based CCC services, you must specify the logical tunnel interface, `LT(y)`, that is associated with the logical tunnel CCC interface, `LT(x)`. (See [“Understanding Pseudowire Redundancy Mobile Backhaul Scenarios”](#) on page 909.)

Finally, for CCC-based conditions, Junos OS only allows `mpls.0` as the matching routing table. For the **address** attribute, Junos OS only allows strings with a logical interface unit format (for example, `lt-0/0/0.0`).

```
[edit policy-options condition primary if-route-exists address-family ccc]
user@PE1# set lt-1/2/0.600
user@PE1# set table mpls.0
user@PE1# set peer-unit 601
```

```
[edit policy-options condition standby if-route-exists address-family ccc]
user@PE1# set lt-1/2/0.600
user@PE1# set table mpls.0
user@PE1# set standby
user@PE1# set peer-unit 601
```

12. Configure the Layer 3 VPN export policy.

If the Layer 2 virtual circuit (VC) is primary, the corresponding provider edge (PE) routing device advertises the attachment circuit's (AC's) subnet with the higher local preference. All aggregation PE devices initially advertise the AC's subnet with the same local preference.

This routing policy allows a higher local preference value to be advertised if the Layer 2 VC is active.

```
[edit policy-options policy-statement l3vpn_export]
user@PE1# set term primary from condition primary
user@PE1# set term primary then local-preference add 300
user@PE1# set term primary then community set l3vpn
user@PE1# set term primary then accept
```

```
user@PE1# set term standby from condition standby
user@PE1# set term standby then local-preference add 30
user@PE1# set term standby then community set l3vpn
user@PE1# set term standby then accept
```

```
user@PE1# set term default then community set l3vpn
```

```
user@PE1# set term default then accept
```

13. Configure the Layer 3 VPN community members.

```
[edit policy-options community l3vpn]
user@PE1# set members target:64511:600
```

14. Configure the Layer 3 VPN import policy, based on the Layer 3 VPN community.

```
[edit policy-options policy-statement l3vpn_import]
user@PE1# set term 1 from community l3vpn
user@PE1# set term 1 then accept
user@PE1# set term default then reject
```

15. Configure OSPF export policy, based on the Layer 3 VPN community.

```
[edit policy-options policy-statement ospf_export term 0]
user@PE1# set from community l3vpn
user@PE1# set then accept
```

16. (Optional) Configure a firewall filter to check the path taken by traffic.

```
[edit firewall family inet filter icmp_inet]
user@PE1# set interface-specific
user@PE1# set term 0 from source-address 10.41.0.101/32 except
user@PE1# set term 0 from source-address 10.0.0.0/8
user@PE1# set term 0 from protocol icmp
user@PE1# set term 0 then count icmp_inet
user@PE1# set term 0 then log
user@PE1# set term 0 then accept
user@PE1# set term 1 then accept
```

17. Configure the routing instance.

This routing instance is in the Layer 2 domain where Device PE1 and Device PE2 are interconnected to the metro ring over multiaccess media (Ethernet). You must include the **vrf-table-label** statement on Device PE1 and Device PE2 to enable advertisement of the direct subnet prefix corresponding to the logical tunnel (lt-) interface toward the Layer 3 domain.

Device PE1 and Device PE2 use OSPF for Layer 3 VPN communication with Device CE1.

```
[edit routing-instances l3vpn]
user@PE1# set instance-type vrf
user@PE1# set interface lt-1/2/0.601
user@PE1# set interface lo0.1
user@PE1# set route-distinguisher 192.168.1.101:64511
user@PE1# set vrf-import l3vpn_import
user@PE1# set vrf-export l3vpn_export
user@PE1# set vrf-table-label
user@PE1# set protocols ospf export ospf_export
user@PE1# set protocols ospf area 0.0.0.0 interface lt-1/2/0.601
user@PE1# set protocols ospf area 0.0.0.0 interface lo0.1
```

18. Configure the autonomous system (AS) ID and router ID.

```
[edit routing-options]
user@PE1# set router-id 192.168.0.101
user@PE1# set autonomous-system 64511
```

Similarly, configure Device PE2.

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show firewall**, **show protocols**, **show policy-options**, **show routing-options**, and **show routing-instances** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

If you are done configuring the devices, enter **commit** from configuration mode.

## Verification

Confirm that the configuration is working properly.

- [Checking Layer 2 Circuits on page 933](#)
- [Checking the Policy Conditions on page 935](#)

### Checking Layer 2 Circuits

**Purpose** Upon Layer 2 virtual circuit (VC) establishment, the output of the **show l2circuit connections** command shows the active and the hot-standby VC. In addition, control-plane details are shown for the hot-standby VC.

**Action** From operational mode, enter the **show l2circuit connections extensive** command.

```
user@A1> show l2circuit connections extensive
```

Layer-2 Circuit Connections:

Legend for connection status (St)

```

**Meaning** From the perspective of Device PE1 and Device PE2, a single Layer 2 circuit is established toward access routers, so there is no standby device information in the CLI output of the **show l2circuit connections** command. Note that no timing and flapping information is provided for the VC acting as the hot-standby. Junos OS only allows these counters to be tracked for the active VC.

### Checking the Policy Conditions

**Purpose** On the PE devices, verify the state of the different conditions defined as part of the Layer3 VPN's egress policy, where 10.41.0.0/24 corresponds to the logical tunnel (y) subnet.

**Action** From operational mode, enter the **show policy conditions detail** command.

```

user@PE1> show policy conditions detail
Configured conditions:
Condition primary (static), event: Existence of a route in a specific routing
table
Dependent routes:
 10.41.0.0/24, generation 8
 192.168.0.104/32, generation 8

Condition standby (static), event: Existence of a route in a specific routing
table
Dependent routes:
None

Condition tables:
Table mpls.0, generation 0, dependencies 0, If-route-exists conditions: primary
(static) standby (static)
Table l3vpn.inet.0, generation 12, dependencies 2

user@PE2> show policy conditions detail
Configured conditions:
Condition primary (static), event: Existence of a route in a specific routing
table
Dependent routes:
 10.41.0.0/24, generation 18

## Extension of Pseudowire Redundancy Condition Logic to Pseudowire Service Logical Interface Overview

---

The pseudowire redundancy feature for mobile backhaul scenarios uses logical tunnel (lt-) paired interfaces as the stitching between Layer 2 and Layer 3 domains. This feature now includes the MPLS pseudowire service logical interface to terminate subscriber interfaces using the ps0.0 interface as the stitching between Layer 2 and Layer 3 domains. This topic describes the functional details of the pseudowire redundancy feature using the ps0.0 interface, which extends the policy logic used in the logical tunnel interfaces.

A pseudowire logical device and its related pseudowire logical interfaces are dependent on the state of the underlying logical transport interface device, which is either the Layer 2 VPN or Layer 2 circuit.

**NOTE:** We recommend that you use unit 0 to represent the transport logical interface for the pseudowire device. Non-zero unit numbers represent *service* logical interfaces used for pseudowire subscriber interfaces.

---

- [Sample Topology on page 936](#)
- [Functionality on page 937](#)
- [Policy Condition for Pseudowire Service Logical Interfaces on page 937](#)

### Sample Topology

[Figure 95 on page 937](#) on page 1 shows the stitching of Layer 2 and Layer 3 domains between the MPLS access node and the MPLS core. The primary or backup pseudowire on the MPLS access side is terminated at the provider edge devices (PE1 and PE2) at the pseudowire logical transport interface (ps0.0). The corresponding pseudowire logical service interfaces (ps0.1 to ps0.n) at the core MPLS cloud are connected to the Layer 3 domain, and these pseudowire logical service interfaces are configured in Layer 3 VPN routing instances.

Figure 95: Sample Topology for Pseudowire Redundancy

This topology results in a Layer 2 circuit across the MPLS access node and provider edge routers, with the pseudowire logical transport interface (ps0.0) acting as the local interface of the Layer 2 circuit terminating at the PE routers.

## Functionality

Figure 95 on page 937 on page 1 shows the functional details of pseudowire redundancy with events between the devices. A1 is the MPLS access node that initiates the primary and backup Layer 2 circuits to the provider edge devices (PE1 and PE2). The Layer 2 circuit is terminated on provider edge devices and then stitched to the Layer 3 VPN.

The functional flow is as follows:

- Create the primary and backup Layer 2 circuit at access node A1.
- Detect both the primary and backup path, advertise the local preference, and stitch the Layer 2 circuit and Layer 3 VPN at the provider edge devices (PE1 and PE2).

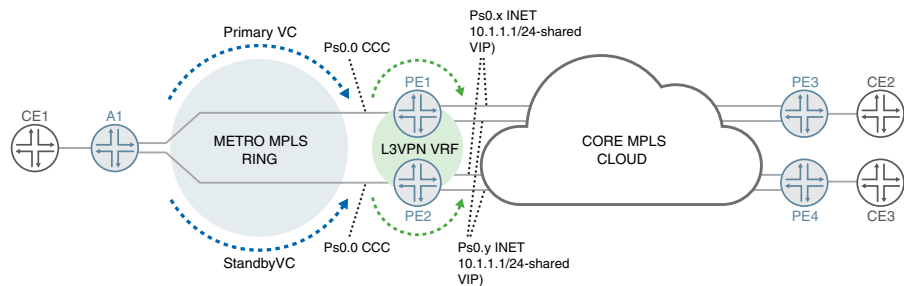

The following pseudowire code is used to notify the standby status from the access node to provider edge devices:

- L2CKT\_PW\_STATUS\_PW\_FWD\_STDBY flag with 0x00000020.

## Policy Condition for Pseudowire Service Logical Interfaces

The policy condition uses pseudowire service logical interfaces to stitch the Layer 2 and Layer 3 domains. Provider edge devices (PE1 and PE2) detect both primary and standby virtual circuits on the metro MPLS side. The primary virtual circuit is stitched to Layer 3 domain at the services side PE1 and PE2 towards the MPLS core. See Figure 96 on page 938 on page 2.

**Figure 96: Pseudowire Service Logical Interface for Pseudowire Redundancy Solution**

A primary Layer 2 circuit exists between access node A1 and provider edge device PE1, and a standby Layer 2 circuit exists between the same access node A1 and provider edge device PE2. The pseudowire service on the transport logical interface (ps0.0) is the local interface for the Layer 2 circuit at PE1 and PE2. At PE1 and PE2, there are multiple Layer 3 VPN instances; for example vrf-x and vrf-y.

The pseudowire service on service logical interfaces ps0.x and ps0.y are configured for the vrf-x and vrf-y routing instances respectively. For example, when the traffic with VLAN ID x originates from the access node to PE1 or PE2 on the Layer 2 circuit, it exits through the pseudowire service on the transport logical interface (ps0.0). Then the pseudowire service on service logical interface ps0.x is selected and sent through the vrf-x instance.

When the pseudowire state is active, the aggregation provider edge device (PE1 or PE2) advertises the subnet of the attachment circuit with the higher local preference value, which is indicated by the user through a manually configured policy.

**NOTE:** When remote provider edge devices receive two inet-vpn prefixes corresponding to the subnet of the attachment circuit, the highest local preference prefix received determines the primary datapath to be elected.

See the following output:

```
[edit policy-options]
condition primary {
 if-route-exists {
 address-family {
 ccc {
 ps0.0;
 table mpls.0;
 }
 }
 }
}
policy-statement l3vpn_export {
 term primary {
 from condition primary;
 then {
 local-preference add 300;
 }
 }
}
```

```
community set l3vpn;
accept;
}
}
}
```

**NOTE:** In policy-statement *name*, under *condition primary*, there is no need to configure the *peer unit*, as it is valid only for the logical tunnel interface. For the pseudowire service logical interface, one-to-many mapping is used.

# Configuring Load Balancing for Layer 2 Circuits

- [Reducing APS Switchover Time in Layer 2 Circuits on page 941](#)

## Reducing APS Switchover Time in Layer 2 Circuits

---

On M320 routers with Channelized OC3/STM1 Circuit Emulation PIC with SFP, you can configure the **fast-aps-switch** statement at the **[edit interfaces *interface-name* sonet-options aps]** hierarchy level to reduce the Automatic Protection Switching (APS) switchover time in Layer 2 circuits. Configuring this statement reduces the APS switchover time only when the Layer 2 circuit encapsulation type for the interface receiving traffic from a Layer 2 circuit neighbor is Structure Agnostic time-division multiplexing (TDM) over Packet (SAToP).

The **fast-aps-switch** statement must be configured on both working and protect circuits. Additionally, to achieve reduction in APS switchover time:

- Per-packet load balancing must be configured.
- Bidirectional switching mode must be configured.
- If the **fast-aps-switch** statement is configured in revertive APS mode, configure an appropriate value for revert time. We recommend that you configure a revert time of 600 seconds for 672 through 1344 Layer 2 circuits.
- To prevent the logical interfaces in the data path from being shut down, configure appropriate hold-time values on all the interfaces in the data path that support TDM.

---

### NOTE:

- The **fast-aps-switch** statement cannot be configured when the APS annex-b option is configured.
  - The interfaces that have the **fast-aps-switch** statement configured cannot be used in virtual private LAN service (VPLS) environments.
- 

The following tasks illustrate how to configure Junos OS to reduce APS switchover time.

**NOTE:** Per-packet load balancing can be configured for a limited set of routes or for all routes. To simplify the steps involved in configuring per-packet load balancing, steps for configuring per-packet load balancing for all routes is covered in this procedure.

- [Configuring Per-Packet Load Balancing on page 942](#)
- [Configuring Fast APS Switchover on page 942](#)

## Configuring Per-Packet Load Balancing

To configure per-packet load balancing for all routes:

1. Configure the **per-packet** option for the **load-balance** statement at the **[edit policy-options policy-statement *policy-name* then]** hierarchy level.

```
[edit policy-options policy-statement policy-name then]
user@host# set load-balance per-packet
```

For example:

```
[edit policy-options policy-statement load-balancing-policy then]
user@host# set load-balance per-packet
```

2. Configure the policy name in the **export** statement at the **[edit routing-options forwarding-table]** hierarchy level.

```
[edit routing-options forwarding-table]
user@host# set export policy-name
```

For example:

```
[edit routing-options forwarding-table]
user@host# set export load-balancing-policy
```

## Configuring Fast APS Switchover

To configure fast APS switchover:

1. On both the working and protect circuits, configure the **fast-aps-switch** statement at the **[edit interfaces *interface-name* sonet-options aps]** hierarchy level.

```
[edit interfaces interface-name sonet-options aps]
user@host# set fast-aps-switch
```

For example:

```
[edit interfaces cstm1-0/0/0 sonet-options aps]
user@host# set fast-aps-switch
```

```
[edit interfaces cstm1-0/1/0 sonet-options aps]
user@host# set fast-aps-switch
```

2. Configure bidirectional switching mode on both the working and protect circuits. To do this, configure the **switching-mode bidirectional** statement at the **[edit interfaces**

*interface-name* sonet-options aps] hierarchy level on both the working and protect circuits.

```
[edit interfaces interface-name sonet-options aps]
user@host# set switching-mode bidirectional
```

For example:

```
[edit interfaces cstm1-0/0/0 sonet-options aps]
user@host# set switching-mode bidirectional
```

```
[edit interfaces cstm1-0/1/0 sonet-options aps]
user@host# set switching-mode bidirectional
```

3. If APS is configured in revertive mode, configure an appropriate value for revert time on both the working and protect circuits. To do this, configure the **revert-time** statement at the [edit interfaces *interface-name* sonet-options aps] hierarchy level on both the working and protect circuits.

```
[edit interfaces interface-name sonet-options aps]
user@host# set revert-time seconds
```

For example:

```
[edit interfaces cstm1-0/0/0 sonet-options aps]
user@host# set revert-time 600
```

```
[edit interfaces cstm1-0/1/0 sonet-options aps]
user@host# set revert-time 600
```

4. To prevent the logical interfaces in the data path from being shut down, configure appropriate hold-time values on *all* interfaces in the data path that support TDM.

```
[edit interfaces interface-name hold-time]
user@host# set up seconds down seconds
```

For example:

```
[edit interfaces cstm1-0/0/0 hold-time]
user@host# set up 1 down 400
```

### Egress Protection LSPs for Layer 2 Circuits

An egress protection LSP provides link protection for link between PE routers and CE devices as illustrated in [Figure 97 on page 946](#).

Figure 97: Egress Protection LSP

Device CE1 is multihomed to router PE1 and router PE2. Device CE2 is multihomed to router PE3 and router PE4. There are two paths connecting devices CE1 and CE2. The working path is CE2-PE3-P1-PE1-CE1, using pseudowire PW1. The protecting path is CE2-PE4-P2-PE2-CE1, using pseudowire PW2. Normally, traffic flows through the working path. When the end-to-end OAM between devices CE1 and CE2 detects a failure on the working path, traffic will be switched from the working path to the protecting path.

In the topology shown in [Figure 97 on page 946](#), if there was a link or node failure in the core network (for example, a link failure from router P1 to PE1, from router PE3 to P1, or a node failure of router P1), MPLS fast reroute can be triggered on the transport LSPs between router PE3 and router PE1 to repair the connection within tens of milliseconds. Egress protection LSPs address the problem of when a link failure occurs at the edge of the network (for example, a link failure on router PE1 to device CE1).

An egress protection LSP has been configured from router PE1 to router PE2. In the event of a link failure between router PE1 and device CE1, traffic can be switched to the egress protection LSP. Traffic from device CE2 can now be routed through path PE3-P1-PE1-PE2 to reach device CE1.

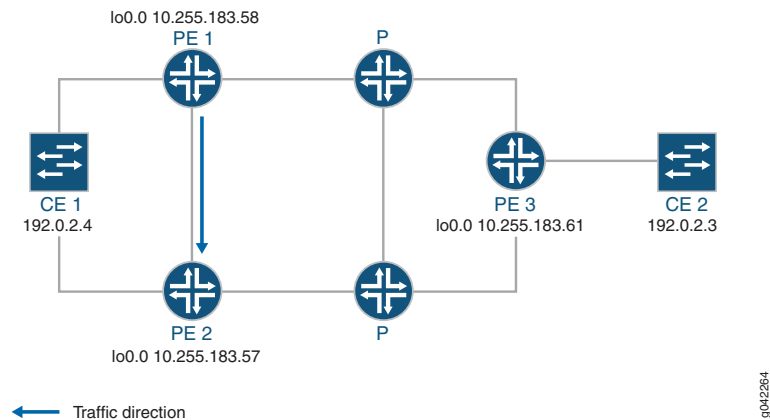

## Configuring Egress Protection Service Mirroring for BGP Signaled Layer 2 Services

Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node. If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

Figure 1 shows a simplified topology of the use case that explains this feature.

**Figure 98: Egress Protection LSP Configured from Router PE1 to Router PE2**

CE1 is multihomed to PE1 and PE2. There are two paths connecting CE1 and CE2. The working path is CE2-PE3-P-PE1-CE1, via pseudowire PW21. The protecting path is CE2-PE3-P-PE2-CE1, via pseudowire PW22. Traffic is flowing through the working path under normal circumstances. When the end-to-end OAM between CE1 and CE2 detects failure on the working path, traffic will be switched from the working path to the protecting path. The end-to-end failure detection and recovery relies on control plane hence should be relatively slow. To achieve faster protection, local repair mechanisms similar to those used by MPLS fast reroute should be used. In Figure 1 above, if link or node failed in the core network (like link failure on P-PE1, P-PE3, or node failure on P), the MPLS fast reroute will happen on the transport LSPs between PE1 and PE3. The failure could be locally repaired within tens of milliseconds. However, if link or node failure happens at the edge (like link failure on PE3-CE2 or node failure on PE3), there is no local repair currently so we have to rely on the CE1-CE2 end-to-end protection to repair the failure.

- Device CE2—Traffic origin
- Router PE3—Ingress PE router
- Router PE1— (Primary) Egress PE router
- Router PE2—Protector PE router
- Device CE1—Traffic destination

When the link between CE1– PE1 goes down, PE1 will briefly redirect that traffic towards CE1, to PE2. PE2 forwards it to CE1 until ingress router PE3 recalculates to forward the traffic to PE2.

Initially the traffic direction was; CE2 – PE3 – P – PE1 – CE1.

When the link between CE1– PE1 goes down, the traffic will be; CE2 – PE3 – P – PE1 – PE2 –CE1. PE3 then recalculates the path; CE2 – PE3 – P – PE2 – CE1.

1. Configure RSVP on PE1, PE2, and PE3.

```
[edit protocols]
user@PE1# set interface all
user@PE2# set interface all
user@PE3# set interface all
```

2. Configure MPLS.

```
[edit protocols mpls]
user@PE1# set interface all
user@PE2# set interface all
user@PE3# set interface all
```

3. Set PE1 as **primary** and PE2 as **protector** nodes.

```
[edit protocols mpls]
user@PE1# set egress-protection context-identifier address primary
user@PE2# set egress-protection context-identifier address protector
```

4. Enable **egress-protection** on PE1 and PE2.

```
[edit protocols bgp]
user@PE1# set group ibgp family l2vpn egress-protection
user@PE2# set group ibgp family l2vpn egress-protection
```

5. Configure LDP and ISIS on PE1, PE2, and PE3.

```
[edit protocols ldp]
user@PE1# set interface all
user@PE2# set interface all
user@PE3# set interface all

[edit protocols isis]
user@PE1# set interface all point-to-point
user@PE2# set interface all point-to-point
user@PE3# set interface all point-to-point
```

6. Configure a load balancing policy at PE1, PE2, and PE3.

```
[edit]
user@PE1# set policy-options policy-statement lb then load-balance per-packet
user@PE2# set policy-options policy-statement lb then load-balance per-packet
user@PE3# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options at PE1, PE2, and PE3, to export routes based on the load balancing policy.

```
[edit]
user@PE1# set routing-options traceoptions file ro.log
user@PE1# set routing-options traceoptions flag normal
user@PE1# set routing-options traceoptions flag route
user@PE1# set routing-options autonomous-system 100
user@PE1# set routing-options forwarding-table export lb

[edit]
user@PE2# set routing-options traceoptions file ro.log
user@PE2# set routing-options traceoptions flag normal
user@PE2# set routing-options traceoptions flag route
user@PE2# set routing-options autonomous-system 100
user@PE2# set routing-options forwarding-table export lb

[edit]
user@PE3# set routing-options traceoptions file ro.log
user@PE3# set routing-options traceoptions flag normal
user@PE3# set routing-options traceoptions flag route
user@PE3# set routing-options autonomous-system 100
user@PE3# set routing-options forwarding-table export lb
```

8. Configure BGP at PE1 to advertise nrli from the routing instance with context-ID as next-hop.

```
[edit]
user@PE1# set routing-instances foo egress-protection context-identifier
context-identifier
```

9. Configure l2vpn at PE1, PE2, and PE3

At PE1:

```
[edit routing-instances]
foo {
 instance-type l2vpn;
 egress-protection {
 context-identifier {
 198.51.100.0;
 }
 }
 interface ge-2/0/2.0;
 route-distinguisher 10.255.183.58:1;
 vrf-target target:9000:1;
 protocols {
 l2vpn {
 encapsulation-type ethernet-vlan;
 site foo {
 site-identifier 1;
 multi-homing;
 site-preference primary;
 interface ge-2/0/2.0 {
 remote-site-id 2;
 }
 }
 }
 }
}
```

```
 }
 }
}
```

At PE2:

```
[edit routing-instances]
foo {
 instance-type l2vpn;
 egress-protection {
 protector;
 }
 interface ge-2/0/2.0;
 route-distinguisher 10.255.183.57:1;
 vrf-target target:9000:1;
 protocols {
 l2vpn {
 encapsulation-type ethernet-vlan;
 site foo {
 site-identifier 1;
 multi-homing;
 site-preference backup;
 interface ge-2/0/2.0 {
 remote-site-id 2;
 }
 }
 }
 }
}
```

At PE3:

```
[edit routing-instances]
foo {
 instance-type l2vpn;
 interface ge-2/1/2.0;
 route-distinguisher 10.255.183.61:1;
 vrf-target target:9000:1;
 protocols {
 l2vpn {
 encapsulation-type ethernet-vlan;
 site foo {
 site-identifier 2;
 interface ge-2/1/2.0;
 }
 }
 }
}
```

## Release History Table

| Release | Description                                                                                                                                        |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node. |

## Example: Configuring an Egress Protection LSP for a Layer 2 Circuit

This example shows how to configure an egress protection LSP.

- [Requirements on page 951](#)
- [Egress Protection LSP Overview on page 951](#)
- [Egress Protection LSP Configuration on page 953](#)

### Requirements

Egress protection LSPs are supported on Juniper Networks MX Series routers only. This requirement applies to the PE routers facilitating the egress protection LSP.

### Egress Protection LSP Overview

If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the connection within tens of milliseconds. An egress protection LSP addresses the problem of when a link failure occurs at the edge of the network (for example, a link failure between a PE router and a CE device). Egress protection LSPs do not address the problem of a node failure at the edge of the network (for example, a failure of a PE router). An egress protection LSP is an RSVP-signaled ultimate hop popping LSP.

This example includes the following configuration concepts and statements that are unique to the configuration of an egress protection LSP:

- **context-identifier**—Specifies an IPV4 address used to define the pair of PE routers participating in the egress protection LSP. The context identifier is used to assign an identifier to the protector PE router. The identifier is propagated to the other PE routers participating in the network, making it possible for the protected egress PE router to signal the egress protection LSP to the protector PE router.
- **egress-protection**—Configures the protector information for the protected Layer 2 circuit and configures the protector Layer 2 circuit at the **[edit protocols l2circuit]** hierarchy level. Configures an LSP as an egress protection LSP at the **[edit protocols mpls label-switched-path lsp-name]** hierarchy level. It also configures the context identifier at the **[edit protocols mpls]** hierarchy level.

- **protected-l2circuit**—Specifies which Layer 2 circuit is to be protected by the egress protect LSP. This statement includes the following sub-statements: **ingress-pe**, **egress-pe**, and **virtual-circuit-id**. These sub-statements specify the address of the PE router at the ingress of the Layer 2 circuit, the address of the PE router at the egress of the Layer 2 circuit, and the Layer 2 circuit's identifier respectively.
- **protector-interface**—Specify the interface used by the egress protection LSP. In the event of a local link failure to a CE device, the egress protect LSP uses the interface specified to communicate with the protector PE router.
- **protector-pe**—Specify the IPv4 address of the protector PE router. The protector PE router must have a connection to the same CE device as the protected PE router for the egress protect LSP to function. This statement includes the following sub-statements: **context-identifier** and **lsp**. The **lsp** statement specifies the LSP to be used as the actual egress protection LSP.

**Figure 99: Egress Protection LSP Configured from Router PE2 to Router PE3**

Pseudowires are configured along two paths, one from router PE1 to router PE2 (pseudowire 12) and one from router PE1 to router PE3 (pseudowire 13). In the event of a failure on the link between router PE2 and device CE2, traffic is switched to the egress protection LSP configured between router PE2 and router PE3 (the protector PE router):

- Device CE1—Traffic origin
- Router PE1—Ingress PE router
- Router PE2—Egress PE router
- Router PE3—Protector PE router
- Device CE2—Traffic destination

This example shows how to configure routers PE1, PE2, and PE3.

## Egress Protection LSP Configuration

- [Step-by-Step Procedure on page 954](#)
- [Results on page 959](#)

**CLI Quick Configuration** To quickly configure an egress protection LSP, copy the following commands into a text file, modify the interface configurations to match your equipment, remove any line breaks, and then paste the commands into the CLI. This group of set commands is for router PE1.

```
set protocols rsvp interface ge-3/1/0.1
set protocols rsvp interface ge-3/1/3.2
set protocols mpls interface ge-3/1/0.1
set protocols mpls interface ge-3/1/3.2
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-3/1/0.1
set protocols ospf area 0.0.0.0 interface ge-3/1/3.2
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ldp interface ge-3/1/0.1
set protocols ldp interface ge-3/1/3.2
set protocols ldp interface lo0.0
set protocols l2circuit neighbor 192.0.2.3 interface fe-3/3/0.1 virtual-circuit-id 32
set protocols l2circuit neighbor 192.0.2.3 interface fe-3/3/0.1 egress-protection
 protector-interface ge-3/1/2.2
set protocols l2circuit neighbor 192.0.2.4 interface ge-3/1/2.2 virtual-circuit-id 33
set policy-options policy-statement load-balance-example then load-balance per-packet
set routing-options router-id 192.0.2.2
set routing-options forwarding-table export load-balance-example
```

To quickly configure an egress protection LSP, copy the following commands into a text file, modify the interface configurations to match your equipment, remove any line breaks, and then paste the commands into the CLI. This group of set commands is for router PE2.

```
[edit]
set protocols rsvp tunnel-services
set protocols rsvp interface ge-2/3/0.3
set protocols rsvp interface ge-2/3/1.4 link-protection
set protocols ldp interface ge-2/3/0.3
set protocols ldp interface ge-2/3/1.4
set protocols ldp interface lo0.0
set protocols ldp upstream-label-assignment
set protocols mpls label-switched-path protected-lsp to 192.0.2.5
set protocols mpls label-switched-path protected-lsp egress-protection
set protocols mpls interface ge-2/3/0.3
set protocols mpls interface ge-2/3/1.4
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-2/3/0.3
set protocols ospf area 0.0.0.0 interface ge-2/3/1.4
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols l2circuit neighbor 192.0.2.2 interface ge-2/0/2.5 virtual-circuit-id 23
set protocols l2circuit neighbor 192.0.2.2 interface ge-2/0/2.5 egress-protection
 protector-pe 192.0.2.4
set protocols l2circuit neighbor 192.0.2.2 interface ge-2/0/2.5 egress-protection
 protector-pe context-identifier 192.0.2.5
```

```
set policy-options policy-statement load-balance-example then load-balance per-packet
set routing-options router-id 192.0.2.3
set routing-options forwarding-table export load-balance-example
```

To quickly configure an egress protection LSP, copy the following commands into a text file, modify the interface configurations to match your equipment, remove any line breaks, and then paste the commands into the CLI. This group of set commands is for router PE3.

```
set protocols rsvp tunnel-services
set protocols rsvp interface ge-2/0/0.6
set protocols rsvp interface ge-2/0/1.7
set protocols mpls interface ge-2/0/0.6
set protocols mpls interface ge-2/0/1.7
set protocols mpls egress-protection context-identifier 192.0.2.5 protector
set protocols ospf traffic-engineering
set protocols ospf area 0.0.0.0 interface ge-2/0/0.6
set protocols ospf area 0.0.0.0 interface ge-2/0/1.7
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ldp interface ge-2/0/0.6
set protocols ldp interface ge-2/0/1.7
set protocols ldp interface lo0.0
set protocols ldp upstream-label-assignment

set protocols l2circuit neighbor 192.0.2.2 interface ge-2/0/3.21 egress-protection
protected-l2circuit ingress-pe 192.0.2.2
set protocols l2circuit neighbor 192.0.2.2 interface ge-2/0/3.21 egress-protection
protected-l2circuit egress-pe 192.0.2.3
set protocols l2circuit neighbor 192.0.2.2 interface ge-2/0/3.21 egress-protection
protected-l2circuit virtual-circuit-id 31
```

---

### Step-by-Step Procedure

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure an egress protection LSP, complete the following steps for router PE1:

1. Configure RSVP. Include the interface linked to router PE2 and the interface linked to router PE3.

```
[edit]
user@PE1# edit protocols rsvp
[edit protocols rsvp]
user@PE1# set interface ge-3/1/0.1
[edit protocols rsvp]
user@PE1# set interface ge-3/1/3.2
```

2. Configure LDP. Include the interface linked to router PE2, the interface linked to router PE3, and the loopback interface.

```
[edit]
```

```

user@PE1# edit protocols ldp
[edit protocols ldp]
user@PE1# set interface ge-3/1/0.1
[edit protocols ldp]
user@PE1# set interface ge-3/1/3.2
[edit protocols ldp]
user@PE1# set interface lo0.0

```

3. Configure MPLS. Include the interface linked to router PE2 and the interface linked to router PE3.

```

[edit]
user@PE1# edit protocols mpls
[edit protocols mpls]
user@PE1# set interface ge-3/1/0.1
[edit protocols mpls]
user@PE1# set interface ge-3/1/3.2

```

4. Configure OSPF. Include the interface linked to router PE2, the interface linked to router PE3, and the loopback interface in the configuration for the OSPF area.

```

[edit]
user@PE1# edit protocols ospf
[edit protocols ospf]
user@PE1# set interface traffic-engineering
[edit protocols ospf]
user@PE1# set area 0.0.0.0 interface ge-3/1/0.1
[edit protocols ospf]
user@PE1# set area 0.0.0.0 interface ge-3/1/3.2
[edit protocols ospf]
user@PE1# set area 0.0.0.0 interface lo0.0 passive

```

5. Configure Layer 2 circuits to use the egress protection LSP to protect against a link failure to device CE1.

```

[edit]
user@PE1# edit protocols l2circuit
[edit protocols l2circuit]
user@PE1# set neighbor 192.0.2.3 interface fe-3/3/0.1 virtual-circuit-id 32
[edit protocols l2circuit]
user@PE1# edit neighbor 192.0.2.3
[edit protocols l2circuit neighbor 192.0.2.3]
user@PE1# set interface fe-3/3/0.1 egress-protection protector-interface ge-3/1/2.2
[edit protocols l2circuit]
user@PE1# set neighbor 192.0.2.4 interface ge-3/1/2.2 virtual-circuit-id 33

```

6. Configure a load balancing policy.

```

[edit]
user@PE1# set policy-options policy-statement load-balance-example then
 load-balance per-packet

```

7. Configure the routing options to export routes based on the load balancing policy.

```
[edit]
user@PE1# set routing-options router-id 192.0.2.2
[edit]
user@PE1# set routing-options forwarding-table export load-balance-example
```

8. If you are done configuring the device, commit the configuration.

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure an egress protection LSP, complete the following steps for router PE2:

1. Configure RSVP. Include the interface linked to the ingress PE router and the interface linked to the CE device.

```
[edit]
user@PE2# edit protocols rsvp
[edit protocols rsvp]
user@PE2# set tunnel-services
[edit protocols rsvp]
user@PE2# set interface ge-2/3/0.3
[edit protocols rsvp]
user@PE2# set interface ge-2/3/1.4 link-protection
```

2. Configure LDP. Include the interface linked to the ingress PE router and the interface linked to the CE device.

```
[edit]
user@PE2# edit protocols ldp
[edit protocols ldp]
user@PE2# set interface ge-2/3/0.3
[edit protocols ldp]
user@PE2# set interface ge-2/3/1.4
[edit protocols ldp]
user@PE2# set interface lo0.0
[edit protocols ldp]
user@PE2# set upstream-label-assignment
```

3. Configure MPLS and the LSP which acts as the egress protection LSP.

```
[edit]
user@PE2# edit protocols mpls
[edit protocols mpls]
user@PE2# set interface ge-2/3/0.3
[edit protocols mpls]
user@PE2# set interface ge-2/3/1.4
[edit protocols mpls]
user@PE2# set label-switched-path protected-lsp to 192.0.2.5
[edit protocols mpls]
user@PE2# set label-switched-path protected-lsp egress-protection
```

## 4. Configure OSPF.

```
[edit]
user@PE2# edit protocols ospf
[edit protocols ospf]
user@PE2# set interface traffic-engineering
[edit protocols ospf]
user@PE2# set interface area 0.0.0.0 interface ge-2/3/0.3
[edit protocols ospf]
user@PE2# set interface area 0.0.0.0 interface ge-2/3/1.4
[edit protocols ospf]
user@PE2# set interface area 0.0.0.0 interface lo0.0 passive
```

## 5. Configure the Layer 2 circuit to use the egress protection LSP.

```
[edit]
user@PE2# edit protocols l2circuit
[edit protocols l2circuit]
user@PE2# set neighbor 192.0.2.2 interface ge-2/0/2.5 virtual-circuit-id 23
[edit protocols l2circuit]
user@PE2# edit neighbor 192.0.2.2
[edit protocols l2circuit neighbor 192.0.2.2]
user@PE2# set interface ge-2/0/2.5 egress-protection protector-pe 192.0.2.4
[edit protocols l2circuit neighbor 192.0.2.2]
user@PE2# set interface ge-2/0/2.5 egress-protection protector-pe
context-identifier 192.0.2.5
```

## 6. Configure a load balancing policy.

```
[edit]
user@PE1# set policy-options policy-statement load-balance-example then
load-balance per-packet
```

## 7. Configure the routing options to export routes based on the load balancing policy.

```
[edit]
user@PE2# set routing-options router-id 192.0.2.3
[edit]
user@PE2# set routing-options forwarding-table export load-balance-example
```

## 8. If you are done configuring the device, commit the configuration.

**Step-by-Step  
Procedure**

To configure an egress protection LSP, complete the following steps for router PE3:

## 1. Configure RSVP. Include the interface linked to the ingress PE router and the interface linked to the CE device.

```
[edit]
user@PE3# edit protocols rsvp
[edit protocols rsvp]
user@PE3# set tunnel-services
[edit protocols rsvp]
user@PE3# set interface ge-2/0/0.6
```

```
[edit protocols rsvp]
user@PE3# set interface ge-2/0/1.7
```

2. Configure LDP. Include the interface linked to the ingress PE router and the interface linked to the CE device.

```
[edit]
user@PE3# edit protocols ldp
[edit protocols ldp]
user@PE3# set interface ge-2/0/0.6
[edit protocols ldp]
user@PE3# set interface ge-2/0/1.7
[edit protocols ldp]
user@PE3# set interface lo0.0
[edit protocols ldp]
user@PE3# set upstream-label-assignment
```

3. Configure MPLS and the LSP which acts as the egress protection LSP.

```
[edit]
user@PE3# edit protocols mpls
[edit protocols mpls]
user@PE3# set interface ge-2/0/0.6
[edit protocols mpls]
user@PE3# set interface ge-2/0/1.7
[edit protocols mpls]
user@PE3# set egress-protection context-identifier 192.0.2.5 protector
```

4. Configure OSPF.

```
[edit]
user@PE3# edit protocols ospf
[edit protocols ospf]
user@PE3# set interface traffic-engineering
[edit protocols ospf]
user@PE3# set area 0.0.0.0 interface ge-2/0/0.6
[edit protocols ospf]
user@PE3# set area 0.0.0.0 interface ge-2/0/1.7
[edit protocols ospf]
user@PE3# set area 0.0.0.0 interface lo0.0 passive
```

5. Configure the Layer 2 circuit to use the egress protection LSP.

```
[edit]
user@PE3# edit protocols l2circuit
[edit protocols l2circuit]
user@PE3# set neighbor 192.0.2.2 interface ge-2/0/3.21 virtual-circuit-id 42
[edit protocols l2circuit]
user@PE3# edit neighbor 192.0.2.2
[edit protocols l2circuit neighbor 192.0.2.2]
user@PE3# set interface ge-2/0/3.21 egress-protection protected-l2circuit ingress-pe
192.0.2.2
[edit protocols l2circuit neighbor 192.0.2.2]
user@PE3# set interface ge-2/0/3.21 egress-protection protected-l2circuit egress-pe
192.0.2.3
```

```
[edit protocols l2circuit neighbor 192.0.2.2]
user@PE3# set interface ge-2/0/3.21 egress-protection
protected-l2circuit virtual-circuit-id 31
```

6. If you are done configuring the device, commit the configuration.

## Results

From configuration mode, confirm your configuration on router PE1 by entering the **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
user@PE1# show protocols
rsvp {
 interface ge-3/1/0.1;
 interface ge-3/1/3.2;
}
mpls {
 interface ge-3/1/0.1;
 interface ge-3/1/3.2;
}
ospf {
 traffic-engineering;
 area 0.0.0.0 {
 interface ge-3/1/0.1;
 interface ge-3/1/3.2;
 interface lo0.0 {
 passive;
 }
 }
}
ldp {
 interface ge-3/1/0.1;
 interface ge-3/1/3.2;
 interface lo0.0;
}
l2circuit {
 neighbor 192.0.2.3 {

```

## Example: Configuring Layer 2 Circuit Protect Interfaces

This example illustrates how you might configure a Layer 2 circuit with protect interfaces. Protect interfaces act as backups for their associated interfaces. The primary interface has priority over the protect interface and carries network traffic as long as it is functional. If the primary interface fails, the protect interface is activated. These interfaces can also share the same virtual path identifier (VPI) or virtual circuit identifier (VCI).

Figure 100 on page 962 shows the network topology used in this example.

**Figure 100: Layer 2 Circuits Using Protect Interfaces**

The following sections describe how to configure a Layer 2 circuit to use a protect interface:

- [Configuring Router PE1 on page 963](#)
- [Configuring Router PE2 on page 964](#)
- [Configuring Router CE1 on page 966](#)
- [Configuring Router CE2 on page 966](#)

## Configuring Router PE1

Configure an interface for traffic to Router CE1 from Router PE1 at the **[edit interfaces]** hierarchy level:

```
[edit interfaces]
so-0/2/2 {
 description "Router CE1 so-0/2/2";
 no-keepalives;
 encapsulation frame-relay-ccc;
 unit 1 {
 encapsulation frame-relay-ccc;
 point-to-point;
 dlci 600;
 }
 unit 2 {
 encapsulation frame-relay-ccc;
 point-to-point;
 dlci 602;
 }
}
```

Configure an interface for traffic to Router CE1 from Router PE1 at the **[edit interfaces]** hierarchy level. Logical interface **so-0/2/0.2** acts as the protect interface for **so-0/2/2.2**, and logical interface **so-0/2/0.1** acts as the protect interface for **so-0/2/2.1**:

```
[edit interfaces]
so-0/2/0 {
 description "to Router CE1 so-0/3/0";
 no-keepalives;
 encapsulation frame-relay-ccc;
 unit 1 {
 encapsulation frame-relay-ccc;
 dlci 600;
 }
 unit 2 {
 encapsulation frame-relay-ccc;
 dlci 602;
 }
}
```

Configure an interface for traffic to Router PE2 from Router PE1 at the **[edit interfaces]** hierarchy level:

```
[edit interfaces]
so-0/2/1 {
 description "to Router PE2 so-1/0/1";
 unit 0 {
 family inet {
 address 192.0.2.0/24 {
 destination 192.0.2.4;
 }
 }
 family iso;
 family mpls;
 }
}
```

```

 }
}

```

Configure an interface for traffic to Router PE2 from Router PE1 at the **[edit interfaces]** hierarchy level:

```

[edit interfaces]
so-0/2/3 {
 description "Router PE2 so-1/0/3";
 unit 0 {
 family inet;
 family iso;
 family mpls;
 }
 lo0 {
 unit 0 {
 family inet {
 address 198.51.100.0/24;
 address 10.100.40.200/32;
 }
 family iso {
 address 47.0005.80ff.f800.0000.0108.0001.1921.6800.4213.00;
 }
 }
 }
}

```

Configure the Layer 2 circuit by including the **l2circuit** statement at the **[edit protocols]** hierarchy level. The logical interfaces for the Layer 2 circuits and their corresponding protect interfaces are included here:

```

[edit protocols]
l2circuit {
 neighbor 10.100.40.210 {
 interface so-0/2/2.2 {
 protect-interface so-0/2/0.2;
 virtual-circuit-id 2;
 no-control-word;
 }
 interface so-0/2/2.1 {
 protect-interface so-0/2/0.1;
 virtual-circuit-id 1;
 no-control-word;
 }
 }
}

```

## Configuring Router PE2

Configure an interface for traffic to Router CE2 from Router PE2:

```

[edit interfaces]
so-1/0/0 {
 description "to Router CE2 so-0/2/0";
 no-keepalives;
 encapsulation frame-relay-ccc;
}

```

```

unit 1 {
 encapsulation frame-relay-ccc;
 point-to-point;
 dlci 700;
}
unit 2 {
 encapsulation frame-relay-ccc;
 point-to-point;
 dlci 702;
}
}

```

Configure an interface for traffic to Router PE1 from Router PE2:

```

[edit interfaces]
so-1/0/1 {
 description "to Router PE1 so-0/2/1";
 unit 0 {
 family inet {
 address 192.0.2.4/32 {
 destination 192.0.2.22;
 }
 }
 family iso;
 family mpls;
 }
}

```

Configure an interface for traffic to Router PE1 from Router PE2:

```

[edit interfaces]
so-1/0/3 {
 description "to Router PE1 so-0/2/3";
 unit 0 {
 family inet;
 family iso;
 family mpls;
 }
}
lo0 {
 unit 0 {
 family inet {
 address 198.51.100.0/24;
 address 10.100.40.210/32;
 }
 family iso {
 address 47.0005.80ff.f800.0000.0108.0001.1921.6800.4216.00;
 }
 }
}
}

```

Configure the Layer 2 circuit at the **[edit protocols]** hierarchy level:

```

[edit protocols]
l2circuit {
 neighbor 10.100.40.200 {
 interface so-1/0/0.1 {

```

```
 virtual-circuit-id 1;
 no-control-word;
 }
 interface so-1/0/0.2 {
 virtual-circuit-id 2;
 no-control-word;
 }
}
}
```

## Configuring Router CE1

Configure an interface for traffic to Router PE1 from Router CE1:

```
[edit interfaces]
so-0/3/0 {
 description "to Router PE1 so-0/2/0";
 no-keepalives;
 encapsulation frame-relay;
 unit 1 {
 dlci 601;
 family inet {
 address 203.0.113.1;
 }
 }
}
}
```

Configure an interface for traffic to Router PE1 from Router CE1:

```
[edit interfaces]
so-0/3/1 {
 description "Router PE1 so-0/2/2";
 no-keepalives;
 encapsulation frame-relay;
 unit 0 {
 dlci 600;
 family inet {

## Configuring Router CE2

Configure an interface for traffic to Router PE2 from Router CE2:

```
[edit interfaces]
so-0/2/0 {
```

```

description "to Router PE2 so-1/0/0";
no-keepalives;
encapsulation frame-relay;
unit 1 {
 dlci 700;
 family inet {
 address 10.10.10.2/24;
 address 203.0.113.5/24;
 address 203.0.113.6/24;
 }
}
unit 2 {
 dlci 702;
 family inet {
 address 203.0.113.7/24;
 }
}
}

```

## Example: Configuring Layer 2 Circuit Switching Protection

Unlike Layer 2 circuit protect interfaces (see [“Example: Configuring Layer 2 Circuit Protect Interfaces” on page 962](#)), which provide traffic protection for paths configured between the PE routers and CE routers, Layer 2 circuit switching protection provides traffic protection for the paths configured between the PE routers. In the event the path used by a Layer 2 circuit fails, traffic can be switched to an alternate path (or protection path). Switching protection is supported for locally switched Layer 2 circuits and provides 1 to 1 protection for each Layer 2 circuit interface.

When you enable Layer 2 circuit switching protection, each Layer 2 circuit interface requires the following paths:

- Working path—Used by the Layer 2 circuit when working normally.
- Protection path—Used by the Layer 2 circuit when the working path fails.
- [Requirements on page 967](#)
- [Overview on page 967](#)
- [Configuration on page 969](#)

## Requirements

This example uses the following hardware and software components:

- MX Series 3D Universal Edge Routers
- Junos OS Release 12.3

## Overview

Each working path can be configured to have either a protection path routed directly to the neighboring PE router (as shown in [Figure 101 on page 968](#)) or indirectly using a pseudowire configured through an intermediate PE router (as shown in

Figure 102 on page 968 and Figure 103 on page 969). The protection path provides failure protection for the traffic flowing between the PE routers. Ethernet OAM monitors the status of these paths. When OAM detects a failure, it reroutes the traffic from the failed working path to the protection path. You can configure OAM to revert the traffic automatically to the working path when it is restored. You can also manually switch traffic between the working path, the protection path, and back.

**NOTE:** Non-stop routing (NSR) and graceful routing engine switchover (GRES) do not support Layer 2 circuit switching protection.

### Topology

Figure 101 on page 968 illustrates Layer 2 circuit local switching. There are two OAM sessions running between Router PE1 and Router PE2. One OAM session is configured over the working path and the other is configured over the protection path.

**Figure 101: Connection Protection Enabled Between Router PE1 and Router PE2**

In Figure 102 on page 968 and Figure 103 on page 969, there are two OAM sessions running between Router PE1 and Router PE2. For Figure 2, one OAM session is configured over the working path between Router PE1 and Router PE2. The other OAM session is configured over the protection path between Router PE1 and Router PE3 to Router PE2.

**Figure 102: Connection Protection Using a Pseudowire Configured through Router PE3 as the Protection Path**

For Figure 103 on page 969, one OAM session is configured over the working path, the pseudowire between Router PE1 and Router PE3, then to Router PE2. The other OAM session is configured on the protect path between Router PE1 and Router PE2.

Figure 103: Connection Protection Using a Pseudowire Configured through Router PE3 as the Working Path

## Configuration

The following sections describe how to configure each of the variations of Layer 2 circuit connection protection:

- [Configuring Connection Protection Between Two PE Routers on page 969](#)
- [Verifying that OAM CFM Connections are Active on page 973](#)
- [Configuring Connection Protection Using Another PE Router for the Protection Path on page 973](#)
- [Verifying that OAM CFM Connections are Active on page 976](#)
- [Configuring Connection Protection Using an Another PE Router for the Working Path on page 977](#)
- [Verifying that OAM CFM Connections are Active on page 980](#)

### Configuring Connection Protection Between Two PE Routers

#### Step-by-Step Procedure

To configure Layer 2 Circuit switching protection as shown in [Figure 101 on page 968](#) on Router PE1:

1. Configure the Layer 2 circuit on Router PE1.
 

```
[edit protocols l2circuit]
user@PE1# set local-switching interface ge-2/0/2.0 connection-protection
user@PE1# set local-switching interface ge-2/0/2.0 end-interface interface
ge-2/0/1.0
user@PE1# set local-switching interface ge-2/0/2.0 end-interface backup-interface
ge-2/0/1.1
```
2. Configure the routing policy on Router PE1.
 

```
[edit policy-options]
user@PE1# set policy-statement protection-policy then load-balance per-packet
```
3. Enable the routing policy on Router PE1.
 

```
[edit routing-options]
user@PE1# set forwarding-table export protection-policy
```
4. Configure OAM on Router PE1. OAM is used to monitor the working path between Router PE1 and Router PE2. In the event of a failure on the working path, traffic is

switched automatically to the protection path. A connectivity fault management (CFM) session is configured on the working path and on the protection path. Begin by configuring the OAM maintenance domain.

```
[edit protocols oam ethernet]
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md level 5
```

5. Configure OAM on Router PE1 for the working path.

```
[edit protocols oam ethernet]
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working continuity-check interval
100ms
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 1000 interface
ge-2/0/1.0
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 1000 interface
working
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 1000 direction down
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 1000 remote-mep
103
```

6. Configure OAM on Router PE1 for the protection path.

```
[edit protocols oam ethernet]
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection continuity-check
interval 100ms
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 1001 interface
ge-2/0/1.1
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 1001 interface
protect
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 1001 direction
down
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 1001 remote-mep
104
```

7. Configure the OAM maintenance domain on Router PE2.

```
[edit protocols oam ethernet]
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md level 5
```

8. Configure OAM on Router PE2 for the working path.

```
[edit protocols oam ethernet]
```

```

user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working continuity-check interval
100ms
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 103 interface
ge-2/0/1.0
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 103 interface working
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 103 direction down
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 103 remote-mep
1000

```

9. Configure OAM on Router PE2 for the protection path.

```

[edit protocols oam ethernet]
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection continuity-check
interval 100ms
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 104 interface
ge-2/0/1.1
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 104 interface
protect
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 104 direction
down
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 104 remote-mep
1001

```

**Results** From configuration mode on Router PE1, confirm your configuration by entering the **show protocols l2circuit**, **show policy-options**, **show routing-options**, and **show protocols oam ethernet** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```

user@host> show protocols l2circuit
local-switching {
 interface ge-2/0/2.0 {
 connection-protection;
 }
 end-interface {
 interface ge-2/0/1.0;
 backup-interface ge-2/0/1.1;
 }
}
}

user@host> show policy-options
policy-statement protection-policy {
 then {
 load-balance per-packet;
 }
}

```

```
}
user@host> show routing-options
forwarding-table {
 export protection-policy;
}
user@host> show protocols oam ethernet
connectivity-fault-management {
 maintenance-domain l2circuit-example-md {
 level 5;
 maintenance-association working {
 continuity-check {
 interval 100ms;
 }
 mep 1000 {
 interface ge-2/0/1.0 working;
 direction down;
 remote-mep 103;
 }
 }
 }
 maintenance-association protection {
 continuity-check {
 interval 100ms;
 }
 mep 1001 {
 interface ge-2/0/1.1 protect;
 direction down;
 remote-mep 104;
 }
 }
}
}
```

From configuration mode on Router PE2, confirm your configuration by entering the **show protocols oam ethernet** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
connectivity-fault-management {
 maintenance-domain l2circuit-example-md {
 level 5;
 maintenance-association working {
 continuity-check {
 interval 100ms;
 }
 mep 103 {
 interface ge-2/0/1.0 working;
 direction down;
 remote-mep 1000;
 }
 }
 }
 maintenance-association protection {
 continuity-check {
 interval 100ms;
 }
 mep 104 {
 interface ge-2/0/1.1 protect;
 }
 }
}
```

```

 direction down;
 remote-mep 1001;
 }
}
}
}

```

### Verifying that OAM CFM Connections are Active

**Purpose** Verify that the CFM connections are active on each of the PE routers.

**Action** Execute the following command on each of the PE routers.

1. Verify that the CFM working connection on Router PE1 is active.

```

user@ PE1> show oam ethernet connectivity-fault-management mep-database
maintenance-domain l2circuit-example-md maintenance-association working
Interface status: Active, Link status: Up

```

2. Verify that the CFM protect connection on Router PE1 is active

```

user@ PE2> show oam ethernet connectivity-fault-management mep-database
maintenance-domain l2circuit-example-md maintenance-association protection
Interface status: Active, Link status: Up

```

3. Verify that the CFM working connection on Router PE2 is active.

```

user@ PE2> show oam ethernet connectivity-fault-management mep-database
maintenance-domain l2circuit-example-md maintenance-association working
Interface status: Active, Link status: Up

```

4. Verify that the CFM protect connection on Router PE2 is active.

```

user@ PE2> show oam ethernet connectivity-fault-management mep-database
maintenance-domain l2circuit-example-md maintenance-association protection
Interface status: Active, Link status: Up

```

### Configuring Connection Protection Using Another PE Router for the Protection Path

**Step-by-Step Procedure** To configure Layer 2 Circuit switching protection as shown in [Figure 102 on page 968](#) on Router PE1:

1. Configure the Layer 2 circuit on Router PE1.

```

[edit protocols l2circuit]
user@PE1# set local-switching interface ge-2/0/2.0 connection-protection
user@PE1# set local-switching interface ge-2/0/2.0 backup-neighbor 192.0.2.2
virtual-circuit-id 2
user@PE1# set local-switching interface ge-2/0/2.0 backup-neighbor 192.0.2.2
community example
user@PE1# set local-switching interface ge-2/0/2.0 end-interface interface
ge-2/0/1.0

```

2. Configure the routing policy on Router PE1.

```
[edit policy-options]
user@PE1# set policy-statement load-balance then load-balance per-packet
user@PE1# set policy-statement protection-policy term protect from community
example
user@PE1# set policy-statement protection-policy term protect then install-nexthop
lsp-regex lsp-protect-*
```

3. Configure the routing options on Router PE1.

```
[edit routing-options]
user@PE1# set forwarding-table export load-balance
```

4. Configure OAM on Router PE1 to setup the maintenance domain. OAM is used to monitor the working path between Router PE1 and Router PE2. In the event of a failure on the working path, traffic is switched automatically to the protection path.

```
[edit protocols oam ethernet]
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md level 5
```

5. Configure OAM on Router PE1 for the working path.

```
[edit protocols oam ethernet]
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 1000 interface
ge-2/0/1.0
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 1000 direction down
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 1000 remote-mep
103
```

6. Configure OAM on Router PE1 for the protection path.

```
[edit protocols oam ethernet]
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 1001 interface
ge-2/0/0.0
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 1001 direction
down
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 1001 remote-mep
104
```

7. Configure OAM on Router PE2 to setup the maintenance domain.

```
[edit protocols oam ethernet]
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md level 5
```

8. Configure OAM on Router PE2 for the working path.

```
[edit protocols oam ethernet]
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 103 interface
ge-2/0/1.0
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 103 direction down
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 103 remote-mep
1000
```

9. Configure OAM on Router PE2 for the protection path.

```
[edit protocols oam ethernet]
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 104 interface
ge-2/0/0.0
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 104 direction
down
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 104 remote-mep
1001
```

**Results** From configuration mode on Router PE1, confirm your configuration by entering the **show protocols l2circuit**, **show policy-options**, **show routing-options**, and **show protocols oam ethernet** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host> show protocols l2circuit
local-switching {
 interface ge-2/0/2.0 {
 connection-protection;
 backup-neighbor 192.0.2.2 {
 virtual-circuit-id 2;
 community example;
 }
 }
 end-interface {
 interface ge-2/0/1.0;
 }
}

user@host> show policy-options
policy-statement load-balance {
 then {
 load-balance per-packet;
 }
}
policy-statement protection-policy {
 term protect {
 from community example;
 then {
 install-nexthop lsp-regex lsp-protect-*;
 }
 }
}
```

```
 }
 }

user@host> show routing-options
forwarding-table {
 export load-balance;
}

user@host> show protocols oam ethernet
connectivity-fault-management {
 maintenance-domain l2circuit-example-md {
 level 5;
 maintenance-association working {
 mep 1000 {
 interface ge-2/0/1.0;
 direction down;
 remote-mep 103;
 }
 }
 maintenance-association protection {
 mep 1001 {
 interface ge-2/0/0.0;
 direction down;
 remote-mep 104;
 }
 }
 }
}
```

From configuration mode on Router PE2, confirm your configuration by entering the **show protocols oam ethernet** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
connectivity-fault-management {
 maintenance-domain l2circuit-example-md {
 level 5;
 maintenance-association working {
 mep 103 {
 interface ge-2/0/1.0;
 direction down;
 remote-mep 1000;
 }
 }
 maintenance-association protection {
 mep 104 {
 interface ge-2/0/0.0;
 direction down;
 remote-mep 1001;
 }
 }
 }
}
```

---

### Verifying that OAM CFM Connections are Active

**Purpose** Verify that the CFM connections are active on each of the PE routers.

**Action** Execute the following command on each of the PE routers.

1. Verify that the CFM working connection on Router PE1 is active.

```
user@ PE1> show oam ethernet connectivity-fault-management mep-database
maintenance-domain l2circuit-example-md maintenance-association working
Interface status: Active, Link status: Up
```

2. Verify that the CFM protect connection on Router PE1 is active

```
user@ PE2> show oam ethernet connectivity-fault-management mep-database
maintenance-domain l2circuit-example-md maintenance-association protection
Interface status: Active, Link status: Up
```

3. Verify that the CFM working connection on Router PE2 is active.

```
user@ PE2> show oam ethernet connectivity-fault-management mep-database
maintenance-domain l2circuit-example-md maintenance-association working
Interface status: Active, Link status: Up
```

4. Verify that the CFM protect connection on Router PE2 is active.

```
user@ PE2> show oam ethernet connectivity-fault-management mep-database
maintenance-domain l2circuit-example-md maintenance-association protection
Interface status: Active, Link status: Up
```

### Configuring Connection Protection Using an Another PE Router for the Working Path

**Step-by-Step Procedure** To configure Layer 2 Circuit switching protection as shown in [Figure 103 on page 969](#) on Router PE1:

1. Configure the Layer 2 circuit on Router PE1.

```
[edit protocols l2circuit]
user@PE1# set neighbor 192.0.2.2 interface ge-2/0/2.0 virtual-circuit-id 2
user@PE1# set neighbor 192.0.2.2 interface ge-2/0/2.0 community example
user@PE1# set neighbor 192.0.2.2 interface ge-2/0/2.0 connection-protection
user@PE1# set neighbor 192.0.2.2 interface ge-2/0/2.0 backup-neighbor 192.0.2.3
virtual-circuit-id 3
user@PE1# set neighbor 192.0.2.2 interface ge-2/0/2.0 backup-neighbor 192.0.2.3
standby
```

2. Configure the policies on Router PE1.

```
[edit policy-options]
user@PE1# set policy-statement load-balance then load-balance per-packet
user@PE1# set policy-statement protection-policy term protect from community
example
user@PE1# set policy-statement protection-policy term protect then install-nexthop
lsp-regex lsp-primary
```

3. Configure the routing options on Router PE1.

```
[edit routing-options]
```

```
user@PE1# set forwarding-table export load-balance
```

4. Configure OAM on Router PE1 to setup the maintenance domain. OAM is used to monitor the working path between Router PE1 and Router PE2. In the event of a failure on the working path, traffic is switched automatically to the protection path.

```
[edit protocols oam ethernet]
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md level 5
```

5. Configure OAM on Router PE1 for the working path.

```
[edit protocols oam ethernet]
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 1000 interface
ge-2/0/0.0
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 1000 direction down
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 1000 remote-mep
103
```

6. Configure OAM on Router PE1 for the protection path.

```
[edit protocols oam ethernet]
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 1001 interface
ge-2/0/1.0
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 1001 direction
down
user@PE1# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 1001 remote-mep
104
```

7. Configure OAM on Router PE2 to setup the maintenance domain.

```
[edit protocols oam ethernet]
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md level 5
```

8. Configure OAM on Router PE2 for the working path.

```
[edit protocols oam ethernet]
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 103 interface
ge-2/0/0.0
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 103 direction down
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association working mep 103 remote-mep
1000
```

9. Configure OAM on Router PE2 for the protection path.

```
[edit protocols oam ethernet]
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 104 interface
ge-2/0/1.0
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 104 direction
down
user@PE2# set connectivity-fault-management maintenance-domain
l2circuit-example-md maintenance-association protection mep 104 remote-mep
1001
```

**Results** From configuration mode on Router PE1, confirm your configuration by entering the **show protocols l2circuit**, **show policy-options**, **show routing-options**, and **show protocols oam ethernet** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host> show protocols l2circuit
neighbor 192.0.2.2 {
 interface ge-2/0/2.0 {
 virtual-circuit-id 2;
 community example;
 connection-protection;
 backup-neighbor 192.0.2.3 {
 virtual-circuit-id 3;
 standby;
 }
 }
}

user@host> show policy-options
policy-statement load-balance {
 then {
 load-balance per-packet;
 }
}
policy-statement protection-policy {
 term protect {
 from community example;
 then {
 install-nexthop lsp-regex lsp-primary;
 }
 }
}

user@host> show routing-options
forwarding-table {
 export load-balance;
}

user@host> show protocols oam ethernet
connectivity-fault-management {
 maintenance-domain l2circuit-example-md {
 level 5;
 }
}
```

```
 maintenance-association working {

 direction down;
 remote-mep 103;
 }
 }
 maintenance-association protection {
 mep 1001 {
 interface ge-2/0/1.0;
 direction down;
 remote-mep 104;
 }
 }
}
```

From configuration mode on Router PE2, confirm your configuration by entering the **show protocols oam ethernet** commands. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
connectivity-fault-management {
 maintenance-domain l2circuit-example-md {
 level 5;
 maintenance-association working {
 mep 103 {
 interface ge-2/0/0.0;
 direction down;
 remote-mep 1000;
 }
 }
 maintenance-association protection {
 mep 104 {
 interface ge-2/0/1.0;
 direction down;
 remote-mep 1001;
 }
 }
 }
}
```

---

### Verifying that OAM CFM Connections are Active

---

**Purpose** Verify that the CFM connections are active on each of the PE routers.

**Action** Execute the following command on each of the PE routers.

1. Verify that the CFM working connection on Router PE1 is active.

```
user@ PE1> show oam ethernet connectivity-fault-management mep-database
maintenance-domain l2circuit-example-md maintenance-association working
Interface status: Active, Link status: Up
```

2. Verify that the CFM protect connection on Router PE1 is active

```
user@ PE2> show oam ethernet connectivity-fault-management mep-database
maintenance-domain l2circuit-example-md maintenance-association protection
Interface status: Active, Link status: Up
```

3. Verify that the CFM working connection on Router PE2 is active.

```
user@ PE2> show oam ethernet connectivity-fault-management mep-database
maintenance-domain l2circuit-example-md maintenance-association working
Interface status: Active, Link status: Up
```

4. Verify that the CFM protect connection on Router PE2 is active.

```
user@ PE2> show oam ethernet connectivity-fault-management mep-database
maintenance-domain l2circuit-example-md maintenance-association protection
Interface status: Active, Link status: Up
```

## Configuring BFD for VCCV for Layer 2 Circuits

---

Bidirectional Forwarding Detection (BFD) support for virtual circuit connection verification (VCCV) allows you to configure a control channel for a pseudowire, in addition to the corresponding operations and management functions to be used over that control channel. BFD provides a low resource mechanism for the continuous monitoring of the pseudowire data path and for detecting data plane failures. This feature provides support for asynchronous mode BFD for VCCV as described in RFC 5885, *Bidirectional Forwarding Detection (BFD) for the Pseudowire Virtual Circuit Connectivity Verification (VCCV)*. You can also use a ping to detect pseudowire failures. However, the processing resources required for a ping are greater than what is needed for BFD. In addition, BFD is capable of detecting data plane failure faster than VCCV ping. BFD for pseudowires is supported for Layer 2 circuits (LDP-based).

Before you begin:

- Configure the device interfaces.

To configure BFD for VCCV:

1. Specify the threshold for the adaptation of the BFD session detection time.

```
[edit protocols l2circuit neighbor IP-address interface interface-name oam
 bfd-liveness-detection]
user@host# set detection-time threshold milliseconds
```

For example, to set a detection time threshold of 40 milliseconds for OAM BFD liveness detection:

```
[edit protocols l2circuit neighbor 192.0.2.1 interface ge-1/1/9.0 oam
 bfd-liveness-detection]
user@host# set detection-time threshold 40
```

2. Configure the virtual circuit ID for the Layer 2 circuit protocol.

```
[edit protocols l2circuit neighbor IP-address interface interface-name]
user@host# set virtual-circuit-id virtual-circuit-id
```

For example, to set the virtual circuit ID as 1 for OAM BFD liveness detection:

```
[edit protocols l2circuit neighbor 192.0.2.1 interface ge-1/1/9.0 oam
 bfd-liveness-detection]
user@host# set virtual-circuit-id 1
```

3. Configure the minimum interval after which the local routing device transmits hello packets and then expects to receive a reply from a neighbor with which it has established a BFD session for the Layer 2 circuit.

```
[edit protocols l2circuit neighbor IP-address interface interface-name oam
 bfd-liveness-detection]
user@host# set minimum-interval milliseconds
```

For example, to set a minimum interval of 300 milliseconds for OAM BFD liveness detection:

```
[edit protocols l2circuit neighbor 192.0.2.1 interface ge-1/1/9.0 oam
 bfd-liveness-detection]
user@host# set minimum-interval 300
```

4. Configure the minimum interval after which the local routing device must receive a reply from a neighbor with which it has established a BFD session for the Layer 2 circuit protocol.

```
[edit protocols l2circuit neighbor IP-address interface interface-name oam
 bfd-liveness-detection]
user@host# set minimum-receive-interval milliseconds
```

For example, to set a minimum receive interval of 10 milliseconds for OAM BFD liveness detection:

```
[edit protocols l2circuit neighbor 192.0.2.1 interface ge-1/1/9.0 oam
 bfd-liveness-detection]
user@host# set minimum-receive-interval 10
```

5. Configure the number of hello packets not received by a neighbor that causes the originating interface to be declared down for the Layer 2 circuit protocol.

```
[edit protocols l2circuit neighbor IP-address interface interface-name oam
 bfd-liveness-detection]
user@host# set multiplier number
```

For example, to set the multiplier as 3 for OAM BFD liveness detection:

```
[edit protocols l2circuit neighbor 192.0.2.1 interface ge-1/1/9.0 oam
 bfd-liveness-detection]
user@host# set multiplier 3
```

6. Configure to disable adaptation.

```
[edit protocols l2circuit neighbor IP-address interface interface-name oam
 bfd-liveness-detection]
user@host# set no-adaptation
```

7. Configure the minimum interval at which the local routing device transmits hello packets to a neighbor with which it has established a BFD session.

```
[edit protocols l2circuit neighbor IP-address interface interface-name oam
 bfd-liveness-detection transmit-interval]
user@host# set minimum-interval milliseconds
```

For example, to set a minimum transmit interval of 5 milliseconds for OAM BFD liveness detection:

```
[edit protocols l2circuit neighbor 192.0.2.1 interface ge-1/1/9.0 oam
 bfd-liveness-detection transmit-interval]
user@host# set minimum-interval 5
```

8. Specify the threshold for the adaptation of the BFD session transmit interval.

```
[edit protocols l2circuit neighbor IP-address interface interface-name oam
 bfd-liveness-detection transmit-interval]
user@host# set threshold milliseconds
```

For example, to set a transmit interval threshold of 30 milliseconds for OAM BFD liveness detection:

```
[edit protocols l2circuit neighbor 192.0.2.1 interface ge-1/1/9.0 oam
 bfd-liveness-detection transmit-interval]
user@host# set threshold 30
```

## Example: Configuring BFD for VCCV for Layer 2 Circuits

This example shows how to configure BFD for VCCV for Layer 2 circuits which enables faster detection of failure in the data path.

- [Requirements on page 985](#)
- [Overview on page 985](#)
- [Configuration on page 986](#)
- [Verification on page 991](#)

### Requirements

This example uses the following hardware and software components:

- Two MX Series 3D Universal Edge Routers
- Junos OS Release 12.1 or later running on all devices

### Overview

Starting with Junos OS Release 12.1, Bidirectional Forwarding Detection (BFD) support for virtual circuit connection verification (VCCV) allows you to configure a control channel for a pseudowire, in addition to the corresponding operations and management functions

to be used over that control channel. BFD provides a low resource mechanism for the continuous monitoring of the pseudowire data path and for detecting data plane failures. This feature provides support for asynchronous mode BFD for VCCV as described in RFC 5885, *Bidirectional Forwarding Detection (BFD) for the Pseudowire Virtual Circuit Connectivity Verification (VCCV)*. You can also use a ping to detect pseudowire failures. However, the processing resources required for a ping are greater than what is needed for BFD. In addition, BFD is capable of detecting data plane failure faster than VCCV ping. BFD for pseudowires is supported for Layer 2 circuits (LDP-based).

To configure BFD for VCCV for Layer 2 circuits, configure the **oam** configuration statement at the **[edit protocols l2circuit neighbor address interface interface-name]** hierarchy level. The **control-channel** configuration statement at the **[edit routing-instances routing-instance-name protocols l2vpn oam]** hierarchy level does not apply to Layer 2 circuit configurations.

## Topology

In the topology, BFD for VCCV for Layer 2 circuits is configured on Device R0.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```

R0 set chassis redundancy graceful-switchover
 set interfaces ge-1/1/9 vlan-tagging
 set interfaces ge-1/1/9 encapsulation vlan-ccc
 set interfaces ge-1/1/9 unit 0 encapsulation vlan-ccc
 set interfaces ge-1/1/9 unit 0 vlan-id 512
 set interfaces ge-2/0/0 unit 0 family inet address 192.0.2.1/24
 set interfaces ge-2/0/0 unit 0 family mpls
 set interfaces lo0 unit 0 family inet address 198.51.100.0/24
 set routing-options nonstop-routing
 set routing-options static route 203.0.113.0/24 next-hop 192.0.2.2
 set routing-options router-id 198.51.100.0
 set protocols rsvp interface ge-2/0/0.0
 set protocols mpls label-switched-path lsp1 to 203.0.113.0
 set protocols mpls interface ge-2/0/0.0
 set protocols ospf traffic-engineering

```

## Configuring Device R0

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure Device R0:

**NOTE:** Repeat this procedure for Device R1 after modifying the appropriate interface names, addresses, and any other parameters for the device.

1. Configure graceful switchover redundancy.
 

```
[edit chassis]
user@R0# set redundancy graceful-switchover
```
2. Configure the interfaces.
 

```
[edit interfaces]
user@R0# set ge-1/1/9 vlan-tagging
user@R0# set ge-1/1/9 encapsulation vlan-ccc
user@R0# set ge-1/1/9 unit 0 encapsulation vlan-ccc
user@R0# set ge-1/1/9 unit 0 vlan-id 512

user@R0# set ge-2/0/0 unit 0 family inet address 192.0.2.1/24
user@R0# set ge-2/0/0 unit 0 family mpls

user@R0# set lo0 unit 0 family inet address 198.51.100.0/24
```
3. Configure the nonstop routing option, the static route, and the router ID routing options.
 

```
[edit routing-options]
user@R0# set nonstop-routing
user@R0# set static route 203.0.113.0/24 next-hop 192.0.2.2
user@R0# set router-id 198.51.100.0
```
4. Configure the RSVP protocol.
 

```
[edit protocols rsvp]
user@R0# set interface ge-2/0/0.0
```
5. Configure the MPLS protocol.
 

```
[edit protocols mpls]
user@R0# set label-switched-path lsp1 to 203.0.113.0
user@R0# set interface ge-2/0/0.0
```
6. Configure the OSPF protocol.

```
[edit protocols ospf]
user@R0# set traffic-engineering
user@R0# set area 0.0.0.0 interface ge-2/0/0.0
```

7. Configure the LDP protocol.

```
[edit protocols ldp]
user@R0# set interface all
```

8. Configure the virtual circuit ID for the neighbor of Layer 2 circuit protocols.

```
[edit protocols l2circuit]
user@R0# set neighbor 203.0.113.0 interface ge-1/1/9.0 virtual-circuit-id 1
```

9. Configure the oam attributes of the Layer 2 circuit protocol.

```
[edit protocols l2circuit]
user@R0# set neighbor 203.0.113.0 interface ge-1/1/9.0 oam bfd-liveness-detection
 minimum-interval 300
user@R0# set neighbor 203.0.113.0 interface ge-1/1/9.0 oam bfd-liveness-detection
 minimum-receive-interval 10
user@R0# set neighbor 203.0.113.0 interface ge-1/1/9.0 oam bfd-liveness-detection
 multiplier 3
user@R0# set neighbor 203.0.113.0 interface ge-1/1/9.0 oam bfd-liveness-detection
 transmit-interval minimum-interval 5
user@R0# set neighbor 203.0.113.0 interface ge-1/1/9.0 oam bfd-liveness-detection
 transmit-interval threshold 30
user@R0# set neighbor 203.0.113.0 interface ge-1/1/9.0 oam bfd-liveness-detection
 detection-time threshold 40
```

## Results

From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show protocols**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R0# show chassis
redundancy {
 graceful-switchover;
}

user@R0# show interfaces
ge-1/1/9 {
 vlan-tagging;
 encapsulation vlan-ccc;
 unit 0 {
 encapsulation vlan-ccc;
 vlan-id 512;
 }
}
ge-2/0/0 {
 unit 0 {
```

```
 family inet {
 address 192.0.2.1/24;
 }
 family mpls;
 }
}
lo0 {
 unit 0 {
 family inet {
 address 198.51.100.0/24;
 }
 }
}

user@R0# show protocols
rsvp {
 interface ge-2/0/0.0;
}
mpls {
 label-switched-path lsp1 {
 to 203.0.113.0;
 }
 interface ge-2/0/0.0;
}
ospf {
 traffic-engineering;
 area 0.0.0.0 {
 interface ge-2/0/0.0;
 }
}
ldp {
 interface all;
}
l2circuit {
 neighbor 203.0.113.0 {
 interface ge-1/1/9.0 {
 virtual-circuit-id 1;
 oam {
 bfd-liveness-detection {
 minimum-interval 300;
 minimum-receive-interval 10;
 multiplier 3;
 transmit-interval {
 minimum-interval 5;
 threshold 30;
 }
 }
 detection-time {
 threshold 40;
 }
 }
 }
 }
}

user@R0# show routing-options
nonstop-routing;
```

```
static {
 route 203.0.113.0/24 next-hop 192.0.2.2;
}
router-id 198.51.100.0;
```

If you are done configuring the device, enter **commit** from configuration mode.

## Verification

Verify that the configuration is working properly.

- [Verifying the Layer 2 Circuit Connections on page 991](#)
- [Verifying the BFD Session on page 992](#)
- [Verifying Detailed BFD Session Information on page 992](#)

### Verifying the Layer 2 Circuit Connections

**Purpose** Verify the connections in a Layer 2 Circuit.

**Action** From operational mode, run the **show l2circuit connections** command for Device R0.

```
user@R0> show l2circuit connections
```

Layer-2 Circuit Connections:

Legend for connection status (St)

|                                 |                                      |
|---------------------------------|--------------------------------------|
| EI -- encapsulation invalid     | NP -- interface h/w not present      |
| MM -- mtu mismatch              | Dn -- down                           |
| EM -- encapsulation mismatch    | VC-Dn -- Virtual circuit Down        |
| CM -- control-word mismatch     | Up -- operational                    |
| VM -- vlan id mismatch          | CF -- Call admission control failure |
| OL -- no outgoing label         | IB -- TDM incompatible bitrate       |
| NC -- intf encaps not CCC/TCC   | TM -- TDM misconfiguration           |
| BK -- Backup Connection         | ST -- Standby Connection             |
| CB -- rcvd cell-bundle size bad | SP -- Static Pseudowire              |
| LD -- local site signaled down  | RS -- remote site standby            |
| RD -- remote site signaled down | HS -- Hot-standby Connection         |
| XX -- unknown                   |                                      |

Legend for interface status

Up -- operational

Dn -- down

Neighbor: 203.0.113.0

| Interface                                                    | Type | St | Time last up        | # Up trans |
|--------------------------------------------------------------|------|----|---------------------|------------|
| ge-1/1/9.0(vc 1)                                             | rmt  | Up | Jun 2 03:19:44 2014 | 1          |
| Remote PE: 203.0.113.0, Negotiated control-word: Yes (Null)  |      |    |                     |            |
| Incoming label: 299792, Outgoing label: 299792               |      |    |                     |            |
| Negotiated PW status TLV: No                                 |      |    |                     |            |
| Local interface: ge-1/1/9.0, Status: Up, Encapsulation: VLAN |      |    |                     |            |
| Flow Label Transmit: No, Flow Label Receive: No              |      |    |                     |            |
| Flow Label Transmit: No, Flow Label Receive: No              |      |    |                     |            |

**Meaning** The output shows the Layer 2 virtual circuit information from Device R0 to its neighbor.

### Verifying the BFD Session

---

**Purpose** Verify the BFD session.

**Action** From operational mode, run the **show bfd session** command for Device R0.

```
user@R0> show bfd session
```

| Address     | State | Interface  | Detect Time | Transmit Interval | Multiplier |
|-------------|-------|------------|-------------|-------------------|------------|
| 203.0.113.7 | Up    | ge-2/0/0.0 | 0.030       | 0.010             | 3          |

```
1 sessions, 1 clients
```

```
Cumulative transmit rate 100.0 pps, cumulative receive rate 100.0 pps
```

**Meaning** The output shows the address, and the interface on which the BFD session is active. The state *Up* indicates that the BFD session is up. The BFD session has a time interval of 30 milliseconds to detect BFD control packets, the transmitting system has a time interval of 10 milliseconds to send BFD control packets, and the transmitting system determines the detection time by multiplying 3 with the time interval. Total number of active BFD sessions and total number of clients that are hosting active BFD sessions. Cumulative transmit rate indicates the total number of BFD control packets transmitted, per second, on all active sessions and cumulative receive rate indicates the total number of BFD control packets received, per second, on all active sessions.

### Verifying Detailed BFD Session Information

---

**Purpose** Verify detailed BFD session information.

**Action** From operational mode, run the **show bfd session extensive** command for Device R0.

```
user@R0> show bfd session extensive
```

| Address     | State | Interface  | Detect Time | Transmit Interval | Multiplier |
|-------------|-------|------------|-------------|-------------------|------------|
| 203.0.113.7 | Up    | ge-2/0/0.0 | 0.030       | 0.010             | 3          |

Client L2CKT-OAM, TX interval 0.005, RX interval 0.010  
 Session up time 03:47:14  
 Local diagnostic None, remote diagnostic None  
 Remote state Up, version 1  
 Replicated  
 Session type: VCCV BFD  
 Min async interval 0.005, min slow interval 1.000  
 Adaptive async TX interval 0.005, RX interval 0.010  
 Local min TX interval 0.005, minimum RX interval 0.010, multiplier 3  
 Remote min TX interval 0.005, min RX interval 0.010, multiplier 3  
 Threshold transmission interval 0.030, Threshold for detection time 0.040  
 Local discriminator 20, remote discriminator 13004  
 Echo mode disabled/inactive  
 Remote is control-plane independent  
 Neighbor address 203.0.113.0, Virtual circuit id 1  
 Session ID: 0x0

1 sessions, 1 clients  
 Cumulative transmit rate 100.0 pps, cumulative receive rate 100.0 pps

**Meaning** The output shows detailed information for the BFD session.

**Related Documentation**

# Troubleshooting Layer 2 Circuits

- [Tracing Layer 2 Circuit Operations on page 995](#)

## Tracing Layer 2 Circuit Operations

---

To trace the creation of and changes to Layer 2 circuits, include the **traceoptions** statement:

```
traceoptions {
 file filename <files number> <size size> <world-readable | no-world-readable>;
 flag flag <flag-modifier> <disable>;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols l2circuit]**
- **[edit logical-systems *logical-system-name* protocols l2circuit]**

Specify the following flags to trace the indicated operations on Layer 2 circuits:

- **connections**—Layer 2 circuit connections (events and state changes)
- **error**—Error conditions
- **FEC**—Layer 2 circuit advertisements received or sent using LDP
- **topology**—Layer 2 circuit topology changes caused by reconfiguration or advertisements received from other PE routers

## Understanding VPWS

---

Virtual private wire service (VPWS) Layer 2 VPNs employ Layer 2 services over MPLS to build a topology of point-to-point connections that connect end customer sites in a VPN. These Layer 2 VPNs provide an alternative to private networks that have been provisioned by means of dedicated leased lines or by means of Layer 2 virtual circuits that employ ATM or Frame Relay. The service provisioned with these Layer 2 VPNs is known as VPWS. You configure a VPWS *instance* on each associated edge device for each VPWS Layer 2 VPN.

Traditional VPNs over Layer 2 circuits require the provisioning and maintenance of separate networks for IP and for VPN services. In contrast, VPWS enables the sharing of a provider's core network infrastructure between IP and Layer 2 VPN services, reducing the cost of providing those services.

Junos OS supports two types of VPWS Layer 2 VPNs:

- Kompella Layer 2 VPNs, which use BGP for autodiscovery and signaling.
- FEC 129 BGP autodiscovery for VPWS, which uses BGP for autodiscovery and LDP as the signaling protocol.

FEC 129 BGP autodiscovery for VPWS requires the **l2vpn-id**, **source-attachment-identifier**, and **target-attachment-identifier** statements. Kompella Layer 2 VPNs require the **site-identifier** and **remote-site-id** statements.

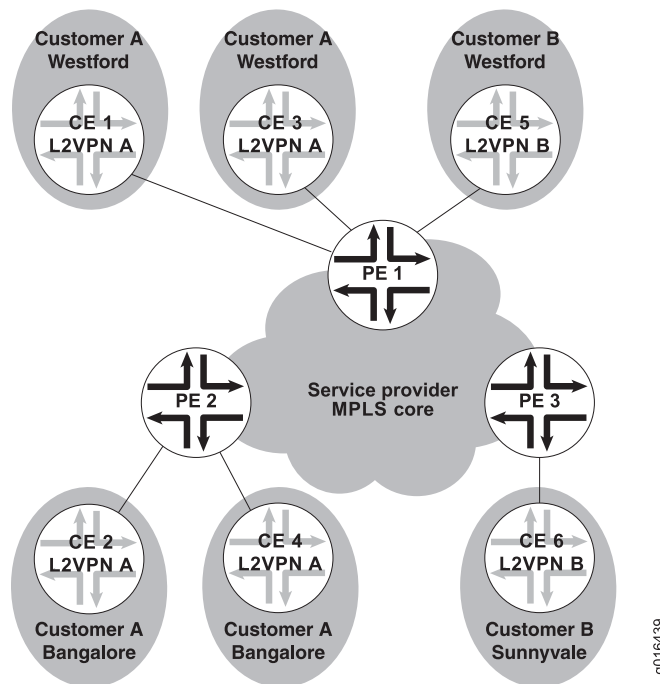

**NOTE:** VPWS creates pseudowires that emulate Layer 2 circuits. A virtual private LAN service (VPLS) network is similar to VPWS, but provides point-to-multipoint traffic forwarding in contrast to the VPWS Layer 2 VPN's point-to-point traffic forwarding. If you need point-to-multipoint service instead of point-to-point service, consider using VPLS instead of VPWS.

A VPWS Layer 2 VPN can have either a full-mesh or a hub-and-spoke topology. The tunneling mechanism in the core network typically is MPLS. However, VPWS can also use other tunneling protocols, such as GRE. VPWS is similar to Martini Layer 2 services over MPLS, and employs a similar encapsulation scheme for forwarding traffic.

Figure 104 on page 1000 illustrates an example of a simple VPWS Layer 2 VPN topology.

Figure 104: VPWS Sample Topology

In this example, the service provider offers VPWS services to Customer A and Customer B. Customer A wants to create a full mesh of point-to-point links between Westford and Bangalore. Customer B needs only a single point-to-point link between Westford and Sunnyvale. The service provider uses BGP and MPLS signaling in the core, and creates a set of unidirectional pseudowires at each provider edge (PE) device to separately cross-connect each customer's Layer 2 circuits.

In order to provision this service, the provider configures two VPWS Layer 2 VPNs, Layer 2 VPN A and Layer 2 VPN B. The circuit cross-connect (CCC) encapsulation type (**ethernet-ccc** or **vlan-ccc**) is configured for each VPWS Layer 2 VPN. All interfaces in a given VPWS Layer 2 VPN must be configured with the VPWS Layer 2 VPN's encapsulation type.

Local and remote site information for the interfaces identifies the cross-connect. Local cross-connects are supported when the interfaces that are connected belong to two different sites configured in the same VPWS instance and on the same PE device.

BGP advertises reachability for the VPNs. The BGP configuration is similar to that used for other VPN services, such as Layer 3 VPNs and VPLS. MPLS is configured to set up base LSPs to the remote PE devices similarly to the other VPN services.

Junos OS provides VPWS support the following configuration methods:

- Pseudowires are manually configured using Forwarding Equivalence Class (FEC) 128.
- Pseudowires are signaled by LDP using FEC 129. This arrangement reduces the configuration burden that is associated with statically configured Layer 2 circuits while still using LDP as the underlying signaling protocol.

## Supported and Unsupported Features

Junos OS supports the following features with VPWS :

- Intra-AS VPWS functionality using BGP for autodiscovery and FEC 129 LDP for pseudowire signaling.
- Graceful Routing Engine switchover.
- Operation, administration, and maintenance (OAM) mechanisms, including Bidirectional Forwarding Detection and MPLS ping.
- FEC 128 LDP signaling with static configuration (in Junos OS this is configured within **protocols l2circuit**). With this option, there is no BGP autodiscovery.

Junos OS does not support the following VPWS functionality:

- Multihoming of customer sites to multiple PE devices using the BGP site model of multihoming.
- Terminating FEC 129 VPWS into a mesh group of an FEC 129 VPLS instance.
- Intra-AS VPWS functionality using BGP for autodiscovery and FEC 128 LDP for pseudowire signaling.
- FEC 129 VPWS without BGP autodiscovery.
- Static configuration of VPWS with FEC 129 signaling.
- Nonstop active routing.
- Multi-segment pseudowires.
- Interworking of FEC 128 and FEC 129 VPWS.
- Statically configured Layer 2 circuit-style pseudowire redundancy.
- Inter-AS deployments.

## Supported VPWS Standards

---

Junos OS substantially supports the following RFCs, which define standards for VPWS and Layer 2 circuits.

- RFC 4447, *Pseudowire Setup and Maintenance Using the Label Distribution Protocol (LDP)*

Junos OS does not support Section 5.3, "The Generalized PwID FEC Element."

- RFC 4448, *Encapsulation Methods for Transport of Ethernet over MPLS Networks*
- RFC 6074, *Provisioning, Auto-Discovery, and Signaling in Layer 2 Virtual Private Networks (L2VPNs)*
- RFC 6391, *Flow-Aware Transport of Pseudowires over an MPLS Packet Switched Network*
- RFC 6790, *The Use of Entropy Labels in MPLS Forwarding*

The following Internet drafts do not define standards, but provide information about Layer 2 technologies. The IETF classifies them as "Historic."

- Internet draft draft-martini-l2circuit-encap-mpls-11.txt, *Encapsulation Methods for Transport of Layer 2 Frames Over IP and MPLS Networks*

Junos OS differs from the Internet draft in the following ways:

- A packet with a sequence number of 0 (zero) is treated as out of sequence.
- Any packet that does not have the next incremental sequence number is considered out of sequence.
- When out-of-sequence packets arrive, the expected sequence number for the neighbor is set to the sequence number in the Layer 2 circuit control word.
- Internet draft draft-martini-l2circuit-trans-mpls-19.txt, *Transport of Layer 2 Frames Over MPLS*

## FAT Flow Labels Overview

A pseudowire is a Layer 2 circuit or service that emulates the essential attributes of a telecommunications service, such as a T1 line, over an MPLS packet-switched network (PSN). The pseudowire is intended to provide only the minimum necessary functionality to emulate the wire with the required resiliency requirements for the given service definition.

In an MPLS network, the flow-aware transport of pseudowires (FAT) flow label, as described in RFC 6391, *Flow-Aware Transport of Pseudowires over an MPLS Packet Switched Network*, is used for load-balancing traffic across LDP-signaled pseudowires for virtual private LAN service (VPLS) and virtual private wire service (VPWS).

When the pseudowire is configured to use the FAT flow labels for load balancing, packets arriving at the ingress router are processed in the following sequence across the path of the pseudowire:

- The ingress router uses the contents of the inbound packet in the hash-key algorithm to calculate the flow-label value.
- The ingress router pushes the flow label to the label stack of the packet.
- The transit routers perform load balancing based only on the label stack.
- The egress router pops the flow label and forwards the packet to its destination.

For load balancing to work based on a flow-label configuration, a version of LDP that supports signaling extensions to use the flow label with pseudowires must be enabled on all routers. The LDP-signaling configuration is identical for VPLS and VPWS pseudowires.

FAT flow labels are supported on the following LDP-signaled forwarding-equivalence classes (FECs) for VPWS and VPLS pseudowires:

- FEC 128 for VPWS—LDP-signaled VPWS with neighbors that are statically configured (BGP autodiscovery is not supported).
- FEC 128 for VPLS—LDP-signaled VPLS with neighbors that are statically configured (BGP autodiscovery is not supported).
- FEC 129 for VPWS—LDP-signaled VPWS with BGP autodiscovery of neighbors.
- FEC 129 for VPLS—LDP-signaled VPLS with BGP autodiscovery of neighbors.

**NOTE:** Flow-aware transport of pseudowires (FAT) flow labels are not supported with Enhanced Dense Port Concentrators (DPCs), and flow labels should not be configured in a system with DPCs. Entropy labels are supported with DPCs with the following restrictions: entropy labels are stripped by DPCs, but entropy labels are not pushed by DPCs.

The interface parameter (Sub-TLV) is used both for FEC 128 and FEC 129 pseudowires. The sub-TLV defined for LDP contains the transmit (T) and receive (R) bits. The T bit advertises the ability to push the flow label. The R bit advertises the ability to pop the flow labels. By default, the signaling behavior of the provider edge (PE) router for any of these pseudowires is to advertise the T and R bits in the label set to 0.

The **flow-label-transmit** and **flow-label-receive** configuration statements provide the ability to set the T bit and R bit advertisement to 1 in the Sub-TLV field, which is part of the interface parameters of the FEC for the LDP label-mapping message. You can use these statements to control the pushing of the load-balancing label and the advertisement of the label to the routing peers in the control plane.

Alternatively, for FEC 128 VPWS pseudowires only, you can configure the following statements to statically configure flow label push and pop operations:

- **flow-label-receive-static** to statically pop the flow label on the pseudowire packets received from the remote PE router.
- **flow-label-transmit-static** to statically push the flow label on the pseudowire packets sent to the remote PE router.

## Understanding Multisegment Pseudowire for FEC 129

### Understanding Multisegment Pseudowire

A pseudowire is a Layer 2 circuit or service that emulates the essential attributes of a telecommunications service, such as a T1 line, over an MPLS packet-switched network (PSN). The pseudowire is intended to provide only the minimum necessary functionality to emulate the wire with the required resiliency requirements for the given service definition.

When a pseudowire originates and terminates on the edge of the same PSN, the pseudowire label is unchanged between the originating and terminating provider edge (T-PE) devices. This is called a single-segment pseudowire (SS-PW).

[Figure 105 on page 1005](#) illustrates an SS-PW established between two PE routers. The pseudowires between the PE1 and PE2 routers are located within the same autonomous system (AS).

Figure 105: L2VPN Pseudowire

In cases where it is impossible to establish a single pseudowire from a local to a remote PE, either because it is unfeasible or undesirable to establish a single control plane between the two PEs, a multisegment pseudowire (MS-PW) is used.

An MS-PW is a set of two or more contiguous SS-PWs that are made to function as a single point-to-point pseudowire. It is also known as switched pseudowire. MS-PWs can go across different regions or network domains. A region can be considered as an interior gateway protocol (IGP) area or a BGP autonomous system that belongs to the same or different administrative domain. An MS-PW spans multiple cores or ASs of the same or different carrier networks. A Layer 2 VPN MS-PW can include up to 254 pseudowire segments.

Figure 106 on page 1005 illustrates a set of two or more pseudowire segments that function as a single pseudowire. The end routers are called terminating PE (T-PE) routers, and the switching routers are called switching PE (S-PE) routers. The S-PE router terminates the tunnels of the preceding and succeeding pseudowire segments in an MS-PW. The S-PE router can switch the control and data planes of the preceding and succeeding pseudowire segments of the MS-PW. An MS-PW is declared to be up when all the single-segment pseudowires are up.

Figure 106: Multisegment Pseudowire

## Using FEC 129 for Multisegment Pseudowire

Currently, there are two types of attachment circuit identifiers (AIs) defined under FEC 129:

- Type 1 AI
- Type 2 AI

The support of an MS-PW for FEC 129 uses type 2 AI. A type 2 AI is globally unique by definition of RFC 5003.

Single-segment pseudowires (SS-PWs) using FEC 129 on an MPLS PSN can use both type 1 and type 2 AI. For an MS-PW using FEC 129, a pseudowire itself is identified as a pair of endpoints. This requires that the pseudowire endpoints be uniquely identified.

In the case of a dynamically placed MS-PW, there is a requirement for the identifiers of attachment circuits to be globally unique, for the purposes of reachability and manageability of the pseudowire. Thus, individual globally unique addresses are allocated to all the attachment circuits and S-PEs that make up an MS-PW.

Type 2 AI is composed of three fields:

- Global\_ID—Global identification, which is usually the AS number.
- Prefix—IPv4 address, which is usually the router ID.
- AC\_ID—Local attachment circuit, which is a user-configurable value.

Since type 2 AI already contains the T-PE's IP address and it is globally unique, from the FEC 129 pseudowire signaling point of view, the combination (AGI, SAI, TAI) uniquely identifies an MS-PW across all interconnected pseudowire domains.

## Establishing a Multisegment Pseudowire Overview

An MS-PW is established by dynamically and automatically selecting the predefined S-PEs and placing the MS-PW between two T-PE devices.

When S-PEs are dynamically selected, each S-PE is automatically discovered and selected using the BGP autodiscovery feature, without the requirement of provisioning the FEC 129 pseudowire-related information on all the S-PEs. BGP is used to propagate pseudowire address information throughout the PSN.

Since there is no manual provisioning of FEC 129 pseudowire information on the S-PEs, the Attachment Group Identifier (AGI) and Attachment Individual Identifier (AI) are reused automatically, and choosing the same set of S-PEs for the pseudowire in both the forwarding and reverse direction is achieved through the active and passive role of each T-PE device.

- Active—The T-PE initiates an LDP label mapping message.
- Passive—The T-PE does not initiate an LDP label mapping message until it receives a label mapping message initiated by the active T-PE. The passive T-PE sends its label mapping message to the same S-PE from where it received the label mapping message

originated from its active T-PE. This ensures that the same set of S-PEs are used in the reverse direction.

## Pseudowire Status Support for Multisegment Pseudowire

- [Pseudowire Status Behavior on T-PE on page 1007](#)
- [Pseudowire Status Behavior on S-PE on page 1007](#)

### Pseudowire Status Behavior on T-PE

The following pseudowire status messages are relevant on the T-PE:

- 0x00000010—Local PSN-facing pseudowire (egress) transmit fault.
- 0x00000001—Generic nonforwarding fault code. This is set as the local fault code. The local fault code is set at the local T-PE, and LDP sends a pseudowire status TLV message with the same fault code to the remote T-PE.
- Fault codes are bit-wise OR'ed and stored as remote pseudowire status codes.

### Pseudowire Status Behavior on S-PE

The S-PE initiates the pseudowire status messages that indicate the pseudowire faults. The SP-PE in the pseudowire notification message hints where the fault was originated.

- When a local fault is detected by the S-PE, a pseudowire status message is sent in both directions along the pseudowire. Since there are no attachment circuits on an S-PE, only the following status messages are relevant:
  - 0x00000008—Local PSN-facing pseudowire (ingress) receive fault.
  - 0x00000010—Local PSN-facing pseudowire (egress) transmit fault.
- To indicate which SS-PW is at fault, an LDP SP-PE TLV is attached with the pseudowire status code in the LDP notification message. The pseudowire status is passed along from one pseudowire to another unchanged by the control plane switching function.
- If an S-PE initiates a pseudowire status notification message with one particular pseudowire status bit, then for the pseudowire status code an S-PE receives, the same bit is processed locally and not forwarded until the S-PE's original status error is cleared.
- An S-PE keeps only two pseudowire status codes for each SS-PW it is involved in – local pseudowire status code and remote pseudowire status code. The value of the remote pseudowire status code is the result of logic or operation of the pseudowire status codes in the chain of SS-PWs preceding this segment. This status code is incrementally updated by each S-PE upon receipt and communicated to the next S-PE. The local pseudowire status is generated locally based on its local pseudowire status.
- Only transmit fault is detected at the SP-PE. When there is no MPLS LSP to reach the next segment, a local transmit fault is detected. The transmit fault is sent to the next downstream segment, and the receive fault is sent to the upstream segment.
- Remote failures received on an S-PE are just passed along the MS-PW unchanged. Local failures are sent to both segments of the pseudowire that the S-PE is involved in.

## Pseudowire TLV Support for MS-PW

MS-PW provides the following support for the LDP SP-PE TLV [RFC 6073]:

- The LDP SP-PE TLVs for an MS-PW include:
  - Local IP address
  - Remote IP address
- An SP-PE adds the LDP SP-PE TLV to the label mapping message. Each SP-PE appends the local LDP SP-PE TLV to the SP-PE list it received from the other segment.
- The pseudowire status notification message includes the LDP SP-PE TLV when the notification is generated at the SP-PE.

## Supported and Unsupported Features

Junos OS supports the following features with MS-PW:

- MPLS PSN for each SS-PW that builds up the MS-PW.
- The same pseudowire encapsulation for each SS-PW in an MS-PW – Ethernet or VLAN-CCC.
- The generalized PWid FEC with T-LDP as an end-to-end pseudowire signaling protocol to set up each SS-PW.
- MP-BGP to autodiscover the two endpoint PEs for each SS-PW associated with the MS-PW.
- Standard MPLS operation to stitch two side-by-side SS-PWs to form an MS-PW.
- Automatic discovery of S-PE so that the MS-PW can be dynamically placed.
- Minimum provisioning of S-PE.
- Operation, administration, and maintenance (OAM) mechanisms, including end-to-end MPLS ping or end-to-any-S-PE MPLS ping, MPLS path trace, end-to-end VCCV, and Bidirectional Forwarding Detection (BFD).
- Pseudowire swithing point (SP) PE TLV for the MS-PW.
- Composite next hop on MS-PW.
- Pseudowire status TLV for MS-PW.

Junos OS does not support the following MS-PW functionality:

- Mix of LDP FEC 128 and LDP FEC 129.
- Static pseudowire where each label is provisioned statically.
- Graceful Routing Engine switchover.
- Nonstop active routing.

- Multihoming.
- Partial connectivity verification (originating from an S-PE) in OAM.

## Understanding FEC 129 BGP Autodiscovery for VPWS

---

The major functional components in a VPWS with FEC 129 are BGP, LDP, and the Layer 2 VPN module of Junos OS. BGP is responsible for distributing the local autodiscovery routes created on each PE device to all other PE devices. LDP is responsible for using the autodiscovery information provided by BGP to set up targeted LDP sessions over which to signal the pseudowires. The Layer 2 VPN is the glue that binds the BGP and LDP functionalities together.

## Supported Standards in FEC 129 BGP Autodiscovery for VPWS

The relevant RFCs for this feature are as follows:

- RFC 4447, *Pseudowire Setup and Maintenance Using the Label Distribution Protocol (LDP)*
- RFC 6074, *Provisioning, Auto-Discovery, and Signaling in Layer 2 Virtual Private Networks (L2VPNs)*

## Routes and Routing Table Interaction in FEC 129 BGP Autodiscovery for VPWS

BGP, LDP, and Layer 2 VPNs interact through different types of routes installed in the `instance.l2vpn.0` table. The routes that are present in the table are autodiscovery routes and pseudowire routes.

- Autodiscovery routes are used by BGP to allow autodiscovery of remote source access individual identifiers (SAIs) (the sources of the point-to-point pseudowires) and PE device addresses. Autodiscovery routes are advertised when you configure the **l2vpn auto-discovery-only** address family.

The format of the autodiscovery routes is a combination of the route distinguisher and the SAI. For example: 10.255.0.1:100:0.0.0.1/96 AD.

[Table 23 on page 1012](#) lists the route elements and the number of associated bytes allocated to each element.

**Table 23: Autodiscovery Route Format**

| Route Element | Bytes   |
|---------------|---------|
| RD            | 8 bytes |
| SAI           | 4 bytes |

The **l2vpn-id** of the FEC 129 VPWS instance is attached to the route in a BGP extended community. One autodiscovery route is advertised for each source attachment identifier (SAI) in the instance.

- Pseudowire routes are installed by the Layer 2 VPN (local) and LDP (remote) to represent the bidirectional components of the pseudowire. For example: NoCtrlWord:5:100:200:2:0.0.0.1/176. The format of the routes is described in [Table 24 on page 1012](#).

**Table 24: Pseudowire Route Format**

| Field Name                                                                                  | Field Description |
|---------------------------------------------------------------------------------------------|-------------------|
| Pseudowire type + control word bit                                                          | 2 bytes           |
| Remote PE address                                                                           | 4 bytes           |
| Attachment group identifier (AGI)                                                           | 8 bytes           |
| The AGI field of the pseudowire route is always set to the <b>l2vpn-id</b> of the instance. |                   |
| SAI                                                                                         | 4 bytes           |
| Target attachment individual identifier (TAII)                                              | 4 bytes           |

## Layer 2 VPN Behavior in FEC 129 BGP Autodiscovery for VPWS

A Layer 2 VPN installs a locally generated autodiscovery route into the instance.l2vpn.0 table for every SAI configured in an FEC 129 VPWS instance. The extended community containing the **l2vpn-id** is attached when the route is added to the instance.l2vpn.0 table.

For each autodiscovered SAI from a remote neighbor where the **l2vpn-id** matches the local **l2vpn-id** and the received SAI matches a locally configured TAI, the Layer 2 VPN obtains an MPLS label and generates a pseudowire route and adds it to the

instance.l2vpn.0 table. The remote PE address is copied from the BGP protocol next hop for the autodiscovery route.

The Layer 2 VPN module of Junos OS is responsible for installing the forwarding routes into the mpls.0 table as usual.

### BGP Autodiscovery Behavior in FEC 129 BGP Autodiscovery for VPWS

Local autodiscovery routes installed by the Layer 2 VPN in the instance.l2vpn.0 table are advertised by BGP to remote PE devices **sl2vpn auto-discovery-only** address family according to the instance and BGP export policies.

On the receiving side, BGP accepts autodiscovery routes from remote peers and installs them in the local bgp.l2vpn.0 table, if they are allowed by inbound policy. The route is installed, and a secondary route is imported into the instance.l2vpn.0 table when an import route target match between the route and instance is found.

### LDP Signaling Behavior in VPWS in FEC 129 BGP Autodiscovery for VPWS

LDP listens for routes from instance.l2vpn.0 for any instance configured for FEC 129 VPWS. These routes are identified by the **instance-type l2vpn** statement in the routing instance and the presence of the **l2vpn-id** statement.

When a BGP autodiscovery route is installed, LDP sets up a targeted session with the remote peer, where the peer address is identified as the protocol next hop of the BGP autodiscovery route.

When a pseudowire route is installed in the instance.l2vpn.0 table, LDP uses the parameters associated with the route to signal the creation of the pseudowire using FEC 129. Upon receiving an FEC 129 label mapping message from a remote peer, LDP installs the pseudowire route in the ldp.l2vpn.0 table.

Upon a successful **l2vpn-id** match with a configured FEC 129 VPWS instance, a secondary pseudowire route is imported to the instance.l2vpn.0 table. If an outgoing pseudowire has not already been set up when the incoming pseudowire signaling is received, LDP initiates the outgoing pseudowire creation as well.

---

### Example: Configuring FEC 129 BGP Autodiscovery for VPWS

This example shows how to configure the virtual private wire service (VPWS), where remote provider edge (PE) devices are automatically discovered dynamically by BGP, and pseudowires are signaled by LDP using FEC 129. This arrangement reduces the configuration burden that is associated with statically configured Layer 2 circuits while still using LDP as the underlying signaling protocol.

- [Requirements on page 1014](#)
- [Overview on page 1014](#)

- [Configuration on page 1018](#)
- [Verification on page 1022](#)

## Requirements

This example requires Junos OS Release 13.2 or later on the PE devices.

## Overview

Because VPWS is a point-to-point service, FEC 129 VPWS routing instances are configured as **instance-type l2vpn**. As with FEC 129 VPLS, FEC 129 VPWS uses the **l2vpn-id** statement to define the Layer 2 VPN of which the routing instance is a member. The presence of the **l2vpn-id** statement designates that FEC 129 LDP signaling is used for the routing instance. The absence of **l2vpn-id** indicates that BGP signaling is used instead.

The point-to-point nature of VPWS requires that you specify the source access individual identifier (SAII) and the target access individual identifier (TAII). This SAII-TAII pair defines a unique pseudowire between two PE devices.

The SAII is specified with the **source-attachment-identifier** statement within the FEC 129 VPWS routing instance. You configure the source attachment identifier and the interfaces to associate with that source attachment identifier. Under each interface, you can configure the TAII with the **target-attachment-identifier** statement. If the configured target identifier matches a source identifier advertised by a remote PE device by way of a BGP autodiscovery message, the pseudowire between that source-target pair is signaled. If there is no match between an advertised source identifier and the configured target identifier, the pseudowire is not established.

### Sample: VPWS Configuration with Multiple Interfaces and Sites

```
routing-instances {
 FEC129-VPWS {
 instance-type l2vpn;
 interface ge-0/0/1.0;
 interface ge-0/0/2.0;
 interface ge-0/0/3.0;
 route-distinguisher 10.255.0.1:200;
 l2vpn-id l2vpn-id:100:200;
 vrf-target target:100:200;
 protocols l2vpn {
 site CUSTOMER-1 {
 source-attachment-identifier 1;
 interface ge-0/0/1.0 {
 target-attachment-identifier 2;
 }
 interface ge-0/0/2.0 {
 target-attachment-identifier 3;
 }
 }
 }
 }
}
```

You can configure multiple interfaces within a site, because each SAII-TAII pair defines a unique pseudowire, as shown with pseudowires 1-2 and 1-3 in the sample configuration.

Both the source and target access identifiers are 4-byte numbers and can only be configured in FEC 129 VPWS instances where the **instance-type** is **l2vpn** and the **l2vpn-id** configuration statement is present.

You can specify the source and target identifiers as plain unsigned integers in the range 1 through 4,292,967,295.

The Layer 2 circuit and Layer 2 VPN services allow many optional parameters to be included on a per-pseudowire basis. FEC 129 VPWS allows such parameters as MTU settings, community tagging, and inclusion of a control word, as shown in this sample configuration:

**Sample: VPWS  
Configuration with  
Optional Configuration  
Parameters**

```
routing-instances {
 FEC129-VPWS {
 instance-type l2vpn;
 interface ge-0/0/1.0;
 interface ge-0/0/2.0;
 interface ge-0/0/3.0;
 route-distinguisher 10.255.0.1:200;
 l2vpn-id l2vpn-id:100:200;
 vrf-target target:100:200;
 protocols l2vpn {
 site CUSTOMER-1 {
 source-attachment-identifier 1;
 community COMM;
 control-word;
 encapsulation-type ethernet;
 ignore-encapsulation-mismatch;
 ignore-mtu-mismatch;
 mtu 1500;
 no-control-word;
 interface ge-0/0/1.0 {
 target-attachment-identifier 2;
 }
 interface ge-0/0/2.0 {
 target-attachment-identifier 3;
 community COMM;
 control-word;
 encapsulation-type ethernet;
 ignore-encapsulation-mismatch;
 ignore-mtu-mismatch;
 mtu 1500;
 no-control-word;
 }
 }
 }
 }
}
```

When configured within the site, the defined parameters affect any pseudowire originating from that site. When configured under an interface, the defined parameters affect that single specific pseudowire. This allows you to manipulate the parameters across all pseudowires associated with a particular local site in one place in the configuration.

Like other point-to-point services, the interfaces configured as members of the FEC 129 VPWS instance must be configured for CCC encapsulation and the CCC address family, as shown here:

```

interfaces {
 ge-0/0/1 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
 }
 ge-0/0/2 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
 }
 ge-0/0/3 {
 encapsulation ethernet-ccc;
 unit 0 {
 family ccc;
 }
 }
}

```

You can use **vlan-ccc** instead of **ethernet-ccc**.

To support the basic FEC 129 VPWS functionality, the BGP sessions on the PE devices also need to be configured with the BGP **auto-discovery-only** address family to allow exchange of the autodiscovery routes. If traditional BGP VPLS or Layer 2 VPN service is also provisioned on the PE devices, the address family **l2vpn signaling** is also required, as shown here:

```

bgp {
 group pe {
 type internal;
 local-address 10.255.0.1;
 family l2vpn {
 auto-discovery-only;
 signaling;
 }
 neighbor 10.255.0.2;
 neighbor 10.255.0.3;
 }
}

```

The following configuration sample shows an FEC 129 VPWS routing instance with the operation, administration, and maintenance (OAM) (ping and BFD) configuration options:

**Sample: VPWS  
Configuration with  
OAM**

```

routing-instances {
 FEC129-VPWS {
 instance-type l2vpn;
 interface ge-0/0/1.0;
 route-distinguisher 10.255.0.1:200;
 l2vpn-id l2vpn-id:100:200;
 vrf-target target:100:200;
 }
}

```

```

protocols l2vpn {
 oam {
 ping-interval 600;
 bfd-liveness-detection {
 minimum-interval 200;
 }
 }
 site CUSTOMER {
 source-attachment-identifier 1;
 oam {
 ping-interval 600;
 bfd-liveness-detection {
 minimum-interval 200;
 }
 }
 }
 interface ge-0/0/1.0 {
 oam {
 ping-interval 600;
 bfd-liveness-detection {
 minimum-interval 200;
 }
 }
 target-attachment-identifier 2;
 }
}
}
}
}

```

OAM options configured under **protocols l2vpn** apply to all sites and pseudowires in the routing instance. OAM options configured under a particular site apply to the pseudowires configured under that site. OAM options configured under a particular interface apply to the pseudowire configured under that interface.

### Topology Diagram

Figure 107 on page 1017 shows the topology used in this example.

This example uses a simple topology with two PE devices and two customer edge (CE) devices.

Figure 107: Simple VPWS Topology

“CLI Quick Configuration” on page 1018 shows the configuration for all of the devices in Figure 107 on page 1017. The section “Step-by-Step Procedure” on page 1019 describes the steps on Device PE1.

## Configuration

**CLI Quick Configuration** To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

**Device CE1**

```
set interfaces ge-2/0/8 unit 0 description CE1_to_PE1
set interfaces ge-2/0/8 unit 0 family inet address 172.16.0.1/24
set interfaces lo0 unit 0 family inet address 192.0.2.5/24
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ospf area 0.0.0.0 interface ge-2/0/8.0
```

**Device CE2**

```
set interfaces ge-2/1/6 unit 0 description CE2_to_PE2
set interfaces ge-2/1/6 unit 0 family inet address 172.16.0.4/24
set interfaces lo0 unit 0 family inet address 192.0.2.6/24
set protocols ospf area 0.0.0.0 interface lo0.0 passive
set protocols ospf area 0.0.0.0 interface ge-2/1/6.0
```

**Device PE1**

```
set interfaces ge-2/0/5 encapsulation ethernet-ccc
set interfaces ge-2/0/5 unit 0 description PE1_to_CE1
set interfaces ge-2/0/5 unit 0 family ccc
set interfaces fe-2/0/10 unit 0 description to_PE2
set interfaces fe-2/0/10 unit 0 family inet address 10.0.0.1/30
set interfaces fe-2/0/10 unit 0 family mpls
set interfaces lo0 unit 0 family inet address 192.0.2.1/24
set protocols mpls interface fe-2/0/10.0
set protocols bgp local-address 192.0.2.1

 source-attachment-identifier 2
set routing-instances FEC129-VPWS protocols l2vpn site TWO interface ge-2/1/7.0
 target-attachment-identifier 1
set routing-options autonomous-system 64510

```

**Step-by-Step Procedure** To configure a FEC 129 VPWS:

1. Configure the interfaces.

```

[edit interfaces]
user@PE1# set ge-2/0/5 encapsulation ethernet-ccc
user@PE1# set ge-2/0/5 unit 0 description PE1_to_CE1
user@PE1# set ge-2/0/5 unit 0 family ccc

user@PE1# set fe-2/0/10 unit 0 description to_PE2
user@PE1# set fe-2/0/10 unit 0 family inet address 10.0.0.1/30
user@PE1# set fe-2/0/10 unit 0 family mpls

user@PE1# set lo0 unit 0 family inet address 192.0.2.1/24

```

2. Configure MPLS on the core-facing interface.

```

[edit protocols mpls]
user@PE1# set interface fe-2/0/10.0

```

3. Configure BGP.

```

[edit protocols bgp]
user@PE1# set local-address 192.0.2.1
user@PE1# set group pe-pe type internal
user@PE1# set group pe-pe family l2vpn auto-discovery-only
user@PE1# set group pe-pe family l2vpn signaling
user@PE1# set group pe-pe neighbor 192.0.2.2

```

4. Configure an interior gateway protocol, such as IS-IS or OSPF.

If you use OSPF, enable traffic engineering. Traffic engineering is supported by IS-IS by default.

```
[edit protocols ospf]
user@PE1# set traffic-engineering
user@PE1# set area 0.0.0.0 interface lo0.0 passive
user@PE1# set area 0.0.0.0 interface fe-2/0/10.0
```

5. Configure LDP on the core-facing interface and on the loopback interface.

```
[edit protocols ldp]
user@PE1# set interface fe-2/0/10.0
user@PE1# set interface lo0.0
```

6. Configure the VPWS routing instance.

LDP listens for routes from instance.l2vpn.0 for any instance configured for FEC 129 VPWS. These routes are identified by the **instance-type l2vpn** statement in the routing instance and the presence of the **l2vpn-id** statement.

Make sure that the **target-attachment-identifier** matches the **source-attachment-identifier** in the remote PE device's corresponding site. In this example, the pseudowire is established between Device PE1 and Device PE2. Device PE1 uses SAI 1 and TAI 2, while Device PE2 uses the opposite, SAI 2 and TAI 1.

```
[edit routing-instances FEC129-VPWS]
user@PE1# set instance-type l2vpn
user@PE1# set interface ge-2/0/5.0
user@PE1# set route-distinguisher 192.0.2.1:100
user@PE1# set l2vpn-id l2vpn-id:100:100
user@PE1# set vrf-target target:100:100
user@PE1# set protocols l2vpn site ONE source-attachment-identifier 1
user@PE1# set protocols l2vpn site ONE interface ge-2/0/5.0
target-attachment-identifier 2
```

7. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@PE1# set autonomous-system 64510
```

8. If you are done configuring the device, commit the configuration.

```
[edit]
user@PE1# commit
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, and **show routing-options** command. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@PE1# show interfaces
```

```

ge-2/0/5 {
 encapsulation ethernet-ccc;
 unit 0 {
 description PE1_to_CE1;
 family ccc;
 }
}
fe-2/0/10 {

## Verification

Confirm that the configuration is working properly.

- [Verifying the Routes on page 1022](#)
- [Checking Connectivity Between the CE Devices on page 1023](#)
- [Checking the VPWS Connections on page 1024](#)
- [Checking Connectivity Between the PE Devices on page 1025](#)

### Verifying the Routes

**Purpose** Verify that the expected routes are learned.

**Action** From operational mode, enter the **show route** command.

```

user@PE1> show route
inet.0: 5 destinations, 5 routes (5 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.0.2.1/24 *[Direct/0] 6d 21:16:32
> via lo0.0
192.0.2.2/24 *[OSPF/10] 6d 21:15:31, metric 1
> to 10.0.0.2 via fe-2/0/10.0
10.0.0.0/30 *[Direct/0] 6d 21:16:31
> via fe-2/0/10.0
10.0.0.1/32 *[Local/0] 6d 21:16:32
Local via fe-2/0/10.0
203.0.113.0/24 *[OSPF/10] 6d 21:16:34, metric 1
MultiRecv

inet.3: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.0.2.2/24 *[LDP/9] 5d 22:25:19, metric 1
> to 10.0.0.2 via fe-2/0/10.0

mpls.0: 8 destinations, 8 routes (8 active, 0 holddown, 0 hidden)

```

```

+ = Active Route, - = Last Active, * = Both

0 *[MPLS/0] 6d 21:16:33, metric 1
 Receive
1 *[MPLS/0] 6d 21:16:33, metric 1
 Receive
2 *[MPLS/0] 6d 21:16:33, metric 1
 Receive
13 *[MPLS/0] 6d 21:16:33, metric 1
 Receive
299808 *[LDP/9] 5d 22:25:19, metric 1
 > to 10.0.0.2 via fe-2/0/10.0, Pop
299808(S=0) *[LDP/9] 5d 22:25:19, metric 1
 > to 10.0.0.2 via fe-2/0/10.0, Pop
299824 *[L2VPN/7] 5d 22:25:18
 > via ge-2/0/5.0, Pop
ge-2/0/5.0 *[L2VPN/7] 5d 22:13:02, metric2 1
 > to 10.0.0.2 via fe-2/0/10.0, Push 299872

bgp.l2vpn.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.0.2.2:100:0.0.0.2/96 AD
 *[BGP/170] 6d 20:51:23, localpref 100, from 192.0.2.2
 AS path: I, validation-state: unverified
 > to 10.0.0.2 via fe-2/0/10.0

ldp.l2vpn.0: 1 destinations, 1 routes (1 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.0.2.2:NoCtrlWord:5:100:100:0.0.0.2:0.0.0.1/176
 *[LDP/9] 5d 22:13:02
 Discard

FEC129-VPWS.l2vpn.0: 4 destinations, 4 routes (4 active, 0 holddown, 0 hidden)
+ = Active Route, - = Last Active, * = Both

192.0.2.1:100:0.0.0.1/96 AD
 *[L2VPN/170] 6d 20:53:26, metric2 1
 Indirect
192.0.2.2:100:0.0.0.2/96 AD
 *[BGP/170] 6d 20:51:23, localpref 100, from 192.0.2.2
 AS path: I, validation-state: unverified
 > to 10.0.0.2 via fe-2/0/10.0
192.0.2.2:NoCtrlWord:5:100:100:0.0.0.1:0.0.0.2/176
 *[L2VPN/7] 6d 20:51:23, metric2 1
 > to 10.0.0.2 via fe-2/0/10.0
192.0.2.2:NoCtrlWord:5:100:100:0.0.0.2:0.0.0.1/176
 *[LDP/9] 5d 22:13:02
 Discard

```

**Meaning** The output shows all the learned routes, including the autodiscovery (AD) routes.

### Checking Connectivity Between the CE Devices

**Purpose** Verify that Device CE1 can ping Device CE2.

**Action** user@CE1> ping 192.0.2.6  
 PING 192.0.2.6 (192.0.2.6): 56 data bytes  
 64 bytes from 192.0.2.6: icmp\_seq=0 ttl=64 time=0.679 ms  
 64 bytes from 192.0.2.6: icmp\_seq=1 ttl=64 time=0.524 ms  
 ^C  
 --- 192.0.2.6 ping statistics ---  
 2 packets transmitted, 2 packets received, 0% packet loss  
 round-trip min/avg/max/stddev = 0.524/0.602/0.679/0.078 ms

**Meaning** The output shows that the VPWS is operational.

### Checking the VPWS Connections

**Purpose** Make sure that all of the FEC 129 VPWS connections come up correctly.

**Action** user@PE1> show l2vpn connections  
 Layer-2 VPN connections:

Legend for connection status (St)  
 EI -- encapsulation invalid      NC -- interface encapsulation not CCC/TCC/VPLS  
 EM -- encapsulation mismatch    WE -- interface and instance encaps not same  
 VC-Dn -- Virtual circuit down   NP -- interface hardware not present  
 CM -- control-word mismatch    -> -- only outbound connection is up  
 CN -- circuit not provisioned   <- -- only inbound connection is up  
 OR -- out of range              Up -- operational  
 OL -- no outgoing label        Dn -- down  
 LD -- local site signaled down   CF -- call admission control failure  
 RD -- remote site signaled down   SC -- local and remote site ID collision  
 LN -- local site not designated   LM -- local site ID not minimum designated  
 RN -- remote site not designated   RM -- remote site ID not minimum designated  
 XX -- unknown connection status   IL -- no incoming label  
 MM -- MTU mismatch            MI -- Mesh-Group ID not available  
 BK -- Backup connection       ST -- Standby connection  
 PF -- Profile parse failure    PB -- Profile busy  
 RS -- remote site standby      SN -- Static Neighbor  
 LB -- Local site not best-site   RB -- Remote site not best-site  
 VM -- VLAN ID mismatch

Legend for interface status  
 Up -- operational  
 Dn -- down

Instance: FEC129-VPWS  
 L2vpn-id: 100:100  
**Local source-attachment-id: 1 (ONE)**

| Target-attachment-id | Type | St | Time last up         | # Up trans |
|----------------------|------|----|----------------------|------------|
| 2                    | rmt  | Up | Nov 28 16:16:14 2012 | 1          |

Remote PE: 192.0.2.2, Negotiated control-word: No  
 Incoming label: 299792, Outgoing label: 299792  
 Local interface: ge-2/0/5.0, Status: Up, Encapsulation: ETHERNET

**Meaning** As expected, the connection is up. The output includes the source attachment ID and the target attachment ID.

### Checking Connectivity Between the PE Devices

|                              |                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>               | Verify that Device PE1 can ping Device PE2. The <code>ping mpls l2vpn fec129</code> command accepts SAs and TAs as integers or IP addresses and also allows you to use the CE-facing interface instead of the other parameters ( <code>instance</code> , <code>local-id</code> , <code>remote-id</code> , <code>remote-pe-address</code> ).                          |
| <b>Action</b>                | <pre> user@PE1&gt; ping mpls l2vpn fec129 instance FEC129-VPWS remote-id 2 remote-pe-address 192.0.2.2 local-id 1 !!!! --- lsping statistics --- 5 packets transmitted, 5 packets received, 0% packet loss  user@PE1&gt; ping mpls l2vpn fec129 interface ge-2/0/5.0 !!!! --- lsping statistics --- 5 packets transmitted, 5 packets received, 0% packet loss </pre> |
| <b>Meaning</b>               | The output shows that the VPWS is operational.                                                                                                                                                                                                                                                                                                                       |
| <b>Related Documentation</b> | <ul style="list-style-type: none"> <li>• <a href="#">Example: Configuring BGP Autodiscovery for LDP VPLS on page 1350</a></li> <li>• <a href="#">Example: Configuring BGP Autodiscovery for LDP VPLS with User-Defined Mesh Groups on page 1367</a></li> </ul>                                                                                                       |

## Example: Configuring MPLS Egress Protection Service Mirroring for BGP Signaled Layer 2 Services

Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node. If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

This example shows how to configure link protection for BGP signaled Layer 2 services.

### Requirements

MX Series Routers running Junos OS Release 14.2 or later.

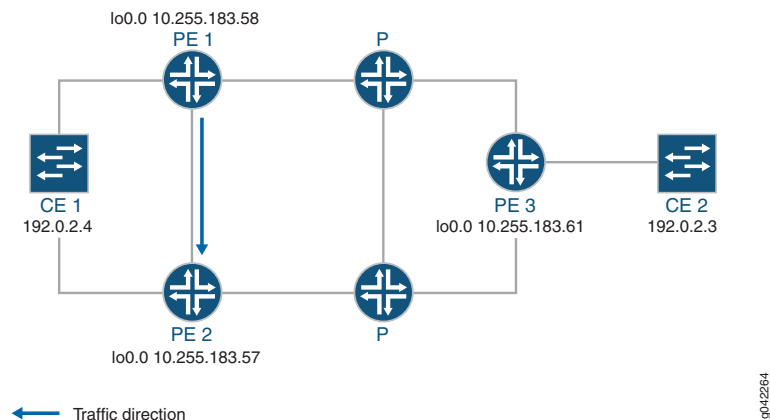

## Overview

If there is a link or node failure in the core network, a protection mechanism such as MPLS fast reroute can be triggered on the transport LSPs between the PE routers to repair the connection within tens of milliseconds. An egress protection LSP addresses the problem of a node-link failure at the edge of the network (for example, a failure of a PE router).

This example includes the following configuration concepts and statements that are unique to the configuration of an egress protection LSP:

- **context-identifier**—Specifies an IPv4 or IPv6 address used to define the pair of PE routers participating in the egress protection LSP. It is assigned to each ordered pair of primary PE and the protector to facilitate protection establishment. This address is globally unique, or unique in the address space of the network where the primary PE and the protector reside.
- **egress-protection**—Configures the protector information for the protected Layer 2 circuit and configures the protector Layer 2 circuit at the `[edit protocols mpls]` hierarchy level. Configures an LSP as an egress protection LSP at the `[edit protocols mpls]` hierarchy level.
- **protector**—Configures the creation of standby pseudowires on the backup PE for link or node protection for the instance.

**Figure 108: Egress Protection LSP Configured from Router PE1 to Router PE2**

In the event of a failure of the egress PE Router PE1, traffic is switched to the egress protection LSP configured between Router PE1 and Router PE2 (the protector PE router):

- Device CE2—Traffic origin
- Router PE3—Ingress PE router
- Router PE1— (Primary) Egress PE router

- Router PE2—Protector PE router
- Device CE1—Traffic destination

When the link between CE1– PE1 goes down, PE1 will briefly redirect that traffic toward CE1, to PE2. PE2 forwards it to CE1 until ingress router PE3 recalculates to forward the traffic to PE2.

Initially the traffic direction was: CE2 – PE3 – P – PE1 – CE1.

When the link between CE1– PE1 goes down, the traffic will be: CE2 – PE3 – P – PE1 – PE2 – CE1. PE3 then recalculates the path: CE2 – PE3 – P – PE2 – CE1.

This example shows how to configure routers PE1, PE2, and PE3.

## Configuration

- [Step-by-Step Procedure on page 1029](#)
- [Results on page 1034](#)

### CLI Quick Configuration

To quickly configure an egress protection LSP, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configurations, copy and then paste the commands into the CLI and enter **commit** from configuration mode.

PE1

```

set protocols rsvp interface all
set protocols rsvp interface fxp0.0 disable
set protocols mpls interface all
set protocols mpls interface fxp0.0 disable
set protocols mpls egress-protection context-identifier 198.51.100.3 primary
set protocols mpls egress-protection context-identifier 198.51.100.3 advertise-mode
 stub-alias
set protocols mpls egress-protection traceoptions file ep size 100m
set protocols mpls egress-protection traceoptions flag all
set protocols bgp traceoptions file bgp.log world-readable
set protocols bgp group ibgp type internal
set protocols bgp group ibgp local-address 10.255.183.58
set protocols bgp group ibgp family inet unicast
set protocols bgp group ibgp family l2vpn signaling egress-protection
set protocols bgp group ibgp neighbor 192.0.2.3

set routing-instances foo protocols l2vpn site foo interface ge-2/1/2.0 remote-site-id 1

```

### Step-by-Step Procedure

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure an egress protection LSP for router PE1:

1. Configure RSVP.
 

```

[edit protocols rsvp]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable

```
2. Configure MPLS to use the egress protection LSP to protect against a link failure to Device CE1.

```
[edit protocols mpls]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
user@PE1# set egress-protection context-identifier 198.51.100.3 primary
user@PE1# set egress-protection context-identifier 198.51.100.3 advertise-mode
stub-alias
user@PE1# set egress-protection traceoptions file ep size 100m
user@PE1# set egress-protection traceoptions flag all
```

3. Configure BGP.

```
[edit protocols bgp]
user@PE1# set traceoptions file bgp.log world-readable
user@PE1# set group ibgp type internal
user@PE1# set group ibgp local-address 10.255.183.58
user@PE1# set group ibgp family inet unicast
user@PE1# set group ibgp family l2vpn signaling egress-protection
user@PE1# set group ibgp neighbor 192.0.2.3
user@PE1# set group ibgp neighbor 192.0.2.4
```

4. Configure IS-IS.

```
[edit protocols isis]
user@PE1# set traceoptions file isis-edge size 10m world-readable
user@PE1# set traceoptions flag error
user@PE1# set level 1 disable
user@PE1# set level 2 wide-metrics-only
user@PE1# set interface all point-to-point
user@PE1# set interface all level 2 metric 10
user@PE1# set interface fxp0.0 disable
```

5. Configure LDP.

```
[edit protocols ldp]
user@PE1# set interface all
user@PE1# set interface fxp0.0 disable
```

6. Configure a load-balancing policy.

```
[edit]
user@PE1# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options to export routes based on the load-balancing policy.

```
[edit routing-options]
user@PE1# set traceoptions file ro.log
user@PE1# set traceoptions flag all
user@PE1# set autonomous-system 100
user@PE1# set forwarding-table export lb
```

8. Configure BGP to advertise nrli from the routing instance with context-ID as next-hop.

```
[edit routing-instances]
user@PE1# set foo instance-type l2vpn
```

```

user@PE1# set foo egress-protection context-identifier 198.51.100.3
user@PE1# set foo interface ge-2/0/2.0
user@PE1# set foo route-distinguisher 10.255.183.58:1
user@PE1# set foo vrf-target target:9000:1

```

9. Configure l2vpn instance to use the egress LSP configured.

```

[edit routing-instances]
user@PE1# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE1# set foo protocols l2vpn site foo site-identifier 1
user@PE1# set foo protocols l2vpn site foo multi-homing
user@PE1# set foo protocols l2vpn site foo site-preference primary
user@PE1# set foo protocols l2vpn site foo interface ge-2/0/2.0 remote-site-id 2

```

10. If you are done configuring the device, enter **commit** from configuration mode.

#### Step-by-Step Procedure

To configure an egress protection LSP for Router PE2:

1. Configure RSVP.

```

[edit protocols rsvp]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable

```

2. Configure MPLS and the LSP that acts as the egress protection LSP.

```

[edit protocols mpls]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
user@PE2# set egress-protection context-identifier 198.51.100.3 protector
user@PE2# set egress-protection context-identifier 198.51.100.3 advertise-mode
stub-alias
user@PE2# set egress-protection traceoptions file ep size 100m
user@PE2# set egress-protection traceoptions flag all

```

3. Configure BGP.

```

[edit protocols bgp]
user@PE2# set traceoptions file bgp.log world-readable
user@PE2# set group ibgp type internal
user@PE2# set group ibgp local-address 10.255.183.57
user@PE2# set group ibgp family inet unicast
user@PE2# set group ibgp family l2vpn signaling
user@PE2# set group ibgp family l2vpn egress-protection
user@PE2# set group ibgp neighbor 192.0.2.3
user@PE2# set group ibgp neighbor 192.0.2.4

```

4. Configure IS-IS.

```

[edit protocols isis]
user@PE2# set traceoptions file isis-edge size 10m world-readable
user@PE2# set traceoptions flag error
user@PE2# set level 1 disable

```

```
user@PE2# set level 2 wide-metrics-only
user@PE2# set interface all point-to-point
user@PE2# set interface all level 2 metric 10
user@PE2# set interface fxp0.0 disable
```

5. Configure LDP.

```
[edit protocols ldp]
user@PE2# set interface all
user@PE2# set interface fxp0.0 disable
```

6. Configure a load-balancing policy.

```
[edit]
user@PE2# set policy-options policy-statement lb then load-balance per-packet
```

7. Configure the routing options to export routes based on the load-balancing policy.

```
[edit routing-options]
user@PE2# set traceoptions file ro.log
user@PE2# set traceoptions flag all
user@PE2# set autonomous-system 100
user@PE2# set forwarding-table export lb
```

8. Configure BGP to advertise nrli from the routing instance with context-ID as next-hop.

```
[edit routing-instances]
user@PE2# set foo instance-type l2vpn
user@PE2# set foo egress-protection protector
user@PE2# set foo interface ge-2/0/2.0
user@PE2# set foo route-distinguisher 10.255.183.57:1
user@PE2# set foo vrf-target target:9000:1
```

9. Configure l2vpn instance to use the egress LSP configured.

```
[edit routing-instances]
user@PE2# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE2# set foo protocols l2vpn site foo hot-standby
user@PE2# set foo protocols l2vpn site foo site-identifier 1
user@PE2# set foo protocols l2vpn site foo multi-homing
user@PE2# set foo protocols l2vpn site foo site-preference backup
user@PE2# set foo protocols l2vpn site foo interface ge-2/0/2.0 remote-site-id 2
```

10. If you are done configuring the device, enter **commit** from configuration mode.

#### Step-by-Step Procedure

To configure an egress protection LSP for Router PE3:

1. Configure RSVP.

```
[edit protocols rsvp]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
```

2. Configure MPLS.  

```
[edit protocols mpls]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
```
3. Configure BGP.  

```
[edit protocols bgp]
user@PE3# set traceoptions file bgp.log world-readable
user@PE3# set group ibgp type internal
user@PE3# set group ibgp local-address 10.255.183.61
user@PE3# set group ibgp family inet unicast
user@PE3# set group ibgp family l2vpn signaling
user@PE3# set group ibgp neighbor 192.0.2.3
user@PE3# set group ibgp neighbor 192.0.2.4
```
4. Configure IS-IS.  

```
[edit protocols isis]
user@PE3# set traceoptions file isis-edge size 10m world-readable
user@PE3# set traceoptions flag error
user@PE3# set level 1 disable
user@PE3# set level 2 wide-metrics-only
user@PE3# set protocols isis interface all point-to-point
[edit protocols isis]
user@PE3# set protocols isis interface all level 2 metric 10
[edit protocols isis]
user@PE3# set protocols isis interface fxp0.0 disable
```
5. Configure LDP.  

```
[edit protocols ldp]
user@PE3# set interface all
user@PE3# set interface fxp0.0 disable
```
6. Configure a load-balancing policy.  

```
[edit]
user@PE3# set policy-options policy-statement lb then load-balance per-packet
```
7. Configure the routing options to export routes based on the load-balancing policy.  

```
[edit routing-options]
user@PE3# set traceoptions file ro.log
user@PE3# set traceoptions flag normal
user@PE3# set traceoptions flag route
user@PE3# set autonomous-system 100
user@PE3# set forwarding-table export lb
```
8. Configure BGP to advertise nlri from the routing instance with context-ID as next-hop.  

```
[edit]
user@PE3# set routing-instances foo instance-type l2vpn
user@PE3# set routing-instances foo interface ge-2/1/2.0
```

```
user@PE3# set routing-instances foo route-distinguisher 10.255.183.61:1
user@PE3# set routing-instances foo vrf-target target:9000:1
```

9. Configure l2vpn to specify the interface that connects to the site and the remote interface to which you want the specified interface to connect.

```
[edit routing-instances]
user@PE3# set foo protocols l2vpn encapsulation-type ethernet-vlan
user@PE3# set foo protocols l2vpn site foo site-identifier 2
user@PE3# set foo protocols l2vpn site foo interface ge-2/1/2.0 remote-site-id 1
```

10. If you are done configuring the device, enter **commit** from configuration.

---

## Results

From configuration mode, confirm your configuration on Router PE1 by entering the **show protocols**, **show policy-options**, and **show routing-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
[edit]

## Verification

Confirm that the configuration is working properly.

- [Verifying the L2VPN Configuration on page 1040](#)
- [Verifying the Routing Instance Details on page 1041](#)
- [Verifying the IS-IS Configuration on page 1041](#)
- [Verifying the MPLS Configuration on page 1042](#)

### Verifying the L2VPN Configuration

**Purpose** Verify that LSP is protected by the connection protection logic.

**Action** From operational mode, run the **show l2vpn connections extensive** command.

```
user@PE2> show l2vpn connections extensive
```

```

Layer-2 VPN connections:
Legend for connection status (St)
EI -- encapsulation invalid NC -- interface encapsulation not CCC/TCC/VPLS
EM -- encapsulation mismatch WE -- interface and instance encaps not same
VC-Dn -- Virtual circuit down NP -- interface hardware not present

```

**Meaning** The **Egress Protection: Yes** output shows that the given PVC is protected by connection protection logic.

### Verifying the Routing Instance Details

**Purpose** Verify the routing instance information and the context identifier configured on the primary, which is used as the next-hop address in case of node-link failure.

**Action** From operational mode, run the **show route foo detail** command.

```

user@PE2> show route foo detail

foo:
Router ID: 0.0.0.0
Type: l2vpn non-forwarding State: Active
Interfaces:
 lt-1/2/0.56
Route-distinguisher: 10.255.255.11:1
Vrf-import: [__vrf-import-foo-internal__]
Vrf-export: [__vrf-export-foo-internal__]
Vrf-import-target: [target:100:200]
Vrf-export-target: [target:100:200]
Fast-reroute-priority: low
Vrf-edge-protection-id: 198.51.100.3
Tables:
 foo.l2vpn.0 : 5 routes (3 active, 0 holddown, 0 hidden)
 foo.l2id.0 : 6 routes (2 active, 0 holddown, 0 hidden)

```

**Meaning** The context-id is set to **198.51.100.3** and the **Vrf-import: [ \_\_vrf-import-foo-internal\_\_ ]** in the output mentions the policy used for rewriting the next-hop address.

### Verifying the IS-IS Configuration

**Purpose** Verify the IS-IS context identifier information.

**Action** From operational mode, run the **show isis context-identifier detail** command.

```
user@PE2> show isis context-identifier detail
```

```
IS-IS context database:
Context L Owner Role Primary Metric
198.51.100.3 2 MPLS Protector pro17-b-1r-R1 0
 Advertiser pro17-b, Router ID 10.255.107.49, Level 2, tlv protector
 Advertiser pro17-b-1r-R1, Router ID 10.255.255.11, Metric 1, Level 2, tlv prefix
```

**Meaning** Router PE2 is the protector and the configured context identifier is in use for the MPLS protocol.

---

### Verifying the MPLS Configuration

**Purpose** Verify the context identifier details on the primary and protector PEs.

**Action** From operational mode, run the **show mpls context-identifier detail** command.

```
user@PE1> show mpls context-identifier detail
```

```
ID: 198.51.100.3
 Type: primary, Metric: 1, Mode: alias
```

```
Total 1, Primary 1, Protector 0
```

```
user@PE2> show mpls context-identifier detail
```

```
ID: 198.51.100.3
 Type: protector, Metric: 16777215, Mode: alias
 Context table: __198.51.100.3__.mpls.0, Label out: 299968
```

```
user@PE2> show mpls egress-protection detail
```

```
Instance Type Protection-Type
foo local-l2vpn Protector
 Route Target 100:200
```

**Meaning** Context-id is **198.51.100.3**, advertise-mode is **alias**, the MPLS table created for egress protection is **\_\_198.51.100.3\_\_.mpls.0**, and the egress instance name is **foo**, which is of type **local-l2vpn**.

## Release History Table

| Release | Description                                                                                                                                        |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 14.2    | Starting in Junos OS Release 14.2, Junos OS supports the restoration of egress traffic when there is a link or node failure in the egress PE node. |

## Understanding Multisegment Pseudowire for FEC 129

### Understanding Multisegment Pseudowire

A pseudowire is a Layer 2 circuit or service that emulates the essential attributes of a telecommunications service, such as a T1 line, over an MPLS packet-switched network (PSN). The pseudowire is intended to provide only the minimum necessary functionality to emulate the wire with the required resiliency requirements for the given service definition.

When a pseudowire originates and terminates on the edge of the same PSN, the pseudowire label is unchanged between the originating and terminating provider edge (T-PE) devices. This is called a single-segment pseudowire (SS-PW).

[Figure 105 on page 1005](#) illustrates an SS-PW established between two PE routers. The pseudowires between the PE1 and PE2 routers are located within the same autonomous system (AS).

Figure 109: L2VPN Pseudowire

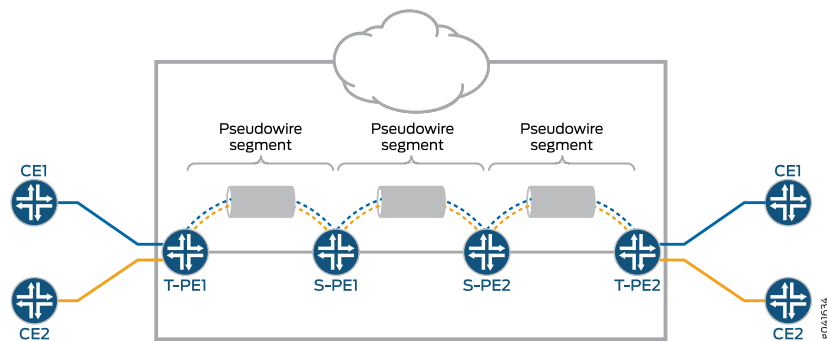

In cases where it is impossible to establish a single pseudowire from a local to a remote PE, either because it is unfeasible or undesirable to establish a single control plane between the two PEs, a multisegment pseudowire (MS-PW) is used.

An MS-PW is a set of two or more contiguous SS-PWs that are made to function as a single point-to-point pseudowire. It is also known as switched pseudowire. MS-PWs can go across different regions or network domains. A region can be considered as an interior

gateway protocol (IGP) area or a BGP autonomous system that belongs to the same or different administrative domain. An MS-PW spans multiple cores or ASs of the same or different carrier networks. A Layer 2 VPN MS-PW can include up to 254 pseudowire segments.

Figure 106 on page 1005 illustrates a set of two or more pseudowire segments that function as a single pseudowire. The end routers are called terminating PE (T-PE) routers, and the switching routers are called switching PE (S-PE) routers. The S-PE router terminates the tunnels of the preceding and succeeding pseudowire segments in an MS-PW. The S-PE router can switch the control and data planes of the preceding and succeeding pseudowire segments of the MS-PW. An MS-PW is declared to be up when all the single-segment pseudowires are up.

**Figure 110: Multisegment Pseudowire**

## Using FEC 129 for Multisegment Pseudowire

Currently, there are two types of attachment circuit identifiers (AIs) defined under FEC 129:

- Type 1 AI
- Type 2 AI

The support of an MS-PW for FEC 129 uses type 2 AI. A type 2 AI is globally unique by definition of RFC 5003.

Single-segment pseudowires (SS-PWs) using FEC 129 on an MPLS PSN can use both type 1 and type 2 AI. For an MS-PW using FEC 129, a pseudowire itself is identified as a pair of endpoints. This requires that the pseudowire endpoints be uniquely identified.

In the case of a dynamically placed MS-PW, there is a requirement for the identifiers of attachment circuits to be globally unique, for the purposes of reachability and manageability of the pseudowire. Thus, individual globally unique addresses are allocated to all the attachment circuits and S-PEs that make up an MS-PW.

Type 2 AI is composed of three fields:

- Global\_ID—Global identification, which is usually the AS number.
- Prefix—IPv4 address, which is usually the router ID.

- AC\_ID—Local attachment circuit, which is a user-configurable value.

Since type 2 All already contains the T-PE's IP address and it is globally unique, from the FEC 129 pseudowire signaling point of view, the combination (AGI, SAll, TAll) uniquely identifies an MS-PW across all interconnected pseudowire domains.

## Establishing a Multisegment Pseudowire Overview

An MS-PW is established by dynamically and automatically selecting the predefined S-PEs and placing the MS-PW between two T-PE devices.

When S-PEs are dynamically selected, each S-PE is automatically discovered and selected using the BGP autodiscovery feature, without the requirement of provisioning the FEC 129 pseudowire-related information on all the S-PEs. BGP is used to propagate pseudowire address information throughout the PSN.

Since there is no manual provisioning of FEC 129 pseudowire information on the S-PEs, the Attachment Group Identifier (AGI) and Attachment Individual Identifier (All) are reused automatically, and choosing the same set of S-PEs for the pseudowire in both the forwarding and reverse direction is achieved through the active and passive role of each T-PE device.

- Active—The T-PE initiates an LDP label mapping message.
- Passive—The T-PE does not initiate an LDP label mapping message until it receives a label mapping message initiated by the active T-PE. The passive T-PE sends its label mapping message to the same S-PE from where it received the label mapping message originated from its active T-PE. This ensures that the same set of S-PEs are used in the reverse direction.

## Pseudowire Status Support for Multisegment Pseudowire

- [Pseudowire Status Behavior on T-PE on page 1045](#)
- [Pseudowire Status Behavior on S-PE on page 1046](#)

---

### Pseudowire Status Behavior on T-PE

The following pseudowire status messages are relevant on the T-PE:

- 0x00000010—Local PSN-facing pseudowire (egress) transmit fault.
- 0x00000001—Generic nonforwarding fault code. This is set as the local fault code. The local fault code is set at the local T-PE, and LDP sends a pseudowire status TLV message with the same fault code to the remote T-PE.
- Fault codes are bit-wise OR'ed and stored as remote pseudowire status codes.

### Pseudowire Status Behavior on S-PE

---

The S-PE initiates the pseudowire status messages that indicate the pseudowire faults. The SP-PE in the pseudowire notification message hints where the fault was originated.

- When a local fault is detected by the S-PE, a pseudowire status message is sent in both directions along the pseudowire. Since there are no attachment circuits on an S-PE, only the following status messages are relevant:
  - 0x00000008—Local PSN-facing pseudowire (ingress) receive fault.
  - 0x00000010—Local PSN-facing pseudowire (egress) transmit fault.
- To indicate which SS-PW is at fault, an LDP SP-PE TLV is attached with the pseudowire status code in the LDP notification message. The pseudowire status is passed along from one pseudowire to another unchanged by the control plane switching function.
- If an S-PE initiates a pseudowire status notification message with one particular pseudowire status bit, then for the pseudowire status code an S-PE receives, the same bit is processed locally and not forwarded until the S-PE's original status error is cleared.
- An S-PE keeps only two pseudowire status codes for each SS-PW it is involved in – local pseudowire status code and remote pseudowire status code. The value of the remote pseudowire status code is the result of logic or operation of the pseudowire status codes in the chain of SS-PWs preceding this segment. This status code is incrementally updated by each S-PE upon receipt and communicated to the next S-PE. The local pseudowire status is generated locally based on its local pseudowire status.
- Only transmit fault is detected at the SP-PE. When there is no MPLS LSP to reach the next segment, a local transmit fault is detected. The transmit fault is sent to the next downstream segment, and the receive fault is sent to the upstream segment.
- Remote failures received on an S-PE are just passed along the MS-PW unchanged. Local failures are sent to both segments of the pseudowire that the S-PE is involved in.

### Pseudowire TLV Support for MS-PW

MS-PW provides the following support for the LDP SP-PE TLV [RFC 6073]:

- The LDP SP-PE TLVs for an MS-PW include:
  - Local IP address
  - Remote IP address
- An SP-PE adds the LDP SP-PE TLV to the label mapping message. Each SP-PE appends the local LDP SP-PE TLV to the SP-PE list it received from the other segment.
- The pseudowire status notification message includes the LDP SP-PE TLV when the notification is generated at the SP-PE.

## Supported and Unsupported Features

Junos OS supports the following features with MS-PW:

- MPLS PSN for each SS-PW that builds up the MS-PW.
- The same pseudowire encapsulation for each SS-PW in an MS-PW – Ethernet or VLAN-CCC.
- The generalized PWid FEC with T-LDP as an end-to-end pseudowire signaling protocol to set up each SS-PW.
- MP-BGP to autodiscover the two endpoint PEs for each SS-PW associated with the MS-PW.
- Standard MPLS operation to stitch two side-by-side SS-PWs to form an MS-PW.
- Automatic discovery of S-PE so that the MS-PW can be dynamically placed.
- Minimum provisioning of S-PE.
- Operation, administration, and maintenance (OAM) mechanisms, including end-to-end MPLS ping or end-to-any-S-PE MPLS ping, MPLS path trace, end-to-end VCCV, and Bidirectional Forwarding Detection (BFD).
- Pseudowire swithing point (SP) PE TLV for the MS-PW.
- Composite next hop on MS-PW.
- Pseudowire status TLV for MS-PW.

Junos OS does not support the following MS-PW functionality:

- Mix of LDP FEC 128 and LDP FEC 129.
- Static pseudowire where each label is provisioned statically.
- Graceful Routing Engine switchover.
- Nonstop active routing.
- Multihoming.
- Partial connectivity verification (originating from an S-PE) in OAM.

## Example: Configuring a Multisegment Pseudowire

This example shows how to configure a dynamic multisegment pseudowire (MS-PW), where the stitching provider edge (S-PE) devices are automatically and dynamically discovered by BGP, and pseudowires are signaled by LDP using FEC 129. This arrangement requires minimum provisioning on the S-PEs, thereby reducing the configuration burden

that is associated with statically configured Layer 2 circuits while still using LDP as the underlying signaling protocol.

- [Requirements on page 1048](#)
- [Overview on page 1048](#)
- [Configuration on page 1054](#)
- [Verification on page 1074](#)
- [Troubleshooting on page 1089](#)

## Requirements

This example uses the following hardware and software components:

- Six routers that can be a combination of M Series Multiservice Edge Routers, MX Series 3D Universal Edge Routers, T Series Core Routers, or PTX Series Packet Transport Routers.
  - Two remote PE devices configured as terminating PEs (T-PEs).
  - Two S-PEs configured as:
    - Route reflectors, in the case of interarea configuration.
    - AS boundary routers or route reflectors, in the case of inter-AS configuration.
- Junos OS Release 13.3 or later running on all the devices.

Before you begin:

1. Configure the device interfaces.
2. Configure OSPF or any other IGP protocol.
3. Configure BGP.
4. Configure LDP.
5. Configure MPLS.

## Overview

Starting with Junos OS Release 13.3, you can configure an MS-PW using FEC 129 with LDP signaling and BGP autodiscovery in an MPLS packet-switched network (PSN). The MS-PW feature also provides operation, administration, and management (OAM) capabilities, such as ping, traceroute, and BFD, from the T-PE devices.

To enable autodiscovery of S-PEs in an MS-PW, include the **auto-discovery-mspw** statement at the **[edit protocols bgp group group-name family l2vpn]** hierarchy level.

```
family l2vpn {
 auto-discovery-mspw;
}
```

The automatic selection of S-PE and dynamic setting up of an MS-PW rely heavily on BGP. BGP network layer reachability information (NLRI) constructed for the FEC 129

pseudowire to autodiscover the S-PE is called an MS-PW NLRI [draft-ietf-pwe3-dynamic-ms-pw-15.txt]. The MS-PW NLRI is essentially a prefix consisting of a route distinguisher (RD) and FEC 129 source attachment identifier (SAII). It is referred to as a BGP autodiscovery (BGP-AD) route and is encoded as **RD:SAII**.

Only T-PEs that are provisioned with type 2 AIs initiate their own MS-PW NLRI respectively. Since a type 2 AI is globally unique, an MS-PW NLRI is used to identify a PE device to which the type 2 AI is provisioned. The difference between a type 1 AI and a type 2 AI requires that a new address family indicator (AFI) and subsequent address family identifier (SAFI) be defined in BGP to support an MS-PW. The proposed AFI and SAFI value pair used to identify the MS-PW NLRI is 25 and 6, respectively (pending IANA allocation).

The AFI and SAFI values support autodiscovery of S-PEs and should be configured on both T-PEs that originate the routes, and the S-PEs that participate in the signaling.

Figure 111 on page 1049 illustrates an inter-area MS-PW setup between two remote PE routers—T-PE1 and T-PE2. The Provider (P) routers are P1 and P2, and the S-PE routers are S-PE1 and S-PE2. The MS-PW is established between T-PE1 and T-PE2, and all the devices belong to the same AS—AS 100. Since S-PE1 and S-PE2 belong to the same AS, they act as route reflectors and are also known as RR 1 and RR 2, respectively.

Figure 112 on page 1050 illustrates an inter-AS MS-PW setup. The MS-PW is established between T-PE1 and T-PE2, where T-PE1, P1, and S-PE1 belong to AS 1, and S-PE2, P2, and T-PE2 belong to AS 2. Since S-PE1 and S-PE2 belong to different ASs, they are configured as ASBR routers and are also known as ASBR 1 and ASBR 2, respectively.

Figure 111: Interarea Multisegment Pseudowire

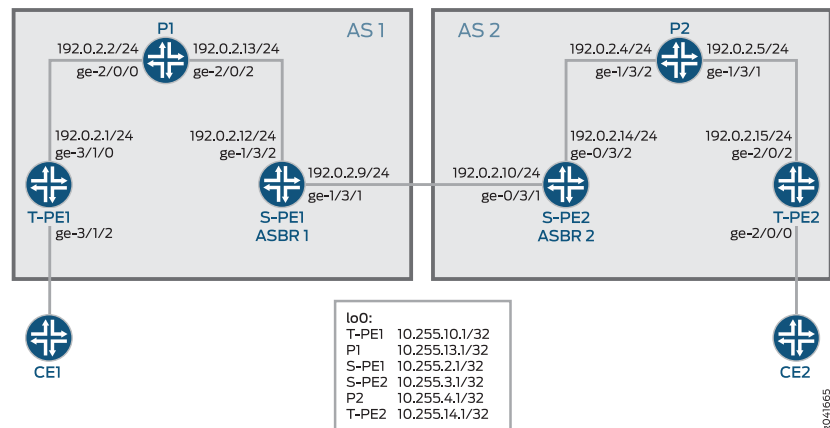

Figure 112: Inter-AS Multisegment Pseudowire

The following sections provide information about how an MS-PW is established in an interarea and inter-AS scenario.

#### Minimum Configuration Requirements on S-PE

In order to dynamically discover both ends of an SS-PW and set up a T-LDP session dynamically, the following is required:

- For interarea MS-PW, each S-PE plays both an ABR and BGP route reflector role.

In the interarea case, as seen in [Figure 111 on page 1049](#), the S-PE plays a BGP route reflector role and reflects the BGP-AD route to its client. A BGP-AD route advertised by one T-PE eventually reaches its remote T-PE. Because of the next-hop-self set by each S-PE, the S-PE or T-PE that receives a BGP-AD route can always discover the S-PE that advertises the BGP-AD in its local AS or local area through the BGP next hop.

- For inter-AS MS-PW, each S-PE plays either an ASBR or a BGP route reflector role.

In an MS-PW, the two T-PEs initiate a BGP-AD route respectively. When the S-PE receives the BGP-AD route through either the IBGP session with the T-PE or through a regular BGP-RR, it sets the next-hop-self before re-advertising the BGP-AD route to one or more of its EBGP peers in the inter-AS case, as seen in [Figure 112 on page 1050](#).

- Each S-PE must set next-hop-self when re-advertising or reflecting a BGP-AD route for the MS-PW.

#### Active and Passive Role of T-PE

To ensure that the same set of S-PEs are being used for a MS-PW in both directions, the two T-PEs play different roles in terms of FEC 129 signaling. This is to avoid different paths being chosen by T-PE1 and T-PE2 when each S-PE is dynamically selected for an MS-PW.

When an MS-PW is signaled using FEC 129, each T-PE might independently start signaling the MS-PW. The signaling procedure can result in an attempt to set up each direction of the MS-PW through different S-PEs.

To avoid this situation, one of the T-PEs must start the pseudowire signaling (active role), while the other waits to receive the LDP label mapping before sending the respective pseudowire LDP label mapping message (passive role). When the MS-PW path is dynamically placed, the active T-PE (the Source T-PE) and the passive T-PE (the Target T-PE) must be identified before signaling is initiated for a given MS-PW. The determination of which T-PE assumes the active role is done based on the SAll value, where the T-PE that has a larger SAll value plays the active role.

In this example, the SAll values of T-PE1 and T-PE 2 are **800:800:800** and **700:700:700**, respectively. Since T-PE1 has a higher SAll value, it assumes the active role and T-PE2 assumes the passive role.

### Directions for Establishing an MS-PW

The directions used by the S-PE for setting up the MS-PW are:

- Forwarding direction—From an active T-PE to a passive T-PE.

In this direction, the S-PEs perform a BGP-AD route lookup to determine the next-hop S-PE to send the label mapping message.

- Reverse direction—From a passive T-PE to an active T-PE.

In this direction, the S-PEs do not perform a BGP-AD route lookup, because the label mapping messages are received from the T-PEs, and the stitching routes are installed in the S-PEs.

In this example, the MS-PW is established in the forwarding direction from T-PE1 to T-PE2. When the MS-PW is placed from T-PE2 to T-PE1, the MS-PW is established in the reverse direction.

### Autodiscovery and Dynamic Selection of S-PE

A new AFI and SAFI value is defined in BGP to support the MS-PWs based on type 2 All. This new address family supports autodiscovery of S-PEs. This address family must be configured on both the T-PEs and S-PEs.

It is the responsibility of the Layer 2 VPN component to dynamically select the next S-PE to use along the MS-PW in the forwarding direction.

- In the forwarding direction, the selection of the next S-PE is based on the BGP-AD route advertised by the BGP and pseudowire FEC information sent by the LDP. The BGP-AD route is initiated by the passive T-PE (T-PE2) in the reverse direction while the pseudowire FEC information is sent by LDP from the active T-PE (T-PE1) in the forwarding direction.
- In the reverse direction, the next S-PE (S-PE2) or the active T-PE (T-PE1) is obtained by looking up the S-PE (S-PE1) that it used to set up the pseudowire in the forwarding direction.

### Provisioning a T-PE

To support FEC 129 type 2 All, the T-PE needs to configure its remote T-PE's IP address, a global ID, and an attachment circuit ID. Explicit paths where a set of S-PEs to use is

explicitly specified on a T-PE is not supported. This eliminates the need to provision each S-PE with a type 2 All.

#### **Stitching an MS-PW**

An S-PE performs the following MPLS label operations before forwarding the received label mapping message to the next S-PE:

1. Pops the MPLS tunnel label.
2. Pops the VC label.
3. Pushes a new VC label.
4. Pushes an MPLS tunnel label used for the next segment.

#### **Establishing an MS-PW**

After completing the necessary configuration, an MS-PW is established in the following manner:

1. The SAll values are exchanged between T-PE1 and T-PE2 using BGP.  
T-PE1 assumes the active T-PE role, because it is configured with a higher SAll value.  
T-PE2 becomes the passive T-PE.
2. T-PE1 receives the BGP-AD route originated by T-PE2. It compares the All values obtained from T-PE2 in the received BGP-AD route against the All values provisioned locally.
3. If the All values match, T-PE1 performs a BGP-AD route lookup to elect the first S-PE (S-PE1).
4. T-PE1 sends an LDP label mapping message to S-PE1.
5. Using the BGP-AD route originated from T-PE2, and the LDP label mapping message received from T-PE1, S-PE1 selects the next S-PE (S-PE2) in the forwarding direction.  
To do this, S-PE1 compares SAll obtained from the BGP-AD route against the TAI from the LDP label mapping message.
6. If the All values match, S-PE1 finds S-PE2 through the BGP next hop associated with the BGP-AD route.

7. The process of selecting S-PE goes on until the last S-PE establishes a T-LDP session with T-PE2. When T-PE2 receives the LDP label mapping message from the last S-PE (S-PE2), it initiates its own label mapping message and sends it back to S-PE2.
8. When all the label mapping messages are received on S-PE1 and S-PE2, the S-PEs install the stitching routes. Thus, when the MS-PW is established in the reverse direction, the S-PEs need not perform BGP-AD route lookup to determine its next hop as it did in the forwarding direction.

### OAM Support for an MS-PW

After the MS-PW is established, the following OAM capabilities can be executed from the T-PE devices:

- Ping

- End-to-End Connectivity Verification Between T-PEs

If T-PE1, S-PEs, and T-PE2 support Control Word (CW), the pseudowire control plane automatically negotiates the use of the CW. Virtual Circuit Connectivity Verification (VCCV) Control Channel (CC) Type 3 will function correctly whether or not the CW is enabled on the pseudowire. However, VCCV Type 1, which is used for end-to-end verification only, is only supported if the CW is enabled.

The following is a sample:

```
user@T-PE1> ping mpls l2vpn fec129 instance instance-name local-id SAll of T-PE1
remote-pe-address address of T-PE2 remote-id TAll of T-PE2
or
```

```
user@T-PE1> ping mpls l2vpn fec129 interface CE1-facing interface
```

- Partial Connectivity Verification from T-PE to Any S-PE

To trace part of an MS-PW, the TTL of the pseudowire label can be used to force the VCCV message to pop out at an intermediate node. When the TTL expires, the S-PE can determine that the packet is a VCCV packet either by checking the CW or by checking for a valid IP header with UDP destination port 3502 (if the CW is not in use). The packet should then be diverted to VCCV processing.

If T-PE1 sends a VCCV message with the TTL of the pseudowire label equal to 1, the TTL expires at the S-PE. T-PE1 can thus verify the first segment of the pseudowire.

The VCCV packet is built according to RFC 4379. All the information necessary to build the VCCV LSP ping packet is collected by inspecting the S-PE TLVs. This use of the TTL is subject to the caution expressed in RFC 5085. If a penultimate LSR between S-PEs or between an S-PE and a T-PE manipulates the pseudowire label TTL, the VCCV message might not emerge from the MS-PW at the correct S-PE.

The following is a sample:

```
user@T-PE1> ping mpls l2vpn fec129 interface CE1-facing interface bottom-label-ttl segment
The bottom-label-ttl value is 1 for S-PE1 and 2 for S-PE2.
```

The **bottom-label-ttl** statement sets the correct VC label TTL, so the packets are popped to the correct SS-PW for VCCV processing.

**NOTE:** Junos OS supports VCCV Type 1 and Type 3 for the MS-PW OAM capability. VCCV Type 2 is not supported.

- Traceroute

Traceroute tests each S-PE along the path of the MS-PW in a single operation similar to LSP trace. This operation is able to determine the actual data path of the MS-PW, and is used for dynamically signaled MS-PWs.

```
user@T-PE1> traceroute mpls l2vpn fec129 interface CE1-facing interface
```

- Bidirectional Forwarding Detection

Bidirectional Forwarding Detection (BFD) is a detection protocol designed to provide fast forwarding path failure detection times for all media types, encapsulations, topologies, and routing protocols. In addition to fast forwarding path failure detection, BFD provides a consistent failure detection method for network administrators. The router or switch can be configured to log a system log (syslog) message when BFD goes down.

```
user@T-PE1> show bfd session extensive
```

## Configuration

- [Configuring an Interarea MS-PW on page 1054](#)
- [Configuring an Inter-AS MS-PW on page 1064](#)

### Configuring an Interarea MS-PW

#### CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
T-PE1 set interfaces ge-3/1/0 unit 0 family inet address 192.0.2.1/24
 set interfaces ge-3/1/0 unit 0 family mpls
 set interfaces ge-3/1/2 encapsulation ethernet-ccc
 set interfaces ge-3/1/2 unit 0
 set interfaces lo0 unit 0 family inet address 10.255.10.1/32 primary
 set routing-options autonomous-system 100
 set protocols mpls interface all
 set protocols mpls interface fxp0.0 disable
 set protocols bgp family l2vpn auto-discovery-mspw
 set protocols bgp group mspw type internal
 set protocols bgp group mspw local-address 10.255.10.1
 set protocols bgp group mspw neighbor 10.255.2.1
 set protocols ospf area 0.0.0.0 interface lo0.0
 set protocols ospf area 0.0.0.0 interface all
```

```

set protocols ospf area 0.0.0.0 interface fxp0.0 disable
set protocols ldp interface all
set protocols ldp interface fxp0.0 disable
set protocols ldp interface lo0.0
set routing-instances ms-pw instance-type l2vpn
set routing-instances ms-pw interface ge-3/1/2.0
set routing-instances ms-pw route-distinguisher 10.10.10.15
set routing-instances ms-pw l2vpn-id l2vpn-id:100:15
set routing-instances ms-pw vrf-target target:100:115
set routing-instances ms-pw protocols l2vpn site CE1 source-attachment-identifier
 800:800:800
set routing-instances ms-pw protocols l2vpn site CE1 interface ge-3/1/2.0
 target-attachment-identifier 700:700:700
set routing-instances ms-pw protocols l2vpn pseudowire-status-tlv
set routing-instances ms-pw protocols l2vpn oam bfd-liveness-detection
 minimum-interval 300

```

```

P1 set interfaces ge-2/0/0 unit 0 family inet address 192.0.2.2/24
 set interfaces ge-2/0/0 unit 0 family mpls
 set interfaces ge-2/0/2 unit 0 family inet address 192.0.2.13/24
 set interfaces ge-2/0/2 unit 0 family mpls
 set interfaces lo0 unit 0 family inet address 10.255.13.1/32 primary
 set routing-options autonomous-system 100
 set protocols mpls interface all
 set protocols mpls interface fxp0.0 disable
 set protocols ospf area 0.0.0.0 interface lo0.0
 set protocols ospf area 0.0.0.0 interface all
 set protocols ospf area 0.0.0.0 interface fxp0.0 disable
 set protocols ldp interface all
 set protocols ldp interface fxp0.0 disable
 set protocols ldp interface lo0.0

```

```

S-PE1 (RR 1) set interfaces ge-1/3/1 unit 0 family inet address 192.0.2.9/24

```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure T-PE1 in the interarea scenario:

**NOTE:** Repeat this procedure for the T-PE2 device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the T-PE1 interfaces.

[edit interfaces]

```
user@T-PE1# set ge-3/1/0 unit 0 family inet address 192.0.2.1/24
```

```
user@T-PE1# set ge-3/1/0 unit 0 family mpls
```

```
user@T-PE1# set ge-3/1/2 encapsulation ethernet-ccc
```

```
user@T-PE1# set ge-3/1/2 unit 0
```

```
user@T-PE1# set lo0 unit 0 family inet address 10.255.10.1/32 primary
```

2. Set the autonomous system number.

[edit routing-options]

```
user@T-PE1# set autonomous-system 100
```

3. Enable MPLS on all the interfaces of T-PE1, excluding the management interface.

[edit protocols]

```
user@T-PE1# set mpls interface all
```

```
user@T-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of intermediate S-PEs that make up the MS-PW using BGP.

```
[edit protocols]
```

```
user@T-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the BGP group for T-PE1.

```
[edit protocols]
```

```
user@T-PE1# set bgp group mspw type internal
```

6. Assign local and neighbor addresses to the mspw group for T-PE1 to peer with S-PE1.

```
[edit protocols]
```

```
user@T-PE1# set bgp group mspw local-address 10.255.10.1
```

```
user@T-PE1# set bgp group mspw neighbor 10.255.2.1
```

7. Configure OSPF on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
```

```
user@T-PE1# set ospf area 0.0.0.0 interface lo0.0
```

```
user@T-PE1# set ospf area 0.0.0.0 interface all
```

```
user@T-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

8. Configure LDP on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
```

```
user@T-PE1# set ldp interface all
```

```
user@T-PE1# set ldp interface fxp0.0 disable
```

```
user@T-PE1# set ldp interface lo0.0
```

9. Configure the Layer 2 VPN routing instance on T-PE1.

```
[edit routing-instances]
```

```
user@T-PE1# set ms-pw instance-type l2vpn
```

10. Assign the interface name for the mspw routing instance.

```
[edit routing-instances]
```

```
user@T-PE1# set ms-pw interface ge-3/1/2.0
```

11. Configure the route distinguisher for the mspw routing instance.

```
[edit routing-instances]
```

```
user@T-PE1# set ms-pw route-distinguisher 10.10.10.10:15
```

12. Configure the Layer 2 VPN ID community for FEC 129 MS-PW.

```
[edit routing-instances]
```

```
user@T-PE1# set ms-pw l2vpn-id l2vpn-id:100:15
```

13. Configure a VPN routing and forwarding (VRF) target for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw vrf-target target:100:115
```

14. Configure the source attachment identifier (SAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 source-attachment-identifier
800:800:800
```

15. Assign the interface name that connects the CE1 site to the VPN, and configure the target attachment identifier (TAI) value using Layer 2 VPN as the routing protocol for the mspw routing instance.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn site CE1 interface ge-3/1/2.0
target-attachment-identifier 700:700:700
```

16. (Optional) Configure T-PE1 to send MS-PW status TLVs.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn pseudowire-status-tlv
```

17. (Optional) Configure OAM capabilities for the VPN.

```
[edit routing-instances]
user@T-PE1# set ms-pw protocols l2vpn oam bfd-liveness-detection
minimum-interval 300
```

**Step-by-Step Procedure** The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure S-PE1 (RR 1) in the interarea scenario:

**NOTE:** Repeat this procedure for the S-PE2 (RR 2) device in the MPLS domain, after modifying the appropriate interface names, addresses, and other parameters.

1. Configure the S-PE1 interfaces.

```
[edit interfaces]
user@S-PE1# set ge-1/3/1 unit 0 family inet address 192.0.2.9/24
user@S-PE1# set ge-1/3/1 unit 0 family mpls

user@S-PE1# set ge-1/3/2 unit 0 family inet address 192.0.2.22/24
user@S-PE1# set ge-1/3/2 unit 0 family mpls
```

```
user@S-PE1# set lo0 unit 0 family inet address 10.255.2.1/32 primary
```

2. Set the autonomous system number.

```
[edit routing-options]
user@S-PE1# set autonomous-system 100
```

3. Enable MPLS on all the interfaces of T-PE1, excluding the management interface.

```
[edit protocols]
user@S-PE1# set mpls interface all
user@S-PE1# set mpls interface fxp0.0 disable
```

4. Enable autodiscovery of S-PE using BGP.

```
[edit protocols]
user@S-PE1# set bgp family l2vpn auto-discovery-mspw
```

5. Configure the BGP group for S-PE1.

```
[edit protocols]
user@S-PE1# set bgp group mspw type internal
```

6. Configure S-PE1 to act as a route reflector.

```
[edit protocols]
user@S-PE1# set bgp group mspw export next-hop-self
user@S-PE1# set bgp group mspw cluster 203.0.113.0
```

7. Assign local and neighbor addresses to the mspw group for S-PE1 to peer with T-PE1 and S-PE2.

```
[edit protocols]
user@S-PE1# set bgp group mspw local-address 10.255.2.1
user@S-PE1# set bgp group mspw neighbor 10.255.10.1 (to T-PE1)
user@S-PE1# set bgp group mspw neighbor 10.255.3.1 (to S-PE2)
```

8. Configure OSPF on all the interfaces of S-PE1, excluding the management interface.

```
[edit protocols]
user@S-PE1# set ospf area 0.0.0.0 interface all
user@S-PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@S-PE1# set ospf area 0.0.0.0 interface lo0.0
```

9. Configure LDP on all the interfaces of S-PE1, excluding the management interface.

```
[edit protocols]
user@S-PE1# set ldp interface all
user@S-PE1# set ldp interface fxp0.0 disable
user@S-PE1# set ldp interface lo0.0
```

10. Define the policy for enabling next-hop-self and accepting BGP traffic on S-PE1.

```
[edit policy-options]
user@S-PE1# set policy-statement next-hop-self then next-hop self
user@S-PE1# set policy-statement send-inet0 from protocol bgp
user@S-PE1# set policy-statement send-inet0 then accept
```

**Results** From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-instances**, **show routing-options**, and **show policy-options** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
T-PE1 user@T-PE1# show interfaces
ge-3/1/0 {
 unit 0 {
 family inet {
 address 192.0.2.1/24;
 }
 family mpls;
 }
}
ge-3/1/2 {
 encapsulation ethernet-ccc;
 unit 0;
}
lo0 {
 unit 0 {
 family inet {
 address 10.255.10.1/32 {
 primary;
 }
 }
 }
}

user@T-PE1# show routing-options
autonomous-system 100;

user@T-PE1# show protocols
mpls {
 interface all;
