Junos® OS Ethernet Interfaces Feature Guide for Routing Devices

The information in this document is current as of the date on the title page.

YEAR 2000 NOTICE

Juniper Networks hardware and software products are Year 2000 compliant. Junos OS has no known time-related limitations through the year 2038. However, the NTP application is known to have some difficulty in the year 2036.

About the Documentation

Documentation and Release Notes

To obtain the most current version of all Juniper Networks® technical documentation, see the product documentation page on the Juniper Networks website at https://www.juniper.net/documentation/.

If the information in the latest release notes differs from the information in the documentation, follow the product Release Notes.

Juniper Networks Books publishes books by Juniper Networks engineers and subject matter experts. These books go beyond the technical documentation to explore the nuances of network architecture, deployment, and administration. The current list can be viewed at https://www.juniper.net/books.

Supported Platforms

For the features described in this document, the following platforms are supported:

- ACX Series
- M Series
- MX Series
- T Series
- PTX Series

Using the Examples in This Manual

If you want to use the examples in this manual, you can use the **load merge** or the **load merge relative** command. These commands cause the software to merge the incoming configuration into the current candidate configuration. The example does not become active until you commit the candidate configuration.

If the example configuration contains the top level of the hierarchy (or multiple hierarchies), the example is a *full example*. In this case, use the **load merge** command.

If the example configuration does not start at the top level of the hierarchy, the example is a *snippet*. In this case, use the **load merge relative** command. These procedures are described in the following sections.

Merging a Full Example

To merge a full example, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration example into a text file, save the file with a name, and copy the file to a directory on your routing platform.

   For example, copy the following configuration to a file and name the file **ex-script.conf**. Copy the **ex-script.conf** file to the **/var/tmp** directory on your routing platform.

   ```
   system {
     scripts {
       commit {
         file ex-script.xsl;
       }
     }
   }
   interfaces {
     fxp0 {
       disable;
       unit 0 {
         family inet {
           address 10.0.0.1/24;
         }
       }
     }
   }
   ```

2. Merge the contents of the file into your routing platform configuration by issuing the **load merge** configuration mode command:

   ```
   [edit]
   user@host# load merge /var/tmp/ex-script.conf
   load complete
   ```

Merging a Snippet

To merge a snippet, follow these steps:

1. From the HTML or PDF version of the manual, copy a configuration snippet into a text file, save the file with a name, and copy the file to a directory on your routing platform.

For example, copy the following snippet to a file and name the file **ex-script-snippet.conf**. Copy the **ex-script-snippet.conf** file to the **/var/tmp** directory on your routing platform.

```
commit {
  file ex-script-snippet.xsl; }
```

2. Move to the hierarchy level that is relevant for this snippet by issuing the following configuration mode command:

```
[edit]
user@host# edit system scripts
[edit system scripts]
```

3. Merge the contents of the file into your routing platform configuration by issuing the **load merge relative** configuration mode command:

```
[edit system scripts]
user@host# load merge relative /var/tmp/ex-script-snippet.conf
load complete
```

For more information about the **load** command, see CLI Explorer.

Documentation Conventions

Table 1 on page xlix defines notice icons used in this guide.

Table 1: Notice Icons

Icon	Meaning	Description
	Informational note	Indicates important features or instructions.
	Caution	Indicates a situation that might result in loss of data or hardware damage.
	Warning	Alerts you to the risk of personal injury or death.
	Laser warning	Alerts you to the risk of personal injury from a laser.
	Tip	Indicates helpful information.
	Best practice	Alerts you to a recommended use or implementation.

Table 2 on page l defines the text and syntax conventions used in this guide.

Table 2: Text and Syntax Conventions

Convention	Description	Examples
Bold text like this	Represents text that you type.	To enter configuration mode, type the **configure** command: user@host> **configure**
`Fixed-width text like this`	Represents output that appears on the terminal screen.	`user@host>` **show chassis alarms** `No alarms currently active`
Italic text like this	• Introduces or emphasizes important new terms. • Identifies guide names. • Identifies RFC and Internet draft titles.	• A policy *term* is a named structure that defines match conditions and actions. • *Junos OS CLI User Guide* • RFC 1997, *BGP Communities Attribute*
Italic text like this	Represents variables (options for which you substitute a value) in commands or configuration statements.	Configure the machine's domain name: [edit] root@# **set system domain-name** *domain-name*
Text like this	Represents names of configuration statements, commands, files, and directories; configuration hierarchy levels; or labels on routing platform components.	• To configure a stub area, include the **stub** statement at the **[edit protocols ospf area area-id]** hierarchy level. • The console port is labeled **CONSOLE**.
< > (angle brackets)	Encloses optional keywords or variables.	**stub <default-metric *metric*>;**
| (pipe symbol)	Indicates a choice between the mutually exclusive keywords or variables on either side of the symbol. The set of choices is often enclosed in parentheses for clarity.	**broadcast | multicast** **(*string1* | *string2* | *string3*)**
# (pound sign)	Indicates a comment specified on the same line as the configuration statement to which it applies.	**rsvp { # Required for dynamic MPLS only**
[ ] (square brackets)	Encloses a variable for which you can substitute one or more values.	**community name members [*community-ids*]**

Indention and braces ({ })	Identifies a level in the configuration hierarchy.	[edit]
		routing-options {
		static {
		route default {
		nexthop *address*;
		retain;
		}
		}
		}

; (semicolon)	Identifies a leaf statement at a configuration hierarchy level.	

Table 2: Text and Syntax Conventions (continued)

Convention	Description	Examples
GUI Conventions		
Bold text like this	Represents graphical user interface (GUI) items you click or select.	• In the Logical Interfaces box, select **All Interfaces**. • To cancel the configuration, click **Cancel**.
> (bold right angle bracket)	Separates levels in a hierarchy of menu selections.	In the configuration editor hierarchy, select **Protocols>Ospf**.

Documentation Feedback

We encourage you to provide feedback, comments, and suggestions so that we can improve the documentation. You can provide feedback by using either of the following methods:

- Online feedback rating system—On any page of the Juniper Networks TechLibrary site at https://www.juniper.net/documentation/index.html, simply click the stars to rate the content, and use the pop-up form to provide us with information about your experience. Alternately, you can use the online feedback form at https://www.juniper.net/documentation/feedback/.
- E-mail—Send your comments to **techpubs-comments@juniper.net**. Include the document or topic name, URL or page number, and software version (if applicable).

Requesting Technical Support

Technical product support is available through the Juniper Networks Technical Assistance Center (JTAC). If you are a customer with an active J-Care or Partner Support Service support contract, or are covered under warranty, and need post-sales technical support, you can access our tools and resources online or open a case with JTAC.

- JTAC policies—For a complete understanding of our JTAC procedures and policies, review the *JTAC User Guide* located at https://www.juniper.net/us/en/local/pdf/resource-guides/7100059-en.pdf.
- Product warranties—For product warranty information, visit https://www.juniper.net/support/warranty/.
- JTAC hours of operation—The JTAC centers have resources available 24 hours a day, 7 days a week, 365 days a year.

Self-Help Online Tools and Resources

For quick and easy problem resolution, Juniper Networks has designed an online self-service portal called the Customer Support Center (CSC) that provides you with the following features:

- Find CSC offerings: https://www.juniper.net/customers/support/
- Search for known bugs: https://prsearch.juniper.net/
- Find product documentation: https://www.juniper.net/documentation/
- Find solutions and answer questions using our Knowledge Base: https://kb.juniper.net/
- Download the latest versions of software and review release notes: https://www.juniper.net/customers/csc/software/
- Search technical bulletins for relevant hardware and software notifications: https://kb.juniper.net/InfoCenter/
- Join and participate in the Juniper Networks Community Forum: https://www.juniper.net/company/communities/
- Open a case online in the CSC Case Management tool: https://www.juniper.net/cm/

To verify service entitlement by product serial number, use our Serial Number Entitlement (SNE) Tool: https://entitlementsearch.juniper.net/entitlementsearch/

Opening a Case with JTAC

You can open a case with JTAC on the Web or by telephone.

- Use the Case Management tool in the CSC at https://www.juniper.net/cm/.
- Call 1-888-314-JTAC (1-888-314-5822 toll-free in the USA, Canada, and Mexico).

For international or direct-dial options in countries without toll-free numbers, see https://www.juniper.net/support/requesting-support.html.

PART 1

Ethernet Interfaces

CHAPTER 1

Ethernet Interfaces Overview

Ethernet Interfaces Overview

Ethernet was developed in the early 1970s at the Xerox Palo Alto Research Center (PARC) as a data-link control layer protocol for interconnecting computers. It was first widely used at 10 megabits per second (Mbps) over coaxial cables and later over unshielded twisted pairs using 10Base-T. More recently, 100Base-TX (Fast Ethernet, 100 Mbps), Gigabit Ethernet (1 gigabit per second [Gbps]), 10-Gigabit Ethernet (10 Gbps), and 100-Gigabit Ethernet (100 Gbps) have become available.

Juniper Networks routers support the following types of Ethernet interfaces:

- Fast Ethernet
- Tri-Rate Ethernet copper
- Gigabit Ethernet
- Gigabit Ethernet intelligent queuing (IQ)
- Gigabit Ethernet IQ2 and IQ2-E
- 10-Gigabit Ethernet IQ2 and IQ2-E
- 10-Gigabit Ethernet
- 10-Gigabit Ethernet dense wavelength-division multiplexing (DWDM)
- 100-Gigabit Ethernet
- Management Ethernet interface, which is an out-of-band management interface within the router
- Internal Ethernet interface, which connects the Routing Engine to the packet forwarding components
- Aggregated Ethernet interface, a logical linkage of Fast Ethernet, Gigabit Ethernet, or 10-Gigabit Ethernet physical connections

MX Series Router Interface Identifiers

Juniper Networks MX Series 3D Universal Edge Routers support several types of line cards, including Dense Port Concentrators (DPCs), Flexible Port Concentrators (FPCs) with associated Physical Interface Cards (PICs), Modular Port Concentrators (MPCs) with associated Modular Interface Cards (MICs), or MICs. FPCs are populated with PICs for various interface types. DPCs and MPCs with associated MICs, and MICs support a variety of port configurations and combine the functions of FPCs and the PICs. The configuration syntax for each type of line card is the same: *type-fpc/pic/port*.

Ports are numbered from 0 through 9 for Gigabit Ethernet and Tri-Rate Ethernet copper interfaces. Port numbers are always 0 for 10-Gigabit Ethernet interfaces.

NOTE: In certain displays, the MX Series routers identify the Packet Forwarding Engine (PFE) rather than the PIC number. PFE 0 corresponds to PIC 0, PFE 1 corresponds to PIC 2, PFE 2 corresponds to PIC 1, and PFE 3 corresponds to PIC 3.

CHAPTER 2

Performing Initial Configuration for Ethernet Interfaces

Example: Configuring Fast Ethernet Interfaces

The following configuration is sufficient to get a Fast Ethernet interface up and running. By default, IPv4 Fast Ethernet interfaces use Ethernet version 2 encapsulation.

```
[edit]
user@host# set interfaces fe-5/2/1 unit 0 family inet address local-address
user@host# show
interfaces {
```

```
    fe-5/2/1 {
      unit 0 {
        family inet {
          address local-address;
        }
      }
    }
  }
```

Related Documentation

- *Ethernet Interfaces Feature Guide for Routing Devices*

Example: Configuring Gigabit Ethernet Interfaces

The following configuration is sufficient to get a Gigabit Ethernet, Tri-Rate Ethernet copper, or 10-Gigabit Ethernet interface up and running. By default, IPv4 Gigabit Ethernet interfaces on MX Series, M Series, and T Series routers use 802.3 encapsulation.

```
[edit]
user@host# set interfaces ge-2/0/1 unit 0 family inet address local-address
user@host# show
interfaces {
  ge-2/0/1 {
    unit 0 {
      family inet {
        address local-address;
      }
    }
  }
}
```

The M160, M320, M120, T320, and T640 2-port Gigabit Ethernet PIC supports two independent Gigabit Ethernet links.

Each of the two interfaces on the PIC is named:

ge-*fpc/pic/*[0.1]

Each of these interfaces has functionality identical to the Gigabit Ethernet interface supported on the single-port PIC.

Related Documentation

- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring Ethernet Physical Interface Properties

1. To configure Fast Ethernet-specific physical interface properties, include the **fastether-options** statement at the **[edit interfaces fe-*fpc/pic/port*]** hierarchy level:

   ```
   [edit interfaces fe-fpc/pic/port]
   user@host# set fastether-options;
   ```

NOTE: The **speed** statement applies to the management Ethernet interface (**fxp0** or **em0**), the Fast Ethernet 12-port and 48-port Physical Interface Card (PIC) interfaces and the MX Series Tri-Rate Ethernet copper interfaces. The Fast Ethernet, **fxp0**, and **em0** interfaces can be configured for 10 Mbps or 100 Mbps (**10m | 100m**). The MX Series Tri-Rate Ethernet copper interfaces can be configured for 10 Mbps, 100 Mbps, or 1 Gbps (**10m | 100m | 1g**). The 4-port and 8-port Fast Ethernet PICs support a speed of 100 Mbps only.

MX Series routers support Gigabit Ethernet automatic line sensing of MDI (Media Dependent Interface) and MDIX (Media Dependent Interface with Crossover) port connections. MDI is the Ethernet port connection typically used on network interface cards (NIC). MDIX is the standard Ethernet port wiring for hubs and switches. This feature allows MX Series routers to automatically detect MDI and MDIX connections and configure the router port accordingly. You can disable this feature by using the **no-auto-mdix** statement at the **[edit interfaces ge-*fpc/pic/port*]** hierarchy level.

NOTE: Junos OS supports Ethernet host addresses with no subnets. This enables you to configure an Ethernet interface as a host address (that is, with a network mask of /32), without requiring a subnet. Such interfaces can serve as OSPF point-to-point interfaces, and MPLS is also supported.

2. To configure physical interface properties specific to Gigabit Ethernet and 10-Gigabit Ethernet, include the **gigether-options** statement at the **[edit interfaces ge-*fpc/pic/port*]** or **[edit interfaces xe-*fpc/pic/port*]** hierarchy level:

   ```
   [edit interfaces ge-fpc/pic/port]
   user@host# set gigether-options ;
   ```

3. For 10-Gigabit Ethernet DWDM-specific physical interface properties, include the **optics-options** statement at the **[edit interfaces ge-*fpc/pic/port*]** hierarchy level:

   ```
   [edit interfaces ge-fpc/pic/port]
   user@ host# set optics-options;
   ```

   To configure Gigabit Ethernet IQ-specific physical interface properties, include the **gigether-options** statement at the **[edit interfaces ge-*fpc/pic/port*]** hierarchy level. These statements are supported on 10-Gigabit Ethernet IQ2 and IQ2-E PIC. Some of these statements are also supported on Gigabit Ethernet PICs with small form-factor pluggable transceivers (SFPs) (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router).

   ```
   [edit interfaces ge-fpc/pic/port]
   user@host# set gigether-options {
   ```

4. To configure 10-Gigabit Ethernet physical interface properties, include the **lan-phy** or **wan-phy** statement at the **[edit interfaces xe-*fpc/pic/port* framing]** hierarchy level.

   [edit interfaces *interface-name*]
   user@host# set framing;

5. To configure OAM 802.3ah support for Ethernet interfaces, include the **oam** statement at the **[edit protocols]** hierarchy level.

   [edit protocols]
   user@host# set oam;

6. To configure Gigabit Ethernet IQ-specific logical interface properties, include the **input-vlan-map**, **output-vlan-map**, **layer2-policer**, and **vlan-tags** statements at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level or **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**.

   [edit interfaces *interface-name* unit *logical-unit-number*]
   user#host# set input-vlan-map;
   user@host# set output-vlan-map;
   user#host# set layer2-policer{
   user@host# set vlan-tags inner *tpid.vlan-id* outer *tpid.vlan-id*;

7. To configure aggregated Ethernet-specific physical interface properties, include the **aggregated-ether-options** statement at the **[edit interfaces ae*x*]** hierarchy level:

   [edit interfaces ae*x*]
   user@host# set aggregated-ether-options;

Related Documentation

- 10-Gigabit Ethernet Framing Overview on page 427
- Example: Configuring Gigabit Ethernet Interfaces on page 6
- Ethernet Interfaces Overview on page 3
- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring the Interface Speed on Ethernet Interfaces

For M Series and T Series Fast Ethernet 12-port and 48-port PIC interfaces, the management Ethernet interface (**fxp0** or **em0**), and the MX Series Tri-Rate Ethernet copper interfaces, you can explicitly set the interface speed. The Fast Ethernet, **fxp0**, and **em0** interfaces can be configured for 10 Mbps or 100 Mbps **(10m | 100m)**. The MX Series Tri-Rate Ethernet copper interfaces can be configured for 10 Mbps, 100 Mbps, or 1 Gbps **(10m | 100m | 1g)**. For information about management Ethernet interfaces and to determine the management Ethernet interface type for your router, see *Understanding Management Ethernet Interfaces* and *Supported Routing Engines by Router*MX Series routers, with MX-DPC and Tri-Rate Copper SFPs, support 20x1 Copper to provide backwards compatibility with 100/10BASE-T and 1000BASE-T operation through an Serial Gigabit Media Independent Interface (SGMII) interface.

1. In configuration mode, go to the **[edit interfaces interface-name]** hierarchy level.

   ```
   [edit ]
   user@host# edit interfaces interface-name
   ```

2. To configure the speed, include the **speed** statement at the **[edit interfaces *interface-name*]** hierarchy level.

   ```
   [edit interfaces interface-name]
   user@host# set speed (10m | 100m | 1g | auto | auto-10m-100m);
   ```

NOTE:

- By default, the M Series and T Series routers management Ethernet interface autonegotiates whether to operate at 10 megabits per second (Mbps) or 100 Mbps. All other interfaces automatically choose the correct speed based on the PIC type and whether the PIC is configured to operate in multiplexed mode (using the **no-concatenate** statement in the **[edit chassis]** configuration hierarchy.
- Starting with Junos OS Release 14.2 the **auto-10m-100m** option allows the fixed tri-speed port to auto negotiate with ports limited by **100m** or **10m**maximum speed. This option must be enabled only for Tri-rate MPC port, that is, 3D 40x 1GE (LAN) RJ45 MIC on MX platform. This option does not support other MICs on MX platform.,
- When you manually configure Fast Ethernet interfaces on the M Series and T Series routers, link mode and speed must both be configured. If both these values are not configured, the router uses autonegotiation for the link and ignores the user-configured settings.
- If the link partner does not support autonegotiation, configure either Fast Ethernet port manually to match its link partner's speed and link mode. When the link mode is configured, autonegotiation is disabled.
- On MX Series routers with tri-rate copper SFP interfaces, if the port speed is negotiated to the configured value and the negotiated speed and interface speed do not match, the link will not be brought up.
- When you configure the Tri-Rate Ethernet copper interface to operate at 1 Gbps, autonegotiation must be enabled.
- Starting with Junos OS Release 11.4, half-duplex mode is not supported on Tri-Rate Ethernet copper interfaces. When you include the **speed** statement, you must include the **link-mode full-duplex** statement at the same hierarchy level.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2 the **auto-10m-100m** option allows the fixed tri-speed port to auto negotiate with ports limited by **100m** or **10m** maximum speed. This option must be enabled only for Tri-rate MPC port, that is, 3D 40x 1GE (LAN) RJ45 MIC on MX platform. This option does not support other MICs on MX platform.
11.4	Starting with Junos OS Release 11.4, half-duplex mode is not supported on Tri-Rate Ethernet copper interfaces. When you include the **speed** statement, you must include the **link-mode full-duplex** statement at the same hierarchy level.

Configuring the Ingress Rate Limit

On Fast Ethernet 8-port, 12-port, and 48-port PIC interfaces only, you can apply port-based rate limiting to the ingress traffic that arrives at the PIC.

To configure an ingress rate limit on a Fast Ethernet 8-port, 12-port, or 48-port PIC interface, include the **ingress-rate-limit** statement at the **[edit interfaces *interface-name* fastether-options]** hierarchy level:

[edit interfaces *interface-name* fastether-options]
ingress-rate-limit *rate*;

rate can range in value from 1 through 100 Mbps.

Understanding Flow Control

Flow control supports lossless transmission by regulating traffic flows to avoid dropping frames during periods of congestion. Flow control stops and resumes the transmission of network traffic between two connected peer nodes on a full-duplex Ethernet physical link. Controlling the flow by pausing and restarting it prevents buffers on the nodes from overflowing and dropping frames. You configure flow control on a per-interface basis.

By default, all forms of flow control are disabled. You must explicitly enable flow control on interfaces to pause traffic.

The MX, T, and PTX Series routers support IEEE 802.3X Ethernet PAUSE method of flow control.

• IEEE 802.3X Ethernet PAUSE on page 11

IEEE 802.3X Ethernet PAUSE

Ethernet PAUSE is a congestion relief feature that works by providing link-level flow control for all traffic on a full-duplex Ethernet link. Ethernet PAUSE works in both directions on the link. In one direction, an interface generates and sends Ethernet PAUSE messages to stop the connected peer from sending more traffic. In the other direction, the interface responds to Ethernet PAUSE messages it receives from the connected peer to stop sending traffic. Ethernet PAUSE also works on aggregated Ethernet interfaces. For example, if the connected peer interfaces are called Node A and Node B:

- When the receive buffers on interface Node A reach a certain level of fullness, the interface generates and sends an Ethernet PAUSE message to the connected peer (interface Node B) to tell the peer to stop sending frames. The Node B buffers store frames until the time period specified in the Ethernet PAUSE frame elapses; then Node B resumes sending frames to Node A.
- When interface Node A receives an Ethernet PAUSE message from interface Node B, interface Node A stops transmitting frames until the time period specified in the Ethernet PAUSE frame elapses; then Node A resumes transmission. (The Node A transmit buffers store frames until Node A resumes sending frames to Node B.)

  In this scenario, if Node B sends an Ethernet PAUSE frame with a time value of 0 to Node A, the 0 time value indicates to Node A that it can resume transmission. This happens when the Node B buffer empties to below a certain threshold and the buffer can once again accept traffic.

Symmetric Flow Control

Symmetric flow control configures both the receive and transmit buffers in the same state. The interface can both send Ethernet PAUSE messages and respond to them (flow control is enabled), or the interface cannot send Ethernet PAUSE messages or respond to them (flow control is disabled).

You configure symmetric flow control by including the **flow-control** statement at the **[edit interfaces *interface-name* ether-options]** hierarchy level.

When you enable symmetric flow control on an interface, the Ethernet PAUSE behavior depends on the configuration of the connected peer. With symmetric flow control enabled, the interface can perform any Ethernet PAUSE functions that the connected peer can perform. (When symmetric flow control is disabled, the interface does not send or respond to Ethernet PAUSE messages.)

Related Documentation

- **flow-control on page 1170**
- Configuring Flow Control on page 12

Configuring Flow Control

By default, the router or switch imposes flow control to regulate the amount of traffic sent out on a Fast Ethernet, Tri-Rate Ethernet copper, Gigabit Ethernet, and 10-Gigabit Ethernet interface. Flow control is not supported on the 4-port Fast Ethernet PIC. This is useful if the remote side of the connection is a Fast Ethernet or Gigabit Ethernet switch.

You can disable flow control if you want the router or switch to permit unrestricted traffic. To disable flow control, include the **no-flow-control** statement:

```
no-flow-control;
```

To explicitly reinstate flow control, include the **flow-control** statement:

```
flow-control;
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name* aggregated-ether-options]
- [edit interfaces *interface-name* ether-options]
- [edit interfaces *interface-name* fastether-options]
- [edit interfaces *interface-name* gigether-options]

NOTE: On the Type 5 FPC, to prioritize control packets in case of ingress oversubscription, you must ensure that the neighboring peers support MAC flow control. If the peers do not support MAC flow control, then you must disable flow control.

Configuring the Link Characteristics on Ethernet Interfaces

Full-duplex communication means that both ends of the communication can send and receive signals at the same time. *Half-duplex* is also bidirectional communication, but signals can flow in only one direction at a time.

By default, the router's management Ethernet interface, **fxp0** or **em0**, autonegotiates whether to operate in full-duplex or half-duplex mode. Fast Ethernet interfaces, can operate in either full-duplex or half-duplex mode, and all other interfaces can operate only in full-duplex mode. For Gigabit Ethernet and 10-Gigabit Ethernet, the link partner must also be set to full duplex.

NOTE: For M Series, MX Series, and most T Series routers, the management Ethernet interface is **fxp0**. For T1600 and T4000 routers configured in a routing matrix, and TX Matrix Plus routers, the management Ethernet interface is **em0**.

NOTE: Automated scripts that you have developed for standalone T1600 routers (T1600 routers that are not in a routing matrix) might contain references to the **fxp0** management Ethernet interface. Before reusing the scripts on T1600 routers in a routing matrix, edit the command lines that reference the **fxp0** management Ethernet interface so that the commands reference the **em0** management Ethernet interface instead.

NOTE: When you configure the Tri-Rate Ethernet copper interface to operate at 1 Gbps, autonegotiation must be enabled.

NOTE: When you manually configure Fast Ethernet interfaces on the M Series and T Series routers, link mode and speed must both be configured. If both these values are not configured, the router uses autonegotiation for the link and ignores the user-configured settings.

NOTE: Member links of an aggregated Ethernet bundle must not be explicitly configured with a link mode. You must remove any such link-mode configuration before committing the aggregated Ethernet configuration.

To explicitly configure an Ethernet interface to operate in either full-duplex or half-duplex mode, include the **link-mode** statement at the **[edit interfaces *interface-name*]** hierarchy level:

[edit interfaces *interface-name*]

link-mode (full-duplex | half-duplex);

NOTE: Starting with Junos OS release 17.4R1 and later, the **link-mode** configuration is not supported for 10-Gigabit Ethernet interfaces.

Configuring MAC Address Filtering for Ethernet Interfaces

Enabling Source Address Filtering

On aggregated Ethernet interfaces, Fast Ethernet, Gigabit Ethernet, Gigabit Ethernet IQ, and Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), you can enable source address filtering to block all incoming packets from a specific MAC address.

To enable the filtering, include the **source-filtering** statement at the following hierarchy levels:

- **[edit interfaces *interface-name* aggregated-ether-options]**
- **[edit interfaces *interface-name* fastether-options]**
- **[edit interfaces *interface-name* gigether-options]**

NOTE: When you integrate a standalone T640 router into a routing matrix, the PIC media access control (MAC) addresses for the integrated T640 router are derived from a pool of MAC addresses maintained by the TX Matrix router. For each MAC address you specify in the configuration of a formerly standalone T640 router, you must specify the same MAC address in the configuration of the TX Matrix router.

Similarly, when you integrate a T1600 or T4000 router into a routing matrix, the PIC MAC addresses for the integrated T1600 or T4000 router are derived from a pool of MAC addresses maintained by the TX Matrix Plus router. For each MAC address you specify in the configuration of a formerly standalone T1600 or T4000 router, you must specify the same MAC address in the configuration of the TX Matrix Plus router.

When source address filtering is enabled, you can configure the interface to receive packets from specific MAC addresses. To do this, specify the MAC addresses in the **source-address-filter *mac-address*** statement at the following hierarchy levels:

- **[edit interfaces *interface-name* aggregated-ether-options]**
- **[edit interfaces *interface-name* fastether-options]**
- **[edit interfaces *interface-name* gigether-options]**

You can specify the MAC address as ***nn*:*nn*:*nn*:*nn*:*nn*:*nn*** or ***nnnn* .*nnnn*.*nnnn***, where **n** is a hexadecimal number. You can configure up to 64 source addresses. To specify more than one address, include the **source-address-filter** statement multiple times.

NOTE: The **source-address-filter** statement is not supported on Gigabit Ethernet IQ and Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router); instead, include the **accept-source-mac** statement. For more information, see "Configuring MAC Address Filtering" on page 544.

If the remote Ethernet card is changed, the interface cannot receive packets from the new card because it has a different MAC address.

Source address filtering does not work when Link Aggregation Control Protocol (LACP) is enabled. This behavior is not applicable to T series routers and PTX Series Packet Transport Routers. For more information about LACP, see "Configuring LACP for Aggregated Ethernet Interfaces" on page 140.

NOTE: On untagged Gigabit Ethernet interfaces, you should not configure the **source-address-filter** statement at the **[edit interfaces ge-*fpc/pic/port* gigether-options]** hierarchy level and the **accept-source-mac** statement at the **[edit interfaces ge-*fpc/pic/port* gigether-options unit *logical-unit-number*]** hierarchy level simultaneously. If these statements are configured for the same interfaces at the same time, an error message is displayed.

On tagged Gigabit Ethernet interfaces, you should not configure the **source-address-filter** statement at the [edit interfaces **[edit interfaces ge-*fpc/pic/port* gigether-options]** hierarchy level and the **accept-source-mac** statement at the **[edit interfaces ge-*fpc/pic/port* gigether-options unit *logical-unit-number*]** hierarchy level with an identical MAC address specified in both filters. If these statements are configured for the same interfaces with an identical MAC address specified, an error message is displayed.

NOTE: The **source-address-filter** statement is not supported on MX Series routers with MPC4E (model numbers: MPC4E-3D-32XGE-SFPP and MPC4E-3D-2CGE-8XGE); instead, include the **accept-source-mac** statement. For more information, see "Configuring MAC Address Filtering" on page 544.

Configuring MAC Address Filtering on PTX Series Packet Transport Routers

This topic describes how to configure MAC filtering on PTX Series Packet Transport Routers. MAC filtering enables you to specify the MAC addresses from which the Ethernet interface can receive packets.

MAC filtering support on PTX Series Packet Transport Routers includes:

- MAC source and destination address filtering for each port.
- MAC source address filtering for each physical interface.
- MAC source address filtering for each logical interface.

When you filter logical and physical interfaces, you can specify up to 1000 MAC source addresses per port.

To configure MAC source address filtering for a physical interface, include the **source-filtering** and **source-address-filter** statements at the **[edit interfaces et-*fpc/pic/port* gigether-options]** hierarchy level:

```
[edit interfaces]
et-x/y/z {
  gigether-options {
    source-filtering;
    source-address-filter {
      mac-address;
    }
  }
}
```

The **source-address-filter** statement configures which MAC source addresses are filtered. The specified physical interface drops all packets from the MAC source addresses you specify. You can specify the MAC address as ***nn:nn:nn:nn:nn:nn*** where ***n*** is a decimal digit. To specify more than one address, include multiple ***mac-address*** options in the **source-address-filter** statement.

To configure MAC source address filtering for a logical interface, include the **accept-source-mac** statement at the **[edit interfaces et-*fpc/pic/port* unit *logical-unit-number*]** hierarchy level:

```
[edit interfaces]
et-x/y/z {
  gigether-options {
    source-filtering;
  }
  unit logical-unit-number {
```

```
      accept-source-mac {
        mac-address mac-address;
      }
    }
  }
```

The **accept-source-mac** statement configures which MAC source addresses are accepted on the logical interface. You can specify the MAC address as ***nn:nn:nn:nn:nn:nn*** where ***n*** is a decimal digit. To specify more than one address, include multiple **mac-address *mac-address*** options in the **accept-source-mac** statement.

After an interface filter is configured, there is an accounting entry that is associated with the MAC address filter. Counters accumulate if there are packets with matching MAC source addresses. You can use the **show interfaces mac-database** Junos OS CLI command to view the address count.

MAC Address Accounting for Dynamically Learned Addresses on Aggregated Ethernet Interfaces Overview

Junos OS supports the capability to compute MAC address statistics for dynamically learned static and destination MAC addresses on physical interfaces. Starting in Junos OS Release 15.1, Junos OS enables you to configure source MAC (SMAC) address and destination MAC (DMAC) address-based accounting for MAC addresses that are dynamically learned on aggregated Ethernet (ae-) interfaces in routed mode. When you include the **mac-learn-enable** statement at the **[edit interfaces ae*x* aggregated-ether-options ethernet-switch-profile]** hierarchy level, dynamic learning of source and destination MAC addresses is enabled. By default, this capability is disabled. When dynamic learning of MAC addresses is enabled for AE interfaces in routed mode, the MAC-filter settings are updated for each of the child links of the AE bundle interface. This feature provides for both the configuration of the mac-learn-enable filter and the display of SMAC and DMAC based accounting information on the aggregated interface in the output of the **show interfaces mac-database *interface-name* mac-address *mac-address*** command.

When this functionality is enabled, source and destination MAC addresses-based accounting is supported on the routed interfaces on MX Series routers with DPCs and MPCs. Support for mixed mode LAG interfaces is also available. This feature supports MAC address accounting for AE interfaces in routed mode (for inet family). Destination MAC-based accounting is supported only for MAC addresses dynamically learned at the ingress interface, including each individual child or member link of the AE bundle. This behavior occurs because MPCs do not support destination MAC address learning. As a result, if a packet exits a child link without passing in the ingress direction through that link, destination MAC (DMAC) accounting for this packet occurs at the child link level and this data is not available at the aggregate level. Dynamic learning of MAC addresses can be supported on only the AE interface or on selective individual member links. MAC learning support on the bundle depends on the capability of individual member links. If a link in the bundle does not contain the capability to support MAC learning or accounting, it is disabled on the AE bundle.

The MAC data for the aggregated bundle is displayed by collecting data form individual child links. This data is collected when the command to display the MAC database is triggered from the CLI. This method of data collection implies that based on the number of child links and the size of the MAC database, the time take to display the database differs. This approach to obtain the current snapshot of the MAC database from the currently active child links is used instead of maintaining a database at the Routing Engine because of the dynamic nature of the MAC database and the overhead required to maintain the database information in synchronization with all the child Packet Forwarding Engines. A difference in the DMAC-based accounting for packets generated from the Routing Engine (packets sent in the host path). On DPCs, these packets are accounted in egress direction (Output Packet/Byte count), whereas on MPCs, these packets are not accounted because DMAC learning is not supported. This difference in behavior also occurs between child links on DPCs and MPCs. Because this feature to enable dynamic learning is related to collecting MAC database statistics from child links based on the command issued from the CLI, there is a impact on the time it takes to display the data on the console based on the size of the MAC database and the number of child-links spread across different FPCs. The limit on the maximum number of MAC addresses that can be learned from an interface does not apply to this dynamic learning of MAC addresses functionality.

Release History Table

Release	Description
15.1	Starting in Junos OS Release 15.1, Junos OS enables you to configure source MAC (SMAC) address and destination MAC (DMAC) address-based accounting for MAC addresses that are dynamically learned on aggregated Ethernet (ae-) interfaces in routed mode.

Configuring Ethernet Loopback Capability

By default, local aggregated Ethernet, Fast Ethernet, Tri-Rate Ethernet copper, Gigabit Ethernet, and 10-Gigabit Ethernet interfaces connect to a remote system. To place an interface in loopback mode, include the **loopback** statement:

```
loopback;
```

NOTE: If you configure a local loopback on a 1-port 10-Gigabit IQ2 and IQ2-E PIC using the **loopback** statement at the **[edit interfaces *interface-name* gigether-options]** hierarchy level, the transmit-path stops working, causing the remote end to detect a link down.

To return to the default—that is, to disable loopback mode—delete the **loopback** statement from the configuration:

```
[edit]
user@host# delete interfaces fe-fpc/pic/port fastether-options loopback
```

To explicitly disable loopback mode, include the **no-loopback** statement:

```
no-loopback;
```

You can include the **loopback** and **no-loopback** statements at the following hierarchy levels:

- **[edit interfaces *interface-name* aggregated-ether-options]**
- **[edit interfaces *interface-name* ether-options]**
- **[edit interfaces *interface-name* fastether-options]**
- **[edit interfaces *interface-name* gigether-options]**

Related Documentation

Ignoring Layer 3 Incomplete Errors

By default, Fast Ethernet, Gigabit Ethernet, and 10-Gigabit Ethernet interfaces count Layer 3 incomplete errors. You can configure the interface to ignore Layer 3 incomplete errors.

To ignore Layer 3 incomplete errors, include the **ignore-l3-incompletes** statement:

```
ignore-l3-incompletes;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* fastether-options]**
- **[edit interfaces *interface-name* gigether-options]**

Configuring Gratuitous ARP

Gratuitous Address Resolution Protocol (ARP) requests help detect duplicate IP addresses. A gratuitous ARP is a broadcast request for a router's own IP address. If a router or switch sends an ARP request for its own IP address and no ARP replies are received, the router- or switch-assigned IP address is not being used by other nodes.

However, if a router or switch sends an ARP request for its own IP address and an ARP reply is received, the router- or switch-assigned IP address is already being used by another node.

Gratuitous ARP replies are reply packets sent to the broadcast MAC address with the target IP address set to be the same as the sender's IP address. When the router or switch receives a gratuitous ARP reply, the router or switch can insert an entry for that reply in the ARP cache. By default, updating the ARP cache on gratuitous ARP replies is disabled on the router or switch.

To enable updating of the ARP cache for gratuitous ARPs:

1. In configuration mode, go to the **[edit interfaces interface-name]** hierarchy level.

   ```
   [edit]
   user@host# edit interfaces interface-name
   ```

2. Include the **gratuitous-arp-reply** statement.

   ```
   [edit interfaces interface-name]
   user@host# set gratuitous-arp-reply
   ```

To restore the default behavior, that is, to disable updating of the ARP cache for gratuitous ARP, delete the **gratuitous-arp-reply** statement from the configuration:

```
[edit interfaces interface-name]
user@host# delete gratuitous-arp-reply;
```

By default, the router or switch responds to gratuitous ARP requests. However, on Ethernet interfaces, you can disable responses to gratuitous ARP requests.

To disable responses to gratuitous ARP requests:

1. In configuration mode, go to the **[edit interfaces interface-name]** hierarchy level.

   ```
   [edit]
   user@host# edit interfaces interface-name
   ```

2. Include the **no-gratuitous-arp-request** statement.

   ```
   [edit interfaces interface-name]
   user@host# set no-gratuitous-arp-request
   ```

To return to the default—that is, to respond to gratuitous ARP requests—delete the **no-gratuitous-arp-request** statement from the configuration:

```
[edit interfaces interface-name]
user@host# delete no-gratuitous-arp-request
```

Adjusting the ARP Aging Timer

By default, the ARP aging timer is set at 20 minutes. In environments with many directly attached hosts, such as metro Ethernet environments, increasing the amount of time between ARP updates by configuring the ARP aging timer can improve performance in an event where having thousands of clients time out at the same time might impact packet forwarding performance. In environments where there are devices connected with lower ARP aging timers (less than 20 minutes), decreasing the ARP aging timer can improve performance by preventing the flooding of traffic toward next hops with expired ARP entries. In most environments, the default ARP aging timer value does not need to be adjusted.

To configure the system-wide ARP aging timer, include the **aging-timer** statement at the **[edit system arp]** hierarchy level:

```
[edit system arp]
user@host# aging-timer minutes
```

The aging timer range is from 1 through 240 minutes. The timer value you configure takes effect as ARP entries expire. In other words, each subsequent refreshed ARP entry receives the new timer value. The new timer value does not apply to ARP entries that exist at the time you commit the configuration.

For more information about statements you can configure at the **[edit system]** hierarchy level, see the *Junos OS Administration Library*.

Configuring Weighted Random Early Detection

On M7i, M10i, M40e, M320, M120, and T Series routers, the Ethernet IQ2 and IQ2-E PIC families extend CoS functionality by supporting network congestion avoidance with weighted random early detection (WRED).

Related Documentation

- For information on configuring WRED, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

Configuring Multicast Statistics Collection on Ethernet Interfaces

T Series and TX Matrix routers support multicast statistics collection on Ethernet interfaces in both ingress and egress directions. The multicast statistics functionality can be configured on a physical interface thus enabling multicast accounting for all the logical interfaces below the physical interface.

The multicast statistics information is displayed only when the interface is configured with the **multicast-statistics** statement, which is not enabled by default.

Multicast statistics collection requires at least one logical interface is configured with family inet and/or inet6; otherwise, the commit for **multicast-statistics** will fail.

The multicast in/out statistics can be obtained via interfaces statistics query through CLI and via MIB objects through SNMP query.

To configure multicast statistics:

1. Include the **multicast-statistics** statement at the **[edit interfaces interface-name]** hierarchy level.

An example of a multicast statistics configuration for a Ethernet interface follows:

```
[edit interfaces]
  ge-fpc/pic/port {
  multicast-statistics;
}
```

To display multicast statistics, use the **show interfaces** ***interface-name*** **statistics detail** command.

Displaying Internal Ethernet Interfaces for a Routing Matrix with a TX Matrix Plus Router

The router internal Ethernet interface connects the Routing Engine with the router's packet forwarding components. The Junos OS automatically configures internal Ethernet interfaces. For TX Matrix Plus routers, the internal Ethernet interfaces are **ixgbe0** and **ixgbe1**. For T1600 routers configured in a routing matrix, the internal Ethernet interfaces are **bcm0** and **em1**. For more information about internal Ethernet interfaces, see *Understanding Internal Ethernet Interfaces*.

NOTE: Do not modify or remove the configuration for the internal Ethernet interface that the Junos OS automatically configures. If you do, the router will stop functioning.

The following example is a sequence of **show interfaces** commands issued in a Junos OS command-line interface (CLI) session with a TX Matrix Plus router in a routing matrix. In the example, the TX Matrix Plus router, which is also called the switch-fabric chassis (SFC), is known by the IP host name **host-sfc-0** and contains redundant Routing Engines. The commands display information about the management Ethernet interface and both internal Ethernet interfaces configured on the Routing Engine to which you are currently logged in:

```
user@host-sfc-0> show interfaces em0 terse
Interface               Admin Link Proto    Local                 Remote
em0                     up    up
em0.0                   up    up   inet     192.168.35.95/24

user@host-sfc-0> show interfaces ixgbe0 terse
Interface               Admin Link Proto    Local                 Remote
ixgbe0                  up    up
ixgbe0.0                up    up   inet     10.34.0.4/8
                                            162.0.0.4/2
                                   inet6    fe80::200:ff:fe22:4/64
                                            fec0::a:22:0:4/64
                                   tnp      0x22000004

user@host-sfc-0> show interfaces ixgbe1 terse
Interface               Admin Link Proto    Local                 Remote
ixgbe1                  up    up
ixgbe1.0                up    up   inet     10.34.0.4/8
                                            162.0.0.4/2
                                   inet6    fe80::200:1ff:fe22:4/64
                                            fec0::a:22:0:4/64
                                   tnp      0x22000004
```

The following example is a sequence of **show interfaces** commands issued in a CLI session with a T1600 router in a routing matrix. In the example, the T1600 router, which is also called the line-card chassis (LCC), is known by the IP host name **host-sfc-0-lcc-2** and contains redundant Routing Engines.

This T1600 router is connected to the routing matrix through a connection in the TXP-SIB-F13 in slot 2 of the SCC. The commands display information about the management Ethernet interface and both internal Ethernet interfaces configured on the Routing Engine to which you are currently logged in:

NOTE: In a routing matrix, the **show interfaces** command displays information about the current router only. If you are logged in to the TX Matrix Plus router, the **show interfaces** command output does not include information about any of the attached T1600 routers. To display interface information about a specific T1600 router in the routing matrix, you must first log in to that router.

The previous example shows a CLI session with the TX Matrix Plus router. To display interface information about the T1600 router known as **host-sfc-0-lcc-2**, first use the **request routing-engine login** command to log in to that LCC.

```
user@host-sfc-0> request routing-engine login lcc 2

CHAPTER 3

Configuring the Management Ethernet Interface

Management Ethernet Interface Overview

The router's management Ethernet interface, **fxp0** or **em0**, is an out-of-band management interface that needs to be configured only if you want to connect to the router through the management port on the front of the router. You can configure an IP address and prefix length for this interface, which you commonly do when you first install the Junos OS:

```
[edit]
user@host# set interfaces (fxp0 | em0) unit 0 family inet address/prefix-length
[edit]
user@host# show
interfaces {
    (fxp0 | em0) {
        unit 0 {
            family inet {
                address/prefix-length;
            }
        }
    }
}
```

To determine which management interface type is supported on a router, locate the router and Routing Engine combination in *Supported Routing Engines by Router* and note its management Ethernet interface type, either **em0** or **fxp0**.

Related Documentation

- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring a Consistent Management IP Address

On routers with multiple Routing Engines, each Routing Engine is configured with a separate IP address for the management Ethernet interface. To access the master Routing Engine, you must know which Routing Engine is active and use the appropriate IP address.

Optionally, for consistent access to the master Routing Engine, you can configure an additional IP address and use this address for the management interface regardless of which Routing Engine is active. This additional IP address is active only on the management Ethernet interface for the master Routing Engine. During switchover, the address moves to the new master Routing Engine.

NOTE: For M Series, MX Series, and most T Series routers, the management Ethernet interface is **fxp0**. For TX Matrix Plus routers and T1600 or T4000 routers configured in a routing matrix, the management Ethernet interface is **em0**.

NOTE: Automated scripts that you have developed for standalone T1600 routers (T1600 routers that are not in a routing matrix) might contain references to the **fxp0** management Ethernet interface. Before reusing the scripts on T1600 routers in a routing matrix, edit the command lines that reference the **fxp0** management Ethernet interface so that the commands reference the **em0** management Ethernet interface instead.

To configure an additional IP address for the management Ethernet interface, include the **master-only** statement at the **[edit groups]** hierarchy level.

In the following example, IP address **10.17.40.131** is configured for both Routing Engines and includes a **master-only** statement. With this configuration, the **10.17.40.131** address is active only on the master Routing Engine. The address remains consistent regardless of which Routing Engine is active. IP address **10.17.40.132** is assigned to **fxp0** on **re0**, and address **10.17.40.133** is assigned to **fxp0** on **re1**.

```
[edit groups re0 interfaces fxp0]
unit 0 {
  family inet {
    address 10.17.40.131/25 {
      master-only;
    }
    address 10.17.40.132/25;
  }
}
[edit groups re1 interfaces fxp0]
unit 0 {
  family inet {
    address 10.17.40.131/25 {
      master-only;
    }
```

```
        address 10.17.40.133/25;
      }
    }
```

This feature is available on all routers that include dual Routing Engines. On the TX Matrix router, this feature is applicable to the switch-card chassis (SCC) only.

- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring the MAC Address on the Management Ethernet Interface

By default, the router's management Ethernet interface uses as its MAC address the MAC address that is burned into the Ethernet card.

NOTE: For M Series, MX Series, and most T Series routers, the management Ethernet interface is **fxp0**. For TX Matrix Plus routers and T1600 routers configured in a routing matrix, and TX Matrix Plus routers with 3D SIBs, T1600 routers, and T4000 routers configured in a routing matrix, the management Ethernet interface is **em0**.

NOTE: Automated scripts that you have developed for standalone T1600 routers (T1600 routers that are not in a routing matrix) might contain references to the **fxp0** management Ethernet interface. Before reusing the scripts on T1600 routers in a routing matrix, edit the command lines that reference the **fxp0** management Ethernet interface so that the commands reference the **em0** management Ethernet interface instead.

To display the MAC address used by the router's management Ethernet interface, enter the **show interface fxp0** or **show interface em0** operational mode command.

To change the management Ethernet interface's MAC address, include the **mac** statement at the **[edit interfaces fxp0]** or **[edit interfaces em0]** hierarchy level:

```
[edit interfaces (fxp0 | em0)]
mac mac-address;
```

Specify the MAC address as six hexadecimal bytes in one of the following formats: ***nnnn.nnnn.nnnn*** (for example, **0011.2233.4455**) or ***nn:nn:nn:nn:nn:nn*** (for example, **00:11:22:33:44:55**).

NOTE: If you integrate a standalone T640 router into a routing matrix, the PIC MAC addresses for the integrated T640 router are derived from a pool of MAC addresses maintained by the TX Matrix router. For each MAC address you specify in the configuration of a formerly standalone T640 router, you must specify the same MAC address in the configuration of the TX Matrix router.

Similarly, if you integrate a standalone T1600 router into a routing matrix, the PIC MAC addresses for the integrated T1600 router are derived from a pool of MAC addresses maintained by the TX Matrix Plus router. For each MAC address you specify in the configuration of a formerly standalone T1600 router, you must specify the same MAC address in the configuration of the TX Matrix Plus router.

CHAPTER 4

Enabling Passive Monitoring on Ethernet Interfaces

Passive Monitoring on Ethernet Interfaces Overview

The Monitoring Services I and Monitoring Services II PICs are designed to enable IP services. You can monitor IPv4 traffic if you have a Monitoring Services PIC installed in the router with the following PICs:

- 10-port Gigabit Ethernet PIC with SFPs
- 4-port Gigabit Ethernet PIC with SFPs
- 2-port Gigabit Ethernet PIC with SFPs
- 1-port 10-Gigabit Ethernet PIC

NOTE: The PICs in the preceding list support only IPv4.

NOTE: Starting with Junos OS Release 9.5, I2.0 based M120 routers and I3.0 based M320 routers with the PICs in the preceding list support passive monitoring. Other M Series and T Series routers with the PICs listed above started supporting passive monitoring before Junos OS Release 7.3. Support for 1-port 10-Gigabit Ethernet PIC with XENPAK on I2.0-based M120 routers and I3.0-based M320 routers was added in Junos OS Release 9.5.

- 4-port 10-Gigabit Ethernet LAN/WAN PIC with XFP (T640, T1600, and T4000 Core Routers) (supported on both WAN-PHY and LAN-PHY modes for both IPv4 and IPv6 addresses)

The following interfaces support passive monitoring on the I3.0-based MX 240, MX 480, and MX 960 routers, starting with Junos OS Release 8.5:

- Type 2 MX FPCs
- Type 3 MX FPCs
- Gigabit Ethernet Enhanced DPC with SFP (DPCE-R-40GE-SFP)
- 4-port 10-Gigabit Ethernet Enhanced DPCs with XFP (DPCE-R-4XGE-XFP)

The following interfaces support passive monitoring on the Trio-based MX 240, MX 480, and MX 960 routers:

- 10-Gigabit Ethernet MPC with SFP+
- 30-Gigabit Ethernet MPC
- 60-Gigabit Ethernet MPC

Passive monitoring is also supported on MX 80 routers with 10-Gigabit Ethernet MPC with SFP+ and 30-Gigabit Ethernet MPC interfaces.

Interfaces configured on the following FPCs and PIC support IPv6 passive monitoring on the T640, T1600, and T4000 routers:

- Enhanced Scaling FPC2
- Enhanced Scaling FPC3
- Enhanced Scaling FPC4
- Enhanced Scaling FPC4.1
- Enhanced II FPC1 (T640 and T1600 routers)
- Enhanced II FPC2 (T640 and T1600 routers)
- Enhanced II FPC3 (T640 and T1600 routers)
- 4-port 10-Gigabit Ethernet LAN/WAN PIC with XFP (supported on both WAN-PHY and LAN-PHY modes for both IPv4 and IPv6 addresses)
- Gigabit Ethernet PIC with SFP
- 10-Gigabit Ethernet PIC with XENPAK (T640 and T1600 routers)
- SONET/SDH OC192/STM64 PICs with XFP (T1600 and T4000 routers)
- SONET/SDH OC48c/STM16 PIC with SFP
- SONET/SDH OC12/STM4 (Multi-Rate) PIC with SFP (T1600 router)
- Type 1 SONET/SDH OC3/STM1 (Multi-Rate) PIC with SFP (T1600 router)

NOTE: **Unlike IPv4 passive monitoring, IPv6 passive monitoring is not supported on Monitoring Services PICs. You must configure port mirroring to forward the packets from the passive monitored ports to other interfaces.**

Release History Table

Release	Description
9.5	Starting with Junos OS Release 9.5, I2.0 based M120 routers and I3.0 based M320 routers with the PICs in the preceding list support passive monitoring.

Related Documentation

- *Ethernet Interfaces Feature Guide for Routing Devices*

Enabling Passive Monitoring on Ethernet Interfaces

When you configure an interface in passive monitoring mode, the Packet Forwarding Engine silently drops packets coming from that interface and destined to the router itself. Passive monitoring mode also stops the Routing Engine from transmitting any packet from that interface. Packets received from the monitored interface can be forwarded to monitoring interfaces. If you include the **passive-monitor-mode** statement in the configuration:

- Gigabit and Fast Ethernet interfaces can support both per-port passive monitoring and per-VLAN passive monitoring. The destination MAC filter on the receive port of the Ethernet interfaces is disabled.
- Ethernet encapsulation options are not allowed.
- Ethernet interfaces do not support the **stacked-vlan-tagging** statement for both IPv4 and IPv6 packets in passive monitor mode.

To enable packet flow monitoring on Ethernet interfaces:

1. In configuration mode, go to the **[edit interfaces interface-name]** hierarchy level.

   ```
   [edit]
   user@host# edit interfaces interface-name
   ```

2. Include the **passive-monitor-mode** statement.

   ```
   [edit interfaces interface-name]
   user@host# set passive-monitor-mode
   ```

For IPv4 monitoring services interfaces, enable packet flow monitoring by including the **family** statement at the **[edit interfaces mo-*fpc/pic/port* unit *logical-unit-number*]** hierarchy level, specifying the **inet** option:

1. In configuration mode, go to the **[edit interfaces mo-fpc/pic/port unit logical-unit-number]** hierarchy level.

   ```
   [edit]
   user@host# edit interfaces mo-fpc/pic/port unit logical-unit-number
   ```

2. Include the **passive-monitor-mode** statement.

   ```
   [edit interfaces mo-fpc/pic/port unit logical-unit-number]
   ```

```
user@host# set family inet
```

For conformity with the cflowd record structure, you must include the **receive-options-packets** and **receive-ttl-exceeded** statements at the **[edit interfaces mo-*fpc/pic/port* unit *logical-unit-number* family inet]** hierarchy level:

1. In configuration mode, go to the **[edit interfaces mo-fpc/pic/port unit logical-unit-number family inet]** hierarchy level.

   ```
   [edit]
   user@host# edit interfaces mo-fpc/pic/port unit logical-unit-number family inet
   ```

2. Include the **receive-options-packets** and **receive-ttl-exceeded** statements.

   ```
   [edit interfaces mo-fpc/pic/port unit logical-unit-number family inet]
   user@host# set receive-options-packets
   user@host# set receive-ttl-exceeded
   ```

IPv6 passive monitoring is not supported on monitoring services PICs. A user must configure port mirroring to forward the packets from the passive monitored ports to other interfaces.

For information on FPCs and PICs that support IPv6 passive monitoring on the T640, T1600, and T4000 routers, see "Passive Monitoring on Ethernet Interfaces Overview" on page 29. Interfaces configured on these FPCs and PICs support IPv6 passive monitoring.

To configure port mirroring, include the **port-mirroring** statement at the **[edit forwarding-options]** hierarchy level.

For the monitoring services interface, you can configure multiservice physical interface properties. For more information, see *Configuring Multiservice Physical Interface Properties* and the *Junos OS Services Interfaces Library for Routing Devices*.

CHAPTER 5

Configuring IEEE 802.1x Port-Based Network Access Control

IEEE 802.1x Port-Based Network Access Control Overview

MX Series routers support the IEEE 802.1x Port-Based Network Access Control (dot1x) protocol on Ethernet interfaces for validation of client and user credentials to prevent unauthorized access to a specified router port. Before authentication is complete, only 802.1x control packets are allowed and forwarded to the router control plane for processing. All other packets are dropped.

Authentication methods used must be 802.1x compliant. Authentication using RADIUS and Microsoft Active Directory servers is supported. The following user/client authentication methods are allowed:

- EAP-MD5 (RFC 3748)
- EAP-TTLS requires a server certificate (RFC 2716)
- EAP-TLS requires a client and server certificate
- PEAP requires only a server certificate

You can use both client and server certificates in all types of authentication except EAP-MD5.

NOTE: On the MX Series router, 802.1x can be enabled on bridged ports only and not on routed ports.

Dynamic changes to a user session are supported to allow the router administrator to terminate an already authenticated session by using the “RADIUS disconnect” message defined in RFC 3576.

Understanding the Administrative State of the Authenticator Port

The administrative state of an authenticator port can take any of the following three states:

- Force authorized—Allows network access to all users of the port without requiring them to be authenticated. This is equivalent to not having any authentication enabled on the port.
- Force unauthorized—Denies network access to all users of the port. This is equivalent to disabling the port.
- Automatic—This is the default mode where the authentication server response determines if the port is opened for traffic or not. Only the successfully authenticated clients are allowed access, all others are denied.

In Junos OS, the default mode is “automatic.” The “force authorized” and “force unauthorized” admin modes are not supported. You can achieve the functionality of “force authorized” mode by disabling **dot1x** on the required port. You can achieve the functionality of “force unauthorized” mode by disabling the port itself.

- *Ethernet Interfaces Feature Guide for Routing Devices*

Understanding the Administrative Mode of the Authenticator Port

Junos OS supports the supplicant mode “single” and not the “single secure” nor “multiple” modes. The “Single” mode option authenticates only the first client that connects to a port. All other clients that connect later (802.1x compliant or noncompliant) are allowed free access on that port without any further authentication. If the first authenticated client logs out, all other users are locked out until a client authenticates again.

- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring the Authenticator

To configure the IEEE 802.1x Port-Based Network Access Control protocol on Ethernet interfaces you must configure the **authenticator** statement at the **[edit protocols dot1x]** hierarchy level. Use the **authentication-profile-name** ***access-profile-name*** statement to specify the authenticating RADIUS server, and use the **interface** statement to specify and configure the Gigabit Ethernet or Fast Ethernet interface on the router specifically for IEEE 802.1x protocol use; both at the **[edit protocols dot1x authenticator]** hierarchy level.

```
[edit protocols dot1x]
authenticator {
  authentication-profile-name access-profile-name;
  interface (xe-fpc/pic/port | ge-fpc/pic/port | fe-fpc/pic/port) {
    maximum-requests seconds;
    quiet-period seconds;
    reauthentication (disable | interval seconds);
    retries integer;
    server-timeout seconds;
    supplicant (single);
    supplicant-timeout seconds;
    transmit-period seconds;
  }
}
```

CHAPTER 6

Configuring IEEE 802.1x Port-Based Network Access Control in Enhanced LAN Mode

802.1X for MX Series Routers in Enhanced LAN Mode Overview

Starting with Junos os Release 14.2, IEEE 802.1X provides network edge security, protecting Ethernet LANs from unauthorized user access. Support is implemented for controlling access to your network through an MX Series router by using several different authentication methods, such as 802.1X, MAC RADIUS, or a captive portal.

This functionality is supported on the following MPCs on MX240, MX480, and MX960 routers in enhanced LAN mode:

- MPC4E with two 100-Gigabit Ethernet ports and eight 10-Gigabit Ethernet ports
- MPC4E with thirty-two 10-Gigabit Ethernet ports
- MPC3E that contains a 2-port 40-Gigabit Ethernet MIC with QSFP+
- MPC1E with forty 1-Gigabit Ethernet ports or twenty 1-Gigabit Ethernet ports

You must reboot the router when you configure or delete the enhanced LAN mode on the router. Configuring the **network-services lan** option implies that the system is running in the enhanced IP mode. When you configure a device to function in MX-LAN mode, only the supported configuration statements and operational show commands that are available for enabling or viewing in this mode are displayed in the CLI interface. If your system contains parameters that are not supported in MX-LAN mode in a configuration file, you cannot commit those unsupported attributes. You must remove the settings that are not supported and then commit the configuration. After the successful CLI commit, a system reboot is required for the attributes to be come effective. Similarly, if you remove the **network-services lan** statement, the system does not run in MX-LAN mode. Therefore, all of the settings that are supported outside of the MX-LAN mode are displayed and are available for definition in the CLI interface. If your configuration file contains settings that are supported only in MX-LAN mode, you must remove those attributes before you commit the configuration. After the successful CLI commit, a system reboot will be required for the CLI settings to take effect. The Layer 2 Next-Generation CLI configuration settings are supported in MX-LAN mode. As a result, the typical MX Series-format of CLI configurations might differ in MX-LAN mode.

This functionality is supported on an MX Series Virtual Chassis combination that functions in enhanced LAN mode (by entering the **network-services lan** statement at the **[edit chassis]** hierarchy level). Port-based network access control is supported on MX240, MX480, and MX960 routers with MPCs in both the MX-LAN mode and the non-MX-LAN mode (with other supported network services modes on MPCs on these routers). To configure the IEEE 802.1x port-based network access control (PNAC) protocol on Ethernet interfaces, you must configure the **authenticator** statement at the **[edit protocols authentication-access- control]** hierarchy level. You can also configure captive portal authentication on a router so that users connected to the switch are authenticated before being allowed to access the network. You can also configure Junos Pulse Access Control Service as the access policy to authenticate and authorize users connected to the switch for admission to the network and for access to protected network resources by using the **uac-policy** statement.

How 802.1X Authentication Works

802.1X authentication works by using an *Authenticator Port Access Entity* (the switch) to block all traffic to and from a supplicant (end device) at the port until the supplicant's credentials are presented and matched on the *Authentication server* (a RADIUS server). When authenticated, the switch stops blocking traffic and opens the port to the supplicant.

The end device is authenticated in either *single* mode, *single-secure* mode, or *multiple* mode:

- **single**—Authenticates only the first end device. All other end devices that connect later to the port are allowed full access without any further authentication. They effectively "piggyback" on the end devices' authentication.
- **single-secure**—Allows only one end device to connect to the port. No other end device is allowed to connect until the first logs out.
- **multiple**—Allows multiple end devices to connect to the port. Each end device will be authenticated individually.

Network access can be further defined using VLANs and firewall filters, which both act as filters to separate and match groups of end devices to the areas of the LAN they require. For example, you can configure VLANs to handle different categories of authentication failures depending upon:

- Whether or not the end device is 802.1X-enabled.
- Whether or not MAC RADIUS authentication has been configured on the switch interfaces to which the hosts are connected.
- Whether the RADIUS authentication server becomes unavailable or sends a RADIUS access-reject message. See *Configuring RADIUS Server Fail Fallback (CLI Procedure)*.

802.1X Features Overview

NOTE: The 802.1X features available on the MX Series routers depend upon which switch you are using.

802.1X features on Juniper Networks MX Series routers are:

- Guest VLAN—Provides limited access to a LAN, typically just to the Internet, for nonresponsive end devices that are not 802.1X-enabled when MAC RADIUS authentication has not been configured on the switch interfaces to which the hosts are connected . Also, a guest VLAN can be used to provide limited access to a LAN for guest users. Typically, the guest VLAN provides access just to the Internet and to other guests' end devices.
- Server-reject VLAN—Provides limited access to a LAN, typically just to the Internet, for responsive end devices that are 802.1X-enabled but that have sent the wrong credentials.
- Server-fail VLAN—Provides limited access to a LAN, typically just to the Internet, for 802.1X end devices during a RADIUS server timeout.

- Dynamic VLAN—Enables an end device, after authentication, to be a member of a VLAN dynamically.
- Private VLAN—Enables configuration of 802.1X authentication on interfaces that are members of private VLANs (PVLANs).
- Dynamic changes to a user session—Allows the switch administrator to terminate an already authenticated session. This feature is based on support of the RADIUS Disconnect Message defined in RFC 3576.
- RADIUS accounting—Sends accounting information to the RADIUS accounting server. Accounting information is sent to the server whenever a subscriber logs in or logs out and whenever a subscriber activates or deactivates a subscription.

Supported Features Related to 802.1X Authentication

802.1X does not replace other security technologies. 802.1X works together with port security features, such as DHCP snooping, dynamic ARP inspection (DAI), and MAC limiting, to guard against spoofing.

Supported features related to authentication include:

- Static MAC bypass—Provides a bypass mechanism to authenticate devices that are not 802.1X-enabled (such as printers). Static MAC bypass connects these devices to 802.1X-enabled ports, bypassing 802.1X authentication.
- MAC RADIUS authentication—Provides a means to enable or disable MAC authentication independently of whether 802.1X authentication is enabled.

Release History Table

Release	Description
14.2	Starting with Junos os Release 14.2, IEEE 802.1X provides network edge security, protecting Ethernet LANs from unauthorized user access. Support is implemented for controlling access to your network through an MX Series router by using several different authentication methods, such as 802.1X, MAC RADIUS, or a captive portal.

Understanding 802.1X and LLDP and LLDP-MED on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, Juniper Networks MX Series routers use Link Layer Discovery Protocol (LLDP) and Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) to learn and distribute device information on network links. The information allows the router to quickly identify a variety of devices, resulting in a LAN that interoperates smoothly and efficiently.

LLDP-capable devices transmit information in type, length, and value (TLV) messages to neighbor devices. Device information can include information such as chassis and port identification and system name and system capabilities. The TLVs leverage this information from parameters that have already been configured in the Juniper Networks Junos operating system (Junos OS).

LLDP-MED goes one step further than LLDP, exchanging IP-telephony messages between the router and the IP telephone.

LLDP and LLDP-MED also provide PoE power management capabilities. LLDP power negotiation allows the router to manage PoE power by negotiating with LLDP-enabled powered devices to dynamically allocate PoE power as needed. LLDP power priority allows an LLDP-enabled powered device to set the PoE power priority on the router interface to which it connects.

The router also uses these protocols to ensure that voice traffic gets tagged and prioritized with the correct values at the source itself. For example, 802.1p CoS and 802.1Q tag information can be sent to the IP telephone.

EX Series routeres support the following basic TLVs:

- **Chassis Identifier**—The MAC address associated with the local system.

  NOTE: **The Chassis ID TLV has a subtype for Network Address Family. LLDP frames are validated only if this subtype has a value of 1 (IPv4) or 2 (IPv6). For any other value, the transmitting device is detected by LLDP as a neighbor and displayed in the output of the "show lldp neighbors" command, but is not assigned to the VLAN.**

- **Port Identifier**—The port identification for the specified port in the local system.
- **Port Description**—Textual description of the interface or the logical unit. The description for the logical unit is used, if available; otherwise, the Port Description TLV will contain the description configured on the physical interface. For example, LAG member interfaces do not contain a logical unit, so only the description configured on the physical interface can be used.
- **System Name**—The user-configured name of the local system. The system name can be a maximum of 256 characters.
- **System Description**—The system description containing information about the software and current image running on the system. This information is not configurable, but taken from the software.
- **System Capabilities**—The primary function performed by the system. The capabilities that system supports; for example, bridge or router. This information is not configurable, but based on the model of the product.
- **Management Address**—The IPv4 or IPv6 management address of the local system.

EX Series routeres support the following 802.3 TLVs:

- **Power via MDI**—A TLV that advertises MDI power support, PSE power pair, and power class information.
- **MAC/PHY Configuration Status**—A TLV that advertises information about the physical interface, such as autonegotiation status and support and MAU type. The information is not configurable, but based on the physical interface structure.

NOTE: The MAC/PHY Configuration Status TLV has a subtype for the PMD Auto-Negotiation Advertised Capability field. This field will contain a value of other or unknown if the LLDP packet was transmitted from a 10-gigabit SFP+ port.

- **Link Aggregation**—A TLV that advertises if the port is aggregated and its aggregated port ID.
- **Maximum Frame Size**—A TLV that advertises the Maximum Transmission Unit (MTU) of the interface sending LLDP frames.
- **Port Vlan**—A TLV that advertises the VLAN name configured on the interface.

EX Series routeres support the following LLDP-MED TLVs:

- **LLDP MED Capabilities**—A TLV that advertises the primary function of the port. The capabilities values range 0 through 15:
  - **0**— Capabilities
  - **1**— Network Policy
  - **2**— Location Identification
  - **3**— Extended Power via MDI-PSE
  - **4**— Inventory
  - **5–15**— Reserved
- LLDP-MED Device Class Values:
  - **0**— Class not defined.
  - **1**— Class 1 Device.
  - **2**— Class 2 Device.
  - **3**— Class 3 Device.
  - **4**— Network Connectivity Device
  - **5–255**— Reserved.
- **Network Policy**—A TLV that advertises the port VLAN configuration and associated Layer 2 and Layer 3 attributes. Attributes include the policy identifier, application types, such as voice or streaming video, 802.1Q VLAN tagging, and 802.1p priority bits and Diffserv code points.
- **Endpoint Location**— A TLV that advertises the physical location of the endpoint.
- **Extended Power via MDI**— A TLV that advertises the power type, power source, power priority, and power value of the port. It is the responsibility of the PSE device (network connectivity device) to advertise the power priority on a port.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, Juniper Networks MX Series routers use Link Layer Discovery Protocol (LLDP) and Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) to learn and distribute device information on network links. The information allows the router to quickly identify a variety of devices, resulting in a LAN that interoperates smoothly and efficiently.

Understanding 802.1X and RADIUS Accounting on MX Series Routers in Enhanced LAN Mode

Juniper Networks MX Series routers support IETF RFC 2866, *RADIUS Accounting*. Starting with Junos OS Release 14.2, you can configure RADIUS accounting on an MX Series router which enables statistical data about users logging onto or off a LAN to be collected and sent to a RADIUS accounting server. The statistical data gathered can be used for general network monitoring, to analyze and track usage patterns, or to bill a user based upon the amount of time or type of services accessed.

To configure RADIUS accounting, specify one or more RADIUS accounting servers to receive the statistical data from the switch, and select the type of accounting data to be collected.

The RADIUS accounting server you specify can be the same server used for RADIUS authentication, or it can be a separate RADIUS server. You can specify a list of RADIUS accounting servers. In the event that the primary server (the first one configured) is unavailable, each RADIUS server in the list is tried in the order in which they are configured in the Juniper Networks Junos operating system (Junos OS).

The RADIUS accounting process between a switch and a RADIUS server works like this:

1. A RADIUS accounting server listens for User Datagram Protocol (UDP) packets on a specific port. For example, on FreeRADIUS, the default port is 1813.

2. The switch forwards an *accounting-request* packet containing an event record to the accounting server. For example, a supplicant is authenticated through 802.1X authentication and connected to the LAN. The event record associated with this supplicant contains an *Acct-Status-Type* attribute whose value indicates the beginning of user service for this supplicant. When the supplicant's session ends, the accounting request will contain an *Acct-Status-Type* attribute value indicating the end of user service. The RADIUS accounting server records this as a stop-accounting record containing session information and the length of the session.

3. The RADIUS accounting server logs these events as start-accounting or stop-accounting records. The records are in a file. On FreeRADIUS, the file name is the server's address; for example, 122.69.1.250.

4. The accounting server sends an *accounting-response* packet back to the switch confirming it has received the accounting request.

5. If the switch does not receive a response from the server, it continues to send accounting requests until an accounting response is returned from the accounting server.

The statistics collected through this process can be displayed from the RADIUS server; to see those statistics, the user accesses the log file configured to receive them.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, you can configure RADIUS accounting on an MX Series router which enables statistical data about users logging onto or off a LAN to be collected and sent to a RADIUS accounting server. The statistical data gathered can be used for general network monitoring, to analyze and track usage patterns, or to bill a user based upon the amount of time or type of services accessed.

Understanding 802.1X and VoIP on MX Series Routers in Enhanced LAN Mode

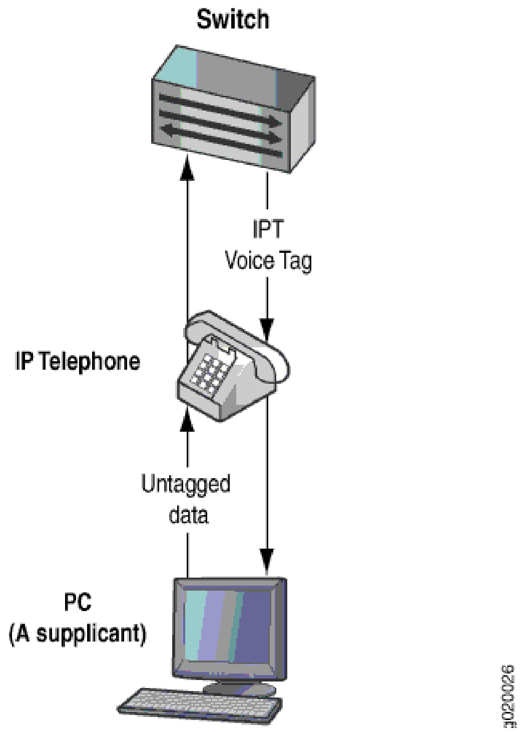
When you use Voice over IP (VoIP), you can connect IP telephones to the router and configure IEEE 802.1X authentication for 802.1X-compatible IP telephones. Starting with Junos OS Release 14.2, 802.1X authentication provides network edge security, protecting Ethernet LANs from unauthorized user access.

VoIP is a protocol used for the transmission of voice through packet-switched networks. VoIP transmits voice calls using a network connection instead of an analog phone line.

When VoIP is used with 802.1X, the RADIUS server authenticates the phone, and Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) provides the class-of-service (CoS) parameters to the phone.

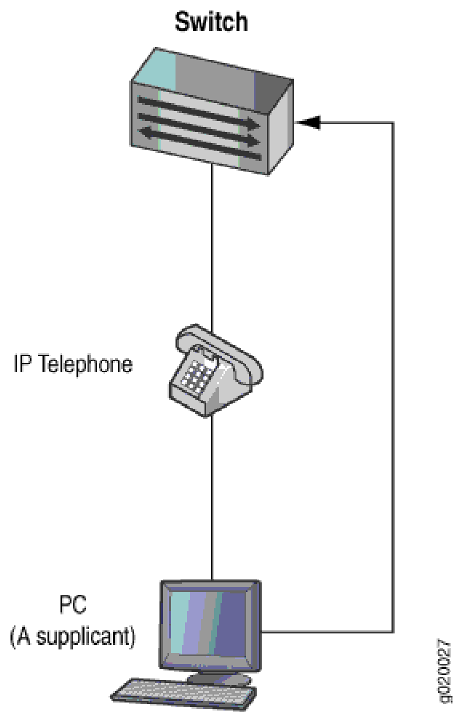
You can configure 802.1X authentication to work with VoIP in multiple supplicant or single supplicant mode. In *multiple-supplicant* mode, the 802.1X process allows multiple supplicants to connect to the interface. Each supplicant will be authenticated individually. For an example of a VoIP multiple supplicant topology, see Figure 1 on page 46.

Figure 1: VoIP Multiple Supplicant Topology



If an 802.1X-compatible IP telephone does not have an 802.1X host but has another 802.1X-compatible device connected to its data port, you can connect the phone to an interface in single-supplicant mode. In *single-supplicant* mode, the 802.1X process authenticates only the first supplicant. All other supplicants who connect later to the interface are allowed full access without any further authentication. They effectively “piggyback” on the first supplicant’s authentication. For an example of a VoIP single supplicant topology, see Figure 2 on page 47 .

Figure 2: VoIP Single Supplicant Topology



If an IP telephone does not support 802.1X, you can configure VoIP to bypass 802.1X and LLDP-MED and have the packets forwarded to a VoIP VLAN,

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, 802.1X authentication provides network edge security, protecting Ethernet LANs from unauthorized user access.

Understanding Guest VLANs for 802.1X on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, guest VLANs can be configured on switches that are using 802.1X authentication to provide limited access—typically only to the Internet—for:

- Corporate guests
- End devices that are not 802.1X-enabled
- Nonresponsive end devices when MAC RADIUS authentication has not been configured on the switch interfaces to which the hosts are connected

A guest VLAN is not used for supplicants sending incorrect credentials. Those supplicants are directed to the server-reject VLAN instead.

For end devices that are not 802.1X-enabled, a guest VLAN can allow limited access to a server from which the non-802.1X-enabled end device can download the supplicant software and attempt authentication again.

A guest VLAN is not used when MAC RADIUS authentication has been configured on the switch interfaces to which the hosts are connected. Some end devices, such as a printer, cannot be enabled for 802.1X. The hosts for such devices should be connected to switch interfaces that are configured for MAC RADIUS authentication.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, guest VLANs can be configured on switches that are using 802.1X authentication to provide limited access—typically only to the Internet

Understanding Dynamic VLANs for 802.1X on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, dynamic VLANs, in conjunction with the 802.1X authentication process, provide secure access to the LAN for end devices belonging to different VLANs on a single port.

When this feature is configured on the RADIUS server, an end device or user authenticating on the RADIUS server is assigned to the VLAN configured for it. The end device or user becomes a member of a VLAN dynamically after successful 802.1X authentication. For information on configuring dynamic VLANs on your RADIUS server, see the documentation for your RADIUS server.

Successful authentication requires that the VLAN ID or VLAN name exist on the router and match the VLAN ID or VLAN name sent by the RADIUS server during authentication. If neither exists, the end device is unauthenticated. If a guest VLAN is established, the unauthenticated end device is automatically moved to the guest VLAN.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, dynamic VLANs, in conjunction with the 802.1X authentication process, provide secure access to the LAN for end devices belonging to different VLANs on a single port.

Understanding Server Fail Fallback and Authentication on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, server fail fallback allows you to specify how end devices connected to the router are supported if the RADIUS authentication server becomes unavailable or sends a RADIUS access-reject message.

Juniper Networks MX Series routers in enhanced LAN mode use authentication to implement access control in an enterprise network. If 802.1X, MAC RADIUS, or captive portal authentication are configured on the interface, end devices are evaluated at the initial connection by an authentication (RADIUS) server. If the end device is configured on the authentication server, the device is granted access to the LAN and the MX Series router opens the interface to permit access.

A RADIUS server timeout occurs if no RADIUS authentication servers are reachable when an end device logs in and attempts to access the LAN. Server fail fallback allows you to specify one of four actions to be taken toward end devices awaiting authentication when the server is timed out:

- *Permit* authentication, allowing traffic to flow from the end device through the interface as if the end device were successfully authenticated by the RADIUS server.
- *Deny* authentication, preventing traffic from flowing from the end device through the interface. This is the default.
- *Move* the end device to a specified VLAN. (The VLAN must already exist on the router.)
- *Sustain* authenticated end devices that already have LAN access and *deny* unauthenticated end devices. If the RADIUS servers time out during reauthentication, previously authenticated end devices are reauthenticated and new users are denied LAN access.

Server fail fallback is triggered most often during reauthentication when the already configured and in-use RADIUS server becomes inaccessible. However, server fail fallback can also be triggered by an end device's first attempt at authentication through the RADIUS server.

Server fail fallback allows you to specify that an end device be moved to a specified VLAN if the router receives a RADIUS access-reject message. The configured VLAN name overrides any attributes sent by the server.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, server fail fallback allows you to specify how end devices connected to the router are supported if the RADIUS authentication server becomes unavailable or sends a RADIUS access-reject message.

Configuring 802.1X RADIUS Accounting on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, RADIUS accounting permits statistical data about users logging onto or off a LAN to be collected and sent to a RADIUS accounting server. The statistical data gathered can be used for general network monitoring, to analyze and track usage patterns, or to bill a user based upon the amount of time or type of services accessed.

To configure basic RADIUS accounting using the CLI:

1. Specify the accounting servers to which the switch will forward accounting statistics:

   ```
   [edit access ]
   user@router# set profile profile1 radius accounting-serveraccounting-server [122.69.1.250
   122.69.1.252]
   ```

2. Define the RADIUS accounting servers:

   ```
   [edit access]
   user@router# set radius-server 122.69.1.250 secret juniper
   user@router# set radius-server 122.69.1.252 secret juniper1
   ```

3. Enable accounting for an access profile:

   ```
   [edit access]
   user@router# set profile profile1 accounting
   ```

4. Configure the RADIUS servers to use while sending accounting messages and updates:

   ```
   [edit access]
   user@router# set profile profile1 accounting order radius
   ```

5. Configure the statistics to be collected on the router and forwarded to the accounting server:

   ```
   [edit access ]
   user@router# set profile profile1 accounting accounting-stop-on-access-deny
   user@router# set profile profile1 accounting accounting-stop-on-failure
   ```

6. Display accounting statistics collected on the router:

   ```
   user@router> show network-access aaa statistics accounting
   Accounting module statistics
     Requests received: 1
     Accounting Response failures: 0
   ```

```
Accounting Response Success: 1
Requests timedout: 0
```

7. Open an accounting log on the RADIUS accounting server using the server's address, and view accounting statistics:

```
[root@freeradius]# cd /usr/local/var/log/radius/radacct/122.69.1.250
[root@freeradius 122.69.1.250]# ls

detail-20071214

[root@freeradius 122.69.1.250]# vi details-20071214

        User-Name = "000347e1bab9"
        NAS-Port = 67
        Acct-Status-Type = Stop
        Acct-Session-Id = "802.1x811912"
        Acct-Input-Octets = 17454

        Acct-Output-Packets = 53
        Acct-Terminate-Cause = Lost-Carrier
        Acct-Input-Gigawords = 0
        Acct-Output-Gigawords = 0
        Called-Station-Id = "00-19-e2-50-52-60"
        Calling-Station-Id = "00-03-47-e1-ba-b9"
        Event-Timestamp = "Sep 10 2008 16:52:39 PDT"
        NAS-Identifier = "esp48t-1b-01"
        NAS-Port-Type = Virtual

        User-Name = "000347e1bab9"
        NAS-Port = 67
        Acct-Status-Type = Start
        Acct-Session-Id = "802.1x811219"
        Called-Station-Id = "00-19-e2-50-52-60"
        Calling-Station-Id = "00-03-47-e1-ba-b9"
        Event-Timestamp = "Sep 10 2008 18:58:52 PDT"
        NAS-Identifier = "esp48t-1b-01"
        NAS-Port-Type = Virtual
```

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, RADIUS accounting permits statistical data about users logging onto or off a LAN to be collected and sent to a RADIUS accounting server.

Related Documentation

Configuring 802.1X Interface Settings on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, IEEE 802.1X authentication provides network edge security, protecting Ethernet LANs from unauthorized user access by blocking all traffic to and from a supplicant (client) at the interface until the supplicant's credentials are presented and matched on the *authentication server* (a RADIUS server). When the supplicant is authenticated, the switch stops blocking access and opens the interface to the supplicant.

NOTE:

- You can also specify an 802.1X exclusion list to specify supplicants can that can bypass authentication and be automatically connected to the LAN.
- You cannot configure 802.1X user authentication on interfaces that have been enabled for Q-in-Q tunneling.
- You cannot configure 802.1X user authentication on redundant trunk groups (RTGs).

Before you begin, specify the RADIUS server or servers to be used as the authentication server.

To configure 802.1X on an interface:

1. Configure the supplicant mode as **single** (authenticates the first supplicant), **single-secure** (authenticates only one supplicant), or **multiple** (authenticates multiple supplicants):

   ```
   [edit protocols authentication-access-control]
   user@switch# set interface ge-0/0/5 supplicant multiple
   ```

2. Enable reauthentication and specify the reauthentication interval:

   ```
   [edit protocols authentication-access-control]
   user@switch# set interface ge-0/0/5/0 dot1x reauthentication interval 5
   ```

3. Configure the interface timeout value for the response from the supplicant:

   ```
   [edit protocols authentication-access-control]
   user@switch# set interface ge-0/0/5 dot1x supplicant-timeout 5
   ```

4. Configure the timeout for the interface before it resends an authentication request to the RADIUS server:

   ```
   [edit protocols authentication-access-control]
   user@switch# set interface ge-0/0/5 server-timeout 5
   ```

5. Configure how long, in seconds, the interface waits before retransmitting the initial EAPOL PDUs to the supplicant:

```
[edit protocols authentication-access-control]
user@switch# set interface ge-0/0/5 dot1x transmit-period 60
```

6. Configure the maximum number of times an EAPOL request packet is retransmitted to the supplicant before the authentication session times out:

```
[edit protocols authentication-access-control]
user@switch# set interface ge-0/0/5 dot1x maximum-requests 5
```

7. Configure the number of times the switch attempts to authenticate the port after an initial failure. The port remains in a wait state during the quiet period after the authentication attempt.

```
[edit protocols authentication-access-control]
user@switch# set interface ge-0/0/5 retries 1
```

NOTE: This setting specifies the number of tries before the switch puts the interface in a "HELD" state.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, IEEE 802.1X authentication provides network edge security, protecting Ethernet LANs from unauthorized user access by blocking all traffic to and from a supplicant (client) at the interface until the supplicant's credentials are presented and matched on the *authentication server* (a RADIUS server).

Configuring LLDP-MED on MX Series Routers in Enhanced LAN Mode

Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) is an extension of LLDP. Starting with Junos OS Release 14.2, the router uses LLDP-MED to support device discovery of VoIP telephones and to create location databases for these telephone locations.

LLDP-MED is turned on by default on MX Series routers.

This topic describes:

- Enabling LLDP-MED on Interfaces on page 54
- Configuring Location Information Advertised by the Router on page 54
- Configuring for Fast Start on page 54

Enabling LLDP-MED on Interfaces

LLDP-MED is enabled on all interfaces by default. If it is disabled, you can enable LLDP-MED by configuring it on all interfaces or on specific interfaces.

To configure LLDP-MED on all interfaces or on a specific interface:

```
[edit protocols lldp-med]
user@router# set interface (LLDP-MED) ge-0/0/2.0
```

Configuring Location Information Advertised by the Router

You can configure the location information that is advertised from the router to the LLDP-MED device. You can specify a civic-based location (geographic location) or a location based on an ELIN (Emergency Location Identification Number):

- To specify a location by geography:

```
[edit protocols lldp-med]
user@router# set interface ge-0/0/2.0 location civic-based country-code US
user@router# set interface ge-0/0/2.0 location civic-based ca-type 1 ca-value "El Dorado County"
user@router# set interface ge-0/0/2.0 location civic-based ca-type 2 ca-value CA
user@router# set interface ge-0/0/2.0 location civic-based ca-type 3 ca-value Somerset
user@router# set interface ge-0/0/2.0 location civic-based ca-type 6 ca-value "Mount Aukum Road"
user@router# set interface ge-0/0/2.0 location civic-based ca-type 19 ca-value 6450
user@router# set interface ge-0/0/2.0 location civic-based ca-type 21 ca-value "Holiday Market"
```

- To specify a location using an **elin** string:

```
[edit protocols lldp-med]
user@router# set interface ge-0/0/2.0 location elin 4085551212
```

Configuring for Fast Start

You can specify the number of LLDP-MED advertisements sent from the router in the first second after it has detected an LLDP-MED device. The default is 3; to set it to another value:

```
[edit protocols lldp-med]
user@router# set fast-start 6
```

NOTE: If an interface is configured as a VoIP interface, then the router does not wait for an attached phone to identify itself as an LLDP-MED device before it performs an LLDP-MED fast start after a graceful Routing Engine switchover (GRES) or a reboot. Instead, it immediately performs an LLDP-MED fast start after a GRES or reboot. This behavior prevents certain models of IP phones from resetting after a GRES.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, the router uses LLDP-MED to support device discovery of VoIP telephones and to create location databases for these telephone locations.

Related Documentation

Configuring LLDP on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, devices use Link Layer Discovery Protocol (LLDP) and Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) to learn and distribute device information on network links.The information enables the device to quickly identify a variety of other devices, resulting in a LAN that interoperates smoothly and efficiently.

This topic describes:

- Enabling LLDP on Interfaces on page 55
- Adjusting LLDP Advertisement Settings on page 56
- Adjusting SNMP Notification Settings of LLDP Changes on page 57
- Specifying a Management Address for the LLDP Management TLV on page 57

Enabling LLDP on Interfaces

LLDP is enabled on all interfaces by default. If it is disabled, you can enable LLDP by configuring it on all interfaces or on specific interfaces.

- To configure LLDP on all interfaces:

```
[edit protocols lldp]
user@router# set interface all
```

- To configure LLDP on a specific interface:

```
[edit protocols lldp]
user@router# set interface interface-name
```

NOTE: On MX Series routers, LLDP cannot be configured on the management Ethernet interface. Issuing the command **set protocols lldp interfaceem0** generates the following error message:

```
error: name: 'em0': Invalid interface
error: statement creation failed: interface
```

Adjusting LLDP Advertisement Settings

You can adjust the following settings for LLDP advertisements for troubleshooting or verification purposes. The default values are applied when LLDP is enabled. For normal operations, we recommend that you do not change the default values.

- To specify the frequency at which LLDP advertisements are sent (in seconds):

  ```
  [edit protocols lldp]
  user@router# set advertisement-interval seconds
  ```

  For example, using the default value:

  ```
  [edit protocols lldp]
  user@router# set advertisement-interval 45
  ```

- To specify the number of seconds that LLDP information is held before it is discarded (the multiplier value is used in combination with the **advertisement-interval** value):

  ```
  [edit protocols lldp]
  user@router# set hold-multiplier seconds
  ```

  For example, using the default value:

  ```
  [edit protocols lldp]
  user@router# set hold-multiplier 5
  ```

- To specify the number of seconds the device delays before sending advertisements to neighbors after a change is made in a TLV (type, length, or value) element in LLDP or in the state of the local system, such as a change in hostname or management address, set the transmit delay. The transmit delay is enabled by default on switches to reduce the delay in notifying neighbors of a change in the local system. The default value is 2 seconds (if the **advertisement-interval** value is set to 8 seconds or more) or 1 second (if the **advertisement-interval** value is set to less than 8 seconds).

  ```
  [edit protocols lldp]
  user@router# set transmit-delay seconds
  ```

  For example:

  ```
  [edit protocols lldp]
  user@router# set transmit-delay 2
  ```

NOTE: The **advertisement-interval** value must be greater than or equal to four times the **transmit-delay** value; otherwise, an error is returned when you attempt to commit the configuration.

Adjusting SNMP Notification Settings of LLDP Changes

You can adjust the following settings for SNMP notifications of LLDP changes. If the values are not specified or if the interval values are set to **0**, the notifications are disabled.

- To specify the frequency at which LLDP database changes are sent (in seconds):

```
[edit protocols lldp]
user@router# set lldp-configuration-notification-interval seconds
```

  For example:

```
[edit protocols lldp]
user@router# set lldp-configuration-notification-interval 600
```

- To configure the time interval for SNMP trap notifications to wait for topology changes (in seconds):

```
[edit protocols lldp]
user@router# set ptopo-configuration-trap-interval seconds
```

  For example:

```
[edit protocols lldp]
user@router# set ptopo-configuration-trap-interval 600
```

- To specify the holding time (used in combination with the **ptopo-configuration-trap-interval** value) to maintain dynamic topology entries (in seconds):

```
[edit protocols lldp]
user@router# set ptopo-configuration-maximum-hold-time seconds
```

  For example:

```
[edit protocols lldp]
user@router# set ptopo-configuration-maximum-hold-time 2147483647
```

Specifying a Management Address for the LLDP Management TLV

You can configure an IPv4 or IPv6 management address to be used in the LLDP Management Address type, length, and value (TLV) messages. Only out-of-band management addresses must be used as the value for the **management-address** statement.

To configure the management address:

```
[edit protocols lldp]
user@router# set management-address ip-address
```

NOTE: Ensure that the interface with the configured management address has LLDP enabled using the **set protocols lldp interface** command. If you configure a customized management address for LLDP on an interface that has LLDP disabled, the **show lldp local-information** command output will not display the correct interface information.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, devices use Link Layer Discovery Protocol (LLDP) and Link Layer Discovery Protocol–Media Endpoint Discovery (LLDP-MED) to learn and distribute device information on network links.

Configuring Server Fail Fallback on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, server fail fallback allows you to specify how end devices connected to the router are supported if the RADIUS authentication server becomes unavailable or sends a RADIUS access-reject message.

802.1X and MAC RADIUS authentication work by using an *authenticator port access entity* (the router) to block all traffic to and from an end device at the interface until the end device's credentials are presented and matched on the *authentication server* (a RADIUS server). When the end device has been authenticated, the router stops blocking and opens the interface to the end device.

When you set up 802.1X or MAC RADIUS authentication on the router, you specify a primary authentication server and one or more backup authentication servers. If the primary authentication server cannot be reached by the router and the secondary authentication servers are also unreachable, a RADIUS server timeout occurs. Because the authentication server grants or denies access to the end devices awaiting authentication, the router does not receive access instructions for end devices attempting access to the LAN and normal authentication cannot be completed. Server fail fallback allows you to configure authentication alternatives that permit the router to take appropriate actions toward end devices awaiting authentication or reauthentication.

NOTE: The authentication fallback method called *server-reject VLAN* provides limited access to a LAN, typically just to the Internet, for responsive end devices that are 802.1X-enabled but that have sent the wrong credentials. If the end device that is authenticated using the server-reject VLAN is an IP phone, voice traffic is not allowed.

To configure basic server fail fallback options using the CLI:

- Configure an interface to allow traffic to flow from a supplicant to the LAN if a RADIUS server timeout occurs (as if the end device had been successfully authenticated by a RADIUS server):

```
[edit protocols authentication-access-control]
user@router# set interface ge-0/0/1 dot1x server-fail permit
```

- Configure an interface to prevent traffic flow from an end device to the LAN (as if the end device had failed authentication and had been rejected by the RADIUS server):

```
[edit protocols authentication-access-control]
user@router# set interface ge-0/0/1 dot1x server-fail deny
```

- Configure an interface to move an end device to a specified VLAN if a RADIUS server timeout occurs (in this case, the VLAN name is **vlan1**):

```
[edit protocols authentication-access-control]
user@router# set interface ge-0/0/1 dot1x server-fail vlan-name vlan1
```

- Configure an interface to recognize already connected end devices as reauthenticated if there is a RADIUS timeout during reauthentication (new users will be denied access):

```
[edit protocols authentication-access-control]
user@router# set interface ge-0/0/1 dot1x server-fail use-cache
```

- Configure an interface that receives a RADIUS access-reject message from the authentication server to move end devices attempting LAN access on the interface to a specified VLAN already configured on the router (in this case, the VLAN name is **vlan-sf**):

```
[edit protocols authentication-access-control]
user@router# set interface ge-0/0/1 dot1x server-reject-vlan vlan-sf
```

NOTE: If an IP phone is authenticated in the server-reject VLAN, voice traffic is not allowed.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, server fail fallback allows you to specify how end devices connected to the router are supported if the RADIUS authentication server becomes unavailable or sends a RADIUS access-reject message.

Understanding Captive Portal Authentication on the MX Series Routers

Starting with Junos OS Release 14.2, captive portal authentication (hereafter referred to as captive portal) allows you to authenticate users on MX Series routers by redirecting Web browser requests to a login page that requires users to input a username and password before they are allowed access to the network.Captive portal controls network access by requiring users to provide information that is authenticated against a RADIUS server database using EAP-MD5, You can also use captive portal to display an acceptable-use policy to users before they access your network.

Juniper Networks Junos Software for MX Series routers provides a template that allows you to easily design and modify the look of the captive portal login page. You enable specific interfaces for captive portal. The first time a client connected to a captive portal interface attempts to access a webpage, the switch presents the captive portal login page. Upon successful authentication, the user is allowed access to the network and to continue to the original page requested.

NOTE: **If Hypertext Transfer Protocol Secure (HTTPS) is enabled, Hypertext Transfer Protocol (HTTP) requests are redirected to an HTTPS connection for the captive portal authentication process. After authentication, the client is returned to the HTTP connection.**

If there are clients that are not HTTP-enabled connected to the captive portal interface, you can allow them to bypass captive portal authentication by adding their MAC address to an authentication whitelist. (If the MAC address has already been learned on the interface, you must clear it using the **clear captive-portal interface** ***interface-name***) before adding it to the whitelist.)

When the user is authenticated by the RADIUS server, any per-user policies (attributes) associated with that user are also sent to the switch.

Limitations of Captive Portal

Captive portal on MX Series routers has the following limitations:

- The captive portal interface must be configured for **family ethernet-switching** and set to port mode access. The VLAN must be configured with a routed VLAN interface (RVI).
- The DHCP gateway IP address for the switch must be configured as the IP address of the routed VLAN interface.
- Captive portal does not support dynamic assignment of VLANs downloaded from the RADIUS server.
- If the user is idle for more than about 5 minutes and there is no traffic passed, the user is required to log back in to the captive portal.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, captive portal authentication (hereafter referred to as captive portal) allows you to authenticate users on MX Series routers by redirecting Web browser requests to a login page that requires users to input a username and password before they are allowed access to the network.

Understanding Authentication Session Timeout on MX Series Routers

Starting with Junos OS Release 14.2, you can specify authentication session timeout values for captive portal authentication sessions and 802.1X and MAC RADIUS authentication sessions.

For captive portal authentication, the length of the session depends on the value configured for the **session-expiry** statement. The remainder of this topic pertains only to 802.1X and MAC RADIUS authentication sessions.

For 802.1X and MAC RADIUS authentication sessions, the timeout of the session depends on the value of **reauthentication interval** for **dot1x authentication**. The authentication session might also end when the MAC table aging time expires because, unless you configure it not to, the session is removed from the authentication session table when the MAC address is removed from the Ethernet switching table.

Information about each 802.1X and MAC RADIUS authentication session—including the associated interfaces and VLANs for each MAC address that is authenticated by 802.1X authentication or MAC RADIUS authentication—is stored in the authentication session table. The authentication session table is tied to the Ethernet switching table (also called the MAC table). Each time the switch detects traffic from a MAC address, it updates the timestamp for that network node in the Ethernet switching table. A timer on the switch periodically checks the timestamp and if its value exceeds the user-configured **mac-table-aging-time** value, the switch removes the MAC address from the Ethernet switching table. When a MAC address ages out of the Ethernet switching table, the entry for that MAC address is also removed from the authentication database, with the result that the session ends.

You can control variables affecting timeout of authentication sessions in the following ways:

- Set the authentication session timeout on all interfaces or on selected interfaces using the **reauthentication** statement.
- Disassociate the authentication session table from the Ethernet switching table using the **no-mac-table-binding** statement. This setting prevents the termination of the authentication session when the associated MAC address ages out of the Ethernet switching table.

Release History Table

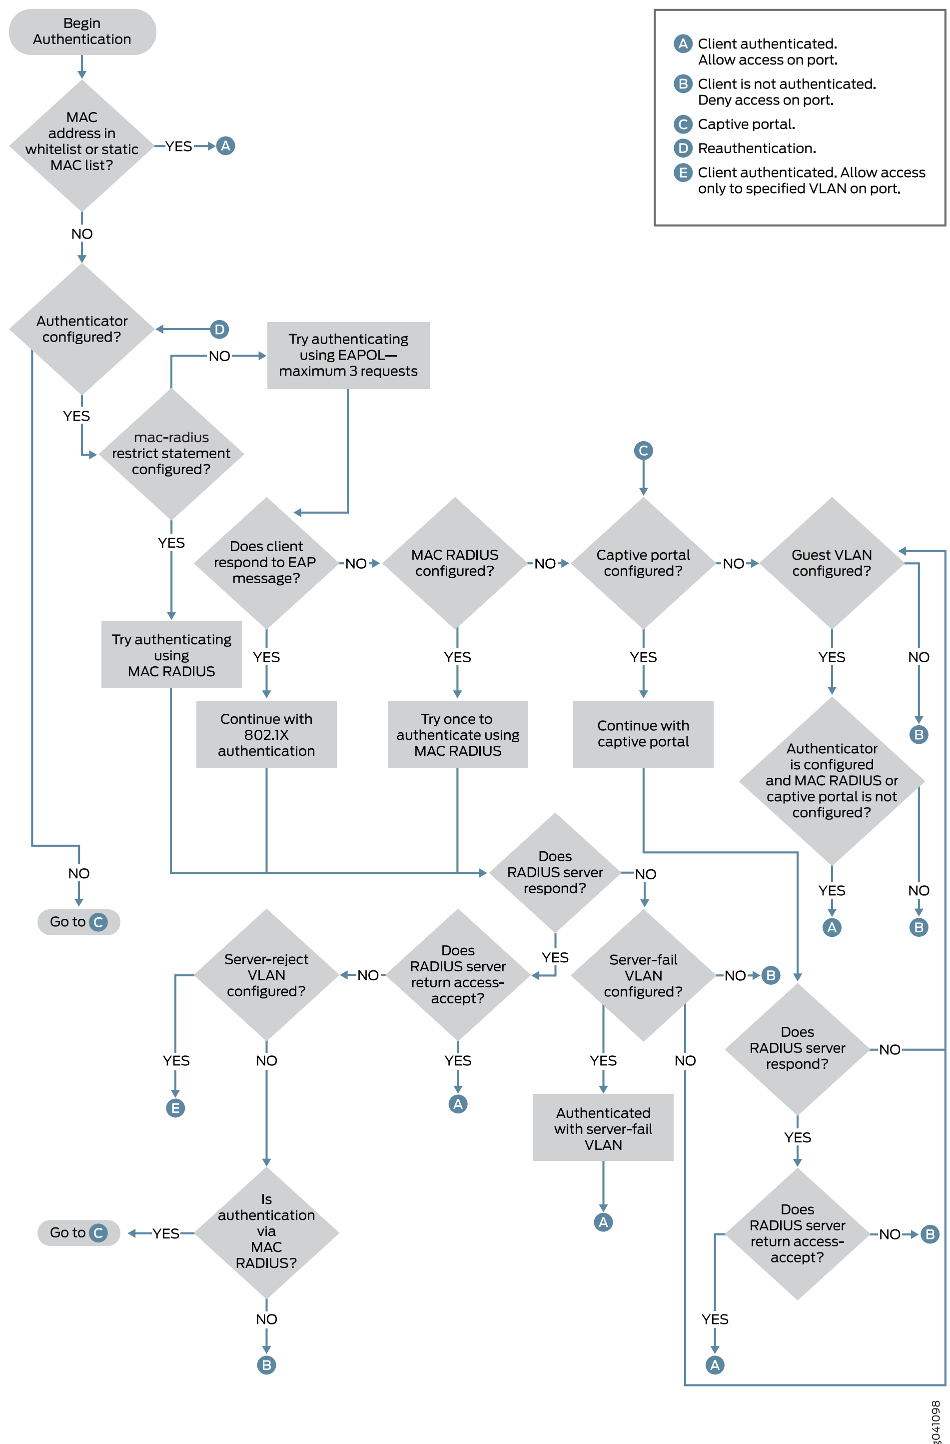
Release	Description
14.2	Starting with Junos OS Release 14.2, you can specify authentication session timeout values for captive portal authentication sessions and 802.1X and MAC RADIUS authentication sessions.

Authentication Process Flow for MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, you can control access to your network through an MX Series router by using several different authentication methods—including 802.1X, MAC RADIUS, or captive portal.

Figure 3 on page 64 illustrates the authentication process:

Figure 3: Authentication Process Flow for an MX Series Router



Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, you can control access to your network through an MX Series router by using several different authentication methods—including 802.1X, MAC RADIUS, or captive portal.

Specifying RADIUS Server Connections on an MX Series Router in Enhanced LAN Mode

IEEE 802.1X and MAC RADIUS authentication both provide network edge security, protecting Ethernet LANs from unauthorized user access by blocking all traffic to and from devices at the interface until the supplicant's credentials or MAC address are presented and matched on the *authentication server* (a RADIUS server). When the supplicant is authenticated, the router stops blocking access and opens the interface to the supplicant.

Starting with Junos OS Release 14.2, to use 802.1X or MAC RADIUS authentication, you must specify the connections on the router for each RADIUS server to which you will connect.

To configure a RADIUS server on the router:

1. Define the IP address of the RADIUS server, the RADIUS server authentication port number, and the secret password. You can define more than one RADIUS server. The secret password on the router must match the secret password on the server:

   ```
   [edit access]
   user@router# set radius-server 10.0.0.100 port 1812 secret abc
   ```

   NOTE: **Specifying the authentication port is optional, and port 1812 is the default. However, we recommend that you configure it in order to avoid confusion as some RADIUS servers might refer to an older default.**

2. (Optional) Specify the IP address by which the router is identified by the RADIUS server. If you do not specify this, the RADIUS server uses the address of the interface sending the RADIUS request. We recommend that you specify this IP address because if the request gets diverted on an alternate route to the RADIUS server, the interface relaying the request might not be an interface on the router.

   ```
   [edit access]
   user@router# set radius-server source-address 10.93.14.100
   ```

3. Configure the authentication order, making **radius** the first method of authentication:

   ```
   [edit access]
   user@router# set profile profile1 authentication-order radius
   ```

4. Create a profile and specify the list of RADIUS servers to be associated with the profile. For example, you might choose to group your RADIUS servers geographically by city.

This feature enables easy modification whenever you want to change to a different sent of authentication servers.

```
[edit access profile]
user@router# set atlanta radius authentication-server 10.0.0.100 10.2.14.200
```

5. Specify the group of servers to be used for 802.1X or MAC RADIUS authentication by identifying the profile name:

```
[edit access profile]
user@router# set protocols authentication-access-control authentication-profile-name
denver
```

6. Configure the IP address of the MX Series router in the list of clients on the RADIUS server. For specifics on configuring the RADIUS server, consult the documentation for your server.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, to use 802.1X or MAC RADIUS authentication, you must specify the connections on the router for each RADIUS server to which you will connect.

Configuring Captive Portal Authentication on MX Series Routers in Enhanced LAN Mode

NOTE: This example uses Junos OS for MX240, MX480, and MX960 routers with support for the Enhanced LAN mode configuration style. If your router does not run MX-LAN mode, you cannot configure port-based authentication settings in the same manner as described in this section. If you remove the network-services lan statement at the [edit chassis] hierarchy level, the system does not run in MX-LAN mode. Therefore, all of the settings that are supported outside of the MX-LAN mode are displayed and are available for definition in the CLI interface. In such a scenario, you must use the statements at the **[edit protocols dot1x]** hierarchy level to configure 802.1x and MAC RADIUS authentication, and the options at the **[edit services captive-portal]** hierarchy level to configure captive portal authentication. In MX-LAN mode, you can configure all the port-based network access control methodologies using the statements at the **[edit protocols authentication-access-control]** hierarchy level.

Starting with Junos OS Release 14.2, configure captive portal authentication (hereafter referred to as captive portal) on an MX Series router so that users connected to the router are authenticated before being allowed to access the network. When the user requests a webpage, a login page is displayed that requires the user to input a username and password. Upon successful authentication, the user is allowed to continue with the original page request and subsequent access to the network.

Before you begin, be sure you have:

- Performed basic bridging and VLAN configuration on the router.
- Generated an SSL certificate and installed it on the router.
- Configured basic access between the MX Series router and the RADIUS server.
- Designed your captive portal login page.

This topic includes the following tasks:

- Configuring Secure Access for Captive Portal on page 67
- Enabling an Interface for Captive Portal on page 67
- Configuring Bypass of Captive Portal Authentication on page 67

Configuring Secure Access for Captive Portal

To configure secure access for captive portal:

1. Associate the security certificate with the Web server and enable HTTPS on the router:

   ```
   [edit]
   user@router# set system services web-management https local-certificate my-signed-cert
   ```

   NOTE: You can enable HTTP instead of HTTPS, but we recommend HTTPS for security purposes.

2. Configure captive portal to use HTTPS:

   ```
   [edit]
   user@router# set protocols custom-options-captive-portal secure-authentication https
   ```

Enabling an Interface for Captive Portal

To enable an interface for use with captive portal authentication:

```
[edit]
user@router# set authentication-access-control interface ge-0/0/10
```

Configuring Bypass of Captive Portal Authentication

You can allow specific clients to bypass captive portal authentication:

```
[edit]
user@router# set authentication-access-control static 00:10:12:e0:28:22
```

NOTE: Optionally, you can use **set authentication-access-control static 00:10:12:e0:28:22 interface ge-0/0/10.0** to limit the scope to the interface.

NOTE: If the client is already attached to the router, you must clear its MAC address from the captive portal authentication by using the **clear captive-portal mac-address** ***session-mac-addr*** command after adding its MAC address to the whitelist. Otherwise the new entry for the MAC address will not be added to the Ethernet switching table and the authentication bypass will not be allowed.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, configure captive portal authentication (hereafter referred to as captive portal) on an MX Series router so that users connected to the router are authenticated before being allowed to access the network.

Designing a Captive Portal Authentication Login Page on an MX Series Router

Starting with Junos OS Release 14.2, you can set up captive portal authentication on your switch to redirect all Web browser requests to a login page that requires the user to input a username and password before they are allowed access.Upon successful authentication, the user is allowed access to the network and redirected to the original page requested.

Junos OS provides a customizable template for the captive portal window that allows you to easily design and modify the look of the captive portal login page. You can modify the design elements of the template to change the look of your captive portal login page and to add instructions or information to the page. You can also modify any of the design elements of a captive portal login page.

The first screen displayed before the captive login page requires the user to read the “Terms and Conditions of Use”. By clicking the Agree button, the user can access the captive portal login page.

Figure 4 on page 69 shows an example of a captive portal login page:

Figure 4: Example of a Captive Portal Login Page

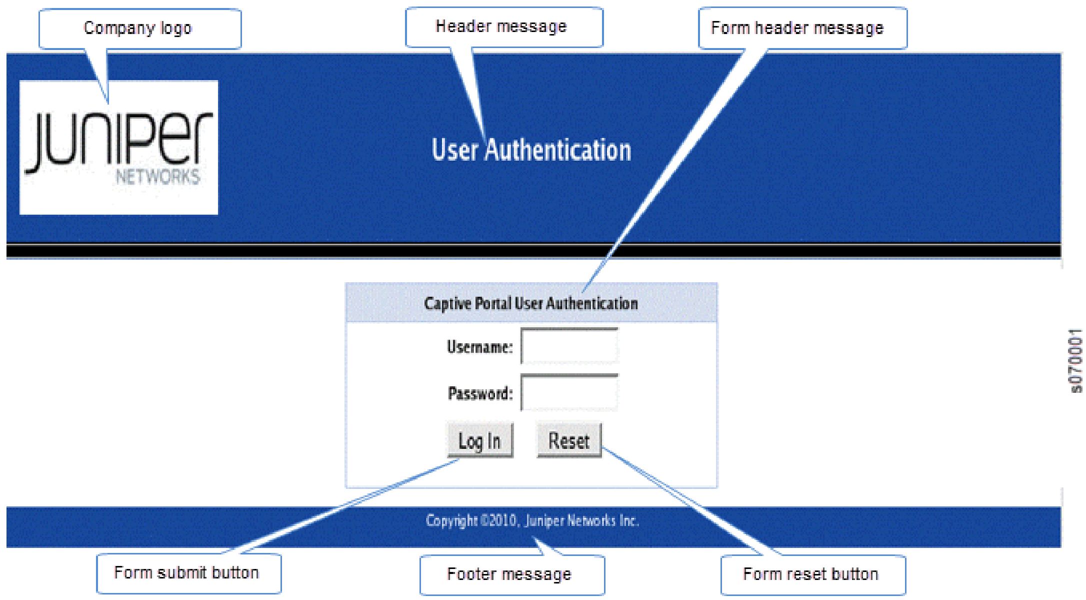


Table 3 on page 69 summarizes the configurable elements of a captive portal login page.

Table 3: Configurable Elements of a Captive Portal Login Page

Element	CLI Statement	Description
Footer background color	**footer-bgcolor** ***hex-color***	The HTML hexadecimal code for the background color of the captive portal login page footer.
Footer message	**footer-message** ***text-string***	Text displayed in the footer of the captive portal login page. You can include copyright information, links, and additional information such as help instructions, legal notices, or a privacy policy The default text shown in the footer is **Copyright @2010, Juniper Networks Inc.**
Footer text color	**footer- text-color** ***color***	Color of the text in the footer. The default color is white.
Form header background color	**form-header-bgcolor** ***hex-color***	The HTML hexadecimal code for the background color of the header bar across the top of the form area of the captive portal login page.
Form header message	**form-header-message** ***text-string***	Text displayed in the header of the captive portal login page. The default text is **Captive Portal User Authentication**
Form header text color	**form-header- text- color** *color*	Color of the text in the form header. The default color is black.
Form reset button label	**form-reset-label** ***label-name***	Using the **Reset** button, the user can clear the username and password fields on the form.
Form submit button label	**form-submit-label** ***label-name***	Using the **Login** button, the user can submit the login information.

Table 3: Configurable Elements of a Captive Portal Login Page (continued)

Element	CLI Statement	Description
Header background color	**header-bgcolor** *hex-color*	The HTML hexadecimal code for the background color of the captive portal login page header.
Header logo	**header-logo** *filename*	Filename of the file containing the image of the logo that you want to appear in the header of the captive portal login page. The image file can be in GIF, JPEG, or PNG format You can upload a logo image file to the switch. Copy the logo to the /var/tmp directory on the switch (during commit, the files are saved to persistent locations). If you do not specify a logo image, the Juniper Networks logo is displayed.
Header message	**header-message** *text-string*	Text displayed in the page header. The default text is **User Authentication**.
Header text color	**header-text- color***color*	Color of the text in the header. The default color is white.
Post-authentication URL	**post-authentication-url** *url*	URL to which the users are directed on successful authentication. By default, users are directed to the page they had originally requested.

To design the captive portal login page:

1. (Optional) Upload your logo image file to the switch:

   `user@router>` **file copy ftp://username:prompt@ftp.hostname.net/var/tmp/my-logo.jpeg**

2. Configure the custom options to specify the background colors and text displayed in the captive portal page:

   `[edit protocols]`
   `user@router#` **set captive-portal-custom-options header-bgcolor #006600**
   set captive-portal-custom-options header-message “Welcome to Our Network”
   set captive-portal-custom-options banner-message “Please enter your username and password”.The banner displays the message ”XXXXXXX” by default. The user can modify this message.
   set custom-options footer-message “Copyright ©2010, Our Network”

Now you can commit the configuration.

NOTE: For the custom options that you do not specify, the default value is used.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, you can set up captive portal authentication on your switch to redirect all Web browser requests to a login page that requires the user to input a username and password before they are allowed access.

Configuring Static MAC Bypass of Authentication on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, you can configure a static MAC bypass list (sometimes called the exclusion list) on the switch to specify MAC addresses of devices allowed access to the LAN without 802.1X or MAC RADIUS authentication requests to the RADIUS server.

To configure the static MAC bypass list:

- Specify a MAC address to bypass authentication:

  ```
  [edit protocols authentication-access-control]
  user@router# set static 00:04:0f:fd:ac:fe
  ```

- Configure a supplicant to bypass authentication if connected through a particular interface:

  ```
  [edit protocols authentication-access-control]
  user@router# set static 00:04:0f:fd:ac:fe interface ge-0/0/5
  ```

- You can configure a supplicant to be moved to a specific VLAN after it is authenticated:

  ```
  [edit protocols authentication-access-control]
  user@router# set static 00:04:0f:fd:ac:fe interface ge-0/0/5 vlan-assignment default-vlan
  ```

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, you can configure a static MAC bypass list (sometimes called the exclusion list) on the switch to specify MAC addresses of devices allowed access to the LAN without 802.1X or MAC RADIUS authentication requests to the RADIUS server.

Controlling Authentication Session Timeouts on an MX Series Router in Enhanced LAN Mode

Starting with Junos OS Release 14.2, for 802.1X and MAC RADIUS authentication sessions, you can specify authentication session timeout values using the **reauthentication** statement.

The session might also end when the MAC table aging time expires, because the session is removed from the authentication session table when the MAC address is removed from the Ethernet switching table. In order to prevent the session from being removed from the authentication session table, you must disassociate the authentication table from the Ethernet switching table using the **no-mac-table-binding** statement.

Before you begin:

- Specify the RADIUS server or servers to be used as the authentication server.
- Configure 802.1X authentication on the router.

To configure the authentication session time on all interfaces:

```
[edit]
user@router# set protocols authentication-access-control interface all dot1x reauthentication seconds ;
```

To configure the authentication session time on a single interface:

```
[edit]
user@router# set protocols authentication-access-control interface interface-name dot1x reauthentication seconds ;
```

To disable removal of authentication sessions from the authentication session table when a MAC address ages out of the Ethernet switching table, remove the binding of the authentication table to the Ethernet switching table.

To remove the binding on all interfaces:

```
[edit]
user@router# set protocols authentication-access-control no-mac-table-binding interface all;
```

To remove the binding on a single interface:

```
[edit]
user@router# set protocols authentication-access-control no-mac-table-binding interface interface-name;
```

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, for 802.1X and MAC RADIUS authentication sessions, you can specify authentication session timeout values using the **reauthentication** statement.

Related Documentation

Configuring MAC RADIUS Authentication on MX Series Routers in Enhanced LAN Mode

Starting with Junos OS Release 14.2, you can permit devices that are not 802.1X-enabled LAN access by configuring MAC RADIUS authentication on the MX Series router interfaces to which the hosts are connected.

NOTE: **You can also allow non-802.1X-enabled devices to access the LAN by configuring their MAC address for static MAC bypass of authentication.**

You can configure MAC RADIUS authentication on an interface that also allows 802.1X authentication, or you can configure either authentication method alone.

If both MAC RADIUS and 802.1X authentication are enabled on the interface, the router first sends the host three EAPOL requests to the host. If there is no response from the host, the router sends the host's MAC address to the RADIUS server to check whether it is a permitted MAC address. If the MAC address is configured as permitted on the RADIUS server, the RADIUS server sends a message to the router that the MAC address is a permitted address, and the router opens LAN access to the nonresponsive host on the interface to which it is connected.

If MAC RADIUS authentication is configured on the interface but 802.1X authentication is not (by using the **mac-radius restrict** option), the router attempts to authenticate the MAC address with the RADIUS server without delaying by attempting 802.1X authentication first.

Before you configure MAC RADIUS authentication, be sure you have:

- Configured basic access between the MX Series router and the RADIUS server.
- Configured MX240, MX480, and MX960 routers to function in enhanced LAN mode by entering the **network-services lan** statement at the **[edit chassis]** hierarchy level.

To configure MAC RADIUS authentication using the CLI:

- On the router, configure the interfaces to which the nonresponsive hosts are attached for MAC RADIUS authentication, and add the **restrict** qualifier for interface **ge-0/0/20** to have it use only MAC RADIUS authentication:

```
[edit]
user@router# set protocols authentication-access-control interface ge-0/0/19 dot1x mac-radius
user@router# set protocols authentication-access-control interface ge-0/0/20 dot1x mac-radius restrict
```

- On a RADIUS authentication server, create user profiles for each nonresponsive host using the MAC address (without colons) of the nonresponsive host as the username and password (here, the MAC addresses are **00:04:0f:fd:ac:fe** and **00:04:ae:cd:23:5f**):

```
[root@freeradius]#
edit /etc/raddb
vi users
00040ffdacfe Auth-type:=Local, User-Password = "00040ffdacfe"
0004aecd235f Auth-type:=Local, User-Password = "0004aecd235f"
```

Release	Description
14.2	Starting with Junos OS Release 14.2, you can permit devices that are not 802.1X-enabled LAN access by configuring MAC RADIUS authentication on the MX Series router interfaces to which the hosts are connected.

Related Documentation

Example: Configuring MAC RADIUS Authentication on an MX Series Router

Starting with Junos OS Release 14.2 to permit hosts that are not 802.1X-enabled to access the LAN, you can configure MAC RADIUS authentication on the router interfaces to which the non-802.1X-enabled hosts are connected. When MAC RADIUS authentication is configured, the router will attempt to authenticate the host with the RADIUS server using the host's MAC address.

This example describes how to configure MAC RADIUS authentication for two non-802.1X-enabled hosts:

Requirements

This example uses the following hardware and software components:

- Junos OS Release 14.2 or later for MX240, MX480, or MX960 routers running in enhanced LAN mode.
- An MX Series router acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- A RADIUS authentication server. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you connect the server to the router, be sure you have:

- Configured enhanced LAN mode on the router.
- Performed basic bridging and VLAN configuration on the router.
- Configured users on the RADIUS authentication server.

Overview and Topology

IEEE 802.1X Port-Based Network Access Control (PNAC) authenticates and permits devices access to a LAN if the devices can communicate with the router using the 802.1X protocol (are 802.1X-enabled). To permit non-802.1X-enabled end devices to access the LAN, you can configure MAC RADIUS authentication on the interfaces to which the end devices are connected. When the MAC address of the end device appears on the interface, the router consults the RADIUS server to check whether it is a permitted MAC address. If the MAC address of the end device is configured as permitted on the RADIUS server, the router opens LAN access to the end device.

You can configure both MAC RADIUS authentication and 802.1X authentication methods on an interface configured for multiple supplicants. Additionally, if an interface is only connected to a non-802.1X-enabled host, you can enable MAC RADIUS and not enable 802.1X authentication using the **mac-radius restrict** option, and thus avoid the delay that occurs while the router determines that the device is does not respond to EAP messages.

Two printers are connected to an MX Series router over interfaces, ge-0/0/19 and ge-0/0/20.

Table 4 on page 76 shows the components in the example for MAC RADIUS authentication.

Table 4: Components of the MAC RADIUS Authentication Configuration Topology

Property	Settings
Router hardware	Ports (ge-0/0/0 through ge-0/0/23)
VLAN name	sales

Table 4: Components of the MAC RADIUS Authentication Configuration Topology (continued)

Property	Settings
Connections to printers	ge-0/0/19, MAC address 00040ffdacfe ge-0/0/20, MAC address 0004aecd235f
RADIUS server	Connected to the router on interface **ge-0/0/10**

The printer with the MAC address 00040ffdacfe is connected to access interface ge-0/0/19. A second printer with the MAC address 0004aecd235f is connected to access interface ge-0/0/20. In this example, both interfaces are configured for MAC RADIUS authentication on the router, and the MAC addresses (without colons) of both printers are configured on the RADIUS server. Interface ge-0/0/20 is configured to eliminate the normal delay while the router attempts 802.1X authentication; MAC RADIUS authentication is enabled and 802.1X authentication is disabled using the **mac radius restrict** option.

Configuration

CLI Quick Configuration

To quickly configure MAC RADIUS authentication, copy the following commands and paste them into the router terminal window:

```
[edit]
set protocols authentication-access-control interface ge-0/0/19 dot1x mac-radius
set protocols authentication-access-control authenticator interface ge-0/0/20 dot1x mac-radius
restrict
```

NOTE: You must also configure the two MAC addresses as usernames and passwords on the RADIUS server, as is done in step 2 of the Step-by-Step Procedure.

Step-by-Step Procedure

Configure MAC RADIUS authentication on the router and on the RADIUS server:

1. On the router, configure the interfaces to which the printers are attached for MAC RADIUS authentication, and configure the **restrict** option on interface **ge-0/0/20**, so that only MAC RADIUS authentication is used:

```
[edit]
user@router# set protocols authentication-access-control interface ge-0/0/19 dot1x
mac-radius
user@router# set protocols authentication-access-control authenticator interface
ge-0/0/20 dot1x mac-radius restrict
```

2. On the RADIUS server, configure the MAC addresses **00040ffdacfe** and **0004aecd235f** as usernames and passwords:

```
[root@freeradius]#
edit /etc/raddb
```

```
vi users
00040ffdacfe Auth-type:=EAP, User-Password = "00040ffdacfe"
0004aecd235f Auth-type:=EAP, User-Password = "0004aecd235f"
```

Results Display the results of the configuration on the router:

```
user@router> show configuration
protocols {
  authentication-access-control {
    authentication-profile-name profile52;
    interface {
      ge-0/0/19.0 {
        dot1x {
          mac-radius;
        }
      }
      ge-0/0/20.0 {
        dot1x {
          mac-radius {
            restrict;
          }
        }
      }
    }
  }
}
```

Verification

Verify that the supplicants are authenticated:

- Verifying That the Supplicants Are Authenticated on page 78

Verifying That the Supplicants Are Authenticated

Purpose After supplicants are configured for MAC RADIUS authentication on the router and on the RADIUS server, verify that they are authenticated and display the method of authentication:

Action Display information about 802.1X-configured interfaces **ge-0/0/19** and **ge-0/0/20**:

```
user@router> show dot1x interface ge-0/0/19.0 detail
ge-0/0/19.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Single
  Number of retries: 3
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Enabled
  Mac Radius Restrict: Disabled
  Reauthentication: Enabled
  Configured Reauthentication interval: 3600 seconds
  Supplicant timeout: 30 seconds
  Server timeout: 30 seconds
  Maximum EAPOL requests: 2
  Guest VLAN member: <not configured>
  Number of connected supplicants: 1
    Supplicant: user101, 00:04:0f:fd:ac:fe
      Operational state: Authenticated
      Authentication method: Radius
      Authenticated VLAN: vo11
      Dynamic Filter: match source-dot1q-tag 10 action deny
      Session Reauth interval: 60 seconds
      Reauthentication due in 50 seconds
```

```
user@router> show dot1x interface ge-0/0/20.0 detail
ge-0/0/20.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Single
  Number of retries: 3
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Enabled
  Mac Radius Restrict: Enabled
  Reauthentication: Enabled
  Configured Reauthentication interval: 3600 seconds
  Supplicant timeout: 30 seconds
  Server timeout: 30 seconds
  Maximum EAPOL requests: 2
  Guest VLAN member: <not configured>
  Number of connected supplicants: 1
    Supplicant: user102, 00:04:ae:cd:23:5f
      Operational state: Authenticated
      Authentcation method: Radius
      Authenticated VLAN: vo11
      Dynamic Filter: match source-dot1q-tag 10 action deny
      Session Reauth interval: 60 seconds
      Reauthentication due in 50 seconds
```

Meaning The sample output from the **show dot1x interface detail** command displays the MAC address of the connected end device in the **Supplicant** field. On interface ge-0/0/19, the MAC address is **00:04:0f:fd:ac:fe**, which is the MAC address of the first printer configured for MAC RADIUS authentication. The **Authentication method** field displays the authentication method as **MAC Radius**. On interface **ge-0/0/20**, the MAC address is

00:04:ae:cd:23:5f, which is the MAC address of the second printer configured for MAC RADIUS authentication. The **Authentication method** field displays the authentication method as **MAC Radius**.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2 to permit hosts that are not 802.1X-enabled to access the LAN, you can configure MAC RADIUS authentication on the router interfaces to which the non-802.1X-enabled hosts are connected.

Example: Setting Up Captive Portal Authentication on an MX Series Router

Starting with Junos OS Release 14.2, you can set up captive portal authentication (hereafter referred to as captive portal) on a router to redirect Web browser requests to a login page that requires the user to input a username and password.Upon successful authentication, the user is allowed to continue with the original page request and subsequent access to the network.

This example describes how to set up captive portal on an MX Series router:

Requirements

This example uses the following hardware and software components:

- An MX Series router that supports captive portal
- Junos OS Release 14.2 or later for MX Series routers

Before you begin, be sure you have:

- Performed basic bridging and VLAN configuration on the router.
- Generated an SSL certificate and installed it on the router.
- Configured basic access between the MX Series router and the RADIUS server.
- Designed your captive portal login page. .

Overview and Topology

This example shows the configuration required on the router to enable captive portal on an interface. To permit a printer connected to the captive portal interface to access the LAN without going through captive portal, add its MAC address to the authentication whitelist. The MAC addresses in this list are permitted access on the interface without captive portal.

The topology for this example consists of one MX Series router connected to a RADIUS authentication server. One interface on the router is configured for captive portal. In this example, the interface is configured in multiple supplicant mode.

Configuration

To configure captive portal on your router:

CLI Quick Configuration

To quickly configure captive portal on the router after completing the tasks in the Requirements section, copy the following commands and paste them into the router terminal window:

```
[edit]
set system services web-management http
set system services web-management https local-certificate my-signed-cert
set protocols captive-portal-custom-options secure-authentication https
set protocols authentication-access-control interface ge-0/0/10.0 supplicant multiple
set protocols authentication-access-control static 00:10:12:e0:28:22
set protocols captive-portal-custom-options post-authentication-url
http://www.my-home-page.com
```

Step-by-Step Procedure

To configure captive portal on the router:

1. Enable HTTP access on the router:

   ```
   [edit]
   user@router# set system services web-management http
   ```

2. To create a secure channel for Web access to the router, configure captive portal for HTTPS:

   NOTE: You can enable HTTP without enabling HTTPS, but we recommend HTTPS for security purposes.

   a. Associate the security certificate with the Web server and enable HTTPS access on the router:

   ```
   [edit]
   user@router# set system services web-management https local-certificate
   my-signed-cert
   ```

   b. Configure captive portal to use HTTPS:

   ```
   [edit]
   user@router# set protocols captive-portal-custom-options secure-authentication
   https
   ```

3. Enable an interface for captive portal:

```
[edit]
user@router# set protocols authentication-access-control interface ge-0/0/10.0 supplicant multiple
```

4. (Optional) Allow specific clients to bypass captive portal:

   NOTE: If the client is already attached to the router, you must clear its MAC address from the captive portal authentication by using the **clear captive-portal mac-address** *mac-address* command after adding its MAC address to the whitelist. Otherwise the new entry for the MAC address will not be added to the Ethernet routering table and authentication bypass will not be allowed.

```
[edit]
user@router# set protocols authentication-access-control static 00:10:12:e0:28:22
```

   NOTE: Optionally, you can use **set ethernet-switching-options authentication-whitelist 00:10:12:e0:28:22 interface ge-0/0/10.0** to limit the scope to the interface.

5. (Optional) To redirect clients to a specified page rather than the page they originally requested, configure the post-authentication URL:

```
[edit services captive-portal]
user@router# set protocols captive-portal-custom-options post-authentication-url http://www.my-home-page.com
```

Results Display the results of the configuration:

```
[edit]
user@router> show
system {
  services {
    web-management {
      http;
      https {
        local-certificate my-signed-cert;
      }
    }
  }
}

            }
        }
    }
}
protocols {
    authentication-access-control {
    static 00:10:12:e0:28:22/48;
        interface {
            ge-0/0/10.0 {
                supplicant multiple;
            }
        }
    custom-captive-portal-options {
        secure-authentication https;
        post-authentication-url http://www.my-home-page.com;
    }
}
```

Verification

To confirm that captive portal is configured and working properly, perform these tasks:

- Verifying That Captive Portal Is Enabled on the Interface on page 83
- Verify That Captive Portal Is Working Correctly on page 83

Verifying That Captive Portal Is Enabled on the Interface

Purpose Verify that captive portal is configured on interface ge-0/0/10.

Action Use the operational mode command **show captive-portal interface *interface-name* detail**:

```
user@router> show captive-portal interface ge-0/0/10.0 detail
ge-0/0/10.0
  Supplicant mode: Multiple
  Number of retries: 3
  Quiet period: 60 seconds
  Configured CP session timeout: 3600 seconds
  Server timeout: 15 seconds
```

Meaning The output confirms that captive portal is configured on interface ge-0/0/10 with the default settings for number of retries, quiet period, CP session timeout, and server timeout.

Verify That Captive Portal Is Working Correctly

Purpose Verify that captive portal is working on the router.

Action Connect a client to interface ge-0/0/10. From the client, open a Web browser and request a webpage. The captive portal login page that you designed should be displayed. After you enter your login information and are authenticated against the RADIUS server, the Web browser should display either the page you requested or the post-authentication URL that you configured.

Troubleshooting

To troubleshoot captive portal, perform these tasks:

Troubleshooting Captive Portal

Problem The router does not return the captive portal login page when a user connected to a captive portal interface on the router requests a Web page.

Solution You can examine the ARP, DHCP, HTTPS, and DNS counters—if one or more of these counters are not incrementing, this provides an indication of where the problem lies. For example, if the client cannot get an IP address, check the router interface to determine whether the DHCP counter is incrementing—if the counter increments, the DHCP packet was received by the router.

```
user@router> show captive-portal firewall ge-0/0/10.0
ge-0/0/10.0
  Filter name: dot1x_ge-0/0/10
Counters:
Name                          Bytes              Packets
dot1x_ge-0/0/10_CP_arp         7616                  119
dot1x_ge-0/0/10_CP_dhcp           0                    0
dot1x_ge-0/0/10_CP_http           0                    0
dot1x_ge-0/0/10_CP_https          0                    0
dot1x_ge-0/0/10_CP_t_dns          0                    0
dot1x_ge-0/0/10_CP_u_dns          0                    0
```

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, you can set up captive portal authentication (hereafter referred to as captive portal) on a router to redirect Web browser requests to a login page that requires the user to input a username and password.

Example: Connecting a RADIUS Server for 802.1X to an MX Series Router

802.1X is the IEEE standard for Port-Based Network Access Control (PNAC). You use 802.1X to control network access. Only users and devices providing credentials that have been verified against a user database are allowed access to the network. Starting with Junos OS Release 14.2, you can use a RADIUS server as the user database for 802.1X authentication, as well as for MAC RADIUS authentication.

This example describes how to connect a RADIUS server to an MX Series router, and configure it for 802.1X:

Requirements

This example uses the following hardware and software components:

- Junos OS Release 14.2 or later for MX240, MX480, or MX960 routers running in enhanced LAN mode and Junos OS Release 14.2R3 for all other routers.
- One router acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- One RADIUS authentication server that supports 802.1X. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you connect the server to the router, be sure you have:

- Configured enhanced LAN mode on the router.
- Performed basic bridging and VLAN configuration on the router.
- Configured users on the RADIUS authentication server.

Overview and Topology

The MX Series router acts as an authenticator Port Access Entity (PAE). It blocks all traffic and acts as a control gate until the supplicant (client) is authenticated by the server. All other users and devices are denied access.

Consider an MX Series router that functions as an authenticator port. It is connected using the interface, ge-0/0/10, over the IP network to a RADIUS server. The router is also linked to a conference room using the interface, ge-0/0/1, to a printer using the interface, ge-0/0/20, to a hub using the interface, ge-0/0/8, and to two supplicants or clients over interfaces, ge-0/0/2 and ge-0/0/9 respectively.

Table 5: Components of the Topology

Property	Settings
Router hardware	MX Series router
VLAN name	**default**
One RADIUS server	Backend database with an address of **10.0.0.100** connected to the switch at port **ge-0/0/10**

In this example, connect the RADIUS server to access port **ge-0/0/10** on the MX Series router. The switch acts as the authenticator and forwards credentials from the supplicant to the user database on the RADIUS server. You must configure connectivity between the MX Series router and the RADIUS server by specifying the address of the server and configuring the secret password. This information is configured in an access profile on the switch.

Configuration

CLI Quick Configuration

To quickly connect the RADIUS server to the switch, copy the following commands and paste them into the switch terminal window:

```
[edit]
set access radius-server 10.0.0.100 secret juniper
set access radius-server 10.0.0.200 secret juniper
set access profile profile1 authentication-order radius
set access profile profile1 radius authentication-server [10.0.0.100 10.0.0.200]
```

Step-by-Step Procedure

To connect the RADIUS server to the switch:

1. Define the address of the servers, and configure the secret password. The secret password on the switch must match the secret password on the server:

   ```
   [edit]
   user@switch# set access radius-server 10.0.0.100 secret juniper
   user@switch# set access radius-server 10.0.0.200 secret juniper
   ```

2. Configure the authentication order, making **radius** the first method of authentication:

   ```
   [edit]
   user@switch# set access profile profile1 authentication-order radius
   ```

3. Configure a list of server IP addresses to be tried in order to authenticate the supplicant:

   ```
   [edit]
   user@switch# set access profile profile1 radius authentication-server [10.0.0.100
   10.0.0.200]
   ```

Results

Display the results of the configuration:

```
user@switch> show configuration access
radius-server {
  10.0.0.100
    port 1812;
    secret "$9$qPT3ApBSrv69rvWLVb.P5"; ## SECRET-DATA
    }
  }
  profile profile1{
    authentication-order radius;
    radius {
      authentication-server 10.0.0.100 10.0.0.200;
```

```
        }
      }
    }
```

Verification

To confirm that the configuration is working properly, perform these tasks:

Verify That the Switch and RADIUS Server are Properly Connected

Purpose Verify that the RADIUS server is connected to the switch on the specified port.

Action Ping the RADIUS server to verify the connection between the switch and the server:

```
user@switch> ping 10.0.0.100
PING 10.0.0.100 (10.0.0.100): 56 data bytes
64 bytes from 10.93.15.218: icmp_seq=0 ttl=64 time=9.734 ms
64 bytes from 10.93.15.218: icmp_seq=1 ttl=64 time=0.228 ms
```

Meaning ICMP echo request packets are sent from the switch to the target server at 10.0.0.100 to test whether it is reachable across the IP network. ICMP echo responses are being returned from the server, verifying that the switch and the server are connected.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, you can use a RADIUS server as the user database for 802.1X authentication, as well as for MAC RADIUS authentication.

Example: Setting Up 802.1X in Conference Rooms to Provide Internet Access to Corporate Visitors on an MX Series Router

Starting with Junos OS Release 14.2, 802.1X on MX Series routers provides LAN access to users who do not have credentials in the RADIUS database.These users, referred to as guests, are authenticated and typically provided with access to the Internet.

This example describes how to create a guest VLAN and configure 802.1X authentication for it.

Requirements

This example uses the following hardware and software components:

- Junos OS Release 14.2 or later for MX240, MX480, or MX960 routers running in enhanced LAN mode.
- One router acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.
- One RADIUS authentication server that supports 802.1X. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you connect the server to the router, be sure you have:

- Configured enhanced LAN mode on the router.
- Performed basic bridging and VLAN configuration on the router.
- Configured users on the RADIUS authentication server.

Overview and Topology

The MX Series router acts as an authenticator Port Access Entity (PAE). It blocks all traffic and acts as a control gate until the supplicant (client) is authenticated by the server. All other users and devices are denied access.

Consider an MX Series router that functions as an authenticator port. It is connected using the interface, ge-0/0/10, over the IP network to a RADIUS server. The router is also linked to a conference room using the interface, ge-0/0/1, to a printer using the interface, ge-0/0/20, to a hub using the interface, ge-0/0/8, and to two supplicants or clients over interfaces, ge-0/0/2 and ge-0/0/9 respectively.

Table 6: Components of the Topology

Property	Settings
Router hardware	MX Series router
VLAN name	**default**
One RADIUS server	Backend database with an address of **10.0.0.100** connected to the switch at port **ge-0/0/10**

In this example, access interface **ge-0/0/1** provides LAN connectivity in the conference room. Configure this access interface to provide LAN connectivity to visitors in the conference room who are not authenticated by the corporate VLAN.

Configuration of a Guest VLAN That Includes 802.1X Authentication

CLI Quick Configuration

To quickly configure a guest VLAN, with 802.1X authentication, copy the following commands and paste them into the switch terminal window:

```
[edit]
set vlans guest-vlan vlan-id 300
set protocols authentication-access-control interface all dot1x guest-vlan guest-vlan
```

Step-by-Step Procedure

To configure a guest VLAN that includes 802.1X authentication on an EX Series switch:

1. Configure the VLAN ID for the guest VLAN:

   ```
   [edit]
   user@switch# set bridge-domains guest-vlan vlan-id 300
   ```

2. Configure the guest VLAN under **dot1x** protocols:

   ```
   [edit]
   user@switch# set protocols authentication-access-control interface all dot1x guest-vlan guest-vlan
   ```

Results

Check the results of the configuration:

```
user@switch> show configuration
protocols {
  authentication-access-control {
    interface {
      all {
        dot1x {
          guest-vlan {
            guest-vlan;
          }
        }
      }
    }
    }
  }
}
bridge-domains {
  guest-vlan {
    vlan-id 300;
  }
}
```

Verification

To confirm that the configuration is working properly, perform these tasks:

- Verifying That the Guest VLAN is Configured on page 90

Verifying That the Guest VLAN is Configured

Purpose Verify that the guest VLAN is created and that an interface has failed authentication and been moved to the guest VLAN.

Action Use the operational mode commands:

user@switch> **show bridge-domain**

```
Instance                     Bridging Domain          Type
            Primary Table                                             Active
vs1                          dynamic                   bridge
            bridge.0                                                  2
vs1                          guest                     bridge
            bridge.0                                                  0
vs1                          guest-vlan                bridge
            bridge.0                                                  0
vs1                          vlan_dyn                  bridge
            bridge.0                                                  0
```

user@switch> **show dot1x interface ge-0/0/1.0 detail**

```
ge-0/0/1.0
  Role: Authenticator
  Administrative state: Auto
  Supplicant mode: Single
  Number of retries: 3
  Quiet period: 60 seconds
  Transmit period: 30 seconds
  Mac Radius: Enabled
  Mac Radius Restrict: Disabled
  Reauthentication: Enabled
  Configured Reauthentication interval: 3600 seconds
  Supplicant timeout: 30 seconds
  Server timeout: 30 seconds
  Maximum EAPOL requests: 2
  Guest VLAN member: guest-vlan
  Number of connected supplicants: 1
    Supplicant: user1, 00:00:00:00:13:23
      Operational state: Authenticated
      Authentication method: Radius
      Authenticated VLAN: vo11
      Dynamic Filter: match source-dot1q-tag 10 action deny
      Session Reauth interval: 60 seconds
      Reauthentication due in 50 seconds
```

Meaning The output from the **show bridge domain** command shows **guest-vlan** as the name of the VLAN and the VLAN ID as **300**.

The output from the **show dot1x interface ge-0/0/1.0 detail** command displays the **Guest VLAN membership** field, indicating that a supplicant at this interface failed 802.1X authentication and was passed through to the **guest-vlan**.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, 802.1X on MX Series routers provides LAN access to users who do not have credentials in the RADIUS database.

Example: Configuring Static MAC Bypass of Authentication on an MX Series Router

Starting with Junos OS Release 14.2, to allow devices to access your LAN through 802.1X-configured interfaces without authentication, you can configure a static MAC bypass list on the MX Series router.The static MAC bypass list, also known as the *exclusion list*, specifies MAC addresses that are allowed on the router without a request to an authentication server.

You can use static MAC bypass of authentication to allow connection for devices that are not 802.1X-enabled, such as printers. If a host's MAC address is compared and matched against the static MAC address list, the nonresponsive host is authenticated and an interface opened for it.

This example describes how to configure static MAC bypass of authentication for two printers:

Requirements

This example uses the following hardware and software components:

- Junos OS Release 14.2 or later for MX240, MX480, or MX960 routers running in enhanced LAN mode.
- One router acting as an authenticator port access entity (PAE). The ports on the authenticator PAE form a control gate that blocks all traffic to and from supplicants until they are authenticated.

Before you connect the server to the router, be sure you have:

- Configured enhanced LAN mode on the router.
- Performed basic bridging and VLAN configuration on the router.
- Configured users on the RADIUS authentication server.

Overview and Topology

To permit printers access to the LAN, add them to the static MAC bypass list. The MAC addresses on this list are permitted access without authentication from the RADIUS server.

Consider an MX Series router that functions as an authenticator port. It is connected using the interface, ge-0/0/10, over the IP network to a RADIUS server. The router is also linked to a conference room using the interface, ge-0/0/1, to a printer using the interface, ge-0/0/20, to a hub using the interface, ge-0/0/8, and to two supplicants or clients over interfaces, ge-0/0/2 and ge-0/0/9 respectively.

The interfaces shown in Table 7 on page 92 will be configured for static MAC authentication.

Table 7: Components of the Static MAC Authentication Configuration Topology

Property	Settings
Router hardware	MX Series router
VLAN name	**default**
Connections to integrated printer/fax/copier machines (no PoE required)	**ge-0/0/19**, MAC address 00:04:0f:fd:ac:fe **ge-0/0/20**, MAC address 00:04:ae:cd:23:5f

The printer with the MAC address 00:04:0f:fd:ac:fe is connected to access interface **ge-0/0/19**. A second printer with the MAC address 00:04:ae:cd:23:5f is connected to access interface **ge-0/0/20**. Both printers will be added to the static list and bypass 802.1X authentication.

Configuration

CLI Quick Configuration

To quickly configure static MAC authentication, copy the following commands and paste them into the router terminal window:

```
[edit]
set protocols authentication-access-control static [00:04:0f:fd:ac:fe 00:04:ae:cd:23:5f]
set protocols authentication-access-control interface all supplicant multiple
set protocols authentication-access-control authenticaton-profile-name profile1
```

Step-by-Step Procedure

Configure static MAC authentication:

1. Configure MAC addresses **00:04:0f:fd:ac:fe** and **00:04:ae:cd:23:5f** as static MAC addresses:

   ```
   [edit protocols]
   user@router# set authentication-access-control static [00:04:0f:fd:ac:fe
   00:04:ae:cd:23:5f]
   ```

2. Configure the 802.1X authentication method:

   ```
   [edit protocols]
   user@router# set authentication-access-control interface all supplicant multiple
   ```

3. Configure the authentication profile name (access profile name) to use for authentication:

   ```
   [edit protocols]
   ```

```
user@router# set authentication-access-control authentication-profile-name profile1
```

NOTE: Access profile configuration is required only for 802.1X clients, not for static MAC clients.

Results Display the results of the configuration:

```
user@router> show
interfaces {
  ge-0/0/19 {
    unit 0 {
      family bridge {
        vlan-id 10;
      }
    }
  }
  ge-0/0/20 {
    unit 0 {
      family bridge {
        vlan-id 10;
      }
    }
  }
}
protocols {
  authentication-access-control {
    authentication-profile-name profile1;
    static [00:04:0f:fd:ac:fe 00:04:ae:cd:23:5f];
    interface {
      all {
        supplicant multiple;
      }
    }
  }
}
```

Verification

To confirm that the configuration is working properly, perform these tasks:

- Verifying Static MAC Bypass of Authentication on page 93

Verifying Static MAC Bypass of Authentication

Purpose Verify that the MAC address for both printers is configured and associated with the correct interfaces.

Action Use the operational mode command:

```
user@switch> show dot1x static-mac-address

MAC address          VLAN-Assignment              Interface
00:04:0f:fd:ac:fe    default                      ge-0/0/19.0
00:04:ae:cd:23:5f    default                      ge-0/0/20.0
```

Meaning The output field **MAC address** shows the MAC addresses of the two printers.

The output field **Interface** shows that the MAC address **00:04:0f:fd:ac:fe** can connect to the LAN through interface **ge-0/0/19.0** and that the MAC address **00:04:ae:cd:23:5f** can connect to the LAN through interface **ge-0/0/20.0**.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, to allow devices to access your LAN through 802.1X-configured interfaces without authentication, you can configure a static MAC bypass list on the MX Series router.

Example: Applying Firewall Filters to Multiple Supplicants on Interfaces Enabled for 802.1X or MAC RADIUS Authentication on MX Series Routers

Starting with Junos OS Release 14.2, on MX Series routers, firewall filters that you apply to interfaces enabled for 802.1X or MAC RADIUS authentication are dynamically combined with the per-user policies sent to the switch from the RADIUS server.The switch uses internal logic to dynamically combine the interface firewall filter with the user policies from the RADIUS server and create an individualized policy for each of the multiple users or nonresponsive hosts that are authenticated on the interface.

This example describes how dynamic firewall filters are created for multiple supplicants on an 802.1X-enabled interface (the same principles shown in this example apply to interfaces enabled for MAC RADIUS authentication):

Requirements

This example uses the following hardware and software components:

- Junos OS Release 14.2 or later for MX Series routers
- One MX Series router

- One RADIUS authentication server. The authentication server acts as the backend database and contains credential information for hosts (supplicants) that have permission to connect to the network.

Before you apply firewall filters to an interface for use with multiple supplicants, be sure you have:

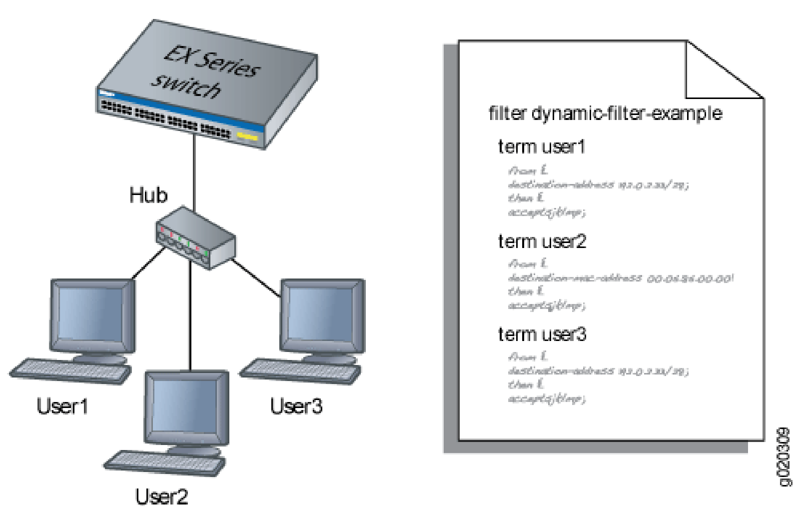
- Set up a connection between the router and the RADIUS server.
- Configured 802.1X authentication on the router, with the authentication mode for interface **ge-0/0/2** set to **multiple**.
- Configured users on the RADIUS authentication server.

Overview and Topology

When the 802.1X configuration on an interface is set to multiple supplicant mode, the system dynamically combines interface firewall filter with the user policies sent to the router from the RADIUS server during authentication and creates separate terms for each user. Because there are separate terms for each user authenticated on the interface, you can, as shown in this example, use counters to view the activities of individual users that are authenticated on the same interface.

When a new user (or a nonresponsive host) is authenticated on an interface, the system adds a term to the firewall filter associated with the interface, and the term (policy) for each user is associated with the MAC address of the user. The term for each user is based on the user-specific filters set on the RADIUS server and the filters configured on the interface. For example, as shown in Figure 5 on page 95, when User1 is authenticated by the MX Series router, the system creates the firewall filter **dynamic-filter-example**. When User2 is authenticated, another term is added to the firewall filter, and so on.

Figure 5: Conceptual Model: Dynamic Filter Updated for Each New User

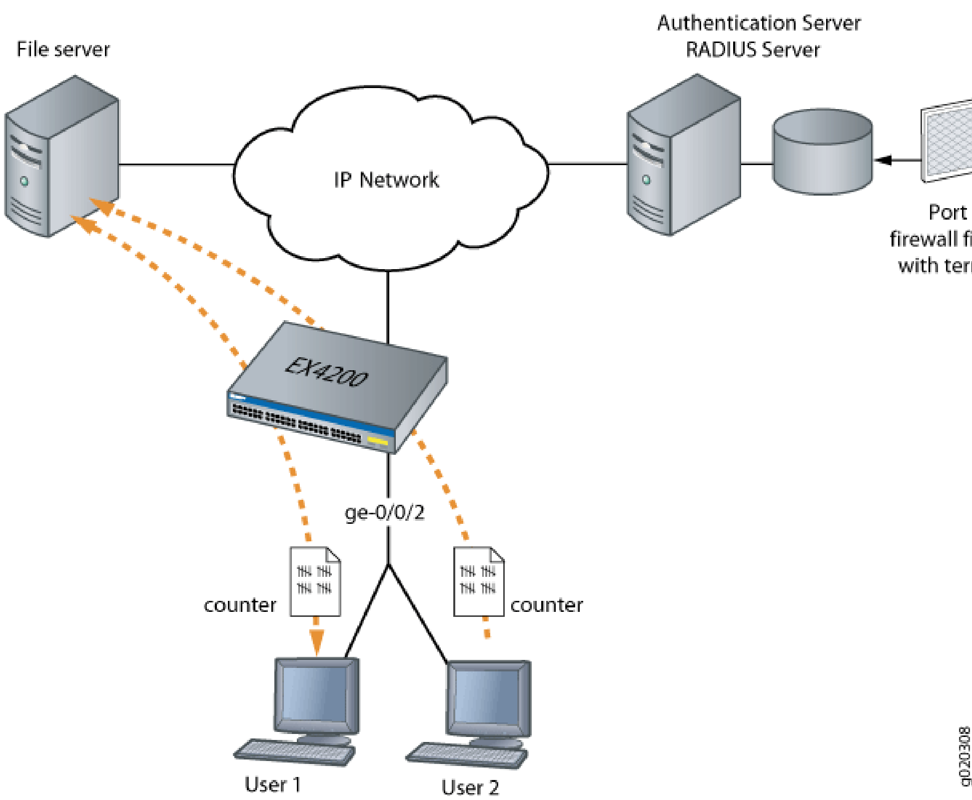


This is a conceptual model of the internal process—you cannot access or view the dynamic filter.

NOTE: If the firewall filter on the interface is modified after the user (or nonresponsive host) is authenticated, the modifications are not reflected in the dynamic filter unless the user is reauthenticated.

In this example, you configure a firewall filter to count the requests made by each endpoint authenticated on interface **ge-0/0/2** to the file server, which is located on subnet **192.0.2.16/28**, and set policer definitions to rate limit the traffic. Figure 6 on page 96 shows the network topology for this example.

Figure 6: Multiple Supplicants on an 802.1X-Enabled Interface Connecting to a File Server



Configuration

To configure firewall filters for multiple supplicants on 802.1X-enabled interfaces:

- Configuring Firewall Filters on Interfaces with Multiple Supplicants on page 96

Configuring Firewall Filters on Interfaces with Multiple Supplicants

CLI Quick Configuration

To quickly configure firewall filters for multiple supplicants on an 802.1X-enabled interface copy the following commands and paste them into the router terminal window:

```
[edit]
set protocols authentication-access-control interface ge-0/0/2 supplicant multiple
set firewall family bridge filter filter1 term term1 from destination-address 192.0.2.16/28
```

set firewall policer p1 if-exceeding bandwidth-limit 1m
set firewall policer p1 if-exceeding burst-size-limit 1k
set firewall family bridge filter filter1 term term1 then count counter1
set firewall family bridge filter filter1 term term2 then policer p1

Step-by-Step Procedure

To configure firewall filters on an interface enabled for multiple supplicants:

1. Configure interface **ge-0/0/2** for multiple supplicant mode authentication:

   ```
   [edit protocols]
   user@router# set authentication-access-control interface ge-0/0/2 supplicant multiple
   ```

2. Set policer definition:

   ```
   user@router# show policer p1 |display set
   set firewall policer p1 if-exceeding bandwidth-limit 1m
   set firewall policer p1 if-exceeding burst-size-limit 1k
   set firewall policer p1 then discard
   ```

3. Configure a firewall filter to count packets from each user and a policer that limits the traffic rate. As each new user is authenticated on the multiple supplicant interface, this filter term will be included in the dynamically created term for the user:

   ```
   [edit firewall family bridge]
   user@router# set filter filter1 term term1 from destination-address 192.0.2.16/28
   user@router# set filter filter1 term term1 then count counter1
   user@router# set filter filter1 term term2 then policer p1
   ```

Results

Check the results of the configuration:

```
user@router> show configuration

firewall {
  family bridge {
    filter filter1 {
      term term1 {
        from {
          destination-address {
            192.0.2.16/28;
          }
        }
        then count counter1;
        term term2 {
        from {
          destination-address {
            192.0.2.16/28;
          }
        }
        then policer p1;
      }
    }
  }
```

```
    policer p1 {
        if-exceeding {
            bandwidth-limit 1m;
                burst-size-limit 1k;
            }
            then discard;
        }
}
protocols {
    authentication-access-control {
        interface ge-0/0/2 {
            supplicant multiple;
        }
    }
```

Verification

To confirm that the configuration is working properly, perform these tasks:

- Verifying Firewall Filters on Interfaces with Multiple Supplicants on page 98

Verifying Firewall Filters on Interfaces with Multiple Supplicants

Purpose Verify that firewall filters are functioning on the interface with multiple supplicants.

Action

1. Check the results with one user authenticated on the interface. In this case, the user is authenticated on **ge-0/0/2**:

```
user@router> show dot1x firewall
Filter: dot1x_ge-0/0/2
Counters
counter1_dot1x_ge-0/0/2_user1 100
```

2. When a second user, User2, is authenticated on the same interface, **ge-0/0/2**, you can verify that the filter includes the results for both of the users authenticated on the interface:

```
user@router> show dot1x firewall
Filter: dot1x-filter-ge-0/0/0
Counters
counter1_dot1x_ge-0/0/2_user1 100
counter1_dot1x_ge-0/0/2_user2 400
```

Meaning The results displayed by the **show dot1x firewall** command output reflect the dynamic filter created with the authentication of each new user. User1 accessed the file server located at the specified destination address 100 times, while User2 accessed the same file server 400 times.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, on MX Series routers, firewall filters that you apply to interfaces enabled for 802.1X or MAC RADIUS authentication are dynamically combined with the per-user policies sent to the switch from the RADIUS server.

CHAPTER 7

Configuring Aggregated Ethernet Interfaces for Increased Throughput and Link Redundancy

Aggregated Ethernet Interfaces Overview

Link aggregation of Ethernet interfaces is defined in the IEEE 802.3ad standard. The Junos OS implementation of 802.3ad balances traffic across the member links within an aggregated Ethernet bundle based on the Layer 3 information carried in the packet. This implementation uses the same load-balancing algorithm used for per-flow load balancing.

NOTE: For information about configuring circuit cross-connects over aggregated Ethernet, see *Circuit and Translational Cross-Connects Overview*.

For information about mixed rates and mixed modes on an aggregated Ethernet bundle, see "Understanding Mixed Rates and Mixed Modes on Aggregated Ethernet Bundles" on page 117.

Platform Support for Aggregated Ethernet Interfaces

You configure an aggregated Ethernet virtual link by specifying the link number as a physical device and then associating a set of ports that have the same speed and are in full-duplex mode. The physical interfaces can be Fast Ethernet, Tri-Rate Ethernet copper, Gigabit Ethernet, Gigabit Ethernet IQ, 10-Gigabit Ethernet IQ, Gigabit Ethernet IQ2 and IQ2-E, or 10-Gigabit Ethernet IQ2 and IQ2-E. Generally, you cannot use a combination of these interfaces within the same aggregated link; however, you can combine Gigabit Ethernet and Gigabit Ethernet IQ interfaces in a single aggregated Ethernet bundle.

Starting with Junos OS Release 13.2, aggregated Ethernet supports the following mixed rates and mixed modes on T640, T1600, T4000, and TX Matrix Plus routers:

- Member links of different modes (WAN and LAN) for 10-Gigabit Ethernet links.
- Member links of different rates: 10-Gigabit Ethernet, 40-Gigabit Ethernet, 50-Gigabit Ethernet, 100-Gigabit Ethernet, and OC192 (10-Gigabit Ethernet WAN mode)

NOTE:

- Member links of 50-Gigabit Ethernet can only be configured using the 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP (PD-1CE-CFP-FPC4).
- Starting with Junos OS Release 13.2, 100-Gigabit Ethernet member links can be configured using the two 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP. This 100-Gigabit Ethernet member link can be included in an aggregated Ethernet link that includes member links of other interfaces as well. In releases before Junos OS Release 13.2, the 100-Gigabit Ethernet member link configured using the two 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP cannot be included in an aggregated Ethernet link that includes member links of other interfaces.

TIP:

Going forward:

- Aggregated Ethernet link with member links of different modes will be referred as *10-Gigabit Ethernet mixed mode aggregated Ethernet link*.
- Aggregated Ethernet link with member links of different rates will be referred as *mixed rate aggregated Ethernet link*.
- These aggregated Ethernet links will generically be referred as *mixed aggregated Ethernet links*.

Table 8 on page 104 lists the platforms and corresponding hardware components that support mixed aggregated Ethernet bundles.

Table 8: Platform Support Matrix for Mixed Aggregated Ethernet Bundles

Rate and Mode	Supported Platform	Supported FPCs	Supported PICs
10-Gigabit Ethernet LAN and WAN (WAN rate: OC192)	T640, T1600, T4000, and TX Matrix Plus routers	• T4000 FPC5 (T4000-FPC5-3D)	• 10-Gigabit Ethernet LAN/WAN PIC with Oversubscription and SFP+ (PF-24XGE-SFPP) • 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-12XGE-SFPP)
		• Enhanced Scaling FPC3 (T640-FPC3-ES)	• 10-Gigabit Ethernet PIC with XENPAK (PC-1XGE-XENPAK)
		• Enhanced Scaling FPC4 (T640-FPC4-ES) • Enhanced Scaling FPC4-1P (T640-FPC4-1P-ES) • T1600 Enhanced Scaling FPC4 (T1600-FPC4-ES)	• 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PD-5-10XGE-SFPP) • 10-Gigabit Ethernet LAN/WAN PIC with XFP (PD-4XGE-XFP)
40-Gigabit Ethernet, 100-Gigabit Ethernet	T4000 and TX Matrix Plus routers	• T4000 FPC5 (T4000-FPC5-3D)	• 100-Gigabit Ethernet PIC with CFP (PF-1CGE-CFP)
	T640, T1600, T4000, and TX Matrix Plus routers	• Enhanced Scaling FPC4 (T640-FPC4-ES) • Enhanced Scaling FPC4-1P (T640-FPC4-1P-ES) • T1600 Enhanced Scaling FPC4 (T1600-FPC4-ES)	• 100-Gigabit Ethernet PIC with CFP (PD-1CE-CFP-FPC4) NOTE: This PIC is available packaged only in an assembly with the T1600-FPC4-ES FPC. • 40-Gigabit Ethernet PIC with CFP (PD-1XLE-CFP)

Enhanced LAG Support on MX Series Routers

Starting in Junos OS Release 14.2, you can configure an enhanced link aggregation group (LAG) on MX Series routers. When you associate a physical interface with an aggregated Ethernet interface, the physical child links are also associated with the parent aggregated Ethernet interface to form a LAG.

In the absence of enhanced LAG support, one child next hop is created for each member link of an aggregated Ethernet interface for each VLAN interface. For example, an aggregate next hop for an aggregated Ethernet interface with 16 member links leads to the installation of 17 next hops per VLAN created. Thus the number of next hops supported on the routers with aggregated Ethernet interfaces is significantly reduced.

With the enhanced LAG support, when the [**edit chassis network-services enhanced-ip**] statement is configured, child next hops are not created for member links and, as a result, a higher number of next hops can be supported.

Note that the enhanced LAG feature is only supported when the router's network services is set to operate in the **enhanced-ip** mode. This feature is not supported when the router's network services is set to operate in the **enhanced-ethernet** mode.

Enhanced LAG Support on PTX Series Routers

Starting in Junos OS Release 18.1, Junos OS supports removal of child next hop usage for aggregated Ethernet Interfaces and clients on PTX Series routers with FPC3-PTX-U2 and FPC3-PTX-U3. Removal of child next hop usage helps reduce the memory and CPU resources required to support aggregated Ethernet Interfaces and improves the overall system performance and scaling numbers. This feature is enabled by default if the network services mode on the router is configured to **enhanced-mode**. You can disable this feature by using the **set chassis aggregated-devices disable-lag-enhanced**. You must reboot the router for the configuration to take effect.

Previously, each unicast next hop over aggregated Ethernet Interfaces resulted in creation of a number of children next hops as well. For an aggregated Ethernet Interface with 16 member links, addition of one unicast next hop over the aggregated Ethernet Interface results in installing total of 17 next hops. As a result, with aggregated Ethernet configuration, the number of next hops supported decreases in proportion to the number of aggregated Ethernet links.

NOTE: Child next hop optimizations are supported for aggregated Ethernet Interfaces, Interfaces that make use of aggregated Ethernet Interfaces, and for both unicast and multicast scenarios.

Configuration Guidelines for Aggregated Ethernet Interfaces

- Aggregated Ethernet interfaces can use interfaces from different FPCs, DPCs, PICs, or MPCs.
- All Juniper routers support at least eight physical interfaces per aggregated Ethernet bundle. See maximum-links configuration page for platform specific limits.
- On M Series and T Series routers, you can create a maximum of 1024 logical interfaces on an aggregated Ethernet interface.
- Simple filters are not supported for interfaces in aggregated Ethernet bundles:
  - On M Series routers, simple filters are supported in Gigabit Ethernet Enhanced Intelligent Queuing interfaces only, except when the interface is part of an aggregated Ethernet bundle.
  - On MX Series routers, simple filters are supported in Enhanced Queuing Dense Port Concentrator (EQ DPC) interfaces only, except when the interface is part of an aggregated Ethernet bundle.

  For more information about simple filters, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.
- On the aggregated Ethernet bundle, no IQ-specific capabilities such as MAC accounting, VLAN rewrites, and VLAN queuing are available. For more information about IQ-specific

capabilities, see “Capabilities of Gigabit Ethernet IQ PICs and Gigabit Ethernet PICs with SFPs” on page 529.

- Aggregated Ethernet interfaces can be either tagged or untagged, with LACP enabled or disabled. Aggregated Ethernet interfaces on MX Series routers support the configuration of **flexible-vlan-tagging** and **native-vlan-id** on dual-tagged frames, which consist of the following configuration statements:
  - inner-tag-protocol-id
  - inner-vlan-id
  - pop-pop
  - pop-swap
  - push-push
  - swap-push
  - swap-swap

  In all cases, you must set the number of aggregated Ethernet interfaces on the chassis. You can also set the link speed and the minimum links in a bundle.
- When configuring mixed aggregated Ethernet bundles on T640, T1600, T4000, and TX Matrix Plus routers, consider the following:
  - A maximum of 16 member links can be configured to form a mixed aggregated Ethernet link.
  - Link Aggregation Control Protocol (LACP), aggregated Ethernet link protection, and LACP link protection are supported only on mixed aggregated Ethernet link configured on a 100-Gigabit Ethernet PIC with CFP (PD-1CE-CFP-FPC4).
  - Traffic distribution is based on the hash calculated on the egress packet header. Hash range is fairly distributed according to member links’ speed. This guarantees hash fairness but it does not guarantee fair traffic distribution depending on the rate of the egress streams.
  - Packets are dropped when the total throughput of the hash flow exiting a member link (or multiple hash flows exiting a single member link) exceeds the link speed of the member link. This can happen when egress member link changes because of a link failure and the hash flow switches to a member link of speed that is less than the total throughput of the hash flow.
  - Rate-based CoS components such as scheduler, shaper, and policer are not supported on mixed rate aggregated Ethernet links. However, the default CoS settings are supported by default on the mixed rate aggregated Ethernet links.
  - Load balancing is performed at the ingress Packet Forwarding Engine. Therefore, you must ensure that the egress traffic on the aggregated Ethernet link enters through the hardware platforms that support mixed aggregated Ethernet bundles. Table 8 on page 104 lists the platforms and corresponding hardware components that support mixed aggregated Ethernet bundles.

- Mixed aggregated Ethernet links can interoperate with non-Juniper Networks aggregated Ethernet member links provided that mixed aggregated Ethernet load balancing is configured at egress.
- Load balancing of the egress traffic across the member links of a mixed rate aggregated Ethernet link is proportional to the rates of the member links.
- Egress multicast load balancing is not supported on mixed aggregated Ethernet interfaces.
- Changing the **edit interfaces ae*x* aggregated-ether-options link-speed** configuration of a mixed aggregated Ethernet link, which is configured on the supported interfaces of on T640, T1600, T4000, and TX Matrix Plus routers, leads to aggregated Ethernet link flapping.
- When configuring a mixed aggregated Ethernet link on a 100-Gigabit Ethernet PIC with CFP (PD-1CE-CFP-FPC4), ensure that you add both the 50-Gigabit Ethernet interfaces of the 100-Gigabit Ethernet PIC with CFP to the aggregated Ethernet bundle. Moreover, both these 50-Gigabit Ethernet interfaces must be included in the same aggregated Ethernet bundle.
- When a mixed aggregated Ethernet link is configured on a 100-Gigabit Ethernet PIC with CFP, changing aggregated Ethernet link protection or LACP link protection configurations leads to aggregated Ethernet link flapping.
- For a single physical link event of an aggregated Ethernet link configured on a 100-Gigabit Ethernet PIC with CFP, the packet loss performance value is twice the original value because of the *two* 50-Gigabit Ethernet interfaces of the 100-Gigabit Ethernet PIC with CFP.
- The **show interfaces ae*x*** command displays the link speed of the aggregated Ethernet interface, which is the sum of the link speeds of all the active member links.

- Use the **show interfaces *aggregate-interface* extensive** and **show interfaces *aggregate.logical-interface*** commands to show the bandwidth of the aggregate. Also, the SNMP object identifier **ifSpeed/ifHighSpeed** shows the corresponding bandwidth on the aggregate logical interface if it is configured properly.

Release History Table

Release	Description
18.1	Starting in Junos OS Release 18.1, Junos OS supports removal of child next hop usage for aggregated Ethernet Interfaces and clients on PTX Series routers with FPC3-PTX-U2 and FPC3-PTX-U3.
14.2	Starting in Junos OS Release 14.2, you can configure an enhanced link aggregation group (LAG) on MX Series routers.
13.2	Starting with Junos OS Release 13.2, 100-Gigabit Ethernet member links can be configured using the two 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP.

Configuring an Aggregated Ethernet Interface

On Fast Ethernet, Tri-Rate Ethernet copper, Gigabit Ethernet, and 10-Gigabit Ethernet interfaces on M Series and T Series routers, you can associate a physical interface with an aggregated Ethernet interface.

NOTE: On a Junos Fusion, you can include extended ports (physical interface on a satellite device that provides a connection to servers or endpoints) or local ports in link aggregation groups (LAGs) and MC-LAGs, but not both. For information on extended ports, see *Understanding Junos Fusion Ports* .

To configure an aggregated Ethernet interface:

1. Specify that you want to configure the link aggregation group interface.

   user@host# **edit interfaces** ***interface-name***

2. Configure the aggregated Ethernet interface.

```
[edit interfaces interface-name]
user@host# set (fastether-options | gigether-options) 802.3ad aex
```

You specify the interface instance number *x* to complete the link association; *x* can be from 0 through 127, for a total of 128 aggregated interfaces on M Series and T Series routers and can be from 1 through 480, for a total of 480 aggregated interfaces on MX Series routers. For MX Series routers running Junos release 14.2R3 and later you can configure a maximum of 1000 aggregated interfaces. Aggregated interfaces are numbered from **ae0** through **ae4092**.

NOTE: On MX2010 and MX2020 routers you can configure a maximum of 800 aggregated interfaces.

You must also include a statement defining **ae*x*** at the **[edit interfaces]** hierarchy level. You can optionally specify other physical properties that apply specifically to the aggregated Ethernet interfaces; for details, see "Ethernet Interfaces Overview" on page 3, and for a sample configuration, see "Example: Configuring Aggregated Ethernet Interfaces" on page 128.

NOTE: In general, aggregated Ethernet bundles support the features available on all supported interfaces that can become a member link within the bundle. As an exception, Gigabit Ethernet IQ features and some newer Gigabit Ethernet features are not supported in aggregated Ethernet bundles.

Gigabit Ethernet IQ and SFP interfaces can be member links, but IQ- and SFP-specific features are not supported on the aggregated Ethernet bundle even if all the member links individually support those features.

You need to configure the correct link speed for the aggregated Ethernet interface to eliminate any warning message.

NOTE: Before you commit an aggregated Ethernet configuration, ensure that link mode is not configured on any member interface of the aggregated Ethernet bundle; otherwise, the configuration commit check fails.

Understanding Ethernet Link Aggregation on ACX Series Routers

Ethernet link aggregation is mechanism for increasing the bandwidth linearly and improving the resiliency of Ethernet links by bundling or combining multiple full-duplex same-speed point-to-point Ethernet links into a single virtual link. The virtual link interface is referred to as link aggregation group (LAG) or aggregated Ethernet (AE) interface. The LAG balances traffic across the member links within an aggregated Ethernet bundle and effectively increases the uplink bandwidth. Another advantage of link aggregation is increased availability, because the LAG is composed of multiple member links. If one member link fails, the LAG continues to carry traffic over the remaining links.

NOTE: ACX Series routers support connectivity fault management (CFM) on aggregated Ethernet interfaces with continuity check interval of 100 milliseconds or higher.

NOTE: ACX5048 and ACX5096 routers support connectivity fault management (CFM) on aggregated Ethernet interfaces with continuity check interval of 1 second or higher.

NOTE: The Ethernet options configurations for ACX5048 and ACX5096 routers differ compared to other ACX Series routers. For more information, see *Understanding Layer 2 Next Generation Mode on ACX Series Routers*.

On ACX Series routers, up to 128 AE interfaces can be created with each AE interface having up to 8 physical interfaces. AE interfaces can be created across PICs and fixed-ports on the chassis.

NOTE: On ACX5048 and ACX5096 routers, up to 64 AE interfaces can be created with each AE interface having up to 16 physical interfaces.

ACX Series routers do not support statistics for aggregated Ethernet interface. However, statistics can be retrieved for member interface.

To configure aggregated Ethernet interface:

1. Specify the number of aggregated Ethernet interfaces to be created:

   ```
   [edit chassis]
   user@host# set aggregated-devices ethernet device-count number
   ```

2. Specify the minimum number of links for the aggregated Ethernet interface (ae*x*), that is, the defined bundle, to be labeled “up”:

NOTE: By default only one link must be up for the bundle to be labeled "up".

```
[edit interfaces]
user@host# set ae0 aggregated-ether-options minimum-links number (1 — 8)
```

3. Specify the link speed for the aggregated Ethernet bundle:

```
[edit interfaces]
user@host# set ae0 aggregated-ether-options link-speed speed (10g | 1g | 100m)
```

4. Specify the members to be included within the aggregated Ethernet bundle:

```
[edit interfaces]
user@host# set ge-1/0/0 gigether-options 802.3ad ae0
user@host# set ge-1/0/1 gigether-options 802.3ad ae0
```

5. Specify an interface family for the aggregated Ethernet bundle:

```
[edit interfaces]
user@host# set ae0 unit 0 family inet address ip-address
```

The above procedure creates an AE interface and they would be up and ready for running the services defined on AE logical interfaces.

AE interfaces can be VLAN-tagged or untagged. You can configure flexible-vlan-tagging, native-vlan-id, and dual-tagging on AE interfaces.

NOTE: Whenever there is a configuration change (AE interface to Gigabit Ethernet interfaces or vice versa), you need to remove the existing configuration, perform a commit, then add the new configuration and again commit the configuration.

To delete an aggregated Ethernet interface:

1. Delete the aggregated Ethernet configuration.

   This step changes the interface state to down and removes the configuration statements related to aex.

```
[edit]
user@host#delete interfaces aex
```

2. Delete the interface from the device count.

```
[edit]
user@host#delete chassis aggregated-devices ethernet device-count
```

For aggregated Ethernet interfaces, you can configure the Link Aggregation Control Protocol (LACP). LACP is one method of bundling several physical interfaces to form one logical interface. You can configure both VLAN-tagged and untagged aggregated Ethernet with or without LACP enabled.

Load Balancing

JUNOS load-balances traffic across member links in an AE bundle based on the Layer 3 information in the packet. You can globally configure what fields are used for load-balancing for inet and MPLS

On ACX Series Routers, the inet family knobs are available at PIC level. You can configure inet family Layer 3 and Layer 4 fields to be used for load-balancing. For bridge family, Layer 2, layer 3 and Layer 4 fields to be used for load-balancing.

ACX Series routers also support load balancing across the member links using Layer 2 source MAC addresses, destination MAC addresses, or both. This can be configured at the **[edit forwarding-options hash-key family multiservice]** hierarchy level. Layer 2 source MAC addresses and destination MAC addresses are used as hash-keys for load balancing.

```
[edit]
forwarding-options {
  hash-key {
    family multiservice {
      destination-mac;
      source-mac;
    }
  }
}
```

NOTE:

- For IP Layer 2 packets, only IP fields are used for load balancing across member links. Source MAC address and destination MAC address are not be used for load balancing.
- For non-IP Layer 2 packets, either Source MAC address or destination MAC address is used as hash-keys for load balancing.
- If you want to hash based on layer 2 fields, then you need to configure **multiservice**.
- If you want to hash based on layer 3 and layer 4 fields, then you need to configure **family (inet | inet6)**

LACP Monitoring

LACP exchanges are made between actors and partners. An actor is the local interface in an LACP exchange. A partner is the remote interface in an LACP exchange.

LACP is defined in IEEE 802.3ad, *Aggregation of Multiple Link Segments*.

LACP is designed to achieve the following:

- Automatic addition and deletion of individual links to the aggregate bundle without user intervention

- Link monitoring to check whether both ends of the bundle are connected to the correct group

The Junos OS implementation of LACP provides link monitoring but not automatic addition and deletion of links.

LACP monitoring can be either distributed or centralized. The default is distributed and it can be overriden by configuring the centralized knob under LACP protocols. LACP exchanges are made between actors and partners. An actor is the local interface in an LACP exchange. A partner is the remote interface in an LACP exchange.

By default, LACP does not initiate a LACP PDU exchange. LACP packets can be configured to exchange LACP PDUs at a rate of 1 packet per second, or a slower rate of 1 packet for 30 seconds.

The LACP mode can be active or passive. If the actor and partner are both in passive mode, they do not exchange LACP packets, which results in the aggregated Ethernet links not coming up. If either the actor or partner is active, they do exchange LACP packets. By default, LACP is turned off on aggregated Ethernet interfaces. If LACP is configured, it is in passive mode by default. To initiate transmission of LACP packets and response to LACP packets, you must configure LACP in active mode.

To enable LACP active mode, include the **lacp** statement at the **[edit interfaces *interface-name* aggregated-ether-options]** hierarchy level, and specify the **active** option:

```
[edit interfaces interface-name aggregated-ether-options]
lacp {
  active;
}
```

NOTE: The LACP process exists in the system only if you configure the system in either active or passive LACP mode.

To restore the default behavior, include the **lacp** statement at the **[edit interfaces *interface-name* aggregated-ether-options]** hierarchy level, and specify the **passive** option:

```
[edit interfaces interface-name aggregated-ether-options]
lacp {
  passive;
}
```

Link Protection

Link protection can be configured on AE interfaces to provide 1:1 link resiliency using LACP. Primary and backup links can be configured within an AE bundle. The primary link is used for all transit traffic and host generated traffic. The backup link is used when the primary link fails.

Link protection is supported only when the AE bundles have no more than 2 member links, one primary and another backup. LACP works in revertive link-protection mode by default and can be configured to work in non-revertive mode.

NOTE: Link protection without LACP (static link protection on AE interfaces) is not supported on all ACX Series routers. Link protection works as expected with LACP configured on the AE bundle.

Configuring Link Protection for Aggregated Ethernet Interfaces

Aggregated Ethernet interfaces support link protection to ensure QoS on the interface.

To configure link protection:

1. Configure the options for an aggregated Ethernet interface.

   user@host# **edit interfaces ae*x* aggregated-ether-options**

2. Configure the link protection mode.

   [edit interfaces ae*x* aggregated-ether-options]
   user@host# **set link-protection**

Disabling Link Protection for Aggregated Ethernet Interfaces

To disable link protection, issue the **delete interface revert ae*x*** configuration command.

user@host# **delete interfaces ae*x* aggregated-ether-options link-protection**

Understanding the Algorithm Used to Hash LAG Bundle

ACX Series routers use a hashing algorithm to determine how to forward traffic over a link aggregation group (LAG) bundle.

The hashing algorithm makes hashing decisions based on values in various packet fields, as well as on some internal values like source port ID and source device ID. You can configure some of the fields that are used by the hashing algorithm.

The hashing algorithm is used to make traffic-forwarding decisions for traffic entering a LAG bundle.

For LAG bundles, the hashing algorithm determines how traffic entering a LAG bundle is placed onto the bundle's member links. The hashing algorithm tries to manage bandwidth by evenly load-balancing all incoming traffic across the member links in the bundle.

The hashing algorithm makes hashing decisions based on values in various packet fields, as well as on some internal values like source port ID and source device ID. The packet fields used by the hashing algorithm varies by the packet's EtherType and, in some instances, by the configuration on the router. The hashing algorithm recognizes the following EtherTypes:

- IPv4

- MPLS

Traffic that is not recognized as belonging to any of these EtherTypes is hashed based on the Layer 2 header. IP and MPLS traffic are also hashed based on the Layer 2 header when a user configures the hash mode as Layer 2 header.

You can configure some fields that are used by the hashing algorithm to make traffic forwarding decisions. You cannot, however, configure how certain values within a header are used by the hashing algorithm.

Note the following points regarding the hashing algorithm:

- The fields selected for hashing are based on the packet type only. The fields are not based on any other parameters, including forwarding decision (bridged or routed) or egress LAG bundle configuration (Layer 2 or Layer 3).
- The same fields are used for hashing unicast and multicast packets. Unicast and multicast packets are, however, hashed differently.

Table 9 on page 115 describes the fields used for hashing by Layer 2 services. The table explains the default behavior and the configurable fields based on the type of traffic received on the Layer 2 service

Table 9: Hashing Behavior for Pseudowire (Layer 2 Circuit) and Bridging Services

Traffic Type	Default Hash Fields	Configurable Fields (Hash keys)
Layer 2	None	Source MAC Address Destination MAC Source MAC and Destination MAC
IP	Source IP and Destination IP	Source MAC Address Destination MAC Source MAC and Destination MAC
MPLS	MPLS label 1 and MPLS label 2	Source MAC Address Destination MAC Source MAC and Destination MAC

Table 10 on page 116 describes the fields used for hashing by Layer 3 services. The table explains the default behavior and the configurable fields based on the type of traffic received on the Layer 3 service

Table 10: Hashing Behavior for IP Services

Traffic Type	Default Hash Fields	Configurable Fields (Hash keys)
IP	Source IP and Destination IP	Layer 3 (Source IP and/or| destination IP) Layer 4 (UDP/TCP source port andr UDP/TCP destination port)

Configuring Aggregated Ethernet Interfaces on PTX Series Packet Transport Routers

IEEE 802.3ad link aggregation enables you to group Ethernet interfaces to form a single link layer interface, also known as a link aggregation group (LAG) or bundle. Link aggregation can be used for point-to-point connections. It balances traffic across the member links within an aggregated Ethernet bundle and effectively increases the uplink bandwidth. Another advantage of link aggregation is increased availability because the LAG is composed of multiple member links. If one member link fails, the LAG continues to carry traffic over the remaining links.

This topic describes how to configure aggregated Ethernet interfaces on PTX Series Packet Transport Routers.

On PTX Series Packet Transport Routers, aggregated Ethernet support includes the following features:

- A consistent interface type (**et *fpc/pic/port***) across all Ethernet interfaces.
- Ability to bundle multiple Ethernet interfaces
- Ability to bundle mixed-rate links on the same aggregated Ethernet interface
- Fault tolerance
- Load balancing between child links
- Advanced features including flexible VLAN tagging and Ethernet services encapsulation

Aggregated Ethernet interfaces can use interfaces from different FPCs or PICs. The following configuration is sufficient to get an aggregated Gigabit Ethernet interface up and running.

```
[edit chassis]
  aggregated-devices {
  ethernet {
    device-count 2;
  }
}
[edit interfaces]
et-0/0/0 {
```

```
gigether-options {
   802.3ad ae0;
   }
}
et-0/0/1 {
   gigether-options {
      802.3ad ae0;
   }
}
ae0 {
   vlan-tagging;
   unit 0 {
      vlan-id 100;
      family inet {
         address 200.200.1.2/24;
      }
   }
   unit 1 {
      vlan-id 101;
      family inet {
         address 200.200.2.2/24;
      }
   }
}
```

- Configuring Mixed Rates and Mixed Modes on Aggregated Ethernet Bundles on page 124

Understanding Mixed Rates and Mixed Modes on Aggregated Ethernet Bundles

You can configure the member links of an aggregated Ethernet bundle with any combination of rates—also known as mixed rates—on T Series, MX Series, and PTX Series routers. The bandwidth that is provided by an aggregated Ethernet bundle can be utilized completely and efficiently when the links are configured with different rates.

You can configure mixed modes on T Series routers. In a mixed-mode configuration, the member links of an aggregated Ethernet bundle are configured in LAN mode as well as in WAN mode for 10-Gigabit Ethernet interfaces.

The following sections provide an overview about mixed rates and mixed modes on various platforms:

- Supported Platforms on page 118
- Aggregated Ethernet Bundle with Mixed Rates and Mixed Modes on T Series Routers on page 118
- Aggregated Ethernet Bundles with Mixed Rates on MX Series Routers on page 121

Supported Platforms

Table 11 on page 118 summarizes the first Junos OS release that supports aggregated Ethernet bundles on the various Juniper Networks routers and their components:

Table 11: Mixed Rates and Mixed Modes Support on Junos OS

Supported Platforms	Junos OS Release
Mixed rates and mixed modes on T640, T1600, T4000, and TX Matrix Plus routers	13.2
Mixed rates on MX240, MX480, MX960, MX2010, and MX2020 routers	14.1R2 14.2
Mixed rates on PTX Series Packet Transport Routers	14.2
Mixed rates on P2-10G-40G-QSFPP PIC and P2-100GE-OTN PIC on PTX5000 routers	15.1

Aggregated Ethernet Bundle with Mixed Rates and Mixed Modes on T Series Routers

The following sections explain mixed rates and mixed modes on T Series routers:

Understanding Mixed Rates and Mixed Modes

Starting with Junos OS Release 13.2, aggregated Ethernet supports the following mixed rates and mixed modes on T640, T1600, T4000, and TX Matrix Plus routers:

- Member links of different modes (WAN and LAN) for 10-Gigabit Ethernet links.
- Member links of different rates: 10-Gigabit Ethernet, 40-Gigabit Ethernet, 50-Gigabit Ethernet, 100-Gigabit Ethernet, and OC192 (10-Gigabit Ethernet WAN mode)

NOTE:

- Member links of 50-Gigabit Ethernet can only be configured using the 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP (PD-1CE-CFP-FPC4).
- Starting with Junos OS Release 13.2, 100-Gigabit Ethernet member links can be configured using the two 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP. This 100-Gigabit Ethernet member link can be included in an aggregated Ethernet link that includes member links of other interfaces as well.

  In releases before Junos OS Release 13.2, the 100-Gigabit Ethernet member link configured using the two 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP cannot be included in an aggregated Ethernet link that includes member links of other interfaces.

Going forward:

- An aggregated Ethernet link with member links of different modes is referred to as *10-Gigabit Ethernet mixed-mode aggregated Ethernet link*.
- An aggregated Ethernet link with member links of different rates is referred to as *mixed-rate aggregated Ethernet link*.
- These aggregated Ethernet links will generically be referred to as *mixed aggregated Ethernet links*.

Platform Support Matrix for Mixed Aggregated Ethernet Bundles

Table 8 on page 104 lists the platforms and corresponding hardware components that support mixed aggregated Ethernet bundles.

Table 12: Platform Support Matrix for Mixed Aggregated Ethernet Bundles

Rate and Mode	Supported Platform	Supported FPCs	Supported PICs
10-Gigabit Ethernet LAN and WAN (WAN rate: OC192)	T640, T1600, T4000, and TX Matrix Plus routers	• T4000 FPC5 (T4000-FPC5-3D)	• 10-Gigabit Ethernet LAN/WAN PIC with Oversubscription and SFP+ (PF-24XGE-SFPP) • 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-12XGE-SFPP)
		• Enhanced Scaling FPC3 (T640-FPC3-ES)	• 10-Gigabit Ethernet PIC with XENPAK (PC-1XGE-XENPAK)
		• Enhanced Scaling FPC4 (T640-FPC4-ES) • Enhanced Scaling FPC4-1P (T640-FPC4-1P-ES) • T1600 Enhanced Scaling FPC4 (T1600-FPC4-ES)	• 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PD-5-10XGE-SFPP) • 10-Gigabit Ethernet LAN/WAN PIC with XFP (PD-4XGE-XFP)

Table 12: Platform Support Matrix for Mixed Aggregated Ethernet Bundles (continued)

Rate and Mode	Supported Platform	Supported FPCs	Supported PICs
40-Gigabit Ethernet, 100-Gigabit Ethernet	T4000 and TX Matrix Plus routers	• T4000 FPC5 (T4000-FPC5-3D)	• 100-Gigabit Ethernet PIC with CFP (PF-1CGE-CFP)
	T640, T1600, T4000, and TX Matrix Plus routers	• Enhanced Scaling FPC4 (T640-FPC4-ES) • Enhanced Scaling FPC4-1P (T640-FPC4-1P-ES) • T1600 Enhanced Scaling FPC4 (T1600-FPC4-ES)	• 100-Gigabit Ethernet PIC with CFP (PD-1CE-CFP-FPC4) NOTE: This PIC is available packaged only in an assembly with the T1600-FPC4-ES FPC. • 40-Gigabit Ethernet PIC with CFP (PD-1XLE-CFP)

Guidelines to Follow When Configuring Aggregated Ethernet Bundles with Mixed Rates and Mixed Modes

In addition to the configuration guidelines for aggregated Ethernet interfaces in “Aggregated Ethernet Interfaces Overview” on page 102, you must consider the following as well when configuring mixed modes and mixed rates on aggregated Ethernet bundles on T640, T1600, T4000, and TX Matrix Plus routers:

- A maximum of 16 member links can be configured to form a mixed aggregated Ethernet link.
- Link Aggregation Control Protocol (LACP), aggregated Ethernet link protection, and LACP link protection are supported only on mixed aggregated Ethernet bundles configured on a 100-Gigabit Ethernet PIC with CFP (PD-1CE-CFP-FPC4).
- Traffic distribution is based on the hash calculated on the egress packet header. Hash range is fairly distributed according to member links’ speed. This guarantees hash fairness but it does not guarantee fair traffic distribution depending on the rate of the egress streams.
- Packets are dropped when the total throughput of the hash flow exiting a member link (or multiple hash flows exiting a single member link) exceeds the link speed of the member link. This can happen when egress member link changes because of a link failure and the hash flow switches to a member link of speed that is less than the total throughput of the hash flow.
- Rate-based CoS components such as scheduler, shaper, and policer are not supported on mixed-rate aggregated Ethernet links. However, the default CoS settings are supported by default on the mixed-rate aggregated Ethernet links.
- Load balancing is performed at the ingress Packet Forwarding Engine. Therefore, you must ensure that the egress traffic on the aggregated Ethernet link enters through the hardware platforms that support mixed aggregated Ethernet bundles. Table 8 on page 104 lists the platforms and corresponding hardware components that support mixed aggregated Ethernet bundles.

- Mixed aggregated Ethernet links can interoperate with non-Juniper Networks aggregated Ethernet member links provided that mixed aggregated Ethernet load balancing is configured at egress.
- Load balancing of the egress traffic across the member links of a mixed-rate aggregated Ethernet link is proportional to the rates of the member links.
- Egress multicast load balancing is not supported on mixed aggregated Ethernet interfaces.
- Changing the **[edit interfaces ae*x* aggregated-ether-options link-speed]** configuration of a mixed aggregated Ethernet link, which is configured on the supported interfaces of on T640, T1600, T4000, and TX Matrix Plus routers, leads to aggregated Ethernet link flapping.
- When configuring a mixed aggregated Ethernet link on a 100-Gigabit Ethernet PIC with CFP (PD-1CE-CFP-FPC4), ensure that you add both the 50-Gigabit Ethernet interfaces of the 100-Gigabit Ethernet PIC with CFP to the aggregated Ethernet bundle. Moreover, both these 50-Gigabit Ethernet interfaces must be included in the same aggregated Ethernet bundle.
- When a mixed aggregated Ethernet link is configured on a 100-Gigabit Ethernet PIC with CFP, changing aggregated Ethernet link protection or LACP link protection configurations leads to aggregated Ethernet link flapping.
- For a single physical link event of an aggregated Ethernet link configured on a 100-Gigabit Ethernet PIC with CFP, the packet loss performance value is twice the original value because of the *two* 50-Gigabit Ethernet interfaces of the 100-Gigabit Ethernet PIC with CFP.
- The **show interfaces ae*x*** command displays the link speed of the aggregated Ethernet interface, which is the sum of the link speeds of all the active member links.

Aggregated Ethernet Bundles with Mixed Rates on MX Series Routers

The following sections explain mixed rates on aggregated Ethernet bundles:

Understanding Mixed Rates

Starting with Junos OS Release 14.2, support for mixed rates on aggregated Ethernet bundles is extended to MX240, MX480, MX960, MX2010, and MX2020 routers, thereby enabling you to configure the member links with any combination of rates—10-Gigabit Ethernet, 40-Gigabit Ethernet, and 100-Gigabit Ethernet—on an aggregated Ethernet bundle.

You must configure the **mixed** statement explicitly at the **[edit interfaces *interface-name* aggregated-ether-options link-speed]** hierarchy level to:

- Enable the mixed-rate configuration on all the aggregated Ethernet bundles on the egress side of the Modular Port Concentrators (MPCs).

- Enable the router to detect child links of different speed values in the aggregated Ethernet bundle.

You can also configure the minimum bandwidth on an aggregated Ethernet bundle when you configure mixed rate on that aggregated Ethernet bundle.

NOTE: **The minimum-link statement cannot be configured with mixed rates.**

Mixed rates cannot be configured for aggregated Ethernet bundles on the egress side of the Dense Port concentrators (DPCs).

When you configure mixed rate on a homogeneous aggregated Ethernet bundle—where all the links in the bundle are of the same speed—the aggregated Ethernet bundle goes down and then comes up with the mixed-rate configuration.

Supported Features

The following features are supported on mixed-rate aggregated Ethernet bundles on MX Series routers:

- Sixty-four links in a bundle.
- Load balancing of traffic in proportion to the member-link speed.
- Non link-protect mode. For more information, see "Configuring Scheduler on Aggregated Ethernet Interfaces Without Link Protection" on page 151.
- LACP for slow and fast interval for periodic transmission of LACP packets.
- Port-based network access control (NAC).
- Scheduler parameters for aggregated interface member links in a scaled manner with the **member-link-scheduler scale** statement at the **[edit class-of-service interfaces]** hierarchy level.
- Layer 3 features only.
- Configuration of following statements as percentages only for mixed rates at the **[edit class-of-service schedulers *scheduler-name*]** hierarchy level:
  - **buffer-size**
  - **excess-rate**
  - **shaping-rate**
  - **transmit-rate**
- Configuration of the following statements for mixed rates at the **[edit class-of-service schedulers *scheduler-name*]** hierarchy level:
  - **drop-profile-map**
  - **excess-priority**

  - **priority**
  - **transmit-rate (rate-limit | exact)**
- The **shared-bandwidth-policer** statement at the **[edit firewall policer *policer-name*]** hierarchy level.
- The **scheduler-maps** *map-name* statement at the **[edit class-of-service]** hierarchy level.
- Unicast load balancing, where the load balancing happens on ingress-only selectors.
- Mulitcast load balancing
- Make-before-break (MBB) for multicast LDP (MLDP) and fast reroute (FRR).
- Source class usage (SCU) and destination class usage (DCU) accounting.
- Families **inet**, **inet6**, and **mpls**.
- Enhanced IP network services.
- LDP tunneling and OAM link fault management (LFM).

The following features are not supported on mixed-rate aggregated Ethernet bundles on MX Series routers:

- Adaptive load balancing
- Hierarchical schedulers on aggregated Ethernet bundles and the scheduling on logical interfaces (per-unit scheduling).
- Shaping rate, where traffic shaping is achieved by specifying the amount of bandwidth to be allocated to a logical interface.
- The **output-traffic-control-profile** statement at the **[edit class-of-service interfaces *interface-name*]** hierarchy level.
- Ingress queuing.
- Options that are configured with nonpercentage values at the **[edit class-of-service schedulers *scheduler-name*]** hierarchy level.
- The **member-link-scheduler replicate** statement at the **[edit class-of-service interfaces *interface-name*]** hierarchy level.
- Mixing LAN mode and WAN mode.
- Aggregated Ethernet link protection and link protection on a 1:1 model.
- LACP link protection.
- Layer 2 features.
- The **target-routing-instance (*routing-instance-name* | default)** statement at the **[edit access domain map *domain-map-name*]** hierarchy level.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, support for mixed rates on aggregated Ethernet bundles is extended to MX240, MX480, MX960, MX2010, and MX2020 routers, thereby enabling you to configure the member links with any combination of rates—10-Gigabit Ethernet, 40-Gigabit Ethernet, and 100-Gigabit Ethernet—on an aggregated Ethernet bundle.
13.2	Starting with Junos OS Release 13.2, 100-Gigabit Ethernet member links can be configured using the two 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP. This 100-Gigabit Ethernet member link can be included in an aggregated Ethernet link that includes member links of other interfaces as well.

Configuring Mixed Rates and Mixed Modes on Aggregated Ethernet Bundles

The following sections explain how to configure mixed rates and mixed modes on various platforms:

Configuring Mixed Rates and Mixed Modes on an Aggregated Ethernet Bundle on T Series Routers

In releases before Junos OS Release 13.2, all interfaces that form an aggregated Ethernet bundle must have the same speed and must be in full-duplex mode. Starting with Junos OS Release 13.2, aggregated Ethernet supports mixed rates and mixed modes on T640, T1600, T4000, and TX Matrix Plus routers. Following mixed rates and mixed modes are supported:

- Member links of different modes (WAN and LAN) for 10-Gigabit Ethernet links.
- Member links of different rates: 10-Gigabit Ethernet, 40-Gigabit Ethernet, 50-Gigabit Ethernet, 100-Gigabit Ethernet, and OC192 (10-Gigabit Ethernet WAN mode)

NOTE:

- Member links of 50-Gigabit Ethernet can be configured using only the 50-Gigabit Ethernet interfaces of the 100-Gigabit Ethernet PIC with CFP (PD-1CE-CFP-FPC4).
- Starting with Junos OS Release 13.2, 100-Gigabit Ethernet member links can be configured using the two 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP. This 100-Gigabit Ethernet member link can be included in an aggregated Ethernet link that includes member links of other interfaces as well. In releases before Junos OS Release 13.2, the 100-Gigabit Ethernet member link configured using the two 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP cannot be included in an aggregated Ethernet link that includes member links of other interfaces.

To configure member links of an aggregated Ethernet bundles in mixed rate or mixed mode on T640, T1600, T4000, and TX Matrix Plus routers:

1. Go to **[edit chassis]** hierarchy level.

   user@host# **edit chassis**

2. Configure the number of aggregated logical devices available to the router:

   [edit chassis]
   user@host# **set aggregated-devices ethernet device-count** *number*

3. Go to the **[edit interfaces]** hierarchy level.

   user@host# **top**
   user@host# **edit interfaces**

4. Configure the minimum number of links that are required for the aggregated Ethernet bundle to be labeled *up*:

   [edit interfaces]

user@host# **set ae*x* aggregated-ether-options minimum-links** *number*

NOTE: By default, only one link needs to be up for the bundle to be labeled *up*.

5. Configure the **link-speed** statement and specify the **mixed** option for the **link-speed** statement to indicate the mixed-rate and mixed-mode support for the aggregated Ethernet bundle configuration.

   [edit interfaces]
   user@host# **set ae*x* aggregated-ether-options link-speed mixed**

   NOTE: It is mandatory to configure the **mixed** option for aggregated Ethernet bundles for the PD-1CE-CFP-FPC4 PIC.

   On aggregated Ethernet bundles in MX Series routers, when the **mixed** statement at the **[edit interfaces ae*x* aggregated-ether-options link-speed]** hierarchy level is not configured, the mixed rate configuration is applied by default.

6. Configure the members links of the aggregated Ethernet bundle.

   [edit interfaces]
   user@host# **set** *interface-name* **gigether-options 802.3ad ae*x***

7. Configure an interface family and an IP address for the aggregated Ethernet bundle.

   [edit interfaces]
   user@host# **set ae*x* unit** *number* **family (inet | inet6 | mpls) address** *address*

8. Commit the configuration.

   [edit interfaces]
   user@host# **commit**

Configuring Mixed Rates on Aggregated Ethernet Bundles on MX Series Routers

Starting with Junos OS Release 14.1R1 and 14.2, support for mixed rates on aggregated Ethernet bundles is extended to MX240, MX480, MX960, MX2010, and MX2020 routers. You can now configure the member links with any combination of rates—10-Gigabit Ethernet, 40-Gigabit Ethernet, and 100-Gigabit Ethernet—on an aggregated Ethernet bundle.

To configure mixed rates on an aggregated Ethernet bundle on MX Series routers:

1. Go to the **[edit chassis]** hierarchy level.

   user@host# **edit chassis**

2. Configure the number of aggregated logical devices available to the router.

   [edit chassis]
   user@host# **set aggregated-devices ethernet device-count *number***

3. Go to the **[edit interfaces]** hierarchy level.

   user@host# **top**
   user@host# **edit interfaces**

4. Configure the **link-speed** statement and specify the **mixed** option for the **link-speed** statement to indicate the mixed-rate support for the aggregated Ethernet bundle configuration.

   [edit interfaces]
   user@host# **set ae*x* aggregated-ether-options link-speed mixed**

5. Configure the members links of the aggregated Ethernet bundle:

   [edit interfaces]
   user@host# **set *interface-name* gigether-options 802.3ad ae*x***

6. Configure an interface family for the aggregated Ethernet bundle as inet, inet6, or mpls:

   [edit interfaces]
   user@host# **set ae*x* unit *number* family (inet | inet6 | mpls)**

7. Configure the minimum bandwidth unit as **bps**, **gbps**, **kbps**, or **mbps** and the bandwidth value from 1 through 128,000.

   [edit interfaces]
   user@host# **set ae*x* aggregated-ether-options minimum-bandwidth bw-unit (bps | gbps | kbps | mbps)**
   user@host# **set ae*x* aggregated-ether-options minimum-bandwidth bw-value *value***

8. Commit the configuration.

   [edit interfaces]
   user@host# **commit**

Release History Table

Release	Description
14.1R1	Starting with Junos OS Release 14.1R1 and 14.2, support for mixed rates on aggregated Ethernet bundles is extended to MX240, MX480, MX960, MX2010, and MX2020 routers.
13.2	Starting with Junos OS Release 13.2, aggregated Ethernet supports mixed rates and mixed modes on T640, T1600, T4000, and TX Matrix Plus routers.
13.2	Starting with Junos OS Release 13.2, 100-Gigabit Ethernet member links can be configured using the two 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP.

Example: Configuring Aggregated Ethernet Interfaces

Aggregated Ethernet interfaces can use interfaces from different FPCs, DPCs, or PICs. The following configuration is sufficient to get an aggregated Gigabit Ethernet interface up and running.

```
[edit chassis]
aggregated-devices {
  ethernet {
    device-count 15;
  }
}
[edit interfaces]
ge-1/3/0 {
  gigether-options {
    802.3ad ae0;
  }
}
ge-2/0/1 {
  gigether-options {
    802.3ad ae0;
  }
}
ae0 {
  aggregated-ether-options {
```

```
            link-speed 1g;
            minimum-links 1;
        }
    }
    vlan-tagging;
    unit 0 {
        vlan-id 1;
        family inet {
            address 10.0.0.1/24;
        }
    }
    unit 1 {
        vlan-id 1024;
        family inet {
            address 10.0.0.2/24;
        }
    }
    unit 2 {
        vlan-id 1025;
        family inet {
            address 10.0.0.3/24;
        }
    }
    unit 3 {
        vlan-id 4094;
        family inet {
            address 10.0.0.4/24;
        }
    }
}
```

Configuring Junos OS for Supporting Aggregated Devices

Junos OS supports the aggregation of physical devices into defined virtual links, such as the link aggregation of Ethernet interfaces defined by the IEEE 802.3ad standard.

Tasks for configuring aggregated devices are:

Configuring Virtual Links for Aggregated Devices

To define virtual links, you need to specify the associations between physical and logical devices within the **[edit interfaces]** hierarchy, and assign the correct number of logical devices by including the **device-count** statement at the **[edit chassis aggregated-devices ethernet]** and **[edit chassis aggregated-devices sonet]** hierarchy levels:

```
[edit chassis]
aggregated-devices {
  ethernet {
    device-count number;
  }
  sonet {
    device-count number;
  }
}
```

The aggregated interfaces are numbered from **ae0** through **ae4091**. The maximum number of aggregated interfaces supported by different routers is listed below:

- For PTX Series routers, you can configure a maximum of 128 aggregated interfaces.
- For M Series and T Series routers, you can configure a maximum of 128 aggregated interfaces (LAG bundles).
- In Junos release 14.2R2 and earlier, you can configure a maximum of 480 aggregated interfaces on MX Series routers.
- In Junos release 14.2R3 and later, you can configure a maximum of 1000 aggregated interfaces on MX240, MX480, and MX960 routers.
- In Junos release 14.2R3 and later, you can configure a maximum of 800 aggregated interfaces on MX2010 and MX2020 routers.
- In Junos OS 15.1F5 and 15.1F6 releases, you can configure a maximum of 480 aggregated interfaces on MX240, MX480, and MX960 routers.
- In Junos OS 15.1F5 and 15.1F6 releases, you can configure a maximum of 800 aggregated interfaces on MX2010 and MX2020 routers.

For SONET/SDH, starting with Junos OS Release 13.2, the maximum number of logical interfaces is 64, numbered from **as0** through **as63**. In releases before Junos OS Release 13.2, the maximum was 16.

Configuring LACP Link Protection at the Chassis Level

Link Aggregation Control Protocol (LACP) is one method of bundling several physical interfaces to form one logical interface. You can configure both VLAN-tagged and untagged aggregated Ethernet with or without LACP enabled. LACP exchanges are made between actors and partners. An actor is the local interface in an LACP exchange. A partner is the remote interface in an LACP exchange.

LACP link protection enables you to force active and standby links within an aggregated Ethernet. You configure LACP link protection by using the **link-protection** and **system-priority** statements at either the chassis or interface level and by configuring port priority at the interface level using the **system-priority** statement. Configuring LACP parameters at the chassis level results in all aggregated Ethernet interfaces using the defined values unless overridden by the LACP configuration on a specific interface.

```
[edit chassis]
aggregated-devices {
  ethernet {
    lacp {
      link-protection {
        non-revertive;
      }
      system-priority priority;
    }
  }
}
```

NOTE: LACP link protection also uses port priority. You can configure port priority at the Ethernet interface **[gigether-options]** hierarchy level using the **port-priority** statement. If you choose not to configure port priority, LACP link protection uses the default value for port priority (127).

See Also

Enabling LACP Link Protection

To enable LACP link protection for aggregated Ethernet interfaces on the chassis, use the **link-protection** statement at the **[edit chassis aggregated-devices ethernet lacp]** hierarchy level:

```
[edit chassis aggregated-devices ethernet lacp]
link-protection {
  non-revertive;
}
```

By default, LACP link protection reverts to a higher-priority (lower-numbered) link when that higher-priority link becomes operational or a link is added to the aggregator that is determined to be higher in priority. However, you can suppress link calculation by adding the **non-revertive** statement to the LACP link protection configuration. In nonrevertive mode, after a link is active and collecting and distributing packets, the subsequent addition of a higher-priority (better) link does not result in a switch, and the current link remains active.

BEST PRACTICE: (MX Series) In a highly scaled configuration over aggregated Ethernet, we recommend that you prevent the router from performing such a switch by including the **non-revertive** statement. Failure to do so may result in some traffic loss if a MIC on which a member interface is located reboots. Using the **non-revertive** statement for this purpose is not effective if both the primary and secondary interfaces are on the MIC that reboots.

CAUTION: **If both ends of an aggregator have LACP link protection enabled, make sure to configure both ends of the aggregator to use the same mode. Mismatching LACP link protection modes can result in lost traffic.**

Configuring System Priority

To configure LACP system priority for aggregated Ethernet interfaces on the chassis, use the **system-priority** statement at the **[edit chassis aggregated-devices ethernet lacp]** hierarchy level:

```
[edit chassis aggregated-devices ethernet lacp]
system-priority priority;
```

The system priority is a 2-octet binary value that is part of the LACP system ID. The LACP system ID consists of the system priority as the two most-significant octets and the interface MAC address as the six least-significant octets. The system with the numerically lower value for system priority has the higher priority. By default, system priority is 127, with a range of 0 through 65,535.

Configuring the Maximum Links Limit

To configure the maximum links limit, use the **maximum-links** statement at the **[edit chassis aggregated-devices]** hierarchy level:

```
[edit chassis aggregated-devices]
maximum-links maximum-links-limit;
```

Configuring PPM on Junos Fusion

If you use Junos Fusion with Junos OS Release 14.2R3, you need to ensure that link aggregation (and STP) work properly by configuring timers for the periodic packet management (PPM) daemons on the aggregation and satellite devices. We recommend using the following timer values:

```
[edit routing-options ppm]
  redistribution-timer 120;
  tcp-keepalive-interval 3000;
  tcp-keepalive-idle 3000;
```

Starting in Junos OS Release 14.2R4, the timer values that ensure proper link aggregation and STP functions are configured by default if you use Junos Fusion with Junos OS.

Release History Table

Release	Description
15.1F5	In Junos OS 15.1F5 and 15.1F6 releases, you can configure a maximum of 480 aggregated interfaces on MX240, MX480, and MX960 routers.
15.1F5	In Junos OS 15.1F5 and 15.1F6 releases, you can configure a maximum of 800 aggregated interfaces on MX2010 and MX2020 routers.
14.2R4	Starting in Junos OS Release 14.2R4, the timer values that ensure proper link aggregation and STP functions are configured by default if you use Junos Fusion with Junos OS.
14.2R3	In Junos release 14.2R3 and later, you can configure a maximum of 1000 aggregated interfaces on MX240, MX480, and MX960 routers.
14.2R3	In Junos release 14.2R3 and later, you can configure a maximum of 800 aggregated interfaces on MX2010 and MX2020 routers.
14.2R3	If you use Junos Fusion with Junos OS Release 14.2R3, you need to ensure that link aggregation (and STP) work properly by configuring timers for the periodic packet management (PPM) daemons on the aggregation and satellite devices.
14.2R2	In Junos release 14.2R2 and earlier, you can configure a maximum of 480 aggregated interfaces on MX Series routers.
13.2	For SONET/SDH, starting with Junos OS Release 13.2, the maximum number of logical interfaces is 64, numbered from **as0** through **as63**.

Configuring the Number of Aggregated Ethernet Interfaces on the Device

By default, no aggregated Ethernet interfaces are created. You must set the number of aggregated Ethernet interfaces on the routing device before you can configure them.

For M Series and T Series routers you can configure a maximum of 128 aggregated interfaces (LAG bundles). On MX Series routers running Junos release 14.2R2 and earlier, you can configure a maximum of 480 aggregated interfaces. For MX Series routers running Junos release 14.2R3 and later you can configure a maximum of 1000 aggregated interfaces. For MX2010 and MX2020 routers you can configure a maximum of 800 aggregated interfaces. In all cases the aggregated interfaces are numbered from **ae0** through **ae4092**

NOTE: On a Junos Fusion Fabric, you can include extended ports (physical interface on a satellite device that provides a connection to servers or endpoints) or local ports in link aggregation groups (LAGs) and MC-LAGs, but not both. For information on extended ports, see *Understanding Junos Fusion Ports* .

For SONET/SDH, starting with Junos OS Release 13.2, the maximum number of logical interfaces is 16, numbered from **as0** through **as15**.

1. Specify that you want to access the aggregated Ethernet configuration on the device.

   user@host# **edit chassis aggregated-devices ethernet**

2. Set the number of aggregated Ethernet interfaces.

   [edit chassis aggregated-devices ethernet]
   user@host# **set device-count** ***number***

You must also specify the constituent physical links by including the **802.3ad** statement at the **[edit interfaces *interface-name* fastether-options]** or **[edit interfaces *interface-name* gigether-options]** hierarchy level.

Release History Table

Release	Description
14.2R2	For MX Series routers running Junos release 14.2R3 and later you can configure a maximum of 1000 aggregated interfaces. For MX2010 and MX2020 routers you can configure a maximum of 800 aggregated interfaces.
13.2	For SONET/SDH, starting with Junos OS Release 13.2, the maximum number of logical interfaces is 16, numbered from **as0** through **as15**.

Related Documentation

- For information about physical links, see Configuring an Aggregated Ethernet Interface on page 108

- For information about configuring aggregated devices, see the *Junos OS Administration Library*.

Configuring Aggregated Ethernet Link Speed

On aggregated Ethernet interfaces, you can set the required link speed for all interfaces included in the bundle. Generally, all interfaces that make up a bundle must have the same speed. If you include in the aggregated Ethernet interface an individual link that has a speed different from the speed that you specify in the **link-speed** parameter, an error message is logged. However, there are exceptions.

Starting with Junos OS Release 13.2, aggregated Ethernet supports mixed rates and mixed modes on T640, T1600, T4000, and TX Matrix Plus routers. For example, these mixes are supported:

- Member links of different modes (WAN and LAN) for 10-Gigabit Ethernet links.
- Member links of different rates: 10-Gigabit Ethernet, 40-Gigabit Ethernet, 50-Gigabit Ethernet, 100-Gigabit Ethernet, and OC192 (10-Gigabit Ethernet WAN mode)

Starting with Junos OS Release 14.1R1 and 14.2, support for mixed rates on aggregated Ethernet bundles is extended to MX240, MX480, MX960, MX2010, and MX2020 routers.

Starting with Junos OS Release 14.2, aggregated Ethernet supports mixed link speeds on PTX Series Packet Transport Routers.

NOTE:

- Member links of 50-Gigabit Ethernet can only be configured using the 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP (PD-1CE-CFP-FPC4).
- Starting with Junos OS Release 13.2, 100-Gigabit Ethernet member links can be configured using the two 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP. This 100-Gigabit Ethernet member link can be included in an aggregated Ethernet link that includes member links of other interfaces as well. In releases before Junos OS Release 13.2, the 100-Gigabit Ethernet member link configured using the two 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP cannot be included in an aggregated Ethernet link that includes member links of other interfaces.

To configure member links of mixed rates and mixed modes on T640, T1600, T4000, TX Matrix Plus, and PTX routers, you need to configure the **mixed** option for the [**edit interfaces ae*x* aggregated-ether-options link-speed**] statement.

To set the required link speed:

1. Specify that you want to configure the aggregated Ethernet options.

   user@host# **edit interfaces *interface-name*** aggregated-ether-options

2. Configure the link speed.

   [edit interfaces *interface-name* aggregated-ether-options]
   user@host# **set link-speed *speed***

   speed can be in bits per second either as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000).

Aggregated Ethernet interfaces on the M120 router can have one of the following speeds:

- **100m**—Links are 100 Mbps.
- **10g**—Links are 10 Gbps.
- **1g**—Links are 1 Gbps.
- **oc192**—Links are OC192 or STM64c.

Aggregated Ethernet links on EX Series switches can be configured to operate at one of the following speeds:

- **10m**—Links are 10 Mbps.
- **100m**—Links are 100 Mbps.
- **1g**—Links are 1 Gbps.
- **10g**—Links are 10 Gbps.
- **50g**—Links are 50 Gbps.

Aggregated Ethernet links on T Series, MX Series, PTX Series routers, and QFX5100, QFX10002, QFX10008, and QFX10016 switches can be configured to operate at one of the following speeds:

- **100g**—Links are 100 Gbps.
- **100m**—Links are 100 Mbps.
- **10g**—Links are 10 Gbps.
- **1g**—Links are 1 Gbps.
- **40g**—Links are 40 Gbps.
- **50g**—Links are 50 Gbps.
- **80g**—Links are 80 Gbps.
- **8g**—Links are 8 Gbps.
- **mixed**—Links are of various speeds.
- **oc192**—Links are OC192.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, aggregated Ethernet supports mixed link speeds on PTX Series Packet Transport Routers.
14.1	Starting with Junos OS Release 14.1R1 and 14.2, support for mixed rates on aggregated Ethernet bundles is extended to MX240, MX480, MX960, MX2010, and MX2020 routers.
13.2	Starting with Junos OS Release 13.2, aggregated Ethernet supports mixed rates and mixed modes on T640, T1600, T4000, and TX Matrix Plus routers.
13.2	Starting with Junos OS Release 13.2, 100-Gigabit Ethernet member links can be configured using the two 50-Gigabit Ethernet interfaces of 100-Gigabit Ethernet PIC with CFP.

Configuring Aggregated Ethernet Minimum Links

On aggregated Ethernet interfaces, you can configure the minimum number of links that must be up for the bundle as a whole to be labeled **up**. By default, only one link must be up for the bundle to be labeled **up**.

To configure the minimum number of links:

1. Specify that you want to configure the aggregated Ethernet options.

   user@host# **edit interfaces** ***interface-name*** **aggregated-ether-options**

2. Configure the minimum number of links.

   [edit interfaces *interface-name* aggregated-ether-options]
   user@host# **set minimum-links** ***number***

On M120, M320, MX Series, T Series, and TX Matrix routers with Ethernet interfaces, and EX 9200 switches, the valid range for **minimum-links** ***number*** is 1 through 16. When the maximum value (16) is specified, all configured links of a bundle must be up for the bundle to be labeled **up**.

On all other routers and on EX Series switches, other than EX8200 switches, the range of valid values for **minimum-links** ***number*** is 1 through 8. When the maximum value (8) is specified, all configured links of a bundle must be up for the bundle to be labeled **up**.

On EX8200 switches, the range of valid values for **minimum-links** ***number*** is 1 through 12. When the maximum value (12) is specified, all configured links of a bundle must be up for the bundle to be labeled **up**.

On MX Series routers, when Link Aggregation Control Protocol (LACP) is enabled on a link aggregation group (LAG) interface along with minimum links configuration, the bundle is considered to be up when the following two conditions are met:

- The specified minimum number of links are up.
- The links are in *collecting distributing* state—that is, collecting and distributing states are merged together to form a combined state (coupled control) for the aggregated port. Because independent control is not possible, the coupled control state machine does not wait for the partner to signal that collection has started before enabling both collection and distribution.

If the number of links configured in an aggregated Ethernet interface is less than the minimum link value configured under the **aggregated-ether-options** statement, the configuration commit fails and an error message is displayed.

Configuring Tagged Aggregated Ethernet Interfaces

To specify aggregated Ethernet interfaces, include the **vlan-tagging** statement at the **[edit interfaces ae*x*]** hierarchy level:

```
[edit interfaces aex]
vlan-tagging;
```

You must also include the **vlan-id** statement:

```
vlan-id number;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

For more information about the **vlan-tagging** and **vlan-id** statements, see "802.1Q VLANs Overview" on page 244.

Related Documentation

- vlan-id on page 1432
- vlan-tagging on page 1445

Configuring Untagged Aggregated Ethernet Interfaces

Packet tagging provides a logical way to differentiate traffic on ports which support multiple virtual local area network (VLAN). While you must configure aggregated Ethernet interfaces to receive tagged traffic, you must also configure aggregated Ethernet interfaces that can receive untagged traffic.

To configure an aggregated Ethernet interface as untagged, remove the **vlan-tagging** statement at the **[edit interfaces ae*x*]** hierarchy level and remove the **vlan-id** statement from the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

NOTE: **You can configure only one logical interface (unit 0) on the port. The logical unit 0 is used to send and receive LACP or marker protocol data units (PDUs) to and from the individual links.**

Table 13 on page 139 lists untagged aggregated Ethernet and LACP support by PIC and router.

Table 13: Untagged Aggregated Ethernet and LACP Support by PIC and Platform

PIC Type	M Series	LACP	T Series	LACP
4-port Fast Ethernet PIC Type 1	Yes	Yes	Yes	Yes
1-port Gigabit Ethernet PIC Type 1	Yes	Yes	Yes	Yes
2-port Gigabit Ethernet PIC Type 2	Yes	Yes	Yes	Yes
4-port Gigabit Ethernet PIC Type 2	Yes	Yes	Yes	Yes
1-port 10-Gigabit Ethernet M160	Yes	Yes	NA	NA
10-port Gigabit Ethernet PIC Type 3	Yes (M120, M320)	Yes	Yes	Yes
1-port 10-Gigabit Ethernet PIC Type 3	N/A	NA	Yes	Yes
8-port Gigabit Ethernet PIC Type 3	Yes	Yes	Yes	Yes

The 8–port Fast Ethernet PIC does not support untagged aggregated Ethernet or LACP.

Syslog messages are logged if you try to configure an untagged aggregated Ethernet interface using an unsupported PIC type.

Related Documentation

- Configuring Tagged Aggregated Ethernet Interfaces on page 138
- Configuring LACP for Aggregated Ethernet Interfaces on page 140.

- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring LACP for Aggregated Ethernet Interfaces

For aggregated Ethernet interfaces, you can configure the Link Aggregation Control Protocol (LACP). LACP is one method of bundling several physical interfaces to form one logical interface. You can configure both VLAN-tagged and untagged aggregated Ethernet with or without LACP enabled.

NOTE: Starting with Junos OS Release 14.1, you can configure aggregated Ethernet interfaces with LACP on logical systems within an MX Series router.

For Multichassis Link Aggregation (MC-LAG), you must specify the **system-id** and **admin key**. MC-LAG peers use the same **system-id** while sending the LACP messages. The **system-id** can be configured on the MC-LAG network device and synchronized between peers for validation.

LACP exchanges are made between actors and partners. An actor is the local interface in an LACP exchange. A partner is the remote interface in an LACP exchange.

LACP is defined in IEEE 802.3ad, *Aggregation of Multiple Link Segments*.

LACP was designed to achieve the following:

- Automatic addition and deletion of individual links to the aggregate bundle without user intervention
- Link monitoring to check whether both ends of the bundle are connected to the correct group

The Junos OS implementation of LACP provides link monitoring but not automatic addition and deletion of links.

The LACP mode can be active or passive. If the actor and partner are both in passive mode, they do not exchange LACP packets, which results in the aggregated Ethernet links not coming up. If either the actor or partner is active, they do exchange LACP packets. By default, LACP is turned off on aggregated Ethernet interfaces. If LACP is configured, it is in passive mode by default. To initiate transmission of LACP packets and response to LACP packets, you must configure LACP in active mode.

NOTE: LACP can link together multiple different physical interfaces, but only features that are supported across all of the linked devices will be supported in the resulting link aggregation group (LAG) bundle. For example, different PICs can support a different number of forwarding classes. If you use link aggregation to link together the ports of a PIC that supports up to 16 forwarding classes with a PIC that supports up to 8 forwarding classes, the resulting LAG bundle will only support up to 8 forwarding classes. Similarly, linking together a PIC that supports WRED with a PIC that does not support it will result in a LAG bundle that does not support WRED.

To enable LACP active mode, include the **lacp** statement at the **[edit interfaces *interface-name* aggregated-ether-options]** hierarchy level, and specify the **active** option:

```
[edit interfaces interface-name aggregated-ether-options]
lacp {
  active;
}
```

NOTE: The LACP process exists in the system only if you configure the system in either active or passive LACP mode.

If you restart the Link Aggregation Control Protocol (LACP) process consecutively without adequate sleep or pause time between the successive restarts, the LACP links might flap. To avoid this problem, you must restart the LACP process only after the refresh time of the periodic packet management (PPM) process is completed.

To restore the default behavior, include the **lacp** statement at the **[edit interfaces *interface-name* aggregated-ether-options]** hierarchy level, and specify the **passive** option:

```
[edit interfaces interface-name aggregated-ether-options]
lacp {
  passive;
}
```

Starting with Junos OS Release 12.2, you can also configure LACP to override the IEEE 802.3ad standard and to allow the standby link always to receive traffic. Overriding the default behavior facilitates subsecond failover.

To override the IEEE 802.3ad standard and facilitate subsecond failover, include the **fast-failover** statement at the **[edit interfaces *interface-name* aggregated-ether-options lacp]** hierarchy level.

When you configure the **accept-data** statement at the **[edit interfaces ae*X* aggregated-ether-options lacp]** hierarchy level, the router processes packets received on a member link irrespective of the LACP state if the aggregated Ethernet bundle is up.

NOTE: When you use the **accept-data** statement at the **[edit interfaces ae*X* aggregated-ether-options lacp]** hierarchy level, this behavior occurs:

- By default, the **accept-data** statement is not configured when LACP is enabled.
- You can configure the **accept-data** statement to improve convergence and reduce the number of dropped packets when member links in the bundle are enabled or disabled.
- When LACP is down and a member link receives packets, the router does not process packets as defined in the IEEE 802.1ax standard. According to this standard, the packets should be dropped, but they are processed instead because the **accept-data** statement is configured.

For more information, see the following sections:

Configuring the LACP Interval

By default, the actor and partner send LACP packets every second. You can configure the interval at which the interfaces send LACP packets by including the **periodic** statement at the **[edit interfaces *interface-name* aggregated-ether-options lacp]** hierarchy level:

[edit interfaces *interface-name* aggregated-ether-options lacp]
periodic *interval*;

The interval can be fast (every second) or slow (every 30 seconds). You can configure different periodic rates on active and passive interfaces. When you configure the active and passive interfaces at different rates, the transmitter honors the receiver's rate.

NOTE: Starting with Junos OS Release 11.4, source address filtering does not work when LACP is enabled., This behavior is not applicable to T Series routers and PTX Series Packet Transport Routers. For more information about source address filtering, see "Configuring MAC Address Filtering for Ethernet Interfaces" on page 14.

Percentage policers are not supported on aggregated Ethernet interfaces with the CCC protocol family configured. For more information about percentage policers, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide*.

Generally, LACP is supported on all untagged aggregated Ethernet interfaces. For more information, see "Configuring Untagged Aggregated Ethernet Interfaces" on page 138.

For M Series Multiservice Edge Routers with enhanced Flexible PIC Concentrators (FPCs) and T Series routers, LACP over VLAN-tagged aggregated Ethernet interfaces is supported. For 8-port, 12-port, and 48-port Fast Ethernet PICs, LACP over VLAN-tagged interfaces is not supported.

LACP **Fast Periodic**, which is achieved by configuring fast (every second) intervals for periodic transmission of LACP packets, is supported with graceful Routing Engine switchover (GRES) on MX Series routers only.

Configuring LACP Link Protection

To force active and standby links within an aggregated Ethernet, you can configure LACP link protection and system priority at the aggregated Ethernet interface level using the **link-protection** and **system-priority** statements. Configuring values at this level results in only the configured interfaces using the defined configuration. LACP interface configuration also enables you to override global (chassis) LACP settings.

LACP link protection also uses port priority. You can configure port priority at the Ethernet interface **[gigether-options]** hierarchy level using the **port-priority** statement. If you choose not to configure port priority, LACP link protection uses the default value for port priority (127).

NOTE:

- When using LACP link protection, you can configure only two member links to an aggregated Ethernet interface: one active and one standby.
- LACP link protection supports per-unit scheduling configuration on aggregated Ethernet interfaces.

Enabling LACP Link Protection

To enable LACP link protection for an aggregated Ethernet interface, use the **link-protection** statement at the **[edit interfaces ae*X* aggregated-ether-options lacp]** hierarchy level:

```
[edit interfaces aeX aggregated-ether-options lacp]
link-protection;
  disable;
  revertive;
  non-revertive;
}
```

By default, LACP link protection reverts to a higher-priority (lower-numbered) link when that higher-priority link becomes operational or a link is added to the aggregator that is determined to be higher in priority. However, you can suppress link calculation by adding the **non-revertive** statement to the LACP link protection configuration. In nonrevertive mode, once a link is active and collecting and distributing packets, the subsequent addition of a higher-priority (better) link does not result in a switch and the current link remains active.

If LACP link protection is configured to be nonrevertive at the global (**[edit chassis]** hierarchy) level, you can add the **revertive** statement to the LACP link protection configuration to override the nonrevertive setting for the interface. In revertive mode, the addition of a higher-priority link to the aggregator results in LACP performing a priority recalculation and switching from the current active link to the new active link.

CAUTION: If both ends of an aggregator have LACP link protection enabled, make sure to configure both ends of the aggregator to use the same mode. Mismatching LACP link protection modes can result in lost traffic.

We strongly recommend that you use LACP on both ends of the aggregator, when you connect an aggregated Ethernet interface with two member interfaces of MX Series routers to any other vendor device. Otherwise, the vendor device (say a Layer 2 switch, or a router) will not be able to manage the traffic coming from the two link aggregated Ethernet bundle. As a result, you might observe the vendor device sending back the traffic to the backup member link of the aggregated Ethernet interface.

Currently, MX-MPC2-3D, MX-MPC2-3D-Q, MX-MPC2-3D-EQ, MX-MPC1-3D, MX-MPC1-3D-Q, and MPC-3D-16XGE-SFPP do not drop traffic coming back to the backup link, whereas DPCE-R-Q-20GE-2XGE, DPCE-R-Q-20GE-SFP, DPCE-R-Q-40GE-SFP, DPCE-R-Q-4XGE-XFP, DPCE-X-Q-40GE-SFP, and DPCE-X-Q-4XGE-XFP drop traffic coming to the backup link.

Configuring LACP System Priority

To configure LACP system priority for aggregated Ethernet interfaces on the interface, use the **system-priority** statement at the **[edit interfaces ae*X* aggregated-ether-options lacp]** hierarchy level:

```
[edit interfaces aeX aggregated-ether-options lacp]
system-priority;
```

The system priority is a 2-octet binary value that is part of the LACP system ID. The LACP system ID consists of the system priority as the two most-significant octets and the interface MAC address as the six least-significant octets. The system with the numerically lower value for system priority has the higher priority. By default, system priority is 127, with a range of 0 to 65,535.

Configuring LACP System Identifier

To configure the LACP system identifier for aggregated Ethernet interfaces, use the **system-id** statement at the **[edit interfaces ae*X* aggregated-ether-options lacp]** hierarchy level:

```
[edit interfaces aeX aggregated-ether-options lacp]
system-id system-id;
```

Starting with Junos OS Release 13.3, youmust not configure the LACP system identifier by using the **system-id *system-id*** statement at the **[edit interfaces ae*X* aggregated-ether-options lacp]** hierarchy level to be all zeros (00:00:00:00:00:00). If you attempt to commit a configuration with the system identifier to be all zeros, an error occurs during the commit operation.

The user-defined system identifier in LACP enables two ports from two separate routers (M Series or MX Series routers) to act as though they were part of the same aggregate group.

The system identifier is a 48-bit (6-byte) globally unique field. It is used in combination with a 16-bit system-priority value, which results in a unique LACP system identifier.

Configuring LACP administrative Key

To configure an administrative key for LACP, include the **admin-key *number*** statement at the **[edit interfaces ae*x* aggregated-ether-options** lacp**]** hierarchy level:

```
[edit interfaces ae x aggregated-ether-options-lacp]
admin-key number;
```

NOTE: **You must configure MC-LAG to configure the admin-key statement. For more information about MC-LAG, see *Configuring Multichassis Link Aggregation on MX Series Routers*.**

Configuring LACP Port Priority

To configure LACP port priority for aggregated Ethernet interfaces, use the **port-priority** statement at the **[edit interfaces *interface-name* gigether-options 802.3ad ae*X* lacp]** or **[edit interfaces *interface-name* fastether-options 802.3ad ae*X* lacp]** hierarchy levels:

```
[edit interfaces interface-name gigether-options 802.3ad aeX lacp]
port-priority priority;
```

The port priority is a 2-octet field that is part of the LACP port ID. The LACP port ID consists of the port priority as the two most-significant octets and the port number as the two least-significant octets. The system with the numerically lower value for port priority has the higher priority. By default, port priority is 127, with a range of 0 to 65,535.

Port aggregation selection is made by each system based on the highest port priority and is assigned by the system with the highest priority. Ports are selected and assigned starting with the highest priority port of the highest priority system and working down in priority from there.

NOTE: **Starting with Junos OS Release 9.3, port aggregation selection (discussed previously) is performed for the active link when LACP link protection is enabled. Without LACP link protection, port priority is not used in port aggregation selection.**

Configuring LACP Hold-Up Timer to Prevent Link Flapping on LAG Interfaces

On link aggregation group (LAG) interfaces, when a member (child) link goes down, its state changes from current to expired. This link might flap from the current state to the expired state and back to current state when it receives intermittent LACP protocol data units (PDUs) and keepalive timeouts. Such flapping can adversely affect the traffic on the link.

To prevent excessive flapping of a LAG child link, you can configure a hold-up timer on the LAG interface that is applicable to all member links on that particular interface. To hold up, in networking terms, means to prevent the transitioning of an interface from down to up for a specified time interval.

When configured, the hold-up timer is triggered when an LACP state machine tries to move to the current state from the expired or default state when it receives an LACP PDU. The hold-up timer is triggered only if the LACP state machine had acquired the current state at least once earlier. The timer is not triggered if LACP attempts to transition to the current state for the first time. LACP monitors the PDUs received on the child link but prevents the link from transitioning to current state. If no flapping is observed when the link receives the PDUs, the hold-up timer expiries and triggers the member link to transition back to the current state. This transition is triggered as soon as the hold-up timer expires and not necessarily when the link receives a PDU.

To configure LACP hold-up timer for LAG interface, use the **hold-time up** statement at the **[edit interfaces aex aggregated-ether-options lacp]** hierarchy level.

NOTE:

- The hold-up timer keeps running even when the interface that receives the LACP PDU moves to the port disable state. The timer is then restarted if, before the timer expires, the interface comes up again and receives an LACP PDU from its neighbor. This ensures that the timer is maintained even during a quick physical port flap.
- When the following events occur, a hold-up timer is not triggered until the member link acquires the current state after the event:
  - LACP daemon restart
  - Deactivation and reactivation of child or aggregated Ethernet interface
  - Deletion and reconfiguration of child or aggregated Ethernet interface
  - System reboot
  - Routing Engine switchover

Tracing LACP Operations

To trace the operations of the LACP process, include the **traceoptions** statement at the **[edit protocols lacp]** hierarchy level:

```
[edit protocols lacp]
traceoptions {

Sample Configuration for Configuring Aggregated Ethernet LACP on Tagged and Untagged Interfaces

Following configurations are examples of configuring aggregated Ethernet LACP on VLAN-tagged and untagged interfaces:

LACP with VLAN-Tagged Aggregated Ethernet

```
[edit interfaces]
fe-5/0/1 {
  fastether-options {
    802.3ad ae0;
  }
}
ae0 {
  aggregated-ether-options {
    lacp {
      active;
    }
  }
  vlan-tagging;
  unit 0 {
    vlan-id 100;
    family inet {
      address 10.1.1.2/24 {
        vrrp-group 0 {
          virtual-address 10.1.1.4;
          priority 200;
        }
      }
    }
  }
}
```

LACP with Untagged Aggregated Ethernet

```
[edit interfaces]
fe-5/0/1 {
  fastether-options {
    802.3ad ae0;
  }
}
ae0 {
  aggregated-ether-options {
    lacp {
      active;
    }
  }
  unit 0 {
    family inet {
      address 10.1.1.2/24 {
        vrrp-group 0 {
          virtual-address 10.1.1.4;
          priority 200;
        }
      }
    }
  }
```

}

Release History Table

Release	Description
14.1	Starting with Junos OS Release 14.1, you can configure aggregated Ethernet interfaces with LACP on logical systems within an MX Series router.
13.3	Starting with Junos OS Release 13.3, youmust not configure the LACP system identifier by using the **system-id** ***system-id*** statement at the **[edit interfaces ae*X* aggregated-ether-options lacp]** hierarchy level to be all zeros (00:00:00:00:00:00).
12.2	Starting with Junos OS Release 12.2, you can also configure LACP to override the IEEE 802.3ad standard and to allow the standby link always to receive traffic. Overriding the default behavior facilitates subsecond failover.
11.4	Starting with Junos OS Release 11.4, source address filtering does not work when LACP is enabled.
9.3	Starting with Junos OS Release 9.3, port aggregation selection (discussed previously) is performed for the active link when LACP link protection is enabled.

Configuring Aggregated Ethernet Link Protection

You can configure link protection for aggregated Ethernet interfaces to provide QoS on the links during operation.

On aggregated Ethernet interfaces, you designate a primary and backup link to support link protection. Egress traffic passes only through the designated primary link. This includes transit traffic and locally generated traffic on the router or switch. When the primary link fails, traffic is routed through the backup link. Because some traffic loss is unavoidable, egress traffic is not automatically routed back to the primary link when the primary link is reestablished. Instead, you manually control when traffic should be diverted back to the primary link from the designated backup link.

NOTE: **Link protection is not supported on MX80.**

Configuring Link Protection for Aggregated Ethernet Interfaces

Aggregated Ethernet interfaces support link protection to ensure QoS on the interface.

To configure link protection:

1. Specify that you want to configure the options for an aggregated Ethernet interface.

   user@host# **edit interfaces ae*x* aggregated-ether-options**

2. Configure the link protection mode.

   [edit interfaces ae*x* aggregated-ether-options]
   user@host# **set link-protection**

Configuring Primary and Backup Links for Link Aggregated Ethernet Interfaces

To configure link protection, you must specify a primary and a secondary, or backup, link.

To configure a primary link and a backup link:

1. Configure the primary logical interface.

   [edit interfaces *interface-name*]
   user@host# **set (fastether-options | gigether-options) 802.3ad ae*x* primary**

2. Configure the backup logical interface.

   [edit interfaces *interface-name*]
   user@host# **set (fastether-options | gigether-options) 802.3ad ae*x* backup**

Reverting Traffic to a Primary Link When Traffic is Passing Through a Backup Link

On aggregated Ethernet interfaces, you designate a primary and backup link to support link protection. Egress traffic passes only through the designated primary link. This includes transit traffic and locally generated traffic on the router or switch. When the primary link fails, traffic is routed through the backup link. Because some traffic loss is unavoidable, egress traffic is not automatically routed back to the primary link when the primary link is reestablished. Instead, you manually control when traffic should be diverted back to the primary link from the designated backup link.

To manually control when traffic should be diverted back to the primary link from the designated backup link, enter the following operational command:

user@host> **request interface revert ae*x***

- Configuring Link Protection for Aggregated Ethernet Interfaces on page 149
- *Ethernet Interfaces Feature Guide for Routing Devices*

Disabling Link Protection for Aggregated Ethernet Interfaces

To disable link protection, issue the **delete interface revert ae*x*** configuration command.

user@host# **delete interfaces ae*x* aggregated-ether-options link-protection**

See Also

- Configuring Link Protection for Aggregated Ethernet Interfaces on page 149
- *Ethernet Interfaces Feature Guide for Routing Devices*

Example: Configuring Aggregated Ethernet Link Protection

The following configuration enables link protection on the **ae0** interface, and specifies the **ge-1/0/0** interface as the primary link and **ge-1/0/1** as the secondary link.

```
[edit interfaces]
ae0 {
  aggregated-ether-options {
    link-protection;
  }
}
[edit interfaces]
ge-1/0/0 {
  gigether-options {
    802.3ad ae0 primary;
  }
}
[edit interfaces]
ge-1/0/1 {
  gigether-options {
    802.3ad ae0 backup;
  }
}
```

Configuring Shared Scheduling on Aggregated Ethernet Interfaces

You can configure shared scheduling on aggregated Ethernet interfaces in link protection mode on Gigabit Ethernet Intelligent Queuing 2 (IQ2) and Ethernet Enhanced IQ2 (IQ2E) PICs on M320 routers.

To configure shared scheduling on aggregated Ethernet interfaces:

1. Specify that you want to configure the options for an aggregated Ethernet interface.

   user@host# **edit interfaces ae*x* aggregated-ether-options**

2. Configure the link protection mode.

   [edit interfaces ae*x* aggregated-ether-options]
   user@host# **set link-protection**

3. Configure shared scheduling.

   [edit interfaces ae*x* aggregated-ether-options]
   user@host# **top**
   [edit]
   user@host# **edit interfaces ae*x* shared-scheduler**

Related Documentation

- Configuring Aggregated Ethernet Link Protection on page 148

Configuring Scheduler on Aggregated Ethernet Interfaces Without Link Protection

On aggregated Ethernet interfaces, you can configure scheduler in non–link-protect mode on the following platforms:

- MX-Series
- M120 and M320 with IQ2 PIC
- T-series platforms (T620 and T320) with IQ2 PIC

The scheduler functions supported are:

- Per unit scheduler
- Hierarchical scheduler
- Shaping at the physical interface

To configure the hierarchical scheduler on aggregated Ethernet interfaces in the non link-protect mode, include the **hierarchical-scheduler** statement at the **[edit interfaces ae*X*]** hierarchy level:

[edit interfaces ae*X* hierarchical-scheduler]

Prior to Junos OS Release 9.6, the hierarchical scheduler mode on these models required the **aggregated-ether-options** statement **link-protection** option. If a **link-protection** option is not specified, the scheduler is configured in non-link-protect mode.

To specify the member link bandwidth derivation based on the equal division model **(scale)** or the replication model **(replicate)** on aggregated Ethernet interfaces, include the **member-link-scheduler (scale | replicate)** option at the **[edit class-of-service interfaces ae*X*]** hierarchy level. The default setting is **scale**.

```
[edit class-of-service interfaces aeX member-link-scheduler (scale | replicate)]
```

NOTE: In link-protect mode, only one link is active at a time and the other link acts as the backup link, whereas in a non link-protect mode, all the links of the aggregate bundle are active at the same time. There is no backup link. If a link goes down or a new link is added to the bundle, traffic redistribution occurs.

Configuring Symmetrical Load Balancing on an 802.3ad Link Aggregation Group on MX Series Routers

Symmetrical Load Balancing on an 802.3ad LAG on MX Series Routers Overview

MX Series routers with Aggregated Ethernet PICs support symmetrical load balancing on an 802.3ad LAG. This feature is significant when two MX Series routers are connected transparently through deep packet inspection (DPI) devices over an LAG bundle. DPI devices keep track of flows and require information of a given flow in both forward and reverse directions. Without symmetrical load balancing on an 802.3ad LAG, the DPIs could misunderstand the flow, leading to traffic disruptions. By using this feature, a given flow of traffic (duplex) is ensured for the same devices in both directions.

Symmetrical load balancing on an 802.3ad LAG utilizes a mechanism of interchanging the source and destination addresses for a hash computation of fields, such as source address and destination address. The result of a hash computed on these fields is used to choose the link of the LAG. The hash-computation for the forward and reverse flow must be identical. This is achieved by swapping source fields with destination fields for the reverse flow. The swapped operation is referred to as *complement hash computation* or **symmetric-hash complement** and the regular (or unswapped) operation as *symmetric-hash computation* or **symmetric-hash**. The swappable fields are MAC address, IP address, and port.

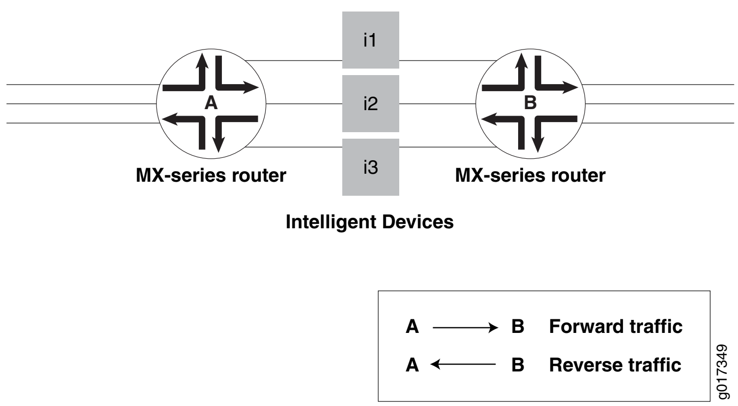
Configuring Symmetric Load Balancing on an 802.3ad LAG on MX Series Routers

You can specify whether symmetric hash or complement hash is done for load-balancing traffic. To configure symmetric hash, use the **symmetric-hash** statement at the **[edit forwarding-options hash-key family inet]** hierarchy level. To configure symmetric hash complement, use the **symmetric-hash complement** statement and option at the **[edit forwarding-options hash-key family inet]** hierarchy level.

These operations can also be performed at the PIC level by specifying a *hash key*. To configure a hash key at the PIC level, use the **symmetric-hash** or **symmetric-hash complement** statement at the **[edit chassis hash-key family inet]** and **[edit chassis hash-key family multiservice]** hierarchy levels.

Consider the example in Figure 7 on page 153.

Figure 7: Symmetric Load Balancing on an 802.3ad LAG on MX Series Routers



Router A is configured with symmetric hash and Router B is configured with symmetric hash complement. Thus, for a given flow *fx*, post hash computation is from Router A to Router B through i2. The reverse traffic for the same flow *fx* is from Router B to Router A through the same i2 device as its hashing (done after swapping source and destination fields) and returns the same link index; since it is performed on the interchanged source and destination addresses.

However, the link chosen may or may not correspond to what was attached to the DPI. In other words, the hashing result should point to the same links that are connected, so that the traffic flows through the same DPI devices in both directions. To make sure this happens, you need to also configure the counterpart ports (ports that are connected to same DPI-iN) with the identical link index. This is done when configuring a child-link into the LAG bundle. This ensures that the link chosen for a given hash result is always the same on either router.

Note that any two links connected to each other should have the same link index and these link indices must be unique in a given bundle.

NOTE:
The following restrictions apply when configuring symmetric load balancing on an 802.3ad LAG on MX Series routers:

- The Packet Forwarding Engine (PFE) can be configured to hash the traffic in either symmetric or complement mode. A single PFE complex cannot work simultaneously in both operational modes and such a configuration can yield undesirable results.
- The per-PFE setting overrides the chassis-wide setting only for the family configured. For the other families, the PFE complex still inherits the chassis-wide setting (when configured) or the default setting.
- This feature supports VPLS, INET, and bridged traffic only.
- This feature cannot work in tandem with the **per-flow-hash-seed load-balancing** option. It requires that all the PFE complexes configured in complementary fashion share the same seed. A change in the seed between two counterpart PFE complexes may yield undesired results.

For additional information, see the *Junos OS VPNs Library for Routing Devices* and the *Junos OS Administration Library*.

Example Configuration Statements

To configure 802.3ad LAG parameters at the bundle level:

```
[edit interfaces]
g(x)e-fpc/pic/port {
  gigether-options {
    802.3ad {
      bundle;
      link-index number;
    }
  }
}
```

where the **link-index *number*** ranges from 0 through 15.

You can check the link index configured above using the **show interfaces** command:

```
[edit forwarding-options hash-key]
family inet {
  layer-3;
  layer-4;
  symmetric-hash {
    [complement;]
  }
}
family multiservice {
  source-mac;
  destination-mac;
```

```
    payload {
    ip {
      layer-3 {
        source-ip-only | destination-ip-only;
      }
      layer-4;
    }
    }
    symmetric-hash {
      [complement;]
    }
}
```

For load-balancing Layer 2 traffic based on Layer 3 fields, you can configure 802.3ad LAG parameters at a per PIC level. These configuration options are available under the chassis hierarchy as follows:

```
[edit chassis]
fpc X {
  pic Y {
    .
    .
    .
    hash-key {
      family inet {
        layer-3;
        layer-4;
        symmetric-hash {
          [complement;]
        }
      }
      family multiservice {
        source-mac;
        destination-mac;
        payload {
          ip {
            layer-3 {
              source-ip-only | destination-ip-only;
            }
            layer-4;
          }
        }
        symmetric-hash {
          [complement;]
        }
      }
    }
    .
    .
    .
  }
}
```

Configuring Symmetrical Load Balancing on Trio-Based MPCs

With some configuration differences, symmetrical load-balancing over an 802.3ad link aggregation group is supported on MX Series routers with Trio-based MPCs.

To achieve symmetrical load-balancing on Trio-Based MPCs, the following needs to be done:

- Compute a Symmetrical Hash

  Both routers must compute the same hash value from the flow in the forward and reverse directions.On Trio-based platforms, the calculated hash value is independent of the direction of the flow, and hence is always symmetric in nature. For this reason, no specific configuration is needed to compute a symmetric hash value on Trio-based platforms.

  However, it should be noted that the fields used to configure the hash should have identical include and exclude settings on both ends of the LAG.

- Configure Link Indexes

  To allow both routers to choose the same link using the same hash value, the links within the LAG must be configured with the same link index on both routers. This can be achieved with the **link-index** statement.

- Enable Symmetric Load Balancing

  To configure symmetric load balancing on Trio-based MPCs, include the **symmetric** statement at the **[edit forwarding-options enhanced-hash-key]** hierarchy level. This statement is applicable to Trio-based platforms only.

  The **symmetric** statement can be used with any protocol family and enables symmetric load-balancing for all aggregated Ethernet bundles on the router. The statement needs to be enabled at both ends of the LAG. This statement is disabled by default.

- Achieve Symmetry for Bridged and Routed Traffic

  In some deployments, the LAG bundle on which symmetry is desired is traversed by Layer 2 bridged traffic in the upstream direction and by IPv4 routed traffic in the downstream direction. In such cases, the computed hash is different in each direction because the Ethernet MAC addresses are taken into account for bridged packets. To overcome this, you can exclude source and destination MAC addresses from the enhanced-hash-key computation.

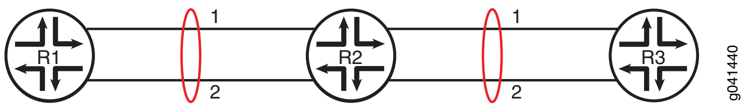
  To exclude source and destination MAC addresses from the enhanced-hash-key computation, include the **no-mac-addresses** statement at the **[edit forwarding-options enhanced-hash-key family multiservice]** hierarchy level. This statement is disabled by default.

When symmetrical load balancing is enabled on Trio-based MPCs, keep in mind the following caveats:

- Traffic polarization is a phenomenon that occurs when using topologies that distribute traffic by using hashing of the same type. When routers are cascaded, traffic polarization can occur, and this can lead to unequal traffic distribution.

Traffic polarization occurs when LAGs are configured on cascaded routers. For example, in Figure 8 on page 157, if a certain flow uses Link 1 of the aggregated Ethernet bundle between Device R1 and Device R2, the flow also uses Link 1 of the aggregated Ethernet bundle between Device R2 and Device R3.

Figure 8: Traffic Polarization on Cascaded Routers When Symmetrical Load Balancing in Enabled on Trio-based MPCs



This is unlike having a random link selection algorithm, where a flow might use Link 1 of the aggregated Ethernet bundle between Device R1 and Device R2, and Link 2 of the aggregated Ethernet bundle between Device R2 and Device R3.

- Symmetric load balancing is not applicable to per-prefix load-balancing where the hash is computed based on the route prefix.
- Symmetric load balancing is not applicable to MPLS or VPLS traffic, because in these scenarios the labels are not the same in both directions.

Example Configurations

- Example Configurations of Chassis Wide Settings on page 157
- Example Configurations of Per–Packet-Forwarding-Engine Settings on page 158

Example Configurations of Chassis Wide Settings

Router A

```
user@host> show configuration forwarding-options hash-key
family multiservice {
  payload {
    ip {
      layer-3;
    }
  }
  symmetric hash;
}
```

Router B

```
user@host> show configuration forwarding-options hash-key
family multiservice {
  payload {
    ip {
      layer-3;
    }
  }
  symmetric-hash {
    complement;
  }
}
```

Example Configurations of Per–Packet-Forwarding-Engine Settings

Router A

```
user@host> show configuration chassis fpc 2 pic 2 hash-key
family multiservice {
   payload {
      ip {
         layer-3;
      }
   }
   symmetric hash;
}
```

Router B

```
user@host> show configuration chassis fpc 2 pic 3 hash-key
family multiservice {
   payload {
      ip {
         layer-3;
      }
   }
   symmetric-hash {
      complement;
   }
}
```

Understanding Aggregated Ethernet Load Balancing

The link aggregation feature is used to bundle several physical aggregated Ethernet interfaces to form one logical interface. One or more links are aggregated to form a virtual link or link aggregation group (LAG). The MAC client treats this virtual link as if it were a single link. Link aggregation increases bandwidth, provides graceful degradation as failure occurs, and increases availability.

In addition to these benefits, an aggregated Ethernet bundle is enhanced to provide load-balancing capabilities that ensure that the link utilization among the member links of the aggregated Ethernet bundle are fully and efficiently utilized.

The load-balancing feature allows a device to divide incoming and outgoing traffic along multiple paths or interfaces in order to reduce congestion in the network. Load balancing improves the utilization of various network paths and provides more effective network bandwidth.

Typically, the applications that use load balancing include:

- Aggregated Interfaces (Layer 2)

Aggregated Interfaces (also called AE for aggregated Ethernet, and AS for aggregated SONET) are a Layer 2 mechanism for load-balancing across multiple interfaces between two devices. Because this is a Layer 2 load-balancing mechanism, all of the individual component links must be between the same two devices on each end. Junos OS supports a non-signaled (static) configuration for Ethernet and SONET, as well as the 802.3ad standardized LACP protocol for negotiation over Ethernet links.

- Equal-Cost Multipath (ECMP) (Layer 3)

  By default, when there are multiple equal-cost paths to the same destination for the active route, Junos OS uses a hash algorithm to choose one of the next-hop addresses to install in the forwarding table. Whenever the set of next hops for a destination changes in any way, the next-hop address is rechosen using the hash algorithm. There is also an option that allows multiple next-hop addresses to be installed in the forwarding table, known as per-packet load balancing.

  ECMP load balancing can be:

  - Across BGP paths (BGP multipath)
  - Within a BGP path, across multiple LSPs

In complex Ethernet topologies, traffic imbalances occur due to increased traffic flow, and load balancing becomes challenging for some of the following reasons:

- Incorrect load balancing by aggregate next hops
- Incorrect packet hash computation
- Insufficient variance in the packet flow
- Incorrect pattern selection

As a result of traffic imbalance, the load is not well distributed causing congestion in certain links, whereas some other links are not efficiently utilized.

To overcome these challenges, Junos OS provides the following solutions for resolving the genuine traffic imbalance on aggregated Ethernet bundles (IEEE 802.3ad).

- Adaptive Load Balancing

  Adaptive load balancing uses a feedback mechanism to correct a genuine traffic imbalance. To correct the imbalance weights, the bandwidth and packet stream of links are adapted to achieve efficient traffic distribution across the links in an AE bundle.

  To configure adaptive load balancing, include the **adaptive** statement at the **[edit interfaces ae*x* aggregated-ether-options load-balance]** hierarchy level.

  NOTE: Adaptive load balancing is not supported if the VLAN ID is configured on the aggregated Ethernet interface. This limitation affects the PTX Series Packet Transport Routers and QFX10000 switches only.

To configure the tolerance value as a percentage, include the **tolerance** optional keyword at the **[edit interfaces ae*x* aggregated-ether-options load-balance adaptive]** hierarchy level.

To configure adaptive load balancing based on packets per second (instead of the default bits per second setting), include the **pps** optional keyword at the **[edit interfaces ae*x* aggregated-ether-options load-balance adaptive]** hierarchy level.

To configure the scan interval for the hash value based on the sample rate for the last two seconds, include the **scan-interval** optional keyword at the **[edit interfaces ae*x* aggregated-ether-options load-balance adaptive]** hierarchy level.

NOTE: The **pps** and **scan-interval** optional keywords are supported on PTX Series Packet Transport Routers only.

- Per-Packet Random Spray Load Balancing

  When the adaptive load-balancing option fails, per-packet random spray load balancing serves as a last resort. It ensures that the members of an AE bundle are equally loaded without taking bandwidth into consideration. Per packet causes packet reordering and hence is recommended only if the applications absorb reordering. Per-packet random spray eliminates traffic imbalance that occurs as a result of software errors, except for packet hash.

  To configure per-packet random spray load balancing, include the **per-packet** statement at the **[edit interfaces ae*x* aggregated-ether-options load-balance]** hierarchy level.

  NOTE: The Per-Packet option for load balancing is not supported on PTX Series Packet Transport Routers.

The aggregated Ethernet load-balancing solutions are mutually exclusive. When more than one of the load-balancing solutions is configured, the solution that is configured last overrides the previously configured one. You can verify the load-balancing solution being used by issuing the **show interfaces ae*x* aggregated-ether-options load-balance** command.

- Example: Configuring Aggregated Ethernet Load Balancing on page 163

Example: Configuring Aggregated Ethernet Load Balancing

This example shows how to configure aggregated Ethernet load balancing.

Requirements

This example uses the following hardware and software components:

- Three MX Series routers with MIC and MPC interfaces or three PTX Series Packet Transport Routers with PIC and FPC interfaces
- Junos OS Release 13.3 or later running on all devices

Overview

Load balancing is required on the forwarding plane when there are multiple paths or interfaces available to the next hop router, and it is best if the incoming traffic is load balanced across all available paths for better link utilization.

Aggregated Ethernet bundle is a typical application that uses load balancing to balance traffic flows across the member links of the bundle (IEEE 802.3ad).

Starting with Junos OS Release 13.3, aggregated Ethernet load balancing is enhanced to provide two solutions for resolving genuine traffic imbalance on aggregated Ethernet bundles on MICs or MPCs of MX Series routers. Starting with Junos OS Release 14.1, aggregated Ethernet load balancing is enhanced to provide two solutions for resolving genuine traffic imbalance on aggregated Ethernet bundles on PICs or FPCs of PTX Series Packet Transport Routers.

The aggregated Ethernet load-balancing solutions are:

- Adaptive—Adaptive load balancing is used in scenarios where flow-based hashing is not sufficient to achieve a uniform load distribution. This load-balancing solution implements a real-time feedback and control mechanism to monitor and manage imbalances in network load.

  The adaptive load-balancing solution corrects the traffic flow imbalance by modifying the selector entries, and periodically scanning the link utilization on each member link of the AE bundle to detect any deviations. When a deviation is detected, an adjustment event is triggered and fewer flows are mapped to the affected member link. As a result, the offered bandwidth of that member link goes down. This causes a continuous feedback loop, which over a period of time ensures that the same amount of byte rate is offered to all the member links, thus providing efficient traffic distribution across each member link in the AE bundle.

To configure adaptive load balancing, include the **adaptive** statement at the **[edit interfaces ae*x* aggregated-ether-options load-balance]** hierarchy level.

NOTE: Adaptive load balancing is not supported if the VLAN ID is configured on the aggregated Ethernet interface. This limitation affects the PTX Series Packet Transport Routers only.

The **pps** option enables load balancing based on the packets-per-second rate. The default setting is bits-per-second load balancing.

The **scan-interval** value configures the length of time for scanning as a multiple of 30 seconds.

The **tolerance** value is the limit to the variance in the packet traffic flow to the aggregated Ethernet links in the bundle. You can specify a maximum of 100-percent variance. When the tolerance attribute is not configured, a default value of 20 percent is enabled for adaptive load balancing. A smaller tolerance value balances better bandwidth, but takes a longer convergence time.

NOTE: The pps and scan-interval optional keywords are supported on PTX Series Packet Transport Routers only.

- Per-packet random spray—When the adaptive load-balancing solution fails, per-packet random spray acts as a last resort. The per-packet random spray load-balancing solution helps to address traffic imbalance by randomly spraying the packets to the aggregate next hops. This ensures that all the member links of the AE bundle are equally loaded, resulting in packet reordering.

  In addition, per-packet random spray identifies the ingress Packet Forwarding Engine that caused the traffic imbalance and eliminates traffic imbalance that occurs as a result of software errors, except for packet hash.

  To configure per-packet random spray load balancing, include the **per-packet** statement at the **[edit interfaces ae*x* aggregated-ether-options load-balance]** hierarchy level.

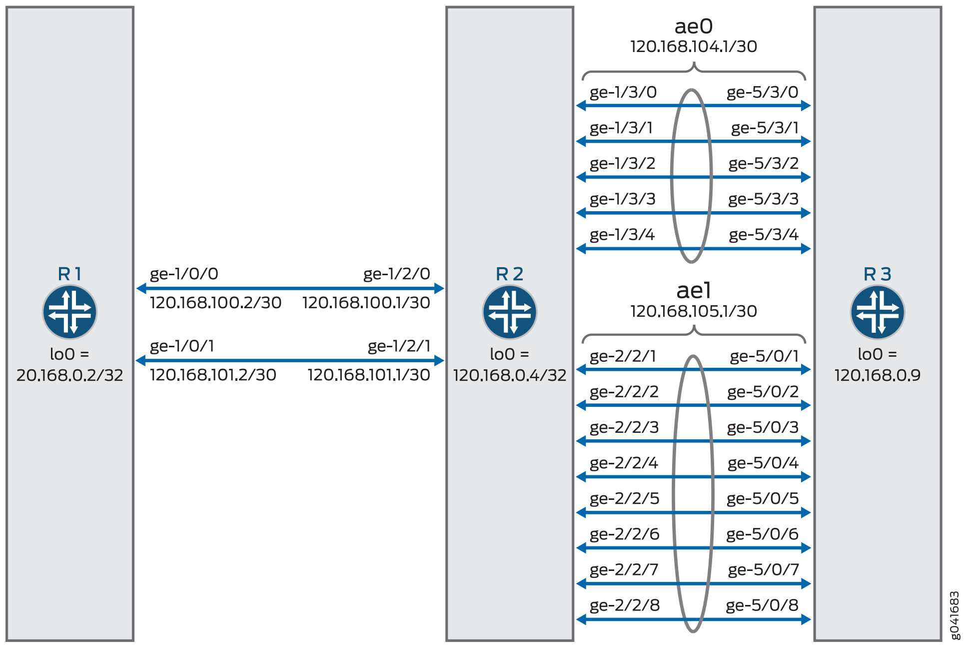
  NOTE: The Per-Packet option for load balancing is not supported on the PTX Series Packet Transport Routers.

The aggregated Ethernet load-balancing solutions are mutually exclusive. When more than one of the load-balancing solutions is configured, the solution that is configured last overrides the previously configured one. You can verify the load-balancing solution being implemented by issuing the **show interfaces ae*x* aggregated-ether-options load-balance** command.

Topology

In this topology, two aggregated Ethernet bundles - ae0 and ae1 - are configured on the links between the R2 and R3 routers.

Figure 9: Aggregated Ethernet Load Balancing



Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

R1

```
set chassis aggregated-devices ethernet device-count 12

Configuring Adaptive Load Balancing

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode*.

To configure the R2 router:

> NOTE: Repeat this procedure for the other routers, after modifying the appropriate interface names, addresses, and any other parameters for each router.

1. Specify the number of aggregated Ethernet interfaces to be created.

   ```
   [edit chassis]
   user@R2# set aggregated-devices ethernet device-count 5
   ```

2. Configure the Gigabit Ethernet interface link connecting R2 to R1.

   ```
   [edit interfaces]
   user@R2# set ge-1/2/0 unit 0 family inet address 120.168.100.1/30
   user@R2# set ge-1/2/0 unit 0 family iso
   user@R2# set ge-1/2/0 unit 0 family mpls

   user@R2# set ge-1/2/1 unit 0 family inet address 120.168.101.1/30
   user@R2# set ge-1/2/1 unit 0 family iso
   user@R2# set ge-1/2/1 unit 0 family mpls
   ```

```
user@R2# set lo0 unit 0 family inet address 120.168.0.4/32
user@R2# set lo0 unit 0 family iso address 49.0001.1201.6800.0004.00
```

3. Configure the five member links of the ae0 aggregated Ethernet bundle.

```
[edit interfaces]
user@R2# set ge-1/3/0 gigether-options 802.3ad ae0
user@R2# set ge-1/3/1 gigether-options 802.3ad ae0
user@R2# set ge-1/3/2 gigether-options 802.3ad ae0
user@R2# set ge-1/3/3 gigether-options 802.3ad ae0
user@R2# set ge-1/3/4 gigether-options 802.3ad ae0
```

4. Configure the eight member links of the ae1 aggregated Ethernet bundle.

```
[edit interfaces]
user@R2# set ge-2/2/1 gigether-options 802.3ad ae1
user@R2# set ge-2/2/2 gigether-options 802.3ad ae1
user@R2# set ge-2/2/3 gigether-options 802.3ad ae1
user@R2# set ge-2/2/4 gigether-options 802.3ad ae1
user@R2# set ge-2/2/5 gigether-options 802.3ad ae1
user@R2# set ge-2/2/6 gigether-options 802.3ad ae1
user@R2# set ge-2/2/7 gigether-options 802.3ad ae1
user@R2# set ge-2/2/8 gigether-options 802.3ad ae1
```

5. Enable aggregate Ethernet load balancing on ae0 of R2.

```
[edit interfaces]
user@R2# set ae0 aggregated-ether-options load-balance adaptive tolerance 10
```

6. Configure the link speed for the ae0 aggregated Ethernet bundle.

```
[edit interfaces]
user@R2# set ae0 aggregated-ether-options link-speed 1g
```

7. Configure LACP on the ae0 aggregated Ethernet bundle.

```
[edit interfaces]
user@R2# set ae0 aggregated-ether-options lacp active
```

8. Configure the interface parameters for the ae0 aggregated Ethernet bundle.

```
[edit interfaces]
user@R2# set ae0 unit 0 family inet address 120.168.104.1/30
user@R2# set ae0 unit 0 family iso
user@R2# set ae0 unit 0 family mpls
```

9. Enable aggregate Ethernet load balancing on ae1 of R2.

```
[edit interfaces]
user@R2# set ae1 aggregated-ether-options load-balance adaptive tolerance 10
```

10. Configure the link speed for the ae1 aggregated Ethernet bundle.

```
[edit interfaces]
```

user@R2# **set ae1 aggregated-ether-options link-speed 1g**

11. Configure LACP on the ae1 aggregated Ethernet bundle.

    [edit interfaces]
    user@R2# **set ae1 aggregated-ether-options lacp active**

12. Configure the interface parameters for the ae1 aggregated Ethernet bundle.

    [edit interfaces]
    user@R2# **set ae1 unit 0 family inet address 120.168.105.1/30**
    user@R2# **set ae1 unit 0 family iso**
    user@R2# **set ae1 unit 0 family mpls**

13. Disable selective aggregate Ethernet statistics.

    [edit accounting-options]
    user@R2# **set selective-aggregate-interface-stats disable**

14. Configure RSVP on all the interfaces of R2 and on the AE bundles.

    [edit protocols]
    user@R2# **set rsvp interface ge-1/2/0.0**
    user@R2# **set rsvp interface ge-1/2/1.0**
    user@R2# **set rsvp interface ae0.0**
    user@R2# **set rsvp interface ae1.0**

15. Configure MPLS on all the interfaces of R2 and on the AE bundles.

    [edit protocols]
    user@R2# **set mpls interface ge-1/2/0.0**
    user@R2# **set mpls interface ge-1/2/1.0**
    user@R2# **set mpls interface ae0.0**
    user@R2# **set mpls interface ae1.0**

16. Configure IS-IS on all the interfaces of R2 and on the AE bundles.

    [edit protocols]
    user@R2# **set isis traffic-engineering family inet shortcuts**
    user@R2# **set isis level 1 disable**
    user@R2# **set isis interface ge-1/2/0.0**
    user@R2# **set isis interface ge-1/2/1.0**
    user@R2# **set isis interface ae0.0**
    user@R2# **set isis interface ae1.0**
    user@R2# **set isis interface lo0.0**

Results

From configuration mode, confirm your configuration by entering the **show chassis**, **show interfaces**, **show accounting-options**, and **show protocols** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R2# show chassis
aggregated-devices {
  ethernet {
    device-count 5;
  }
}
```

```
user@R2# show interfaces

Meaning The member links of the ae0 aggregated Ethernet bundle are fully utilized with adaptive load balancing.

See Also • Understanding Aggregated Ethernet Load Balancing on page 158

Load Balancing and Ethernet Link Aggregation Overview

You can create a link aggregation group (LAG) for a group of Ethernet ports. Layer 2 bridging traffic is load balanced across the member links of this group, making the configuration attractive for congestion concerns as well as for redundancy. You can configure up to 128 LAG bundles on M Series, and T Series routers, and 480 LAG bundles on MX Series routers and EX9200 switches. Each LAG bundle contains up to 16 links. (Platform support depends on the Junos OS release in your installation.)

By default, the hash key mechanism to load-balance frames across LAG interfaces is based on Layer 2 fields (such as frame source and destination address) as well as the input logical interface (unit). The default LAG algorithm is optimized for Layer 2 switching. Starting with Junos OS Release 10.1, you can also configure the load balancing hash key for Layer 2 traffic to use fields in the Layer 3 and Layer 4 headers using the **payload** statement. For more information, see "Configuring Load Balancing on a LAG Link" on page 177.In a Layer 2 switch, one link is overutilized and other links are underutilized.

Release History Table

Release	Description
10.1	Starting with Junos OS Release 10.1, you can also configure the load balancing hash key for Layer 2 traffic to use fields in the Layer 3 and Layer 4 headers using the **payload** statement.

- *payload*

Example: Configuring Load Balancing on a LAG Link

This example configures the load-balancing hash key to use the source Layer 3 IP address option and Layer 4 header fields as well as the source and destination MAC addresses for load balancing on a link aggregation group (LAG) link:

```
[edit]
forwarding-options {
  hash-key {
    family multiservice {
      source-mac;
      destination-mac;
      payload {
        ip {
          layer-3 {
            source-ip-only;
          }
          layer-4;
        }
      }
    }
  }
}
```

NOTE: Any change in the hash key configuration requires a reboot of the FPC for the changes to take effect.

Related Documentation

Configuring Load Balancing on a LAG Link

You can configure the load balancing hash key for Layer 2 traffic to use fields in the Layer 3 and Layer 4 headers inside the frame payload for load-balancing purposes using the **payload** statement. You can configure the statement to look at **layer-3** (and **source-ip-only** or **destination-ip-only** packet header fields) or **layer-4** fields. You configure this statement at the **[edit forwarding-options hash-key family multiservice]** hierarchy level.

You can configure Layer 3 or Layer 4 options, or both. The **source-ip-only** or **destination-ip-only** options are mutually exclusive. The **layer-3-only** statement is not available on MX Series routers.

By default, Junos implementation of 802.3ad balances traffic across the member links within an aggregated Ethernet bundle based on the Layer 3 information carried in the packet.

For more information about link aggregation group (LAG) configuration, see the *Junos OS Network Interfaces Library for Routing Devices*.

Stateful Load Balancing for Aggregated Ethernet Interfaces Using 5-Tuple Data

When multiple flows are transmitted out of an aggregated Ethernet (**ae**) interface, the flows must be distributed across the different member links evenly to enable an effective and optimal load-balancing behavior. To obtain a streamlined and robust method of load-balancing, the member link of the aggregated Ethernet interface bundle that is selected each time for load balancing plays a significant part. In Junos OS releases earlier than Release 13.2R1, on MX Series routers with Trio-based FPCs (MPCs), the selection of a member link of the **ae** interface bundle or the next-hop (or unilist of next-hops) for equal-cost multipath ECM) links is performed using a balanced mode next-hop selection methodology and an unbalanced mode of member link or next-hop selection methodology. The balanced mode of link selection uses 'n' bits in a precomputed hash value if it needs to select one of 2^n (2 raised to the power of n) next-hop in the unilist. The unbalanced mode of member-link or next-hop selection uses 8 bits in a precomputed hash to select an entry in a selector table, which is randomly done with the member link IDs of the link aggregation group (LAG) or **ae**bundle.

The term balanced versus unbalanced indicates whether a selector table is used for load balancing mechanism or not. The LAG bundle uses the unbalanced mode (selector table balancing) to balance the traffic across member links. When the traffic flows are minimal, the following problems might occur with the unbalanced mode: The link selection logic utilizes only subset bits of the precomputed hash. Regardless of the efficiency of the hashing algorithm, it is only the compressed representation of a flow. Because the inter-flow variance is very low, the resultant hashes and the subset that are computed do not provide the necessary variability to effectively utilize all the LAG member links. An excessive amount of random nature exists in the hash computation and also in the selector table. As a result, the deviation from being an optimal load-balancing technique for each child link that is selected is higher when the number of flows is lower.

The deviation per child link is defined as

Vi = ((Ci - (M/N)))/N

where

- Vi denotes the deviation for that child link 'i'.
- i denotes the child link member/index.
- Ci represents the packets transmitted for that child link 'i'.
- M signifies the total packets transmitted on that LAG bundle.
- N denotes the number of child links in that LAG.

Because of these drawbacks, for smaller number of flows, or flows with less inter-flow variance, the link utilization is skewed, and a high probability of a few child links not being utilized entirely exists. Starting with Junos OS Release 13.2R1, the capability to perform uniform load balancing and also perform rebalancing is introduced on MX Series routers with MPCs, except MPC3Es and MPC4Es. Rebalancing is not supported when load-balancing is skewed or distorted owing to a change in the number of flows.

The mechanism to record and retain states for the flows and distribute the traffic load accordingly is added. As a result, for m number of flows, they are distributed among n member links of a LAG bundle or among the unilist of next-hops in an ECMP link. This method of splitting the load among member links is called *stateful load balancing* and it uses 5-tuple information (source and destination addresses, protocol, source and destination ports). Such a method can be mapped directly to the flows, or to a precompute hash based on certain fields in the flow. As a result, the deviation observed on each child link is reduced.

This mechanism works efficiently only for minimal number of flows (less than thousands of flows, approximately). For a larger number of flows (between 1000 and 10,000 flows), we recommend that distributed Trio-based load-balancing mechanism is used.

Consider a sample scenario in which 'n' links in the LAG are identified with link IDs of 0 through n-1. A hash table or a flow table is used to record the flows as and when they show up. The hashing key is constructed using the fields that uniquely identify a flow. The result of the lookup identifies the link_id that the flow is currently using. For each packet, the flow table based on the flow identifier is examined. If a match is found, it denotes a packet that belongs to a flow that is previously processed or detected. The link ID is associated with the flow. If a match is not found, it is the first packet that belongs to the flow. The link ID is used to select the link and the flow is inserted into the flow table.

To enable per-flow load balancing based on hash values, include the **per-flow** statement at the at the **[edit interfaces ae*X* unit *logical-unit-number* forwarding-options load-balance-stateful]** hierarchy level. By default, Junos OS uses a hashing method based only on the destination address to elect a forwarding next hop when multiple equal-cost paths are available. All Packet Forwarding Engine slots are assigned the same hash value by default. To configure the load-balancing algorithm to dynamically rebalance the LAG using existing parameters, include the **rebalance *interval*** statement at the **[edit interfaces ae*X* unit *logical-unit-number* forwarding-options load-balance-stateful]** hierarchy level. This parameter periodically load balances traffic by providing a synchronized rebalance switchover across all the ingress Packet Forwarding Engines (PFEs) over a rebalance interval. You can specify the interval as a value in the range of 1 through 1000 flows per minute. To configure the load type, include the **load-type (low | medium | high)** statement at the **[edit interfaces ae*X* unit *logical-unit-number* forwarding-options load-balance-stateful]** hierarchy level.

The **stateful per-flow** option enables the load-balancing capability on AE bundles. The **rebalance** option clears the load balance state at specified intervals. The **load** option informs the Packet Forwarding Engine regarding the appropriate memory pattern to be used. If the number of flows that flow on this aggregated Ethernet interface is less (between 1 and 100 flows), then the **low** keyword can be used. Similarly for relatively higher flows (between 100 and 1000 flows), the **medium** keyword can be used and the **large** keyword can be used for the maximum flows (between 1000 and 10,000 flows). The approximate number of flows for effective load-balancing for each keyword is a derivative.

The **clear interfaces ae*X* unit *logical-unit-number* forwarding-options load-balance state** command clears the load balance state at the hardware level and enables rebalancing from the cleaned up, empty state. This clear state is triggered only when you use this command. The **clear interfaces aggregate forwarding-options load-balance state** command clears all the aggregate Ethernet interface load balancing states and re-creates them newly.

Guidelines for Configuring Stateful Load Balancing for Aggegated Ethernet Interfaces or LAG Bundles

Keep the following points in mind while configuring stateful load-balancing for aggregated Ethernet interfaces:

- When a child link is removed or added, a new aggregate selector is selected and traffic flows onto the new selector. Because the selector is empty, flows are filled in the selector. This behavior causes redistribution of flows because the old state is lost. This is the existing behavior without enabling stateful per-flow load-balancing.
- Stateful per-flow load-balancing functions on AE interfaces if the incoming traffic reaches the MPC1E, MPC2E, MPC3E-3D, MPC5E, and MPC6E line cards. Any other type of line card does not rigger this functionality. Appropriate CLI errors are displayed if the MPCs do not support this capability.

  With the ingress line card as MPC and the egress line card as MPC or DPC, this feature works properly. Stateful load-balancing is not supported if the ingress line card is a DPC and the egress line card is a DPC or an MPC.
- This capability is not supported for multicast traffic (native/flood).
- Enabling the rebalance option or clearing the load balance state can cause packet reordering for active flows because different sets of links can be selected for traffic flows.
- Although the feature performance is high, it consumes significant amount of line card memory. Approximately, 4000 logical interfaces or 16 aggregated Ethernet logical interfaces can have this feature enabled on supported MPCs. However, when the Packet Forwarding Engine hardware memory is low, depending upon the available memory, it falls back to the default load balancing mechanism. A system logging message is generated in such a situation and sent to the Routing Engine. A restriction on the number of AE interfaces that support stateful load-balancing does not exist; the limit is determined by the line cards.
- If the traffic flows become aged frequently, then the device needs to remove or refresh the load balancing states. As a result, you must configure rebalancing or run the clear command at periodic intervals for proper load-balancing. Otherwise, traffic skewing can occur. When a child link goes down or comes up, the load balancing behavior does not undergo changes on existing flows. This condition is to avoid packet reordering. New flows pick up the child link that come up. If you observe load distribution to be not very effective, you can clear the load-balancing states or use rebalancing functionality to cause an automatic clearance of the hardware states. When you configure the rebalancing facility, traffic flows can get redirected to different links, which can cause packet reordering.

Release History Table

Release	Description
13.2R1	Starting with Junos OS Release 13.2R1, the capability to perform uniform load balancing and also perform rebalancing is introduced on MX Series routers with MPCs, except MPC3Es and MPC4Es.

Configuring Stateful Load Balancing on Aggregated Ethernet Interfaces

The mechanism to record and retain states for the flows and distribute the traffic load accordingly is added. As a result, for m number of flows, they are distributed among n member links of a LAG bundle or among the unilist of next-hops in an ECMP link. This method of splitting the load among member links is called *stateful load balancing* and it uses 5-tuple information (source and destination addresses, protocol, source and destination ports). Such a method can be mapped directly to the flows, or to a precompute hash based on certain fields in the flow. As a result, the deviation observed on each child link is reduced.

To configure stateful load balancing on **ae** interface bundles:

1. Specify that you want to configure an aggregated Ethernet interface.

   [edit]
   user@R2# **set interfaces ae*X* unit *logical-unit-number***

2. Specify that you want to configure stateful load-balancing.

   [edit interfaces ae*X* unit *logical-unit-number*]
   user@R2# **edit forwarding-options load-balance-stateful**

3. Enable the mechanism to perform an even, effective distribution of traffic flows across member links of an aggregated Ethernet interface (**ae**) bundle on MX Series routers with MPCs, except MPC3Es and MPC4Es.

   [edit interfaces ae*X* unit *logical-unit-number* load-balance-stateful]
   user@R2# **set per-flow**

4. Configure periodic rebalancing of traffic flows of an aggregated Ethernet bundle by clearing the load balance state at a specified interval.

   [edit interfaces ae*X* unit *logical-unit-number* load-balance-stateful]
   user@R2# **set rebalance *interval***

5. Define the load-balancing type to inform the Packet Forwarding Engine regarding the appropriate memory pattern to be used for traffic flows. The approximate number of flows for effective load-balancing for each keyword is a derivative.

   [edit interfaces ae*X* unit *logical-unit-number* load-balance-stateful]

user@R2# **set load-type (low | medium | large)**

6. Configure the address family and IP address for the **ae** interface.

   [edit interfaces]
   user@R2# **set ae0 aggregated-ether-options load-balance adaptive tolerance 10**

7. Configure the link speed for the ae0 aggregated Ethernet bundle.

   [edit interfaces ae*X* unit *logical-unit-number*]]
   user@R2# **set family *family-name* address *address***

- Stateful Load Balancing for Aggregated Ethernet Interfaces Using 5-Tuple Data on page 178

Configuring Adaptive Load Balancing

This topic describes how to configure adaptive load balancing. Adaptive load balancing maintains efficient utilization of member link bandwidth for an aggregated Ethernet (AE) bundle. Adaptive load balancing uses a feedback mechanism to correct traffic load imbalance by adjusting the bandwidth and packet streams on links within an AE bundle.

Before you begin:

- Configure a set of interfaces with a protocol family and IP address. These interfaces can make up the membership for the AE bundle.
- Create an AE bundle by configuring a set of router interfaces as aggregated Ethernet and with a specific AE group identifier.

To configure adaptive load balancing for an AE bundles:

1. Enable adaptive load balancing on the AE bundle:

   [edit interfaces ae-*x* aggregated-ether-options load-balance]
   user@router# **set adaptive**

   NOTE: **To configure adaptive load balancing on aggregated Ethernet bundles with mixed link speeds, use the following statement:**

   user@router# **set interfaces ae0 aggregated-ether-options link-speed *mixed* load-balance *adaptive***

2. Configure the scan interval value for adaptive load balancing on the AE bundle. The scan interval value determines the length of the traffic scan by multiplying the integer value with a 30-second time period:

   [edit interfaces ae-*x* aggregated-ether-options load-balance adaptive]
   user@router# **set scan-interval *multiplier***

3. Configure the tolerance percentage value. The tolerance value determines the allowed deviation in the traffic rates among the members of the AE bundle before the router triggers an adaptive load balancing update:

   [edit interfaces ae-*x* aggregated-ether-options load-balance adaptive]
   user@router# **set tolerance** ***percentage***

4. (Optional) Enable packet-per-second-based adaptive load balancing on the AE bundle:

   [edit interfaces ae-*x* aggregated-ether-options load-balance adaptive]
   user@router# **set pps**

Understanding Independent Micro BFD Sessions for LAG

Starting with Junos OS Release 13.3, this feature is supported on the following PIC/FPC types:

- PC-1XGE-XENPAK (Type 3 FPC)
- PD-4XGE-XFP (Type 4 FPC)
- PD-5-10XGE-SFPP (Type 4 FPC)
- 24x10GE (LAN/WAN) SFPP, 12x10GE (LAN/WAN) SFPP, 1x100GE Type 5 PICs
- All MPCs on MX Series with Ethernet MICs
- FPC-PTX-P1-A on PTX5000 with 10-Gigabit Ethernet interfaces
- FPC2-PTX-P1A on PTX5000 with 10-Gigabit Ethernet interfaces in Junos OS Release 14.1 and later
- All FPCs on PTX Series with Ethernet interfaces in Junos OS Release 14.1R3 and later 14.1 releases, and Junos 14.2 and later

TIP: See *PTX Series PIC/FPC Compatibility* for a list of PICs that are supported on each PTX Series FPC.

The Bidirectional Forwarding Detection (BFD) protocol is a simple detection protocol that quickly detects failures in the forwarding paths. A link aggregation group (LAG) combines multiple links between devices that are in point-to-point connections, thereby increasing bandwidth, providing reliability, and allowing load balancing. To run a BFD session on LAG interfaces, configure an independent, asynchronous mode BFD session on every LAG member link in a LAG bundle. Instead of a single BFD session monitoring the status of the UDP port, independent micro BFD sessions monitor the status of individual member links.

The individual BFD sessions determine the Layer 2 and Layer 3 connectivity of each member link in the LAG. Once a BFD session is established on a particular link, the member links are attached to the LAG and the load balancer either by a static configuration or by the Link Aggregation Control Protocol (LACP). If the member links are attached to the LAG by a static configuration, the device control process acts as the client to the micro BFD session. When member links are attached to the LAG by the LACP, the LACP acts as the client to the micro BFD session.

When the micro BFD session is up, a LAG link is established and data is transmitted over that LAG link. If the micro BFD session on a member link is down, that particular member link is removed from the load balancer, and the LAG managers stop directing traffic to that link. These micro BFD sessions are independent of each other despite having a single client that manages the LAG interface.

NOTE: **Starting with Junos OS Release 13.3, IANA has allocated 01-00-5E-90-00-01 as the dedicated MAC address for micro BFD. Dedicated MAC mode is used by default for micro BFD sessions, in accordance with the latest draft for BFD over LAG.**

Micro BFD sessions run in the following modes:

- Distribution Mode—Micro BFD sessions are distributed by default at Layer 3.
- Non-Distribution Mode—You can configure the BFD session to run in this mode by including the **no-delegate-processing** statement under periodic packet management (PPM). In this mode, the packets are being sent or received by the Routing Engine at Layer 2.

A pair of routing devices in a LAG exchange BFD packets at a specified, regular interval. The routing device detects a neighbor failure when it stops receiving a reply after a specified interval. This allows the quick verification of member link connectivity with or without LACP. A UDP port distinguishes BFD over LAG packets from BFD over single-hop IP.

NOTE: **IANA has allocated 6784 as the UDP destination port for micro BFD.**

To enable failure detection for LAG networks for aggregated Ethernet interfaces:

- Include the **bfd-liveness-detection** statement in the configuration.
- Specify a hold-down interval value to set the minimum time that the BFD session must remain up before a state change notification is sent to the other members in the LAG network.

- Specify the minimum interval that indicates the time interval for transmitting and receiving data.
- Starting with Junos OS Release 14.1, specify the neighbor in a BFD session. In releases prior to Junos OS Release 16.1, you must configure the loopback address of the remote destination as the neighbor address. Beginning with Junos OS Release 16.1, you can also configure this feature with aggregated Ethernet interface address of the remote destination as the neighbor address.

  CAUTION: Deactivate bfd-liveness-detection at the **[edit interfaces aex aggregated-ether-options]** hierarchy level or deactivate the aggregated Ethernet interface before changing the neighbor address from loopback IP address to aggregated Ethernet interface IP address. Modifying the local and neighbor address without deactivating **bfd-liveness-detection** or the aggregated Ethernet interface first might cause micro BFD sessions failure.

  NOTE: Beginning with Release 16.1R2, Junos OS checks and validates the configured micro BFD **local-address** against the interface or loopback IP address before the configuration commit. Junos OS performs this check on both IPv4 and IPv6 micro BFD address configurations, and if they do not match, the commit fails.

NOTE: This feature works only when both the devices support BFD. If BFD is configured at one end of the LAG, this feature does not work.

For the IPv6 address family, disable duplicate address detection before configuring this feature with AE interface addresses. To disable duplicate address detection, include the **dad-disable** statement at the **[edit interface *aex* unit *y* family inet6]** hierarchy level.

Release History Table

Release	Description
16.1	Beginning with Junos OS Release 16.1, you can also configure this feature with aggregated Ethernet interface address of the remote destination as the neighbor address.
16.1	Beginning with Release 16.1R2, Junos OS checks and validates the configured micro BFD **local-address** against the interface or loopback IP address before the configuration commit.
14.1	Starting with Junos OS Release 14.1, specify the neighbor in a BFD session. In releases prior to Junos OS Release 16.1, you must configure the loopback address of the remote destination as the neighbor address.
13.3	Starting with Junos OS Release 13.3, IANA has allocated 01-00-5E-90-00-01 as the dedicated MAC address for micro BFD.

Example: Configuring Independent Micro BFD Sessions for LAG

This example shows how to configure an independent micro BFD session for aggregated Ethernet interfaces.

Requirements

This example uses the following hardware and software components:

- MX Series routers with Junos Trio chipset
- T Series routers with Type 4 FPC or Type 5 FPC

  BFD for LAG is supported on the following PIC types on T-Series:

  - PC-1XGE-XENPAK (Type 3 FPC),
  - PD-4XGE-XFP (Type 4 FPC),

    - PD-5-10XGE-SFPP (Type 4 FPC),
    - 24x10GE (LAN/WAN) SFPP, 12x10GE (LAN/WAN) SFPP, 1X100GE Type 5 PICs
- PTX Series routers with 24X10GE (LAN/WAN) SFPP
- Junos OS Release 13.3 or later running on all devices

Overview

The example includes two routers that are directly connected. Configure two aggregated Ethernet interfaces, AE0 for IPv4 connectivity and AE1 for IPv6 connectivity. Configure micro BFD session on the AE0 bundle using IPv4 addresses as local and neighbor endpoints on both routers. Configure micro BFD session on the AE1 bundle using IPv6 addresses as local and neighbor endpoints on both routers. This example verifies that independent micro BFD sessions are active in the output.

Topology

Figure 10 on page 187 shows the sample topology.

Figure 10: Configuring an Independent Micro BFD Session for LAG

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Router R0

```
set interfaces ge-1/0/1 unit 0 family inet address 20.20.20.1/30

Configuring a Micro BFD Session for Aggregated Ethernet Interfaces

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see "*Using the CLI Editor in Configuration Mode*" in the *CLI User Guide*.

NOTE: Repeat this procedure for Router R1, modifying the appropriate interface names, addresses, and any other parameters for each router.

To configure a micro BFD session for aggregated Ethernet interfaces on Router R0:

1. Configure the physical interfaces.

   ```
   [edit interfaces]
   user@R0# set ge-1/0/1 unit 0 family inet address 20.20.20.1/30
   user@R0# set ge-1/0/1 unit 0 family inet6 address 3ffe::1:1/126
   user@R0# set xe-4/0/0 gigether-options 802.3ad ae0
   user@R0# set xe-4/0/1 gigether-options 802.3ad ae0
   user@R0# set xe-4/1/0 gigether-options 802.3ad ae1
   user@R0# set xe-4/1/1 gigether-options 802.3ad ae1
   ```

2. Configure the loopback interface.

   ```
   [edit interfaces]
   user@R0# set lo0 unit 0 family inet address 10.255.106.107/32
   user@R0# set lo0 unit 0 family inet6 address 201:DB8:251::aa:aa:1/128
   ```

3. Configure an IP address on the aggregated Ethernet interface ae0 with either IPv4 or IPv6 addresses, as per your network requirements.

   ```
   [edit interfaces]
   user@R0# set ae0 unit 0 family inet address 10.0.0.1/30
   ```

4. Set the routing option, create a static route, and set the next-hop address.

   NOTE: You can configure either an IPv4 or IPv6 static route, depending on your network requirements.

   ```
   [edit routing-options]
   user@R0# set nonstop-routing
   user@R0# set static route 30.30.30.0/30 next-hop 10.0.0.2
   user@R0# set rib inet6.0 static route 3ffe::1:2/126 next-hop 5555::2
   ```

5. Configure the Link Aggregation Control Protocol (LACP).

   ```
   [edit interfaces]
   user@R0# set ae0 aggregated-ether-options lacp active
   ```

6. Configure BFD for the aggregated Ethernet interface ae0, and specify the minimum interval, local IP address, and the neighbor IP address.

```
[edit interfaces]
user@R0# set ae0 aggregated-ether-options bfd-liveness-detection
  minimum-interval 100
user@R0# set ae0 aggregated-ether-options bfd-liveness-detection multiplier 3
user@R0# set ae0 aggregated-ether-options bfd-liveness-detection neighbor
  10.255.106.102
user@R0# set ae0 aggregated-ether-options bfd-liveness-detection local-address
  10.255.106.107
user@R0# set ae0 aggregated-ether-options minimum-links 1
user@R0# set ae0 aggregated-ether-options link-speed 10g
```

7. Configure an IP addresse on the aggregated Ethernet interface ae1.

   You can assign either IPv4 or IPv6 addresses as per your network requirements.

```
[edit interfaces]
user@R0# set ae1 unit 0 family inet6 address 5555::1/126
```

8. Configure BFD for the aggregated Ethernet interface ae1.

```
[edit interfaces]
user@R0# set ae1 aggregated-ether-options bfd-liveness-detection
  minimum-interval 100
user@R0# set ae1 aggregated-ether-options bfd-liveness-detection multiplier 3
user@R0# set ae1 aggregated-ether-options bfd-liveness-detection neighbor
  201:DB8:251::bb:bb:1
user@R0# set ae1 aggregated-ether-options bfd-liveness-detection local-address
  201:DB8:251::aa:aa:1
user@R0# set ae1 aggregated-ether-options minimum-links 1
user@R0# set ae1 aggregated-ether-options link-speed 10g
```

NOTE: Beginning with Junos OS Release 16.1, you can also configure this feature with the AE interface address as the local address in a micro BFD session.

Beginning with Release 16.1R2, Junos OS checks and validates the configured micro BFD **local-address** against the interface or loopback IP address before the configuration commit. Junos OS performs this check on both IPv4 and IPv6 micro BFD address configurations, and if they do not match, the commit fails.

9. Configure tracing options for BFD for troubleshooting.

```
[edit protocols]
user@R0# set bfd traceoptions file bfd
user@R0# set bfd traceoptions file size 100m
user@R0# set bfd traceoptions file files 10
user@R0# set bfd traceoptions flag all
```

Results

From configuration mode, enter the **show interfaces**, **show protocols**, and **show routing-options** commands and confirm your configuration. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R0> show interfaces
traceoptions {
  flag bfd-events;
}
ge-1/0/1 {
  unit 0 {
    family inet {
      address 20.20.20.1/30;
    }
    family inet6 {
      address 3ffe::1:1/126;
    }
  }
}
xe-4/0/0 {
  enable;
  gigether-options {
    802.3ad ae0;
  }
}

            address 5555::1/126;
        }
    }
}
```

```
user@R0> show protocols
bfd {
    traceoptions {
        file bfd size 100m files 10;
        flag all;
    }
}
```

```
user@R0> show routing-options
nonstop-routing ;
    rib inet6.0 {
    static {
        route 3ffe:1:2/126 {
            next-hop 5555::2;
        }
    }
}
static {
    route 30.30.30.0/30 {
        next-hop 10.0.0.2;
    }
}
```

If you are done configuring the device, commit the configuration.

```
user@R0# commit
```

Verification

Confirm that the configuration is working properly.

- Verifying That the Independent BFD Sessions Are Up on page 193
- Viewing Detailed BFD Events on page 195

Verifying That the Independent BFD Sessions Are Up

Purpose Verify that the micro BFD sessions are up, and view details about the BFD sessions.

Action From operational mode, enter the **show bfd session extensive** command.

```
user@R0> show bfd session extensive
                                                  Detect   Transmit
Address                  State     Interface      Time     Interval  Multiplier
10.255.106.102                Up        xe-4/0/0       9.000     3.000        3

 Client LACPD, TX interval 0.100, RX interval 0.100
 Session up time 4d 23:13, previous down time 00:00:06
 Local diagnostic None, remote diagnostic None
 Remote heard, hears us, version 1
 Replicated
 Session type: Micro BFD
 Min async interval 0.100, min slow interval 1.000
 Adaptive async TX interval 0.100, RX interval 0.100
 Local min TX interval 0.100, minimum RX interval 0.100, multiplier 3
 Remote min TX interval 3.000, min RX interval 3.000, multiplier 3
 Local discriminator 21, remote discriminator 75
 Echo mode disabled/inactive
 Remote is control-plane independent
  Session ID: 0x0

                                                  Detect   Transmit
Address                  State     Interface      Time     Interval  Multiplier
10.255.106.102                Up        xe-4/0/1       9.000     3.000        3

 Client LACPD, TX interval 0.100, RX interval 0.100

                                                  Detect    Transmit
Address                  State     Interface      Time      Interval  Multiplier
201:DB8:251::bb:bb:1               UP        xe-4/1/0       9.000     3.000
      3
 Client LACPD, TX interval 0.100, RX interval 0.100
 Session up time 4d 23:13
 Local diagnostic None, remote diagnostic None
 Remote not heard, hears us, version 1
 Replicated
 Session type: Micro BFD
 Min async interval 0.100, min slow interval 1.000
 Adaptive async TX interval 0.100, RX interval 0.100
 Local min TX interval 1.000, minimum RX interval 0.100, multiplier 3
 Remote min TX interval 3.000, min RX interval 3.000, multiplier 3
 Local discriminator 16, remote discriminator 66
 Echo mode disabled/inactive, no-absorb, no-refresh
 Remote is control-plane independent
  Session ID: 0x0

4 sessions, 4 clients
Cumulative transmit rate 2.0 pps, cumulative receive rate 1.7 pps
```

Meaning The Micro BFD field represents the independent micro BFD sessions running on the links in a LAG. The TX interval *item*, RX interval *item* output represents the setting configured with the **minimum-interval** statement. All of the other output represents the default settings for BFD. To modify the default settings, include the optional statements under **bfd-liveness-detection** statement.

Viewing Detailed BFD Events

Purpose View the contents of the BFD trace file to assist in troubleshooting, if required.

Action From operational mode, enter the **file show /var/log/bfd** command.

```
user@R0> file show /var/log/bfd

Configuring Multicast Statistics Collection on Aggregated Ethernet Interfaces

T Series and TX Matrix routers support multicast statistics collection on aggregated Ethernet interfaces in both ingress and egress directions. The multicast statistics functionality can be configured on a physical interface thus enabling multicast accounting for all the logical interfaces below the physical interface.

The multicast statistics information is displayed only when the interface is configured with the **multicast-statistics** statement, which is not enabled by default.

Multicast statistics collection requires at least one logical interface is configured with family inet or inet6; otherwise, the commit for **multicast-statistics** will fail.

The multicast in/out statistics can be obtained via interfaces statistics query through CLI and via MIB objects through SNMP query.

To configure multicast statistics:

1. Include the **multicast-statistics** statement at the **[edit interfaces interface-name]** hierarchy level.

An example of a multicast statistics configuration for an aggregated Ethernet interface follows:

```
[edit interfaces]
ae0 {
  multicast-statistics;
}
```

To display multicast statistics, use the **show interfaces** ***interface-name*** **statistics detail** command.

Deleting an Aggregated Ethernet Interface

There are two approaches to deleting an aggregated Ethernet interface:

- You can delete an aggregated Ethernet interface from the interface configuration. The Junos OS removes the configuration statements related to **ae***x* and sets this interface to down state.
- You can also permanently remove the aggregated Ethernet interface from the device configuration by deleting it from the device-count on the routing device.

To delete an aggregated Ethernet interface:

1. Delete the aggregated Ethernet configuration.

   This step changes the interface state to down and removing the configuration statements related to **ae***x*.

   ```
   [edit]
   user@host# delete interfaces aex
   ```

2. Delete the interface from the device count.

   ```
   [edit]
   user@host# delete chassis aggregated-devices ethernet device-count
   ```

Configuring Distributed Periodic Packet Management

Periodic packet management (PPM) is responsible for processing a variety of time-sensitive periodic tasks so that other processes can more optimally direct their resources.

The responsibility for PPM processing on the switch is distributed between the Routing Engine and the access interfaces for all protocols that use PPM by default. This distributed model provides a faster response time for protocols that use PPM than the response time provided by the nondistributed model.

If distributed PPM is disabled, the PPM process runs on the Routing Engine only.

You can disable distributed PPM for all protocols that use PPM. You can also disable distributed PPM for Link Aggregation Control Protocol (LACP) packets only.

BEST PRACTICE: **We generally recommend that you disable distributed PPM only if Juniper Networks Customer Service advises you to do so. You should disable distributed PPM only if you have a compelling reason to disable it.**

This topic describes:

- Disabling or Enabling Distributed Periodic Packet Management Globally on page 198
- Disabling or Enabling Distributed Periodic Packet Management for LACP Packets on page 198

Disabling or Enabling Distributed Periodic Packet Management Globally

Distributed PPM is enabled by default. Disable distributed PPM if you need to move all PPM processing to the Routing Engine. Enable distributed PPM if it was previously disabled and you need to run distributed PPM.

To disable distributed PPM:

```
[edit routing-options]
user@switch# set ppm no-delegate-processing
```

To enable distributed PPM if it was previously disabled:

```
[edit routing-options]
user@switch# delete ppm no-delegate-processing
```

Disabling or Enabling Distributed Periodic Packet Management for LACP Packets

Distributed PPM is enabled by default. Disable distributed PPM for only LACP packets if you need to move all PPM processing for LACP packets to the Routing Engine.

To disable distributed PPM for LACP packets:

```
[edit protocols]
user@switch# set lacp ppm centralized
```

To enable distributed PPM for LACP packets if it was previously disabled:

```
[edit protocols]
user@switch# delete lacp ppm centralized
```

ITU-T Y.1731 ETH-LM, ETH-SLM, and ETH-DM on Aggregated Ethernet Interfaces Overview

Starting with Junos OS Relase 16.1R1, you can configure ITU-T Y.1731 standard-compliant Ethernet loss measurement (ETH-LM), Ethernet synthetic loss measurement (ETH-SLM), and Ethernet delay measurement (ETH- DM) capabilities on aggregated Ethernet (ae) interfaces. These ITU-T Y.1731 OAM services or performance monitoring techniques can be measured by on-demand mode (triggered through the CLI) or by proactive mode (triggered by the iterator application). These performance monitoring functionalities are supported on the following platforms:

- MX Series routers with 16-port 10-Gigabit Ethernet MPCs and Trio-based FPCs (MPCs), where the same level of support for the Ethernet services OAM mechanisms on non-aggregated Ethernet interfaces is available on AE interfaces
- MX2020 routers
- ETH-DM is supported on MPC3E and MPC4E modules with only software timestamping
- ETH-SLM is supported on MPC3E and MPC4E modules.

Also, connectivity fault management (CFM) sessions established on the AE interfaces can be distributed to the Packet Forwarding Engine, apart from being handled on the Routing engine. This capability to distribute CFM sessions is useful in both scaled topologies and gracful Routing Engine switchover (GRES) for CFM sessions.

Connectivity fault management (CFM) sessions operate in centralized mode over AE interfaces by default. Y.1731 performance monitoring (PM) is supported on centralized CFM sessions over AE interfaces. Also, distribution of CFM session over AE interfaces to line cards is supported from Junos OS Release 13.3. To enable the distribution of CFM sessions and to operate in centralized mode, include the **ppm delegate-processing** statement at the **[edit routing-options ppm]** hierarchy level. The mechanism that enables distribution of CFM sessions over AE interfaces provides the underlying infrastructure to support PM over AE interfaces. In addition, periodic packet management (PPM) handles time-sensitive periodic processing and performs such processes as sending process-specific packets and gathering statistics. With PPM processes running distributed on both the Routing Engine and the Packet Forwarding Engine, you can run performance monitoring processes on the Packet Forwarding Engine.

For Ethernet delay measurement, hardware-assisted timestamping is supported on AE interfaces, similar to the support that exists on non-AE interfaces. Only hardware-based timestamping is supported because it is performed in the received path of the protocol data unit (PDU) packets, whereas software-based timestamping needs to be performed on the transmitted path and is not supported. For software timestamping, ETH-DM PDUs need to be transmitted and received on the same line card (same member of the AE interface). All the received ETH-DM PDUs are always redirected to the anchor Packet Forwarding Engine. In the transmission path, if the interface on the anchor Packet Forwarding Engine goes down, then the OAM pdus are redirected to one of the subordinate or member FPCs. Therefore, the processing of ETH-DM PDUs always occurs at the CPU of the line card or module that hosts the anchor Packet Forwarding Engine. ETH-DM is supported on AE interfaces with CCC, bridge, virtual private LAN service (VPLS), and inet address families. ETH-DM is supported for both active-active and active-standby modes of AE interfaces. For one-way delay measurement (1DM), the system clocks of the initiator MEP that transmits a request frame and the responder MEP that receives a reply frame need to be synchronized.

For Ethernet loss measurement on AE interfaces, with the active-standby mode of the interfaces, transmission and reception of PDUs is always through the Packet Forwarding Engine that hosts the active link. For the active-standby mode of the AE interfaces, you can configure a maximum of only two member links. ETH-LM is supported only when all the active member or child links are on the same Packet Forwarding Engine. For the downstream maintenance endpoints (MEPs), ETH-LM is supported for CCC, VPLS, and bridge address families, and for upward MEPs, ETH-LM is supported only for CCC families. In the transmission path, with active-standby links of AE interfaces, whenever the active child link fails, if the standby link is non-local, the packets are redirected to the new active link. When this redirection occurs, the ETH-LM counters are reset. If the standby link is on same Packet Forwarding Engine as the active link, then the counters are not reset because the counters are read on the local Packet Forwarding Engine memory and to prevent the other end of the session to treat new Packet Forwarding Engine counters as losses owing to reset of the counters. In the received path, with active-standby links of AE interfaces, all the child links are programmed in the input list using next-hops to redirect the packets to the anchor FPC after copying the counters in the Packet Forwarding Engine. For Ethernet synthetic loss measurement (SLM), processing of SLM PDUs for requests and responses similar to other protocols from the line card CPU is implemented. All other computation and data are software-based. ETH-SLM is supported on AE interfaces for CCC, bridge, VPLS, and inet families.

NOTE: Starting with Junos OS Release 16.1, Ethernet loss measurement over an aggregated Ethernet (ae) interface is not supported when the enhanced LAG functionality is enabled on a router. The enhanced LAG capability is enabled by default when you configure enhanced IP services mode by including the **network-services enhanced-ip** statement at the **[edit chassis]** hierarchy level. For Ethernet loss measurement to work properly, you must disable the enhanced LAG functionality by entering the **set chassis aggregated-devices disable-lag-enhanced** statement. Also, CFM is not supported when enhanced LAG is enabled.

Starting with Junos OS Release 16.1, performance monitoring for connectivity fault management (by including the **performance-monitoring** statement and its substatements at the **[edit protocols oam ethernet connectivity-fault-management]** hierarchy level) is not supported when the network-to-network (NNI) or egress interface is an aggregated Ethernet interface with member links on DPCs.

Before you can start an ETH-DM, ETH-LM, or ETH-SLM measurement sessions across an aggregated Ethernet service, you must configure two MX Series routers to support these measurement sessions. On each router, configure two physical or logical AE interfaces connected by a VLAN by including the **interface ae-*fpc/pic/port* unit *logical-unit-number*** **vlan-id *vlan-id*** statement at the **[edit interfaces]** hierarchy level and on each router, attach the peer MEPs to the interfaces by including the **mep mep-id interface *interface-name* (protect | working)** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name*]** hierarchy level.

Release History Table

Release	Description
16.1R1	Starting with Junos OS Relase 16.1R1, you can configure ITU-T Y.1731 standard-compliant Ethernet loss measurement (ETH-LM), Ethernet synthetic loss measurement (ETH-SLM), and Ethernet delay measurement (ETH- DM) capabilities on aggregated Ethernet (ae) interfaces.
16.1	Starting with Junos OS Release 16.1, Ethernet loss measurement over an aggregated Ethernet (ae) interface is not supported when the enhanced LAG functionality is enabled on a router.
16.1	Starting with Junos OS Release 16.1, performance monitoring for connectivity fault management (by including the **performance-monitoring** statement and its substatements at the **[edit protocols oam ethernet connectivity-fault-management]** hierarchy level) is not supported when the network-to-network (NNI) or egress interface is an aggregated Ethernet interface with member links on DPCs.

Guidelines for Configuring Performance Monitoring Functionalities on Aggregated Ethernet Interfaces

Keep the following points in mind while you configure ETH-LM, ETH-SLM, and ETH-DM capabilities on aggregated Ethernet (ae-) interfaces:

- The scaling limits and performance considerations for distributed periodic packet management (PPM) sessions. The scaling limits for distributed PPM sessions over aggregated Ethernet (AE) interfaces are identical to the maximum supported numbers for continuity check messages (CCM) over AE interfaces.
- SLA iterators always coexist with CCM sessions. Therefore, while configuring a scaled environment, you must account for CCM sessions should be accounted along with SLA iterators. The following table describes the maximum number of distributed PM sessions you can configure for different CCM intervals per line card and per router (system-wide value).
- A mixed operation of distributed and centralized modes for performance monitoring (PM) sessions is not supported on AE interfaces, if the interfaces that form the aggregated Ethernet bundle are in mixed mode.
- The limitations for performance monitoring (PM) capabilities for non-AE interfaces apply equally well for AE interfaces. For example, flapping of sessions resets the PM statistics.

- The limitations that exist with distributed PPM sessions are valid for performance monitoring capabilities over AE interfaces because measurements are always performed on CCM sessions.
- For ETH-LM over AE interfaces in an active-standby setup, if active and standby line cards are swapped, then the measurements during this window are ignored.
- For ETH-DM over AE interfaces, the additional time that is taken for packet transmission (packets are redirected to anchor in the received [Rx] direction and to the active child FPC in the transmitted [Tx] direction) is computed in the delay measurement.
- For ETH-LM over AE interfaces, in an active-standby setup, whenever the link failover from the active interface to the standby interface happens, the counters are reset.

Targeted Distribution of Static Logical interfaces Across Aggregated Ethernet Member Links

This document provides an overview of targeted distribution of static logical interfaces across aggregated Ethernet member links, and an example for configuring targeted distribution.

- Targeted Distribution of Static Logical interfaces Across Aggregated Ethernet Member Links Overview on page 202
- Example: Configuring Targeted Distribution for Accurate Policy Enforcement on Logical Interfaces Across Aggregated Ethernet Member Links on page 203

Targeted Distribution of Static Logical interfaces Across Aggregated Ethernet Member Links Overview

Targeted distribution provides a mechanism to direct traffic through specified links for an aggregated Ethernet bundle, and also assigns roles to member links to handle link failure scenarios.

The targeted distribution of static logical interfaces is also used to accurately enforce egress class-of-service (CoS) profiles. Without this feature, the enforcement of egress class-of-service profiles is distributed among the individual member interface schedulers, shapers, or policers instantiated in each Packet Forwarding Engine that hosts a member link. In the absence of targeted distribution of aggregated Ethernet bundles, traffic destined through a logical interface of a bundle can exit through any of the members based on the hashing algorithm. As a result, it is not possible to determine which link is used to forward traffic. Distributed egress policy enforcement relies on traffic load balancing, which might not be accurate all the time. With targeted distribution, logical interface traffic is directed to a certain member link or a number of member links. Targeted distribution ensures an accurate policy enforcement that is no longer distributed for a given logical interface.

NOTE: Irrespective of the family configured for the logical interface, the targeted distribution feature is applicable to both Layer 3 and Layer 2 interfaces.

You can form distribution lists consisting of member links of the aggregated Ethernet bundle and you can assign roles to these lists, such as primary, backup, and standby. A distribution list specified as primary ensures that traffic is load-balanced among all the links in the primary list. If all links within the primary list are up, traffic is forwarded on those links. If some of the links within a primary list fail, the remaining links carry traffic. If all links within the primary list go down, only then the links in the backup list start carrying traffic. If some of links within the backup list fail, the remaining links in the backup list carry traffic. If all the links within the primary list and the backup list go down, only then the links in the standby list start carrying traffic. When the primary member links come back online, they continue to carry traffic.

You can configure distribution lists for primary links and backup links. The remaining links are added to a defined standby list. You can make changes to the distribution lists and their roles by configuring them again. When targeted distribution lists are deleted, all links carry traffic. When you commit the configuration, the member links are assigned the specified roles irrespective of whether the links are up or down.

NOTE: The feature is supported only on MX Series routers with MPCs, and with the **enhanced-ip** configuration enabled.

The outbound traffic of a Layer 3 host is distributed among all the member links of an aggregated Ethernet bundle. Targeted distribution is implemented only for the transit traffic.

Example: Configuring Targeted Distribution for Accurate Policy Enforcement on Logical Interfaces Across Aggregated Ethernet Member Links

This example shows how to configure targeted distribution lists for aggregated Ethernet member links as primary, or backup. Member links are assigned membership to the distribution lists. Logical interfaces of the aggregated Ethernet are then assigned membership to the primary list and the backup list.

- Requirements on page 203
- Overview on page 204
- Configuration on page 204
- Verification on page 207

Requirements

This example uses the following software and hardware components:

- Junos OS Release 16.1 and later releases

- One MX Series 3D Universal Edge Router

Overview

Targeted distribution provides a mechanism to direct traffic through specified links of an aggregated Ethernet bundle, and also assigns roles to member links to handle link failure scenarios.

You can configure targeted distribution to load-balance the traffic between the aggregated Ethernet bundle member links. You can map a logical interface to a single link only for the outgoing traffic.

This example uses the **apply-groups** configuration for specifying the distribution lists for the logical interfaces of the aggregated Ethernet member links. You can use the apply-groups statement to inherit the Junos OS configuration statements from a configuration group. The apply-groups configuration statement in the example shows the odd numbered member links of the aggregated Ethernet bundle being assigned the primary list dl2 and even numbered member links being assigned primary list dl1.

The aggregated Ethernet interface used in this example is ae10 with units 101, 102, 103, and 104. The Gigabit Ethernet interface, ge-0/0/3 is specified as distribution list dl1 and ge-0/0/4 as dl2. The logical interface unit numbers of the aggregated Ethernet bundle ending in an odd number are assigned to the distribution list *dl1* as the primary list, and those ending in an even number are assigned the distribution list *dl2* as the primary list.

To configure targeted distribution you must:

1. Create a global apply group.
2. Assign each member of the aggregated Ethernet interface to a different distribution list.
3. Attach the apply group to the aggregated Ethernet interface.
4. Create the logical interfaces. The apply group automatically assigns the distribution lists to each member of the aggregated Ethernet bundle as required.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, copy and paste the commands into the CLI at the **[edit]** hierarchy level, and then enter **commit** from configuration mode.

```
[edit groups GR-AE-ACCESS-DISTRIBUTION]
user@host# set interfaces <ae*> unit <*[1 3 5 7 9]> description “matched-odd”
  targeted-distribution primary-list dl2
user@host# set interfaces <ae*> unit <*[1 3 5 7 9]> description “matched-odd”
  targeted-distribution backup-list dl1
user@host# set interfaces <ae*> unit <*[0 2 4 6 8]> description “matched-even”
  targeted-distribution primary-list dl1
user@host# set interfaces <ae*> unit <*[0 2 4 6 8]> description “matched-even”
  targeted-distribution backup-list dl2
```

```
user@host# set interfaces ge-0/0/3 apply-groups-except INTF gigether-options 802.3ad
  ae10 distribution-list dl1
user@host# set interfaces ge-0/0/4 apply-groups-except INTF gigether-options 802.3ad
  ae10 distribution-list dl2
user@host# set interfaces <ae*> apply-groups GR-AE-ACCESS-DISTRIBUTION
user@host# set interfaces <ae*> flexible-vlan-tagging encapsulation
  flexible-ethernet-services unit 101 vlan-id 101 family inet address 10.1.0.1/16
user@host# set interfaces <ae*> flexible-vlan-tagging encapsulation
  flexible-ethernet-services unit 102 vlan-id 102 family inet address 10.2.0.1/16
user@host# set interfaces <ae*> flexible-vlan-tagging encapsulation
  flexible-ethernet-services unit 103 vlan-id 103 family inet address 10.3.0.1/16
user@host# set interfaces <ae*> flexible-vlan-tagging encapsulation
  flexible-ethernet-services unit 104 vlan-id 104 family inet address 10.4.0.1/16
```

To configure targeted distribution:

1. Create a global apply group and specify the primary list and the backup list.

```
[edit groups GR-AE-ACCESS-DISTRIBUTION]
user@host# set interfaces <ae*> unit <*[1 3 5 7 9]> description "matched-odd"
  targeted-distribution primary-list dl2
user@host# set interfaces <ae*> unit <*[1 3 5 7 9]> description "matched-odd"
  targeted-distribution backup-list dl1
user@host# set interfaces <ae*> unit <*[0 2 4 6 8]> description "matched-even"
  targeted-distribution primary-list dl1
user@host# set interfaces <ae*> unit <*[0 2 4 6 8]> description "matched-even"
  targeted-distribution backup-list dl2
```

2. Assign each member of the aggregated Ethernet bundle to a different distribution list.

```
[edit]
user@host# set interfaces ge-0/0/3 apply-groups-except INTF gigether-options
  802.3ad ae10 distribution-list dl1
[edit]
user@host# set interfaces ge-0/0/4 apply-groups-except INTF gigether-options
  802.3ad ae10 distribution-list dl2
```

3. Attach the defined apply group to the aggregated Ethernet interface.

```
[edit]
user@host# set interfaces ae10 apply-groups GR-AE-ACCESS-DISTRIBUTION
```

4. Create the logical interfaces and configure its provisions.

```
[edit]
user@host# set interfaces ae10 apply-groups GR-AE-ACCESS-DISTRIBUTION
user@host# set interfaces ae10 flexible-vlan-tagging encapsulation
  flexible-ethernet-services set unit 101 vlan-id 101 family inet address 10.1.0.1/16
user@host# set interfaces ae10 flexible-vlan-tagging encapsulation
  flexible-ethernet-services unit 102 vlan-id 102 family inet address 10.2.0.1/16
user@host# set interfaces ae10 flexible-vlan-tagging encapsulation
  flexible-ethernet-services unit 103 vlan-id 103 family inet address 10.3.0.1/16
user@host# set interfaces ae10 flexible-vlan-tagging encapsulation
  flexible-ethernet-services unit 104 vlan-id 104 family inet address 10.4.0.1/16
```

Results From configuration mode, confirm your configuration by using the **show** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
user@host# show groups GR-AE-ACCESS-DISTRIBUTION
interfaces {
  <ae*> {
    unit "<*[1 3 5 7 9]>" {
      description "matched odd";
      targeted-distribution {
        primary-list dl2;
        backup-list dl1;
      }
    }
    unit "<*[0 2 4 6 8]>" {
      description "matched even";
      targeted-distribution {
        primary-list dl1;
        backup-list dl2;
      }
    }
  }
}
```

```
user@host# show interfaces ge-0/0/3

unit 101 {
  vlan-id 101;
  family inet {
    address 10.1.0.1/16 {
    }
  }
}
unit 102 {
  vlan-id 102;
```

```
    family inet {
      address 10.2.0.1/16 {
      }
    }
  }
  unit 103 {
    vlan-id 103;
    family inet {
      address 10.3.0.1/16 {
      }
    }
  }
  unit 104 {
    vlan-id 104;
    family inet {
      address 10.4.0.1/16 {
      }
    }
  }
```

Verification

Verifying Targeted Distribution of Logical Interfaces

Purpose Verify that the logical interfaces are assigned to the distribution lists.

Action To verify that the logical interfaces are assigned to the distribution lists, enter the **show interfaces detail or extensive** command.

The **show interfaces detail or extensive** command output shows the logical interfaces ending in an odd number being assigned to the distribution list, *dl1* (**ge-0/0/3**) and those ending in an even number being assigned distribution list, *dl2* (**ge-0/0/4**) by default. If there is a failure of either of those interfaces, the logical interfaces switch to the interfaces in the backup list or continue to use the active member interface. For example, on the aggregated Ethernet bundle, **ae10.101**, the primary interface shown is **ge-0/0/4** and on the aggregated Ethernet bundle **ae10.102**, the primary interface is **ge-0/0/3** and similarly for the other logical interfaces.

```

CHAPTER 8

Configuring Ethernet Automatic Protection Switching for High Availability

Ethernet Automatic Protection Switching Overview

Ethernet automatic protection switching (APS) is a linear protection scheme designed to protect VLAN based Ethernet networks.

With Ethernet APS, a protected domain is configured with two paths, a working path and a protection path. Both working and protection paths can be monitored using an Operations Administration Management (OAM) protocol like Connectivity Fault Management (CFM). Normally, traffic is carried on the working path (that is, the working path is the active path), and the protection path is disabled. If the working path fails, its protection status is marked as degraded (DG) and APS switches the traffic to the protection path, then the protection path becomes the active path.

APS uses two modes of operation, linear 1+1 protection switching architecture and linear 1:1 protection switching architecture. The linear 1+1 protection switching architecture operates with either unidirectional or bidirectional switching. The linear 1:1 protection switching architecture operates with bidirectional switching.

In the linear 1+1 protection switching architecture, the normal traffic is copied and fed to both working and protection paths with a permanent bridge at the source of the protected domain. The traffic on the working and protection transport entities is transmitted simultaneously to the sink of the protected domain, where a selection between the working and protection transport entities is made.

In the linear 1:1 protection switching architecture, the normal traffic is transported on either the working path or on the protection path using a selector bridge at the source of the protection domain. The selector at the sink of the protected domain selects the entity that carries the normal traffic.

Unidirectional and Bidirectional Switching

Unidirectional switching utilizes fully independent selectors at each end of the protected domain. Bidirectional switching attempts to configure the two end points with the same bridge and selector settings, even for a unidirectional failure. Unidirectional switching can protect two unidirectional failures in opposite directions on different entities.

Selective and Merging Selectors

In the linear 1:1 protection switching architecture, where traffic is sent only on the active path, there are two different ways in which the egress direction (the direction out of the protected segment) data forwarding can act: selective selectors and merging selectors. A selective selector forwards only traffic that is received from both the paths regardless of which one is currently active. In other words, with a merging selector the selection of the currently active path only affects the ingress direction. Merging selectors minimize the traffic loss during a protection switch, but they do not guarantee the delivery of the data packets in order.

Revertive and Nonrevertive Switching

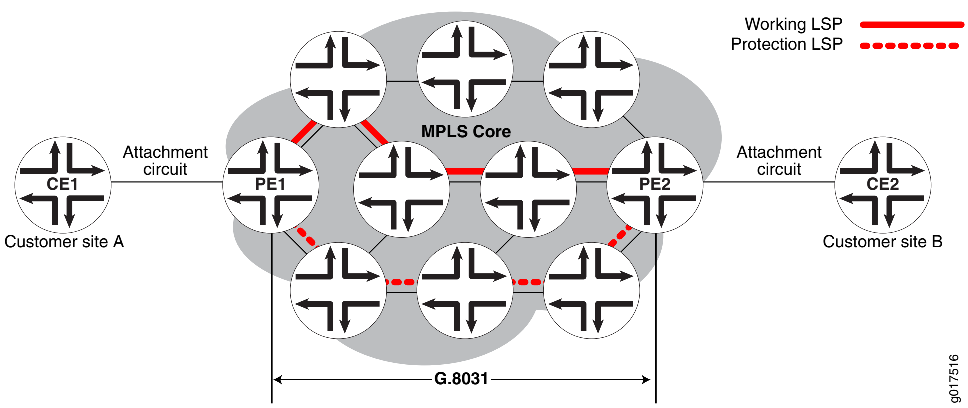
For revertive switching, traffic is restored to the working path after the conditions causing the switch have cleared.

For nonrevertive switching, traffic is allowed to remain on the protection path even after the conditions causing the switch have cleared.

NOTE: **The configuration on both the provider edge (PE) routers have to be either in revertive mode or non-revertive mode.**

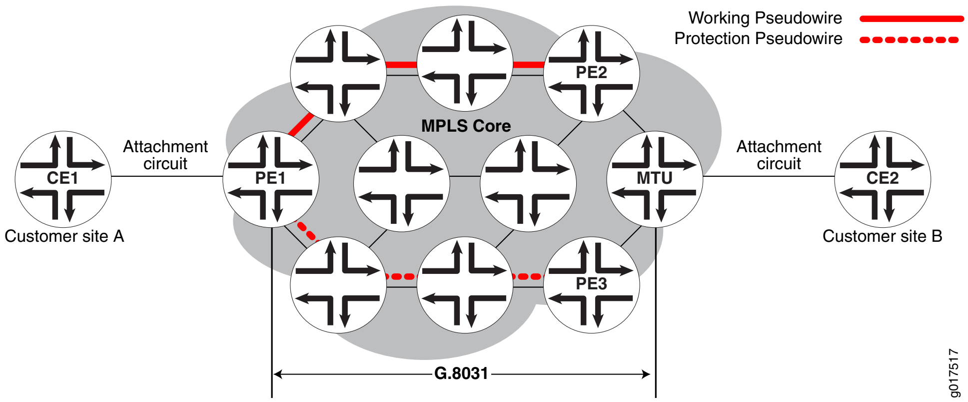
Protection Switching Between VPWS Pseudowires

Figure 11: Connections Terminating on Single PE



In the scenario diagramed in Figure 11 on page 214, a Virtual Private Wire Service (VPWS) is provisioned between customer sites A and B using a single pseudowire (layer 2 circuit) in the core network, and two Multiprotocol Label Switching (MPLS) Label Switched Paths (LSPs) are provisioned, one for the working path and the other one for the protection path. CFM CCM will be used to monitor the status of each LSP. Provider edge routers PE1 and PE2 run G.8031 Ethernet APS to select one of the LSPs as the active path. Once the active path is elected at the source end of the protection group, PE1 forwards to traffic from site A to the elected active path. At the sink end of the protection group, PE2 implements a merging selector, meaning it forwards the traffic coming from both the LSPs to the customer site B.

Figure 12: Connections Terminating on a Different PE



In the scenario represented in Figure 12 on page 215, a VPWS is provisioned between customer sites A and B using two pseudowires (layer 2 circuit) in the core network, one for the working path and the other for the protection path. CFM CCM will be used to monitor the status of each pseudowire.

Provider edge router PE1 and MTU run G.8031 Ethernet APS to select one of the pseudowires as the active path. Once the active path is elected at the source end of the protection group, PE1 forwards the traffic from site A to the elected active path. At the sink end of the protection group, MTU implements a merging selector, meaning it forwards the traffic coming from both the pseudowires to customer site B.

CLI Configuration Statements

```
[edit protocols protection-group]
ethernet-aps profile1{
   protocol g8031;
   revert-time seconds;
   hold-time 0-10000ms;
   local-request lockout;
}
```

revert-time- By default, protection logic restores the use of the working path once it recovers. The revert-time statement specifies how much time should elapse before the path for data should be switched from Protection to Working once recovery for Working has occurred. A revert-time of zero indicates no reversion. It will default to 300 sec (5 minutes) if not configured.

hold-time- Once a failure is detected, APS waits until this timer expires before initiating the protection switch. The range of the hold-time timer is 0 to 10,000 milliseconds. It will default to zero if not configured.

local-request- Configuring this value to lockout or force-switch will trigger lockout or force-switch operation on the protection groups using this profile.

Related Documentation

- Mapping of CCM Defects to APS Events on page 216
- Example: Configuring Protection Switching Between Psuedowires on page 217

Mapping of CCM Defects to APS Events

The continuity check message (CCM) engine marks the status of working and protected transport entities as either Down, Degraded, or Up.

Down—The monitored path is declared down if any of the following Multiple End Point (MEP) defects occur:

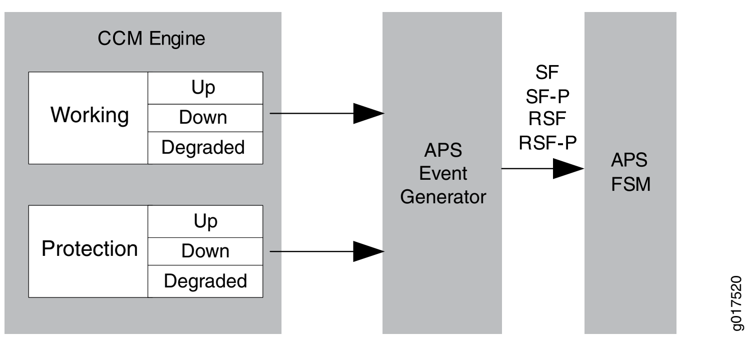
- Interface down
- CCM expiry
- RDI indicating signal failure

Degraded—The monitored path is declared degraded if any of the following MEP defects occur:

- FRR on
- FRR-ACK on

Up—The monitored path is declared up in the absence of any of the above events.

Figure 13: Understanding APS Events



As show in Figure 13 on page 216, the APS event generator generates the following APS events based on the status of the working and protection paths:

- **SF**—Signal failure on working path
- **RSF**—Working path recovers from signal failure
- **SF-P**—Signal failure on protection path
- **RSF-P**—Protection path recovers from signal failure

Example: Configuring Protection Switching Between Psuedowires

- Requirements on page 217
- Overview and Topology on page 217
- Configuration on page 217

Requirements

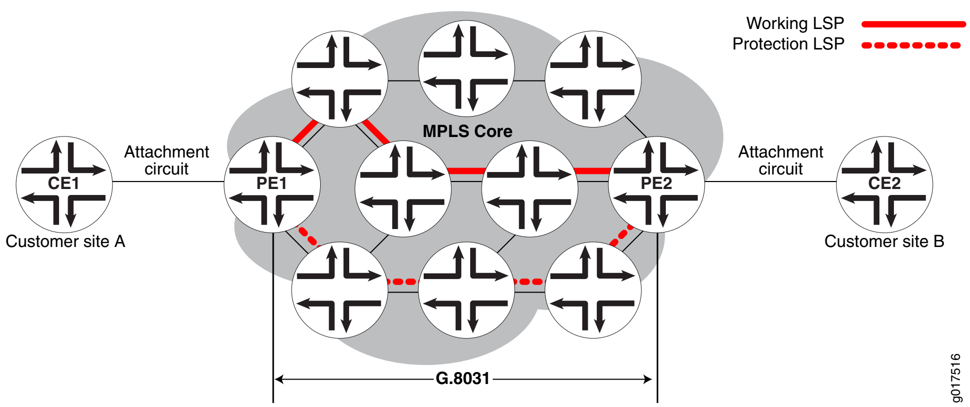
This example uses the following hardware and software components:

- Junos OS Release 11.2 or later
- 2 MX Series PE routers

Overview and Topology

The physical topology of the protection switching between psuedowires example is shown in Figure 14 on page 217.

Figure 14: Topology of a Network Using VPWS Psuedowires



The following definitions describe the meaning of the device abbreviations used in Figure 14 on page 217.

- Customer edge (CE) device—A device at the customer site that provides access to the service provider's VPN over a data link to one or more provider edge (PE) routers.
- Provider edge (PE) device—A device, or set of devices, at the edge of the provider network that presents the provider's view of the customer site.

Configuration

Step-by-Step Procedure

To configure protection switching between psuedowires, perform these tasks:

1. Configure automatic protection switching.

```
protocols {
  protection-group {
    ethernet-aps {
      profile-1 {
        protocol g8031;
        hold-time 1000s;
        revert-time 5m;
      }
    }
  }
```

2. Configure the connectivity fault management.

```
ethernet {
  oam {
    connectivity-fault-management {
      maintenance-domain md1 {
      level 5;
```

3. Configure the continuity check message for the working path.

```
maintenance-association W {
  protect maintenance-association P {
    aps-profile profile-1;
  }
  continuity-check {
    interval 1s;
  }
  mep 100 {
    interface ge-1/0/0.0 working;
    direction down;
    auto-discovery;
  }
}
```

4. Configure the continuity check message for the protection path.

```
maintenance-association P {
  continuity-check {
    interval 1s;
  }
  mep 100 {
    interface ge-1/0/0.0 protect;
    direction down;
    auto-discovery;
  }
}
```

Results Check the results of the configuration:

```
protocols {
  protection-group {
    ethernet-aps {
```

```
            profile-1 {
                protocol g8031;
                hold-time 1000s;
                revert-time 5m;
            }
        }
    }
    ethernet {
        oam {
            connectivity-fault-management {
                maintenance-domain md1 {
                    level 5;
                    maintenance-association W {
                        protect maintenance-association P {
                            aps-profile profile-1;
                        }
                        continuity-check {
                            interval 1s;
                        }
                        mep 100 {
                            interface ge-1/0/0.0 working;
                            direction down;
                            auto-discovery;
                        }
                    }
                    maintenance-association P {
                        continuity-check {
                            interval 1s;
                        }
                        mep 100 {
                            interface ge-1/0/0.0 protect;
                            direction down;
                            auto-discovery;
                        }
                    }
                }
            }
        }
    }
```

CHAPTER 9

Configuring Ethernet Ring Protection Switching for High Availability

Ethernet Ring Protection Switching Overview

Ethernet ring protection switching (ERPS) helps achieve high reliability and network stability. Links in the ring will never form loops that fatally affect the network operation and services availability. The basic idea of an Ethernet ring is to use one specific link to protect the whole ring. This special link is called a *ring protection link (RPL)*. If no failure happens in other links of the ring, the RPL blocks the traffic and is not used. The RPL is controlled by a special node called an *RPL owner*. There is only one RPL owner in a ring. The RPL owner is responsible for blocking traffic over the RPL. Under ring failure conditions, the RPL owner is responsible for unblocking traffic over the RPL. A ring failure results in protection switching of the RPL traffic. An automatic protection switching (APS) protocol is used to coordinate the protection actions over the ring. Protection switching blocks traffic on the failed link and unblocks the traffic on the RPL. When the failure clears, revertive protection switching blocks traffic over the RPL and unblocks traffic on the link on which the failure is cleared.

NOTE: ERPS on AE interfaces is not supported on ACX Series routers.

The following standards provide detailed information on Ethernet ring protection switching:

- ITU-T Recommendation G.8032/Y.1344 version 1 and 2, *Ethernet Ring protection switching*. G.8032v1 supports a single ring topology and G.8032v2 supports multiple rings and ladder topology.

  NOTE: EX2300 and EX3400 switches support G.8032v1 only.

- ITU-T Y.1731, *OAM functions and mechanisms for Ethernet-based networks*

For additional information on configuring Ethernet ring protection switching on EX Series switches, see *Example: Configuring Ethernet Ring Protection Switching on EX Series Switches*.

For additional information on configuring Ethernet ring protection switching on MX Series routers, see the *Layer 2 Configuration Guide* for a complete example of Ethernet rings and information about STP loop avoidance and prevention.

Understanding Ethernet Ring Protection Switching Functionality

Acronyms

The following acronyms are used in the discussion about Ethernet ring protection switching (ERPS):

- MA—Maintenance association
- MEP—Maintenance association end point
- OAM—Operations, administration, and management (Ethernet ring protection switching uses connectivity fault management daemon)
- FDB—MAC forwarding database
- STP—Spanning Tree Protocol
- RAPS—Ring automatic protection switching
- WTB—Wait to block. Note that WTB is always disabled on EX2300 and EX3400 switches because it is not supported in ERPSv1. Any configuration you make to the WTB setting on EX2300 and EX3400 switches has no effect. The output from the CLI command 'show protection-group ethernet-ring node-state detail' lists a WTB setting but that setting has no effect on EX2300 and EX4300 switches.
- WTR—Wait to restore. Note that on EX2300 and EX3400 switches only, the WTR configuration must be 5-12 minutes.
- RPL—Ring protection link

Ring Nodes

Multiple nodes are used to form a ring. There are two different node types:

- Normal node—The node has no special role on the ring.
- RPL owner node—The node owns the RPL and blocks or unblocks traffic over the RPL.

Ring Node States

The following are the different states for each node of a specific ring:

- init—Not a participant of a specific ring.
- idle—No failure on the ring; the node is performing normally. For a normal node, traffic is unblocked on both ring ports. For the RPL owner or RPL neighbor, traffic is blocked on the ring port that connects to the RPL and unblocked on the other ring port.
- protection—A failure occurred on the ring. For a normal node, traffic is blocked on the ring port that connects to the failing link and unblocked on working ring ports. For the RPL owner, traffic is unblocked on both ring ports if they connect to non-failure links.
- pending—The node is recovering from failure or its state after a **clear** command is used to remove the previous manual command. When a protection group is configured, the node enters the pending state. When a node is in pending state, the WTR or WTB timer will be running. All nodes are in pending state till WTR or WTB timer expiry.

- force switch—A force switch is issued. When a force switch is issued on a node in the ring all nodes in the ring will move into the force switch state.

NOTE: **EX2300 and EX3400 switches do not support force switch.**

- manual switch—A manual switch is issued. When a manual switch is issued on a node in the ring all nodes in the ring will move into the manual switch state.

NOTE: **EX2300 and EX3400 switches do not support manual switch.**

There can be only one RPL owner for each ring. The user configuration must guarantee this, because the APS protocol cannot check this.

Default Logging of Basic State Transitions on EX Series Switches

Starting with Junos OS Release 14.1X53-D15, EX Series switches automatically log basic state transitions for the ERPS protocol. Starting with Junos OS Release 18.2R1, EX2300 and EX3400 switches automatically log basic state transitions for the ERPS protocol. No configuration is required to initiate this logging. Basic state transitions include ERPS interface transitions from up to down, and down to up; and ERPS state transitions from idle to protection, and protection to idle.

The basic state transitions are logged in a single file named **erp-default**, which resides in the **/var/log** directory of the switch. The maximum size of this file is 15 MB.

Default logging for ERPS can capture initial ERPS interface and state transitions, which can help you troubleshoot issues that occur early in the ERPS protocol startup process. However, if more robust logging is needed, you can enable traceoptions for ERPS by entering the **traceoptions** statement in the **[edit protocols protection-group]** hierarchy.

Be aware that for ERPS, only default logging or traceoptions can be active at a time on the switch. That is, default logging for ERPS is automatically enabled and if you enable traceoptions for ERPS, the switch automatically disables default logging. Conversely, if you disable traceoptions for ERPS, the switch automatically enables default logging.

Logical Ring

You can define multiple logical-ring instances on the same physical ring. The logical ring feature currently supports only the physical ring, which means that two adjacent nodes of a ring must be physically connected and the ring must operate on the physical interface, not the VLAN. Multiple ring instances are usually defined with trunk mode ring interfaces.

FDB Flush

When ring protection switching occurs, normally an *FDB flush* is executed. The Ethernet ring control module uses the same mechanism as the STP to trigger the FDB flush. The Ethernet ring control module controls the ring port physical interface's default STP index to execute the FDB flush.

NOTE: Optimized flushing is not supported on EX2300 and EX3400 switches.

Starting with Junos OS Release 14.2, the FDB flush depends on the RAPS messages received on the both the ports of the ring node.

Traffic Blocking and Forwarding

Ethernet ring control uses the same mechanism as the STP to control forwarding or discarding of user traffic. The Ethernet ring control module sets the ring port physical interface default STP index state to forwarding or discarding in order to control user traffic.

RPL Neighbor Node

Starting with Junos OS Release 14.2, ring protection link neighbor nodes are supported. An RPL neighbor node is adjacent to the RPL and is not the RPL owner. If a node is configured with one interface as the protection-link-end and no protection-link-owner is present in its configuration, the node is an RPL neighbor node.

NOTE: RPL neighbor node is not supported on EX2300 and EX3400 switches.

RAPS Message Blocking and Forwarding

The router or switch treats the ring automatic protection switching (RAPS) message the same as it treats user traffic for forwarding RAPS messages between two ring ports. The ring port physical interface default STP index state also controls forwarding RAPS messages between the two ring ports. Other than forwarding RAPS messages between the two ring ports, as shown in Figure 15 on page 225, the system also needs to forward the RAPS message between the CPU (Ethernet ring control module) and the ring port. This type of forwarding does not depend on the ring port physical interfaces' STP index state. The RAPS message is always sent by the router or switch through the ring ports, as shown in Figure 16 on page 225. A RAPS message received from a discarding ring port is sent to the Ethernet ring control module, but is not sent to the other ring port.

Figure 15: Protocol Packets from the Network to the Router

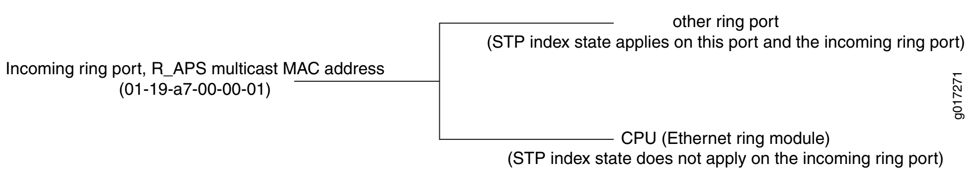

Figure 16: Protocol Packets from the Router or Switch to the Network

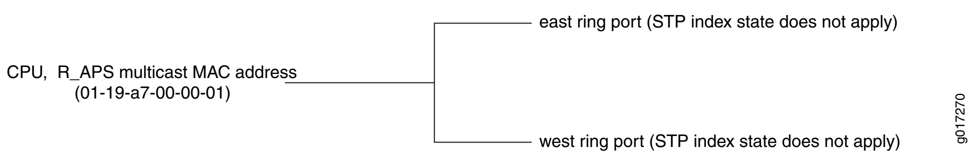

Juniper Networks switches and Juniper Networks routers use different methods to achieve these routes.

The switches use forwarding database entries to direct the RAPS messages. The forwarding database entry (keyed by the RAPS multicast address and VLAN) has a composite next hop associated with it—the composite next hop associates the two ring interfaces with the forwarding database entry and uses the split horizon feature to prevent sending the packet out on the interface that it is received on. This is an example of the forwarding database entry relating to the RAPS multicast MAC (a result of the **show ethernet-switching table detail** command):

```
VLAN: v1, Tag: 101, MAC: 01:19:a7:00:00:01, Interface: ERP
Interfaces:                  ge-0/0/9.0, ge-0/0/3.0
Type: Static
Action: Mirror
Nexthop index: 1333
```

The routers use an implicit filter to achieve ERP routes. Each implicit filter binds to a bridge domain. Therefore, the east ring port control channel and the west ring port control channel of a particular ring instance must be configured to the same bridge domain. For each ring port control channel, a filter term is generated to control RAPS message forwarding. The filter number is the same as the number of bridge domains that contain the ring control channels. If a bridge domain contains control channels from multiple rings, the filter related to this bridge domain will have multiple terms and each term will relate to a control channel. The filter has command parts and control-channel related parts, as follows:

- Common terms:
  - ```
    term 1: if [Ethernet type is not OAM Ethernet type (0x8902)
    ]               { accept packet }
    ```
  - ```
    term 2: if [source MAC address belongs to this bridge]
                 { drop packet, our packet loop through the ring and come back
                     to home}
    ```
  - ```
    term 3: if [destination is the RAPS PDU multicast address(0x01,0x19,0xa7,
                      0x00,0x00,0x01] AND[ring port STP status is DISCARDING]
                  { send to CPU }
    ```
- Control channel related terms:
  - ```
          if [destination is the RAPS PDU multicast
    address(0x01,0x19,0xa7,0x00,0x00,
             0x01] AND[ring port STP status is FORWARDING] AND [Incoming
    interface
              IFL equal to control channel IFL]
             { send packet to CPU and send to the other ring port }
          default term: accept packet.
    ```

Dedicated Signaling Control Channel

For each ring port, a dedicated signaling control channel with a dedicated VLAN ID must be configured. In Ethernet ring configuration, only this control logical interface is configured and the underlying physical interface is the physical ring port. Each ring requires that two control physical interfaces be configured. These two logical interfaces must be configured in a bridge domain for routers (or the same VLAN for switches) in order to forward RAPS protocol data units (PDUs) between the two ring control physical interfaces. If the router control channel logical interface is not a trunk port, only control logical interfaces will be configured in ring port configuration. If this router control channel logical interface is a trunk port, in addition to the control channel logical interfaces, a dedicated VLAN ID must be configured for routers. For switches, always specify either a VLAN name or VLAN ID for all links.

RAPS Message Termination

The RAPS message starts from the originating node, travels through the entire ring, and terminates in the originating node unless a failure is present in the ring. The originating node must drop the RAPS message if the source MAC address in the RAPS message belongs to itself. The source MAC address is the node's node ID.

Revertive and Non-revertive Modes

In revertive operation, once the condition causing a switch has cleared, traffic is blocked on the RPL and restored to the working transport entity. In nonrevertive operation, traffic is allowed to use the RPL if it has not failed, even after a switch condition has cleared.

NOTE: Non-revertive mode is not supported on EX2300 and EX3400 switches.

Multiple Rings

The Ethernet ring control module supports multiple rings in each node (two logical interfaces are part of each ring). The ring control module also supports the interconnection of multiple rings. Interconnection of two rings means that two rings might share the same link or share the same node. Ring interconnection is supported only using non-virtual-channel mode. Ring interconnection using virtual channel mode is not supported.

NOTE: Interconnection of multiple rings is not supported on EX2300 and EX3400 switches.

Node ID

For each node in the ring, a unique *node ID* identifies each node. The node ID is the node's MAC address.

For routers only, you can configure this node ID when configuring the ring on the node or automatically select an ID like STP does. In most cases, you will not configure this and the router will select a node ID, like STP does. It should be the manufacturing MAC address. The ring node ID should not be changed, even if you change the manufacturing MAC address. Any MAC address can be used if you make sure each node in the ring has a different node ID. The node ID on switches is selected automatically and is not configurable.

Ring ID

The ring ID is used to determine the value of the last octet of the MAC destination address field of the RAPS protocol data units (PDUs) generated by the ERP control process. The ring ID is also used to discard any RAPS PDU, received by this ERP control process with a non-matching ring ID. Ring ID values 1 through 239 are supported.

Bridge Domains with the Ring Port (MX Series Routers Only)

On the routers, the protection group is seen as an abstract logical port that can be configured to any bridge domain. Therefore, if you configure one ring port or its logical interface in a bridge domain, you must configure the other related ring port or its logical interface to the same bridge domain. The bridge domain that includes the ring port acts as any other bridge domain and supports the IRB Layer 3 interface.

Wait-to-Block Timer

The RPL owner node uses a delay timer before initiating an RPL block in revertive mode of operation or before reverting to IDLE state after clearing manual commands. The Wait-to-Block (WTB) timer is used when clearing **force switch** and **manual switch** commands. As multiple **force switch** commands are allowed to coexist in an Ethernet ring, the WTB timer ensures that clearing of a single **force switch** command does not trigger the re-blocking of the RPL. When clearing a **manual switch** command, the WTB timer prevents the formation of a closed loop due to a possible timing anomaly where the RPL Owner Node receives an outdated remote **manual switch** request during the recovery process.

When recovering from a **manual switch** command, the delay timer must be long enough to receive any latent remote **force switch**, signal failure, or **manual switch** commands. This delay timer is called the WTB timer and is defined to be 5 seconds longer than the guard timer. This delay timer is activated on the RPL Owner Node. When the WTB timer expires, the RPL Owner Node initiates the reversion process by transmitting an RAPS (NR, RB) message. The WTB timer is deactivated when any higher-priority request preempts it.

NOTE: The Wait To Block Timer (WTB) is always disabled on EX2300 and EX3400 switches because it is not supported in ERPSv1. Any configuration you make to the WTB setting has no effect. The output from the CLI command 'show protection-group ethernet-ring node-state detail' lists a WTB setting but that setting has no effect.

Adding and Removing a Node

Starting with Junos OS Release 14.2, you can add or remove a node between two nodes in an Ethernet ring. Nodes are added or removed using the **force switch** command.

NOTE: EX2300 and EX3400 switches do not support force switch.

Release History Table

Release	Description
18.2R1	Starting with Junos OS Release 18.2R1, EX2300 and EX3400 switches automatically log basic state transitions for the ERPS protocol.
14.2	Starting with Junos OS Release 14.2, the FDB flush depends on the RAPS messages received on the both the ports of the ring node.
14.2	Starting with Junos OS Release 14.2, ring protection link neighbor nodes are supported.
14.2	Starting with Junos OS Release 14.2, you can add or remove a node between two nodes in an Ethernet ring.
14.1X53-D15	Starting with Junos OS Release 14.1X53-D15, EX Series switches automatically log basic state transitions for the ERPS protocol.

Configuring Ethernet Ring Protection Switching

The inheritance model follows:

```
protection-group {
  ethernet-ring ring-name (
    node-id mac-address;
    ring-protection-link-owner;
    east-interface {
      control-channel channel-name {
      ring-protection-link-end;
    }
    west-interface {
      node-id mac-address;
      control-channel channel-name {
      ring-protection-link-end;
    }
    data-channel {
      vlan number;
    }
    guard-interval number;
    restore-interval number;
  }
}
```

For each ring, a protection group must be configured. There may be several rings in each node, so there should be multiple protection groups corresponding to the related Ethernet rings.

Three interval parameters (**restore-interval**, **guard-interval**, and **hold-interval**) can be configured at the protection group level. These configurations are global configurations and apply to all Ethernet rings if the Ethernet ring doesn't have a more specific configuration for these values. If no parameter is configured at the protection group level, the global configuration of this parameter uses the default value.

Example: Ethernet Ring Protection Switching Configuration on MX Routers

This example describes how to configure Ethernet ring protection switching on an MX Series router:

Requirements

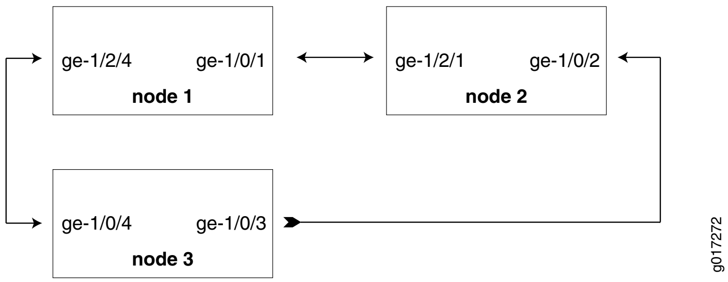
This example uses the following hardware and software components:

- Router node 1 running Junos OS with two Gigabit Ethernet interfaces.
- Router node 2 running Junos OS with two Gigabit Ethernet interfaces.
- Router node 3 running Junos OS with two Gigabit Ethernet interfaces.

Ethernet Ring Overview and Topology

This section describes a configuration example for a three-node ring. The ring topology is shown in Figure 17 on page 231.

Figure 17: Example of a Three-Node Ring Topology



The configuration in this section is only for the RAPS channel. The bridge domain for user traffic is the same as the normal bridge domain. The only exception is if a bridge domain includes a ring port, then it must also include the other ring port of the same ring.

Configuring a Three-Node Ring

To configure Ethernet Ring Protection Switching on a three-node ring, perform these tasks:

- Configuring Ethernet Ring Protection Switching on a Three-Node Ring on page 231

Configuring Ethernet Ring Protection Switching on a Three-Node Ring

Step-by-Step Procedure

1. **Configuring Node 1**

```
interfaces {
     ge-1/0/1 {
          vlan-tagging;
          encapsulation flexible-ethernet-services;
          unit 1 {
               encapsulation vlan-bridge;
               vlan-id 100;
          }
     }
     ge-1/2/4 {
          vlan-tagging;
          encapsulation flexible-ethernet-services;
          unit 1 {
               encapsulation vlan-bridge;
               vlan-id 100;
               }
          }
     }
     bridge-domains {
          bd1 {
               domain-type bridge;
               interface ge-1/2/4.1;
               interface ge-1/0/1.1;
               }
          }
     protocols {
          protection-group {
               ethernet-ring pg101 {
                    node-id 00:01:01:00:00:01;
                    ring-protection-link-owner;
                    east-interface {
                         control-channel ge-1/0/1.1;
```

```
                    ring-protection-link-end;
                    }
                west-interface {
                    control-channel ge-1/2/4.1;
                    }
                }
            }
        }
    protocols {
        oam {
            ethernet {
                connectivity-fault-management {
                    action-profile rmep-defaults {
                        default-action {
                            interface-down;
                            }
                        }
                    maintenance-domain d1 {
                        level 0;
                        maintenance-association 100 {
                            mep 1 {
                                interface ge-1/0/1;
                                remote-mep 2 {
                                   action-profile rmep-defaults;

                                    }
                                }
                            }
                        }
                    maintenance-domain d2 {
                        level 0;
                        maintenance-association 100 {
                            mep 1 {
                                interface ge-1/2/4;
                                remote-mep 2 {
                                   action-profile rmep-defaults;

                                    }
                                }
                            }
                        }
                    }
                }
            }
        }
    }
```

2. **Configuring Node 2**

```
interfaces {
    ge-1/0/2 {
        vlan-tagging;
        encapsulation flexible-ethernet-services;
        unit 1 {
             encapsulation vlan-bridge;
             vlan-id 100;
        }
    }

    ge-1/2/1 {
        vlan-tagging;
```

```
        encapsulation flexible-ethernet-services;
        unit 1 {
            encapsulation vlan-bridge;
            vlan-id 100;
        }
    }
}

bridge-domains {
    bd1 {
        domain-type bridge;
        interface ge-1/2/1.1;
        interface ge-1/0/2.1;
    }
}

protocols {
    protection-group {
        ethernet-ring pg102 {
            east-interface {
                control-channel ge-1/0/2.1;
            }
            west-interface {
                control-channel ge-1/2/1.1;
            }
        }
    }
}

protocols {
    oam {
        ethernet {
            connectivity-fault-management {
                action-profile rmep-defaults {
                    default-action {
                        interface-down;
                    }
                }
                maintenance-domain d1 {
                    level 0;
                    maintenance-association 100 {
                        mep 2 {
                            interface ge-1/2/1;
                            remote-mep 1 {
                                action-profile rmep-defaults;
                            }
                        }
                    }
                }
                maintenance-domain d3 {
                    level 0;
                    maintenance-association 100 {
                        mep 1 {
                            interface ge-1/0/2;
                            remote-mep 2 {
                                action-profile rmep-defaults;
                            }
                        }
                    }
```

```
                }
            }
        }
    }
}
```

3. **Configuring Node 3**

```
interfaces {
    ge-1/0/4 {
        vlan-tagging;

                            }
                        }
                    }
                }
            }
        }
    }
```

Examples: Ethernet RPS Output

This section provides output examples based on the configuration shown in "Example: Ethernet Ring Protection Switching Configuration on MX Routers" on page 230. The show commands used in these examples can help verify configuration and correct operation.

Normal Situation—RPL Owner Node

If the ring has no failure, the **show** command will have the following output for Node 1:

```
user@node1> show protection-group ethernet-ring aps

Ethernet Ring Name  Request/state  No Flush  Ring Protection Link Blocked
pg101               NR             No        Yes

Originator  Remote Node ID
Yes

user@node1> show protection-group ethernet-ring interface
Ethernet ring port parameters for protection group pg101

Interface    Control Channel  Forward State  Ring Protection Link End
ge-1/0/1     ge-1/0/1.1       discarding     Yes
ge-1/2/4     ge-1/2/4.1       forwarding     No

Signal Failure  Admin State
Clear          IFF ready
Clear          IFF ready

user@node1> show protection-group ethernet-ring node-state
Ethernet ring    APS State    Event         Ring Protection Link Owner
pg101            idle         NR-RB         Yes

Restore Timer  Quard Timer  Operation state
disabled       disabled    operational
```

```
user@node1> show protection-group ethernet-ring statistics group-name pg101
Ethernet Ring statistics for PG pg101
RAPS sent                          : 1
RAPS received                      : 0
Local SF happened:                 : 0
Remote SF happened:                : 0
NR event happened:                 : 0
NR-RB event happened:              : 1
```

Normal Situation—Other Nodes

For Node 2 and Node 3, the outputs should be the same:

```
user@node2> show protection-group ethernet-ring aps
Ethernet Ring Name  Request/state  No Flush  Ring Protection Link Blocked
pg102               NR             No        Yes

Originator  Remote Node ID
No          00:01:01:00:00:01
```

```
user@node2> show protection-group ethernet-ring interface
Ethernet ring port parameters for protection group pg102

Interface    Control Channel  Forward State  Ring Protection Link End
ge-1/2/1     ge-1/2/1.1       forwarding     No
ge-1/0/2     ge-1/0/2.1       forwarding     No

Signal Failure  Admin State
Clear          IFF ready
Clear          IFF ready
```

```
user@node2> show protection-group ethernet-ring node-state
Ethernet ring    APS State    Event         Ring Protection Link Owner
pg102            idle         NR-RB         No

Restore Timer  Quard Timer  Operation state
disabled       disabled    operational
```

```
user@node2> show protection-group ethernet-ring statistics group-name pg102
Ethernet Ring statistics for PG pg101
RAPS sent                          : 0
RAPS received                      : 1
Local SF happened:                 : 0
Remote SF happened:                : 0
NR event happened:                 : 0
NR-RB event happened:              : 1
```

Failure Situation—RPL Owner Node

If the ring has a link failure between Node 2 and Node 3, the **show** command will have the following outputs for Node 1:

```
user@node1> show protection-group ethernet-ring aps
Ethernet Ring Name  Request/state  No Flush  Ring Protection Link Blocked
pg101               SF             NO        No

Originator  Remote Node ID
No          00:01:02:00:00:01
```

```
user@node1> show protection-group ethernet-ring interface
```

```
Ethernet ring port parameters for protection group pg101

Interface    Control Channel  Forward State  Ring Protection Link End
ge-1/0/1     ge-1/0/1.1       forwarding     Yes
ge-1/2/4     ge-1/2/4.1       forwarding     No

Signal Failure  Admin State
Clear           IFF ready
Clear           IFF ready
```

```
user@node1> show protection-group ethernet-ring node-state
Ethernet ring    APS State    Event         Ring Protection Link Owner
pg101            protected    SF            Yes

Restore Timer  Quard Timer  Operation state
disabled       disabled     operational
```

```
user@node1> show protection-group ethernet-ring statistics group-name pg101
Ethernet Ring statistics for PG pg101
RAPS sent                        : 1
RAPS received                    : 1
Local SF happened:               : 0
Remote SF happened:              : 1
NR event happened:               : 0
NR-RB event happened:            : 1
```

Failure Situation—Other Nodes

For Node 2 and Node 3, the outputs should be the same:

```
user@node2> show protection-group ethernet-ring aps
Ethernet Ring Name  Request/state  No Flush  Ring Protection Link Blocked
pg102               SF             No        No

Originator  Remote Node ID

CHAPTER 10

Configuring MAC Address Validation on Static Ethernet Interfaces

MAC Address Validation on Static Ethernet Interfaces Overview

MAC address validation enables the router to validate that received packets contain a trusted IP source and an Ethernet MAC source address.

MAC address validation is supported on AE, Fast Ethernet, Gigabit Ethernet, and 10–Gigabit Ethernet interfaces (with or without VLAN tagging) on MX Series routers only.

There are two types of MAC address validation that you can configure:

- Loose—Forwards packets when both the IP source address and the MAC source address match one of the trusted address tuples.

  Drops packets when the IP source address matches one of the trusted tuples, but the MAC address does not support the MAC address of the tuple

  Continues to forward packets when the source address of the incoming packet does not match any of the trusted IP addresses.

- Strict—Forwards packets when both the IP source address and the MAC source address match one of the trusted address tuples.

  Drops packets when the MAC address does not match the tuple's MAC source address, or when IP source address of the incoming packet does not match any of the trusted IP addresses.

Configuring MAC Address Validation on Static Ethernet Interfaces

MAC address validation enables the router to validate that received packets contain a trusted IP source and an Ethernet MAC source address. MAC address validation is supported on AE, Fast Ethernet, Gigabit Ethernet, and 10–Gigabit Ethernet interfaces (with or without VLAN tagging) on MX Series routers only.

To configure MAC address validation on static Ethernet Interfaces:

1. In the configuration mode, at the [**edit**] hierarchy level, configure the static Ethernet interface.

   [edit]
   user@host# edit interfaces *interface-name*

2. Configure the protocol family and the logical unit of the interface at the [**edit interfaces *interface-name***] hierarchy level. While configuring the protocol family, specify **inet** as the protocol family.

   [edit interfaces *interface-name*]
   user@host# edit unit *logical-unit-number* family inet

3. Configure MAC address validation on the static Ethernet Interface. You can specify the type of MAC address validation you require. Possible values are: Strict and Loose. You can also specify the interface address.

   [edit interfaces *interface-name*] unit *logical-unit-number* family inet
   user@host# set mac-validate *option* address *address*

4. Configure the static ARP entry by specifying the IP address and the MAC address that are to be mapped. The IP address specified must be part of the subnet defined in the enclosing **address** statement. The MAC address must be specified as hexadecimal bytes in the following formats: ***nnnn.nnnn.nnnn*** or ***nn:nn:nn:nn:nn:nn*** format. For instance, you can use either **0011.2233.4455** or **00:11:22:33:44:55**.

   [edit interfaces *interface-name* unit *logical-unit-number* family inet address
     interface-address
   user@host# set arp *ip-address* mac *mac-address*

Disabling MAC Address Learning of Neighbors Through ARP or Neighbor Discovery for IPv4 and IPv6 Neighbors

The Junos OS provides the **no-neighbor-learn** configuration statement at the **[edit interfaces *interface-name* unit *interface-unit-number* family inet]** and **[edit interfaces *interface-name* unit *interface-unit-number* family inet6]** hierarchy levels.

To disable ARP address learning by not sending arp-requests and not learning from ARP replies for IPv4 neigbors, include the **no-neighbor-learn** statement at the **[edit interfaces *interface-name* unit *interface-unit-number* family inet**] hierarchy level:

```
[edit interfaces interface-name unit interface-unit-number family inet]
no-neighbor-learn;
```

To disable neighbor discovery for IPv6 neighbors, include the **no-neighbor-learn** statement at the **[edit interfaces *interface-name* unit *logical-unit-number* family inet6]** hierarchy level:

```
[edit interfaces interface-name unit interface-unit-number family inet6]
no-neighbor-learn;
```

CHAPTER 11

Configuring 802.1Q VLANs

802.1Q VLANs Overview

For Ethernet, Fast Ethernet, Tri-Rate Ethernet copper, Gigabit Ethernet, 10-Gigabit Ethernet, and aggregated Ethernet interfaces supporting VPLS, the Junos OS supports a subset of the IEEE 802.1Q standard for channelizing an Ethernet interface into multiple logical interfaces, allowing many hosts to be connected to the same Gigabit Ethernet switch, but preventing them from being in the same routing or bridging domain.

802.1Q VLAN IDs and Ethernet Interface Types

You can partition the router into up to 4095 different VLANs—depending on the router model and the physical interface types—by associating logical interfaces with specific VLAN IDs.

VLAN ID 0 is reserved for tagging the priority of frames. VLAN IDs 1 through 511 are reserved for normal VLANs. VLAN IDs 512 and above are reserved for VLAN circuit cross-connect (CCCs).

For Gigabit Ethernet IQ interfaces and Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), you can configure flexible Ethernet services encapsulation on the physical interface. With flexible Ethernet services encapsulation, VLAN IDs from 1 through 511 are no longer reserved for normal VLANs.

The maximum number of user-configurable VLANs is 15 on each port of the Dense-FE PIC (8-port/12-port/48-port).

Table 14 on page 245 lists VLAN ID range by interface type.

Table 14: VLAN ID Range by Interface Type

Interface Type	VLAN ID Range
Aggregated Ethernet for Fast Ethernet	1 through 1023
Aggregate Ethernet for Gigabit Ethernet	1 through 4094
4-port, 8-port, and 12-port Fast Ethernet	1 through 1023
48-port Fast Ethernet	1 through 4094
Tri-Rate Ethernet copper	1 through 4094
Gigabit Ethernet	1 through 4094
Gigabit Ethernet IQ	1 through 4094
10-Gigabit Ethernet	1 through 4094
100-Gigabit Ethernet	1 through 4094
Management and internal Ethernet interfaces	1 through 1023

NOTE: For Gigabit Ethernet IQ and Gigabit Ethernet PICs with SFPs (except the built-in Gigabit Ethernet port on the M7i router), VLAN IDs on a single interface can differ from each other.

Because IS-IS has an 8-bit limit for broadcast multiaccess media, you cannot set up more than 255 adjacencies over Gigabit Ethernet using VLAN tagging. For more information, see the *Junos OS Routing Protocols Library*.

Configuring Dynamic 802.1Q VLANs

You can configure the router to dynamically create VLANs when a client accesses an interface and requests a VLAN ID that does not yet exist. When a client accesses a VLAN interface, the router instantiates a VLAN dynamic profile that you have associated with the interface. Using the settings in the dynamic profile, the router extracts information about the client from the incoming packet (for example, the interface and unit values), saves this information in the routing table, and creates a VLAN or stacked VLAN ID for the client from a range of VLAN IDs that you configure for the interface.

Dynamically configuring VLANs or stacked VLANs requires the following general steps:

1. Configure a dynamic profile for dynamic VLAN or dynamic stacked VLAN creation.
2. Associate the VLAN or stacked VLAN dynamic profile with the interface.
3. Specify the Ethernet packet type that the VLAN dynamic profile accepts.
4. Define VLAN ranges for use by the dynamic profile when creating VLAN IDs.

For procedures on how to configure dynamic VLANs and dynamic stacked VLANs for client access, see the *Junos OS Broadband Subscriber Management and Services Library*.

Related Documentation

- *Ethernet Interfaces Feature Guide for Routing Devices*

Enabling VLAN Tagging

You can configure the router to receive and forward single-tag frames, dual-tag frames, or a mixture of single-tag and dual-tag frames.

NOTE: **If you configure VLAN tagging on Gigabit Ethernet IQ, IQ2, and IQ2-E interfaces on M320, M120, and T Series routers, Junos OS creates an internal logical interface that reserves 50 Kbps of bandwidth from Gigabit Ethernet IQ interfaces and 2 Mbps of bandwidth from Gigabit Ethernet IQ2 and IQ2-E interfaces. As a result, the effective available bandwidth for these interface types is now 999.5 Mbps and 998 Mbps, respectively.**

1. To configure the router to receive and forward single-tag frames with 802.1Q VLAN tags, include the **vlan-tagging** statement at the **[edit interfaces *interface-name*]** hierarchy level:

   [edit interfaces *interface-name*]
   user@host# vlan-tagging;

2. To configure the router to receive and forward dual-tag frames with 802.1Q VLAN tags, include the **stacked-vlan-tagging** statement at the **[edit interfaces *interface-name*]** hierarchy level:

   [edit interfaces *interface-name*]
   user@host# stacked-vlan-tagging;

3. Mixed tagging is supported for Gigabit Ethernet interfaces on Gigabit Ethernet IQ2 and IQ2-E, and IQ or IQE PICs on M Series and T Series routers, for all router Gigabit and 10-Gigabit Ethernet interfaces on MX Series routers, and for aggregated Ethernet interfaces with member links in IQ2 and IQ2-E PICs or in MX Series DPCs. Mixed tagging enables to configure two logical interfaces on the same Ethernet port, one with single-tag framing and one with dual-tag framing.

   NOTE: **Mixed tagging is not supported on Fast Ethernet interfaces.**

   To configure mixed tagging:

   a. Configure the **flexible-vlan-tagging** statement at the **[edit interfaces ge-*fpc/pic/port*]** hierarchy level.

      [edit interfaces ge-*fpc/pic/port*]
      user@host#flexible-vlan-tagging;

   b. Configure the **vlan-tags** statement with **inner** and **outer** options or the **vlan-id** statement at the **[edit interfaces ge-*fpc/pic/port* unit *logical-unit-number*]** hierarchy level:

      [edit interfaces ge-*fpc/pic/port* unit *logival-unit-number*]

```
user@host# vlan-id number;
family family {
  address address;
}
user@host# vlan-tags inner tpid.vlan-id outer tpid.vlan-id;
family family {
  address address;
}
```

NOTE: If you configure the physical interface MTU for mixed tagging, then you must increase the MTU to 4 bytes more than the MTU value you would configure for a standard VLAN-tagged interface.

For example, if the MTU value is configured to be 1018 on a VLAN-tagged interface, then the MTU value on a flexible VLAN tagged interface must be 1022—4 bytes more. The additional 4 bytes accommodates the future addition of a stacked VLAN tag configuration on the same physical interface.

If the same physical interface MTU value is configured on both the VLAN and flexible VLAN-tag routers, the L2 circuit configuration does not come up and a MTU mismatch is logged. However, normal traffic flow is unaffected.

For encapsulation type **flexible-ethernet-services**, all VLAN IDs are valid.

4. For 1-, 4-, and 8-port Gigabit Ethernet IQ2 and IQ2-E PICs, for 1-port 10-Gigabit Ethernet IQ2 and IQ2-E PICs, for all MX Series router Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces configured for 802.1Q flexible VLAN tagging, and for aggregated Ethernet interfaces on IQ2 and IQ2-E PICs or MX Series DPCs, you can configure mixed tagging support for untagged packets on a port. Untagged packets are accepted on the same mixed VLAN-tagged port. To accept untagged packets, include the **native-vlan-id** statement and the **flexible-vlan-tagging** statement at the **[edit interfaces *interface-name*]** hierarchy level:

   ```
   [edit interfaces ge-fpc/pic/port]
   flexible-vlan-tagging;
   native-vlan-id number;
   ```

   The logical interface on which untagged packets are to be received must be configured with the same native VLAN ID as that configured on the physical interface. To configure the logical interface, include the **vlan-id** statement (matching the **native-vlan-id** statement on the physical interface) at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

Sending Untagged Traffic Without VLAN ID to Remote End

Send traffic without the native VLAN ID (*native-vlan-id*) to the remote end of the network if untagged traffic is received.

If this option is not configured, then *native-vlan-id* is added to untagged traffic. But if this option is configured, then *native-vlan-id* is not added to untagged traffic.

NOTE:

- This feature works only on MX series routers with MPCs/MICs. Configuring this option with DPC results in no behavior change. But, if this option is configured with Aggregated Ethernet (AE) in which the sub interfaces reside across MPCs/MICs and DPC, MPCs/MICs and DPC will show a different behavior.
- In the egress direction, this feature is disrupted by VLAN normalization. Because of normalization, the egress interface cannot distinguish between untagged traffic and tagged traffic. And untagged traffic is sent out with *native-vlan-id*. Consider this while configuring both VLAN normalization and new *native-vlan-id* option.

  There will be a problem with ingress firewall filter if filter term includes *native-vlan-id*. With **no-native-vlan-insert** option configured, *native-vlan-id* will not be inserted to untagged traffic. So, firewall filter term will not match with untagged traffic. But if incoming traffic have VLAN ID which is equal to *native-vlan-id*, then firewall filter term will match and firewall will work.
- When this feature is used with AE, all sub-interfaces of AE should be in same type of FPC.

Configuring Flexible VLAN Tagging on PTX Series Packet Transport Routers

This topic describes how to configure flexible VLAN tagging on PTX Series Packet Transport Routers. In addition to VLAN tagging and stacked VLAN tagging, you can configure a port for flexible tagging. With flexible VLAN tagging, you can configure two logical interfaces on the same Ethernet port, one with single-tag framing and one with dual-tag framing.

To configure mixed tagging, include the **flexible-vlan-tagging** statement at the **[edit interfaces et-*fpc/pic/port*]** hierarchy level. You must also include the **vlan-tags** statement with **inner** and **outer** options or the **vlan-id** statement at the **[edit interfaces et-*fpc/pic/port* unit *logical-unit-number*]** hierarchy level:

```
[edit interfaces et-fpc/pic/port]
flexible-vlan-tagging;
unit logical-unit-number {
   vlan-id number;
}
unit logical-unit-number {
   vlan-tags inner tpid.vlan-id outer tpid.vlan-id;
}
```

Related Documentation

- Enabling VLAN Tagging on page 247

Binding VLAN IDs to Logical Interfaces

This topic describes how to configure logical interfaces to receive and forward VLAN-tagged frames:

To configure a logical interface to receive and forward VLAN-tagged frames, you must bind a VLAN ID, a range of VLAN IDs, or a list of VLAN IDs to the logical interface. Table 15 on page 251 lists the configuration statements you use to bind VLAN IDs to logical interfaces, organized by scope of the VLAN IDs used to match incoming packets. You can configure these statements at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level or at the **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

Table 15: Configuration Statements Used to Bind VLAN IDs to Logical Interfaces

Scope of VLAN ID Matching	Type of VLAN Framing Supported on the Logical Interface	
	Single-Tag Framing	Dual-Tag Framing
VLAN ID	**vlan-id** *vlan-id*;	**vlan-tags outer** *tpid*.<*vlan-id*> **inner** *tpidvlan-id*;
VLAN ID Range	**vlan-id-range** *vlan-id–vlan-id*;	**vlan-tags outer** *tpid.vlan-id* **inner-range** *tpid.vlan-id–vlan-id*;
VLAN ID List	**vlan-id-list** [*vlan-id vlan-id–vlan-id*];	**vlan-tags outer** <*tpid.*>*vlan-id* **inner-list** [*vlan-id vlan-id–vlan-id*];

NOTE: The **inner-list** option of the **vlan-tags** statement does not support Tag Protocol ID (TPID) values.

1. A logical interface that you have associated (bound) to a particular VLAN ID will receive and forward incoming frames that contain a matching VLAN ID. To bind a VLAN ID to a single-tag logical interface, include the **vlan-id** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level or at the **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

   [edit interfaces *interface-name* unit *logical-unit-number*]
   user@host# vlan-id *vlan-id*;

   To configure an Ethernet interface to support single-tag logical interfaces, include the **vlan-tagging** statement at the **[edit interfaces *ethernet-interface-name*]** hierarchy level. To support mixed tagging, include the **flexible-vlan-tagging** statement instead.

2. To bind a VLAN ID to a dual-tag logical interface, include the **vlan-tags** statement at the **[edit interfaces *ethernet-interface-name* unit *logical-unit-number*]** hierarchy level or at the **[edit logical-systems *logical-system-name* interfaces *ethernet-interface-name* unit *logical-unit-number*]** hierarchy level:

   [edit interfaces *ethernet-interface-name* unit *logical-unit-number*]
   vlan-tags inner <*tpid.*>*vlan-id* outer <*tpid.*>*vlan-id*;

To configure an Ethernet interface to support dual-tag logical interfaces, include the **stacked-vlan-tagging** statement at the **[edit interfaces *ethernet-interface-name*]** hierarchy level. To support mixed tagging, include the **flexible-vlan-tagging** statement instead.

3. A VLAN range can be used by service providers to interconnect multiple VLANs belonging to a particular customer over multiple sites. Using a VLAN ID range conserves switch resources and simplifies configuration. To bind a range of VLAN IDs to a single-tag logical interface, include the **vlan-id-range** statement at the **[edit interfaces *ethernet-interface-name* unit *logical-unit-number*]** hierarchy level or at the **[edit logical-systems *logical-system-name* interfaces *ethernet-interface-name* unit *logical-unit-number*]** hierarchy level.

   [edit interfaces *ethernet-interface-name* unit *logical-unit-number*]
   vlan-id-range *vlan-id-vlan-id*;

4. To bind a range of VLAN IDs to a dual-tag logical interface, include the **vlan-tags** statement. Use the **inner–list** option to specify the VLAN IDs as an inclusive range by separating the starting VLAN ID and ending VLAN ID with a hyphen. You can include the statement at the **[edit interfaces *ethernet-interface-name* unit *logical-unit-number*]** hierarchy level or at the **[edit logical-systems *logical-system-name* interfaces *ethernet-interface-name* unit *logical-unit-number*]** hierarchy level.

   [edit interfaces *ethernet-interface-name* unit *logical-unit-number*]
   vlan-tags inner–list [*vlan-id vlan-id–vlan-id*] outer <*tpid*.>*vlan-id*;

   To configure an Ethernet interface to support dual-tag logical interfaces, include the **stacked-vlan-tagging** statement at the **[edit interfaces *ethernet-interface-name*]** hierarchy level. To support mixed tagging, include the **flexible-vlan-tagging** statement instead.

In Junos OS Release 9.5 and later, on MX Series routers and in Junos OS Release 12.2R2 and later on EX Series switches, you can bind a list of VLAN IDs to a single logical interface, eliminating the need to configure a separate logical interface for every VLAN or VLAN range. A logical interface that accepts packets tagged with any VLAN ID specified in a VLAN ID list is called a *VLAN-bundled* logical interface.

You can use VLAN-bundled logical interfaces to configure circuit cross-connects between Layer 2 VPN routing instances or Layer 2 circuits. Using VLAN-bundled logical interfaces simplifies configuration and reduces use of system resources such as logical interfaces, next hops, and circuits.

As an alternative to configuring multiple logical interfaces (one for each VLAN ID and one for each range of VLAN IDs), you can configure a single VLAN-bundled logical interface based on a list of VLAN IDs.

NOTE: The **vlan-id** option is not supported to achieve VLAN normalization on VPLS instances that are configured with **vlan-id-list**. However, you can use the **vlan-maps** option to achieve VLAN normalization.

1. To bind a list of VLAN IDs to a single-tag logical interface, include the **vlan-id-list** statement at the **[edit interfaces *ethernet-interface-name* unit *logical-unit-number*]** hierarchy level or at the **[edit logical-systems *logical-system-name* interfaces *ethernet-interface-name* unit *logical-unit-number*]** hierarchy level. Specify the VLAN IDs in the list individually by using a space to separate each ID, as an inclusive list by separating the starting VLAN ID and ending VLAN ID with a hyphen, or as a combination of both.

   [edit interfaces *ethernet-interface-name* unit *logical-unit-number*]
   user@host# vlan-id-list [*vlan-id vlan-id–vlan-id*];

   To configure an Ethernet interface to support single-tag logical interfaces, include the **vlan-tagging** statement at the **[edit interfaces *ethernet-interface-name*]** hierarchy level. To support mixed tagging, include the **flexible-vlan-tagging** statement instead.

2. To bind a list of VLAN IDs to a dual-tag logical interface, include the **vlan-tags** statement at the **[edit interfaces *ethernet-interface-name* unit *logical-unit-number*]** hierarchy level or at the **[edit logical-systems *logical-system-name* interfaces *ethernet-interface-name* unit *logical-unit-number*]** hierarchy level. Use the **inner-list** option to specify the VLAN IDs individually by using a space to separate each ID, as an inclusive list by separating the starting VLAN ID and ending VLAN ID with a hyphen, or as a combination of both.

   [edit interfaces *ethernet-interface-name* unit *logical-unit-number*]
   user@host# vlan-tags inner-list [*vlan-id vlan-id–vlan-id*] outer <*tpid*>*vlan-id*;

   NOTE: The **inner-list** option of the **vlan-tags** statement does not support Tag Protocol ID (TPID) values.

To configure an Ethernet interface to support dual-tag logical interfaces, include the **stacked-vlan-tagging** statement at the **[edit interfaces *ethernet-interface-name*]** hierarchy level. To support mixed tagging, include the **flexible-vlan-tagging** statement instead.

The following sample configuration configures two different lists of VLAN IDs on two different logical ports.

```
[edit interfaces]
ge-1/1/0 {
    vlan-tagging; # Only for single-tagging
    encapsulation flexible-ethernet-services;
    unit 10 {
        encapsulation vlan-ccc;
        vlan-id-list [20 30–40 45];
    }
}
ge-1/1/1 {
    flexible-vlan-tagging; # Only for mixed tagging
    encapsulation flexible-ethernet-services;
    unit 10 {
        encapsulation vlan-ccc;
        vlan-id-list [1 10 20 30–40];
    }
    unit 20 {
        encapsulation vlan-ccc;
        vlan-tags outer 200 inner-list [50–60 80 90–100];
    }
}
```

In the example configuration above, **ge-1/1/0** supports single-tag logical interfaces, and **ge-1/1/1** supports mixed tagging. The single-tag logical interfaces **ge-1/1/0.10** and **ge-1/1/1.20** each bundle lists of VLAN IDs. The dual-tag logical interface **ge-1/1/1.20** bundles lists of inner VLAN IDs.

TIP: You can group a range of identical interfaces into an interface range and then apply a common configuration to that interface range. For example, in the above example configuration, both interfaces ge-1/1/0 and ge-1/1/1 have the same physical encapsulation type of **flexible-ethernet-services**. Thus you can define an interface range with the interfaces ge-1/1/0 and ge-1/1/1 as its members and apply the encapsulation type flexible-ethernet-services to that defined interface range.

Associating VLAN IDs to VLAN Demux Interfaces

The following sections describe how to configure VLAN demux interfaces to receive and forward VLAN-tagged frames:

Associating VLAN IDs to VLAN Demux Interfaces Overview

To configure a VLAN demux interface to receive and forward VLAN-tagged frames, you must associate a VLAN ID or dual tagged (stacked) VLAN ID to the interface. Table 16 on page 255 shows the configuration statements you use to associate VLAN IDs to VLAN demux interfaces, depending on the VLAN tag framing you use:

Table 16: Configuration Statements Used to Associate VLAN IDs to VLAN Demux Interfaces

	Single-Tag Framing	Dual-Tag Framing
Statement Format	vlan-id *vlan-id*;	vlan-tags outer *tpid*.<*vlan-id*> inner *tpidvlan-id*;

You can include all of the statements at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**
- **[edit interfaces *demux0* unit *logical-unit-number*]**

Associating a VLAN ID to a VLAN Demux Interface

A VLAN demux interface that you have associated to a particular VLAN ID receives and forwards incoming frames that contain a matching VLAN ID. You can associate a VLAN ID to a single-tag logical interface or to a dual-tagged (stacked) logical interface.

Associating a VLAN ID to a Single-Tag VLAN Demux Interface

To associate a VLAN ID to a single-tag VLAN demux interface, include the **vlan-id** statement at the **[edit interfaces *demux0* unit *logical-unit-number*]** hierarchy level:

```
vlan-id vlan-id;
```

To configure an interface to support single-tag logical interfaces, you must also include the **vlan-tagging** statement at the **[edit interfaces *interface-name*]** hierarchy level. To support mixed tagging, include the **flexible-vlan-tagging** statement instead.

See Also

- *Configuring a VLAN Demultiplexing Interface*

Associating a VLAN ID to a Dual-Tag VLAN Demux Interface

To associate a VLAN ID to a dual-tag VLAN demux interface, include the **vlan-tags** statement at the **[edit interfaces *demux0* unit *logical-unit-number*]** hierarchy level:

vlan-tags inner <*tpid*.>*vlan-id* outer <*tpid*.>*vlan-id*;

To configure an interface to support dual-tag logical interfaces, include the **stacked-vlan-tagging** statement at the **[edit interfaces *interface-name*]** hierarchy level. To support mixed tagging, include the **flexible-vlan-tagging** statement instead.

See Also

- 802.1Q VLANs Overview on page 244
- *Configuring a VLAN Demultiplexing Interface*
- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring VLAN and Extended VLAN Encapsulation

To configure encapsulation on an interface, enter the **encapsulation** statement at the **[edit interfaces *interface-name*]** hierarchy level:

```
[edit interfaces interface-name]
user@host# encapsulation type
```

The following list contains important notes regarding VLAN encapsulation:

- Starting with Junos OS Release 8.1, , Gigabit Ethernet IQ, Gigabit Ethernet PICs with small form-factor pluggable optics (SFPs), and MX Series router Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces with VLAN tagging enabled can use **flexible-ethernet-services**, **vlan-ccc** , or **vlan-vpls** encapsulation.
- Starting with Junos OS Release 9.5, aggregated Ethernet interfaces configured for VPLS can use **flexible-ethernet-services**, **vlan-ccc**, or **vlan-vpls**.
- Ethernet interfaces in VLAN mode can have multiple logical interfaces. In CCC and VPLS modes, VLAN IDs from 1 through 511 are reserved for normal VLANs, and VLAN IDs 512 through 4094 are reserved for CCC or VPLS VLANs. For 4-port Fast Ethernet interfaces, you can use VLAN IDs 512 through 1024 for CCC or VPLS VLANs. For encapsulation type **flexible-ethernet-services**, all VLAN IDs are valid.
- For flexible Ethernet services, Ethernet VLAN CCC and VLAN VPLS, you can also configure the encapsulation type that is used inside the VLAN circuit itself. To do this, include the **encapsulation** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level or at the **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.
- You cannot configure a logical interface with VLAN CCC or VLAN VPLS encapsulation unless you also configure the physical device with the same encapsulation or with flexible Ethernet services encapsulation. In general, the logical interface must have a VLAN ID of 512 or higher; if the VLAN ID is 511 or lower, it will be subject to the normal destination filter lookups in addition to source address filtering. However if you configure flexible Ethernet services encapsulation, this VLAN ID restriction is removed.

- Gigabit Ethernet, 4-port Fast Ethernet, MX Series router Gigabit Ethernet, Tri-Rate Ethernet copper, 10-Gigabit Ethernet, and aggregated Ethernet interfaces with VLAN tagging enabled can use **extended-vlan-ccc** or **extended-vlan-vpls**, which allow 802.1Q tagging.
- For extended VLAN CCC and extended VLAN VPLS encapsulation, all VLAN IDs 1 and higher are valid. VLAN ID 0 is reserved for tagging the priority of frames.
- For extended VLAN CCC, the VLAN IDs on ingress and egress interfaces must be the same. For back-to-back connections, all VLAN IDs must be the same.

Release History Table

Release	Description
9.5	Starting with Junos OS Release 9.5, aggregated Ethernet interfaces configured for VPLS can use **flexible-ethernet-services**, **vlan-ccc**, or **vlan-vpls**.
8.1	Starting with Junos OS Release 8.1, , Gigabit Ethernet IQ, Gigabit Ethernet PICs with small form-factor pluggable optics (SFPs), and MX Series router Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces with VLAN tagging enabled can use **flexible-ethernet-services**, **vlan-ccc** , or **vlan-vpls** encapsulation.

Configuring a Layer 2 VPN Routing Instance on a VLAN-Bundled Logical Interface

This topic describes how to configure a Layer 2 VPN routing instance on a logical interface bound to a list of VLAN IDs.

- Configuring a VLAN-Bundled Logical Interface to Support a Layer 2 VPN Routing Instance on page 257
- Specifying the Interface Over Which VPN Traffic Travels to the CE Router on page 258
- Specifying the Interface to Handle Traffic for a CCC on page 258

Configuring a VLAN-Bundled Logical Interface to Support a Layer 2 VPN Routing Instance

To configure a VLAN-bundled logical interface, specify the list of VLAN IDs by including the **vlan-id-list** statement or the **vlan-tags** statement on a provider edge (PE) router:

```
interfaces {
  ethernet-interface-name {
    vlan-tagging; # Support single- or dual-tag logical interfaces
    flexible-vlan-tagging; # Support mixed tagging
    encapsulation (extended-vlan-ccc | flexible-ethernet-services);
    unit logical-unit-number {
```

```
            vlan-id-list [vlan-id vlan-id–vlan-id]; # For single-tag
            vlan-tags outer <tpid.>vlan-id inner-list [vlan-id vlan-id–vlan-id]; # For dual-tag
        }
        . . .
    }
}
```

You can include the statements at the following hierarchy levels:

- **[edit]**
- **[edit logical-systems *logical-system-name*]**

See Also

- 802.1Q VLANs Overview on page 244
- *Ethernet Interfaces Feature Guide for Routing Devices*

Specifying the Interface Over Which VPN Traffic Travels to the CE Router

To configure a Layer 2 VPN routing instance on a PE router, include the **instance-type** statement and specify the value **l2vpn**. To specify an interface connected to the router, include the **interface** statement and specify the VLAN-bundled logical interface:

```
instance-type l2vpn;
interface logical-interface-name;
```

You can include the statements at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name*]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]**

See Also

- 802.1Q VLANs Overview on page 244
- *Ethernet Interfaces Feature Guide for Routing Devices*

Specifying the Interface to Handle Traffic for a CCC

To configure the VLAN-bundled logical interface as the interface to handle traffic for a circuit connected to the Layer 2 VPN routing instance, include the following statements:

```
protocols {
    l2vpn {
        (control-word | no-control-word);
        encapsulation-type (ethernet | ethernet-vlan);
        site site-name {
            site-identifier identifier;
            interface logical-interface-name { # VLAN-bundled logical interface
                . . . interface-options . . .
            }
        }
    }
}
```

You can include the statements at the same hierarchy level at which you include the **instance-type l2vpn** and **interface** ***logical-interface-name*** statements:

- **[edit routing-instances** ***routing-instance-name*****]**
- **[edit logical-systems** ***logical-system-name*** **routing-instances** ***routing-instance-name*****]**

To enable a Layer 2 VPN routing instance on a PE router, include the **l2vpn** statement. For more information, see the *Junos OS VPNs Library for Routing Devices*.

The **encapsulation-type** statement specifies the Layer 2 protocol used for traffic from the customer edge (CE) router. If the Layer 2 VPN routing instance is being connected to a single-tag Layer 2 circuit, specify **ethernet** as the encapsulation type. If the Layer 2 VPN routing instance is being connected to a dual-tag Layer 2 circuit, specify **ethernet-vlan** as the encapsulation type.

To specify the interface to handle traffic for a circuit connected to the Layer 2 VPN routing instance, include the **interface** statement and specify the VLAN-bundled logical interface.

See Also

- 802.1Q VLANs Overview on page 244
- Example: Configuring a Layer 2 VPN Routing Instance on a VLAN-Bundled Logical Interface on page 259

- *Ethernet Interfaces Feature Guide for Routing Devices*

Example: Configuring a Layer 2 VPN Routing Instance on a VLAN-Bundled Logical Interface

The following configuration shows that the single-tag logical interface **ge-1/0/5.0** bundles a list of VLAN IDs, and the logical interface **ge-1/1/1.0** supports IPv4 traffic using IP address 10.30.1.130 and can participate in an MPLS path.

```
[edit interfaces]
ge-1/0/5 {
  vlan-tagging;
  encapsulation extended-vlan-ccc;
  unit 0 { # VLAN-bundled logical interface
    vlan-id-list [513 516 520-525];
  }
}
  ge-1/1/1 {
    unit 0 {
      family inet {
        address 10.30.1.1/30;
      }
      family mpls;
    }
  }
```

The following configuration shows the type of traffic supported on the Layer 2 VPN routing instance:

```
[edit protocols]
```

```
rsvp {
    interface all;
    interface lo0.0;
}
mpls {
    label-switched-path lsp {
        to 10.255.69.128;
    }
    interface all;
}
bgp {
    group g1 {
        type internal;
        local-address 10.255.69.96;
        family l2vpn {
            signaling;
        }
        neighbor 10.255.69.128;
    }
}
ospf {
    traffic-engineering;
    area 0.0.0.0 {
        interface lo0.0;
        interface ge-1/1/1.0;
    }
}
```

The following configuration shows that the VLAN-bundled logical interface is the interface over which VPN traffic travels to the CE router and handles traffic for a CCC to which the VPN connects.

```
[edit routing-instances]
red {
    instance-type l2vpn;
    interface ge-1/0/5.0; # VLAN-bundled logical interface
    route-distinguisher 10.255.69.96:100;
    vrf-target target:1:1;
    protocols {
        l2vpn {
            encapsulation-type ethernet; # For single-tag VLAN logical interface
            site CE_ultima {
                site-identifier 1;
                interface ge-1/0/5.0;
            }
        }
    }
}
```

NOTE: Because the VLAN-bundled logical interface supports single-tag frames, Ethernet is the Layer 2 protocol used to encapsulate incoming traffic. Although the connection spans multiple VLANs, the VLANs are bundled and therefore can be encapsulated as a single VLAN.

However, with Ethernet encapsulation, the circuit signal processing does not check that the VLAN ID list is the same at both ends of the CCC connection.

Specifying the Interface Over Which VPN Traffic Travels to the CE Router

To configure a Layer 2 VPN routing instance on a PE router, include the **instance-type** statement and specify the value **l2vpn**. To specify an interface connected to the router, include the **interface** statement and specify the VLAN-bundled logical interface:

```
instance-type l2vpn;
interface logical-interface-name;
```

You can include the statements at the following hierarchy levels:

- **[edit routing-instances *routing-instance-name*]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]**

Related Documentation

- 802.1Q VLANs Overview on page 244
- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring Access Mode on a Logical Interface

Enterprise network administrators can configure a single logical interface to accept untagged packets and forward the packets within a specified bridge domain. A logical interface configured to accept untagged packets is called an *access interface* or *access port*. Access interface configuration is supported on MX Series routers only.

To configure access mode on a logical interface, use the **interface-mode access** statement at the **[edit interfaces *interface-name* unit *logical-unit-number* family bridge]** hierarchy level or at the **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family bridge]** hierarchy level.

When an untagged packet is received on an access interface, the packet is accepted, the configured VLAN ID is added to the packet, and the packet is forwarded within the bridge domain that is configured with the matching VLAN ID.

The following example configures a logical interface as an access port with a VLAN ID of 20:

```
[edit interfaces ge-1/2/0]
unit 0 {
  family bridge {
    interface-mode access;
    vlan-id 20;
  }
}
```

Related Documentation

- 802.1Q VLANs Overview on page 244
- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring a Logical Interface for Trunk Mode

As an alternative to configuring a logical interface for each VLAN, enterprise network administrators can configure a single logical interface to accept untagged packets or packets tagged with any VLAN ID specified in a list of VLAN IDs. Using a VLAN ID list conserves switch resources and simplifies configuration. A logical interface configured to accept packets tagged with any VLAN ID specified in a list is called a *trunk interface* or *trunk port*. Trunk interface configuration is supported on MX Series routers only. Trunk interfaces support integrated routing and bridging (IRB).

To configure a logical interface to accept any packet tagged with a VLAN ID that matches the list of VLAN IDs, include the **interface-mode** statement and specify the **trunk** option:

```
interface-mode trunk;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number* family bridge]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family bridge]**

Related Documentation

- 802.1Q VLANs Overview on page 244
- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring the VLAN ID List for a Trunk Interface

To configure the list of VLAN IDs to be accepted by the trunk port, include the **vlan-id-list** statement and specify the list of VLAN IDs. You can specify individual VLAN IDs with a space separating the ID numbers, specify a range of VLAN IDs with a dash separating the ID numbers, or specify a combination of individual VLAN IDs and a range of VLAN IDs.

vlan-id-list [*number number-number*];

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number* family bridge interface-mode trunk]**

- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family bridge interface-mode trunk]**

When a packet is received that is tagged with a VLAN ID specified in the trunk interface list of VLAN IDs, the packet is accepted and forwarded within the bridge domain that is configured with the matching VLAN ID.

When a packet is received that is tagged with a VLAN ID not specified in the trunk interface list of VLAN IDs, the native VLAN ID is pushed in front of the existing VLAN tag or tags and the packet is forwarded within the bridge domain that is configured with the matching VLAN ID.

When an untagged packet is received on a trunk interface, the native VLAN ID is added to the packet and the packet is forwarded within the bridge domain that is configured with the matching VLAN ID.

A bridge domain configured with a matching VLAN ID must be configured before the trunk interface is configured. To learn more about configuring bridge domains, see the *Junos Routing Protocols Configuration Guide*.

Related Documentation

- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring a Trunk Interface on a Bridge Network

On MX Series routers, you can configure a trunk interface on a bridge network.

The following output sample shows trunk port configuration on a bridge network:

```
user@host# run show interfaces
ge-0/0/0 {
    flexible-vlan-tagging;
    encapsulation flexible-ethernet-services;
    unit 0 {
        encapsulation vlan-bridge;
        vlan-id 1;
    }
}
ge-2/0/0 {
    unit 0 {
        family bridge {
            interface-mode trunk;
            vlan-id-list 1-200;
        }
    }
}
ge-2/0/1 {
    flexible-vlan-tagging;
    encapsulation flexible-ethernet-services;
    unit 0 {
        encapsulation vlan-bridge;
        vlan-id 1;
    }
}
```

If you want **igmp-snooping** to be functional for a bridge domain, then you should not configure **interface-mode** and **irb** for that bridge domain. Such a configuration commit succeeds, but IGMP snooping is not functional, and a message informing the same is displayed as shown after the sample configuration below:

```
user@host# run show configuration
interfaces {
    ge-5/1/1 {
        flexible-vlan-tagging;
        native-vlan-id 1;
        unit 0 {
            family bridge {
                interface-mode trunk;
                vlan-id-list 401;
            }
        }
    }
    irb {
        unit 401 {
            family inet {
                address 192.168.2.2/27;
            }
        }
    }
}
protocols {
    igmp {
        interface all;
    }
}
bridge-domains {
    VLAN-401 {
        vlan-id 401;
        routing-interface irb.401;
        protocols {
            igmp-snooping;
        }
    }
}
```

```
user@host# commit
[edit bridge-domains]
  'VLAN-401'
    IGMP Snooping not supported with IRB and trunk mode interface ge-5/1/1.0
commit complete
```

To achieve IGMP snooping for a bridge domain, you should use such a configuration as shown in the following example:

```
user@host# run show configuration
interfaces {
    ge-0/0/1 {
        flexible-vlan-tagging;
        native-vlan-id 1;
        encapsulation flexible-ethernet-services;
        unit 0 {
            encapsulation vlan-bridge;
            vlan-id 401;
```

```
        }
    }
    irb {
        unit 401 {
            family inet {
                address 192.168.2.2/27;
            }
        }
    }
}
protocols {
    igmp {
        interface all;
    }
}
bridge-domains {
    VLAN-401 {
        vlan-id 401;
        interface ge-0/0/1.0;
        routing-interface irb.401;
        protocols {
            igmp-snooping;
        }
    }
}
```

```
user@host# commit
commit complete
```

Configuring a VLAN-Bundled Logical Interface to Support a Layer 2 VPN Routing Instance

To configure a VLAN-bundled logical interface, specify the list of VLAN IDs by including the **vlan-id-list** statement or the **vlan-tags** statement on a provider edge (PE) router:

```
interfaces {
  ethernet-interface-name {
    vlan-tagging; # Support single- or dual-tag logical interfaces
    flexible-vlan-tagging; # Support mixed tagging
    encapsulation (extended-vlan-ccc | flexible-ethernet-services);
    unit logical-unit-number {
      vlan-id-list [vlan-id vlan-id–vlan-id]; # For single-tag
      vlan-tags outer <tpid.>vlan-id inner-list [vlan-id vlan-id–vlan-id]; # For dual-tag
    }
    ...
  }
}
```

You can include the statements at the following hierarchy levels:

- **[edit]**

- **[edit logical-systems *logical-system-name*]**

Configuring a VLAN-Bundled Logical Interface to Support a Layer 2 VPN Routing Instance

To configure a VLAN-bundled logical interface, specify the list of VLAN IDs by including the **vlan-id-list** statement or the **vlan-tags** statement:

```
interfaces {
  ethernet-interface-name {
    vlan-tagging; # Support single- or dual-tag logical interfaces
    flexible-vlan-tagging; # Support mixed tagging
    encapsulation (extended-vlan-ccc | flexible-ethernet-services);
    unit logical-unit-number {
      encapsulation vlan–ccc; # Required for single-tag
      vlan-id-list [vlan-id vlan-id–vlan-id]; # For single-tag
      vlan-tags outer tpid.vlan-id inner-list [vlan-id vlan-id–vlan-id]; # For dual-tag
    }
    . . .
  }
}
```

You can include the statements at the following hierarchy levels:

- **[edit]**
- **[edit logical-systems *logical-system-name*]**

For a single-tag logical interface, include the **encapsulation** statement and specify **vlan-ccc** so that CCC circuit encapsulation is used inside the Layer 2 circuit.

NOTE: In the case of a dual-tag logical interface, the Junos OS automatically uses the vlan-ccc encapsulation type.

Configuring a Layer 2 Circuit on a VLAN-Bundled Logical Interface

This topic describes how to configure a Layer 2 circuit on a logical interface bound to a list of VLAN IDs.

- Configuring a VLAN-Bundled Logical Interface to Support a Layer 2 VPN Routing Instance on page 267
- Specifying the Interface to Handle Traffic for a CCC Connected to the Layer 2 Circuit on page 268

Configuring a VLAN-Bundled Logical Interface to Support a Layer 2 VPN Routing Instance

To configure a VLAN-bundled logical interface, specify the list of VLAN IDs by including the **vlan-id-list** statement or the **vlan-tags** statement:

```
interfaces {
  ethernet-interface-name {
    vlan-tagging; # Support single- or dual-tag logical interfaces
    flexible-vlan-tagging; # Support mixed tagging
    encapsulation (extended-vlan-ccc | flexible-ethernet-services);
    unit logical-unit-number {
      encapsulation vlan–ccc; # Required for single-tag
      vlan-id-list [vlan-id vlan-id–vlan-id]; # For single-tag
      vlan-tags outer tpid.vlan-id inner-list [vlan-id vlan-id–vlan-id]; # For dual-tag
    }
    . . .
  }
}
```

You can include the statements at the following hierarchy levels:

- **[edit]**
- **[edit logical-systems *logical-system-name*]**

For a single-tag logical interface, include the **encapsulation** statement and specify **vlan-ccc** so that CCC circuit encapsulation is used inside the Layer 2 circuit.

NOTE: In the case of a dual-tag logical interface, the Junos OS automatically uses the **vlan-ccc** encapsulation type.

Specifying the Interface to Handle Traffic for a CCC Connected to the Layer 2 Circuit

To configure the VLAN-bundled logical interface as the interface to handle traffic for a circuit connected to the Layer 2 circuit, include the following statements:

```
l2circuit {
  neighbor address {
    interface logical-interface-name {
      virtual-circuit-id number;
      no-control-word;
    }
  }
}
```

You can include the statements at the following hierarchy levels:

- **[edit protocols]**
- **[edit logical-systems *logical-system-name* protocols]**

To enable a Layer 2 circuit, include the **l2circuit** statement.

To configure the router as a neighbor for a Layer 2 circuit, specify the neighbor address using the **neighbor** statement.

To specify the interface to handle traffic for a circuit connected to the Layer 2 circuit, include the **interface** statement and specify the VLAN-bundled logical interface.

Example: Configuring a Layer 2 Circuit on a VLAN-Bundled Logical Interface

The following configuration shows that the single-tag logical interface **ge-1/0/5.0** bundles a list of VLAN IDs, and the logical interface **ge-1/1/1.0** supports IPv4 traffic using IP address 10.30.1.1/30 and can participate in an MPLS path.

```
[edit interfaces]
ge-1/0/5 {
  vlan-tagging;
  encapsulation extended-vlan-ccc;
  unit 0 { # VLAN-bundled logical interface
    vlan-id-list [513 516 520-525];
  }
}
ge-1/1/1 {
  unit 0 {
    family inet {
      address 10.30.1.1/30;
```

```
        }
        family mpls;
    }
}
```

The following configuration shows the type of traffic supported on the Layer 2 VPN routing instance, and shows that the VLAN-bundled logical interface handles traffic for a CCC to which the Layer 2 circuit connects:

```
[edit protocols]
rsvp {
    interface all;
    interface lo0.0;
}
mpls {
    label-switched-path lsp {
        to 10.255.69.128;
    }
    interface all;
}
ospf {
    traffic-engineering;
    area 0.0.0.0 {
        interface lo0.0;
        interface ge-1/1/1.0;
    }
}
ldp {
    interface ge-1/1/1.0;
    interface ge-1/0/5.0; # VLAN-bundled logical interface
    interface lo0.0;
}
l2circuit {
    neighbor 10.255.69.128 {
        interface ge-1/0/5.0 { # VLAN-bundled logical interface
            virtual-circuit-id 3;
            no-control-word;
        }
    }
}
```

Guidelines for Configuring VLAN ID List-Bundled Logical Interfaces That Connect CCCs

For MX Series routers, you can bind a list of VLAN IDs to a logical interface, configure a Layer 2 VPN routing instance or Layer 2 circuit on the logical interface, and then use the logical interface to configure a circuit cross-connect (CCC) to another Layer 2 VPN routing instance or Layer 2 circuit.

A CCC allows you to configure transparent connections between two circuits so that packets from the source circuit are delivered to the destination circuit with, at most, the Layer 2 address being changed. You configure a CCC by connecting circuit interfaces of the same type. For more information, see *Circuit and Translational Cross-Connects Overview*.

NOTE: **The Junos OS supports binding of Ethernet logical interfaces to lists of VLAN IDs on MX Series routers only. For all other routers, you can bind an Ethernet logical interface to only a single VLAN ID or to a single range of VLAN IDs.**

The following configuration guidelines apply to bundling lists of VLAN IDs to Ethernet logical interfaces used to configure CCCs:

Guidelines for Configuring Physical Link-Layer Encapsulation to Support CCCs

To enable a physical interface to support VLAN-bundled logical interfaces that you will use to configure a CCC, you must specify one of the following physical link-layer encapsulation types as the value of the **encapsulation** statement at the **[edit interfaces *interface-name*]** hierarchy level:

```
[edit interfaces interface-name]
encapsulation (extended-vlan-ccc | flexible-ethernet-services);
```

- **extended-vlan-ccc**—For Ethernet interfaces with standard TPID tagging.
- **flexible-ethernet-services**—For supported Gigabit Ethernet interfaces for which you want to configure multiple per-unit Ethernet encapsulations.

For more information about configuring the encapsulation on a physical interface, see *Configuring Interface Encapsulation on Physical Interfaces*.

Guidelines for Configuring Logical Link-Layer Encapsulation to Support CCCs

For VLAN-bundled logical interfaces that you use to configure a CCC, specific logical link-layer encapsulation types are used inside the circuits themselves.

Table 17 on page 271 describes the logical link-layer encapsulation types used within circuits connected using VLAN-bundled logical interfaces of the same type.

Table 17: Encapsulation Inside Circuits CCC-Connected by VLAN-Bundled Logical Interfaces

Encapsulation Inside the Circuit	Layer 2 Circuit Joined by Configuring an Interface-to-Interface CCC Connection	
	Layer 2 VPN Routing Instance	Layer 2 Circuit
Syntax	encapsulation-type (ethernet | ethernet-vlan);	encapsulation vlan-ccc;
Hierarchy Level	[edit routing-instances *routing-instance-name* protocols l2vpn], [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols l2vpn]	[edit interfaces *ethernet-interface-name* unit *logical-unit-number*], [edit logical-systems *logical-system-name* interfaces *ethernet-interface-name* unit *logical-unit-number*]
Usage Guidelines	See the *Junos OS VPNs Library for Routing Devices*.	See *Configuring Interface Encapsulation on Logical Interfaces*, *Circuit and Translational Cross-Connects Overview*, and *Defining the Encapsulation for Switching Cross-Connects*.
For a Single-Tag Logical Interface	The MX Series router automatically uses **ethernet** as the Layer 2 protocol used to encapsulate incoming traffic. Although the connection spans multiple VLANs, the VLANs are bundled and therefore can be encapsulated as a single VLAN. **NOTE:** With **ethernet** encapsulation, the circuit signal processing does not check that the VLAN ID list is the same at both ends of the CCC connection.	Configure the MX Series router to use **vlan-ccc** as the logical link-layer encapsulation type.
For a Dual-Tag Logical Interface	Configure the MX Series router to use **ethernet-vlan** as the Layer 2 protocol to encapsulate incoming traffic. With **ethernet-vlan** encapsulation, circuit signal processing checks that the VLAN ID list is the same at both ends of the CCC connection. If a VLAN ID list mismatch is detected, you can view the error condition in the **show interfaces** command output.	The MX Series router automatically uses **vlan-ccc** as the logical link-layer encapsulation type, regardless of the value configured.

Related Documentation

- *Defining the Encapsulation for Switching Cross-Connects*

Specifying the Interface to Handle Traffic for a CCC

To configure the VLAN-bundled logical interface as the interface to handle traffic for a circuit connected to the Layer 2 VPN routing instance, include the following statements:

```
protocols {
  l2vpn {
    (control-word | no-control-word);
    encapsulation-type (ethernet | ethernet-vlan);
    site site-name {
```

```
        site-identifier identifier;
        interface logical-interface-name { # VLAN-bundled logical interface
          . . . interface-options . . .
        }
      }
    }
  }
```

You can include the statements at the same hierarchy level at which you include the **instance-type l2vpn** and **interface *logical-interface-name*** statements:

- **[edit routing-instances *routing-instance-name*]**
- **[edit logical-systems *logical-system-name* routing-instances *routing-instance-name*]**

To enable a Layer 2 VPN routing instance on a PE router, include the **l2vpn** statement. For more information, see the *Junos OS VPNs Library for Routing Devices*.

The **encapsulation-type** statement specifies the Layer 2 protocol used for traffic from the customer edge (CE) router. If the Layer 2 VPN routing instance is being connected to a single-tag Layer 2 circuit, specify **ethernet** as the encapsulation type. If the Layer 2 VPN routing instance is being connected to a dual-tag Layer 2 circuit, specify **ethernet-vlan** as the encapsulation type.

To specify the interface to handle traffic for a circuit connected to the Layer 2 VPN routing instance, include the **interface** statement and specify the VLAN-bundled logical interface.

CHAPTER 12

Configuring Private VLANs

Understanding Private VLANs

VLANs limit broadcasts to specified users. Private VLANs (PVLANs) take this concept a step further by limiting communication within a VLAN. PVLANs accomplish this by restricting traffic flows through their member switch ports (which are called *private ports*) so that these ports communicate only with a specified uplink trunk port or with specified ports within the same VLAN. The uplink trunk port or link aggregation group (LAG) is usually connected to a router, firewall, server, or provider network. Each PVLAN typically contains many private ports that communicate only with a single uplink port, thereby preventing the ports from communicating with each other.

PVLANs provide Layer 2 isolation between ports within a VLAN, splitting a broadcast domain into multiple discrete broadcast subdomains by creating secondary VLANs (community VLANs and an isolated VLAN) inside a primary VLAN. Ports within the same community VLAN can communicate with each other. Ports within an isolated VLAN can communicate *only* with a single uplink port.

Just like regular VLANs, PVLANs are isolated on Layer 2 and require one of the following options to route Layer 3 traffic among the secondary VLANs:

- A promiscuous port connection with a router
- A routed VLAN interface (RVI)

NOTE: To route Layer 3 traffic among secondary VLANs, a PVLAN needs only one of the options mentioned above. If you use an RVI, you can still implement a promiscuous port connection to a router with the promiscuous port set up to handle only traffic that enters and exits the PVLAN.

PVLANs are useful for restricting the flow of broadcast and unknown unicast traffic and for limiting the communication between known hosts. Service providers use PVLANs to keep their customers isolated from each other. Another typical use for a PVLAN is to provide per-room Internet access in a hotel.

NOTE: You can configure a PVLAN to span switches that support PVLANs.

This topic explains the following concepts regarding PVLANs on EX Series switches:

Why Use PVLANs

PVLANs are useful for restricting the flow of broadcast and unknown unicast traffic and for limiting the communication between hosts.The need to segregate a single VLAN is particularly useful in the following deployment scenarios:

- Server farms—A typical Internet service provider uses a server farm to provide Web hosting for numerous customers. Locating the various servers within a single server farm provides ease of management. Security concerns arise if all servers are in the same VLAN because Layer 2 broadcasts go to all servers in the VLAN.
- Metropolitan Ethernet networks—A metro service provider offers Layer 2 Ethernet access to assorted homes, rental communities, and businesses. The traditional solution of deploying one VLAN per customer is not scalable and is difficult to manage, leading

to potential waste of IP addresses. PVLANs provide a more secure and more efficient solution.

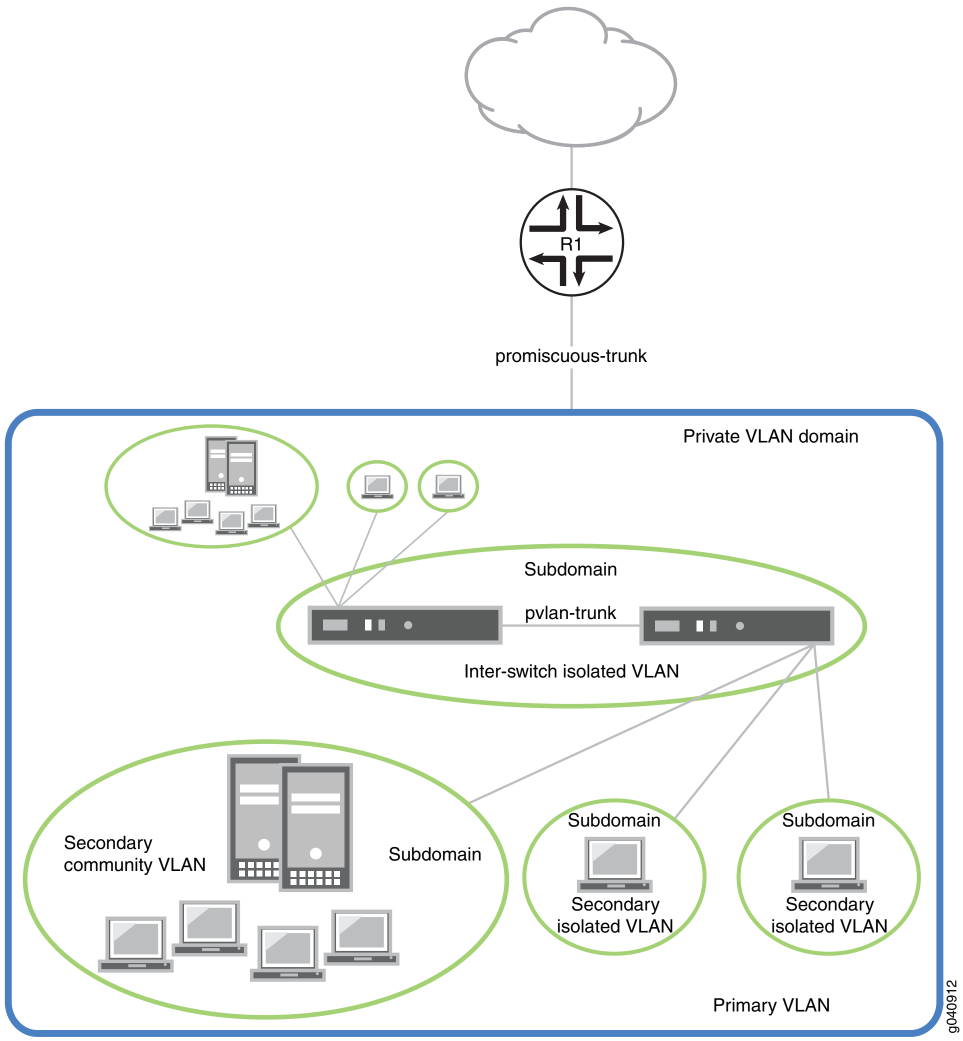
Typical Structure and Primary Application of PVLANs

A PVLAN can be configured on a single switch or can be configured to span multiple switches. The types of domains and ports are:

- Primary VLAN—The primary VLAN of the PVLAN is defined with an 802.1Q tag (VLAN ID) for the complete PVLAN. The primary PVLAN can contain multiple secondary VLANs (one isolated VLAN and multiple community VLANs).
- Isolated VLAN/isolated port—A primary VLAN can contain only one isolated VLAN. An interface within an isolated VLAN can forward packets only to a promiscuous port or the Inter-Switch Link (ISL) port. An isolated interface cannot forward packets to another isolated interface; and an isolated interface cannot receive packets from another isolated interface. If a customer device needs to have access *only* to a gateway router, the device must be attached to an isolated trunk port.
- Community VLAN/community port—You can configure multiple community VLANs within a single PVLAN. An interface within a specific community VLAN can establish Layer 2 communications with any other interface that belongs to the same community VLAN. An interface within a community VLAN can also communicate with a promiscuous port or the ISL port. If you have, for example, two customer devices that you need to isolate from other customer devices but that must be able to communicate with one another, use community ports.
- Promiscuous port—A promiscuous port has Layer 2 communications with all interfaces in the PVLAN, regardless of whether an interface belongs to an isolated VLAN or a community VLAN. A promiscuous port is a member of the primary VLAN but is not included within any secondary subdomain. Layer 3 gateways, DHCP servers, and other trusted devices that need to communicate with endpoint devices are typically connected to a promiscuous port.
- Inter-Switch Link (ISL)—An ISL is a trunk port that connects multiple switches in a PVLAN and contains two or more VLANs. It is required only when a PVLAN spans multiple switches.

The configured PVLAN is the *primary* domain (primary VLAN). Within the PVLAN, you configure *secondary* VLANs, which become subdomains nested within the primary domain. A PVLAN can be configured on a single switch or can be configured to span multiple switches. The PVLAN shown in Figure 18 on page 278 includes two switches, with a primary PVLAN domain and various subdomains.

Figure 18: Subdomains in a PVLAN



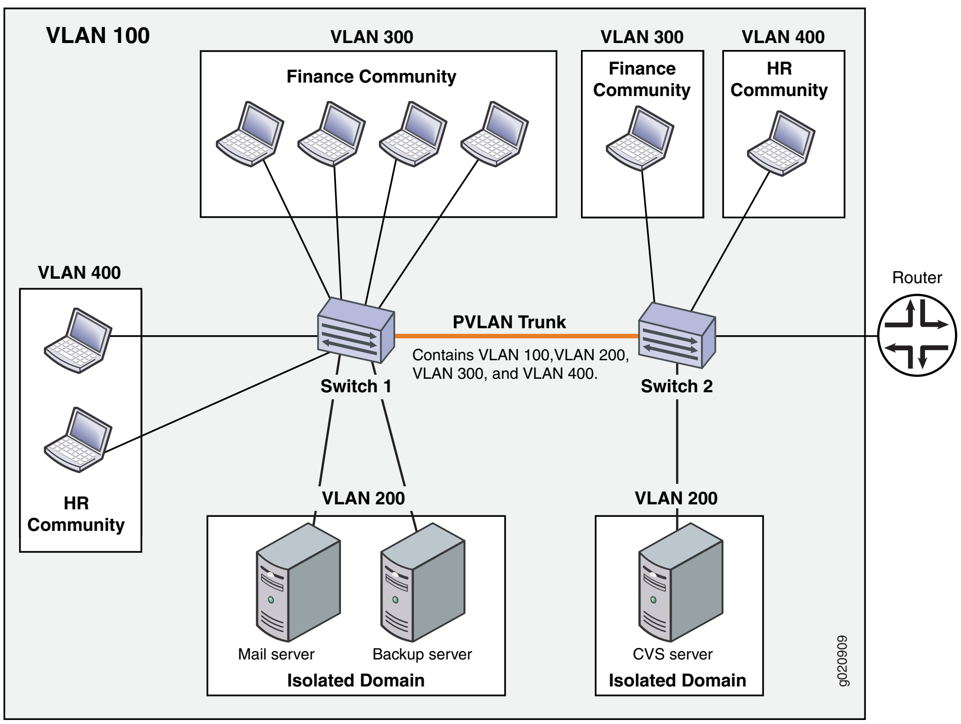
As shown in Figure 20 on page 280, a PVLAN has only one primary domain and multiple secondary domains. The types of domains are:

- Primary VLAN—VLAN used to forward frames downstream to isolated and community VLANs. The primary VLAN of the PVLAN is defined with an 802.1Q tag (VLAN ID) for the complete PVLAN. The primary PVLAN can contain multiple secondary VLANs (one isolated VLAN and multiple community VLANs).
- Secondary isolated VLAN—VLAN that receives packets only from the primary VLAN and forwards frames upstream to the primary VLAN. The isolated VLAN is a secondary VLAN nested within the primary VLAN. A primary VLAN can contain only one isolated VLAN. An interface within an isolated VLAN (isolated interface) can forward packets only to a promiscuous port or the PVLAN trunk port. An isolated interface cannot forward packets to another isolated interface; nor can an isolated interface receive packets from another isolated interface. If a customer device needs to have access *only* to a router, the device must be attached to an isolated trunk port.

- Secondary interswitch isolated VLAN—VLAN used to forward isolated VLAN traffic from one switch to another through PVLAN trunk ports. 802.1Q tags are required for interswitch isolated VLANs because IEEE 802.1Q uses an internal tagging mechanism by which a trunking device inserts a 4-byte VLAN frame identification tab into the packet header. An interswitch isolated VLAN is a secondary VLAN nested within the primary VLAN.
- Secondary community VLAN—VLAN used to transport frames among members of a community (a subset of users within the VLAN) and to forward frames upstream to the primary VLAN. A community VLAN is a secondary VLAN nested within the primary VLAN. You can configure multiple community VLANs within a single PVLAN. An interface within a specific community VLAN can establish Layer 2 communications with any other interface that belongs to the same community VLAN. An interface within a community VLAN can also communicate with a promiscuous port or the PVLAN trunk port.

Figure 19 on page 279 shows a PVLAN spanning multiple switches, where the primary VLAN (**100**) contains two community domains (**300** and **400**) and one interswitch isolated domain.

Figure 19: PVLAN Spanning Multiple Switches

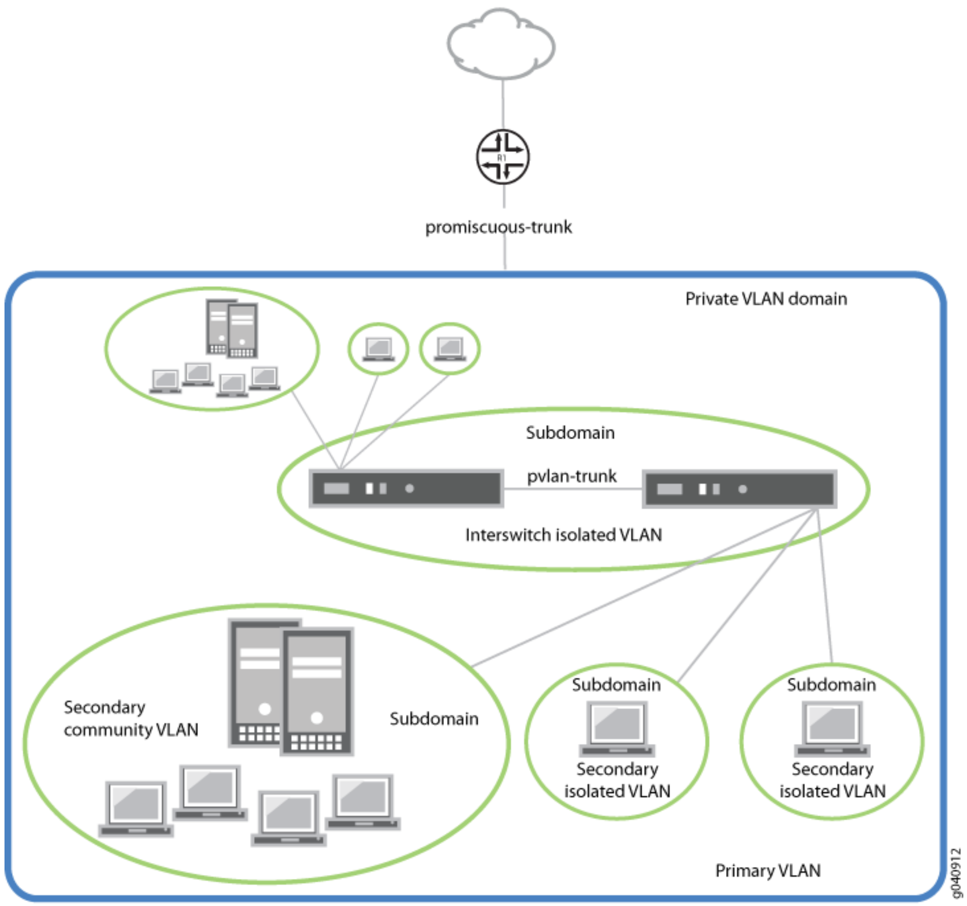


NOTE: Primary and secondary VLANs count against the limit of 4089 VLANs supported on the QFX Series. For example, each VLAN in Figure 19 on page 279 counts against this limit.

Typical Structure and Primary Application of PVLANs on MX Series Routers

The configured PVLAN becomes the primary domain, and secondary VLANs become subdomains that are nested inside the primary domain. A PVLAN can be created on a single router. The PVLAN shown in Figure 20 on page 280 includes one router, with one primary PVLAN domain and multiple secondary subdomains.

Figure 20: Subdomains in a PVLAN With One Router



The types of domains are:

- Primary VLAN—VLAN used to forward frames downstream to isolated and community VLANs.
- Secondary isolated VLAN—VLAN that receives packets only from the primary VLAN and forwards frames upstream to the primary VLAN.
- Secondary interswitch isolated VLAN—VLAN used to forward isolated VLAN traffic from one router to another through PVLAN trunk ports.
- Secondary community VLAN—VLAN used to transport frames among members of a community, which is a subset of users within the VLAN, and to forward frames upstream to the primary VLAN.

NOTE: PVLANs are supported on MX80 routers, on MX240, MX480, and MX960 routers with DPCs in enhanced LAN mode, on MX Series routers with MPC1, MPC2, and Adaptive Services PICs.

Typical Structure and Primary Application of PVLANs on EX Series Switches

NOTE: The primary VLAN of the PVLAN is defined with an 802.1Q tag (VLAN ID) for the complete PVLAN. On EX9200 switches, each secondary VLAN must also be defined with its own separate VLAN ID.

Figure 21 on page 281 shows a PVLAN on a single switch, where the primary VLAN (VLAN **100**) contains two community VLANs (VLAN **300** and VLAN **400**) and one isolated VLAN (VLAN **50**).

Figure 21: Private VLAN on a Single EX Switch

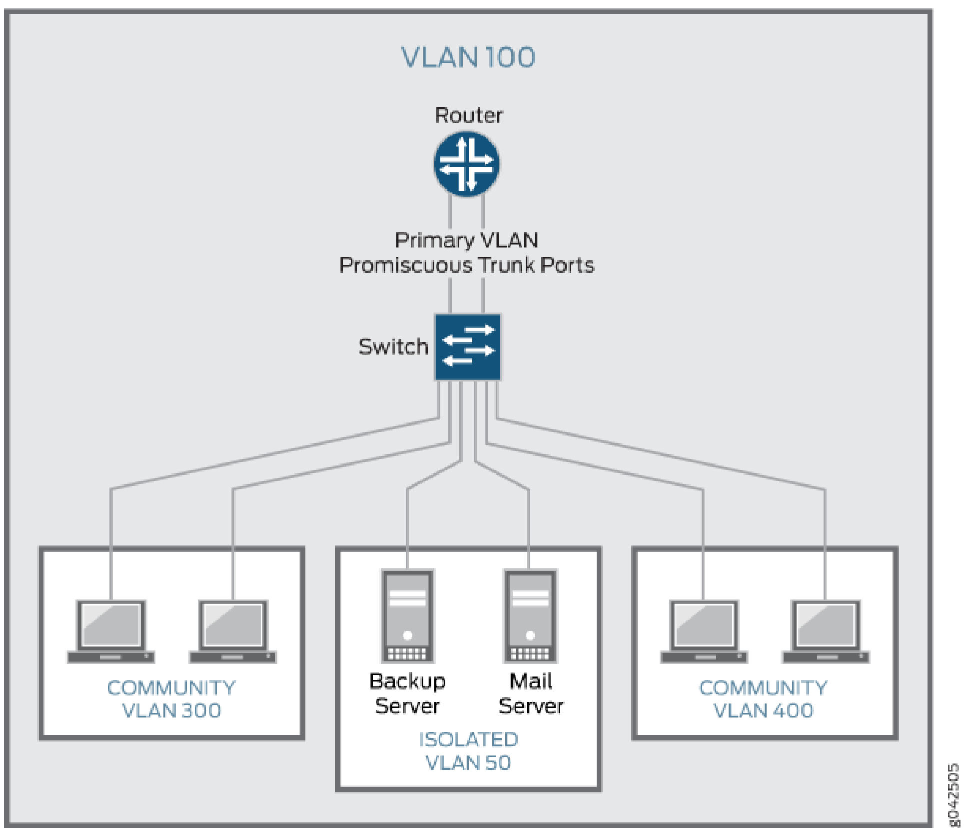


Figure 22 on page 282 shows a PVLAN spanning multiple switches, where the primary VLAN (VLAN **100**) contains two community VLANs (VLAN **300** and VLAN **400**) and one isolated VLAN (VLAN 200). It also shows that Switches 1 and 2 are connected through an interswitch link (PVLAN trunk link).

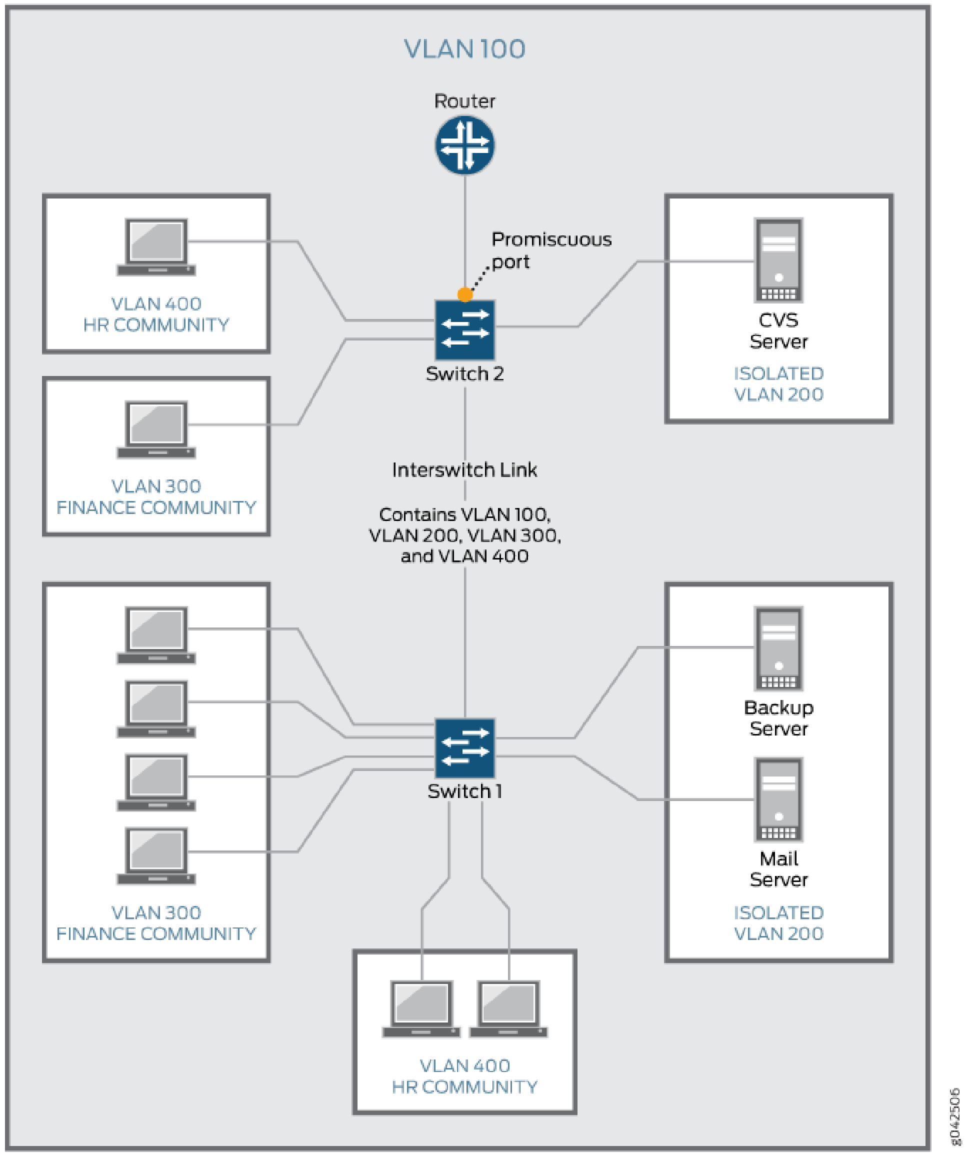
Figure 22: PVLAN Spanning Multiple EX Series Switches



Also, the PVLANs shown in Figure 21 on page 281 and Figure 22 on page 282 use a promiscuous port connected to a router as the means to route Layer 3 traffic among the community and isolated VLANs. Instead of using the promiscuous port connected to a router, you can configure an RVI on the switch in Figure 21 on page 281 or one of the switches shown in Figure 22 on page 282 (on some EX switches).

To route Layer 3 traffic between isolated and community VLANs, you must either connect a router to a promiscuous port, as shown in Figure 21 on page 281 and Figure 22 on page 282, or configure an RVI.

If you choose the RVI option, you must configure one RVI for the primary VLAN in the PVLAN domain. This RVI serves the entire PVLAN domain regardless of whether the domain includes one or more switches. After you configure the RVI, Layer 3 packets received by the secondary VLAN interfaces are mapped to and routed by the RVI.

When setting up the RVI, you must also enable proxy Address Resolution Protocol (ARP) so that the RVI can handle ARP requests received by the secondary VLAN interfaces.

For information about configuring PVLANs on a single switch and on multiple switches, see *Creating a Private VLAN on a Single EX Series Switch (CLI Procedure)* and *Creating a Private VLAN Spanning Multiple EX Series Switches (CLI Procedure)*, respectively. For information about configuring an RVI, see *Configuring a Routed VLAN Interface in a Private VLAN on an EX Series Switch (CLI Procedure)*.

Routing Between Isolated and Community VLANs

To route Layer 3 traffic between isolated and community VLANs, you must connect an external router or switch to a trunk port of the primary VLAN. The trunk port of the primary VLAN is a *promiscuous* port; therefore, it can communicate with *all* the ports in the PVLAN.

PVLANs Use 802.1Q Tags to Identify Packets

When packets are marked with a customer-specific 802.1Q tag, that tag identifies ownership of the packets for any switch or router in the network. Sometimes, 802.1Q tags are needed within PVLANs to keep track of packets from different subdomains. Table 18 on page 283 indicates when a VLAN 802.1Q tag is needed on the primary VLAN or on secondary VLANs.

Table 18: When VLANs in a PVLAN Need 802.1Q Tags

	On a Single Switch	On Multiple Switches
Primary VLAN	Specify an 802.1Q tag by setting a VLAN ID.	Specify an 802.1Q tag by setting a VLAN ID.
Secondary VLAN	No tag needed on VLANs.	VLANs need 802.1Q tags: • Specify an 802.1Q tag for each community VLAN by setting a VLAN ID. • Specify the 802.1Q tag for an isolation VLAN ID by setting an isolation ID.

PVLANs Use IP Addresses Efficiently

PVLANs provide IP address conservation and efficient allocation of IP addresses. In a typical network, VLANs usually correspond to a single IP subnet. In PVLANs, the hosts in all secondary VLANs belong to the same IP subnet because the subnet is allocated to the primary VLAN. Hosts within the secondary VLAN are assigned IP addresses based on IP subnets associated with the primary VLAN, and their IP subnet masking information reflects that of the primary VLAN subnet. However, each secondary VLAN is a separate broadcast domain.

PVLAN Port Types and Forwarding Rules

PVLANs can use up to six different port types. The network depicted in Figure 19 on page 279 uses a promiscuous port to transport information to the router, community ports to connect the finance and HR communities to their respective switches, isolated ports to connect the servers, and a PVLAN trunk port to connect the two switches. PVLAN ports have different restrictions:

- Promiscuous trunk port—A promiscuous port has Layer 2 communications with all the interfaces that are in the PVLAN, regardless of whether the interface belongs to an isolated VLAN or a community VLAN. A promiscuous port is a member of the primary VLAN, but is not included within one of the secondary subdomains. Layer 3 gateways, DHCP servers, and other trusted devices that need to communicate with endpoint devices are typically connected to a promiscuous port.
- PVLAN trunk link—The PVLAN trunk link, which is also known as the interswitch link, is required only when a PVLAN is configured to span multiple switches. The PVLAN trunk link connects the multiple switches that compose the PVLAN.
- PVLAN trunk port—A PVLAN trunk port is required in multiswitch PVLAN configurations to span the switches. The PVLAN trunk port is a member of all VLANs within the PVLAN (that is, the primary VLAN, the community VLANs, and the interswitch isolated VLAN), and it carries traffic from the primary VLAN and all secondary VLANs. It can communicate with all ports other than the isolated ports.

  Communication between a PVLAN trunk port and an isolated port is usually unidirectional. A PVLAN trunk port's membership in the interswitch isolated VLAN is egress-only, meaning that an isolated port can forward packets to a PVLAN trunk port, but a PVLAN trunk port does not forward packets to an isolated port (unless the packets ingressed on a promiscuous access port and are therefore being forwarded to all the secondary VLANs in the same primary VLAN as the promiscuous port).
- Secondary VLAN trunk port (not shown)—Secondary trunk ports carry secondary VLAN traffic. For a given private VLAN, a secondary VLAN trunk port can carry traffic for only one secondary VLAN. However, a secondary VLAN trunk port can carry traffic for multiple secondary VLANs as long as each secondary VLAN is a member of a different primary VLAN. For example, a secondary VLAN trunk port can carry traffic for a community VLAN that is part of primary VLAN pvlan100 and also carry traffic for an isolated VLAN that is part of primary VLAN pvlan400.
- Community port—Community ports communicate among themselves and with their promiscuous ports. Community ports serve only a select group of users. These interfaces are separated at Layer 2 from all other interfaces in other communities or isolated ports within their PVLAN.
- Isolated access port—Isolated ports have Layer 2 connectivity only with promiscuous ports and PVLAN trunk ports—an isolated port cannot communicate with another isolated port even if these two ports are members of the same isolated VLAN (or interswitch isolated VLAN) domain. Typically, a server, such as a mail server or a backup server, is connected on an isolated port. In a hotel, each room would typically be

connected on an isolated port, meaning that room-to-room communication is not possible, but each room can access the Internet on the promiscuous port.

- Promiscuous access port (not shown)—These ports carry untagged traffic. Traffic that ingresses on a promiscuous access port is forwarded to all secondary VLAN ports on the device. If traffic ingresses into the device on a VLAN-enabled port and egresses on a promiscuous access port, the traffic is untagged on egress. If tagged traffic ingresses on a promiscuous access port, the traffic is discarded.
- Interswitch link port—An interswitch link (ISL) port is a trunk port that connects two routers when a PVLAN spans those routers. The ISL port is a member of all VLANs within the PVLAN (that is, the primary VLAN, the community VLANs, and the isolated VLAN).

  Communication between an ISL port and an isolated port is unidirectional. An ISL port's membership in the interswitch isolated VLAN is egress-only, meaning that incoming traffic on the ISL port is never assigned to the isolated VLAN. An isolated port can forward packets to a PVLAN trunk port, but a PVLAN trunk port cannot forward packets to an isolated port. Table 20 on page 285 summarizes whether Layer 2 connectivity exists between the different types of ports.

Table 19 on page 285 summarizes Layer 2 connectivity between the different types of ports within a PVLAN on EX Series switches that support ELS.

Table 19: PVLAN Ports and Layer 2 Forwarding on EX Series switches that support ELS

From Port Type	To Isolated Ports?	To Promiscuous Ports?	To Community Ports?	To Inter-Switch Link Port?
Isolated	Deny	Permit	Deny	Permit
Promiscuous	Permit	Permit	Permit	Permit
Community 1	Deny	Permit	Permit	Permit

Table 20: PVLAN Ports and Layer 2 Connectivity

Port Type	Promiscuous Trunk	PVLAN Trunk	Secondary Trunk	Community	Isolated Access	Promiscuous access
Promiscuous trunk	Yes	Yes	Yes	Yes	Yes	Yes
PVLAN trunk	Yes	Yes	Yes	Yes—same community only	Yes	Yes
Secondary Trunk	Yes	Yes	No	Yes	No	Yes
Community	Yes	Yes	Yes	Yes—same community only	No	Yes
Isolated access	Yes	Yes—unidirectional only	No	No	No	Yes

Table 20: PVLAN Ports and Layer 2 Connectivity (continued)

Port Type	Promiscuous Trunk	PVLAN Trunk	Secondary Trunk	Community	Isolated Access	Promiscuous access
Promiscuous access	Yes	Yes	Yes	Yes	Yes	No

Table 21 on page 286 summarizes whether or not Layer 2 connectivity exists between the different types of ports within a PVLAN.

Table 21: PVLAN Ports and Layer 2 Connectivity on EX Series Switches without ELS Support

Port Type To: → From:↓	Promiscuous	Community	Isolated	PVLAN Trunk	RVI
Promiscuous	Yes	Yes	Yes	Yes	Yes
Community	Yes	Yes—same community only	No	Yes	Yes
Isolated	Yes	No	No	Yes NOTE: This communication is unidirectional.	Yes
PVLAN trunk	Yes	Yes—same community only	Yes NOTE: This communication is unidirectional.	Yes	Yes
RVI	Yes	Yes	Yes	Yes	Yes

As noted in Table 21 on page 286, Layer 2 communication between an isolated port and a PVLAN trunk port is unidirectional. That is, an isolated port can only send packets to a PVLAN trunk port, and a PVLAN trunk port can only receive packets from an isolated port. Conversely, a PVLAN trunk port cannot send packets to an isolated port, and an isolated port cannot receive packets from a PVLAN trunk port.

NOTE: If you enable **no-mac-learning** on a primary VLAN, all isolated VLANs (or the interswitch isolated VLAN) in the PVLAN inherit that setting. However, if you want to disable MAC address learning on any community VLANs, you must configure **no-mac-learning** on each of those VLANs.

Creating a PVLAN

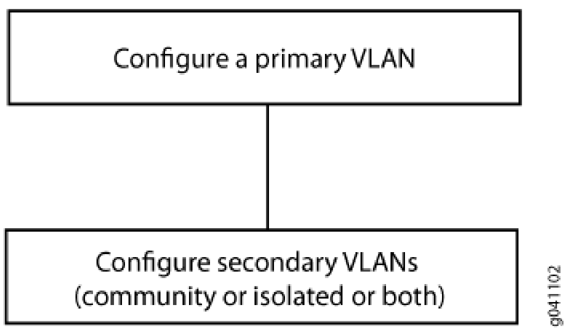
The flowchart shown in Figure 23 on page 287 gives you a general idea of the process for creating PVLANs. If you complete your configuration steps in the order shown, you will not violate these PVLAN rules. (In the PVLAN rules, configuring the PVLAN trunk port applies only to a PVLAN that spans multiple routers.)

- The primary VLAN must be a tagged VLAN.
- If you are going to configure a community VLAN ID, you must first configure the primary VLAN.
- If you are going to configure an isolation VLAN ID, you must first configure the primary VLAN.

NOTE: **Configuring a voice over IP (VoIP) VLAN on PVLAN interfaces is not supported.**

Configuring a VLAN on a single router is relatively simple, as shown in Figure 23 on page 287.

Figure 23: Configuring a PVLAN on a Single Switch



Configuring a primary VLAN consists of these steps:

1. Configure the primary VLAN name and 802.1Q tag.
2. Set **no-local-switching** on the primary VLAN.
3. Configure the promiscuous trunk port and access ports.
4. Make the promiscuous trunk and access ports members of the primary VLAN.

Within a primary VLAN, you can configure secondary community VLANs or secondary isolated VLANs or both. Configuring a secondary community VLAN consists of these steps:

1. Configure a VLAN using the usual process.

2. Configure access interfaces for the VLAN.

3. Assign a primary VLAN to the community VLAN,

Isolated VLANs are created internally when the isolated VLAN has access interfaces as members and the option **no-local-switching** is enabled on the primary VLAN.

802.1Q tags are required for interswitch isolated VLANs because IEEE 802.1Q uses an internal tagging mechanism by which a trunking device inserts a 4-byte VLAN frame identification tab into the packet header.

Trunk ports are only needed for multirouter PVLAN configurations—the trunk port carries traffic from the primary VLAN and all secondary VLANs.

Limitations of Private VLANs

The following constraints apply to private VLAN configurations:

- An access interface can belong to only one PVLAN domain, that is, it cannot participate in two different primary VLANs.
- A trunk interface can be a member of two secondary VLANs as long as the secondary VLANs are in two *different* primary VLANs. A trunk interface cannot be a member of two secondary VLANs that are in the *same* primary VLAN.
- A single region of Multiple Spanning Tree Protocol (MSTP) must be configured on all VLANs that are included within the PVLAN.
- VLAN Spanning Tree Protocol (VSTP) is not supported.
- IGMP snooping is not supported with private VLANs.
- Routed VLAN interfaces are not supported on private VLANs
- Routing between secondary VLANs in the same primary VLAN is not supported.
- Some configuration statements cannot be specified on a secondary VLAN. You can configure the following statements at the **[edit vlans *vlan-name* switch-options]** hierarchy level *only* on the primary PVLAN.
- If you want to change a primary VLAN to be a secondary VLAN, you must first change it to a normal VLAN and commit the change. For example, you would follow this procedure:
  1. Change the primary VLAN to be a normal VLAN.
  2. Commit the configuration.
  3. Change the normal VLAN to be a secondary VLAN.
  4. Commit the configuration.

Follow the same sequence of commits if you want to change a secondary VLAN to be a primary VLAN. That is, make the secondary VLAN a normal VLAN and commit that change and then change the normal VLAN to be a primary VLAN.

The following features are *not* supported on PVLANs on Junos switches with support for the ELS configuration style:

- DHCP security features (DHCP snooping, dynamic ARP inspection, IP source guard)
- Egress VLAN firewall filters
- Ethernet ring protection (ERP)
- Flexible VLAN tagging
- *global-mac-statistics*
- Integrated routing and bridging (IRB) interface
- Multicast snooping or IGMP snooping
- Multichassis link aggregation groups (MC-LAGs)
- Port mirroring
- Q-in-Q tunneling
- VLAN Spanning Tree Protocol (VSTP)
- Voice over IP (VoIP)

You can configure the following statements at the **[edit vlans *vlan-name* switch-options]** hierarchy level only on the primary PVLAN:

- *mac-table-size*
- *no-mac-learning*
- *mac-statistics*
- *interface-mac-limit*

Bridge Domains Setup in PVLANs on MX Series Routers

Bridge domain capabilities are used to support PVLANs on MX Series routers. Although this functionality is similar to the PVLAN mechanism on EX Series switches, the difference is that only one isolation VLAN can be configured for all isolated ports on MX routers instead of one isolation VLAN permissible per isolated port on EX Series switches.

Assume a sample deployment in which a primary VLAN named VP contains ports p1, p2, t1, t2, i1, i2, cx1, and cx2. The port types of these configured ports are as follows:

- Promiscuous ports = p1, p2
- ISL ports = t1, t2
- Isolated ports = i1, i2
- Community VLAN = Cx
- Community ports = cx1, cx2

Bridge domains are provisioned for each of the VLANs, namely, Vp, Vi, and Vcx. Assume the bridge domains to be configured as follows:

Vp—BD_primary_Vp (ports contained are p1, t1, i1, i2, cx1, cx2)

Vi—BD_isolate_Vi (ports contained are p1, t1, *i1, *i2)

Vcx—BD_community_Vcx (ports contained are p1, t1, cx1, cx2)

The bridge domains for community, primary, and isolated VLANs are automatically created by the system internally when you configure a bridge domain with a trunk interface, access interface, or interswitch link. The bridge domains contain the same VLAN ID corresponding to the VLANs. To use bridge domains for PVLANs, you must configure the following additional attributes:

- **community-vlans** option—This option is specified on all community vlans and for community BDs created internally.
- **isolated-vlan** option—This option denotes the vlan tag to be used for isolation BD created internally for each PVLAN/BD. This setting is required.
- **inter-switch-link** option with the **interface-mode trunk** statement at the **[edit interfaces interface-name family bridge]** or the **[edit interfaces interface-name unit logical-unit-number family bridge]** hierarchy level—This configuration specifies whether the particular interface assumes the role of interswitch link for the PVLAN domains of which it is a member.

You can use the **vlan-id** configuration statement for PVLAN ports to identify the port role. All the logical interfaces involved in PVLANs must be configured with a VLAN ID and the Layer 2 process uses this VLAN tag to classify a port role as promiscuous, isolated, or community port by comparing this value with the VLANs configured in the PVLAN bridge domain (using the **bridge-domains** statement at the **[edit]** hierarchy level). The ISL port role is identified by the **inter-switch-link** option. The VLAN ID for ISL port is required and must be set to to the primary VLAN ID. The ISL must be a trunk interface. A list of VLAN IDs is not needed because the Layer 2 process creates such a list internally based on PVLAN bridge domain configuration. For untagged promiscuous, isolated or community, logical interfaces or ports, access mode must be used as the interface mode. For tagged promiscuous, isolated, or community interfaces, trunk mode must be specified as the interface mode.

The bridge domain interface families are enhanced to include ingress-only and egress-only association. The association for the interface family bridge domain (IFBD) is created in the following manner:

- For BD_primary_Vp, IFBD for i1, i2, cx1 and cx2 are egress only.
- BD_isolate_Vi, IFBD for p1 will be egress only and for i1 and i2 are ingress only.
- BD_community_Vcx , IFBD for p1 are egress only. VLAN translation rules ensure the following VLAN mappings to work properly:
  - VLAN mapping on promiscuous ports: On promiscuous ports, the Vlan Vi is mapped to Vlan Vp on egress interfaces. Similarly on promiscuous ports, Vcx is also be mapped to Vp.
  - VLAN mapping on isolation ports: On tagged isolated ports, the VLAN tag, Vp, is mapped to Vi on egress.
  - VLAN mapping on community ports: On tagged community ports, the VLAN tag, Vp, is mapped to Vcx on egress.

A management bridge domain for PVLAN that exists only in the Layer 2 address learning process called PBD to denote bridge domain for VLAN is used by the system. This bridge domain has the same name as the user-configured name. Under this bridge domain, one primary PVLAN bridge domain for the primary vlan, one isolation bridge domain for the isolation vlan, and one community bridge domain for each community vlan are programmed internally. You might find separate bridge domains for the PVLAN ports to be useful if you want to configure a policy for a specific community VLAN or isolation VLAN.

The management bridge domain maintains a list to include all internal bridge domains that belong to this PVLAN bridge domain. Isolation and community bridge domains contain a pointer or a flag to indicate that this bridge domain is for PVLANs and maintain the information about the primary bridge domain index and primary VLAN. All this information is available across the bridge domain interfaces that are mapped to this bridge domain. MAC learning occurs only in the primary bridge domain and the MAC forwarding entry is programmed into the primary bridge domain only. As a result, the isolation bridge domain and all community bridge domains share the same forwarding table as the primary bridge domain.

For the isolation bridge domain, BD_isolate_Vi, isolation port i1 and i2 function as a non-local-switch access port and the flood group for this bridge domain contains only the promiscuous port, p1, and ISL ports, t1 and t2.

Bridging Functions With PVLANs

This topic describes how bridging is implemented on MX Series routers that will help with understanding the unique enhancements involved in implementing PVLAN bridging procedures. Consider two ports in a bridging domain with the respective ports on different FPCs and different Packet Forwarding Engines. When a packet enters a port, the following is the flow, assuming it is a tagged packet:

1. As the starting process, a VLAN lookup is performed to determine which bridging domain the packet forms. The result of the lookup identifies the bridging domain id (bd_id), mesh group id (mg_id). With these parameters, other related information configured for this bridging domain is discovered.
2. A source MAC address (SMAC) lookup is performed to find out whether this MAC addresses is learned or not. If it is not a learned address, an MLP packet (route for flooding traffic to MAC learning chips) is sent to all the other Packet Forwarding Engines that are mapped with this bridging domain. In addition, an MLP packet is also sent to the host.
3. A destination MAC address (DMAC) lookup using the tuple (bridge domain ID, VLAN, and destination MAC address).
4. If a match is observed for the MAC address, the result of the lookup points to the egress next-hop. The egress Packet Forwarding Engine is used to forward the packet.
5. If a miss occurs during the lookup, the flood next-hop is determined using the mesh group ID to flood the packet.

The following two significant conditions are considered in PVLAN bridging: Only a specific port to another port forwarding is permitted. A packet drop occurs on the egress interface after traversing and consuming the fabric bandwidth. To avoid traffic dropping, the decision on whether the packet needs to be dropped arrives before traversing the fabric, thereby saving the fabric bandwidth during DoS attacks. Because multiple overlapping bridge domains exist, which denotes that the same port (promiscuous or interswitch link) appears as a member in multiple bridge domains, the MAC addresses learned in one port must be visible to ports on another bridge domain. For example, a MAC address learned on a promiscuous port must be visible to both an isolated port (isolated bridge domain) and a community port (community bridge domain) on the various community bridge domains.

To resolve this problem, a shared VLAN is used for PVLAN bridging. In the shared VLAN model, all the MACs learned across all the ports are stored in the same bridge domain (primary VLAN BD) and same VLAN (primary VLAN). When the VLAN lookup is done for the packet, the PVLAN port, PVLAN bridge domain, and the PVLAN tag or ID are also used. The following processes occur with a shared VLAN methodology:

- A source MAC address (SMAC) lookup is performed to find out whether this MAC address is learned or not. If it is not a learned address, an MLP packet (route for flooding traffic to MAC learning chips) is sent to all the other Packet Forwarding Engines that are mapped with this bridging domain. In addition, an MLP packet is also sent to the host.
- A destination MAC address (DMAC) lookup using the tuple (bridge domain ID, VLAN, and destination MAC address).
- If a match is observed for the MAC address, the result of the lookup points to the egress next-hop. The egress Packet Forwarding Engine is used to forward the packet.
- If a miss occurs during the lookup, the flood next-hop is determined using the mesh group ID to flood the packet.
- If a match occurs, the group ID is derived from the VLAN lookup table and the following validation is performed to enforce primary VLAN forwarding:

```
Steps   Source  Destination      Action
Step 1     0    {*}       Permit
Step 2     {*}    0        Permit
Step 3     1    1        Drop
Step 4   X <-> Y (X > 1 and Y > 1 and X ≠ Y Drop
```

Here, {*} is a wildcard in regular expression notation referring to any value. Step 1 ensures all forwarding from promiscuous or inter switch link ports to any other port is permitted. Step 2 ensures all forwarding from any port to promiscuous or interswitch link ports is permitted. Step 3 ensures any isolated port to another isolated port is dropped. Step 4 ensures community port forwarding is permitted only within same community(X == Y) and dropped when its across community (X ff Y).

Flow of Frames on PVLAN Ports Overview

This topic describes the manner in which traffic that enters the different PVLAN ports, such as promiscuous, isolated, and interswitch link VLANs, is processed. Sample configuration scenarios are used to describe the transmission and processing of packets.

Assume a sample deployment in which a primary VLAN named VP contains ports, p1, p2, t1, t2, i1, i2, cx1, and cx2. The port types of these configured ports are as follows:

- Promiscuous ports = p1, p2
- ISL ports = t1, t2
- Isolated ports = i1, i2
- Community VLAN = Cx
- Community ports = cx1, cx2

Bridge domains are provisioned for each of the VLANs, namely, Vp, Vi, and Vcx. Assume the bridge domains to be configured as follows:

Vp—BD_primary_Vp (ports contained are p1, t1, i1, i2, cx1, cx2)

Vi—BD_isolate_Vi (ports contained are p1, t1, *i1, *i2)

Vcx—BD_community_Vcx (ports contained are p1, t1, cx1, cx2)

The bridge domains for community, primary, and isolated VLANs are automatically created by the system internally when you configure a bridge domain with a trunk interface, access interface, or interswitch link. The bridge domains contain the same VLAN ID corresponding to the VLANs. To use bridge domains for PVLANs, you must configure the following additional attributes:

Ingress Traffic on Isolated Ports

Consider an ingress port, i1. i1 is mapped to a bridge domain named BD_isolate_Vi. BD_isolate_Vi does not have any isolated ports as an egress member. Frames can only be sent in the egress direction on p1 and t1. When a frame is sent out on p1, it is tagged with the tag of Primary VLAN Vp. A VLAN translation of Vi to Vp is performed. When a frame is propagated out of t1, it is tagged with the tag Vi.

Ingress Traffic on Community ports

Consider an ingress port as cx1. cx1 is mapped to bridge domain BD_community_Vcx. Because of the VLAN membership with the bridge domain, frames can be sent out of p1, t1, cx1, cx2. When a frame is traversed out on p1, it is tagged with tag of Primary VLAN Vp [VLAN translation]. When a frame goes out of t1, it is tagged with tag Vcx.

Ingress Traffic on Promiscuous Ports

Consider a promisicious port p1 as the ingress port. p1 is mapped to bridge domain BD_primary_Vp. Frames can go out of any member port. When a frame goes out of t1, it is tagged with tag Vp. If another promiscuous port exists, that frame is also sent out with Vp.

Ingress Traffic on Interswitch Links

With the Vlan tag Vp, assume the ingress port as t1 mapped to bridge domain BD_primary_Vp. Frames can go out of any member port. When a frame goes out of p1, it is tagged with tag Vp. With the Vlan tag Vi, t1 mapped to bridge domain BD_isolate_Vi. The frame can not egress isolated ports as they are ingress-only members of BD_isolate_Vi. When a frame goes out on p1, it is tagged with tag of Primary VLAN Vp (VLAN translation). When a frame goes out of any other trunk port, it contains the Vi tag. With the Vlan tag Vcx, t1 is mapped to BD_community_Vcx. Frames can go out of p1, t1, cx1, and cx2. When a frame goes out on p1, it is tagged with the tag of primary VLAN Vp (VLAN translation).

Packet Forwarding in PVLANs

Consider a primary VLAN with the following configuration of ports:

```
Promiscuous  P1 P2
Inter Switch Link  L1 L2
Isolated     I1 I2
Community1    C11 C12
Community2    C21 C22
```

Internally, one global BD called the primary vlan BD is created that consists of all the ports. One isolation bridge domain consisting of all isolation ports in addition the promiscuous and ISL ports and one bridge domain per community is defined consisting of community ports in addition to the promiscuous and ISL ports internally configured in the system. The bridge domains with the PVLAN ports are as follows:

```
Primary Vlan BD P1 P2 L1 L2 I1 I2 C11 C12 C21 C22
Isolated BD           I1 I2 P1 P2 L1 L2
Community1 BD         C11 C12 P1 P2 L1 L2
Community 2 BD          C21 C22 P1 P2 L1 L2
```

The following PVLAN forwarding events take place among these ports with the appropriate VLAN translation as described in the following table:

Port Type To: → From:↓	Isolated	Community	Promiscuous	Inter-switch Link
Isolated	Dropped	Dropped	Primary VLAN tag to Isolation VLAN tag.	If received with the primary VLAN tag, translate to the isolation VLAN Tag; else dropped
Promiscuous	Dropped	No translation if it is the same community; else dropped.	Primary VLAN tag to Community VLAN tag.	If received with primary VLAN tag, translate to community VLAN tag; else no translation if received with same community vlan else dropped.
Community	Isolated VLAN tag to Primary VLAN tag	Community VLAN tag to Primary VLAN tag	No translation	If received with isolation or community VLAN tag, translate to Primary VLAN tag; else no translation
Interswitch Link	No translation	No translation	No translation	No translation

Guidelines for Configuring PVLANs on MX Series Routers

Consider the following guidelines while you configure PVLANs on MX Series routers that function in enhanced LAN mode:

- PVLANs are supported on MX80 routers, on MX240, MX480, and MX960 routers with DPCs in LAN mode, on MX Series routers with MPCs.
- Isolated ports, promiscuous ports, community ports, and interswitch links (ISL) adhere to the following rules of tagging and forwarding:
  - The frames received on the primary VLAN on promiscuous ports can go to any port.
  - The frames received on isolated ports can only go to promiscuous ports and ISL ports.
  - The frames received on community ports can only go to ports of the same community, promiscuous ports, and ISL ports.
  - The frames received on ISL ports with an isolation VLAN tag or ID can only go to promiscuous ports or ISL ports.
  - The frames received on ISL ports with a community VLAN tag can only go to promiscuous ports, ISL ports, or ports belonging to a corresponding community port.
  - The frames being sent out of promiscuous ports should have a primary VLAN tag or should be untagged. It is considered untagged if the port is configured as an untagged member of the primary VLAN. The frames going out of isolated or community ports are generally untagged. However, they can also be tagged depending on the port configuration. In any case, the configured VLAN tag must be the same as the related isolated VLAN tag or community VLAN tag.
  - The frames going out of ISL ports are tagged with the primary VLAN if they are received on a promiscuous port. An untagged frame cannot exit out of an ISL port in the context of a primary VLAN, isolated VLAN, or community VLAN, but for any other VLAN, it can be untagged depending on the configuration.
  - The frames going out of ISL ports are tagged with an isolated VLAN (isolation ID) if received on the isolated port.
  - The frames going out of ISL ports are tagged with the community VLAN tag, if it is received on the corresponding community port.
- Graceful Routing Engine switchover (GRES) is supported for PVLANs.
- A virtual switch instance that contains a bridge domain associated with logical interfaces is supported.
- Aggregated Ethernet (ae) interfaces for all types of ports are supported.
- Virtual private LAN service (VPLS) instances is not supported. Integrated routing and bridging (IRB) interfaces in PVLANs are supported.
- MX Series Virtual Chassis configuration is not supported.

- MC-LAG interfaces are not supported. All ports that are associated with PVLAN bridge domains cannot be mc-ae interfaces.
- IGMP snooping is not supported. Q-in-Q tunneling is not supported.

Configuring PVLANs on MX Series Routers in Enhanced LAN Mode

You can configure a private VLAN (PVLAN) on a single MX Series router to span multiple MX Series routers. VLANs limit broadcasts to specified users. You need to specify the interswitch link (ISL) for a PVLAN, the PVLAN port types, and secondary VLANs for the PVLAN. You must create a virtual switch routing instance with a bridge domain, and associate the interfaces with the bridge domain. You can specify the secondary VLANs as isolated or community VLANs in the bridge domain.

Before you begin configuring a PVLAN, make sure you have:

- Created and configured the necessary VLANs. See "Configuring VLAN and Extended VLAN Encapsulation" on page 256 and "Enabling VLAN Tagging" on page 247.
- Configured MX240, MX480, and MX960 routers to function in enhanced LAN mode by entering the **network-services lan** statement at the **[edit chassis]** hierarchy level.

  You must reboot the router when you configure or delete the enhanced LAN mode on the router. Configuring the **network-services lan** option implies that the system is running in the enhanced IP mode. When you configure a device to function in MX-LAN mode, only the supported configuration statements and operational show commands that are available for enabling or viewing in this mode are displayed in the CLI interface.

  If your system contains parameters that are not supported in MX-LAN mode in a configuration file, you cannot commit those unsupported attributes. You must remove the settings that are not supported and then commit the configuration. After the successful CLI commit, a system reboot is required for the attributes to become effective. Similarly, if you remove the **network-services lan** statement, the system does not run in MX-LAN mode. Therefore, all of the settings that are supported outside of the MX-LAN mode are displayed and are available for definition in the CLI interface. If your configuration file contains settings that are supported only in MX-LAN mode, you must remove those attributes before you commit the configuration. After the successful CLI commit, a system reboot is required for the CLI parameters to take effect. The Layer 2 Next-Generation CLI configuration settings are supported in MX-LAN mode. As a result, the typical format of CLI configurations might differ in MX-LAN mode.

To configure a PVLAN:

1. Create a promiscuous port for the PVLAN.

   [edit interfaces]
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge interface-mode trunk**

user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge vlan-id** *vlan-id*

2. Create the interswitch link (ISL) trunk port for the PVLAN.

   [edit interfaces]
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge interface-mode trunk inter-switch-link**
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge vlan-id** *vlan-id*

3. Create the isolated port for the PVLAN. The port is identified as an isolated port or a community port, based on the VLAN ID or the list of VLAN IDs to which the interface corresponds. For example, if you configure a port with a VLAN ID of 50, and if you specify a VLAN ID of 50 as the isolated VLAN or tag in the bridge domain, the port is considered as an isolation port.

   [edit interfaces]
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge interface-mode access**
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge vlan-id** *vlan-id*

4. Create the community port for the PVLAN. The port is identified as an isolated port or a community port, based on the VLAN ID or the list of VLAN IDs to which the interface corresponds. For example, if you configure a port with a VLAN ID of 50, and if you specify a VLAN ID of 50 as the community VLAN or tag in the bridge domain, the port is considered as a community port.

   [edit interfaces]
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge interface-mode access**
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge vlan-id** *vlan-id*

5. Create a virtual switch instance with a bridge domain and associate the logical interfaces.

   [edit routing-instances]
   user@host# **set** *routing-instance-name* **instance-type virtual-switch**
   user@host# **set** *routing-instance-name* **interface** *interface-name* **unit** *logical-unit-number*
   user@host# **set** *routing-instance-name* **bridge-domains** *bridge-domain-name*

6. Specify the primary, isolated, and community VLAN IDs, and associate the VLANs with the bridge domain.

   [edit routing-instances *instance-name* bridge-domains *bridge-domain-name*]
   user@host# **set vlan-id** *vlan-id*
   user@host# **set isolated-vlan** *vlan-id*
   user@host# **set community-vlans** *[number number-number]*

Example: Configuring PVLANs with Secondary VLAN Trunk Ports and Promiscuous Access Ports on a QFX Series Switch

This example shows how to configure secondary VLAN trunk ports and promiscuous access ports as part of a private VLAN configuration. Secondary VLAN trunk ports carry secondary VLAN traffic.

For a given private VLAN, a secondary VLAN trunk port can carry traffic for only one secondary VLAN. However, a secondary VLAN trunk port can carry traffic for multiple secondary VLANs as long as each secondary VLAN is a member of a different private (primary) VLAN. For example, a secondary VLAN trunk port can carry traffic for a community VLAN that is part of primary VLAN pvlan100 and also carry traffic for an isolated VLAN that is part of primary VLAN pvlan400.

To configure a trunk port to carry secondary VLAN traffic, use the *isolated* and **interface** statements, as shown in steps 12 and 13 of the example configuration for Switch 1.

NOTE: **When traffic egresses from a secondary VLAN trunk port, it normally carries the tag of the primary VLAN that the secondary port is a member of. If you want traffic that egresses from a secondary VLAN trunk port to retain its secondary VLAN tag, use the *extend-secondary-vlan-id* statement.**

A promiscuous access port carries untagged traffic and can be a member of only one primary VLAN. Traffic that ingresses on a promiscuous access port is forwarded to the ports of the secondary VLANs that are members of the primary VLAN that the promiscuous access port is a member of. This traffic carries the appropriate secondary VLAN tags when it egresses from the secondary VLAN ports if the secondary VLAN port is a trunk port.

To configure an access port to be promiscuous, use the *promiscuous* statement, as shown in step 12 of the example configuration for Switch 2.

If traffic ingresses on a secondary VLAN port and egresses on a promiscuous access port, the traffic is untagged on egress. If tagged traffic ingresses on a promiscuous access port, the traffic is discarded.

Requirements

This example uses the following hardware and software components:

- Two QFX devices
- Junos OS Release 12.2 or later for the QFX Series

Overview and Topology

Figure 24 on page 300 shows the topology used in this example. Switch 1 includes several primary and secondary private VLANs and also includes two secondary VLAN trunk ports configured to carry secondary VLANs that are members of primary VLANs pvlan100 and pvlan400.

Switch 2 includes the same private VLANs. The figure shows xe-0/0/0 on Switch 2 as configured with promiscuous access ports or promiscuous trunk ports. The example configuration included here configures this port as a promiscuous access port.

The figure also shows how traffic would flow after ingressing on the secondary VLAN trunk ports on Switch 1.

Figure 24: PVLAN Topology with Secondary VLAN Trunk Ports and Promiscuous Access Port

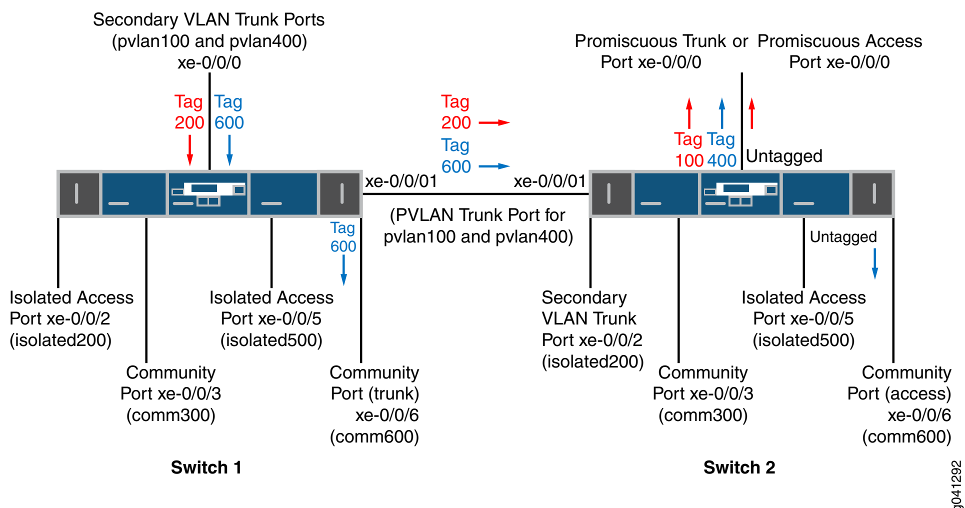

Table 22 on page 300 and Table 23 on page 301 list the settings for the example topology on both switches.

Table 22: Components of the Topology for Configuring a Secondary VLAN Trunk on Switch 1

Component	Description
pvlan100, ID 100	Primary VLAN
pvlan400, ID 400	Primary VLAN
comm300, ID 300	Community VLAN, member of pvlan100
comm600, ID 600	Community VLAN, member of pvlan400
isolation-vlan-id 200	VLAN ID for isolated VLAN, member of pvlan100

Table 22: Components of the Topology for Configuring a Secondary VLAN Trunk on Switch 1 (continued)

Component	Description
isolation–vlan-id 500	VLAN ID for isolated VLAN, member of pvlan400
xe-0/0/0.0	Secondary VLAN trunk port for primary VLANs pvlan100 and pvlan400
xe-0/0/1.0	PVLAN trunk port for primary VLANs pvlan100 and pvlan400
xe-0/0/2.0	Isolated access port for pvlan100
xe-0/0/3.0	Community access port for comm300
xe-0/0/5.0	Isolated access port for pvlan400
xe-0/0/6.0	Community trunk port for comm600

Table 23: Components of the Topology for Configuring a Secondary VLAN Trunk on Switch 2

Component	Description
pvlan100, ID 100	Primary VLAN
pvlan400, ID 400	Primary VLAN
comm300, ID 300	Community VLAN, member of pvlan100
comm600, ID 600	Community VLAN, member of pvlan400
isolation-vlan-id 200	VLAN ID for isolated VLAN, member of pvlan100
isolation–vlan-id 500	VLAN ID for isolated VLAN, member of pvlan400
xe-0/0/0.0	Promiscuous access port for primary VLANs pvlan100
xe-0/0/1.0	PVLAN trunk port for primary VLANs pvlan100 and pvlan400
xe-0/0/2.0	Secondary trunk port for isolated VLAN, member of pvlan100
xe-0/0/3.0	Community access port for comm300
xe-0/0/5.0	Isolated access port for pvlan400
xe-0/0/6.0	Community access port for comm600

Configuring the PVLANs on Switch 1

CLI Quick Configuration

To quickly create and configure the PVLANs on Switch 1, copy the following commands and paste them into a switch terminal window:

```
[edit]
```

```
set interfaces xe-0/0/0 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/1 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/1 unit 0 family ethernet-switching vlan members pvlan100
set interfacesxe-0/0/1 unit 0 family ethernet-switching vlan members pvlan400
set interfaces xe-0/0/2 unit 0 family ethernet-switching port-mode access
set interfaces xe-0/0/3 unit 0 family ethernet-switching port-mode access
set interfaces xe-0/0/5 unit 0 family ethernet-switching port-mode access
set interfaces xe-0/0/6 unit 0 family ethernet-switching port-mode trunk
set vlans pvlan100 vlan-id 100
set vlans pvlan400 vlan-id 400
set vlans pvlan100 pvlan
set vlans pvlan400 pvlan
set vlans pvlan100 interface xe-0/0/1.0 pvlan-trunk
set vlans pvlan400 interface xe-0/0/1.0 pvlan-trunk
set vlans comm300 vlan-id 300
set vlans comm300 primary-vlan pvlan100
set vlans comm300 interface xe-0/0/3.0
set vlans comm600 vlan-id 600
set vlans comm600 primary-vlan pvlan400
set vlans comm600 interface xe-0/0/6.0
set vlans pvlan100 pvlan isolation-vlan-id 200
set vlans pvlan400 pvlan isolation-vlan-id 500
set vlans pvlan100 interface xe-0/0/0.0 isolated
set vlans pvlan400 interface xe-0/0/0.0 isolated
set vlans comm600 interface xe-0/0/0.0
set vlans pvlan100 interface xe-0/0/2.0 isolated
set vlans pvlan400 interface xe-0/0/5.0 isolated
```

Step-by-Step Procedure

To configure the private VLANs and secondary VLAN trunk ports:

1. Configure the interfaces and port modes:

```
[edit interfaces]
user@switch# set xe-0/0/0 unit 0 family ethernet-switching port-mode trunk
user@switch# set xe-0/0/1 unit 0 family ethernet-switching port-mode trunk
user@switch# set xe-0/0/1 unit 0 family ethernet-switching vlan members pvlan100
user@switch# set xe-0/0/1 unit 0 family ethernet-switching vlan members pvlan400
user@switch# set xe-0/0/2 unit 0 family ethernet-switching port-mode access
user@switch# set xe-0/0/3 unit 0 family ethernet-switching port-mode access
user@switch# set xe-0/0/5 unit 0 family ethernet-switching port-mode access
user@switch# set xe-0/0/6 unit 0 family ethernet-switching port-mode access
```

2. Create the primary VLANs:

```
[edit vlans]
user@switch# set pvlan100 vlan-id 100
user@switch# set pvlan400 vlan-id 400
```

NOTE: Primary VLANs must always be tagged VLANs, even if they exist on only one device.

3. Configure the primary VLANs to be private:

```
[edit vlans]
user@switch# set pvlan100 pvlan
user@switch# set pvlan400 pvlan
```

4. Configure the PVLAN trunk port to carry the private VLAN traffic between the switches:

```
[edit vlans]
user@switch# set pvlan100 interface xe-0/0/1.0 pvlan-trunk
user@switch# set pvlan400 interface xe-0/0/1.0 pvlan-trunk
```

5. Create secondary VLAN comm300 with VLAN ID 300:

```
[edit vlans]
user@switch# set comm300 vlan-id 300
```

6. Configure the primary VLAN for comm300:

```
[edit vlans]
user@switch# set comm300 primary-vlan pvlan100
```

7. Configure the interface for comm300:

```
[edit vlans]
user@switch# set comm300 interface xe-0/0/3.0
```

8. Create secondary VLAN comm600 with VLAN ID 600:

```
[edit vlans]
user@switch# set comm600 vlan-id 600
```

9. Configure the primary VLAN for comm600:

```
[edit vlans]
user@switch# set comm600 primary-vlan pvlan400
```

10. Configure the interface for comm600:

```
[edit vlans]
user@switch# set comm600 interface xe-0/0/6.0
```

11. Configure the interswitch isolated VLANs:

```
[edit vlans]
user@switch# set pvlan100 pvlan isolation-vlan-id 200
user@switch# set pvlan400 pvlan isolation-vlan-id 500
```

NOTE: When you configure a secondary VLAN trunk port to carry an isolated VLAN, you must also configure an *isolation-vlan-id*. This is true even if the isolated VLAN exists only on one switch.

12. Enable trunk port xe-0/0/0 to carry secondary VLANs for the primary VLANs:

```
[edit vlans]
user@switch# set pvlan100 interface xe-0/0/0.0 isolated
user@switch# set pvlan400 interface xe-0/0/0.0 isolated
```

13. Configure trunk port xe-0/0/0 to carry comm600 (member of pvlan400):

```
[edit vlans]
user@switch# set comm600 interface xe-0/0/0.0
```

NOTE: You do not need to explicitly configure xe-0/0/0 to carry the isolated VLAN traffic (tags 200 and 500) because all the isolated ports in pvlan100 and pvlan400—including xe-0/0/0.0—are automatically included in the isolated VLANs created when you configured **isolation-vlan-id 200** and **isolation-vlan-id 500**.

14. Configure xe-0/0/2 and xe-0/0/6 to be isolated:

```
[edit vlans]
user@switch# set pvlan100 interface xe-0/0/2.0 isolated
user@switch# set pvlan400 interface xe-0/0/5.0 isolated
```

Results

Check the results of the configuration on Switch 1:

```
[edit]
user@switch# show
interfaces {
  xe-0/0/0 {
    unit 0 {
      family ethernet-switching {
        port-mode trunk;
        vlan {
          members pvlan100;
          members pvlan400;
        }
      }
    }
  }
  xe-0/0/1 {
    unit 0 {
      family ethernet-switching {
        port-mode trunk;
        vlan {
          members pvlan100;
          members pvlan400;
        }
      }
```

```
        }
      }
      xe-0/0/2 {
        unit 0 {
          family ethernet-switching {
            port-mode access;
          }
        }
      }
      xe-0/0/3 {
        unit 0 {
          family ethernet-switching {
            port-mode access;
          }
        }
      }
      xe-0/0/5 {
        unit 0 {
          family ethernet-switching {
            port-mode access;
          }
        }
      }
      xe-0/0/6 {
        unit 0 {
          family ethernet-switching {
            port-mode trunk;
          }
        }
      }
    }
    vlans {
      comm300 {
        vlan-id 300;
          interface {
          xe-0/0/3.0;
        }
        primary-vlan pvlan100;
      }
      comm600 {
        vlan-id 600;
          interface {
          xe-0/0/6.0;
        }
        primary-vlan pvlan400;
      }
      pvlan100 {
        vlan-id 100;
        interface {
          xe-0/0/0.0;
          xe-0/0/2.0;
          xe-0/0/3.0;
          xe-0/0/1.0 {
            pvlan-trunk;
          }
        }
```

```
      no-local-switching;
      isolation-id 200;
    }
    pvlan400 {
      vlan-id 400;
      interface {
        xe-0/0/0.0;
        xe-0/0/5.0;
        xe-0/0/6.0;
        xe-0/0/1.0 {
          pvlan-trunk;
        }
      }
      no-local-switching;
      isolation-id 500;
    }
  }
```

Configuring the PVLANs on Switch 2

The configuration for Switch 2 is almost identical to the configuration for Switch 1. The most significant difference is that xe-0/0/0 on Switch 2 is configured as a promiscuous trunk port or a promiscuous access port, as Figure 24 on page 300 shows. In the following configuration, xe-0/0/0 is configured as a promiscuous access port for primary VLAN pvlan100.

If traffic ingresses on VLAN-enabled port and egresses on a promiscuous access port, the VLAN tags are dropped on egress and the traffic is untagged at that point. For example, traffic for comm600 ingresses on the secondary VLAN trunk port configured on xe-0/0/0.0 on Switch 1 and carries tag 600 as it is forwarded through the secondary VLAN. When it egresses from xe-0/0/0.0 on Switch 2, it will be untagged if you configure xe-0/0/0.0 as a promiscuous access port as shown in this example. If you instead configure xe-0/0/0.0 as a promiscuous trunk port (port-mode trunk), the traffic for comm600 carries its primary VLAN tag (400) when it egresses.

CLI Quick Configuration

To quickly create and configure the PVLANs on Switch 2, copy the following commands and paste them into a switch terminal window:

```
[edit]
set interfaces xe-0/0/0 unit 0 family ethernet-switching port-mode access
set interfaces xe-0/0/1 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/1 unit 0 family ethernet-switching vlan members pvlan100
set interfaces xe-0/0/1 unit 0 family ethernet-switching vlan members pvlan400
set interfaces xe-0/0/2 unit 0 family ethernet-switching port-mode trunk
set interfaces xe-0/0/3 unit 0 family ethernet-switching port-mode access
set interfaces xe-0/0/5 unit 0 family ethernet-switching port-mode access
set interfaces xe-0/0/6 unit 0 family ethernet-switching port-mode access
set vlans pvlan100 vlan-id 100
set vlans pvlan400 vlan-id 400
set vlans pvlan100 pvlan
set vlans pvlan400 pvlan
set vlans pvlan100 interface xe-0/0/1.0 pvlan-trunk
set vlans pvlan400 interface xe-0/0/1.0 pvlan-trunk
set vlans comm300 vlan-id 300
```

```
set vlans comm300 primary-vlan pvlan100
set vlans comm300 interface xe-0/0/3.0
set vlans comm600 vlan-id 600
set vlans comm600 primary-vlan pvlan400
set vlans comm600 interface xe-0/0/6.0
set vlans pvlan100 pvlan isolation-vlan-id 200
set vlans pvlan400 pvlan isolation-vlan-id 500
set vlans pvlan100 interface xe-0/0/0.0 promiscuous
set vlans pvlan100 interface xe-0/0/2.0 isolated
set vlans pvlan400 interface xe-0/0/5.0 isolated
```

Step-by-Step Procedure

To configure the private VLANs and secondary VLAN trunk ports:

1. Configure the interfaces and port modes:

```
[edit interfaces]
user@switch# set xe-0/0/0 unit 0 family ethernet-switching port-mode access
user@switch# set xe-0/0/1 unit 0 family ethernet-switching port-mode trunk
user@switch# set xe-0/0/1 unit 0 family ethernet-switching vlan members pvlan100
user@switch# set xe-0/0/1 unit 0 family ethernet-switching vlan members pvlan400
user@switch# set xe-0/0/2 unit 0 family ethernet-switching port-mode trunk
user@switch# set xe-0/0/3 unit 0 family ethernet-switching port-mode access
user@switch# set xe-0/0/5 unit 0 family ethernet-switching port-mode access
user@switch# set xe-0/0/6 unit 0 family ethernet-switching port-mode access
```

2. Create the primary VLANs:

```
[edit vlans]
user@switch# set pvlan100 vlan-id 100
user@switch# set pvlan400 vlan-id 400
```

3. Configure the primary VLANs to be private:

```
[edit vlans]
user@switch# set pvlan100 pvlan
user@switch# set pvlan400 pvlan
```

4. Configure the PVLAN trunk port to carry the private VLAN traffic between the switches:

```
[edit vlans]
user@switch# set pvlan100 interface xe-0/0/1.0 pvlan-trunk
user@switch# set pvlan400 interface xe-0/0/1.0 pvlan-trunk
```

5. Create secondary VLAN comm300 with VLAN ID 300:

```
[edit vlans]
user@switch# set comm300 vlan-id 300
```

6. Configure the primary VLAN for comm300:

```
[edit vlans]
user@switch# set comm300 primary-vlan pvlan100
```

7. Configure the interface for comm300:

```
[edit vlans]
user@switch# set comm300 interface xe-0/0/3.0
```

8. Create secondary VLAN comm600 with VLAN ID 600:

```
[edit vlans]
user@switch# set comm600 vlan-id 600
```

9. Configure the primary VLAN for comm600:

```
[edit vlans]
user@switch# set comm600 primary-vlan pvlan400
```

10. Configure the interface for comm600:

```
[edit vlans]
user@switch# set comm600 interface xe-0/0/6.0
```

11. Configure the interswitch isolated VLANs:

```
[edit vlans]
user@switch# set pvlan100 pvlan isolation-vlan-id 200
user@switch# set pvlan400 pvlan isolation-vlan-id 500
```

12. Configure access port xe-0/0/0 to be promiscuous for pvlan100:

```
[edit vlans]
user@switch# set pvlan100 interface xe-0/0/0.0 promiscuous
```

NOTE: A promiscuous access port can be a member of only one primary VLAN.

13. Configure xe-0/0/2 and xe-0/0/6 to be isolated:

```
[edit vlans]
user@switch# set pvlan100 interface xe-0/0/2.0 isolated
user@switch# set pvlan400 interface xe-0/0/5.0 isolated
```

Results

Check the results of the configuration on Switch 2:

```
[edit]
user@switch# show
interfaces {
  xe-0/0/0 {
    unit 0 {
      family ethernet-switching {
        port-mode access;
        vlan {
```

```
                members pvlan100;
              }
            }
          }
        }
          xe-0/0/1 {
          unit 0 {
            family ethernet-switching {
              port-mode trunk;
              vlan {
                members pvlan100;
                members pvlan400;
              }
            }
          }
        }
        xe-0/0/2 {
          unit 0 {
            family ethernet-switching {
              port-mode trunk;
            }
          }
        }
        xe-0/0/3 {
          unit 0 {
            family ethernet-switching {
              port-mode access;
            }
          }
        }
        xe-0/0/5 {
          unit 0 {
            family ethernet-switching {
              port-mode access;
            }
          }
        }
        xe-0/0/6 {
          unit 0 {
            family ethernet-switching {
              port-mode access;
            }
          }
        }
      vlans {
        comm300 {
          vlan-id 300;
            interface {
            xe-0/0/3.0;
          }
          primary-vlan pvlan100;
        }
        comm600 {
          vlan-id 600;
            interface {
            xe-0/0/6.0;
```

```
        }
        primary-vlan pvlan400;
      }
      pvlan100 {
        vlan-id 100;
        interface {
          xe-0/0/0.0;
          xe-0/0/2.0;
          xe-0/0/3.0;
          xe-0/0/1.0 {
            pvlan-trunk;
          }
        }
        no-local-switching;
        isolation-id 200;
      }
      pvlan400 {
        vlan-id 400;
        interface {
          xe-0/0/5.0;
          xe-0/0/6.0;
          xe-0/0/1.0 {
            pvlan-trunk;
          }
        }
        no-local-switching;
        isolation-id 500;
      }
    }
```

Verification

To confirm that the configuration is working properly, perform these tasks:

- Verifying That the Private VLAN and Secondary VLANs Were Created on page 310
- Verifying The Ethernet Switching Table Entries on page 311

Verifying That the Private VLAN and Secondary VLANs Were Created

Purpose Verify that the primary VLAN and secondary VLANs were properly created on Switch 1.

Action Use the **show vlans** command:

```
user@switch> show vlans private-vlan

Name              Role        Tag     Interfaces
pvlan100          Primary     100     xe-0/0/0.0, xe-0/0/1.0, xe-0/0/2.0,
xe-0/0/3.0
__iso_pvlan100__  Isolated    200     xe-0/0/2.0
comm300           Community   300     xe-0/0/3.0

pvlan400          Primary     400     xe-0/0/0.0, xe-0/0/1.0, xe-0/0/5.0,
xe-0/0/6.0
__iso_pvlan400__  Isolated    500     xe-0/0/5.0
comm600           Community   600    xe-0/0/6.0
```

Meaning The output shows that the private VLANs were created and identifies the interfaces and secondary VLANs associated with them.

Verifying The Ethernet Switching Table Entries

Purpose Verify that the Ethernet switching table entries were created for primary VLAN pvlan100.

Action Show the Ethernet switching table entries for pvlan100.

```
user@switch> show ethernet-switching table vlan pvlan100 private-vlan
Ethernet-switching table: 0 unicast entries
  pvlan100              *                 Flood          - All-members
  pvlan100              00:10:94:00:00:02 Learn            xe-0/0/2.0
  __iso_pvlan100__      *                 Flood          - All-members
  __iso_pvlan100__      00:10:94:00:00:02 Replicated      - xe-0/0/2.0
```

IRB Interfaces in Private VLANs on MX Series Routers

You can configure integrated routing and bridging (IRB) interfaces in a private VLAN (PVLAN) on a single MX router to span multiple MX routers. PVLANs limit the communication within a VLAN by restricting traffic flows through their member switch ports (which are called “private ports”) so that these ports communicate only with a specified uplink trunk port or with specified ports within the same VLAN. IRB provides simultaneous support for Layer 2 bridging and Layer 3 routing on the same interface. IRB enables you to route packets to another routed interface or to another bridge domain that has an IRB interface configured. You configure a logical routing interface by including the **irb** statement at the **[edit interfaces]** hierarchy level and include that interface in the bridge domain.

PVLANs are supported on MX80 routers, on MX240, MX480, and MX960 routers with DPCs in LAN mode, and on MX Series routers with MPC1, MPC2, and Adaptive Services PICs. This functionality is supported only on MX240, MX480, and MX960 routers that function in enhanced LAN mode (by entering the **network-services lan** statement at the **[edit chassis]** hierarchy level).

IRB in PVLANs replaces the external router used for routing across VLANs. The routing operations in the absence of IRB occur through external router connected to promiscuous port. This behavior takes care of all the routed frames for all the ports defined under the PVLAN domain. In this case, no layer 3 exchange occurs on MX Series routers in enhanced

LAN mode for this PVLAN bridge domain. In the case of IRB, the Layer 3 interface is associated with the primary VLAN that is configured and is considered to be a single Layer 3 interface for the entire PVLAN domain. The ingress routed traffic from all ports in the PVLAN domain needs to be mapped to this IRB interface. The egress of the IRB interface take places under the PVLAN. For a PVLAN domain spanning multiple switches, only one IRB interface can be configured in one switch. This IRB interface represent whole PVLAN domain to interact with the Layer 3 domains. An IRB interface only associates with the primary bridge domain and all Layer 3 forwarding occurs only in the primary bridge domain. When a Layer 3 packet is received in an isolated port or a promiscuous port, the device first locates the secondary bridge domain, based on secondary bridge domain to find primary bridge domain identifier. If the destination MAC address is the local IRB MAC address, the microcode transmits the packet to IRB interface associated with primary bridge domain for further processing. The same procedure occurs for receiver Layer 3 packets in an interswitch link (ISL) port with the isolated or community VLAN tag.

For the ingress Layer 3 packet with Layer 3 forwarding logic sent to IRB interfaces associated with a PVLAN bridge domain, the device processes and determines the ARP entry to send packet to the related interface that might be an isolated port or a community port. The microcode appends or translates the packet VLAN ID to the isolation or community vlan ID based on the port type. The VLAN ID is removed if the related port is untagged. A special operational case exists for Layer 3 packets that are forwarded to remote isolated or community port through the ISL link. The Layer 3 packet might contain the primary bridge domain VLAN ID and the remote node performs the translation or pop operation when it sends the packet out on the related port. This method of processing is different from Layer 2 domains. Because all forwarding base on ARP must be unicast traffic and in the remote node, the port that must be used to forward is known and the transmission of PVLAN ID occurs properly.

An ARP entry carries only the primary bridge domain information. When an ARP response is received from an isolated port or a promiscuous port, the system identifies the secondary bridge domain, and based on the secondary bridge domain, it attempts to retrieve the primary bridge domain identifier. ARP packets eventually reach the IRB interface associated with the primary bridge domain. The kernel considers this ARP packet as a normal bridge domain and creates and maintains the ARP entry only for the primary bridge domain. The same procedure is adopted for ARP request packets that are destined for the local IRB MAC address. The response is transmitted through the IRB interface and appropriate VLAN translation or a pop operation is performed, depending on the received interface.

Guidelines for Configuring IRB Interfaces in PVLANs on MX Series Routers

Keep the following points in mind when you configure IRB interfaces for PVLANs:

- All of the IP applications such as IP multicast, IPv4, IPv6, and VRRP that are compatible with IRB in normal bridge domains function properly when IRB for PVLAN bridge domains is configured.
- MC-LAG interfaces are not supported. All ports that are associated with PVLAN bridge domains cannot be mc-ae interfaces.

- IGMP snooping is not supported.
- A virtual switch instance that contains a bridge domain associated with logical interfaces is supported.
- Q-in-Q tunneling is not supported.
- Logical systems are not supported.
- Virtual private LAN service (VPLS) and Etherent VPN (EVPN) in virtual switch routing instances are not supported. A validation is performed if you attempt to configure Layer 3 interfaces in a secondary VLAN.
- MX Series Virtual Chassis configuration is not supported.

Forwarding of Packets Using IRB Interfaces in PVLANs

This topic describes how PVLAN packet forwarding operates with IRB interfaces on MX Series routers in enhanced LAN mode. The IRB interface operates as a Layer 3 gateway for all members of a bridging domain. All the members of bridging domain are assumed to be in the same subnet as the subnet of the IRB interface, which works as a gateway.

Consider a sample deployment scenario in which two routers, Router1 and Router2, are configured with a PVLAN. On Router1, the promiscuous port is P1, interswitch link is L1, isolated port is I1, and two community ports are C11 and C21. Similarly, on Router2, the promiscuous port is P2, interswitch link is L2, isolated port is I2, and two community ports are C12 and C22. In the example configuration, the two routers are interconnected through an ISL link, L1 with L2. A PVLAN domain is defined across these two routers encompassing a subdomain of isolated ports (I1, I2), and Community1 ports (C11, C12), and Community2 ports (C21, C22). Because all the ports are in the same subnet, without IRB, switching capability works across ports, across routers following the PVLAN rules. When the end-host needs to reach out cross the subnet, you must configure IRB on the bridging domain. From an end-host perspective, to reach out across the bridging domain, it needs to be configured with the IRB IP address as the default gateway address. All Layer 3 connectivity is established by processing ARP request and ARP responses. The following sections describe the different scenarios encountered for Layer 3 traffic support in PVLANs.

Incoming ARP Requests on PVLAN Ports

ARP requests enter a PVLAN port as broadcast packets. All packets that enter in the ingress direction of a PVLAN domain contain their bridge domain ID translated into the primary VLAN bridge domain ID. In this case, the bridge domain ID contained in the ARP packet is also translated be to the bridge domain ID of the primary VLAN. When IRB is configured in a bridging domain, the IRB MAC address is added to the MAC table as an eligible destination MAC address on the primary VLAN bridge domain ID. The ARP request is flooded to all ports of the secondary bridging domain in which it was received and, in addition, a copy is sent to the IRB logical interface.

When an IRB logical interface receives this packet, it sends the packet to the host as an ARP packet with the primary BD and the Layer 2 logical interface on which it is received. The PVLAN domain learns the source MAC address of the ARP packet and the kernel learns the sender IP of the ARP packet, and triggers a next-hop installation. If the ARP request is destined for IRB IP address, then an ARP response is sent. If proxy ARP is enabled on IRB, IRB responds with an ARP reply if the destination IP address is known.

The preceding configuration case describes a scenario the ARP request came on Local PVLAN port. If the ARP request is received on a remote PVLAN port, then it is flooded on all the ports of the remote PVLAN domain. Because IRB is configured only on one router of the PVLAN domain, on the remote PVLAN, the flooding is on all the ports. As part of the flooding in the remote PVLAN domain, a copy of the packet is sent to the ISL port. The ISL port processes this packet as though it was received on the local isolated port or community port and the aforementioned method of processing takes place

Outgoing ARP Responses on PVLAN Ports

When a ARP request is received in the kernel, both the bridge domain ID and the receiving Layer 2 logical interface are transmitted. A next-hop installation is triggered to create a next-hop to the Layer 2 logical interface for the sender IP address with the IRB MAC Address as the destination MAC address and the sender MAC address as the source MAC address, with both these addresses appearing as Layer 2 rewrite during the next-hop. If the ARP request queries for the IRB IP address, then an ARP response is sent to the receiving Layer 2 logical interface. If the ARP request queries for an IP address other than the IRB IP address, it is processed as though proxy ARP is enabled on IRB or it is discarded. Because all ARP requests are processed as being received on the primary VLAN, the response is also sent with the primary VLAN. However, when it reaches the receiving Layer 2 logical interface, the appropriate VLAN translation takes place.

The preceding scenario describes an ARP response being sent on a local PVLAN port. If the ARP request is received from a remote PVLAN domain, the receiving Layer 2 logical interface is the ISL port. In this case, the ARP response is sent to the ISL port, on the remote PVLAN domain, the ARP response received on the ISL port is forwarded to the same port where the ARP request is received. This behavior is possible because the source MAC address of the ARP request is learned on the shared VLAN.

Outgoing ARP Requests on PVLAN Ports

When IRB has to advertise a ARP request, it uses the kernel flood next-hop for the primary VLAN and floods to all the ports in the local PVLAN domain. The receiving ISL port also floods the packet to the remote PVLAN domain. Although the ARP request is constructed with the primary VLAN, in the egress direction, appropriate VLAN translation or VLAN pop is performed using the specific port.

Incoming ARP Responses on PVLAN Ports

ARP responses are unicast packets with the destination MAC address as the IRB MAC Address. When such a packet is received on the local PVLAN domain where IRB is enabled, it is forwarded to the IRB logical interface. When the packet arrives at the IRB logical interface, it is propagated to the host. The kernel triggers a next-hop installation with the appropriate Layer 2 rewrite. This operation works properly for ARP responses received on the local PVLAN port. If the ARP response is received on a remote PVLAN port, it is forwarded similar to a normal Layer 2 packet because IRB is not enabled in such a scenario. When the ARP request is sent out from the local PVLAN domain, the receiving ISL port in the remote PVLAN domain might have learned the IRB MAC address on that port, and this address is used to forward the packet to the IRB logical interface.

Receipt of Layer 3 Packets on PVLAN Ports

The packet is received with the IRB MAC address as the destination MAC address and it is processed through the IRB logical interface. The packet is forwarded in the same manner as a regular IP packet.

Configuring IRB Interfaces in PVLAN Bridge Domains on MX Series Routers in Enhanced LAN Mode

You can configure integrated routing and bridging (IRB) interfaces in a private VLAN (PVLAN) on a single MX router to span multiple MX routers. PVLANs limit the communication within a VLAN by restricting traffic flows through their member switch ports (which are called “private ports”) so that these ports communicate only with a specified uplink trunk port or with specified ports within the same VLAN. IRB provides simultaneous support for Layer 2 bridging and Layer 3 routing on the same interface. IRB enables you to route packets to another routed interface or to another bridge domain that has an IRB interface configured. You configure a logical routing interface and include that interface in the virtual switch instance that contains the bridge domain. You can specify the secondary VLANs as isolated or community VLANs in the bridge domain.

Before you begin configuring a PVLAN, make sure you have:

- Created and configured the necessary VLANs. See “Configuring VLAN and Extended VLAN Encapsulation” on page 256 and “Enabling VLAN Tagging” on page 247.
- Configured MX240, MX480, and MX960 routers to function in enhanced LAN mode by entering the **network-services lan** statement at the **[edit chassis]** hierarchy level.

  You must reboot the router when you configure or delete the enhanced LAN mode on the router. Configuring the **network-services lan** option implies that the system is running in the enhanced IP mode. When you configure a device to function in MX-LAN mode, only the supported configuration statements and operational show commands that are available for enabling or viewing in this mode are displayed in the CLI interface.

  If your system contains parameters that are not supported in MX-LAN mode in a configuration file, you cannot commit those unsupported attributes. You must remove the settings that are not supported and then commit the configuration. After the successful CLI commit, a system reboot is required for the attributes to become effective. Similarly, if you remove the **network-services lan** statement, the system does not run in MX-LAN mode. Therefore, all of the settings that are supported outside of the MX-LAN mode are displayed and are available for definition in the CLI interface. If your configuration file contains settings that are supported only in MX-LAN mode, you must remove those attributes before you commit the configuration. After the successful CLI commit, a system reboot is required for the CLI parameters to take effect. The Layer 2 Next-Generation CLI configuration settings are supported in MX-LAN mode. As a result, the typical format of CLI configurations might differ in MX-LAN mode.

To configure an IRB interface in a PVLAN bridge domain associated with a virtual switch instance:

1. Create a promiscuous port for the PVLAN.

   [edit interfaces]
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge interface-mode trunk**
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge vlan-id** *vlan-id*

2. Create the interswitch link (ISL) trunk port for the PVLAN.

   [edit interfaces]
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge interface-mode trunk inter-switch-link**
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge vlan-id** *vlan-id*

3. Create the isolated port for the PVLAN. The port is identified as an isolated port or a community port, based on the VLAN ID or the list of VLAN IDs to which the interface corresponds. For example, if you configure a port with a VLAN ID of 50, and if you specify a VLAN ID of 50 as the isolated VLAN or tag in the bridge domain, the port is considered as an isolation port.

   [edit interfaces]
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge interface-mode access**
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge vlan-id** *vlan-id*

4. Create the community port for the PVLAN. The port is identified as an isolated port or a community port, based on the VLAN ID or the list of VLAN IDs to which the interface corresponds. For example, if you configure a port with a VLAN ID of 50, and if you specify a VLAN ID of 50 as the community VLAN or tag in the bridge domain, the port is considered as a community port.

   [edit interfaces]
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge interface-mode access**
   user@host# **set interface** *interface-name* **unit** *logical-unit-number* **family bridge vlan-id** *vlan-id*

5. Create a virtual switch instance with a bridge domain and associate the logical interfaces.

   [edit routing-instances]
   user@host# **set** *routing-instance-name* **instance-type virtual-switch**
   user@host# **set** *routing-instance-name* **interface** *interface-name* **unit** *logical-unit-number*
   user@host# **set** *routing-instance-name* **bridge-domains** *bridge-domain-name*

6. Create an IRB interface and specify the IRB interface in the bridge domain associated with the virtual switch instance. IRB provides simultaneous support for Layer 2 bridging and Layer 3 IP routing on the same interface. IRB enables you to route local packets to another routed interface or to another bridge domain that has a Layer 3 protocol configured.

   [edit]
   user@host# **set interfaces irb unit *logical-unit-number* family *family-name* address *ip-address***
   [edit routing-instances *instance-name* bridge-domains *bridge-domain-name*]
   user@host# **set routing-interface irb unit *logical-unit-number***

7. Specify the primary, isolated, and community VLAN IDs, and associate the VLANs with the bridge domain.

   [edit routing-instances *instance-name* bridge-domains *bridge-domain-name*]
   user@host# **set vlan-id *vlan-id***
   user@host# **set isolated-vlan *vlan-id***
   user@host# **set community-vlans *[number number-number]***

Example: Configuring an IRB Interface in a Private VLAN on a Single MX Series Router

For security reasons, it is often useful to restrict the flow of broadcast and unknown unicast traffic and to even limit the communication between known hosts. The private VLAN (PVLAN) feature on MX Series routers allows an administrator to split a broadcast domain into multiple isolated broadcast subdomains, essentially putting a VLAN inside a VLAN.

This example describes how to create an integrated routing and bridging (IRB) interface in a PVLAN bridge domain associated with a virtual switch instance on a single MX Series router:

NOTE: **Configuring a voice over IP (VoIP) VLAN on PVLAN interfaces is not supported.**

Requirements

This example uses the following hardware and software components:

- One MX Series router in enhanced LAN mode.

- Junos OS Release 15.1 or later for MX Series routers

Before you begin configuring a PVLAN, make sure you have:

- Created and configured the necessary VLANs. See "Configuring VLAN and Extended VLAN Encapsulation" on page 256 and "Enabling VLAN Tagging" on page 247.
- Configured MX240, MX480, and MX960 routers to function in enhanced LAN mode by entering the **network-services lan** statement at the **[edit chassis]** hierarchy level.

Overview and Topology

In a large office with multiple buildings and VLANs, you might need to isolate some workgroups or other endpoints for security reasons or to partition the broadcast domain. This configuration example shows a simple topology to illustrate how to create a PVLAN with one primary VLAN and four community VLANs, as well as two isolated ports.

Assume a sample deployment in which a primary VLAN named VP contains ports, p1, p2, t1, t2, i1, i2, cx1, and cx2. The port types of these configured ports are as follows:

- Promiscuous ports = p1, p2
- ISL ports = t1, t2
- Isolated ports = i1, i2
- Community VLAN = Cx
- Community ports = cx1, cx2

An IRB interface, irb.0, is configured and mapped to the bridge domain in the virtual switch instance.

Bridge domains are provisioned for each of the VLANs, namely, Vp, Vi, and Vcx. Assume the bridge domains to be configured as follows:

Vp—BD_primary_Vp (ports contained are p1, t1, i1, i2, cx1, cx2)

Vi—BD_isolate_Vi (ports contained are p1, t1, *i1, *i2)

Vcx—BD_community_Vcx (ports contained are p1, t1, cx1, cx2)

The bridge domains for community, primary, and isolated VLANs are automatically created by the system internally when you configure a bridge domain with a trunk interface, access interface, or interswitch link. The bridge domains contain the same VLAN ID corresponding to the VLANs. To use bridge domains for PVLANs, you must configure the following additional attributes:

Configuration

To configure an IRB interface in a PVLAN, perform these tasks:

CLI Quick Configuration

To quickly create and configure a PVLAN and include an IRB interface in a PVLAN bridge domain associated with a virtual switch instance, copy the following commands and paste them into the router terminal window:

Configuring an IRB Interface

```
set interfaces irb unit 0 family inet address 22.22.22.1/24
```

Configuring Promiscuous, ISL, Isolated, and Community Ports

```
set interfaces ge-0/0/9 unit 0 family bridge interface-mode trunk
set interfaces ge-0/0/9 unit 0 family bridge vlan-id 100
set interfaces ge-0/0/13 unit 0 family bridge interface-mode trunk
set interfaces ge-0/0/13 unit 0 family bridge vlan-id 100
set interfaces ge-0/0/10 unit 0 family bridge interface-mode access
set interfaces ge-0/0/10 unit 0 family bridge vlan-id 10
set interfaces ge-0/0/12 unit 0 family bridge interface-mode access
set interfaces ge-0/0/12 unit 0 family bridge vlan-id 10
set interfaces ge-0/0/1 unit 0 family bridge interface-mode access
set interfaces ge-0/0/1 unit 0 family bridge vlan-id 50
set interfaces ge-0/0/2 unit 0 family bridge interface-mode access
set interfaces ge-0/0/2 unit 0 family bridge vlan-id 50
set interfaces ge-0/0/3 unit 0 family bridge interface-mode access
set interfaces ge-0/0/3 unit 0 family bridge vlan-id 60
set interfaces ge-0/0/4 unit 0 family bridge interface-mode access
set interfaces ge-0/0/4 unit 0 family bridge vlan-id 60
```

Configuring a Virtual Switch Instance With Bridge Domain Interfaces

```
set routing-instances vs-1 instance-type virtual-switch
set routing-instances vs-1 interface ge-0/0/1.0
set routing-instances vs-1 interface ge-0/0/2.0
set routing-instances vs-1 interface ge-0/0/3.0
set routing-instances vs-1 interface ge-0/0/4.0
set routing-instances vs-1 interface ge-0/0/9.0
set routing-instances vs-1 interface ge-0/0/10.0
set routing-instances vs-1 interface ge-0/0/12.0
set routing-instances vs-1 interface ge-0/0/13.0
set routing-instances vs-1 bridge-domains bd1
```

Specify the IRB Interface and Primary, Isolated, and Community VLAN IDs in the Bridge Domain

```
set routing-instances vs1 bridge-domains bd1 vlan-id 100
set routing-instances vs1 bridge-domains bd1 isolated-vlan 10
set routing-instances vs1 bridge-domains bd1 community-vlans [50 60]
set routing-instances vs1 bridge-domains bd1 routing-interface irb.0
```

Step-by-Step Procedure

To configure the interswitch link (ISL) for a PVLAN, the PVLAN port types, and secondary VLANs for the PVLAN:

1. Create an IRB interface.

```
[edit interfaces]
user@host# set interfaces irb unit 0 family inet address 22.22.22.1/24
```

2. Create a promiscuous port for the PVLAN.

```
[edit interfaces]
user@host# set ge-0/0/9 unit 0 family bridge interface-mode trunk
user@host# set ge-0/0/9 unit 0 family bridge vlan-id 100
```

3. Create the interswitch link (ISL) trunk port for the PVLAN.

```
[edit interfaces]
user@host# set ge-0/0/13 unit 0 family bridge interface-mode trunk inter-switch-link
user@host# set ge-0/0/13 unit 0 family bridge vlan-id 100
```

4. Create the isolated ports for the PVLAN.

```
[edit interfaces]
user@host# set ge-0/0/10 unit 0 family bridge interface-mode access
user@host# set ge-0/0/10 unit 0 family bridge vlan-id 10
user@host# set ge-0/0/12 unit 0 family bridge interface-mode access
user@host# set ge-0/0/12 unit 0 family bridge vlan-id 10
```

5. Create the community ports for the PVLAN.

```
[edit interfaces]
user@host# set ge-0/0/1 unit 0 family bridge interface-mode access
user@host# set ge-0/0/1 unit 0 family bridge vlan-id 50
user@host# set ge-0/0/2 unit 0 family bridge interface-mode access
user@host# set ge-0/0/2 unit 0 family bridge vlan-id 50
user@host# set ge-0/0/3 unit 0 family bridge interface-mode access
user@host# set ge-0/0/3 unit 0 family bridge vlan-id 60
user@host# set ge-0/0/4 unit 0 family bridge interface-mode access
user@host# set ge-0/0/4 unit 0 family bridge vlan-id 60
```

6. Create a virtual switch instance with a bridge domain and associate the logical interfaces.

```
[edit routing-instances]
user@host# set vs-1 instance-type virtual-switch
user@host# set vs-1 interface ge-0/0/1.0
user@host# set vs-1 interface ge-0/0/2.0
user@host# set vs-1 interface ge-0/0/3.0
user@host# set vs-1 interface ge-0/0/4.0
user@host# set vs-1 interface ge-0/0/9.0
user@host# set vs-1 interface ge-0/0/10.0
user@host# set vs-1 interface ge-0/0/12.0
user@host# set vs-1 interface ge-0/0/13.0
user@host# set vs-1 bridge-domains bd1
```

7. Specify the IRB interface, primary, isolated, and community VLAN IDs, and associate the VLANs with the bridge domain.

```
[edit routing-instances vs1 bridge-domains bd1]
user@host# set vlan-id 100
user@host# set isolated-vlan 10
user@host# set community-vlans [50 60]
user@host# set routing-interface irb.0
```

Results

Check the results of the configuration:

```
[edit]
[interfaces]
    ge-0/0/9 {
        unit 0 {
            family bridge {
  interface-mode trunk;
      vlan-id 100;            Promiscuous port by vlan id
            }
        }
    }

    ge-0/0/13 {
        unit 0 {
            family bridge {
  interface-mode trunk inter-switch-link;   ISL trunk
  vlan-id 100;
            }
        }
    }

    ge-0/0/10 {
        unit 0 {
            family bridge {
                  interface-mode access;
                  vlan-id 10;             isolated port by vlan ID
             }
        }
    }

    ge-0/0/12 {
        unit 0 {
            family bridge {
                  interface-mode access;
                  vlan-id 10;             isolated port by vlan ID
             }
        }
    }
    ge-0/0/1 {
        unit 0 {
            family bridge {

                   routing-interface irb.0 /* IRB interface */
      }
}
}
```

Verification

To confirm that the configuration is working properly, perform these tasks:

- Verifying That the Private VLAN and Secondary VLANs Were Created on page 323

Verifying That the Private VLAN and Secondary VLANs Were Created

Purpose Verify that the primary VLAN and secondary VLANs were properly created on the switch.

Action Use the **show bridge domain** command:

```
user@host> show bridge domain
Routing instance          Bridge domain            VLAN ID     Interfaces
default-switch                   bd1-primary-100          100
                                                                     ge-0/0/9.0
                                          ge-0/0/10.0
                                                                    ge-0/0/12.0
                                                                    ge-0/0/13.0
                                                                     ge-0/0/1.0
                                                                     ge-0/0/2.0
                                                                     ge-0/0/3.0

                                                                     ge-0/0/4.0
default-switch                 bd1-isolation-10          10
                                                                       ge-0/0/9.0
                                                                        ge-0/0/10.0
                                                                      ge-0/0/12.0
                                                                      ge-0/0/13.0

default-switch                   bd1-comunity-50          50
                                                                       ge-0/0/9.0
                                                                        ge-0/0/13.0
                                                                        ge-0/0/1.0
                                                                       ge-0/0/2.0

default-switch                    bd1-comunity-60          60
                                                                       ge-0/0/9.0
                                                                        ge-0/0/13.0
                                                                     ge-0/0/3.0
                                                                      ge-0/0/4.0
```

Meaning The output shows that the primary VLAN was created and identifies the interfaces and secondary VLANs associated with it.

CHAPTER 13

Configuring Layer 2 Bridging Interfaces

Layer 2 Bridging Interfaces Overview

Bridging operates at Layer 2 of the OSI reference model while routing operates at Layer 3. A set of logical ports configured for bridging can be said to constitute a bridging domain.

A bridging domain can be created by configuring a routing instance and specifying the instance-type as **bridge**.

Integrated routing and bridging (IRB) is the ability to:

- Route a packet if the destination MAC address is the MAC address of the router and the packet **ethertype** is IPv4, IPv6, or MPLS.
- Switch all multicast and broadcast packets within a bridging domain at layer 2.
- Route a copy of the packet if the destination MAC address is a multicast address and the **ethertype** is IPv4 or IPv6.
- Switch all other unicast packets at Layer 2.
- Handle supported Layer 2 control packets such as STP and LACP.
- Handle supported Layer 3 control packets such as OSPF and RIP.

Configuring Layer 2 Bridging Interfaces

Integrated routing and bridging interfaces are logical Layer 3 VLAN interfaces that route traffic between bridge domains (VLANs). So, an IRB logical interface is usually associated with a bridge domain or VLAN. The IRB logical interface also functions as the gateway IP address for the other devices on the same sub-network that are associated with the same VLAN. IRB interfaces support Layer 2 bridging and Layer 3 routing on the same interface. As a result, IRB interfaces enable the router to act both as a router and as a Layer 2 switch at the same time.

NOTE: **If the status of all Layer 2 logical interfaces in the bridge domain is down, the status of the irb logical interface is also down.**

To configure an IRB logical interface:

1. In configuration mode, at the [**edit bridge-domains**] hierarchy level, configure the bridge domain by specifying the name of the bridge and the VLAN ID.

   [edit bridge-domains]
   user@host# set *bridge-domain-name* vlan-id *vlan-id*

2. Configure an interface in trunk mode and include the interface in the appropriate bridge domain using the **vlan-id-list** command at the [**edit interfaces**] hierarchy level.

   [edit interfaces]
   user@host# set *interfacetype-fpc/pic/port* vlan-tagging
   user@host# set *interfacetype-fpc/pic/port* unit *logical-unit-number* family bridge interface-mode trunk
   user@host# set *interfacetype-fpc/pic/port* unit *logical-unit-number* family bridge vlan-id-list *vlan-id*

3. Configure the IRB interface at the [**edit interfaces**] hierarchy level and specify the associated IP address.

   [edit interfaces]
   user@host# set interfaces irb unit *logical-unit-number* family inet address *address*

4. Configure the IRB interface as the routing interface for the bridge domain at the [**edit bridge-domains**] hierarchy level.

   [edit bridge-domains]
   user@host# set *bridge-domain- name* vlan-id *vlan-id* routing-interface irb.*logical-interface-number*

Example: Configuring the MAC Address of an IRB Interface

This example shows how to configure the media access control (MAC) address of an integrated routing and bridging (IRB) interface for devices with Modular Port Concentrator (MPC) cards . An IRB interface is a Layer 3 routing interface that is used in a bridge domain or virtual private LAN service (VPLS) routing.

Requirements

This example requires the following hardware and software components:

- MX Series routers with MPC cards.
- Junos OS Release 13.2 or later running on all devices.

Overview

Junos OS Release 13.2 and later support the assignment of MAC addresses to IRB logical interfaces. The IRB logical interfaces provide support for simultaneous Layer 2 bridging and Layer 3 routing within the same bridge domain. Packets that arrive on an interface of the bridge domain are either switched or routed, based on the destination MAC address of the packet. The packets with the router's Layer 2 virtual MAC address, which is manually configured, are switched to Layer 2 interfaces.

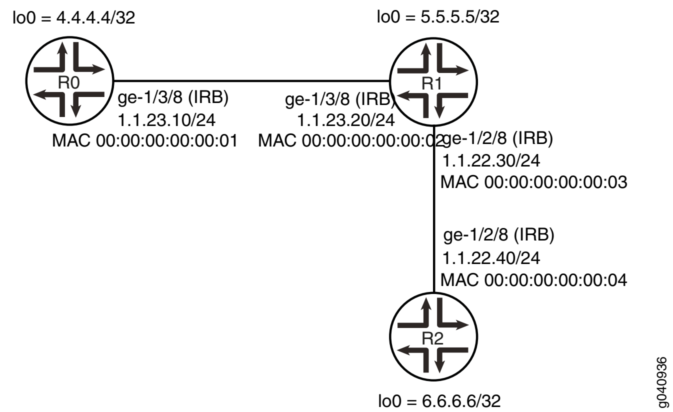
Configuring a MAC address of an IRB logical interface allows the use of a transparent firewall between two VLANs on the same switch. When both VLANs are on the same subnet and traffic from one VLAN needs to go through the firewall to the host on the other VLAN, then the VLAN tag is changed to communicate with the host on the other VLAN.

Before the introduction of this feature, if the MAC address of an IRB logical interface was the same for both VLANs, the firewall dropped the traffic. This new feature allows you to configure distinct MAC addresses for different VLANs, which facilitates the exchange of traffic between two VLANs on the same switch.

In case of VPLS multihoming, if there is a failover of the primary provider edge (PE) router to a secondary PE router, the MAC address of an IRB changes. The hosts connected to the customer edge (CE) router must change their Address Resolution Protocol (ARP) for IRB's IP and MAC address. This feature allows you to configure the same MAC address for IRB interfaces in both the primary and secondary PE routers and eliminates the need for changing the ARP binding of the IRB logical interface in CE routers, in case of a failover.

Figure 25 on page 328 shows the sample topology.

Figure 25: Configuring the MAC Address of an IRB Interface



In this example you configure MAC address of IRB logical interfaces.

Configuration

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

Router R0

```
set interfaces ge-1/3/8 vlan-tagging
set interfaces ge-1/3/8 encapsulation flexible-ethernet-services
set interfaces ge-1/3/8 unit 10 encapsulation vlan-bridge

Configuring the MAC Address of an IRB Interface

Step-by-Step Procedure

The following example requires that you navigate various levels in the configuration hierarchy. For information about navigating the CLI, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

NOTE: Repeat this procedure for Juniper Networks Routers R1 and R2, modifying the appropriate interface names, addresses, and any other parameters for each router.

To configure the MAC address of an IRB interface on Router R0:

1. Configure the physical interfaces.

```
[edit interfaces ge-1/3/8]
user@R0# set vlan-tagging
user@R0# set encapsulation flexible-ethernet-services
user@R0# set unit 10 encapsulation vlan-bridge
user@R0# set unit 10 vlan-id 10
```

2. Configure the IRB logical interface.

```
[edit interfaces irb]
user@R0# set unit 10 family inet address 1.1.23.1/24
user@R0# set unit 10 family mpls
user@R0# set unit 10 mac 00:00:00:00:00:01

[edit interfaces]
user@R0# set lo0 unit 10 family inet address 4.4.4.4/32
```

3. Configure the RSVP protocol.

```
[edit protocols rsvp]
user@R0# set interface irb.10
```

4. Configure the MPLS protocol.

```
[edit protocols mpls]
user@R0# set label-switched-path R0-1-R2 to 6.6.6.6
user@R0# set label-switched-path R0-1-R2 install 6.6.6.6/32 active
user@R0# set label-switched-path R0-1-R2 no-cspf
user@R0# set interface irb.10
user@R0# set interface irb.10
```

5. Configure the BGP protocol.

```
[edit protocols BGP]
user@R0# set group ibgp type internal
user@R0# set group ibgp local-address 4.4.4.4
user@R0# set group ibgp neighbor 6.6.6.6
```

6. Configure the OSPF protocol.

```
[edit protocols ospf]
user@R0# set area 0.0.0.0 interface irb.10
user@R0# set area 0.0.0.0 interface lo0.10 passive
```

7. Configure the LDP protocol.

```
[edit protocols ldp]
user@R0# set interface irb.10
user@R0# set interface lo0.10
```

8. Configure the autonomous system (AS) number.

```
[edit routing-options]
user@R0# set autonomous-system 400
```

9. Configure the bridge domains.

```
[edit]
user@R0# set bridge-domains lsbd1 vlan-id 10
user@R0# set bridge-domains lsbd1 interface ge-1/3/8.10
user@R0# set bridge-domains lsbd1 routing-interface irb.10
```

Results

From configuration mode, enter the **show interfaces**, **show protocols** and **show bridge-domains**, commands and confirm your configuration. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```
user@R0# show interfaces
ge-1/3/8 {
   unit 10 {
      encapsulation vlan-bridge;
      vlan-id 10;
   }
}
irb {
   unit 10 {
      family inet {
         mtu 1450;
         address 1.1.1.1/24;
         address 1.1.23.1/24;
      }
```

```
            family mpls;
            mac 00:00:00:00:00:01;
        }
    }
    lo0 {
        unit 10 {
            family inet {
                address 4.4.4.4/32;
            }
        }
    }
    user@R0# show protocols
    rsvp {
        interface irb.10;
    }
        mpls {
            label-switched-path R0-1-R2 {
                to 6.6.6.6;
                install 6.6.6.6/32 active;
                no-cspf;
            }
            interface irb.10;
        }
        bgp {
            group ibgp {
                type internal;
                local-address 4.4.4.4;
                neighbor 6.6.6.6;
            }
        }
        ospf {
            area 0.0.0.0 {
                interface irb.10;
                interface lo0.10 {
                    passive;
                }
            }
        }
        ldp {
            interface irb.10;
            interface lo0.10;
        }
    user@R0# show bridge-domains
    lsbd1 {
        vlan-id 10;
        interface ge-1/3/8.10;
        routing-interface irb.10;
    }
```

If you are done configuring the devices, commit the configuration.

```
user@host# commit
```

Verification

Confirm that the configuration is working properly.

- Verifying the MAC Address of the IRB Interface on page 333

Verifying the MAC Address of the IRB Interface

Purpose Verify that the specified MAC address is assigned to the IRB interface.

Action From operational mode, run the **show interfaces irb** command on the device.

user@host# **show interfaces irb**

```
Physical interface: irb, Enabled, Physical link is Up

CHAPTER 14

Configuring Link Layer Discovery Protocol

LLDP Overview

The Link Layer Discovery Protocol (LLDP) is an industry-standard, vendor-neutral method to allow networked devices to advertise capabilities, identity, and other information onto a LAN. The Layer 2 protocol, detailed in IEEE 802.1AB-2005, replaces several proprietary protocols implemented by individual vendors for their equipment.

LLDP allows network devices that operate at the lower layers of a protocol stack (such as Layer 2 bridges and switches) to learn some of the capabilities and characteristics of LAN devices available to higher layer protocols, such as IP addresses. The information gathered through LLDP operation is stored in a network device and is queried with SNMP. Topology information can also be gathered from this database.

Some of the information that can be gathered by LLDP (only minimal information is mandatory) is:

- System name and description
- Port name and description
- VLAN name and identifier
- IP network management address
- Capabilities of the device (for example, switch, router, or server)
- MAC address and physical layer information
- Power information
- Link aggregation information

NOTE: LLDP media endpoint discovery (LLDP-MED) is not supported on T Series routers.

LLDP frames are sent at fixed intervals on each port that runs LLDP. LLDP protocol data units (LLDP PDUs) are sent inside Ethernet frames and identified by their destination Media Access Control (MAC) address (**01:80:C2:00:00:0E**) and Ethertype (**0x88CC**). Mandatory information supplied by LLDP is chassis ID, port ID, and a time-to-live value for this information.

LLDP is a powerful way to allow Layer 2 devices to gather details about other network-attached devices.

Configuring LLDP

You configure LLDP by including the **lldp** statement and associated parameters at the **[edit protocols]** hierarchy level. The complete set of LLDP statements follows:

```
lldp {
  advertisement-interval seconds;
  disable;
  hold-multiplier number;
  interface (all | interface-name) {
    disable;
  }
  lldp-configuration-notification-interval seconds;
  management-address ip-management-address;;
  port-description-type {
    interface-alias;
    interface-description;
  }
  port-id-subtype {
    interface-name;
    locally-assigned;
  }
  ptopo-configuration-maximum-hold-time seconds;
  ptopo-configuration-trap-interval seconds;
  traceoptions {
    file filename <files number> <size size> <world-readable | no-world-readable>;
    flag flag <flag-modifier> <disable>;
  }
  transmit-delay seconds
}
```

The following statements have default values:

- **advertisement-interval**—The default value is 30 seconds. The allowable range is from 5 through 32768 seconds.
- **hold-multiplier**—The default values is 4. The allowable range is from 2 through 10.
- **ptopo-configuration-maximum-hold-time**—The default value is 300 seconds. The allowable range is from 1 through 2147483647 seconds.
- **transmit-delay**—The default values is 2 seconds. The allowable range is from 1 through 8192 seconds.

The following statements must be explicitly configured:

- **lldp-configuration-notification-interval**—The allowable range is from 0 through 3600 seconds. There is no default value.
- **ptopo-configuration-trap-interval**—The allowable range is from 1 through 2147483647 seconds. There is no default value.

LLDP is enabled on all interfaces by default. If it is disabled, you can enable LLDP by configuring it on all interfaces or on specific interfaces.

NOTE: **The interface-name must be the physical interface (for example, ge-1/0/0) and not a logical interface (unit).**

- To configure LLDP on all interfaces:

  ```
  [edit protocols lldp]
  user@switch# set interface all
  ```

- To configure LLDP on a specific interface:

  ```
  [edit protocols lldp]
  user@switch# set interface interface-name
  ```

To disable LLDP, include the **disable** option:

- To disable LLDP on all interfaces:

  ```
  [edit protocols lldp]
  user@switch# set interface all disable
  ```

- To disable LLDP on a specific interface:

  ```
  [edit protocols lldp]
  user@switch# set interface interface-name disable
  ```

Starting with Junos OS Release 14.2, you can configure management interfaces, such as fxp0 or me0, on MX Series routers to send LLDP frames to and receive LLDP frames from neighboring LLDP interfaces. To configure the management interfaces, nclude the **interface** ***interface-name*** statement at the **[edit protocols lldp]** and **[edit routing-instances**

routing-instance-name **protocols lldp]** hierarchy levels. By default, the functionality to send LLDP frames is enabled. You can also specify a management interface with the **show lldp neighbors interface** ***interface-name*** command to view configuration details about LLDP neighbors for the corresponding management interface.

To configure LLDP on a T Series router within a TX Matrix, you must specify the interface name in the LLDP configuration for the TX Matrix. For information about interface names for TX Matrix routers, see *TX Matrix Router Chassis and Interface Names*. For information about FPC numbering, see *Routing Matrix with a TX Matrix Router FPC Numbering*.

Starting with Junos OS Release 14.2, LLDP is supported on extended ports in the Junos Fusion technology.For information about interface names in the Junos Fusion technology, see *Understanding Junos Fusion Ports* .

The advertisement interval determines the frequency that an LLDP interface sends LLDP advertisement frames. The default value is 30 seconds. The allowable range is from 5 through 32768 seconds. You adjust this parameter by including the **advertisement-interval** statement at the **[edit protocols lldp]** hierarchy level.

The hold multiplier determines the multiplier to apply to the advertisement interval. The resulting value in seconds is used to cache learned LLDP information before discard. The default value is 4. When used with the default advertisement interval value of 30 seconds, this makes the default cache lifetime 120 seconds. The allowable range of the hold multiplier is from 2 through 10. You adjust this parameter by including the **hold-multiplier** statement at the **[edit protocols lldp]** hierarchy level.

The transmit delay determines the delay between any two consecutive LLDP advertisement frames. The default value is 2 seconds. The allowable range is from 1 through 8192 seconds. You adjust this parameter by including the **transmit-delay** statement at the **[edit protocols lldp]** hierarchy level.

The physical topology configuration maximum hold time determines the time interval for which an agent device maintains physical topology database entries. The default value is 300 seconds. The allowable range is from 1 through 2147483647 seconds. You adjust this parameter by including the **ptopo-configuration-maximum-hold-time** statement at the **[edit protocols lldp]** hierarchy level.

The LLDP configuration notification interval determines the period for which trap notifications are sent to the SNMP Master Agent when changes occur in the database of LLDP information. This capability is disabled by default. The allowable range is from 0 (disabled) through 3600 seconds. You adjust this parameter by including the **lldp-configuration-notification-interval** statement at the **[edit protocols lldp]** hierarchy level.

The physical topology configuration trap interval determines the period for which trap notifications are sent to the SNMP Master Agent when changes occur in the global physical topology statistics. This capability is disabled by default. The allowable range is from 0 (disabled) through 3600 seconds. The LLDP agent sends traps to the SNMP Master Agent if this interval has a value greater than 0 and there is any change during the **lldp-configuration-notification-interval** trap interval. You adjust this parameter by including the **ptopo-configuration-trap-interval** statement at the **[edit protocols lldp]** hierarchy level.

By default, LLDP generates the SNMP index of the interface for the port ID Type, Length, and Value (TLV). Starting with Junos OS Release 12.3R1, you can generate the interface name as the port ID TLV. To do so, include the **interface-name** statement at the **[edit protocols lldp** port-id-subtype] hierarchy level. When the **interface-name** statement is configured on the remote LLDP neighbor, the **show lldp neighbors** command output displays the interface name in the **Port ID** field rather than the SNMP index of the interface, which is displayed by default. If you change the default behavior of generating the SNMP index of the interface as the Port ID TLV, you can reenable the default behavior by including the **locally-assigned** statement at the **[edit protocols lldp** port-id-subtype] hierarchy level.

NOTE: Starting with Junos OS Release 12.3, the value of the MIB variable **lldpLocPortId** depends on the SNMP MIB object entity that is used to generate the port ID TLV. If the port ID TLV generation is configured to use the interface name in the **set port-id-subtype interface-name** command, then the value of the MIB variable **lldpLocPortId** is the interface name and not the SNMP index.

Release History Table

Release	Description
14.2	Starting with Junos OS Release 14.2, you can configure management interfaces, such as fxp0 or me0, on MX Series routers to send LLDP frames to and receive LLDP frames from neighboring LLDP interfaces.
14.2	Starting with Junos OS Release 14.2, LLDP is supported on extended ports in the Junos Fusion technology.
12.3	Starting with Junos OS Release 12.3R1, you can generate the interface name as the port ID TLV.
12.3	Starting with Junos OS Release 12.3, the value of the MIB variable **lldpLocPortId** depends on the SNMP MIB object entity that is used to generate the port ID TLV.

- Example: Configuring LLDP on page 342

- *TX Matrix Router Chassis and Interface Names*
- *Monitoring a Routing Matrix with a TX Matrix Router*

Example: Configuring LLDP

The following example configures LLDP on interface **ge-1/1/1** but disables LLDP on all other interfaces, explicitly configures the default values for all automatically enabled features, and configures a value of 30 seconds for the LLDP configuration notification interval and a value of 30 seconds for the physical topology trap interval.

```
[edit]
protocols {
  lldp {
    advertisement-interval 30;
    hold-multiplier 4;
    interface all {
      disable;
    }
    interface ge-1/1/1;
    lldp-configuration-notification-interval 30;
    ptopo-configuration-maximum-hold-time 300;
    ptopo-configuration-trap-interval 30;
    transmit-delay 2;
  }
}
```

You verify operation of LLDP with several show commands:

- **show lldp <detail>**
- **show lldp neighbors** ***interface-name***
- **show lldp statistics** ***interface-name***
- **show lldp local-information**
- **show lldp remote-global-statisitics**

You can clear LLDP neighbor information or statistics globally or on an interface:

- **clear lldp neighbors** ***interface-name***
- **clear lldp statistics** ***interface-name***

You can display basic information about LLDP with the **show lldp detail** command:

```
user@host> show lldp detail
LLDP                    : Enabled
Advertisement interval  : 30 Second(s)
Transmit delay          : 2 Second(s)
Hold timer              : 4 Second(s)
Notification interval   : 30 Second(s)
Config Trap Interval    : 300 Second(s)
Connection Hold timer   : 60 Second(s)

Interface      LLDP       Neighbor count
ge-1/1/1       Enabled    0

LLDP basic TLVs supported:
Chassis identifier, Port identifier, Port description, System name, System
```

```
description, System capabilities, Management address.

LLDP 802 TLVs supported:
Link aggregation, Maximum frame size, MAC/PHY Configuration/Status, Port VLAN ID,
 Port VLAN name.
```

For more details about the output of these commands, see the CLI Explorer.

- Example: Configuring LLDP on page 342

Tracing LLDP Operations

To trace LLDP operational traffic, you can specify options in the global **traceoptions** statement included at the **[edit routing-options]** hierarchy level, and you can specify LLDP-specific options by including the **traceoptions** statement:

```
traceoptions {
  file filename <files number> <size size> <world-readable | no-world-readable>;
  flag flag <flag-modifier> <disable>;
}
```

You can include this statement at the following hierarchy levels:

- **[edit protocols lldp]**
- **[edit routing-instances *routing-instance-name* protocols lldp]**

You can specify the following LLDP-specific options in the LLDP **traceoptions** statement:

- **all**—Trace all operations.
- **config**—Log configuration events.
- **interface**—Trace interface update events.
- **protocol**—Trace protocol information.
- **rtsock**—Trace real-time socket events.
- **vlan**—Trace VLAN update events.

NOTE: Use the trace flag **all** with caution. This flag may cause the CPU to become very busy.

For general information about tracing and global tracing options, see the statement summary for the global **traceoptions** statement in the *Junos OS Routing Protocols Library*.

CHAPTER 15

Configuring VRRP and VRRP for IPv6

VRRP and VRRP for IPv6 Overview

You can configure the Virtual Router Redundancy Protocol (VRRP) and VRRP for IPv6 for the following interfaces:

- Ethernet
- Fast Ethernet
- Tri-Rate Ethernet copper
- Gigabit Ethernet
- 10-Gigabit Ethernet LAN/WAN PIC
- Ethernet logical interfaces

VRRP and VRRP for IPv6 allow hosts on a LAN to make use of redundant routers on that LAN without requiring more than the static configuration of a single default route on the hosts. The VRRP routers share the IP address corresponding to the default route configured on the hosts. At any time, one of the VRRP routers is the master (active) and the others are backups. If the master fails, one of the backup routers becomes the new master router, thus always providing a virtual default router and allowing traffic on the LAN to be routed without relying on a single router.

VRRP is defined in RFC 3768, *Virtual Router Redundancy Protocol*.

For VRRP and VRRP for IPv6 overview information, configuration guidelines, and statement summaries, see the *Junos OS High Availability Library for Routing Devices*.

Related Documentation

- Configuring VRRP and VRRP for IPv6 on page 346
- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring VRRP and VRRP for IPv6

To configure VRRP or VRRP for IPv6, include the **vrrp-group** or **vrrp-inet6-group** statement, respectively. These statements are available at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number* family inet address *address*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family inet address *address*]**

The VRRP and VRRP IPv6 configuration statements are as follows:

```
(vrrp-group | vrrp-inet-group) group-number {
  (accept-data | no-accept-data);
  advertise-interval seconds;
  authentication-key key;
  authentication-type authentication;
  fast-interval milliseconds;
  (preempt | no-preempt) {
    hold-time seconds;
  }
  priority-number number;
  track {
    priority-hold-time;
    interface interface-name {
      priority-cost priority;
      bandwidth-threshold bits-per-second {
        priority-cost;
      }
    }
  }
  virtual-address [ addresses ];
}
```

You can configure VRRP IPv6 with a global unicast address.

To trace VRRP and VRRP for IPv6 operations, include the **traceoptions** statement at the **[edit protocols vrrp]** hierarchy level:

```
[edit protocols vrrp]
traceoptions {
  file <filename> <files number <match regular-expression <microsecond-stamp>
    <size size> <world-readable | no-world-readable>;
  flag flag;
  no-remote-trace;
}
```

When there are multiple VRRP groups, there is a few seconds delay between the time the first gratuitous ARP is sent out and the rest of the gratuitous ARP are sent. Configuring failover-delay compensates for this delay. To configure the failover delay from 500 to 2000 milliseconds for VRRP and VRRP for IPv6 operations, include the **failover-delay *milliseconds*** statement at the **[edit protocols vrrp]** hierarchy level:

```
[edit protocols vrrp]
failover-delay milliseconds;
```

To configure the startup period for VRRP and VRRP for IPv6 operations, include the **startup-silent-period** statement at the **[edit protocols vrrp]** hierarchy level:

```
[edit protocols vrrp]
startup-silent-period seconds;
```

To enable VRRPv3, set the **version-3** statement at the **[edit protocols vrrp]** hierarchy level:

```
[edit protocols vrrp]
version-3;
```

CHAPTER 16

Configuring Point-to-Point Protocol over Ethernet

PPPoE Overview

The Point-to-Point Protocol over Ethernet (PPPoE) connects multiple hosts on an Ethernet LAN to a remote site through a single customer premises equipment (CPE) device. Hosts share a common digital subscriber line (DSL), a cable modem, or a wireless connection to the Internet.

To use PPPoE, you must configure the router as a PPPoE client, encapsulate PPP packets over Ethernet, and initiate a PPPoE session.

M120, M320, and MX Series routers can be configured as a PPPoE access concentrator server. To configure a PPPoE server on an M120, M320, or MX Series Ethernet logical interface, specify PPPoE encapsulation, include the **pp0** statement for the pseudo PPPoE physical interface, and include the **server** statement in the PPPoE options under the logical interface.

NOTE: **PPPoE encapsulation is not supported on M120, M320, or MX Series routers on an ATM2 IQ interface.**

Multiple hosts can be connected to the Services Router, and their data can be authenticated, encrypted, and compressed before the traffic is sent to the PPPoE session on the Services Router's Fast Ethernet or ATM-over-ADSL interface. PPPoE is easy to configure and enables services to be managed on a per-user basis rather than on a per-site basis.

This overview contains the following topics:

PPPoE Interfaces

The PPPoE configuration is the same for both interfaces. The only difference is the encapsulation for the underlying interface to the access concentrator:

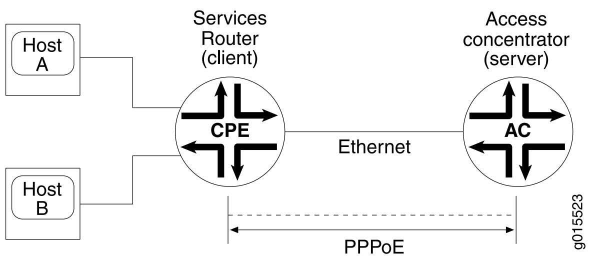
- If the interface is Fast Ethernet, use a PPPoE encapsulation.
- If the interface is ATM over ADSL, use a PPPoE over ATM encapsulation.

The PPPoE interface on M120 or M320 routers acting as a access concentrator can be a Gigabit Ethernet or 10-Gigabit Ethernet interface.

Ethernet Interface

The Services Router encapsulates each PPP frame in an Ethernet frame and transports the frames over an Ethernet loop. Figure 26 on page 351 shows a typical PPPoE session between a Services Router and an access concentrator on the Ethernet loop.

Figure 26: PPPoE Session on an Ethernet Loop



PPPoE Stages

PPPoE has two stages, the discovery stage and the PPPoE session stage. In the discovery stage, the client discovers the access concentrator by identifying the Ethernet media access control (MAC) address of the access concentrator and establishing a PPPoE session ID. In the PPPoE session stage, the client and the access concentrator build a point-to-point connection over Ethernet, based on the information collected in the discovery stage.

NOTE: **If you configure a specific access concentrator name on the client and the same access concentrator name server is available, then a PPPoE session is established. If there is a mismatch between the access concentrator names of the client and the server, the PPPoE session gets closed.**

If you do not configure the access concentrator name, the PPPoE session starts using any available server in the network.

PPPoE Discovery Stage

A Services Router initiates the PPPoE discovery stage by broadcasting a PPPoE active discovery initiation (PADI) packet. To provide a point-to-point connection over Ethernet, each PPPoE session must learn the Ethernet MAC address of the access concentrator and establish a session with a unique session ID. Because the network might have more than one access concentrator, the discovery stage allows the client to communicate with all of them and select one.

NOTE: **A Services Router cannot receive PPPoE packets from two different access concentrators on the same physical interface.**

The PPPoE discovery stage consists of the following steps:

1. PPPoE active discovery initiation (PADI)—The client initiates a session by broadcasting a PADI packet on the LAN to request a service.
2. PPPoE active discovery offer (PADO)—Any access concentrator that can provide the service requested by the client in the PADI packet replies with a PADO packet that contains it own name, the unicast address of the client, and the service requested. An access concentrator can also use the PADO packet to offer other services to the client.

3. PPPoE active discovery request (PADR)—From the PADOs it receives, the client selects one access concentrator based on its name or the services offered and sends it a PADR packet to indicate the service or services needed.

4. PPPoE active discovery session-Confirmation (PADS)—When the selected access concentrator receives the PADR packet, it accepts or rejects the PPPoE session.

   - To accept the session, the access concentrator sends the client a PADS packet with a unique session ID for a PPPoE session and a service name that identifies the service under which it accepts the session.

   - To reject the session, the access concentrator sends the client a PADS packet with a service name error and resets the session ID to zero.

PPPoE Session Stage

The PPPoE session stage starts after the PPPoE discovery stage is over. The access concentrator can start the PPPoE session after it sends the PADS packet to the client, or the client can start the PPPoE session after it receives a PADS packet from the access concentrator. A Services Router supports multiple PPPoE sessions on each interface, but no more than 256 PPPoE sessions on all interfaces on the Services Router.

Each PPPoE session is uniquely identified by the Ethernet address of the peer and the session ID. After the PPPoE session is established, data is sent as in any other PPP encapsulation. The PPPoE information is encapsulated within an Ethernet frame and is sent to a unicast address. In this stage, both the client and the server must allocate resources for the PPPoE logical interface.

After a session is established, the client or the access concentrator can send a PPPoE active discovery termination (PADT) packet anytime to terminate the session. The PADT packet contains the destination address of the peer and the session ID of the session to be terminated. After this packet is sent, the session is closed to PPPoE traffic.

Optional CHAP Authentication

For interfaces with PPPoE encapsulation, you can configure interfaces to support the PPP Challenge Handshake Authentication Protocol (CHAP). When you enable CHAP on an interface, the interface can authenticate its peer and be authenticated by its peer.

If you configure an interface to handle incoming CHAP packets only (by including the **passive** statement at the **[edit interfaces *interface-name* ppp-options chap]** hierarchy level), the interface does not challenge its peer. However, if the interface is challenged, it responds to the challenge. If you do not include the **passive** statement, the interface always challenges its peer.

For more information about CHAP, see *Configuring the PPP Challenge Handshake Authentication Protocol*.

Configuring PPPoE

- Configuring the Protocol MTU PPPoE on page 358
- Example: Configuring a PPPoE Server Interface on an M120 or M320 Router on page 359

Overview

To configure PPPoE on an M120 or M320 Multiservice Edge Router or MX Series Universal Edge Router operating as an access concentrator, perform the following tasks:

1. Configure PPPoE encapsulation for an Ethernet interface.
2. Specify the logical Ethernet interface as the underlying interface for the PPPoE session.
3. Optionally, configure the maximum transmission unit (MTU) of the interface.
4. Configure the operational mode as server.
5. Configure the PPPoE interface address.
6. Configure the destination PPPoE interface address.
7. Optionally, configure the MTU size for the protocol family.
8. Starting in Junos OS Release 10.0, optionally, configure one or more PPPoE service name tables and the action taken for each service in the tables.
9. Starting in Junos OS Release 12.3, optionally, disable the sending of PADS messages that contain certain error tags.

NOTE: Starting in Junos OS Release 10.4, when you configure a static PPPoE logical interface, you must include the **pppoe-options** subhierarchy at the **[edit interfaces pp0 unit *logical-unit-number*]** hierarchy level or at the **[edit logical-systems *logical-system-name* interfaces pp0 unit *logical-unit-number*]** hierarchy level. If you omit the **pppoe-options** subhierarchy from the configuration, the commit operation fails.

Setting the Appropriate Encapsulation on the PPPoE Interface

For PPPoE on an Ethernet interface, you must configure encapsulation on the logical interface and use PPP over Ethernet encapsulation.

For PPPoE on an ATM-over-ADSL interface, you must configure encapsulation on both the physical and logical interfaces. To configure encapsulation on an ATM-over-ADSL physical interface, use Ethernet over ATM encapsulation. To configure encapsulation on an ATM-over-ADSL logical interface, use PPPoE over AAL5 LLC encapsulation. LLC encapsulation allows a single ATM virtual connection to transport multiple protocols.

NOTE: PPPoE encapsulation is not supported on an M120 or M320 router on an ATM2 IQ interface.

When you configure a point-to-point encapsulation such as PPP on a physical interface, the physical interface can have only one logical interface (only one **unit** statement) associated with it.

To configure physical interface properties, include the **encapsulation** statement at the **[edit interfaces *interface-name*]** hierarchy level:

```
[edit interfaces interface-name]
encapsulation ethernet-over-atm;
```

To configure logical interface encapsulation properties, include the **encapsulation** statement:

```
encapsulation ppp-over-ether;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

Perform the task appropriate for the interface on which you are using PPPoE. For more information on how to configure PPoE encapsulation on an ethernet interface and on an ATM-over-ADSL interface, see "Configuring PPPoE Encapsulation on an Ethernet Interface" on page 355 and "Configuring PPPoE Encapsulation on an ATM-over-ADSL Interface" on page 355.

Configuring PPPoE Encapsulation on an Ethernet Interface

Both the client and the server must be configured to support PPPoE. To configure PPPoE encapsulation on an Ethernet interface, include the **encapsulation** statement:

```
encapsulation ppp-over-ether;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces pp0 unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces pp0 unit *logical-unit-number*]**

Configuring PPPoE Encapsulation on an ATM-over-ADSL Interface

To configure the PPPoE encapsulation on a ATM-over-ADSL interface, perform the following steps:

1. Include the **encapsulation** statement at the **[edit interfaces *interface-name*]** hierarchy level, and specify **ethernet-over-atm**:

   ```
   [edit interfaces pp0]
   encapsulation ethernet-over-atm;
   ```

2. Configure LLC encapsulation on the logical interface by including the **encapsulation** statement and specifying **ppp-over-ether-over-atm-llc**:

   ```
   encapsulation ppp-over-ether-over-atm-llc;
   ```

You can include this statement at the following hierarchy levels:

- **[edit interfaces pp0 unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces pp0 unit *logical-unit-number*]**

Configuring the PPPoE Underlying Interface

To configure the underlying Fast Ethernet, Gigabit Ethernet, 10-Gigabit Ethernet, or ATM interface, include the **underlying-interface** statement:

```
underlying-interface interface-name;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces pp0 unit *logical-unit-number* pppoe-options]**
- **[edit logical-systems *logical-system-name* interfaces pp0 unit *logical-unit-number* pppoe-options]**

Specify the logical Ethernet, Fast Ethernet, Gigabit Ethernet, 10-Gigabit Ethernet, or ATM interface as the underlying interface—for example, **at-0/0/1.0** (ATM VC), **fe-1/0/1.0** (Fast Ethernet interface), or **ge-2/0/0** (Gigabit Ethernet interface).

Identifying the Access Concentrator

When configuring a PPPoE client, identify the access concentrator by a unique name by including the **access-concentrator** statement:

```
access-concentrator name;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces pp0 unit *logical-unit-number* pppoe-options]**
- **[edit logical-systems *logical-system-name* interfaces pp0 unit *logical-unit-number* pppoe-options]**

Configuring the PPPoE Automatic Reconnect Wait Timer

By default, after a PPPoE session is terminated, the session attempts to reconnect immediately. When configuring a PPPoE client, you can specify how many seconds to wait before attempting to reconnect, by including the **auto-reconnect** statement:

```
auto-reconnect seconds;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces pp0 unit *logical-unit-number* pppoe-options]**
- **[edit logical-systems *logical-system-name* interfaces pp0 unit *logical-unit-number* pppoe-options]**

You can configure the reconnection attempt to occur in 0 through 4,294,967,295 seconds after the session terminates.

Configuring the PPPoE Service Name

When configuring a PPPoE client, identify the type of service provided by the access concentrator—such as the name of the Internet service provider (ISP), class, or quality of service—by including the **service-name** statement:

```
service-name name;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces pp0 unit *logical-unit-number* pppoe-options]**
- **[edit logical-systems *logical-system-name* interfaces pp0 unit *logical-unit-number* pppoe-options]**

Configuring the PPPoE Server Mode

When configuring a PPPoE server, identify the mode by including the **server** statement:

```
server;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces pp0 unit *logical-unit-number* pppoe-options]**
- **[edit logical-systems *logical-system-name* interfaces pp0 unit *logical-unit-number* pppoe-options]**

Configuring the PPPoE Client Mode

When configuring a PPPoE client, identify the mode by including the **client** statement:

```
client;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces pp0 unit *logical-unit-number* pppoe-options]**
- **[edit logical-systems *logical-system-name* interfaces pp0 unit *logical-unit-number* pppoe-options]**

Configuring the PPPoE Source and Destination Addresses

When configuring a PPPoE client or server, assign source and destination addresses—for example, **192.168.1.1/32** and **192.168.1.2**. To assign the source and destination address, include the **address** and **destination** statements:

```
address address {
  destination address;
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces pp0.0 family inet]**
- **[edit logical-systems *logical-system-name* interfaces pp0.0 family inet]**

Deriving the PPPoE Source Address from a Specified Interface

For a router supporting PPPoE, you can derive the source address from a specified interface—for example, the loopback interface, **lo0.0**—and assign a destination address—for example, **192.168.1.2**. The specified interface must include a logical unit number and have a configured IP address. To derive the source address and assign the destination address, include the **unnumbered-address** and **destination** statements:

```
unnumbered-address interface-name destination address;
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces pp0.0 family inet]**
- **[edit logical-systems *logical-system-name* interfaces pp0.0 family inet]**

Configuring the PPPoE IP Address by Negotiation

You can have the PPPoE client router obtain an IP address by negotiation with the remote end. This method might require the access concentrator to use a RADIUS authentication server. To obtain an IP address from the remote end by negotiation, include the **negotiate-address** statement:

```
negotiate-address;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces pp0.0 family (inet | inet6 | mpls)]**
- **[edit logical-systems *logical-system-name* interfaces pp0.0 family (inet | inet6 | mpls)]**

Configuring the Protocol MTU PPPoE

You can configure the maximum transmission unit (MTU) size for the protocol family. Specify a range from 0 through 5012 bytes. Ensure that the size of the media MTU is equal to or greater than the sum of the protocol MTU and the encapsulation overhead. To set the MTU, include the **mtu** statement:

```
mtu bytes;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces pp0.0 family (inet | inet6 | mpls)]**
- **[edit logical-systems *logical-system-name* interfaces pp0.0 family (inet | inet6 | mpls)]**

You can modify the MTU size of the interface by including the **mtu *bytes*** statement at the **[edit interfaces pp0]** hierarchy level:

```
[edit interfaces pp0]
mtu bytes;
```

The default media MTU size used and the range of available sizes on a physical interface depends on the encapsulation used on that interface.

Example: Configuring a PPPoE Server Interface on an M120 or M320 Router

Configure a PPPoE server over a Gigabit Ethernet interface:

```
[edit interfaces]
ge-1/0/0 {
   vlan-tagging;
   unit 1 {
      encapsulation ppp-over-ether;
      vlan-id 10;
   }
}
pp0 {
   unit 0 {
      pppoe-options {
         underlying-interface ge-1/0/0.0;
         server;
      }
      ppp-options {
      }
      family inet {
         address 22.2.2.1/32 {
            destination 22.2.2.2;
         }
      }
   }
}
```

Release History Table

Release	Description
12.3	Starting in Junos OS Release 12.3, optionally, disable the sending of PADS messages that contain certain error tags.
10.4	Starting in Junos OS Release 10.4, when you configure a static PPPoE logical interface, you must include the **pppoe-options** subhierarchy at the **[edit interfaces pp0 unit *logical-unit-number*]** hierarchy level or at the **[edit logical-systems *logical-system-name* interfaces pp0 unit *logical-unit-number*]** hierarchy level.
10.0	Starting in Junos OS Release 10.0, optionally, configure one or more PPPoE service name tables and the action taken for each service in the tables.

Disabling the Sending of PPPoE Keepalive Messages

When configuring the client, you can disable the sending of keepalive messages on a logical interface by including the **no-keepalives** statement:

```
no-keepalives;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces pp0 unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces pp0 unit *logical-unit-number*]**

Verifying a PPPoE Configuration

Purpose You can use show commands to display and verify the PPPoE configuration.

Action To verify a PPPoE configuration, you can issue the following operational mode commands:

- **show interfaces at-*fpc/pic/port* extensive**
- **show interfaces pp0**
- **show pppoe interfaces**
- **show pppoe version**
- **show pppoe service-name-tables**
- **show pppoe sessions**
- **show pppoe statistics**
- **show pppoe underlying-interfaces**

For more information about these operational mode commands, see CLI Explorer.

Tracing PPPoE Operations

The Junos OS trace feature tracks PPPoE operations and records events in a log file. The error descriptions captured in the log file provide detailed information to help you solve problems.

By default, nothing is traced. When you enable the tracing operation, the default tracing behavior is as follows:

1. Important events are logged in a file called **pppoed** located in the **/var/log** directory. You cannot change the directory (**/var/log**) in which trace files are located.

2. When the file **pppoed** reaches 128 kilobytes (KB), it is renamed **pppoed.0**, then **pppoed.1**, and finally **pppoed.2**, until there are three trace files. Then the oldest trace file (**pppoed.2**) is overwritten.

   You can optionally specify the number of trace files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB). (For more information about how log files are created, see the System Log Explorer.)

By default, only the user who configures the tracing operation can access log files. You can optionally configure read-only access for all users.

To configure PPPoE tracing operations:

1. Specify that you want to configure tracing options.

   ```
   [edit protocols pppoe]
   user@host# edit traceoptions
   ```

2. (Optional) Configure the name for the file used for the trace output.
3. (Optional) Configure the number and size of the log files.
4. (Optional) Configure access to the log file.
5. (Optional) Configure a regular expression to filter logging events.
6. (Optional) Configure flags to filter the operations to be logged.

Optional PPPoE traceoptions operations are described in the following sections:

- Configuring the PPPoE Trace Log Filename on page 361
- Configuring the Number and Size of PPPoE Log Files on page 362
- Configuring Access to the PPPoE Log File on page 362
- Configuring a Regular Expression for PPPoE Lines to Be Logged on page 362
- Configuring the PPPoE Tracing Flags on page 362

Configuring the PPPoE Trace Log Filename

By default, the name of the file that records trace output for PPPoE is **pppoed**. You can specify a different name with the **file** option.

See Also

- Tracing PPPoE Operations on page 360
- **traceoptions (PPPoE) on page 1411**

Configuring the Number and Size of PPPoE Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format ***.number*.gz**. The newest archived file is **.0.gz** and the oldest archived file is ***.(maximum number)-1*.gz**. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, ***filename***, reaches 2 MB, ***filename*** is compressed and renamed ***filename*.0.gz**, and a new file called ***filename*** is created. When the new ***filename*** reaches 2 MB, ***filename*.0.gz** is renamed ***filename*.1.gz** and ***filename*** is compressed and renamed ***filename*.0.gz**. This process repeats until there are 20 trace files. Then the oldest file, ***filename*.19.gz**, is simply overwritten when the next oldest file, ***filename*.18.gz** is compressed and renamed to ***filename*.19.gz**.

- **traceoptions (PPPoE) on page 1411**

Configuring Access to the PPPoE Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

See Also

- Tracing PPPoE Operations on page 360
- **traceoptions (PPPoE) on page 1411**

Configuring a Regular Expression for PPPoE Lines to Be Logged

By default, the trace operation output includes all lines relevant to the logged events.

You can refine the output by including regular expressions to be matched.

See Also

- Tracing PPPoE Operations on page 360
- **traceoptions (PPPoE) on page 1411**

Configuring the PPPoE Tracing Flags

By default, no events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

To configure the flags for the events to be logged, configure the flags:

- [edit protocols pppoe traceoptions]
  user@host# **set flag authentication**

Configuring the Number and Size of PPPoE Log Files

You can optionally specify the number of compressed, archived trace log files to be from 2 through 1000. You can also configure the maximum file size to be from 10 KB through 1 gigabyte (GB); the default size is 128 kilobytes (KB).

The archived files are differentiated by a suffix in the format ***.number*.gz**. The newest archived file is **.0.gz** and the oldest archived file is ***.(maximum number)-1*.gz**. When the current trace log file reaches the maximum size, it is compressed and renamed, and any existing archived files are renamed. This process repeats until the maximum number of archived files is reached, at which point the oldest file is overwritten.

For example, you can set the maximum file size to 2 MB, and the maximum number of files to 20. When the file that receives the output of the tracing operation, ***filename***, reaches 2 MB, ***filename*** is compressed and renamed ***filename*.0.gz**, and a new file called ***filename*** is created. When the new ***filename*** reaches 2 MB, ***filename*.0.gz** is renamed ***filename*.1.gz** and ***filename*** is compressed and renamed ***filename*.0.gz**. This process repeats until there are 20 trace files. Then the oldest file, ***filename*.19.gz**, is simply overwritten when the next oldest file, ***filename*.18.gz** is compressed and renamed to ***filename*.19.gz**.

Configuring Access to the PPPoE Log File

By default, only the user who configures the tracing operation can access the log files. You can enable all users to read the log file and you can explicitly set the default behavior of the log file.

Related Documentation

- Tracing PPPoE Operations on page 360
- **traceoptions (PPPoE) on page 1411**

Configuring a Regular Expression for PPPoE Lines to Be Logged

By default, the trace operation output includes all lines relevant to the logged events.

You can refine the output by including regular expressions to be matched.

Related Documentation

- Tracing PPPoE Operations on page 360
- **traceoptions (PPPoE) on page 1411**

Configuring the PPPoE Tracing Flags

By default, no events are logged. You can specify which events and operations are logged by specifying one or more tracing flags.

To configure the flags for the events to be logged, configure the flags:

- [edit protocols pppoe traceoptions]
  user@host# **set flag authentication**

Related Documentation

- Tracing PPPoE Operations on page 360

Configuring the Severity Level to Filter Which PPPoE Messages Are Logged

The messages associated with a logged event are categorized according to severity level. You can use the severity level to determine which messages are logged for the event type. The severity level that you configure depends on the issue that you are trying to resolve. In some cases you might be interested in seeing all messages relevant to the logged event, so you specify **all** or **verbose**. Either choice generates a large amount of output. You can specify a more restrictive severity level, such as **notice** or **info** to filter the messages . By default, the trace operation output includes only messages with a severity level of **error**.

To configure the type of messages to be logged:

- Configure the message severity level.

  [edit protocols pppoe]

user@host# **set level *severity***

CHAPTER 17

Configuring Restricted and Unrestricted Proxy ARP

Restricted and Unrestricted Proxy ARP Overview

By default, the Junos OS responds to an Address Resolution Protocol (ARP) request only if the destination address of the ARP request is local to the incoming interface.

For Ethernet Interfaces, you can configure the router or switches to proxy-reply to the ARP requests using the restricted or unrestricted proxy ARP configuration.

You might want to configure restricted or unrestricted proxy ARP for routers that act as provider edge (PE) devices in Ethernet Layer 2 LAN switching domains.

NOTE: **From Junos OS Release 10.0 onward, Junos OS does not respond to proxy ARP requests with the default route 0.0.0.0. This behavior is in compliance with RFC 1027.**

Restricted Proxy ARP

Restricted proxy ARP enables the router or switch to respond to the ARP requests in which the physical networks of the source and target are not the same and the router or switch has an active route to the target address in the ARP request. The router does not reply if the target address is on the same subnet and the same interface as the ARP requestor.

Unrestricted Proxy ARP

Unrestricted proxy ARP enables the router or switch to respond to any ARP request, on condition that the router has an active route to the destination address of the ARP request. The route is not limited to the incoming interface of the request, nor is it required to be a direct route.

WARNING: If you configure unrestricted proxy ARP, the proxy router replies to ARP requests for the target IP address on the same interface as the incoming ARP request. This behavior is appropriate for cable modem termination system (CMTS) environments, but might cause Layer 2 reachability problems if you enable unrestricted proxy ARP in other environments.

When an IP client broadcasts the ARP request across the Ethernet wire, the end node with the correct IP address responds to the ARP request and provides the correct MAC address. If the unrestricted proxy ARP feature is enabled, the router response is redundant and might fool the IP client into determining that the destination MAC address within its own subnet is the same as the address of the router.

NOTE: While the destination address can be remote, the source address of the ARP request must be on the same subnet as the interface upon which the ARP request is received. For security reasons, this rule applies to both unrestricted and restricted proxy ARP.

Topology Considerations for Unrestricted Proxy ARP

In most situations, you should not configure the router or switch to perform unrestricted proxy ARP. Do so only for special situations, such as when cable modems are used. Figure 27 on page 368 and Figure 28 on page 369 show examples of situations in which you might want to configure unrestricted proxy ARP.

In Figure 27 on page 368, the edge device is not running any IP protocols. In this case, you configure the core router to perform unrestricted proxy ARP. The edge device is the client of the proxy.

In Figure 28 on page 369, the Broadband Remote Access Server (B-RAS) routers are not running any IP protocols. In this case, you configure unrestricted proxy ARP on the B-RAS interfaces. This allows the core device to behave as though it is directly connected to the end users.

Figure 27: Edge Device Case for Unrestricted Proxy ARP

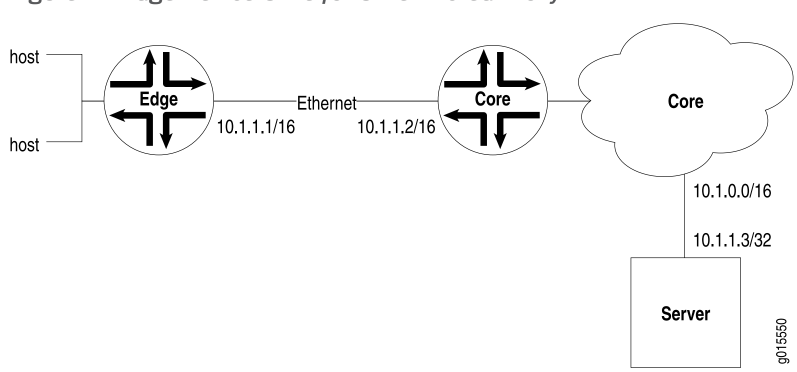

Figure 28: Core Device Case for Unrestricted Proxy ARP

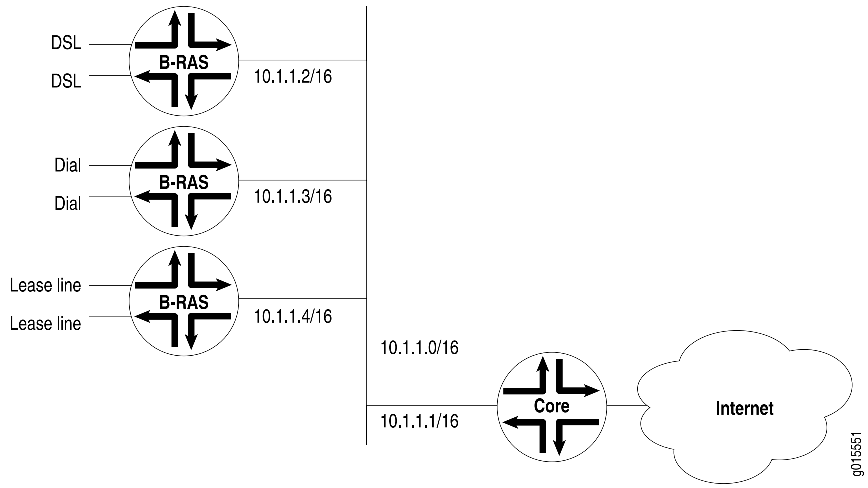

Related Documentation

- Configuring Restricted and Unrestricted Proxy ARP on page 369
- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring Restricted and Unrestricted Proxy ARP

To configure restricted or unrestricted proxy ARP, include the **proxy-arp** statement:

```
proxy-arp (restricted |unrestricted);
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

To return to the default—that is, to disable restricted or unrestricted proxy ARP—delete the **proxy-arp** statement from the configuration:

```
[edit]
user@host# delete interfaces interface-name unit logical-unit-number proxy-arp
```

You can track the number of restricted or unrestricted proxy ARP requests processed by the router or switch by issuing the **show system statistics arp** operational mode command.

NOTE: When proxy ARP is enabled as default or unrestricted, the router or switch responds to any ARP request as long as the device has an active route to the target address of the ARP request. This gratuitous ARP behavior can result in an error when the receiving interface and target response interface are the same and the end device (for example, a client) performs a duplicate address check. To prevent this error, configure the router or switch interface with the **no-gratuitous-arp-reply** statement. See “Configuring Gratuitous ARP” on page 19 for information about how to disable responses to gratuitous ARP requests.

CHAPTER 18

Configuring Static ARP Table Entries

Static ARP Table Entries Overview

For Fast Ethernet, Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces, you can configure static ARP table entries, defining mappings between IP and MAC addresses.

Related Documentation

- Configuring Static ARP Table Entries For Mapping IP Addresses to MAC Addresses on page 372

- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring Static ARP Table Entries For Mapping IP Addresses to MAC Addresses

By default, the device responds to an Address Resolution Protocol (ARP) request only if the destination address of the ARP request is on the local network of the incoming interface. For Fast Ethernet or Gigabit Ethernet interfaces, you can configure static ARP entries that associate the IP addresses of nodes on the same Ethernet subnet with their media access control (MAC) addresses. These static ARP entries enable the device to respond to ARP requests even if the destination address of the ARP request is not local to the incoming Ethernet interface.

Also, unlike dynamically learned ARP entries, static ARP entries do not age out. You can also configure static ARP entries in a troubleshooting situation or if your device is unable to learn a MAC address dynamically.

NOTE: By default, an ARP policer is installed that is shared among all the Ethernet interfaces on which you have configured the **family inet** statement. By including the **arp** statement at the **[edit interfaces *interface-name* unit *logical-unit-number* family inet policer]** hierarchy level, you can apply a specific ARP-packet policer to an interface. This feature is not available on EX Series switches.

To configure static ARP entries:

1. In the configuration mode, at the [**edit**] hierarchy level, configure the router interface on which the ARP table entries for the router is configured.

   ```
   [edit]
   user@host# edit interfaces interface-name
   ```

2. Configure the protocol family, the logical unit of the interface, and the interface address of the router interface at the [**edit interfaces *interface-name***] hierarchy level. While configuring the protocol family, specify **inet** as the protocol family.

   NOTE: When you need to conserve IP addresses, you can configure an Ethernet interface to be unnumbered by including the **unnumbered-address** statement at the **[edit interfaces *interface-name* unit *logical-unit-number* family inet]** hierarchy level.

   ```
   [edit interfaces interface-name]
   user@host# edit unit logical-unit-number family inet address interface-address
   ```

3. Configure a static ARP entry by specifying the IP address and the MAC address that are to be mapped to each other. The IP address specified must be part of the subnet defined in the enclosing **address** statement. The MAC address must be specified as hexadecimal bytes in the following formats: ***nnnn.nnnn.nnnn*** or ***nn:nn:nn:nn:nn:nn*** format. For instance, you can use either **0011.2233.4455** or **00:11:22:33:44:55**.

[edit interfaces *interface-name* unit *logical-unit-number* family inet address
interface-address
user@host# set arp *ip-address* mac *mac-address*

4. Configure another static ARP entry by specifying the IP address and the MAC address that are to be mapped to each other. You can also associate a multicast MAC address with a unicast IP address by including the **multicast-mac** option with the **arp** statement. You can optionally configure the router to respond to ARP requests for the specified IP address by using the **publish** option with the **arp** statement.

   NOTE: For unicast MAC addresses only, if you include the **publish** option, the router or switch replies to proxy ARP requests.

   [edit interfaces *interface-name* unit *logical-unit-number* family inet address
   interface-address
   user@host# set arp *ip-address* multicast-mac *mac-address* publish

NOTE: The Junos OS supports the IPv6 static neighbor discovery cache entries, similar to the static ARP entries in IPv4.

CHAPTER 19

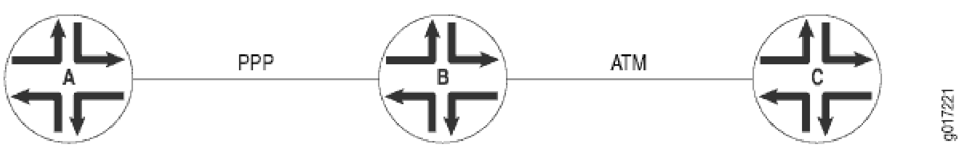
Configuring TCC and Layer 2.5 Switching

TCC and Layer 2.5 Switching Overview

Translational cross-connect (TCC) allows you to forward traffic between a variety of Layer 2 protocols or circuits. It is similar to its predecessor, CCC. However, while CCC requires the same Layer 2 encapsulations on both sides of a router (such as Point-to-Point Protocol [PPP] or Frame Relay-to-Frame Relay), TCC lets you connect different types of Layer 2 protocols interchangeably. With TCC, combinations such as PPP-to-ATM and Ethernet-to-Frame Relay cross-connections are possible. Also, TCC can be used to create Layer 2.5 VPNs and Layer 2.5 circuits.

Consider a sample topology (Figure 29 on page 375) in which you can configure a full-duplex Layer 2.5 translational cross-connect between Router A and Router C, using a Juniper Networks router, Router B, as the TCC interface. In this topology, Router B strips all PPP encapsulation data from frames arriving from Router A and adds ATM encapsulation data before the frames are sent to Router C. All Layer 2 negotiations are terminated at the interconnecting router (Router B).

Figure 29: Sample Translation Cross-Connect Topology



TCC functionality is different from standard Layer 2 switching. TCC only swaps Layer 2 headers. No other processing, such as header checksums, time-to-live (TTL) decrementing, or protocol handling, is performed. Currently, TCC is supported in IPv4, ISO, and MPLS.

Ethernet TCC is supported on interfaces that carry IPv4 traffic only. For 8-port, 12-port, and 48-port Fast Ethernet PICs, TCC and extended VLAN CCC are not supported. For 4-port Gigabit Ethernet PICs, extended VLAN CCC and extended VLAN TCC are not supported.

Related Documentation

- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring VLAN TCC Encapsulation

VLAN TCC encapsulation allows circuits to have different media on either side of the forwarding path. VLAN TCC encapsulation supports TPID 0x8100 only. You must include configuration statements at the logical and physical interface hierarchy levels.

To configure VLAN TCC encapsulation, include the **encapsulation** statement and specify the **vlan-tcc** option:

```
[edit interfaces interface-name unit logical-unit-number]
encapsulation vlan-tcc;
```

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

Additionally, configure the logical interface by including the **proxy** and **remote** statements:

```
proxy {
  inet-address;
}
remote {
  (inet-address | mac-address);
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number* family tcc]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family tcc]**

The proxy address is the IP address of the non-Ethernet TCC neighbor for which the TCC router is acting as a proxy.

The remote address is the IP or MAC address of the remote router. The **remote** statement provides ARP capability from the TCC switching router to the Ethernet neighbor. The MAC address is the physical Layer 2 address of the Ethernet neighbor.

When VLAN TCC encapsulation is configured on the logical interface, you also must specify flexible Ethernet services on the physical interface. To specify flexible Ethernet services, include the **encapsulation** statement at the **[edit interfaces *interface-name*]** hierarchy level and specify the **flexible-ethernet-services** option:

```
[edit interfaces interface-name]
encapsulation flexible-ethernet-services;
```

Extended VLAN TCC encapsulation supports TPIDs 0x8100 and 0x9901. Extended VLAN TCC is specified at the physical interface level. When configured, all units on that interface must use VLAN TCC encapsulation, and no explicit configuration is needed on logical interfaces.

One-port Gigabit Ethernet, 2-port Gigabit Ethernet, and 4-port Fast Ethernet PICs with VLAN tagging enabled can use VLAN TCC encapsulation. To configure the encapsulation on a physical interface, include the **encapsulation** statement at the **[edit interfaces *interface-name*]** hierarchy level and specify the **extended-vlan-tcc** option:

```
[edit interfaces interface-name]
encapsulation extended-vlan-tcc;
```

For VLAN TCC encapsulation, all VLAN IDs from 1 through 1024 are valid. VLAN ID 0 is reserved for tagging the priority of frames.

Extended VLAN TCC is not supported on 4-port Gigabit Ethernet PICs.

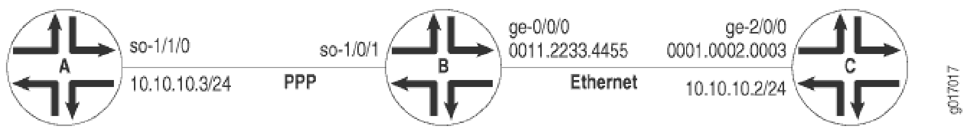
Related Documentation

- **encapsulation on page 1135**
- **remote on page 1340**
- **proxy on page 1330**
- TCC and Layer 2.5 Switching Overview on page 375
- Configuring Translation Cross-Connect Interface Switching on page 378
- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring Translation Cross-Connect Interface Switching

To configure a full-duplex Layer 2.5 translation cross-connect between two routers (A and C), you can configure a Juniper Networks router (Router B) as the TCC interface. Ethernet TCC encapsulation provides an Ethernet wide area circuit for interconnecting IP traffic. Consider the topology in Figure 30 on page 378 where the Router A-to-Router B circuit is PPP, and the Router B-to-Router C circuit accepts packets carrying standard TPID values.

Figure 30: Sample Topology of Layer 2.5 Translational Cross-Connect



If traffic flows from Router A to Router C, the Junos OS strips all PPP encapsulation data from incoming packets and adds Ethernet encapsulation data before forwarding the packets. If traffic flows from Router C to Router A, the Junos OS strips all Ethernet encapsulation data from incoming packets and adds PPP encapsulation data before forwarding the packets.

To configure the router as the translational cross-connect interface:

1. In the configuration mode, at the [**edit**] hierarchy level, first configure the interface that is connected to Router A.

   ```
   [edit]
   user@host# edit interfaces interface-name
   ```

2. (Optional) Specify the description of the interface. For example, you could specify the interface name on Router A that is connected to this interface.

   ```
   [edit interfaces interface-name]
   user@host# set description description
   ```

3. Specify the encapsulation. If the Router A to Router B circuit is PPP, then specify **ppp-tcc** as the encapsulation. If the Router A to Router B circuit is frame relay, specify **frame-relay-tcc**.

   ```
   [edit interfaces interface-name]
   user@host# set encapsulation encapsulation-type
   ```

4. In the configuration mode, at the [**edit**] hierarchy level, first configure the interface that is connected to Router C.

   ```
   [edit]
   user@host# edit interfaces interface-name
   ```

5. (Optional) Specify the description of this interface. For example, you could specify the interface name on Router C that is connected to this interface.

```
[edit interfaces interface-name]
user@host# set description description
```

6. Specify the encapsulation. If the Router B to Router C circuit is Ethernet, then specify **ethernet-tcc** as the encapsulation. If the Router B to Router C circuit is ATM, specify **atm-tcc-vc-mux**.

```
[edit interfaces interface-name]
user@host# set encapsulation encapsulation-type
```

7. Specify the IP address or MAC address of the remote router to provide address resolution protocol (ARP) for the TCC router's Ethernet-based neighbor using the **remote** statement. You must specify the statement at the [**edit interfaces interface-name unit unit-number family tcc**] hierarchy level. You can a specify the MAC address of the remote router instead of the IP address. The MAC address is the physical Layer 2 address of the Ethernet neighbor.

```
[edit interfaces interface-name]
user@host# set unit 0 family family remote inet-address ip-address
```

8. Specify the IP address of the non-Ethernet TCC neighbor for which the TCC router is acting as a proxy using the **proxy** statement. You must specify the statement at the [**edit interfaces interface-name unit unit-number family tcc**] hierarchy level.

```
[edit interfaces interface-name]
user@host# set unit 0 family family proxy inet-address ip-address
```

To verify the TCC connection, use the **show connections** command on TCC router.

CHAPTER 20

Configuring Link Degrade Monitoring

Link Degrade Monitoring Overview

Link degrade monitoring enables you to monitor the quality of physical links on Ethernet interfaces (10-Gigabit, 40-Gigabit, and 100-Gigabit) and take corrective action when the link quality degrades beyond a certain level. You can configure this feature by applying the **link-degrade-monitor** statement at the **[edit interfaces *interface-name*]** hierarchy level. When configured on your device, this feature continuously monitors bit error rate (BER) value of the link and initiates a corrective action (media-based) when the BER value breaches a user-configured threshold. The feature can detect a BER value as low as 10^{-13} through 10^{-5}, helping you prevent or minimize packet drops in physical links.

You can configure autorecovery or manual recovery method for the degraded link. In the case of manual recovery, you need to use the **request interface link-degrade-recover** *interface-name* statement to recover the degraded link. If autorecovery is configured, automatic recovery of the degraded link is attempted at the user configured intervals, and when the link's BER value is within the configured limit, the link is recovered.

NOTE: Layer 2 and Layer 3 protocols already support physical link monitoring. So do Ethernet links through the Link Fault Signaling (LFS) protocol. However, these existing mechanisms cannot detect BER ranges that are very low (for example, 10^{-13} through 10^{-5}).

Supported Platforms

Table 25 on page 382 lists the platform series and line cards that support link degrade monitoring.

Table 25: Line Cards that Support Link Degrade Monitoring

Platform Series	MPC Line Cards Supported	DPC Line Cards Supported

MX	• MPC4E-3D-2CGE-8XGE
	• MPC4E-3D-32XGE-SFPP
	• MPC-3D-16XGE-SFP

CHAPTER 21

Configuring Power-over-Ethernet on ACX Series

Understanding PoE on ACX Series Universal Metro Routers

Power over Ethernet (PoE) is the implementation of the IEEE 802.3af and IEEE 802.3at standards that allows both data and electrical power to pass over a copper Ethernet LAN cable.

Juniper Networks provides PoE on ACX2000 Universal Metro Routers that allows power delivery up to 65 W per PoE port. PoE ports transfer electrical power and data to remote devices over standard twisted-pair cables in an Ethernet network. Using the PoE ports, you can plug in devices that require both network connectivity and electrical power, such as voice over IP (VoIP) and wireless LAN access points.

You can configure the ACX2000 Universal Metro Router to act as a power sourcing equipment (PSE), supplying power to powered devices that are connected on designated ports.

This topic contains the following sections: :

ACX2000 PoE Specifications

Table 26 on page 384 lists the PoE specifications for the ACX2000 routers.

Table 26: PoE Specifications for the ACX2000 Routers

Specifications	For ACX2000 Universal Metro Routers
Supported standards	• IEEE 802.3 AF • IEEE 802.3 AT (PoE+) • Legacy (pre-standards)
Supported ports	Supported on only two Gigabit Ethernet ports (ge-0/1/3 and ge-0/1/7).
Total PoE power sourcing capacity	130 W
Default per port power limit	32 W
Maximum per port power limit	65 W
Power management modes	• **class**—Power allocated for each interface can be configured. • **static**—Power allocated for interfaces is based on the class of powered device connected. • **high-power**—Power allocated for interfaces up to 65 W per port.

PoE Classes and Power Ratings

A powered device is classified based on the maximum power that it draws across all input voltages and operational modes. When class-based power management mode is configured on the ACX2000 routers, power is allocated taking into account the maximum power ratings defined for the different classes of devices.

Table 27 on page 384 lists the classes and their power ratings as specified by the IEEE standards.

Table 27: ACX2000 Universal Metro Router PoE Specifications

Class	Usage	Minimum Power Levels Output from PoE Port
0	Default	15.4 W
1	Optional	4.0 W
2	Optional	7.0 W
3	Optional	15.4 W
4	Reserved	Class 4 power devices are eligible to receive power up to 30 W according to the IEEE standards.

PoE Options

For ACX2000 Universal Metro Routers that support PoE ports, the factory default configuration enables PoE on the PoE-capable ports, with default settings in effect. You might not have to do any additional configuration if the default settings work for you. Table 28 on page 385 shows the PoE configuration options and their default settings for the PoE controller and for the PoE interfaces.

Table 28: PoE Configuration Options and Default Settings

Option	Default	Description
PoE Controller Options		
guard-band	0 W	Reserves up to 19 W power from the PoE power budget to be used in the case of a spike in PoE power consumption.
management	static	Sets the PoE power management mode for the router. The power management mode determines how power to a PoE interface is allocated: • **class**—Power allocated for each interface can be configured. • **static**—Power allocated for interfaces is based on the class of powered device connected. • **high-power**—Power allocated for interfaces up to 65 W per port.
Interface Options		
disable (Power over Ethernet)	Not included in default configuration	When included in the configuration, disables PoE on the interface. The interface maintains network connectivity but no longer supplies power to a connected powered device. Power is not allocated to the interface.
priority (Power over Ethernet)	low	Sets an interface's power priority to either **low** or **high**. If power is insufficient for all PoE interfaces, the PoE power to low-priority interfaces is shut down before power to high-priority interfaces is shut down. Among interfaces that have the same assigned priority, the power priority is determined by port number, with lower-numbered ports having higher priority.
telemetries	Not included in default configuration	When included in the configuration, enables the logging of power consumption records on an interface. Logging occurs every 5 minutes for 1 hour unless you specify a different value for ***interval (Power over Ethernet)*** or ***duration***.

Related Documentation

- Example: Configuring PoE on ACX2000 Routers on page 385
- Example: Disabling a PoE Interface on ACX2000 Routers on page 390

Example: Configuring PoE on ACX2000 Routers

Power over Ethernet (PoE) ports supply electric power over the same ports that are used to connect network devices. These ports allow you to plug in devices that need both network connectivity and electric power, such as voice over IP (VoIP) phones, wireless access points, and IP cameras.

This example shows how to configure PoE to deliver power up to 65 W on ACX2000 interfaces:

- Requirements on page 386
- Overview on page 386
- Configuration on page 387
- Verification on page 388

Requirements

This example uses the following software and hardware components:

- Junos OS Release 12.2 or later for ACX Series routers
- An ACX2000 router that supports PoE

Before you configure PoE, be sure you have:

- Performed the initial router configuration. See *ACX Series Autoinstallation Overview*,*Verifying Autoinstallation on ACX Series Universal Metro Routers*, and *Boot Sequence on ACX Series Routers* for details.

Overview

This example consists of a router that has eight ports. Only two ports—ge-0/1/3 and ge-0/1/7—support PoE, which means they provide both network connectivity and electric power for powered devices such as VoIP telephones, wireless access points, and IP security cameras that require power up to 65 W. The remaining six ports provide only network connectivity. You use the standard ports to connect devices that have their own power sources, such as desktop and laptop computers, printers, and servers.

Table 29 on page 386 details the topology used in this configuration example.

Table 29: Components of the PoE Configuration

Property	Settings
Hardware	ACX2000 router with 8 Gigabit Ethernet ports: Two PoE interfaces (ge-0/1/3 and ge-0/1/7) and 6 non-PoE interfaces (ge-0/1/0, ge-0/1/1, ge-0/1/2, ge-0/1/4, ge-0/1/5, ge-0/1/6).
VLAN name	default
Connection to a wireless access point (requires PoE)	ge-0/1/7
Power port priority	high
Maximum power available to PoE port	65 W
PoE management mode	high-power

Table 29: Components of the PoE Configuration (continued)

Property	Settings
Direct connections to desktop PCs, file servers, integrated printer/fax/copier machines (no PoE required)	ge-0/1/0 through ge-0/1/2
Unused ports (for future expansion)	ge-0/1/4 through ge-0/1/6

Configuration

To configure PoE on an ACX2000 router:

CLI Quick Configuration

To quickly configure this example, copy the following commands, paste them into a text file, remove any line breaks, change any details necessary to match your network configuration, and then copy and paste the commands into the CLI at the **[edit]** hierarchy level.

```
set poe management high-power guard-band 19
set poe interface ge-0/1/3 priority high maximum-power 65 telemetries
```

Step-by-Step Procedure

The following example requires you to navigate various levels in the configuration hierarchy. For instructions on how to do that, see *Using the CLI Editor in Configuration Mode* in the *CLI User Guide*.

To configure PoE:

1. Set the PoE management mode to **high-power**.

   ```
   [edit]
   user@host# set poe management high-power
   ```

   NOTE:
   - Set the PoE management mode to **high-power** only when the power requirement is more than 32 W and up to 65 W. If the power requirement is less than or equal to 32 W, then you do not need to set the PoE management mode to **high-power**.
   - The default management mode is **static**. In this mode, the power sourcing equipment can deliver power up to 32 W.

2. Reserve power wattage in case of a spike in PoE consumption.

   ```
   [edit]
   user@host# set poe guard-band 19
   ```

3. Enable PoE.

   ```
   [edit]
   user@host# edit poe interface ge-0/1/3
   ```

4. Set the power port priority.

```
[edit poe interface ge-0/1/3]
user@host# set priority high
```

5. Set the maximum PoE power for a port.

```
[edit poe interface ge-0/1/3]
user@host# set maximum-power 65
```

NOTE: Set the maximum PoE power for a port only when the power requirement is more than 32 W and up to 65 W. If the power requirement is less than or equal to 32 W, then you do not need to configure the maximum PoE power.

6. Enable the logging of PoE power consumption.

```
[edit poe interface ge-0/1/3]
user@host# set telemetries
```

Results

In configuration mode, confirm your configuration by entering the **show poe interface ge-0/1/3** command. If the output does not display the intended configuration, repeat the configuration instructions in this example to correct it.

```
[edit]
  user@host# show poe interface ge-0/1/3
  priority high;
  maximum-power 65;
telemetries;
```

If you are done configuring the device, enter **commit** in configuration mode.

Verification

To confirm that the configuration is working properly, perform these tasks:

- Verifying the Status of PoE Interfaces on page 388
- Verifying the Telemetry Data (History) for the Specified Interface on page 389
- Verifying PoE Global Parameters on page 389

Verifying the Status of PoE Interfaces

Purpose Verify that the PoE interfaces are enabled and set to the desired priority settings.

Action In operational mode, enter the **show poe interface ge-0/1/3** command.

```
user@host> show poe interface ge-0/1/3
PoE interface status:
PoE interface                : ge-0/1/3
Administrative status        : Enabled
Operational status           : Powered-up
Power limit on the interface : 65 W
Priority                     : High
Power consumed               : 6.6 W
Class of power device        : 0
```

Meaning The **show poe interface ge-0/1/3** command lists PoE interfaces configured on the ACX2000 router, with their status, priority, power consumption, and class.

Verifying the Telemetry Data (History) for the Specified Interface

Purpose Verify the PoE interface's power consumption over a specified period.

Action In operational mode, enter the **show poe telemetries interface** command.

For all records:

```
user@host> show poe telemetries interface ge-0/1/3 all
Interface  Sl No    Timestamp                Power    Voltage
              1     Mon May 14 00:45:05 2012 14.2 W   53.9 V
              2     Mon May 14 00:44:04 2012 14.2 W   53.9 V
              3     Mon May 14 00:43:03 2012 14.2 W   53.9 V
```

For a specific number of records:

```
user@host> show poe telemetries interface ge-0/1/3 2
Interface  Sl No    Timestamp                Power    Voltage
              1     Mon May 14 00:45:05 2012 14.2 W   53.9 V
              2     Mon May 14 00:44:04 2012 14.2 W   53.9 V
```

Meaning The telemetry status displays the power consumption history for the specified interface, provided telemetry has been configured for that interface.

Verifying PoE Global Parameters

Purpose Verify global parameters such as guard band, power limit, and power consumption.

Action In operational mode, enter the **show poe controller** command.

```
user@host> show poe controller
Controller  Maximum  Power        Guard    Management   Status        Lldp
index       power    consumption  band                               Priority
```

```
0         130.0 W   14.2 W          0 W      high-power    UP
```

Meaning The **show poe controller** command lists the global parameters configured on the router.

Related Documentation

- Understanding PoE on ACX Series Universal Metro Routers on page 383

Example: Disabling a PoE Interface on ACX2000 Routers

This example shows how to disable PoE on all interfaces or on a specific interface.

Requirements

Before you begin:

- Configure PoE on all interfaces. See "Example: Configuring PoE on ACX2000 Routers" on page 385.

Overview

In this example, you disable PoE on all interfaces and on a specific interface, which in this case is ge-0/1/3.

Configuration

Step-by-Step Procedure

- Disable PoE on all interfaces.

  [edit]
  user@host# **set poe interface all disable**

- Disable PoE on a specific interface.

  [edit]
  user@host# **set poe interface ge-0/1/3 disable**

Verification

To verify the configuration is working properly, enter the **show poe interface** command.

```
user@host> show poe interface

Interface     Admin       Oper     Max        Priority       Power          Class
              status      status   power                     consumption
 ge-0/1/3     Disabled    Disabled 32.0W      Low            0.0W            0
 ge-0/1/7     Disabled    Disabled 32.0W      Low            0.0W            0
```

```
user@host> show poe interface ge-0/1/3

PoE interface status:
PoE interface                : ge-0/1/3
Administrative status        : Disabled
Operational status           : Disabled
Power limit on the interface : 32.0 W
Priority                     : Low
Power consumed               : 0.0 W
Class of power device        : 0
```

- Understanding PoE on ACX Series Universal Metro Routers on page 383

Troubleshooting PoE Interfaces on ACX2000 Universal Metro Routers

Problem

Description: A Power over Ethernet (PoE) interface is not supplying power to the powered device.

Solution

Check for the items shown in Table 30 on page 391.

Table 30: Troubleshooting a PoE Interface

Items to Check	Explanation
Is interface PoE enabled?	Only interfaces **ge-0/1/3** and **ge-0/1/7** can function as PoE ports.
Has PoE capability been disabled for that interface?	Use the **show poe interface** command to check PoE interface status.
Is the cable properly seated in the port socket?	Check the hardware.
Does the powered device require more power than is available on the interface?	Use the **show poe interface** command to check the maximum power provided by the interface.
If the ***telemetries*** option has been enabled for the interface, check the history of power consumption.	Use the **show poe telemetries** command to display the history of power consumption.

PART 2

Gigabit Ethernet Interfaces

CHAPTER 22

Configuring 10-Gigabit Ethernet LAN/WAN PICs

10-port 10-Gigabit Ethernet LAN/WAN PIC Overview

This section describes the main features and caveats of the 10-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (model number PD-5-10XGE-SFPP) and specifies which routers support this PIC.

The 10–port 10-Gigabit Ethernet LAN/WAN PIC (PD-5-10XGE-SFPP) is supported on Juniper Networks T640 Core Routers, T1600 Core Routers, and T4000 Core Routers. It has the following features:

- Access to all 10-Gigabit Ethernet port counters through SNMP
- Intelligent handling of oversubscribed traffic in applications such as data centers and dense-core uplinks
- Line-rate operation for five 10-Gigabit Ethernet ports from each port group, or a total WAN bandwidth of 100 Gbps with Packet Forwarding Engine bandwidth of 50 Gbps
- Flexible encapsulation, source address and destination address media access control (MAC) filtering, source address MAC learning, MAC accounting, and MAC policing

- Interface encapsulations, such as the following:
  - **ethernet-ccc**—Ethernet cross-connect
  - **vlan-ccc**—802.1Q tagging for a cross-connect
  - **ethernet-tcc**—Ethernet translational cross-connect
  - **vlan-tcc**—Virtual LAN (VLAN) translational cross-connect
  - **extended-vlan-ccc**—Standard Tag Protocol Identifier (TPID) tagging for a cross-connect
  - **ethernet-vpls**—Ethernet virtual private LAN service
  - **vlan-vpls**—VLAN virtual private LAN service
  - **flexible-ethernet-services**—Allows per-unit Ethernet encapsulation configuration
- WAN PHY features, such as the following:
  - WAN PHY mode on a per-port basis
  - Insertion and detection of path trace messages
  - Ethernet WAN Interface Sublayer (WIS) object

NOTE: The T4000 Core Router supports only LAN PHY mode in Junos OS Release 12.1R1. Starting with Junos OS Release 12.1R2, WAN PHY mode is supported on the T4000 routers with the 12-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-12XGE-SFPP). Starting with Junos OS Release 12.2, WAN PHY mode is supported on the T4000 routers with the 24-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-24XGE-SFPP).

- Single, stacked, and flexible VLAN tagging modes
- Native VLAN configuration to allow untagged frames to be received on the tagged interfaces
- Maximum transmission unit (MTU) size of up to 9192 bytes for Ethernet frames
- Link aggregation group (LAG) on single chassis
- Interoperability with other 10-Gigabit Ethernet PICs in M Series and T Series routers in the LAN PHY and WAN PHY modes
- Interrupt-driven link-down detection mechanism
- Two-to-one oversubscription of traffic across a port group

  Traffic from 10 ingress ports to the Packet Forwarding Engine traffic is statically mapped to one of the 5 egress ports. 10 Gbps of bandwidth toward the Packet Forwarding Engine is shared by two ingress ports (called a *port group*), thereby achieving two-to-one oversubscription. This scheme provides two-to-one oversubscription across a port group and not across the entire PIC.

- Four queues per physical interface on ingress and eight queues per physical interface on egress
- A separate control queue per physical interface to ensure that the control packets are not dropped during oversubscribed traffic. The control queue can be disabled in the CLI.
- Optical diagnostics
- Behavior aggregate (BA) classification (IPv4 DSCP, IPv6 DSCP, Inet precedence, IEEE 802.1P, IEEE 802.1AD, MPLS EXP) and fixed classification
- Weighted round-robin scheduling with two queue priorities (low and strict-high)
- Committed information rate and peak information rate shaping on a per-queue basis
- Excess information rate configuration for allocation of excess bandwidth
- IEEE 802.3ah Operation, Administration, and Maintenance (OAM)-related operations, such as the following:
  - Link fault management
  - Link discovery
  - Graceful Routing Engine Switchover
- IEEE 802.3ag Operation, Administration, and Maintenance (OAM)-related operations, such as the following:
  - Connectivity fault management (CFM)
  - Linktrace
  - Loopback
  - Graceful Routing Engine switchover (GRES)

The 10-port 10-Gigabit Ethernet LAN/WAN PIC has the following caveats:

- Source address and destination address MAC filtering takes place after oversubscription is handled.
- Oversubscription on the PIC operates across a port group of two ports and not at the PIC level.
- Queuing is not supported at the logical interface level.
- Committed information rate and peak information rate configurations are not supported at the physical interface level.
- There is limited packet buffering of 2 MB.
- Delay-bandwidth buffering configuration is not supported.
- Multifield classifiers are not supported at the PIC level.

  The multifield classification can be done at the Packet Forwarding Engine using the firewall filters, which overrides the classification done at the PIC level. The multifield classification at the Packet Forwarding Engine occurs after the PIC handles the oversubscribed traffic.

- Egress MAC policer statistics not supported.
- Byte counters are not supported at the queue level.
- Only TPID (0x8100) is supported.
- Line-timing mode is not supported.
- MAC-level Rx VLAN tagged frames counter is not supported.
- OAM unified in-service software upgrade (unified ISSU) is not supported.
- OAM remote loopback is not supported.

The 10-port 10-Gigabit Ethernet LAN/WAN PIC (PD-5-10XGE-SFPP) supports link aggregation. For bandwidth aggregation, load sharing, and link protection, LAG can be enabled. Once aggregated Ethernet is enabled, Link Aggregation Control Protocol (LACP) forms an aggregated bundle of member links.

Only features that are supported across all of the linked devices will be supported in the resulting LAG bundle. The following caveats apply to LAG bundles that involve 10-port 10-Gigabit Ethernet LAN/WAN PIC (PD-5-10XGE-SFPP) ports:

- Non-standard TPID for VLAN tagging is not supported, except for 0x8100.
- The number of user created IFLs is limited to 4065/PIC and 1022/port.
- Classifier tables are limited to 8 for each BA classifier type.
- Forwarding classes are limited to 8.
- The **guaranteed-rate** and **shaping-rate** statements are not supported at the IFD level.
- The **per-unit-scheduler** and **hierarchical-scheduler** statements are not supported.
- Only the **strict-high** and **low** levels of scheduling priorities are supported.
- The **excess-priority** configuration is not supported.
- The **buffer-size** configuration under **schedulers** is not supported.
- WRED is not supported.
- srTCM and trTCM are not supported.
- Shared scheduler mode is not supported.

Table 31 on page 398 10-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PD-5-10XGE-SFPP).

Table 31: Capabilities of 10-Gigabit Ethernet LAN/WAN PICs

Capability	Support
Maximum VLANs per PIC	4065
Maximum VLANs per port	1022

Table 31: Capabilities of 10-Gigabit Ethernet LAN/WAN PICs (continued)

Capability	Support
MAC learning per port	960
MAC accounting per port	960
MAC filtering per port	960 (64 filters per physical or logical interface) 960 filters across multiple logical interfaces
MAC policers	128 ingress Mac policers 128 egress Mac policers
Classifers	Eight classifiers per PIC for each BA classifier type

Release History Table

Release	Description
12.2	Starting with Junos OS Release 12.2, WAN PHY mode is supported on the T4000 routers with the 24-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-24XGE-SFPP).
12.1R2	Starting with Junos OS Release 12.1R2, WAN PHY mode is supported on the T4000 routers with the 12-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-12XGE-SFPP).

12-port 10-Gigabit Ethernet LAN/WAN PIC on Type 5 FPC Overview

The 10-Gigabit Ethernet LAN/WAN PIC on Type 5 FPC is a 12-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (model number, PF-12XGE-SFPP) on T4000 Core Routers.

The following features are supported on the 10-Gigabit Ethernet LAN/WAN PIC on Type 5 FPC:

- Access to all 10-Gigabit Ethernet port counters through SNMP.
- Logical interface–level MAC filtering, accounting, policing, and learning for source media access control (MAC).
- Flexible encapsulation.
- Single, stacked, and flexible VLAN tagging modes.
- Native VLAN configuration to allow untagged frames to be received on the tagged interfaces.
- Maximum transmission unit (MTU) size of up to 9192 bytes for Ethernet frames.
- Link aggregation group (LAG) on single chassis.
- Interoperability with other 10-Gigabit Ethernet PICs on M Series and T Series routers in LAN PHY mode.
- Eight queues per physical interface on egress.
- Behavior aggregate (BA) classification (IPv4 DSCP, IPv6 DSCP, Inet precedence, IEEE 802.1P, IEEE 802.1AD, MPLS EXP) and fixed classification.
- Defining the VLAN rewrite operation to be applied to the incoming and outgoing frames on logical interfaces on this PIC.

  NOTE: **Only the Tag Protocol Identifier (TPID) 0x8100 is supported.**

- Interface encapsulations, such as the following:
  - **untagged**—Default encapsulation, when other encapsulation is not configured.
    - You can configure only one logical interface (unit 0) on the port.
    - You cannot include the **vlan-id** statement in the configuration of the logical interface.
  - **vlan-tagging**—Enable VLAN tagging for all logical interfaces on the physical interface.
  - **stacked-vlan-tagging**—Enable stacked VLAN tagging for all logical interfaces on the physical interface.
  - **ethernet-ccc**—Ethernet cross-connect.
  - **ethernet-tcc**—Ethernet translational cross-connect.
  - **vlan-ccc**—802.1Q tagging for a cross-connect.
  - **vlan-tcc**—Virtual LAN (VLAN) translational cross-connect.
  - **extended-vlan-ccc**—Standard Tag Protocol Identifier (TPID) tagging for a cross-connect.
  - **extended-vlan-tcc**—Standard Tag Protocol Identifier (TPID) tagging for an Ethernet translational cross-connect.

- **ethernet-vpls**—Ethernet virtual private LAN service.
- **vlan-vpls**—VLAN virtual private LAN service.
- **flexible-ethernet-services**—Allows per-unit Ethernet encapsulation configuration.

- The following Layer 3 protocols are also supported:
  - IPv4
  - IPv6
  - MPLS
- WAN PHY features, such as the following:
  - WAN PHY mode on a per-port basis.
  - Insertion and detection of path trace messages.
  - Ethernet WAN Interface Sublayer (WIS) object.

NOTE: The T4000 Core Router supports only LAN PHY mode in Junos OS Release 12.1R1. Starting with Junos OS Release 12.1R2, WAN PHY mode is supported on T4000 routers with 12-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+.

The 10-Gigabit Ethernet LAN/WAN PIC on Type 5 FPC does not support:

- MAC filtering, accounting, and policing for destination MAC at the logical interface level.

NOTE: Because destination MAC filtering is not supported, the hardware is configured to accept all the multicast packets. This enables the OSPF protocol to work.

- Premium MAC policers at the logical interface level.
- MAC filtering, accounting, and policing at the physical interface level.
- Multiple TPIDs

Capability	Support
Maximum logical interfaces per PIC	32,000
Maximum logical interfaces per port	For IPv4 the limit is 4093. For IPv6 the limit is 1022.
Classifers	Eight classifiers per PIC for each BA classifier type

24-port 10-Gigabit Ethernet LAN/WAN PIC on Type 5 FPC Overview

This section describes the main features and caveats of the 24-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (model number PF-24XGE-SFPP).

The following major software features are supported on the 24-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (model number PF-24XGE-SFPP):

- Twenty-four 10-Gigabit Ethernet interfaces in two-to-one oversubscription of traffic in oversubscribed mode or 12 ports in line-rate mode. For more information about oversubscribed mode and line-rate mode, see the "Configuring Line-Rate Mode on 10-Gigabit Ethernet LAN/WAN PICs Supporting Oversubscription" on page 404.
- Traffic is classified as control traffic or best-effort traffic with non-class-of-service-aware tail drops of best-effort traffic in oversubscribed mode.

  The aggregate bandwidth of all the ports together is 120 Gbps. No hard partitioning of bandwidth is done—that is, if one port group is active, it can support 120 Gbps traffic. The bandwidth for best-effort traffic is shared among all the 24 ports.

  Note that the preclassification is restricted to two traffic classes, and is not user-configurable.
- All Junos OS configuration commands supported on the existing 10-Gigabit Ethernet LAN/WAN PIC with SFP+.
- The output of the **show interfaces extensive** operational mode command now displays preclassification queue counters.
- Line-rate mode operation of the first 12 ports can be achieved by using the **[set chassis fpc *fpc-number* pic *pic-number* linerate-mode]** command. By default, the 24-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ works in oversubscribed mode.
- LAN PHY mode and WAN PHY mode on a per-port basis. WAN PHY mode can be achieved by using the **[set interfaces *interface-name* framing wan-phy]** command.
- WAN PHY features, such as the following:
  - Insertion and detection of path trace messages.
  - Ethernet WAN Interface Sublayer (WIS) object.
- Aggregated Ethernet is supported only in line-rate mode.
- Link aggregation group (LAG) is supported only in line-rate mode.
- 4000 logical interfaces per physical interface and 32,000 logical interfaces per chassis.
- Access to all 10-Gigabit Ethernet port counters through SNMP.

NOTE: Graceful Routing Engine switchover (GRES) and nonstop active routing (NSR) are now supported on T4000 routers.

- Configuring Line-Rate Mode on 10-Gigabit Ethernet LAN/WAN PICs Supporting Oversubscription on page 404

Modes of Operation of 10-Gigabit Ethernet PICs

10-Gigabit Ethernet PICs operate in the following modes:

- Line-rate mode—By default, the 12-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-12XGE-SFPP) operates in line-rate mode.

  In a 24-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-24XGE-SFPP), 12 ports (ports 0–11)can operate in line-rate mode . To configure the PF-24XGE-SFPP PIC to operate in line-rate mode, include the **linerate-mode** statement at the **[edit chassis set fpc *fpc-number* pic *pic-number*]** hierarchy level.

- Oversubscribed mode—In this mode, all ports on the PIC are enabled with two-to-one oversubscription. In a PF-24XGE-SFPP PIC, by default, two-to-one oversubscription of traffic is achieved in oversubscribed mode—Traffic from 24 ingress ports to the Packet Forwarding Engine is statically mapped to one of the 12 egress ports. 10 Gbps of bandwidth traffic moving toward the Packet Forwarding Engine is shared by two ingress ports (called a port group), thereby achieving two-to-one oversubscription. This scheme provides two-to-one oversubscription across a port group and not across the entire PIC.

  NOTE: PF-12XGE-SFPP PIC always operates at line rate.

- Mixed-rate mode or dual-rate mode—Dual-rate mode or mixed-rate mode for PF-24XGE-SFPP allows you to configure a mix of port speeds of 1 Gbps and 10 Gbps. However, on PF-12XGE-SFPP, note that you can configure port speeds of either 1 Gbps and 10 Gbps when the PIC is in line rate mode. You can enable mixed-rate mode and set port speeds with the **mixed-rate-mode** and **speed 1G |10G** statements respectively at the **[edit chassis fpc *x* pic *y*]** hierarchy level. You can disable mixed-rate mode with the **delete chassis fpc *x* pic *y* mixed-rate-mode** statement.

  NOTE: To change the port speed from 10 Gbps to 1 Gbps on the PF-24XGE-SFPP and PF-12XGE-SFPP PICs, SFP optics is required.

- **mixed-rate-mode on page 1261**

Configuring Line-Rate Mode on 10-Gigabit Ethernet LAN/WAN PICs Supporting Oversubscription

For 10-Gigabit Ethernet LAN/WAN PICs supporting oversubscription, oversubscribed Ethernet mode is set by default. To configure these PICs in line-rate mode, include the **linerate-mode** statement at the **[edit chassis set fpc *fpc-number* pic *pic-number*]** hierarchy level:

```
[edit chassis]
set fpc fpc-number pic pic-number linerate-mode;
```

To return to the default oversubscribed Ethernet mode, delete the **linerate-mode** statement at the **[edit chassis fpc *fpc-number* pic *pic-number*]** hierarchy level.

NOTE: When the mode of operation of a PIC is changed, the PIC is taken offline and then brought back online immediately.

The following 10-Gigabit Ethernet LAN/WAN PICs support line-rate mode:

- 10-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (model number PD-5-10XGE-SFPP)
- 24-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (model number PF-24XGE-SFPP)

Configuring Control Queue Disable on a 10-port 10-Gigabit Ethernet LAN/WAN PIC

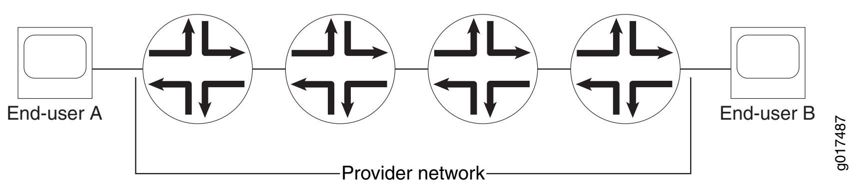
On a 10-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (model number PD-5-10XGE-SFPP), a control queue is used to queue all control packets received on an ingress port. This ensures that control protocol packets do not get dropped randomly when there is congestion due to oversubscription. The following control protocols are supported:

- OSPF
- OSPF3

- VRRP
- IGMP
- RSVP
- PIM
- BGP
- BFD
- LDP
- IS-IS
- RIP
- RIPV6
- LACP
- ARP
- IPv6 NDP
- Connectivity fault management (CFM)
- Link fault management (LFM)

These control packets can either terminate locally or transit through the router. The control queue has a rate limiter to limit the control traffic to 2 Mbps (fixed, not user-configurable) per port. Hence, if transit control traffic is taking too much bandwidth, then it can cause drops on locally terminating control traffic, as shown in Figure 31 on page 405.

Figure 31: Control Queue Rate Limiter Scenario



If the end users generate a mass of malicious traffic for which the port number is 179 (BGP), the router dispatches that traffic to the ingress control queue. Further, if congestion occurs in this ingress control queue due to this malicious traffic, the provider's network control packets may be affected.

In some applications, this can be perceived as a new vulnerability. To address this concern, you can disable the control queue feature. With the control queue feature disabled, you must take precautions to protect control traffic through other means, such as mapping control packets (using BA classification) to a queue that is marked strict-high or is configured with a high CIR.

You can disable the control queue for all ports on the PIC. To disable the control queue, use the **set chassis fpc *n* pic *n* no-pre-classifier** command. By default, the **no-pre-classifier** statement is not configured and the control queue is operational.

Deleting the **no-pre-classifier** statement re-enables the control queue feature on all ports of the 10-Gigabit Ethernet LAN/WAN PIC.

NOTE:

- This functionality is applicable both in OSE and line-rate modes.
- The control queue feature is enabled by default in both OSE and line-rate modes, which can be overridden by the user configuration.
- When the control queue is disabled, various **show queue** commands will show *control queue* in the output. However, all control queue counters are reported as zeros.
- Changing this configuration (enabling or disabling the control queue feature) results in the PIC being taken offline and brought back online.

Once the control queue is disabled, the Layer 2/Layer 3 control packets are subject to queue selection based on BA classification. However, some control protocol packets will not be classified using BA classification, because they might not have a VLAN, MPLS, or IP header. These are:

- Untagged ARP packets
- Untagged Layer 2 control packets such as LACP or Ethernet OAM
- Untagged IS-IS packets

When the control queue feature is disabled, untagged ARP, IS-IS, and other untagged Layer 2 control packets will go to the restricted queue corresponding to the forwarding class associated with queue 0, as shown in the following two examples.

Forwarding Untagged Layer2 Control Packets to Queue 3

With this configuration, the forwarding class (FC) associated with queue 0 is "be" (based on the **forwarding-class** statement configuration). "be" maps to restricted-queue number 3 (based on the "restricted-queue" configuration). Hence, with this particular configuration, untagged ARP, IS-IS, and other untagged Layer 2 control packets will go to ingress queue 3 (not to ingress queue 0).

```
[edit chassis]
forwarding-classes {
  queue 0 be;
  queue 1 af-low8;
  queue 2 af-high;
  queue 3 ef;
  queue 4 ops_control;
  queue 5 net_control;
  queue 6 af-low10_12;
  }
  restricted-queues {
    forwarding-class ef queue-num 0;
    forwarding-class af-low8 queue-num 1;
    forwarding-class af-low10_12 queue-num 1;
    forwarding-class af-high queue-num 2;
    forwarding-class be queue-num 3;
```

```
}
```

Forwarding Untagged Layer2 Control Packets to Queue 3

With this configuration, the FC associated with queue 0 is "ef" (based on the **forwarding-class** statement configuration). "ef" maps to restricted-queue number 0 (based on the **restricted-queue** statement configuration). Hence, with this particular configuration, untagged ARP, IS-IS, and other untagged Layer 2 control packets would go to ingress queue 0.

For tagged ARP, IS-IS, or Layer2 control packets, users should configure an explicit dot1p/dot1ad classifier to make sure these packets are directed to the correct queue. Without an explicit dot1p/dot1ad classifier, tagged ARP, IS-IS, or Layer 2 control packets will go to the restricted-queue corresponding to the forwarding class associated with queue 0.

```
[edit chassis]
forwarding-classes {
  queue 0 ef; <<< ef and be are interchanged
  queue 1 af-low8;
  queue 2 af-high;
  queue 3 be; <<< ef and be are interchanged
  queue 4 ops_control;
  queue 5 net_control;
  queue 6 af-low10_12;
  }
  restricted-queues {
    forwarding-class ef queue-num 0;
    forwarding-class af-low8 queue-num 1;
    forwarding-class af-low10_12 queue-num 1;
    forwarding-class af-high queue-num 2;
    forwarding-class be queue-num 3;
  }
```

Example: Handling Oversubscription on a 10-Gigabit Ethernet LAN/WAN PIC

Table 32 on page 408 lists the scenarios of handling oversubscription on the 10-port 10-Gigabit Ethernet LAN/WAN PIC for different combinations of port groups and active ports on the PIC.

Table 32: Handling Oversubscription on 10-Gigabit Ethernet LAN/WAN PICs

Number of Port Groups with Two Active Ports (A)	Number of Port Groups with One Active Port (B)	Total Number of Ports Used on PIC (C = Ax2 + B)	Status of Oversubscription and Throughput
0	1	1	Oversubscription is not active. Each port will receive 10 Gbps throughput.
0	2	2	Oversubscription is not active. Each port will receive 10 Gbps throughput.
0	5	5	Oversubscription is not active. Each port will receive 10 Gbps throughput.
1	0	2	Oversubscription is active. Each port will receive 5 Gbps throughput (with default shaper configuration).
1	4	6	Oversubscription is active for the port group that has two active ports. Each port in this port group will receive 5 Gbps throughput (with default shaper configuration). For the remaining four ports, oversubscription is not active. Each port will receive 10 Gbps throughput.
3	0	6	Oversubscription is active. Each port will receive 5 Gbps throughput (with default shaper configuration).
5	0	10	Oversubscription is active on all 10 ports (5 port groups). Each port will receive 5 Gbps throughput (with default shaper configuration).

Configuring Mixed-Rate Mode Operation

To configure mixed-rate mode operation for a PF-24XGE-SFPP PIC:

1. Navigate to the **[edit chassis]** hierarchy level.
2. On a T4000 router, configure the mixed-rate mode by including the **mixed-rate-mode** statement at the **[edit chassis fpc *slot-number* pic *pic-number*]** hierarchy level.

[edit chassis]
user@host# **set fpc *fpc-slot* pic pic-number mixed-rate-mode**

On an LCC in a routing matrix, configure the mixed-rate mode by including the **mixed-rate-mode** statement at the **[edit chassis lcc *lcc number* fpc *slot-number* pic *pic-number*]** hierarchy level.

[edit chassis]
user@host# **set lcc *lcc number* fpc *fpc-slot* pic pic-number mixed-rate-mode**

3. Specify the port and the port speed that need to be configured. You can use one of the following speed attributes for this configuration.

   [edit chassis]
   user@host# **set fpc *fpc-slot* pic *pic-number* port port-number speed 1G;**
   user@host# **set fpc *fpc-slot* pic *pic-number* port port-number speed 10G;**
   user@host# **set lcc *lcc number* fpc *fpc-slot* pic pic-number speed 1G;**
   user@host# **set lcc *lcc number* fpc *fpc-slot* pic pic-number speed 10G;**

   NOTE: On a 12 port 10-Gigabit Ethernet PIC (PF-12XGE-SFPP), you can configure the port speed as 1G by including the **set fpc *fpc-slot* pic *pic-number* port port-number speed 1G** statement at the **[edit chassis]** hierarchy level.

   NOTE: To change the port speed from 10 Gbps to 1 Gbps on PF-24XGE-SFPP and PF-12XGE-SFPP PICs, SFP optics is required.

To disable mixed-rate mode operation, include the **delete chassis fpc *x* pic *y* mixed-rate-mode** statement at the **[edit chassis]** hierarchy level.

P2-10G-40G-QSFPP PIC Overview

Starting with Junos OS Release 14.1R2 and 14.2R1, the PTX5000 Packet Transport Router supports the P2-10G-40G-QSFPP PIC on the FPC2-PTX-P1A FPC.

All the ports on the P2-10G-40G-QSFPP PIC are plugged into quad small form-factor pluggable plus transceivers (QSFP+) that, in turn, are connected to fiber-optic cables that support both 10-Gigabit Ethernet standards and 40-Gigabit Ethernet standards, thereby enabling you to configure the PIC to operate either in 10-Gigabit Ethernet mode or in 40-Gigabit Ethernet mode.

Starting from Junos OS Release 14.2R3 and 16.1R1, you can configure the ports on the PIC in 10-Gigabit Ethernet mode or 40-Gigabit Ethernet mode at the port group level.

The following sections describe the P2-10G-40G-QSFPP PIC and the various framing modes that are supported on it:

Understanding Dual Configuration on P2-10G-40G-QSFPP PIC

All the ports on the P2-10G-40G-QSFPP PIC are QSFP+ based—that is, all the ports are connected to fiber-optic cables by means of QSFP+ transceivers.

The QSFP+ module—which includes the transceiver and the fiber-optic cable—supports the following standards on the P2-10G-40G-QSFPP PIC:

- 10-Gigabit Ethernet in LAN PHY framing mode (also known as native Ethernet mode) and WAN PHY framing mode.

  Note that the ports follow a 4-level interface-naming convention—et-*fpc/pic/QSFP+ port*:*channel* in this mode.

- 40-Gigabit Ethernet in LAN PHY framing mode.

  Note that the ports follow a 3-level interface-naming convention—et-*fpc/pic/QSFP+ port* in this mode.

NOTE: **The P2-10G-40G-QSFPP PIC provides forty-eight 10-Gigabit Ethernet ports or twelve 40-Gigabit Ethernet ports. or .**

The PIC can be configured either in 10-Gigabit Ethernet mode or in 40-Gigabit Ethernet mode with the **set chassis fpc *fpc-number* pic pic-number pic-mode (10G | 40G)** configuration command. By default, the PIC is configured in 10-Gigabit Ethernet LAN PHY framing mode.

NOTE:
If you want configure the PIC in 10-Gigabit Ethernet mode to operate in 40-Gigabit Ethernet mode, you must:

1. Delete all the interfaces in the PIC at the **[edit interfaces]** hierarchy level.
2. Configure the PIC to operate in 40-Gigabit Ethernet mode by using the **set chassis fpc *fpc-slot* pic *pic-slot* pic-mode 40G** configuration command and commit.

The PIC reboots and starts operating in the new mode.

The same procedure is applicable when you can configure the PIC in 40-Gigabit Ethernet PIC to operate in 10-Gigabit Ethernet mode. In this case, you must execute the **set chassis fpc *fpc-slot* pic *pic-slot* pic-mode 10G** configuration mode command.

To check the current diagnostics of the PIC, you must run the relevant operational mode CLI commands such as **show chassis hardware**, **show interfaces diagnostics optics *interface-name***,

Understanding Port Group

The FPC2-PTX-P1A FPC on PTX5000 routers can host two PICs and has eight Packet Forwarding Engines. The first four Packet Forwarding Engines on the FPC are associated with PIC 0 and the next four are associated with PIC 1.

All ports associated to one Packet Forwarding Engine compose a port group. Each PIC supports four Packet Forwarding Engines. Therefore, four port groups exist for each P2-10G-40G-QSFPP PIC.

Each Packet Forwarding Engine providesthroughput of 120 Gbps.

Points to Remember

Consider the following points when configuring the PIC at the port group level:

- You can configure the ports in 10-Gigabit Ethernet mode or in 40-Gigabit Ethernet mode at the port group level.
- You can configure the port speed only on the first port in the port group. That is, you must configure the port speed for the port group on the ports numbered 0, 3, 6, and 9—the first ports in the respective port groups. An error message is logged when you try to configure the speed on any other port in the port group and this configuration will not have any effect on the PIC.
- You can configure the port speed of a port group only when the value of the **pic-mode** statement at the **[edit chassis fpc *fpc-slot* pic *pic-slot* pic-mode]** is set to 10G or when the statement is not configured.
- You cannot configure different speeds for the ports in the same port group.
- You can configure different speeds for different port groups.

Port Group in 10-Gigabit Ethernet Mode

Each Packet Forwarding Engine supports twelve 10-Gigabit Ethernet ports in LAN PHY or in WAN PHY framing mode.

Note that when a port group is configured from 10-Gigabit Ethernet mode to 40-Gigabit Ethernet mode, the ports with 4-level interface-naming convention are deleted and three 40-Gigabit Ethernet mode ports with 3-level interface-naming convention are created.

Note that when the configuration of a port group is changed from 10-Gigabit Ethernet mode to 40-Gigabit Ethernet mode, the configuration of the twelve 10-Gigabit Ethernet ports is deleted and the 4-level interface-naming convention of the ports is also lost. Instead, three 40-Gigabit Ethernet ports are configured and these ports adhere to the 3-level interface-naming convention

Port Group in 40-Gigabit Ethernet Mode

Each Packet Forwarding Engine supports three 40-Gigabit Ethernet ports in LAN PHY framing mode.

Note that when the configuration of a port group is changed from 40-Gigabit Ethernet mode to 10-Gigabit Ethernet mode, the configuration of the three 40-Gigabit Ethernet ports is deleted and the 3-level interface-naming convention of the ports is also lost. Instead, twelve 10-Gigabit Ethernet ports are configured and these ports adhere to the 4-level interface-naming convention.

Port Number Mapping When Port Groups Are Configured

Table 33 on page 413shows the port numbering in 40-Gigabit Ethernet mode and in 10-Gigabit Ethernet mode at the port group level.

Table 33: Port Number Mapping When Port Groups Are Configured

10-Gigabit Ethernet Mode

A 10-Gigabit Ethernet interface can operate in 10-Gigabit Ethernet LAN PHY framing mode or in 10-Gigabit Ethernet WAN PHY framing mode.

You can configure a 10-Gigabit Ethernet interface at the **[edit interface *interface-name* framing-mode (lan-phy | wan-phy)]** hierarchy level to operate in 10-Gigabit Ethernet LAN PHY framing mode or in 10-Gigabit Ethernet WAN PHY framing mode.

Each P2-10G-40G-QSFPP PIC provides 48 physical interfaces. The interfaces are represented by the 4-level interface-naming convention—et-*fpc/pic/QSFP+ port*:*channel*, where the value of the *QSFP+ port* option ranges from 0 through 11 and the value of the *channel* option ranges from 0 through 3.

- Framing Mode Overview on page 417
- Supported Features on LAN PHY and WAN PHY Framing Mode on page 418

Framing Mode Overview

When a P2-10G-40G-QSFPP PIC is configured in 10-Gigabit Ethernet framing mode, it can operate in one of the following framing modes:

- LAN PHY framing mode. Note that by default, the PIC is in 10-Gigabit Ethernet LAN PHY framing mode. You can configure loopback at the **[edit interfaces *interface-name* sonet-options loopback]** hierarchy level.

NOTE: The ports are set to LAN PHY framing mode by default when the **framing-mode** statement is not configured at the **[edit interface *interface-name*]** hierarchy level.

- WAN PHY framing mode

Supported Features on LAN PHY and WAN PHY Framing Mode

The following features are supported in LAN PHY and WAN PHY framing mode when the PIC operates in 10-Gigabit Ethernet mode:

- The following are supported for WAN interface sublayer statistics, defects, and alarms when the PIC operates in WAN PHY framing mode:
  - GR 253 standard.
  - **show interfaces** ***interfaces-name*** operational mode command displays WAN interface sublayer statistics, defects and alarms.
  - Interrupt-driven notification for WAN interface sublayer defects.
  - Path trace and trigger options for WAN interface sublayer alarms.
  - Transmitting and receiving J1 (path trace) messages—J1 is a part of path overhead in a WAN interface sublayer frame.
- Line loopback and local loopback. Loopback is configured at the **[edit interfaces *interface-name* sonet-options loopback]** hierarchy level in WAN PHY framing mode.
- The defects PHY LOL (loss of light) and PHY PLL (loss of PLL lock) are detected and reported at the physical level in WAN PHY framing mode.

Fast reroute (FRR) in WAN PHY framing mode:

- Enable or disable preemptive fast reroute (FRR) options at the **[edit interfaces *interface-name* otn-options preemptive-fast-reroute]** hierarchy level.
- Configure thresholds and interval for the optical channel data unit (ODU) signal degradation (**odu-signal-degrade**) and the configurable pre-FEC bit error rate (BER) (**ber-threshold-signal-degrade**) at the **[edit interfaces *interface-name* otn-options odu-signal-degrade]** hierarchy level and the **[edit interfaces *interface-name* otn-options signal-degrade]** hierarchy level, respectively.

40-Gigabit Ethernet Mode

You can configure twelve 40-Gigabit Ethernet interfaces that operate in LAN PHY framing mode. The interfaces are represented by the 3-level interface-naming convention et-*fpc/pic/QSFP+ port*, where the value of the *QSFP+ port* variable ranges from 0 through 11.

Related Documentation

- Configuring the P2-10G-40G-QSFPP PIC on page 419

Configuring the P2-10G-40G-QSFPP PIC

Starting with Junos OS Release 14.1R2, PTX5000 supports the P2-10G-40G-QSFPP PIC on the FPC2-PTX-P1A FPC. You can configure the P2-10G-40G-QSFPP PIC to operate either in 10-Gigabit Ethernet mode or in 40-Gigabit Ethernet mode..

The following tasks explain how to configure the P2-10G-40G-QSFPP PIC in 10-Gigabit Ethernet mode or in 40-Gigabit Ethernet mode and to configure the framing modes on it.

Configuring the PIC in 10-Gigabit Ethernet Mode or in 40-Gigabit Ethernet Mode

To configure the P2-10G-40G-QSFPP PIC in 10-Gigabit Ethernet mode or in 40-Gigabit Ethernet mode:

1. In configuration mode, go to the **[edit chassis]** hierarchy level.

   ```
   [edit]
   user@host# edit chassis
   ```

2. Configure the PIC in 10-Gigabit Ethernet mode or in 40-Gigabit Ethernet mode after specifying the required FPC slot and PIC slot. Note that all the PIC ports in a PIC are configured at once with this configuration command.

   ```
   [edit chassis]
   user@host# set fpc fpc-slot pic pic-slot pic-mode (10G | 40G)
   ```

Configuring the PIC in 10-Gigabit Ethernet Mode to Operate in 40-Gigabit Ethernet Mode

To configure the P2-10G-40G-QSFPP PIC that is configured in 10-Gigabit Ethernet mode to operate in 40-Gigabit Ethernet mode:

1. In configuration mode, go to the **[edit interfaces]** hierarchy level.

   ```
   [edit]
   ```

user@host# **edit interfaces**

2. Delete all the interfaces in the PIC, commit, and then move to the top of the hierarchy level.

   [edit interfaces]
   user@host# **delete** ***interface-name***
   user@host# **delete ...**
   user@host# **commit**
   user@host# **top**

3. Configure the PIC to operate in 40-Gigabit Ethernet mode and commit.

   [edit]
   user@host# **set chassis fpc** ***fpc-slot*** **pic** ***pic-slot*** **pic-mode 40G**
   user@host# **commit**

After the configuration is committed, the PIC reboots and starts operating in the 40-Gigabit Ethernet mode. You can now configure the parameters, such as encapsulation, framing mode, and so on, for the twelve 40-Gigabit Ethernet interfaces in the PIC as needed.

Configuring the PIC in 40-Gigabit Ethernet Mode to Operate in 10-Gigabit Ethernet Mode

To configure the P2-10G-40G-QSFPP PIC that is configured in 40-Gigabit Ethernet mode to operate in 10-Gigabit Ethernet mode:

1. In configuration mode, go to the **[edit interfaces** ***interfaces-name*****]** hierarchy level.

   [edit]
   user@host# **edit interfaces** ***interface-name***

2. Delete all the interfaces in the PIC, commit, and then move to the top of the hierarchy level.

   [edit interfaces]
   user@host# **delete** ***interface-name***
   user@host# **delete ...**
   user@host# **commit**
   user@host# **top**

3. Configure the PIC to operate in 10-Gigabit Ethernet mode and commit.

   [edit]
   user@host# **set chassis fpc** ***fpc-slot*** **pic** ***pic-slot*** **pic-mode 10G**
   user@host# **commit**

After the configuration is committed, the PIC reboots and starts operating in the 10-Gigabit Ethernet mode. You can now configure the parameters, such as encapsulation, framing mode, and so on, for the forty-eight 10-Gigabit Ethernet interfaces in the PIC as needed.

Configuring the PIC at Port Group Level

Before You Begin

Verify that the **pic-mode** statement at the **[edit chassis fpc *fpc-slot* pic *pic-slot* pic-mode]** is not configured or that its value is set to 10G.

To configure a port group in the P2-10G-40G-QSFPP PIC to operate in 10-Gigabit Ethernet mode or 40-Gigabit Ethernet mode:

1. In configuration mode, go to the **[edit chassis fpc *fpc-slot* pic *pic-slot*]** hierarchy level.

   [edit]
   user@host# **edit chassis fpc *fpc-slot* pic *pic-slot***

2. Configure the port number as 0, 3, 6, or 9 and the speed as 10G or 40G. Note that you can configure the port speed only on the first port in the port group. That is, configure the port speed only on the ports numbered 0, 3, 6, and 9. An error message is displayed when you try to configure the speed on any other port in the port group.

   [edit chassis fpc *fpc-slot* pic *pic-slot*]
   user@host# **set port *port-number* speed (10G | 40G)**

NOTE: A system log message is logged when you try to configure a different port speed on a port when the port group is operating at another speed.

Configuring Framing Mode on P2-10G-40G-QSFPP PIC

You can configure LAN PHY, or WAN PHY framing mode when the PIC is operating in 10-Gigabit Ethernet mode. You can configure LAN PHY framing mode when the PIC is operating in 40-Gigabit Etherent mode. The following tasks explain how to configure the various framing modes on the PIC:

- Configuring LAN PHY or WAN PHY Framing Mode in 10-Gigabit Ethernet Mode on page 421
- Configuring LAN PHY Framing Mode in 40-Gigabit Ethernet Mode on page 422

Configuring LAN PHY or WAN PHY Framing Mode in 10-Gigabit Ethernet Mode

To configure the P2-10G-40G-QSFPP PIC in 10-Gigabit Ethernet mode to operate in LAN PHY framing mode or in WAN PHY framing mode, you must configure the framing mode individually on all the interfaces:

1. In configuration mode, go to the **[edit interfaces *interfaces-name*]** hierarchy level, where the interface name is in et-*fpc/pic/port*:*channel* format.

   [edit]
   user@host# **edit interfaces *interface-name***

2. Configure the framing mode as LAN PHY or WAN PHY and commit.

[edit interfaces *interface-name*]
user@host# **set framing (lan-phy | wan-phy)**
user@host# **commit**

For example, you can configure the framing mode as LAN PHY or WAN PHY on the et-1/1/1:0 interface.

Configuring LAN PHY Framing Mode in 40-Gigabit Ethernet Mode

To configure the P2-10G-40G-QSFPP PIC in 40-Gigabit Ethernet mode to operate in LAN PHY framing mode:

1. In configuration mode, go to the **[edit interfaces** ***interfaces-name*****]** hierarchy level, where the interface name is in et-*fpc/pic/port* format.

   [edit]
   user@host# **edit interfaces** ***interface-name***

2. Configure the framing mode as LAN PHY and commit.

   [edit interfaces *interface-name*]
   user@host# **set framing (lan-phy)**
   user@host# **commit**

   For example, you can configure the framing mode as LAN PHY on the et-2/2/2 interface.

Release History Table

Release	Description
14.1R2	Starting with Junos OS Release 14.1R2, PTX5000 supports the P2-10G-40G-QSFPP PIC on the FPC2-PTX-P1A FPC.

Related Documentation

• P2-10G-40G-QSFPP PIC Overview on page 409

Example: Configuring the P2-10G-40G-QSFPP PIC

Requirements

This example uses the following hardware and software components:

- Junos OS Release 14.1R2 or Junos OS Release 14.2 or later
- One PTX5000 router with P2-10G-40G-QSFPP PIC

Overview

Starting with Junos OS Release 14.1R2 and 14.2R1, PTX5000 supports the P2-10G-40G-QSFPP PIC on the FPC2-PTX-P1A FPC.

All the ports on the P2-10G-40G-QSFPP PIC are QSFP+ based—that is, all the ports are connected to fiber-optic cables by means of QSFP+ transceivers. The P2-10G-40G-QSFPP PIC provides forty-eight 10-Gigabit Ethernet ports or twelve 40-Gigabit Ethernet ports.

The QSFP+ module—which includes the transceiver and the fiber-optic cable—supports the following standards on the P2-10G-40G-QSFPP PIC:

- 10-Gigabit Ethernet in LAN PHY framing mode (also known as native Ethernet mode) and WAN PHY framing mode.
- 40-Gigabit Ethernet in LAN PHY framing mode.

Configuration

To configure the P2-10G-40G-QSFPP PIC to operate in 10-Gigabit Ethernet mode, and to set the framing mode and other options on an interface on this PIC, perform the following tasks:

- Configuring the P2-10G-40G-QSFPP PIC in 10-Gigabit Ethernet Mode on page 423
- Configuring the Framing Mode on an Interface on page 423
- Configuring the Interface Options on page 424
- Verification on page 424

Configuring the P2-10G-40G-QSFPP PIC in 10-Gigabit Ethernet Mode

Step-by-Step Procedure

Configure the PIC in 10-Gigabit Ethernet mode.

1. In configuration mode, go to the **[edit chassis]** hierarchy level.

   ```
   [edit]
   user@host# edit chassis
   ```

2. Configure the PIC in 10-Gigabit Ethernet mode after specifying the required FPC slot and PIC slot. Note that the PIC restarts after the configuration is committed and all the ports in the PIC come up in the 10-Gigabit Ethernet mode.

   ```
   [edit chassis]
   user@host# set fpc 1 pic 1 pic-mode 10G
   ```

Configuring the Framing Mode on an Interface

Step-by-Step Procedure

To configure an interface *et-1/1/1:0* in the P2-10G-40G-QSFPP PIC to operate in LAN PHY framing mode:

1. In configuration mode, go to the **[edit interfaces et-1/1/1:0]** hierarchy level.

```
[edit]
user@host# edit interfaces et-1/1/1:0
```

2. Configure the framing mode for the interface as LAN PHY and commit.

   ```
   [edit interfaces et-1/1/1:0]
   user@host# set framing lan-phy
   user@host# commit
   ```

   Similarly, you can configure LAN PHY or WAN PHY framing mode for the other interfaces in the PIC.

Configuring the Interface Options

Step-by-Step Procedure

Configure the interface options for the interface et-1/1/1:0 as needed. The following procedure configures a few interface-specific options.

1. In configuration mode, go to the **[edit interfaces et-1/1/1:0]** hierarchy level.

   ```
   [edit]
   user@host# edit interfaces et-1/1/1:0
   ```

2. Configure the encapsulation as ethernet-ccc.

   ```
   [edit interfaces et-1/1/1:0]
   user@host# set encapsulation ethernet-ccc
   ```

3. Configure the family as CCC for the logical interface 0.

   ```
   [edit interfaces et-1/1/1:0]
   user@host# set unit 0 family ccc
   ```

4. Enable flow control to regulate the flow of packets from the router to the remote side of the network connection.

   ```
   [edit interfaces et-1/1/1:0 gigether-options]
   user@host# set flow-control
   ```

5. Enable loopback mode for the interface, commit the configuration, and exit the configuration mode.

   ```
   [edit interfaces et-1/1/1:0 gigether-options]
   user@host# set loopback
   user@host# commit
   user@host# quit
   ```

Verification

Displaying Interface Details

Purpose To display interface-specific details of the et-1/1/1:0 interface.

Action Execute the **show interfaces et-1/1/1:0** operational command.

```
user@host# run show interfaces et-1/1/1:0
Interface index: 525, SNMP ifIndex: 522
  Link-level type: Ethernet, MTU: 1514, MRU: 0, LAN-PHY mode, Speed: 10Gbps, BPDU
 Error:
None, MAC-REWRITE Error: None, Loopback: None, Source filtering: Disabled,
  Flow control: Enabled
  Device flags   : Present Running Down
  Interface flags: Hardware-Down SNMP-Traps Internal: 0x4000
  Link flags     : None
  CoS queues     : 8 supported, 8 maximum usable queues
  Current address: ac:4b:c8:f6:af:68, Hardware address: ac:4b:c8:f6:af:68

  Input rate     : 0 bps (0 pps)
  Output rate    : 0 bps (0 pps)
  Active alarms  : LINK
  Active defects : LINK
  PCS statistics                      Seconds
    Bit errors                             0
    Errored blocks                         1
  Interface transmit statistics: Disabled
```

Meaning The interface details are displayed. Note that to display information for an interface in 10-Gigabit Ethernet mode for the P2-10G-40G-QSFPP PIC, you must use the et-*fpc*/*pic*/*port*:*channel* format.

Release History Table

Release	Description

Related Documentation

- P2-10G-40G-QSFPP PIC Overview on page 409

CHAPTER 23

Configuring 10-Gigabit Ethernet Framing

10-Gigabit Ethernet Framing Overview

The 10-Gigabit Ethernet interfaces support operation in two modes:

- 10GBASE-R, LAN Physical Layer Device (LAN PHY)
- 10GBASE-W, WAN Physical Layer Device (WAN PHY)

When the external interface is running in LAN PHY mode, it bypasses the WIS sublayer to directly stream block-encoded Ethernet frames on a 10-Gigabit Ethernet serial interface. When the external interface is running in WAN PHY mode, it uses the WIS sublayer to transport 10-Gigabit Ethernet frames in an OC192c SONET payload.

WAN PHY mode is supported on MX240, MX480, MX960, T640, T1600, T4000 and PTX Series Packet Transport routers only.

NOTE: **The T4000 Core Router supports only LAN PHY mode in Junos OS Release 12.1R1. Starting with Junos OS Release 12.1R2, WAN PHY mode is supported on the T4000 routers with the 12-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-12XGE-SFPP). Starting with Junos OS Release 12.2, WAN PHY mode is supported on the T4000 routers with the 24-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-24XGE-SFPP).**

Although the external interface provides a lower throughput when running in WAN PHY mode because of the extra SONET overhead, it can interoperate with SONET section or line level repeaters. This creates an advantage when the interface is used for long-distance, point-to-point 10-Gigabit Ethernet links. When the external interface is running in WAN PHY mode, some SONET options are supported. For information about SONET options supported on this interface, see *Configuring SONET Options for 10-Gigabit Ethernet Interfaces*.

NOTE: SONET or SDH framing mode configuration **framing (sdh | sonet)** is not applicable on the 10-Gigabit Ethernet ports. Configuring the **wan-phy** framing mode on the 10-Gigabit Ethernet ports allows the interface to accept SONET or SDH frames without further configuration.

Release History Table

Release	Description
12.2	Starting with Junos OS Release 12.2, WAN PHY mode is supported on the T4000 routers with the 24-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-24XGE-SFPP).
12.1R2	Starting with Junos OS Release 12.1R2, WAN PHY mode is supported on the T4000 routers with the 12-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-12XGE-SFPP).

Related Documentation

Understanding WAN Framing for 10-Gigabit Ethernet Trio Interfaces

If you use the **wan-phy** statement option at the **[edit interfaces xe-*fpc*/*pic*/0 framing]** hierarchy level to configure Trio WAN mode framing for 10-Gigabit Ethernet interfaces, then the alarm behavior of the link, although in full compliance with the IEEE 802.3ae 10-Gigabit Ethernet standard, might not be as expected.

In particular:

- The interface does not distinguish between loss of light (LOL), loss of phase lock loop (PLL), or loss of signal (LOS). If a loss of PLL or LOS alarm occurs, then both PLL and LOS alarms are raised. LOL is also raised because there is no separate LOL indication from the hardware.
- The interface does not raise LOS, PLL, or LOL alarms when the fiber in disconnected from the interface port. You must remove the hardware to raise this alarm.
- The interface line-level alarm indicator signal (AIS-L) is not always raised in response to a loss of framing (LOF) defect alarm.
- If the AIS-L or path-level AIS (AIS-P) occurs, the interface path-level loss of code delineation (LCD-P) is not detected. LCD-P is seen during the path-level remote defect indicator (RDI-P) alarm.
- If an AIS-L alarm occurs, the AIS-P is not detected, but the LOP alarm is detected.

None of the alarm issues are misleading, but they make troubleshooting the root cause of problems more complex.

Related Documentation

- **framing on page 1179**
- Configuring 10-Gigabit Ethernet Framing on page 429
- 10-Gigabit Ethernet Framing Overview on page 427

- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring 10-Gigabit Ethernet Framing

The 10-Gigabit Ethernet interfaces uses the interface type **xe-*fpc/pic/port***. On single port devices, the port number is always zero.

The **xe-*fpc/pic/port*** interface inherits all the configuration commands that are used for gigabit Ethernet (**ge-*fpc/pic/port***) interfaces.

To configure LAN PHY or WAN PHY operating mode, include the **framing** statement with the **lan-phy** or **wan-phy** option at the **[edit interfaces xe-*fpc* /*pic*/0]** hierarchy level.

```
[edit interfaces xe-fpc/pic/0 framing]
framing (lan-phy | wan-phy);
```

NOTE:

- The T4000 Core Router supports only LAN PHY mode in Junos OS Release 12.1R1. Starting with Junos OS Release 12.1R2, WAN PHY mode is supported on the T4000 routers with the 12-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-12XGE-SFPP). Starting with Junos OS Release 12.2, WAN PHY mode is supported on the T4000 routers with the 24-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+ (PF-24XGE-SFPP).
- On PTX Series Transport Routers, WAN PHY mode is supported only on the 24-port 10-Gigabit Ethernet LAN/WAN PIC with SFP+
- When the PHY mode changes, interface traffic is disrupted because of port reinitialization.

To display interface information, use the operational mode command **show interfaces xe-*fpc/pic/port* extensive**.

NOTE:

- SONET or SDH framing mode configuration **framing (sdh | sonet)** is not applicable on the 10-Gigabit Ethernet ports. Configuring the **wan-phy** framing mode on the 10-Gigabit Ethernet ports allows the interface to accept SONET or SDH frames without further configuration.
- If you configure the WAN PHY mode on an aggregated Ethernet interface, you must set the aggregated Ethernet link speed to OC192.

CHAPTER 24

Configuring 10-Gigabit Ethernet Notification of Link Down Alarm

Gigabit Ethernet Notification of Link Down Alarm Overview

Notification of link down alarm generation and transfer is supported for all 10-Gigabit Ethernet PIC interfaces on M120 and M320 routers. On the MX Series and T series routers, notification of link down alarm generation and transfer is supported for all Gigabit Ethernet Interfaces (1-Gigabit, 10-Gigabit, and 100-Gigabit).

Related Documentation

- *Ethernet Interfaces Feature Guide for Routing Devices*

10-Gigabit Ethernet Notification of Link Down for Optics Options Overview

Notification of link down is supported for IQ2 10-Gigabit Ethernet interfaces and MX Series DPCs. You can use link down notification to help identify optical link connectivity problems.

For information on configuring link down notification, see “Configuring 10-Gigabit Ethernet Link Down Notification for Optics Options Alarm or Warning” on page 432.

Related Documentation

- Configuring 10-Gigabit Ethernet Link Down Notification for Optics Options Alarm or Warning on page 432

- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring Gigabit Ethernet Notification of Link Down Alarm

Notification of link down alarm generation and transfer is supported for all 10-Gigabit Ethernet PIC interfaces on M120 and M320 routers. On the MX Series and T Series routers, notification of link down alarm generation and transfer is supported for all Gigabit Ethernet Interfaces (1-Gigabit, 10-Gigabit, and 100-Gigabit).

To configure this option, include the **asynchronous-notification** statement at the **[edit interfaces ge-** ***fpc/pic/port*** **gigether-options]** hierarchy level:

```
[edit interfaces]
ge-fpc/pic/port {
  gigether-options {
    asynchronous-notification;
  }
}
```

Configuring 10-Gigabit Ethernet Link Down Notification for Optics Options Alarm or Warning

To configure this option, include the **alarm** or **warning** statement at the **[edit interfaces ge-** ***fpc/pic/port*** **optics-options]** hierarchy level:

```
[edit interfaces]
ge-fpc/pic/port {
  optics-options {
    alarm alarm-name {
      (syslog | link-down);
      }
    warning warning-name {
      (syslog | link-down);
      }
  }
}
```

CHAPTER 25

Configuring 40-Gigabit Ethernet PICs

40-Gigabit Ethernet PIC Overview

The 40-Gigabit Ethernet PIC with CFP (PD-1XLE-CFP) is a 1-port 40-Gigabit Ethernet Type 4 PIC with C form-factor pluggable transceiver (CFP) optics supported on T640, T1600, and T4000 routers. The 40-Gigabit Ethernet PIC occupies FPC slot 0 or 1 in the Type 4 FPC and it is similar to any regular PIC such as the 4-port 10-Gigabit Ethernet LAN/WAN PIC with XFP (PD-4XGE-XFP) PIC. The CFP information appears under the PIC information in the show command output.

The 40-Gigabit Ethernet PIC with CFP supports flexible Ethernet services encapsulation and MAC accounting.

MAC learning, MAC policing, and Layer 2 rewrite features are not supported.

The 40-Gigabit Ethernet PIC with CFP supports the following features:

- Encapsulation protocols such as:
  - Layer 2 protocols
    - Ethernet CCC, Ethernet TCC, and Ethernet VPLS
    - VLAN CCC
    - Extended VLAN TCC
    - VLAN VPLS
    - Flexible Ethernet service
  - Layer 3 protocols
    - IPv4
    - IPv6

    - MPLS

- CFP Multi-Source Agreement (MSA)-compliant management data input/output (MDIO) control features (transceiver dependent).
- Graceful Routing Engine switchover (GRES) (in all PIC and chassis configurations).
- Interface creation:
    - When the PIC is brought online, the router creates one interface, et-*x*/*y*/0, where *x* represents the FPC slot number and *y* represents PIC slot number. The physical interface represents internal Ethernet Packet Forwarding Engines.
    - The FPC slot number ranges from 0 through 7 in T640, T1600, and T4000 routers. The PIC slot numbers are 0 and 1.
    - Packet Forwarding Engine 0 is the physical interface 0, and Packet Forwarding Engine 1 is the physical interface 1.
- 802.3 link aggregation:
    - The configuration of the 40-Gigabit Ethernet PIC with CFP complies with that of the existing 1-Gigabit or 10-Gigabit Ethernet PIC and aggregated Ethernet interfaces.
    - An aggregate bundle that consists purely of 40-Gigabit Ethernet PICs supports a maximum of 40-Gigabit Ethernet links depending on the system implementation.

For Junos OS configuration information about this PIC, see “Configuring 40-Gigabit Ethernet PICs” on page 435. For hardware compatibility information, see the *T1600 PICs Supported* topic in the *T1600 Core Router Hardware Guide* hardware guide and the *T640 PICs Supported* topic in the *T640 Core Router Hardware Guide* hardware guide, and the *T4000 PICs Supported* topic in the *T4000 Core Router Hardware Guide* hardware guide.

Configuring 40-Gigabit Ethernet PICs

You can configure the following features on the 40-Gigabit Ethernet PIC with CFP (PD-1XLE-CFP):

- Flexible Ethernet services encapsulation
- Source address MAC filtering
- Destination address MAC filtering
- MAC accounting for receive (**Rx**) and transmit (**Tx**)
- Multiple tag protocol ID (TPID) support
- Channels defined by two stacked VLAN tags
- Channels defined by **flex-vlan-tagging**
- IP service for stacked VLAN tags
- IP service for nonstandard TPID

The following features are not supported on the 40-Gigabit Ethernet PIC with CFP:

- MAC learning
- MAC policing
- Layer 2 rewrite

NOTE: Each 40-Gigabit Ethernet PIC with CFP creates a single et- physical interface in the Routing Engine and Packet Forwarding Engine.

The 40-Gigabit Ethernet PIC with CFP supports aggregated Ethernet configuration to achieve higher throughput capability, whereby the configuration is similar to the 1-Gigabit or 10-Gigabit aggregated Ethernet interface configuration. A maximum of 40-Gigabit Ethernet PIC links can be bundled into a single aggregated Ethernet configuration depending on the system implementation.

To configure the 40-Gigabit Ethernet PIC with CFP:

1. Perform the media configuration.

   The command used to configure the media for the 40-Gigabit Ethernet PIC with CFP is the same as that for other Ethernet PICs, such as the 4-port 10-Gigabit Ethernet PIC.

2. Specify the logical interfaces.

A single physical interface is created when the 40-Gigabit Ethernet PIC with CFP is brought online (et-*x*/*y*/0, where *x* represents the FPC slot number and *y* represents the PIC slot number). For more information, see “Configuring Access Mode on a Logical Interface” on page 261 and “Configuring a Logical Interface for Trunk Mode” on page 262.

3. Configure the 802.3 link aggregation.

   - You must explicitly configure an aggregated interface on the 40-Gigabit Ethernet PIC with CFP that includes the 40-Gigabit Ethernet interfaces. For more information, see “Configuring an Aggregated Ethernet Interface” on page 108.
   - The configuration of the 40-Gigabit Ethernet PIC with CFP complies with the configuration of the 1-Gigabit Ethernet PIC, 10-Gigabit Ethernet PIC, and the aggregated Ethernet interfaces. In each aggregated bundle, Junos OS supports a maximum of 40-Gigabit Ethernet links. For more information, see “Configuring an Aggregated Ethernet Interface” on page 108 and “10-port 10-Gigabit Ethernet LAN/WAN PIC Overview” on page 395.

4. Configure the Packet Forwarding Engine features.

   The 40-Gigabit Ethernet PIC with CFP supports all classification, firewall filters, queuing model, and rewrite functionality features of the Gigabit Ethernet PICs. To configure these parameters, see “Configuring Gigabit Ethernet Policers” on page 539, “Configuring MAC Address Filtering” on page 544, and “Stacking and Rewriting Gigabit Ethernet VLAN Tags Overview” on page 559.

MPC3E MIC Overview

The MPC3E supports two separate slots for MICs. MICs provide the physical interface and are installed into the MPCs.

The MPC3E supports these MICs as field replaceable units (FRUs):

- *100-Gigabit Ethernet MIC with CFP* (model number MIC3-3D-1X100GE-CFP)
- *100-Gigabit Ethernet MIC with CXP* (model number MIC3-3D-1X100GE-CXP)
- 10-port 10-Gigabit Ethernet MIC with SFPP (model number MIC3-3D-10XGE-SFPP)
- 2-port *40-Gigabit Ethernet MIC with QSFP+* (model number MIC3-3D-2X40GE-QSFPP)

The MPC3E has two separate configurable MIC slots. Each MIC corresponds to a single PIC and the mapping between the MIC and PIC is 1 to 1 (one MIC is treated as one PIC). The MIC plugged into slot 0 corresponds to PIC 0 and the MIC plugged into slot 1 corresponds to PIC 2.

The MPC3E also supports these legacy MICs:

- 20-port *Gigabit Ethernet MIC with SFP* (model number MIC-3D-20GE-SFP)
- 2-port *10-Gigabit Ethernet MICs with XFP* (model number MIC-3D-2XGE-XFP)

The 100-Gigabit Ethernet CFP MIC supports the IEEE standards—compliant 100BASE-LR4 interface, using the 100G CFP optical transceiver modules for connectivity. The 100-Gigabit Ethernet CXP MIC supports the 100BASE-SR10 interface, using 100-Gigabit CXP optical transceiver modules for connectivity. The 2-port 40-Gigabit Ethernet QSFPP MIC supports the 40BASE-SR4 interface and uses quad small form-factor pluggable (QSFPP) optical transceivers for connectivity. The 10-port 10-Gigabit Ethernet SFPP MIC uses SFP+ optical transceiver modules for connectivity.

For detailed information about each MIC, see *100-Gigabit Ethernet MIC with CFP*, *100-Gigabit Ethernet MIC with CXP*, *40-Gigabit Ethernet MIC with QSFP+*. For information about supported hardware and transceivers, see *MPC3E*.

The MPC3E supports these features:

- Optical diagnostics and related alarms
- Virtual Router Redundancy Protocol (VRRP) support
- IEEE 802.1Q virtual LANs (VLANs) support
- Synchronous Ethernet
- Remote monitoring (RMON) and Ethernet statistics (EtherStats)
- Source MAC learning
- MAC accounting and policing—Dynamic local address learning of source MAC addresses
- Flexible Ethernet encapsulation
- Multiple Tag Protocol Identifiers (TPIDs)

NOTE: The MPC3E supports Ethernet interfaces only. SONET interfaces are not supported.

For information about the supported and unsupported Junos OS features for this MPC, see “Protocols and Applications Supported by the MPC3E (MX-MPC3E)” in the *MX Series Interface Module Reference*.

100-Gigabit Ethernet Type 4 PIC with CFP Overview

The 100-Gigabit Ethernet PIC (model number PD-1CE-CFP-FPC4) is a 1-port 100-Gigabit Ethernet Type 4 PIC with 100-gigabit small form-factor pluggable (CFP) transceiver. This PIC is available only as packaged in an assembly with the T1600-FPC4-ES FPC. The 100-Gigabit Ethernet PIC occupies PIC slots 0 and 1 in the T1600-FPC4-ES FPC. For information about supported transceivers and hardware, see *100-Gigabit Ethernet PIC with CFP (T1600 Router)*.

The 100-Gigabit Ethernet PIC supports flexible encapsulation and MAC accounting.

MAC learning, MAC policing, and Layer 2 rewrite functionality are not supported.

The ingress flow can be filtered based on the VLAN source and destination addresses. Ingress frames can also be classified according to VLAN, stacked VLAN, source address, VLAN source address, and stacked VLAN source address. VLAN manipulation on egress frames are supported on both outer and inner VLAN tags.

The following features are supported:

- The following encapsulation protocols are supported:
  - Layer 2 protocols
    - Ethernet CCC, Ethernet TCC, Ethernet VPLS
    - VLAN CCC
    - Extended VLAN TCC
    - VLAN VPLS
    - Flexible Ethernet service

- Layer 3 protocols
  - IPv4
  - Ipv6
  - MPLS
- CFP MSA compliant MDIO control features (transceiver dependent).
- Graceful Routing Engine switchover (GRES) is supported in all PIC and chassis configurations.
- Interface creation:
  - When the PIC, is brought online, the router creates two 50 gigabit capable interfaces, **et-*x*/0/0:0** and **et-*x*/0/0:1**, where *x* represents the FPC slot number. Each physical interface represents two internal 50 gigabit Ethernet Packet Forwarding Engines. Two logical interfaces are configured under each physical interface.
  - Packet Forwarding Engine 0 is physical interface 0, Packet Forwarding Engine 1 is physical interface 1
- 802.3 link aggregation:

  Same rate or same mode link aggregation:

  - Two logical interfaces are created for each 100-Gigabit Ethernet PIC. To utilize bandwidth beyond 50 gigabits per second, an aggregate interface must be explicitly configured on the 100-Gigabit Ethernet PIC that includes the two 50 gigabit interfaces.
  - Each 100 gigabit Ethernet aggregate consumes one of the router-wide aggregated Ethernet device pools. The number of 100-Gigabit Ethernet PICs cannot exceed the router-wide limit, which is 128 for Ethernet.
  - In each aggregate bundle, each 100-Gigabit Ethernet PIC consumes two members. Hence, an aggregate bundle that consists purely of 100-Gigabit Ethernet PICs supports a maximum of half of the software limit for the number of members. Therefore, with a maximum of 16 links, up to 8 100-Gigabit Ethernet links are supported.
  - Combining 100-Gigabit Ethernet PICs into aggregate interfaces with other Ethernet PICs is not permitted. However, other Ethernet PICs can also be configured within the same T1600 with 100-Gigabit Ethernet PICs, and used in separate aggregate interfaces.
  - Multiple (Juniper Networks) Type 4 100-Gigabit Ethernet PICs on a T1600 router can be combined into a static aggregated Ethernet bundle to connect to a different type of 100 gigabit Ethernet PIC on a remote router (Juniper Networks or other vendors). LACP is not supported in this configuration.

Mixed rate or mixed mode link aggregation:

- Starting with Junos OS Release 13.2, aggregated Ethernet supports mixed rates and mixed modes on 100-Gigabit Ethernet PIC.
- Static link protection and Link Aggregation Control Protocol (LACP) is supported on mixed aggregated Ethernet link configured on a 100-Gigabit Ethernet PIC.
- When configuring a mixed aggregated Ethernet link on a 100-Gigabit Ethernet PIC, ensure that you add both the 50-Gigabit Ethernet interfaces of the 100-Gigabit Ethernet PIC to the aggregated Ethernet bundle. Moreover, both these 50-Gigabit Ethernet interfaces must be included in the same aggregated Ethernet bundle.
- For a single physical link event of an aggregated Ethernet link configured on a 100-Gigabit Ethernet PIC, the packet loss performance value is twice the original value because of the *two* 50-Gigabit Ethernet interfaces of the 100-Gigabit Ethernet PIC.

- Software Packet Forwarding Engine—Supports all Gigabit Ethernet PIC classification, firewall filter, queuing model, and rewrite functionality.
- Egress traffic performance—Maximum egress throughput is 100 gigabits per second on the physical interface, with 50 gigabits per second on the two assigned logical interfaces.
- Ingress traffic performance—Maximum ingress throughput is 100 gigabits per second on the physical interface, with 50 gigabits per second on the two assigned logical interfaces. To achieve 100 gigabits per second ingress traffic performance, use one of the interoperability modes described below. For example, if VLAN steering mode is not used when connecting to a remote 100 gigabits per second interface (that is on a different 100 gigabits per second PIC on a Juniper Networks router or a different vendor's equipment), then all ingress traffic will try to use one of the 50 gigabits per second Packet Forwarding Engines, rather than be distributed among the two 50 gigabits per second Packet Forwarding Engines, resulting in a total of 50 gigabits per second ingress performance.
- Interoperability modes—The 100-Gigabit Ethernet PIC supports interoperability with through configuration in one of the following two forwarding option modes:
  - *SA multicast mode*—In this mode, the 100-Gigabit Ethernet PIC supports interconnection with other Juniper Networks 100-Gigabit Ethernet PICs (Model: PD-1CE-CFP) interfaces only.
  - *VLAN steering mode*—In this mode, the 100-Gigabit Ethernet Type 4 PIC with CFP supports interoperability with 100 gigabit Ethernet interfaces from other vendors only.

Related Documentation

- Configuring 100-Gigabit Ethernet Type 4 PIC With CFP on page 444
- *T1600 Core Router Hardware Guide*
- *100-Gigabit Ethernet PIC with CFP (T1600 Router)*
- *100-Gigabit Ethernet PIC with CFP (T4000 Router)*

Configuring 100-Gigabit Ethernet Type 4 PIC With CFP

You can configure the following features on the 100-Gigabit Ethernet Type 4 PIC with CFP (PD-1CE-CFP-FPC4):

- Flexible Ethernet services encapsulation
- Source address MAC filtering
- Destination address MAC filtering
- MAC accounting in RX
- Channels defined by two stacked VLAN tags
- Channels defined by flex-vlan-tagging
- IP service for stacked VLAN tags
- Layer 2 rewrite

The following features are not supported on the 100-Gigabit Ethernet Type 4 PIC with CFP:

- Multiple TPID
- IP service for non-standard TPID
- MAC learning
- MAC policing

NOTE:

- For the 100-Gigabit Ethernet Type 4 PIC with CFP, only the PIC0 **online** and **offline** CLI commands are supported. The PIC1 **online** and **offline** CLI commands are not supported.
- Each 100-Gigabit Ethernet Type 4 PIC with CFP creates two et- physical interfaces, defined as 50-gigabit physical interfaces in the Routing Engine and Packet Forwarding Engine. By default, these are independent physical interfaces and are not configured as an aggregated Ethernet interface.

To configure a 100-Gigabit Ethernet Type 4 PIC with CFP:

1. Perform the media configuration:

   The 100-Gigabit Ethernet Type 4 PIC with CFP features a 100 gigabit per second pipe. The media-related configuration commands for **et-*x*/0/0:0** and **et-*x*/0/0:1** must both be configured at the same time and configured with the same value, otherwise the commit operation fails.

   When configuring to activate or deactivate the interface, if the interface contains the described media-related configuration, it must activate and deactivate both units 0 and 1 at the same time, otherwise the commit operation fails.

   The following media configuration commands have the above described restriction:

   - # **set interfaces et-x/0/0:1 disable**
   - # **set interfaces et-x/0/0:1 gigether-options loopback**
   - # **set interfaces et-x/0/0:1 mtu yyy**

   Due to an MTU restriction, the vlan-tagging and flexible-vlan-tagging configuration on et-x/0/0:0 and et-x/0/0:1 must be same, otherwise the commit operation fails.

2. Specify the logical interfaces:

   a. Two physical interfaces are created when the 100-Gigabit Ethernet Type 4 PIC with CFP is brought online (**et-*x*/0/0:0** and **et-*x*/0/0:1**, where *x* represents the FPC slot number). Each physical interface represents two internal 50-gigabit Ethernet Packet Forwarding Engines.

   b. Two logical interfaces are configured under each physical interface: Packet Forwarding Engine 0 is physical interface 0 and Packet Forwarding Engine 1 is physical interface 1.

3. Configure the 802.3 link aggregation:

   a. The 100-Gigabit Ethernet PIC supports aggregated Ethernet configuration to achieve higher throughput capability, whereby configuration is similar to the 1G/10G aggregated Ethernet interface configuration.

   b. Two physical interfaces are created for each 100-Gigabit Ethernet Type 4 PIC with CFP. To utilize bandwidth beyond 50 gigabits, a same rate and same mode aggregated Ethernet interface must be explicitly configured on the 100-Gigabit Ethernet Type 4 PIC with CFP that includes these two 50-gigabit interfaces.

   c. Each 100-Gigabit Ethernet Type 4 PIC with CFP aggregate consumes one of the router-wide aggregated Ethernet device pools. In Junos OS with 100-Gigabit Ethernet PICs, you cannot exceed the router limit of 128 Ethernet PICs.

   d. In each aggregated bundle, each 100-Gigabit Ethernet Type 4 PIC with CFP consumes two aggregate members. Hence, an aggregated bundle consisting of only one 100-Gigabit Ethernet Type 4 PIC with CFP supports only up to half of the Junos OS limit for the number of members. The Junos OS supports a maximum of 16 links for up to 8 100-Gigabit Ethernet Type 4 PIC with CFP links.

NOTE:
The 100-Gigabit Ethernet Type 4 PIC with CFP has the following restrictions for same rate and same mode aggregated Ethernet configuration:

- Both physical interfaces belonging to the same 100-Gigabit Ethernet PIC must be included in the same aggregated Ethernet physical interfaces. The aggregation of the 100-Gigabit Ethernet PIC interface is always an even number of physical interfaces.
- The 100-Gigabit Ethernet PIC physical interface cannot be configured in the aggregated interface with any other type of physical interface.
- The maximum supported number of aggregated 100-Gigabit Ethernet PIC interfaces is half of the number that the Junos OS supports for 1G/10G aggregated Ethernet. For example, if Junos OS supports 16 ports of 10-gigabit Ethernet aggregation, it supports 8 ports of 100-Gigabit Ethernet PIC aggregation. This is because each port of the 100-Gigabit Ethernet PIC port using 2 physical interfaces (et-x/0/0:0 and et-x/0/0:1), where each physical interface represents 50 gigabits of traffic capacity.

e. Starting with Junos OS Release 13.2, aggregated Ethernet supports mixed rates and mixed modes on 100-Gigabit Ethernet PIC. When configuring a mixed aggregated Ethernet link on a 100-Gigabit Ethernet PIC, ensure that you add both the 50-Gigabit Ethernet interfaces of the 100-Gigabit Ethernet PIC to the aggregated Ethernet bundle. Moreover, both these 50-Gigabit Ethernet interfaces must be included in the same aggregated Ethernet bundle.

NOTE:

The 100-Gigabit Ethernet Type 4 PIC with CFP has the following restrictions for mixed rate and mixed mode aggregated Ethernet configuration:

- A maximum of 16 member links can be configured to form a mixed aggregated Ethernet link.
- Traffic distribution is based on the hash calculated on the egress packet header. Hash range is fairly distributed according to member links' speed. This guarantees hash fairness but it does not guarantee fair traffic distribution depending on the rate of the egress streams.
- Packets are dropped when the total throughput of the hash flow exiting a member link (or multiple hash flows exiting a single member link) exceeds the link speed of the member link. This can happen when egress member link changes because of a link failure and the hash flow switches to a member link of speed that is less than the total throughput of the hash flow.
- Rate-based CoS components such as scheduler, shaper, and policer are not supported on mixed rate aggregated Ethernet links. However, the default CoS settings are supported by default on the mixed rate aggregated Ethernet links.
- Load balancing is performed at the ingress Packet Forwarding Engine. Therefore, you must ensure that the egress traffic on the aggregated Ethernet link enters through the hardware platforms that support mixed aggregated Ethernet bundles.
- Mixed aggregated Ethernet links can interoperate with non-Juniper Networks aggregated Ethernet member links provided that mixed aggregated Ethernet load balancing is configured at egress.
- Load balancing of the egress traffic across the member links of a mixed rate aggregated Ethernet link is proportional to the rates of the member links.
- Egress multicast load balancing is not supported on mixed aggregated Ethernet interfaces.
- Changing the **edit interfaces ae*x* aggregated-ether-options link-speed** configuration of a mixed aggregated Ethernet link, which is configured on the supported interfaces of on T640, T1600, T4000, and TX Matrix Plus routers, leads to aggregated Ethernet link flapping.
- When a mixed aggregated Ethernet link is configured on a 100-Gigabit Ethernet PIC, changing aggregated Ethernet link protection configurations leads to aggregated Ethernet link flapping.
- For a single physical link event of an aggregated Ethernet link configured on a 100-Gigabit Ethernet PIC, the packet loss performance value is twice the original value because of the *two* 50-Gigabit Ethernet interfaces of the 100-Gigabit Ethernet PIC with CFP.

- The **show interfaces ae*x*** command displays the link speed of the aggregated Ethernet interface, which is the sum of the link speeds of all the active member links.

4. Configure the Packet Forwarding Engine features:

   a. The 100-Gigabit Ethernet Type 4 PIC with CFP supports all classification, firewall filters, queuing model, and rewrite functionality features of the Gigabit Ethernet PICs. To configure these parameters, see "Configuring Gigabit Ethernet Policers" on page 539, "Configuring MAC Address Filtering" on page 544, and "Stacking and Rewriting Gigabit Ethernet VLAN Tags Overview" on page 559.

NOTE: When using the **show interfaces extensive** command with a 100-Gigabit Ethernet Type 4 PIC with CFP, the "Filter statistics" section will not be displayed because the hardware does not include those counters.

Release History Table

Release	Description
13.2	Starting with Junos OS Release 13.2, aggregated Ethernet supports mixed rates and mixed modes on 100-Gigabit Ethernet PIC.

Configuring VLAN Steering Mode for 100-Gigabit Ethernet Type 4 PIC with CFP

In Junos OS Release 10.4 and later, you can configure the 100-Gigabit Ethernet Type 4 PIC with CFP (PD-1CE-CFP-FPC4) to interoperate with routers using 100 gigabit Ethernet interfaces from other vendors by using the **forwarding-mode** statement with the **vlan-steering** option at the **[edit chassis fpc *slot* pic *slot*]** hierarchy level. On ingress, the router compares the outer VLAN ID against the user-defined VLAN ID and VLAN mask combination and steers the packet accordingly. You can program a custom VLAN ID and corresponding mask for PFE0.

General information on the VLAN steering mode:

- In VLAN steering mode, the SA multicast parameters are not used for packet steering.
- In SA multicast bit steering mode, the VLAN ID and VLAN masks are not used for packet steering.

- Configuration to set the packet distribution mode and VLAN steering rule is done through CLI commands. Both CLI commands result in a PIC reboot.
- There are three possible tag types of ingress packet:
  - Untagged ingress packet—The packet is sent to PFE1.
  - Ingress packet with one VLAN—The packet is forwarded to the corresponding PFE based on the VLAN ID.
  - Ingress packet with two VLANs—The packet is forwarded to the corresponding PFE based on the outer VLAN ID.
- If no VLAN rule is configured, all tagged packets are distributed to PFE0.
- VLAN rules describe how the router distributes packets. Two VLAN rules are provided by the CLI:
  - Odd-Even rule—Odd number VLAN IDs go to PFE1; even number of VLAN IDs go to PFE0.
  - Hi-Low rule—VLAN IDs 1 through 2047 go to PFE0; VLAN IDs 2048 through 4096 go to PFE1.
- When the 100-Gigabit Ethernet Type 4 PIC with CFP is configured in VLAN steering mode, it can be configured in a two physical interfaces mode or in aggregate Ethernet (AE) mode:
  - Two physical interfaces mode—When the PIC is in the two physical interfaces mode, it creates the physical interfaces **et-*x/0/0*:*0*** and **et-*x/0/0*:*1***. Each physical interface can configure its own logical interface and VLAN. The CLI enforces the following restrictions at the commit time:
    - The VLAN ID configuration must comply with the selected VLAN rule.
    - The previous restriction implies that the same VLAN ID cannot be configured on both physical interfaces.
  - AE mode—When the PIC is in aggregated Ethernet mode, the two physical interfaces on the same PIC are aggregated into one AE physical interface. The PIC egress traffic is based on an AE internal hash algorithm. The PIC ingress traffic steering is based on the customized VLAN ID rule. The CLI enforces the following restrictions at the commit time:
    - The PICs AE working in VLAN steering mode includes both links of that PIC, and only the links of that PIC.
    - The PIC AE working in SA multicast steering mode can include more than one 100-Gigabit Ethernet Type 4 PIC with CFP to achieve more than 100 gigabit Ethernet capacity.

To configure SA multicast mode, use the **set chassis fpc *slot* pic *slot* forwarding-mode sa-multicast** command.

SA Multicast Mode

To configure SA multicast mode on a Juniper Networks 100-Gigabit Ethernet Type 4 PIC with CFP in FPC 0, PIC 0 for interconnection with another Juniper Networks 100-Gigabit Ethernet PIC, use the **set chassis fpc *slot* pic *slot* forwarding-mode sa-multicast** command. You can use the **show forwarding-mode** command to view the resulting configuration, as follows:

```
[edit chassis fpc slot pic slot]
user@host# show forwarding-mode
forwarding-mode {
  sa-multicast;
}
```

VLAN Steering Mode

To configure the Juniper Networks 100-Gigabit Ethernet Type 4 PIC with CFP for VLAN steering mode for interoperation with a 100 gigabit Ethernet interface from another vendor's router, use the **set chassis fpc *slot* pic *slot* forwarding-mode vlan-steering** command with the **vlan-rule (high-low | odd-even)** statement. You can use the **show forwarding-mode** command to view the resulting configuration, as follows:

```
[edit chassis fpc slot pic slot]
user@host# show forwarding-mode
forwarding-mode {
  vlan-steering {
    vlan-rule odd-even;
  }
}
```

100-Gigabit Ethernet Type 5 PIC with CFP Overview

The 100-Gigabit Ethernet PIC is a 1-port 100-Gigabit Ethernet Type 5 PIC with C form-factor pluggable transceiver (CFP) with model number PF-1CGE-CFP.

The following features are supported on 100-Gigabit Ethernet Type 5 PIC with CFP:

- Access to all 100-Gigabit Ethernet port counters through SNMP.
- Logical interface–level MAC filtering, accounting, policing, and learning for source media access control (MAC).
- Channels defined by two stacked VLAN tags.
- Channels defined by **flex-vlan-tagging**.
- IP service for stacked VLAN tags.
- Defining the rewrite operation to be applied to the incoming and outgoing frames on logical interfaces on this PIC.

NOTE: Only the Tag Protocol Identifier (TPID) 0x8100 is supported.

- Interface encapsulations, such as the following:
  - **untagged**—Default encapsulation, when other encapsulation is not configured.
    - You can configure only one logical interface (unit 0) on the port.
    - You cannot include the **vlan-id** statement in the configuration of the logical interface.
  - **vlan-tagging**—Enable VLAN tagging for all logical interfaces on the physical interface.
  - **stacked-vlan-tagging**—Enable stacked VLAN tagging for all logical interfaces on the physical interface.
  - **ethernet-ccc**—Ethernet cross-connect.
  - **ethernet-tcc**—Ethernet translational cross-connect.
  - **vlan-ccc**—802.1Q tagging for a cross-connect.
  - **vlan-tcc**—Virtual LAN (VLAN) translational cross-connect.
  - **extended-vlan-ccc**—Standard TPID tagging for an Ethernet cross-connect.
  - **extended-vlan-tcc**—Standard TPID tagging for an Ethernet translational cross-connect.
  - **flexible-ethernet-services**—Allows per-unit Ethernet encapsulation configuration.
  - **ethernet-vpls**—Ethernet virtual private LAN service.
  - **vlan-vpls**—VLAN virtual private LAN service.
- The following Layer 3 protocols are also supported:
  - IPv4
  - IPv6
  - MPLS
- CFP Multi-Source Agreement (MSA) compliant Management Data Input/Output (MDIO) control features (transceiver dependent).
- 802.3 link aggregation:
  - The configuration of the 100-Gigabit Ethernet Type 5 PIC with CFP complies with that of the existing 1-Gigabit or 10-Gigabit Ethernet PIC and aggregated Ethernet interfaces.
- Interoperability mode—Interoperability with the 100-Gigabit Ethernet Type 4 PIC with CFP through configuration in **sa-multicast** forwarding mode.
- Juniper Networks enterprise-specific Ethernet Media Access Control (MAC) MIB

- The 100-Gigabit Ethernet Type 5 PIC with CFP supports all Gigabit Ethernet PIC classification, firewall filters, queuing model, and Layer 2 rewrite functionality features of the Gigabit Ethernet PICs. To configure these parameters, see “Configuring Gigabit Ethernet Policers” on page 539, “Configuring MAC Address Filtering” on page 544, and “Stacking and Rewriting Gigabit Ethernet VLAN Tags Overview” on page 559.
- A Type 5 FPC can support up to two 100-Gigabit Ethernet PICs. Both the PICs (that is, PIC 0 and PIC 1) can be offline or online independently.

The following features are not supported on the 100-Gigabit Ethernet Type 5 PIC with CFP:

- MAC filtering, accounting, and policing for destination MAC at the logical interface level.

NOTE: **Because destination MAC filtering is not supported, the hardware is configured to accept all the multicast packets. This configuration enables the OSPF protocol to work.**

- Premium MAC policers at the logical interface level.
- MAC filtering, accounting, and policing at the physical interface level.
- Multiple TPIDs.
- IP service for nonstandard TPID.

Table 38 on page 452 lists the capabilities of 100-Gigabit Ethernet Type 5 PIC with CFP.

Table 38: Capabilities of 100-Gigabit Ethernet Type 5 PIC with CFP

Capability	Support
Maximum logical interfaces per PIC	4093
Maximum logical interfaces per port	For IPv4 the limit is 4093. For IPv6 the limit is 1022.

100-Gigabit Ethernet Interfaces Interoperability

Juniper Networks Junos operating system (Junos OS) supports a variety of 100-Gigabit Ethernet interfaces. The 100-Gigabit Ethernet standard, introduced by IEEE 802.3ba-2010, enables transmission of Ethernet frames at the rate of 100 gigabits per second (Gbps).

It is used for very high speed transmission of voice and data signals across the numerous world-wide fiber-optic networks.

Interface interoperability refers to the ability of an interface to interoperate with other router interfaces. You can enable interoperability between different 100-Gigabit Ethernet interfaces by performing specific configuration tasks. The following sections list the 100-Gigabit Ethernet interfaces, corresponding interoperable interfaces, and links to the interoperability tasks and reference information.

Interoperability of the MIC-3D-1X100GE-CFP MIC with PICs on Other Routers

Table 39 on page 453 lists the Interoperability with the 100-Gigabit Ethernet MIC with CFP.

Interoperability Between the 100-Gigabit Ethernet PICs PD-1CE-CFP-FPC4 and PF-1CGE-CFP

You can enable interoperability between the 100-Gigabit Ethernet PICs PD-1CE-CFP-FPC4 and PF-1CGE-CFP by:

- Enabling source address (SA) multicast bit steering mode on the 100-Gigabit Ethernet PIC PF-1CGE-CFP.
- Configuring the two 50-Gigabit Ethernet physical interfaces on the 100-Gigabit Ethernet PIC PD-1CE-CFP-FPC4 as one aggregated Ethernet physical interface.

SA multicast mode uses the multicast bit in the source MAC address for packet steering. By default, the SA multicast bit is set to 0 for all packets sent by the 100-Gigabit Ethernet PIC PF-1CGE-CFP. The 100-Gigabit Ethernet PIC PD-1CE-CFP-FPC4 looks at the bit and forwards the packets to either Packet Forwarding Engine 0 or Packet Forwarding Engine 1. When the PIC sends out a packet, the multicast bit is set based on the egress Packet Forwarding Engine number (0 or 1).

The default packet steering mode for PD-1CE-CFP-FPC4 is SA multicast bit mode. No SA multicast configuration is required to enable this mode.

PD-1CE-CFP-FPC4 uses two 50 Gpbs Packet Forwarding Engines to achieve 100 Gbps throughput. The 50-Gigabit Ethernet physical interfaces are created when the 100-Gigabit Ethernet PIC is plugged in. The two physical interfaces are visible and configuration is allowed on both the physical interfaces. You must configure the physical interfaces on PD-1CE-CFP-FPC4 in static link aggregation group (LAG) mode without enabling Link Aggregation Control Protocol (LACP). This ensures that a single 100-Gigabit aggregated interface is visible on the link connecting to the 100-Gigabit Ethernet PIC PF-1CGE-CFP instead of two independent 50-Gigabit Ethernet interfaces.

NOTE: If you try to enable the interoperability between the 100-Gigabit Ethernet PICs PD-1CE-CFP-FPC4 and PF-1CGE-CFP without configuring PD-1CE-CFP-FPC4 (with two 50-Gigabit Ethernet interfaces) in static LAG mode, then there are issues in forwarding or routing protocols. For example, if you create two untagged logical interfaces—one each on the two 50-Gigabit Ethernet interfaces—on PD-1CE-CFP-FPC4 and one untagged logical interface on PF-1CGE-CFP, then PF-1CGE-CFP does not learn about one of the 50-Gigabit Ethernet interfaces on PD-1CE-CFP-FPC4.

Interoperability Between the 100-Gigabit Ethernet PICs PD-1CE-CFP-FPC4 and P1-PTX-2-100GE-CFP

You can enable interoperability between the 100-Gigabit Ethernet PIC PD-1CE-CFP-FPC4 and the 100-Gigabit Ethernet PIC P1-PTX-2-100GE-CFP by:

- Configuring the two 50-Gigabit Ethernet physical interfaces on the 100-Gigabit Ethernet PIC PD-1CE-CFP-FPC4 as one aggregated Ethernet physical interface.
- Configuring source address (SA) multicast bit steering mode on the 100-Gigabit Ethernet PIC P1-PTX-2-100GE-CFP.

SA multicast bit steering mode uses the multicast bit in the source MAC address for packet steering.

NOTE: **When SA multicast bit steering mode is configured on a PTX Series Packet Transport Router 100-Gigabit Ethernet port, VLANs are not supported for that port.**

The 100-Gigabit Ethernet PIC PD-1CE-CFP-FPC4 uses two 50-Gpbs Packet Forwarding Engines to achieve 100-Gbps throughput. The 50-Gigabit Ethernet physical interfaces are created when the 100-Gigabit Ethernet PIC is plugged in. The two physical interfaces are visible and configuration is allowed on both the physical interfaces. You must configure the physical interfaces on the 100-Gigabit Ethernet PIC PD-1CE-CFP-FPC4 in static link aggregation group (LAG) mode without enabling Link Aggregation Control Protocol (LACP). This ensures that a single 100-Gigabit aggregated interface is visible on the link connecting to the 100-Gigabit Ethernet PIC P1-PTX-2-100GE-CFP.

On the 100-Gigabit Ethernet PIC PD-1CE-CFP-FPC4, ingress packets are forwarded to either Packet Forwarding Engine number 0 or 1 based on the SA multicast bit in the received packet. The SA multicast bit of egress packets is set based on whether the packet is forwarded from Packet Forwarding Engine number 0 or 1. As the default packet steering mode is SA multicast bit steering mode, no configuration is necessary to enable this mode.

On the 100-Gigabit Ethernet PIC P1-PTX-2-100GE-CFP, the SA multicast bit is ignored in ingress packets. When SA multicast bit steering mode is enabled, the SA multicast bit in the egress packets is set to 0 or 1 based on the flow hash value that is computed internally by the Packet Forwarding Engine complex for each packet. No CLI configuration is required to generate the flow hash value as this computation is done automatically. The flow hash algorithm uses fields in the packet header to compute the flow hash value. By default, the SA multicast bit is set to 0 in egress packets. You must configure SA multicast bit steering mode to enable interoperability with the 100-Gigabit Ethernet PIC PD-1CE-CFP-FPC4 .

NOTE: If you try to enable the interoperability between the 100-Gigabit Ethernet PICs PD-1CE-CFP-FPC4 and P1-PTX-2-100GE-CFP without configuring PD-1CE-CFP-FPC4 (with two 50-Gigabit Ethernet interfaces) in static LAG mode, then there are issues in forwarding or routing protocols. For example, if you create two untagged logical interfaces—one each on the two 50-Gigabit Ethernet interfaces—on the PD-1CE-CFP-FPC4 and one untagged logical interface on the P1-PTX-2-100GE-CFP, then P1-PTX-2-100GE-CFP does not learn about one of the 50-Gigabit Ethernet interfaces on PD-1CE-CFP-FPC4.

Related Documentation

- Configuring the Interoperability Between the 100-Gigabit Ethernet PICs P1-PTX-2-100GE-CFP and PD-1CE-CFP-FPC4 on page 460

- Interoperability Between the 100-Gigabit Ethernet PICs PD-1CE-CFP-FPC4 and PF-1CGE-CFP on page 454

Configuring the Interoperability Between the 100-Gigabit Ethernet PICs PF-1CGE-CFP and PD-1CE-CFP-FPC4

You can enable interoperability between the 100-Gigabit Ethernet PICs PD-1CE-CFP-FPC4 and PF-1CGE-CFP by performing the following tasks:

- Configuring SA Multicast Bit Steering Mode on the 100-Gigabit Ethernet PIC PF-1CGE-CFP on page 457
- Configuring Two 50-Gigabit Ethernet Physical Interfaces on the 100-Gigabit Ethernet PIC PD-1CE-CFP-FPC4 as One Aggregated Ethernet Interface on page 458

Configuring SA Multicast Bit Steering Mode on the 100-Gigabit Ethernet PIC PF-1CGE-CFP

To enable the interoperability between the 100-Gigabit Ethernet PICs PD-1CE-CFP-FPC4 and PF-1CGE-CFP, you need to enable source address (SA) multicast bit steering mode on PF-1CGE-CFP.

To configure SA multicast mode on PF-1CGE-CFP:

1. Specify the FPC and PIC information on the chassis.

   [edit]
   user@host# **edit chassis fpc** ***slot*** **pic** ***slot***

   For example:

   [edit]
   user@host# **edit chassis fpc 1 pic 0**

2. Configure the interoperation mode (SA multicast bit steering mode).

   [edit chassis fpc *slot* pic *slot*]

user@host# **set forwarding-mode sa-multicast**

For example:

[edit fpc 1 pic 0]
user@host# **set forwarding-mode sa-multicast**

3. Verify the configuration.

[edit]
user@host# **show chassis**

```
fpc 1 {
    pic 0 {
        forwarding-mode {
            sa-multicast;
        }
    }
}
```

NOTE: The default packet steering mode for the 100-Gigabit Ethernet PIC PD-1CE-CFP-FPC4 is SA multicast bit mode. No SA multicast configuration is required to enable this mode.

Configuring Two 50-Gigabit Ethernet Physical Interfaces on the 100-Gigabit Ethernet PIC PD-1CE-CFP-FPC4 as One Aggregated Ethernet Interface

To enable the interoperability between the 100-Gigabit Ethernet PICs PD-1CE-CFP-FPC4 and PF-1CGE-CFP or P1-PTX-2-100GE-CFP, you need to configure the two 50-Gigabit Ethernet physical interfaces on PD-1CE-CFP-FPC4 as one aggregated Ethernet physical interface. This ensures that a single 100-Gigabit aggregated interface is visible on the link connecting to PF-1CGE-CFP or P1-PTX-2-100GE-CFP instead of two independent 50-Gigabit Ethernet interfaces.

When the PIC is in aggregated Ethernet mode, the two physical interfaces on the same PIC are aggregated into one aggregated Ethernet physical interface. When the PIC is configured with two physical interfaces, it creates the physical interfaces et-*fpc/pic/*0:0 and et-*fpc/pic/*0:1, where *fpc* is the FPC slot number and *pic* is the PIC slot number. For example, to configure two physical interfaces for PIC slot 0 in FPC slot 5:

1. Specify the number of aggregated Ethernet interfaces to be created.

[edit chassis]
user@host# **set aggregated devices ethernet device-count *count***

For example:

[edit chassis]
user@host# **set aggregated devices ethernet device-count 1**

2. Specify the members to be included within the aggregated Ethernet bundle.

   [edit interfaces]
   user@host# **set *interface-name* gigether-options 802.3ad *bundle***

   The following example shows how to configure two physical interfaces for PIC 0 on a T1600 router.

   [edit interfaces]
   user@host# **set et-5/0/0:0 gigether-options 802.3ad ae0**
   user@host# **set et-5/0/0:1 gigether-options 802.3ad ae0**

3. Verify the configuration at the chassis.

   [edit]
   user@host# **show chassis**

```
aggregated-devices {
    ethernet {
        device-count 1;
    }
}
```

4. Verify the configuration at the interface.

   [edit]
   user@host# **show interfaces**

```
et-5/0/0:0 {
    gigether-options {
        802.3ad ae0;
    }
}
et-5/0/0:1 {
    gigether-options {
        802.3ad ae0;
    }
}
```

Configuring the Interoperability Between the 100-Gigabit Ethernet PICs P1-PTX-2-100GE-CFP and PD-1CE-CFP-FPC4

You can enable interoperability between the 100-Gigabit Ethernet PICs PD-1CE-CFP-FPC4 and P1-PTX-2-100GE-CFP by performing the following tasks:

Configuring SA Multicast Bit Steering Mode on 100-Gigabit Ethernet PIC P1-PTX-2-100GE-CFP

To enable the interoperability between the 100-Gigabit Ethernet PICs PD-1CE-CFP-FPC4 and P1-PTX-2-100GE-CFP, you must enable source address (SA) multicast bit steering mode on P1-PTX-2-100GE-CFP.

NOTE: When you configure the SA multicast bit steering mode on the PTX Series PIC P1-PTX-2-100GE-CFP, we recommend that you do not configure the PIC ports as member links of an aggregated Ethernet interface because this prevents load balancing on the peering T Series PIC PD-1CE-CFP-FPC4. This T Series PIC must be in aggregated Ethernet mode to share bandwidth between its two 50-Gigabit Ethernet interfaces.

To configure SA multicast bit steering mode on the 100-Gigabit Ethernet PIC P1-PTX-2-100GE-CFP:

1. Specify the FPC, PIC, and port information on the chassis.

   [edit]
   user@host# **edit chassis fpc *slot* pic *slot* port *port-number***

   For example:

   [edit]
   user@host# **edit chassis fpc 1 pic 0 port 0**

2. Configure the interoperation mode (SA multicast bit steering mode).

   [edit chassis fpc 1 pic 0]
   user@host# **set forwarding-mode sa-multicast**

3. Verify the configuration.

   [edit]
   user@host# **show chassis**

```
fpc 1 {
    pic 0 {
        port 0 {
            forwarding-mode {
                sa-multicast;
```

```
                }
            }
        }
    }
```

NOTE: As the default packet steering mode for the 100-Gigabit Ethernet PIC PD-1CE-CFP-FPC4 is SA multicast bit steering mode, no configuration is necessary to enable this mode.

Configuring Two 50-Gigabit Ethernet Physical Interfaces on the 100-Gigabit Ethernet PIC PD-1CE-CFP-FPC4 as One Aggregated Ethernet Interface

To enable the interoperability between the 100-Gigabit Ethernet PICs PD-1CE-CFP-FPC4 and PF-1CGE-CFP or P1-PTX-2-100GE-CFP, you need to configure the two 50-Gigabit Ethernet physical interfaces on PD-1CE-CFP-FPC4 as one aggregated Ethernet physical interface. This ensures that a single 100-Gigabit aggregated interface is visible on the link connecting to PF-1CGE-CFP or P1-PTX-2-100GE-CFP instead of two independent 50-Gigabit Ethernet interfaces.

When the PIC is in aggregated Ethernet mode, the two physical interfaces on the same PIC are aggregated into one aggregated Ethernet physical interface. When the PIC is configured with two physical interfaces, it creates the physical interfaces et-*fpc*/*pic*/0:0 and et-*fpc*/*pic*/0:1, where *fpc* is the FPC slot number and *pic* is the PIC slot number. For example, to configure two physical interfaces for PIC slot 0 in FPC slot 5:

1. Specify the number of aggregated Ethernet interfaces to be created.

   [edit chassis]
   user@host# **set aggregated devices ethernet device-count *count***

   For example:

   [edit chassis]
   user@host# **set aggregated devices ethernet device-count 1**

2. Specify the members to be included within the aggregated Ethernet bundle.

   [edit interfaces]
   user@host# **set *interface-name* gigether-options 802.3ad *bundle***

   The following example shows how to configure two physical interfaces for PIC 0 on a T1600 router.

   [edit interfaces]
   user@host# **set et-5/0/0:0 gigether-options 802.3ad ae0**
   user@host# **set et-5/0/0:1 gigether-options 802.3ad ae0**

3. Verify the configuration at the chassis.

   [edit]
   user@host# **show chassis**

   ```
   aggregated-devices {
       ethernet {
   ```

```
            device-count 1;
        }
    }
```

4. Verify the configuration at the interface.

   [edit]
   user@host# **show interfaces**
   ```
   et-5/0/0:0 {
       gigether-options {
           802.3ad ae0;
       }
   }
   et-5/0/0:1 {
       gigether-options {
           802.3ad ae0;
       }
   }
   ```

CHAPTER 27

Configuring Gigabit Ethernet OTN Options

Gigabit Ethernet OTN Options

The following example shows the configuration settings for Gigabit Ethernet OTN options:

```
[edit interfaces ge-fpc/pic/port]
otn-options {
  bytes (otn-options) transmit-payload-type value;
  fec (efec | gfec | gfec-sdfec | none );
  (is-ma | no-is-ma);
  (laser-enable | no-laser-enable);
  (line-loopback | no-line-loopback);
  (local-loopback | no-local-loopback);
  (odu-ttim-action-enable | no-odu-ttim-action-enable);
  (otu-ttim-action-enable | no-otu-ttim-action-enable);
  odu-delay-management {
    (bypass | no-bypass);
    (monitor-end-point | no-monitor-end-point);
    number-of-frames value;
    (no-start-measurement | start-measurement;
  }
  odu-signal-degrade {
    ber-threshold-clear value;
    ber-threshold-signal-degrade value;
    interval value;
  }
  (prbs | no-prbs);
  preemptive-fast-reroute {
    (backward-frr-enable | no-backward-frr-enable);
    (signal-degrade-monitor-enable | no-signal-degrade-monitor-enable);
    odu-backward-frr-enable | no-odu-backward-frr-enable;
    odu-signal-degrade-monitor-enable | no-odu-signal-degrade-monitor-enable;
  }
  rate {
    (fixed-stuff-bytes | no-fixed-stuff-bytes);
    oc192;
    otu4;
    (pass-through | no-pass-through);
  }
  signal-degrade {
    ber-threshold-clear value;
    ber-threshold-signal-degrade value;
    interval value;
  }
  tca tca-identifier (enable-tca | no-enable-tca) (threshold number | threshold-24hrs
    number);
  transport-monitoring;
  trigger trigger-identifier;
  tti tti-identifier;
}
```

NOTE: The Gigabit Ethernet interface and the XENPAK interface support the read/write overhead bytes only for the APS/PPC (bytes 0 through 3).

You can use the following show commands to view the OTN configuration:

- **show interfaces extensive**—See the CLI Explorer for command details.
- **show chassis hardware**—See the CLI Explorer for command details.

- **show chassis pic**—See the CLI Explorer for command details.

10-Gigabit Ethernet OTN Options Configuration Overview

MX240, MX480, MX960, MX2010, MX2020, T320, T640, T1600, PTX3000, and PTX5000 routers support Optical Transport Network (OTN) interfaces, including the 10-Gigabit Ethernet DWDM OTN PIC, and provide ITU-T G.709 support. Use the **set** otn-options statement at the **[edit interfaces if-*fpc/pic/port*]** hierarchy level to configure the OTN options.

MX2020, MX2010, MX960, MX480, and MX240 routers support OTN interfaces on MPC5E and MPC6E. MPC5E-40G10G and MPC5EQ-10G40G support OTN on 10-Gigabit Ethernet interfaces but not on 40-Gigabit Ethernet interfaces. The OTN MIC MIC6-10G-OTN on MPC6E supports OTN on 10-Gigabit Ethernet interfaces on MX2020 and MX2010 routers. OTN support on the specified MX Series routers includes:

- International Telecommunications Union (ITU)-standard OTN performance monitoring and alarm management
- Transparent transport of 24 10-Gigabit Ethernet signals with optical channel data unit 2 (ODU2) and ODU2e framing on a per-port basis
- Pre-forward error correction (pre-FEC)-based bit error rate (BER). Fast reroute (FRR) uses the pre-FEC BER as an indication of the condition of an OTN link.

To configure the OTN options on the specified MX routers, use the **set** otn-options statement at the **[edit interfaces *interfaceType-fpc/pic/port*]** hierarchy level.

Ethernet DWDM Interface Wavelength Overview

Dense wavelength-division multiplexing (DWDM) interfaces are supported on 10-Gigabit Ethernet DWDM PICs, MICs, and MPCs; the 10-Gigabit Ethernet LAN/WAN OTN PIC; and the 100-Gigabit Ethernet DWDM OTN PIC. When a tunable optic transceiver is available, you can configure the DWDM interfaces with full C-band International Telecommunication Union (ITU)-Grid tunable optics, as defined in the following specifications:

- *Intel TXN13600 Optical Transceiver I2C Interface and Customer EEPROM Preliminary Specification*, July 2004.
- *I2C Reference Document for 300-Pin MSA 10G and 40G Transponder*, Edition 4, August 04, 2003.

By default, the wavelength is 1550.12 nanometers (nm), which corresponds to 193.40 terahertz (THz).

Configuring the 10-Gigabit or 100-Gigabit Ethernet DWDM Interface Wavelength

To configure the wavelength on 10-Gigabit Ethernet or 100-Gigabit Ethernet dense wavelength-division multiplexing (DWDM) and OTN interfaces, include the **wavelength** statement at the **[edit interfaces *interface-name* optics-options]** hierarchy level:

```
[edit interfaces interface-name optics-options]
wavelength nm;
```

To display the currently tuned wavelength and frequency for the interface, use the **show interfaces *interface-name*** operational mode command.

For interface diagnostics, issue the **show interfaces diagnostics optics *interface-name*** operational mode command.

Table 43 on page 466 shows configurable wavelengths and the corresponding frequency for each configurable wavelength.

Table 43: Wavelength-to-Frequency Conversion Matrix

Wavelength (nm)	Frequency (THz)	Wavelength (nm)	Frequency (THz)	Wavelength (nm)	Frequency (THz)

Understanding the P1-PTX-24-10G-W-SFPP PIC

Starting from Junos OS Release 14.2, a 24–port 10-Gigabit Ethernet OTN PIC—P1-PTX-24-10G-W-SFPP—is supported on the FPC-PTX-P1-A and FPC2-PTX-P1A FPCs in PTX5000 routers, and the FPC-SFF-PTX-P1-A and FPC-SFF-PTX-T FPCs in PTX3000 routers. The P1-PTX-24-10G-W-SFPP PIC provides twenty-four 10-Gigabit Ethernet interfaces, that are independently configurable in LAN PHY or WAN PHY framing mode or in optical channel transport unit in OTU2e, OTU1e, or OTU2 mode.

The following sections explain this PIC in detail:

- Interface Features on page 468
- Layer 2 and Layer 3 Features on page 470
- OTN Alarms and Defects on page 471
- TCA Alarms on page 472

Interface Features

The following interface features are supported on the P1-PTX-24-10G-W-SFPP PIC:

- Twenty-four 10-Gigabit Ethernet interfaces, which are independently configurable in LAN PHY or WAN PHY mode or in OTU2e, OTU1e, or OTU2 signal mode. Each interface is terminated by means of a CFP2 transceiver.
- The interfaces are named with prefix *et*.
- Gigabit Ethernet local loopback.
- Link-level pause frames—You can halt the Ethernet interface from transmitting packets for a configured period of time.
- Interface hold timer and interface damping—You can set the **hold-time** statement (in milliseconds) to damp interface transitions.
- External clock.
- Nonstandard tag protocol identifier (TPID):

  - For each 10-Gigabit Ethernet port, you can configure up to eight TPIDs by using the **tag-protocol-id** statement at the **[edit interfaces interface-name gigether-options ethernet-switch-profile]** hierarchy level.
  - The **tag-protocol-id** statement can be configured only on the first port (port 0) of the PIC. If any other (nonzero) port has the **tag-protocol-id** configuration, the Routing Engine registers an error in the system log and the configuration is ignored.
  - The **tag-protocol-id** statement configured on port 0 of the PIC also applies to the rest of the ports on that PIC.
- Generic forward error correction (GFEC),ultra forward error correction (UFEC), enhanced forward error correction (EFEC), and no-FEC modes of operation are supported.
- Diagnostics tools:
  - Line loopback
  - Local loopback
- Fast reroute (FRR)—Based on configurable pre-FEC, bit error rate (BER) is supported and is configured using the **ber-threshold-signal-degrade** statement at the **[edit interfaces *interface-name* otn-options signal-degrade]** hierarchy level.
- *jnx-ifotn.mib* and *otn-mib* as defined in RFC 3591. Note that according to Junos OS security standard, configurable parameters are not supported through SNMP. Only the *get* operation is available through SNMP.
- FEC statistics—corrected errors and corrected error ratio.
- OTN payload pseudorandom binary sequence (PRBS) generation and checking by enabling or disabling PRBS with the **prbs** or **no-prbs** statement at the **[edit interfaces *interface-name* otn-options]** hierarchy level.
- At the physical interface level, **flexible-ethernet-service**, **ethernet-ccc**, and **ethernet-tcc** encapsulations are supported. For **flexible-ethernet-service** encapsulation, the logical level supports **enet2**, **vlan-ccc**, and **vlan-tcc** encapsulations.
- At the logical interface level **dix**, **vlan-ccc**, and **vlan-tc**c encapsulations are supported.
- SNMP management of the PIC based on RFC 3591, Definitions of Managed Objects for the Optical Interface Type:
  - Set functionality
  - Juniper Networks Black-Link MIB
  - IFOTN MIB
  - Optics MIB
  - FRU MIB
- 15-minute and 1-day performance monitoring and historic statistics.
  - Near-end and far-end performance monitoring
  - Threshold-crossing alerts

  - BER performance monitoring
  - FEC performance monitoring
  - Optical performance monitoring

The following features are not supported on the P1-PTX-24-10G-W-SFPP PIC:

- Source MAC learning for accounting
- MAC policing
- Physical interface-level encapsulations—**vlan-ccc**, **extended-vlan-ccc**, and **extended-vlan-tcc**
- Logical interface-level encapsulation—**vlan-vpls**
- VLAN rewrite for **ccc** encapsulation
- Per queue flow control
- Generic framing procedure-framed (GFP-F) mapping modes over OTN
- General communication channel (GCC)
- OTN interface-level Automatic Protection Switching (APS)
- Insertion, monitoring, and display of OTN header overhead byte
- Optical harness support
- Transport interface and state model (GR-1093)
- Trace tone support

Layer 2 and Layer 3 Features

The following Layer 2 and Layer 3 features are supported on the P1-PTX-24-10G-W-SFPP PIC:

- MAC detect link up and link down based on local fault signal or remote fault signal.
- MAC statistics.
- Flow control.
- MAC oversized packet counters based on default MTU value or user-configured MTU value.
- Per-port destination address MAC filter.
- Per-port source address MAC filter.
- Per-physical interface source address MAC filter.
- Per logical interface source address MAC accounting.
- Maximum of 1000 source MAC filter per physical interface.
- Maximum of 32,000 filter terms to share across all filter features.

- Aggregated Ethernet supports 64 child links that can be configured using the **set chassis aggregated-devices maximum-links** configuration command.
- Maximum of 1024 logical interfaces on an aggregated Ethernet physical interface.
- Support for V LAN tagging, flexible VLAN tagging, and stacked VLAN tagging.
- LACP.
- Link protection.
- 802.3 ah OAM.
- 802.1 ag OAM.
- MPLS FRR.
- SNMP.
- Supports per-VLAN queuing (using Packet Forwarding Engine).

OTN Alarms and Defects

The following OTN alarms and defects are supported on the P1-PTX-24-10G-W-SFPP PIC:

- LOS—Loss Of Signal
- LOF—Loss Of Frame
- LOM—Loss Of Multiframe
- SSF—Server Signal Failure
- TSF—Trail Signal Fail
- OTU-FEC-DEG—Forward Error Correction Degraded
- OTU-FEC-EXE—Excessive Errors, FEC_FAIL from the transponder
- OTU-AIS—Alarm Indication Signal or all ones signal
- OTU-BDI—Backward Defect Identification
- OTU-IAE—Incoming Alignment Error
- OTU-BIAE—Backward Incoming Alignment Error
- OTU-TTIM—Destination Access Point Identifier [DAPI], Source Access Point Identifier [SAPI], or both mismatch from expected to received
- OTU-SD—Signal Degrade
- OTU-SF—Signal Fail
- CSF—Client Signal Failure
- ODU-LCK—(ODU lock triggers for PM [path monitoring])
- ODU-AIS—(alarm indication signal or all ones signal)
- ODU-OCI—(open connection error)

- ODU-BDI—(backward defect indication)
- ODU-IAE—(incoming alignment error)
- ODU-DAPI-TTIM—DAPI or DAPI/SAPI mismatch from expected to receive
- ODU-SAPI-TTIM—SAPI or DAPI/SAPI mismatch from expected to receive
- ODU-BEI—Backward Error Indication
- ODU-SSF—Server Signal Fail
- ODU-TSF—Trail Signal Fail
- ODU-SD—Signal Degrade
- ODU-SF—Signal Fail
- OPU-PTM—Payload Type Mismatch

TCA Alarms

Threshold-crossing alarms (TCA) are alarms that are activated when a certain configurable threshold—near-end measurement threshold or far-end measurement threshold—is crossed and remains so until the end of the 15 minute interval for parameters such as OTU and ODU. The following alarms are supported:

- Background block error threshold (BBE)
- Errored seconds threshold (ES)
- Severely errored seconds threshold (SES)
- Unavailable seconds threshold (UAS)

Related Documentation

- Configuring OTN Interfaces on P1-PTX-24-10G-W-SFPP PIC on page 472

Configuring OTN Interfaces on P1-PTX-24-10G-W-SFPP PIC

Starting from Junos OS Release 14.2, a 24–port 10-Gigabit Ethernet OTN PIC—P1-PTX-24-10G-W-SFPP—is supported on the FPC-PTX-P1-A and FPC2-PTX-P1A FPCs in PTX5000 routers, and the FPC-SFF-PTX-P1-A and FPC-SFF-PTX-T FPCsin PTX3000 routers. To configure an OTN interface on the P1-PTX-24-10G-W-SFPP PIC, you must configure interface-specific options and the OTN-related options for the interface.

To configure the interface-specific options:

1. Go to the **[edit interface *interface-name*]** hierarchy level, where *interface-name* is in the et-*fpc/pic/port* format.

   [edit]
   user@host# **edit interfaces *interface-name***

2. Configure the VLAN tagging option on the OTN interface to enable the reception and transmission of 802.1Q VLAN-tagged frames on the interface.

   [edit interfaces *interface-name*]
   user@host# **set vlan-tagging**

3. Configure the maximum transmission unit (MTU) size in bytes for the interface.

   [edit interfaces *interface-name*]
   user@host# **set mtu *bytes***

4. Configure a VLAN ID for the interface.

   [edit interfaces *interface-name*]
   user@host# **set vlan-id *number***

5. Configure the family for the interface.

   [edit interfaces *interface-name*]
   user@host# **set family *family-name***

6. Configure an IP address for the interface.

   [edit interfaces *interface-name*]
   user@host# **set address *address***

To configure the OTN-related options on the interface:

1. Go to the **[edit interface *interface-name* otn-options]** hierarchy level:

   [edit interfaces *interface-name*]
   user@host# **edit otn-options**

2. Enable the OTN mode as OTU2e, OTU1e, or OTU2 for the interface.

   [edit interfaces *interface-name* otn-options]
   user@host# **set rate fixed-stuff-bytes|no-fixed-stuff-bytes|oc192**

   NOTE: **fixed-stuff-bytes** is for OTU2e rate, **no-fixed-stuff-bytes** is for OTU1e rate and **oc192** is for OTU2 rate. OTU2e and OTU1e rates are applicable for LAN PHY framing mode. OTU2 is applicable for WAN PHY framing mode. Framing mode is to set through the **set interfaces framing** configuration statement.

3. Enable the laser on the OTN interface. The laser is disabled by default for all OTN interfaces.

   [edit interfaces *interface-name* otn-options]
   user@host# **set laser-enable**

4. Set an trail trace identifier for the source access point and for the destination access point for ODU and OTU on the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# **set tti (odu-dapi | odu-expected-receive-dapi | odu-expected-receive-sapi | odu-sapi | otu-dapi | otu-expected-receive-dapi | otu-expected-receive-sapi | otu-sapi)** ***tti-identifier***

5. Ignore the trigger for the defect or set the hold time.

   Configure the hold time for the defect trigger as:

   - *up* with a value—Wait for the hold time delay before clearing the alarm when the defect is absent on the OTN interface.
   - *down* with a value—Wait for the hold time delay before raising the alarm when the defect occurs for the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# **set trigger (oc-lof | oc-lom | oc-los | oc-tsf | odu-ais | odu-bdi | odu-bei | odu-iae | odu-lck | odu-oci | odu-sd | odu-ttim |opu-ptim | otu-ais | otu-bdi | otu-fec-deg | otu-fec-exe | otu-iae | otu-sd | otu-ttim) (hold-time (down** ***value*** **| up** ***value*****) | ignore)**

6. Enable the threshold crossing alarms for the OTN interface along with the trigger for the defect.

   [edit interfaces *interface-name* otn-options]
   user@host# **set tca (odu-tca-bbe | odu-tca-es | odu-tca-ses | odu-tca-uas | otu-tca-bbe | otu-tca-es | otu-tca-ses | otu-tca-uas) (enable-tca | no-enable-tca | threshold)**

7. Set the OTN header bytes as a transmit payload type from 0 bytes through 255 bytes for the packets that are transmitted on the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# **set bytes transmit-payload-type** ***value***

8. Configure the forward error correction (FEC) mode as Generic Forward Error Correction (GFEC), Enhanced Forward Error Correction (EFEC), Ultra Forward Error Correction (UFEC), or no-FEC (none) for the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# **set fec (gfec | ufec | efec | none)**

9. Enable a consequent action as listed in the ITU-T G.798 standard for ODU trail trace identifier mismatch (TTIM) on the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# **set odu-ttim-action-enable**

10. Enable a consequent action as listed in the ITU-T G.798 standard for OTU trail trace identifier mismatch (TTIM) on the OTN interface.

```
[edit interfaces interface-name otn-options]
user@host# set otu-ttim-action-enable
```

11. Configure the threshold value for signal degradation when an alarm needs to be raised. Configure the threshold value after signal degradation when the alarm needs to be cleared. When you configure the interval along with the **ber-threshold-signal-degrade *value*** statement, the bit error rate (BER) must stay above the signal degradation threshold for the configured interval after which the alarm is raised. When the interval is configured along with the **ber-threshold-clear *value*** statement, then BER must stay below the clear threshold for the configured interval after which the alarm is cleared.

```
[edit interfaces interface-name otn-options signal-degrade]
user@host# set ber-threshold-signal-degrade value
user@host# set ber-threshold-clear value
user@host# set interval value
```

12. Enable the following actions for the **preemptive-fast-reroute** statement:

    - Backward FRR—Insert the local pre-FEC status into the transmitted OTN frames and monitor the received OTN frames for the pre-FEC status.

    ```
    [edit interfaces interface-name otn-options preemptive-fast-reroute]
    user@host# set backward-frr-enable
    ```

    - Monitoring of signal degradation of pre-FEC OTN frames.

    ```
    [edit interfaces interface-name otn-options preemptive-fast-reroute]
    user@host# set signal-degrade-monitor-enable
    ```

100-Gigabit Ethernet OTN Options Configuration Overview

PTX Series routers support optical transport network (OTN) interfaces, including the 100-Gigabit DWDM OTN PIC, which supports:

- Transparent transport of two 100-Gigabit Ethernet signals with Optical Channel Transport Unit 4 (OTU4) framing.
- International Telecommunications Union (ITU)-standard OTN performance monitoring (PM) and alarm management.

- Dual polarization quadrature phase shift keying (DP-QPSK) modulation and soft-decision forward error correction (SD-FEC) for long haul and metro applications.
- Pre-forward error correction (pre-FEC)-based bit error rate (BER) monitoring. Pre-FEC BER monitoring uses the pre-FEC BER as an indication of the condition of an OTN link. See “Understanding Pre-FEC BER Monitoring and BER Thresholds” on page 477 for more information.

For more information about the 100-Gigabit DWDM OTN PIC, see *100-Gigabit DWDM OTN PIC* in the *PTX Series Interface Module Reference*.

PTX Series routers also support the 100-Gigabit Ethernet OTN PIC (P2-100GE-OTN), which provides four 100-Gigabit Ethernet interfaces, independently configurable in LAN PHY framing mode or in optical channel transport unit 4 (OTU4) mode. See “Understanding the P2-100GE-OTN PIC” on page 500 for more information.

See “Supported OTN Options on PTX Series Routers” on page 485 for a comparison of the features supported on PTX Series OTN PICs.

MX2020, MX2010, MX960, MX480, and MX240 routers support OTN interfaces on MPC5E and MPC6E. MPC5E-100G10G and MPC5EQ-100G10G support 100-Gigabit Ethernet OTN interfaces and 10-Gigabit Ethernet OTN interfaces on MX240, MX480, and MX960 routers. The OTN MIC MIC6-100G-CFP2 on MPC6E supports OTN on 100-Gigabit Ethernet interfaces on MX2020 and MX2010 routers. OTN support on the specified MX Series routers includes:

- International Telecommunications Union (ITU)-standard OTN performance monitoring (PM) and alarm management
- Transparent transport of two 100-Gigabit Ethernet signals with optical channel transport unit 4 (OTU4) framing.
- Generic forward error correction (Generic FEC)

To configure the OTN options for PTX Series routers and specific MX Series routers, use the **set** otn-options statement at the **[edit interfaces *interfaceType-fpc/pic/port*]** hierarchy level.

Use the **set** optics-options statement at the **[edit interfaces *interfaceType-fpc/pic/port*]** hierarchy level to configure the optics options.

Use the *show interfaces extensive*, **show interfaces diagnostics optics (Gigabit Ethernet, 10-Gigabit Ethernet, 40-Gigabit Ethernet, 100-Gigabit Ethernet, and Virtual Chassis Port)**, and **show interfaces transport pm** commands to view optics and OTN PM information. To display the current time interval and clear the channel service unit (CSU) alarm and defect counters, use the **clear interfaces interval** command.

Understanding Pre-FEC BER Monitoring and BER Thresholds

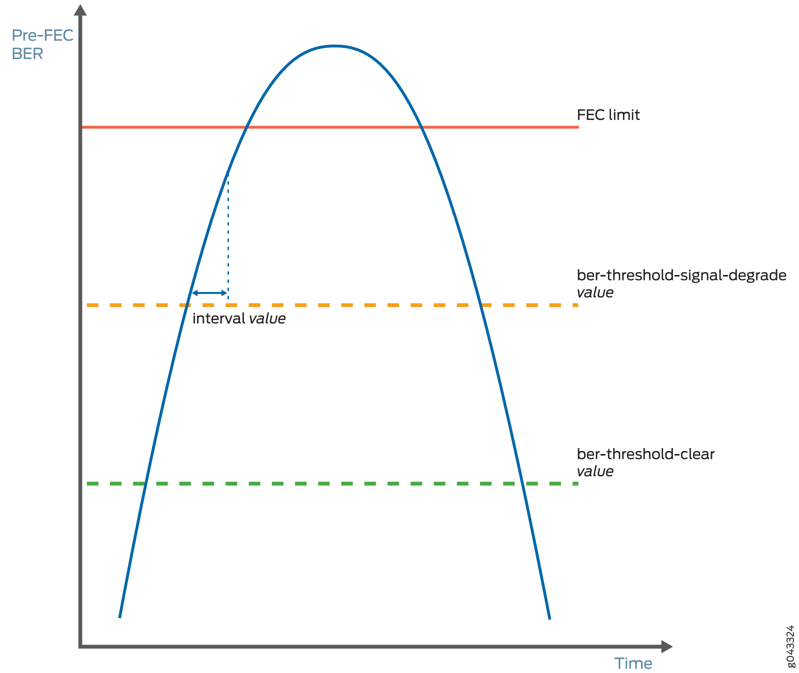
Optical transport network (OTN) interfaces on PTX Series Packet Transport Routers support monitoring the condition of an OTN link by using the pre-forward error correction (pre-FEC) bit error rate (BER). The following PICs support pre-FEC BER monitoring:

- P1-PTX-2-100G-WDM
- P2-100GE-OTN
- P1-PTX-24-10G-W-SFPP

The PICs use forward error correction (FEC) to correct bit errors in the received data. As long as the pre-FEC BER is below the FEC limit, all bit errors are successfully identified and corrected and, therefore, no packet loss occurs. The system monitors the pre-FEC BER on each port. This gives an early warning of link degradation. By configuring an appropriate pre-FEC BER threshold and interval, you enable the PIC to take preemptive action before the FEC limit is reached. If this pre-FEC BER threshold logic is combined with MPLS fast reroute, then packet loss can be minimized or prevented.

You must specify both the signal degradation threshold (**ber-threshold-signal-degrade**) and the interval (**interval**) for the interface. The threshold defines the BER criteria for a signal degrade condition and the interval defines the minimum duration over which the BER must exceed the threshold before an alarm is raised. The relationship between the threshold and the interval is illustrated in Figure 32 on page 478. After an alarm is raised, if the BER returns to a level below the threshold clear value (**ber-threshold-clear**), the alarm is cleared.

Figure 32: Pre-FEC BER Monitoring



With pre-FEC BER monitoring enabled, when the configured pre-FEC BER signal degrade threshold is reached, the PIC stops forwarding packets to the remote interface and raises an interface alarm. Ingress packets continue to be processed. If pre-FEC BER monitoring is used with MPLS fast reroute or another link protection method, then traffic is rerouted to a different interface.

You can also configure backward fast reroute to insert the local pre-FEC status into transmitted OTN frames, notifying the remote interface of signal degradation. The remote interface can use the information to reroute traffic to a different interface. If you use pre-FEC BER monitoring together with backward fast reroute, then notification of signal degradation and rerouting of traffic occurs in less time than that required through a Layer 3 protocol.

Include the signal-degrade-monitor-enable and backward-frr-enable statements at the **[edit interfaces *interface-name* otn-options preemptive-fast-reroute]** hierarchy level to enable pre-FEC BER monitoring and backward fast reroute.

NOTE: When you configure pre-FEC BER signal degrade monitoring, we recommend that you configure both the **signal-degrade-monitor-enable** and the **backward-frr-enable** statements.

You can also configure the pre-FEC BER thresholds that raise or clear a signal degrade alarm and the time interval for the thresholds. If the BER thresholds and interval are not configured, the default values are used.

When a received signal degrade alarm is active and backward fast reroute is enabled, a specific flag is inserted into the trasmitted OTN overhead. The remote PIC at the opposite end of the link monitors the OTN overhead, thus enabling both ends to initiate traffic rerouting in the event of a signal degrade condition. When the signal degrade condition is cleared, the OTN overhead flag is returned to a normal state.

The pre-FEC BER signal degrade threshold value defines a specific amount of system margin relative to the BER correction limit (or FEC limit) of the PIC's receive FEC decoder. Each PIC has a set FEC limit—it is intrinsic to the FEC decoder implementation.

NOTE: The examples below use Q^2-factor measurements (also known as Q-factor). Q^2-factor is expressed in units of decibels relative to a Q^2-factor of zero (dBQ). Q^2-factor enables you to describe system margin in linear terms in contrast to BER values, which are nonlinear in nature. After you determine the thresholds, you must convert the threshold values from Q^2-factor to BER to enter them in the CLI by using scientific notation. BER can be converted to Q^2-factor by using the following equation:

Q^2-factor = 20 * log10 (sqrt(2) * erfcinv(2 * *BER*))

TIP: To convert between Q^2-factor and BER in a spreadsheet program, you can approximate the values by using the following formulas:

- To calculate Q^2-factor:

  = 20 * LOG10(–NORMSINV(*BER*))

- To calculate BER:

  = 1 – NORMSDIST(10^(0.05 * *Q^2-factor*))

Table 44 on page 479 shows the relationship between the fixed FEC limit, the configurable signal degrade threshold, and the configurable clear threshold for different PICs. In this example, approximately 1 dBQ of system margin has been set between the FEC limit, signal degrade threshold, and clear threshold.

Table 44: Example—Signal Degrade and Clear Threshold Values at 1 dBQ

PIC	FEC Type	FEC Limit		Signal Degrade Threshold		Clear Threshold	
		Q^2-Factor	BER	Q^2-Factor	BER	Q^2-Factor	BER
P1-PTX-2-100G-WDM	SD-FEC	6.7 dBQ	1.5E–2	7.7 dBQ	7.5E–3	8.7 dBQ	3.0E–3
P2-100GE-OTN	G.709 GFEC	11.5 dBQ	8.0E–5	12.5 dBQ	1.1E–5	13.5 dBQ	1.0E–6

Table 44: Example—Signal Degrade and Clear Threshold Values at 1 dBQ (continued)

PIC	FEC Type	FEC Limit		Signal Degrade Threshold		Clear Threshold	
		Q^2-Factor	BER	Q^2-Factor	BER	Q^2-Factor	BER
P1-PTX-24-10G-W-SFPP	G.975.1 I.4 (UFEC)	9.1 dBQ	2.2E–3	10.1 dBQ	6.9E–4	11.1 dBQ	1.6E–4
	G.975.1 I.7 (EFEC)	9.6 dBQ	1.3E–3	10.6 dBQ	3.6E–4	11.6 dBQ	7.5E–5
	G.709 GFEC	11.5 dBQ	8.0E–5	12.5 dBQ	1.1E–5	13.5 dBQ	1.0E–6

To adjust the signal degrade threshold, you must first decide on a new system margin target and then calculate the respective BER value (using the equation to convert from Q^2-factor to BER). Table 45 on page 480 shows the values if 3 dBQ of system margin relative to the FEC limit is required for the signal degrade threshold (while maintaining the clear threshold at 1 dBQ relative to the signal degrade threshold).

NOTE: The choice of system margin is subjective, as you might want to optimize your thresholds based on different link characteristics and fault tolerance and stability objectives. For guidance about configuring pre-FEC BER monitoring and BER thresholds, contact your Juniper Networks representative.

Table 45: Example—Signal Degrade and Clear Thresholds After Configuration

PIC	FEC Type	FEC Limit		Signal Degrade Threshold		Clear Threshold	
		Q^2-Factor	BER	Q^2-Factor	BER	Q^2-Factor	BER
P1-PTX-2-100G-WDM	SD-FEC	6.7 dBQ	1.5E–2	9.7 dBQ	1.1E–3	10.7 dBQ	2.9E–4
P2-100GE-OTN	G.709 GFEC	11.5 dBQ	8.0E–5	14.5 dBQ	4.9E–8	15.5 dBQ	1.1E–9
P1-PTX-24-10G-W-SFPP	G.975.1 I.4 (UFEC)	9.1 dBQ	2.2E–3	12.1 dBQ	2.8E–5	13.1 dBQ	3.1E–6
	G.975.1 I.7 (EFEC)	9.6 dBQ	1.3E–3	12.6 dBQ	1.1E–5	13.6 dBQ	9.1E–7
	G.709 GFEC	11.5 dBQ	8.0E–5	14.5 dBQ	4.8E–8	15.5 dBQ	1.1E–9

Include the ber-threshold-signal-degrade, ber-threshold-clear, and interval statements at the **[edit interfaces *interface-name* otn-options signal-degrade]** hierarchy level to configure the BER thresholds and time interval.

NOTE: Configuring a high BER threshold for signal degradation and a long interval might cause the internal counter register to be saturated. Such a configuration is ignored by the router, and the default values are used instead. A system log message is logged for this error.

Configuring 100-Gigabit DWDM OTN PICs

PTX Series routers support optical transport network (OTN) interfaces, including the 100-Gigabit DWDM OTN PIC (P1-PTX-2-100G-WDM). See "100-Gigabit Ethernet OTN Options Configuration Overview" on page 475.

To configure the 100-Gigabit DWDM OTN PIC:

1. Configure the interface wavelength.

   [edit interfaces *interface-name* optics-options]
   user@host# **set wavelength** *nm*

   See **wavelength**.

   NOTE: See *100-Gigabit DWDM OTN PIC Integrated Transceiver Optical Interface Specifications* for a list of wavelengths supported by the P1-PTX-2-100G-WDM PIC.

2. Enable the laser.

   [edit interfaces *interface-name* otn-options]
   user@host# **set laser-enable**

3. (Optional) Set the tca.

   [edit interfaces *interface-name* otn-options]
   user@host# **set tca** ***tca-identifier*** (enable-tca | no-enable-tca) (threshold *number* | threshold-24hrs *number*)

   See **tca**.

4. (Optional) Set the trace identifiers.

   [edit interfaces *interface-name* otn-options]
   user@host# **set tti** ***tti-identifier tti-identifier-name***

See tti.

5. (Optional) Specify defect triggers.

   [edit interfaces *interface-name* otn-options]
   user@host# **set trigger *trigger-identifier***

   See trigger.

6. (Optional) Enable VLAN tagging. See *Enabling VLAN Tagging*.

7. (Optional) Set the media MTU. See *Configuring the Media MTU*.

8. (Optional) Set the unit VLAN ID, family **inet**, and IP address.

   [edit interfaces *interface-name*]
   user@host# **set vlan-id *number***
   user@host# **set family inet**
   user@host# **set address *address***

9. (Optional) Enable pre-FEC BER signal-degrade monitoring and backward fast reroute to monitor the pre-FEC BER status of the link and to insert the local pre-FEC status into transmitted OTN frames.

   [edit interfaces *interface-name* otn-options preemptive-fast-reroute]
   user@host# **set signal-degrade-monitor-enable**
   user@host# **set backward-frr-enable**

See signal-degrade-monitor-enable and backward-frr-enable.

10. (Optional) Configure the bit error rate (BER) thresholds for signal degradation used for monitoring the pre-forward error correction (pre-FEC) status of the OTN link.

    a. Set the BER signal-degrade threshold.

        [edit interfaces *interface-name* otn-options signal-degrade]
        user@host# **set ber-threshold-signal-degrade** ***value***

    b. Set the BER threshold to clear signal-degrade alarms.

        [edit interfaces *interface-name* otn-options signal-degrade]
        user@host# **set ber-threshold-clear** ***value***

    c. Set the time interval for signal-degrade collection. After the BER threshold for signal-degrade is crossed for ten consecutive intervals, an alarm is raised. If the BER threshold for signal-degrade clear is crossed for ten consecutive intervals, the alarm is cleared. For example, if the interval is configured as 10 ms, then the BER must stay above the signal degradation threshold for 100 ms (10 ms * 10 intervals) for the alarm to be raised, or below the clear threshold for 100 ms for the alarm to be cleared.

        [edit interfaces *interface-name* otn-options signal-degrade]
        user@host# **set interval** ***value***

        NOTE: Configuring a high BER threshold for signal degradation and a long interval might cause the internal counter register to be saturated. Such a configuration is ignored by the router, and the default values are used instead. A system log message is logged for this error.

        See ber-threshold-signal-degrade, ber-threshold-clear, and interval.

    NOTE: See "Understanding Pre-FEC BER Monitoring and BER Thresholds" on page 477 for more information about pre-FEC BER monitoring and determining BER threshold settings.

Understanding the P2-100GE-OTN PIC

Starting with Junos OS Release 14.1R2 and 14.2, a 100-Gigabit Ethernet OTN PIC—P2-100GE-OTN—is supported on the FPC2-PTX-P1A FPC in PTX5000 routers. The P2-100GE-OTN PIC provides 4-port 100-Gigabit Ethernet interfaces, which are independently configurable in LAN PHY framing mode or in optical channel transport unit 4 (OTU4) mode. Each interface is terminated by means of a CFP2 transceiver. The FPC2-PTX-P1A FPC supports two P2-100GE-OTN PICs, in which each 100-Gigabit Ethernet port is mapped to a Packet Forwarding Engine in the FPC.

Starting from Junos OS Release 15.1, you can configure the interfaces on the P2-100GE-OTN PIC on PTX5000 routers, to be a part of the mixed rates and mixed mode aggregated Ethernet bundles.

For information about mixed rates, see "Understanding Mixed Rates and Mixed Modes on Aggregated Ethernet Bundles" on page 117.

Starting from Junos OS Release 15.1, you can configure port-based pseudowire class of service (CoS) classification which includes Layer 3 IPv4, IPv6, and MPLS classification for interfaces with ethernet-ccc encapsulation.

The following sections explain this PIC in detail:

Interface Features

The following interface features are supported on a P2-100GE-OTN PIC:

- 4-port 100-Gigabit Ethernet interfaces, which are independently configurable in LAN PHY framing mode or in OTU4 signal mode. Each interface is terminated by means of a CFP2 transceiver.
- Each port maps to a single Packet Forwarding Engine in the FPC2-PTX-P1A FPC.
- The interfaces are named with prefix *et*.
- Gigabit Ethernet local loopback.
- Link-level pause frames—You can halt the Ethernet interface from transmitting packets for a configured period of time.
- Interface hold timer and interface damping—You can set the **hold-time** statement (in milliseconds) to damp interface transitions.
- External clock

- Nonstandard tag protocol identifier (TPID):
  - For each 100-Gigabit Ethernet port, you can configure up to eight TPIDs by using the **tag-protocol-id** statement at the **[edit interfaces interface-name gigether-options ethernet-switch-profile]** hierarchy level.
  - The **tag-protocol-id** statement can be configured only on the first port (port 0) of the PIC. If any other (nonzero) port has the **tag-protocol-id** configuration, the Routing Engine registers an error in the system log and the configuration is ignored.
  - The **tag-protocol-id** statement configured on port 0 of the PIC also applies to the rest of the ports on that PIC.
- The interface *Link Down* event always generates an interrupt; however, the interface *Link Up* event does not generate an interrupt. Therefore, the interface link-up event is detected during the 1-second PIC periodic polling process.
- Generic forward error correction (GFEC) (G.709) and no-FEC modes of operation.
- Diagnostics tools:
  - Line loopback
  - Local loopback
- Fast reroute (FRR)—Based on configurable pre-FEC, bit error rate (BER) is supported and is configured using the **ber-threshold-signal-degrade** statement at the **[edit interfaces *interface-name* otn-options signal-degrade]** hierarchy level.
- *jnx-ifotn.mib* and *otn-mib* as defined in RFC 3591. Note that according to Junos OS security standard, configurable parameters are not supported through SNMP. Only the *get* operation is available through SNMP.
- FEC statistics—corrected errors and corrected error ratio.
- OTN payload pseudorandom binary sequence (PRBS) generation and checking by enabling or disabling PRBS with the **prbs** or **no-prbs** statement at the **[edit interfaces *interface-name* otn-options]** hierarchy level.
- Optical channel data unit (ODU)-level delay measurement.
- At the physical interface level, **flexible-ethernet-service**, **ethernet-ccc**, and **ethernet-tcc** encapsulations are supported. For the **flexible-ethernet-service** encapsulation, the logical level supports **enet2**, **vlan-ccc**, and **vlan-tcc** encapsulations.
- At the logical interface level, **dix**, **vlan-ccc**, and **vlan-tc**c encapsulations are supported.
- Interoperability between 100-Gigabit Ethernet interfaces with CFP transceiver and 100-Gigabit Ethernet interfaces with CFP2 transceiver in LAN PHY framing mode and in OTU4 mode.

The following features are not supported on the P2-100GE-OTN PIC:

- Source MAC learning for accounting
- MAC policing

- Physical interface-level encapsulations—**vlan-ccc**, **extended-vlan-ccc**, and **extended-vlan-tcc**
- Logical interface-level encapsulation—**vlan-vpls**
- VLAN rewrite for **ccc** encapsulation
- Per-queue flow control
- Generic framing procedure-framed (GFP-F) mapping modes over OTN
- General communication channel (GCC)
- OTN interface-level Automatic Protection Switching (APS)
- Insertion, monitoring, and display of OTN header overhead byte
- Black link MIB for integration with transponders
- Optical harness support
- Transport interface and state model (GR-1093)
- Trace tone support
- 15-minute and 1-day performance monitoring counters and historic counters

Layer 2 and Layer 3 Features

The following Layer 2 and Layer 3 features are supported on the P2-100GE-OTN PIC:

- MAC detect link up and link down based on local fault signal or remote fault signal.
- MAC statistics.
- Flow control.
- MAC oversized packet counters based on default MTU value or user-configured MTU value.
- Per-port destination address MAC filter.
- Per-port source address MAC filter.
- Per-physical interface source address MAC filter.
- Per-logical interface source address MAC accounting.
- Maximum of 1000 source MAC filter per physical interface.
- Maximum of 32,000 filter terms to share across all filter features.
- Aggregated Ethernet supports 64 child links that can be configured using the **set chassis aggregated-devices maximum-links** configuration command.
- Maximum of 1024 logical interfaces on an aggregated Ethernet physical interface.
- Support for VLAN tagging, flexible VLAN tagging, and stacked VLAN tagging.
- LACP.
- Link protection.

- 802.3 ah OAM.
- 802.1 ag OAM.
- MPLS FRR.
- SNMP.
- Supports per-VLAN queuing (using Packet Forwarding Engine).

OTN Alarms and Defects

The following OTN alarms and defects are supported on the P2-100GE-OTN PIC:

- LOS—Loss Of Signal
- LOF—Loss Of Frame
- LOM—Loss Of Multiframe
- OTU—Degrade
- OTU—AIS
- OTU—IAE
- OTU—BDI
- OTU—TTIM
- OTU—Signal Degrade
- OTU—Signal Fail
- ODU—Signal Fail
- OTU-FEC—Degrade
- OTU-FEC—Excessive errors
- ODU—Signal Degrade
- ODU—AIS
- ODU—BDI
- ODU—OCI
- ODU—LCK
- ODU—TTIM
- OPU—PTM

TCA Alarms

Threshold-crossing alarms (TCA) are alarms that are activated when a certain configurable threshold—near-end measurement threshold or far-end measurement threshold—is crossed and remains so until the end of the 15 minute interval for parameters such as OTU and ODU. The following alarms are supported:

- Background block error threshold (BBE)
- Errored seconds threshold (ES)
- Severely errored seconds threshold (SES)
- Unavailable seconds threshold (UAS)

Release History Table

Release	Description
15.1	Starting from Junos OS Release 15.1, you can configure the interfaces on the P2-100GE-OTN PIC on PTX5000 routers, to be a part of the mixed rates and mixed mode aggregated Ethernet bundles.
15.1	Starting from Junos OS Release 15.1, you can configure port-based pseudowire class of service (CoS) classification which includes Layer 3 IPv4, IPv6, and MPLS classification for interfaces with ethernet-ccc encapsulation.

Configuring OTN Interfaces on P2-100GE-OTN PIC

To configure an OTN interface on the P2-100GE-OTN PIC you must configure interface-specific options and OTN-related options for the interface.

To configure the interface-specific options:

1. Go to the **[edit interface *interface-name*]** hierarchy level, where *interface-name* is in the et-*fpc/pic/port* format.

   ```
   [edit]
   user@host# edit interfaces interface-name
   ```

2. Configure VLAN tagging on the OTN interface to enable the reception and transmission of 802.1Q VLAN-tagged frames on the interface.

   ```
   [edit interfaces interface-name ]
   user@host# set vlan-tagging
   ```

3. Configure the maximum transmission unit (MTU) size in bytes for the interface.

   ```
   [edit interfaces interface-name ]
   user@host# set mtu bytes
   ```

4. Configure a VLAN ID for the interface.

   [edit interfaces *interface-name*]
   user@host# **set vlan-id *number***

5. Configure the family for the interface.

   [edit interfaces *interface-name*]
   user@host# **set family *family-name***

6. Configure an IP address for the interface.

   [edit interfaces *interface-name*]
   user@host# **set address *address***

To configure the OTN-related options on the interface:

1. Go to the **[edit interface *interface-name* otn-options]** hierarchy level:

   [edit]
   user@host# **edit interfaces *interface-name* otn-options**

2. Enable the laser on the OTN interface. The laser is disabled by default for all OTN interfaces.

   [edit interfaces *interface-name* otn-options]
   user@host# **set laser-enable**

3. Set an trail trace identifier for the source access point and for the destination access point for ODU and OTU on the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# **set tti (odu-dapi | odu-expected-receive-dapi | odu-expected-receive-sapi | odu-sapi | otu-dapi | otu-expected-receive-dapi | otu-expected-receive-sapi | otu-sapi) *tti-identifier***

4. Ignore the trigger for the defect or set the hold time.

   Configure the hold time for the defect trigger as:

   - *up* with a value—Wait for the hold time delay before clearing the alarm when the defect is absent on the OTN interface.
   - *down* with a value—Wait for the hold time delay before raising the alarm when the defect occurs for the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# **set trigger (oc-lof | oc-lom | oc-los | oc-tsf | odu-ais | odu-bdi | odu-bei | odu-iae | odu-lck | odu-oci | odu-sd | odu-ttim |opu-ptim | otu-ais | otu-bdi | otu-fec-deg | otu-fec-exe | otu-iae | otu-sd | otu-ttim) (hold-time (down *value* | up *value*) | ignore)**

5. Enable the threshold crossing alarms for the OTN interface along with the trigger for the defect.

   - In Junos OS Release 14.1R2 only:

     [edit interfaces *interface-name* otn-options trigger]
     user@host# **set tca (odu-tca-bbe | odu-tca-es | odu-tca-ses | odu-tca-uas | otu-tca-bbe | otu-tca-es | otu-tca-ses | otu-tca-uas) (enable-tca | no-enable-tca | threshold)**

   - In Junos OS Release 14.2 and later:

     [edit interfaces *interface-name* otn-options]
     user@host# **set tca (odu-tca-bbe | odu-tca-es | odu-tca-ses | odu-tca-uas | otu-tca-bbe | otu-tca-es | otu-tca-ses | otu-tca-uas) (enable-tca | no-enable-tca | threshold)**

6. Set the OTN header bytes as a transmit payload type from 0 bytes through 255 bytes for the packets that are transmitted on the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# **set bytes transmit-payload-type *value***

7. Configure the forward error correction (FEC) mode as Generic Forward Error Correction (GFEC) or none for the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# **set fec (gfec | none)**

8. Enable line loopback or local host loopback for the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# **set line-loopback**
   user@host# **set local-loopback**

9. Enable an ODU locked maintenance signal on the OTN interface to send the signal pattern 01010101.

   [edit interfaces *interface-name* otn-options]
   user@host# **set insert-odu-lck**

10. Enable an ODU open connection indication signal on the OTN interface to send to send the signal pattern 01100110.

    [edit interfaces *interface-name* otn-options]
    user@host# **set insert-odu-oci**

11. Enable a consequent action as listed in the ITU-T G.798 standard for ODU trail trace identifier mismatch (TTIM) on the OTN interface.

    [edit interfaces *interface-name* otn-options]
    user@host# **set odu-ttim-action-enable**

12. Enable a consequent action as listed in the ITU-T G.798 standard for OTU trail trace identifier mismatch (TTIM) on the OTN interface.

[edit interfaces *interface-name* otn-options]
user@host# **set otu-ttim-action-enable**

13. Configure the OTN payload pseudorandom binary sequence (PRBS) on the OTN interface.

    [edit interfaces *interface-name* otn-options]
    user@host# **set prbs**

14. Configure OTN mode as OTU4 for the OTN interface.

    [edit interfaces *interface-name* otn-options]
    user@host# **set rate otu4**

15. Configure the threshold value for signal degradation when an alarm needs to be raised. Configure the threshold value after signal degradation when the alarm needs to be cleared. When you configure the interval along with the **ber-threshold-signal-degrade *value*** statement, the bit error rate (BER) must stay above the signal degradation threshold for the configured interval after which the alarm is raised. When the interval is configured along with the **ber-threshold-clear *value*** statement, then BER must stay below the clear threshold for the configured interval after which the alarm is cleared.

    [edit interfaces *interface-name* otn-options signal-degrade]
    user@host# **set ber-threshold-signal-degrade *value***
    user@host# **set ber-threshold-clear *value***
    user@host# **set interval *value***

16. Enable the following actions for the **preemptive-fast-reroute** statement:

    - Backward FRR—Insert the local pre-FEC status into the transmitted OTN frames and monitor the received OTN frames for the pre-FEC status.

      [edit interfaces *interface-name* otn-options preemptive-fast-reroute]
      user@host# **set backward-frr-enable**

    - ODU backward FRR—Insert the ODU status into the transmitted OTN frames and monitor the received OTN frames for the ODU BER status.

      [edit interfaces *interface-name* otn-options preemptive-fast-reroute]
      user@host# **set odu-backward-frr-enable**

    - Monitoring of signal degradation of pre-FEC OTN frames.

      [edit interfaces *interface-name* otn-options preemptive-fast-reroute]
      user@host# **set signal-degrade-monitor-enable**

    - Monitoring of signal degradation of ODU BER in the received OTN frames.

      [edit interfaces *interface-name* otn-options preemptive-fast-reroute]
      user@host# **set odu-signal-degrade-monitor-enable**

17. Configure the following options for ODU BER signal degradation on the OTN interface:

    - Configure the threshold for signal degradation for ODU BER when an alarm needs to be raised.

[edit interfaces *interface-name* otn-options odu-signal-degrade]
user@host# **set ber-threshold-signal-degrade** ***value***

- Configure the threshold for ODU BER after signal degradation when the alarm needs to be cleared.

  [edit interfaces *interface-name* otn-options odu-signal-degrade]
  user@host# **set ber-threshold-clear** ***value***

- When you configure the interval along with the **ber-threshold-signal-degrade** ***value*** statement, the ODU bit error rate (BER) must stay above the signal degradation threshold for the configured interval after which the alarm is raised. When the interval is configured along with the **ber-threshold-clear** ***value*** statement, then ODU BER must stay below the clear threshold for the configured interval after which the alarm is cleared.

  [edit interfaces *interface-name* otn-options odu-signal-degrade]
  user@host# **set interval** ***value***

Understanding the MIC3-100G-DWDM MIC

Starting from Junos OS Release 15.1F5, the 100-Gigabit DWDM OTN MIC—MIC3-100G-DWDM—is supported on MPC3E (MX-MPC3E-3D) and MPC3E NG (MPC3E-3D-NG) on the MX240, MX480, MX960, MX2010, and MX2020 routers. The MIC3-100G-DWDM MIC provides a single 100-Gigabit Ethernet interface port that supports DP-QPSK with coherent reception and OTU4 and OTU4 (v) framing modes.

The interfaces on MIC3-100G-DWDM MIC are named with prefix *et*. For more information, see *Interface Naming Overview*.

The following sections explain the features of this MIC in detail:

Interface Features

The following interface features are supported on the MIC3-100G-DWDM MIC:

- Single port 100-Gigabit Ethernet interface with OTU4 (v) framing. DP-QPSK modulation with coherent reception using a CFP2-ACO DWDM optical transceiver.
- Gigabit Ethernet local loopback.
- Diagnostics tools:

- Line loopback
- Local loopback
- Optical Channel Data Unit (ODU) Open Connection Error
- Optical Channel Data Unit (ODU) Lock Maintenance Signal

- Types of forward error corrections (FEC):
  - GFEC (generic forward error correction)
  - HGFEC (high gain forward error correction)
  - SDFEC (soft-decision forward error correction)
- The following MIB modules continue to be supported (and no new MIB is introduced):
  - MIB module to describe Black Link extension to RFC 3591 (jnxoptIfExtMibModule)
  - MIB module to manage the OTN interface (jnxIfOtnMib)
  - MIB module to manage the Optics interface (jnxIfOpticsMib)
  - MIB module to manage OTN FRUs (jnxFruMib)
- Interoperability with the 100-Gigabit DWDM OTN PIC (P1-PTX-2-100G-WDM) is not supported.
- Support for interoperability with other vendors' 100 Gigabit Ethernet interfaces.
- Source MAC learning for accounting
- MAC policing
- Physical interface-level encapsulations—**vlan-ccc**, **extended-vlan-ccc**, and **extended-vlan-tcc**
- Logical interface-level encapsulation—**vlan-vpls**
- VLAN rewrite for **ccc** encapsulation
- Per-queue flow control
- 15-minute and 1-day performance monitoring and historic statistics.
  - Near-end and far-end performance monitoring
  - Threshold-crossing alarms
  - BER performance monitoring
  - FEC performance monitoring
  - Optical performance monitoring
- Insertion, monitoring, and display of OTN header overhead
- Transport interface and state model (GR-1093)

Layer 2 and Layer 3 Features

The following Layer 2 and Layer 3 features are supported on the MIC3-100G-DWDM MIC:

- Per-port destination address MAC filter.
- Per-port source address MAC filter.
- Per-physical interface source address MAC filter.
- Maximum of 1000 source MAC filter per physical interface.
- Maximum of 32,000 filter terms to share across all filter features.
- Flexible VLAN tagging.
- 802.3 ah OAM.
- 802.1 ag OAM.

OTN Alarms and Defects

The following OTN alarms and defects are supported on the MIC3-100G-DWDM MIC:

Optical Channel(OC) Alarms and Defects

- OC-LOS—Loss Of Signal
- OC-LOF—Loss Of Frame
- OC-LOM—Loss Of Multiframe
- OC-Wavelength-Lock—Wavelength Lock

Optical Channel Data Unit (ODU) Defects

- ODU-AIS—ODU Alarm Indication Signal
- ODU-BDI—ODU Backward Defect Indication
- ODU-BIAE—ODU Backward Incoming Alignment Error
- ODU-IAE—ODU Incoming Alignment Error
- ODU-LCK—ODU Locked
- ODU-LTC—ODU Loss of Tandem Connection
- ODU-OCI—ODU Open Connection Error
- ODU-SSF—ODU Server Signal Failure
- ODU-TSF—ODU Trail Signal Failure
- ODU-TTIM—ODU Trail Trace Identifier Mismatch

Optical Channel Transport Unit (OTU) Defects

- OTU-AIS—OTU Alarm Indication Signal
- OTU-BDI—OTU Backward Defect Indication
- OTU-BIAE—OTU Backward Incoming Alignment Error
- OTU-FEC-DEG—OTU Forward Error Correction Degrade

- OTU-FEC-EXCESS-FEC—OTU Forward Error Correction Excessive FEC Errors
- OTU-IAE—OTU Incoming Alignment Error
- OTU-SSF—OTU Server Signal Failure
- OTU-TSF—OTU Trail Signal Failure
- OTU-TTIM—OTU Trail Trace Identifier Mismatch

Threshold-Crossing Alarms

Threshold-crossing alarms (TCA) are alarms that are activated when a certain configurable threshold —near-end measurement threshold or far-end measurement threshold—is crossed and remains so until the end of the 15 minutes interval for parameters such as OTU and ODU. The following alarms are supported:

- Background block error threshold (BBE)
- Errored seconds threshold (ES)
- Severely errored seconds threshold (SES)
- Unavailable seconds threshold (UES)

Release History Table

Release	Description
15.1F5	Starting from Junos OS Release 15.1F5, the 100-Gigabit DWDM OTN MIC—MIC3-100G-DWDM—is supported on MPC3E (MX-MPC3E-3D) and MPC3E NG (MPC3E-3D-NG) on the MX240, MX480, MX960, MX2010, and MX2020 routers.

Configuring OTN Interfaces on MIC3-100G-DWDM MIC

Starting from Junos OS Release 15.1F5, the 100-Gigabit DWDM OTN MIC—MIC3-100G-DWDM—is supported on MPC3E (MX-MPC3E-3D) and MPC3E NG (MPC3E-3D-NG) on the MX240, MX480, MX960, MX2010, and MX2020 routers. To configure an OTN interface on the MIC3-100G-DWDM MIC, you must configure interface-specific options and OTN-related options for the interface.

To configure the interface-specific options:

1. Configure VLAN tagging at the [**edit interface interface-name**] hierarchy level, where interface-name is in the **et-*fpc/pic/port***format.

   [edit interfaces *interface-name*]
   user@host# set vlan-tagging

2. Configure the maximum transmission unit (MTU) size in bytes for the interface.

   [edit interfaces *interface-name*]
   user@host# set mtu *value*

3. Configure a VLAN ID for the interface.

   [edit interfaces *interface-name*]
   user@host# set vlan-id *number*

4. Configure the family for the interface.

   [edit interfaces *interface-name*]
   user@host# set family *family-name*

5. Configure an IP address for the interface.

   [edit interfaces *interface-name*]
   user@host# set address *address*

To configure the optics-specific options on the interface:

1. Specify the optical transmit laser output power in dBm at the [**edit interface** ***interface-name*** **optics-options**] hierarchy level. The default transmit laser output value is 0 dBm.

   [edit interfaces *interface-name* optics-options]
   user@host# set tx-power *value*

2. Specify the wavelength of the optics in nanometers. For a list of wavelengths supported, see wavelength.

   [edit interfaces *interface-name* optics-options]
   user@host# set wavelength nm

To configure the OTN-specific options on the interface:

1. At the [**edit interfaces** ***interface-name*** **otn-options**] enable the laser on the OTN interface. The laser is disabled by default for all OTN interfaces.

   [edit interfaces *interface-name* otn-options]
   user@host# set laser-enable

2. Set an trail trace identifier for the source access point and for the destination access point for ODU and OTU on the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# set tti (odu-dapi | odu-expected-receive-dapi | odu-expected-receive-sapi | odu-sapi | otu-dapi | otu-expected-receive-dapi | otu-expected-receive-sapi | otu-sapi)

3. By default, triggers are ignored. Specify defect triggers and the set the trigger hold time for the trigger. Possible values for the trigger hold time are as follows: down—Delay

before marking interface down when defect occurs (1..65534 milliseconds) and up—Delay before marking interface up when defect is absent (1..65534 milliseconds).

NOTE: The hold time value only impacts the alarm reporting time and does not mark an interface down when the defect occurs. To mark the interface up or down, you must also configure the physical interface hold time at the [edit interfaces *interface-name*] hierarchy level.

[edit interfaces *interface-name* otn-options]
user@host# set trigger (oc-lof | oc-lom | oc-los | oc-tsf | odu-ais | odu-bdi | odu-bei | odu-iae | odu-lck | odu-oci | odu-sd | odu-ttim |opu-ptim | otu-ais | otu-bdi | otu-fec-deg | otu-fec-exe | otu-iae | otu-sd | otu-ttim) (hold-time (down value | up value) | ignore)

4. Enable the threshold crossing alarms for the OTN interface along with the trigger for the defect.

   [edit interfaces *interface-name* otn-options]
   user@host# set tca (odu-tca-bbe | odu-tca-es | odu-tca-ses | odu-tca-uas | otu-tca-bbe | otu-tca-es | otu-tca-ses | otu-tca-uas) (enable-tca | no-enable-tca | threshold)

5. Set the OTN header bytes as a transmit payload type from 0 bytes through 255 bytes for the packets that are transmitted on the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# set bytes transmit-payload-type value

6. Configure the forward error correction (FEC) mode for the OTN interface. Possible values are: Generic Forward Error Correction (GFEC), or High Gain Forward Error Correction (HGFEC) or Soft Decision Forward Error Correction (SDFEC). The default forward error correction mode is SDFEC.

   [edit interfaces *interface-name* otn-options]
   user@host# set fec (gfec | hgfec | sdfec)

7. Enable line loopback or local host loopback for the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# set line-loopback
   user@host# set local-loopback

8. Enable an ODU locked maintenance signal on the OTN interface to send the signal pattern 01010101.

   [edit interfaces *interface-name* otn-options]
   user@host# set insert-odu-lck

9. Enable an ODU open connection indication signal on the OTN interface to send to send the signal pattern 01100110.

   [edit interfaces *interface-name* otn-options] user@host# set insert-odu-oci

10. Enable a consequent action as listed in the ITU-T G.798 standard for ODU trail trace identifier mismatch (TTIM) on the OTN interface.

    [edit interfaces *interface-name* otn-options]
    user@host# set odu-ttim-action-enable

11. Enable a consequent action as listed in the ITU-T G.798 standard for OTU trail trace identifier mismatch (TTIM) on the OTN interface.

    [edit interfaces *interface-name* otn-options]
    user@host# set out-ttim-action-enable

12. Configure the OTN payload pseudorandom binary sequence (PRBS) on the OTN interface.

    [edit interfaces *interface-name* otn-options]
    user@host# set prbs

13. Configure the line rate or speed of the OTN signal to OTU4 (100Gbps) for the OTN interface.

    NOTE: If you specify a value other than OTU4, the value is ignored. To verify the line rate, use the **show interfaces *interface-name* extensive** command.

    [edit interfaces *interface-name* otn-options]
    user@host# set rate otu4

14. Configure the threshold value for signal degradation when an alarm needs to be raised. Configure the threshold value after signal degradation when the alarm needs to be cleared. When you configure the interval along with the **ber-threshold-signal-degrade *value*** statement, the bit error rate (BER) must stay above the signal degradation threshold for the configured interval after which the alarm is raised. When the interval is configured along with the **ber-threshold-clear *value*** statement, then BER must stay below the clear threshold for the configured interval after which the alarm is cleared.

    [edit interfaces *interface-name* otn-options signal-degrade]
    user@host# set ber-threshold-signal-degrade value
    user@host# set ber-threshold-clear value
    user@host# set interval value

15. Enable the following actions for the preemptive-fast-reroute statement:

    - Backward FRR—Insert the local pre-FEC status into the transmitted OTN frames and monitor the received OTN frames for the pre-FEC status.

      [edit interfaces *interface-name* otn-options preemptive-fast-reroute]
      user@host# set backward-frr-enable

- ODU backward FRR—Insert the ODU status into the transmitted OTN frames and monitor the received OTN frames for the ODU BER status.

  [edit interfaces *interface-name* otn-options preemptive-fast-reroute]
  user@host# **set odu-backward-frr-enable**

- Monitoring of signal degradation of pre-FEC OTN frames.

  [edit interfaces *interface-name* otn-options preemptive-fast-reroute]
  user@host# **set signal-degrade-monitor-enable**

- Monitoring of signal degradation of ODU BER in the received OTN frames.

  [edit interfaces *interface-name* otn-options preemptive-fast-reroute]
  user@host# **set odu-signal-degrade-monitor-enable**

16. Configure the following options for ODU BER signal degradation on the OTN interface:

- Configure the threshold for signal degradation for ODU BER when an alarm needs to be raised.

  [edit interfaces *interface-name* otn-options odu-signal-degrade]
  user@host# **set ber-threshold-signal-degrade *value***

- Configure the threshold for ODU BER after signal degradation when the alarm needs to be cleared.

  [edit interfaces *interface-name* otn-options odu-signal-degrade]
  user@host# **set ber-threshold-clear *value***

- When you configure the interval along with the **ber-threshold-signal-degrade *value*** statement, the ODU bit error rate (BER) must stay above the signal degradation threshold for the configured interval after which the alarm is raised. When the interval is configured along with the **ber-threshold-clear *value*** statement, then ODU BER must stay below the clear threshold for the configured interval after which the alarm is cleared.

  [edit interfaces *interface-name* otn-options odu-signal-degrade]
  user@host# **set interval *value***

Understanding the PTX-5-100G-WDM PIC

Starting with Junos OS Release 15.1F6, the 5-port 100-Gigabit DWDM OTN PIC—PTX-5-100G-WDM—is supported on the PTX3000 and the PTX5000 routers. The PTX-5-100G-WDM PIC provides five 100-Gigabit Ethernet interface ports that support dual-polarization quadrature phase shift keying (DP-QPSK) modulation with coherent reception and OTU4 and OTU4 (v) framing modes.

The interfaces on the PTX-5-100G-WDM PIC are named with the prefix *et*. For more information, see *Interface Naming Overview*.

NOTE: **The 5-port 100-Gigabit DWDM OTN PIC is not directly interoperable with the 2-port 100-Gigabit DWDM OTN PIC (P1-PTX-2-100G-WDM), but they can both operate over the same DWDM line system.**

The following sections explain the features of this PIC in detail:

Interface Features

The following interface features are supported on the PTX-5-100G-WDM PIC:

- Five-port 100-Gigabit Ethernet interface with OTU4 (v) framing and DP-QPSK modulation with coherent reception using a CFP2-ACO DWDM optical transceiver.
- Gigabit Ethernet local loopback.
- Diagnostics tools:
  - Line loopback
  - Local loopback
  - Optical Channel Data Unit (ODU) Open Connection Error
  - Optical Channel Data Unit (ODU) Lock Maintenance Signal
- Types of forward error corrections (FEC):
  - GFEC (generic forward error correction)

    NOTE: **GFEC mode is not supported on Junos OS Release 15.1F6. Junos OS Release 15.1F6-S1 supports GFEC mode. Contact customer support for the Junos OS Release 15.1F6-S1.**

  - SDFEC (soft-decision forward error correction)
- The following MIB features continue to be supported (and no new MIB is introduced):

  - MIB module to describe Black Link extension to RFC 3591 (jnxoptIfExtMibModule). The Black Link extension enables an optical transceiver of a vendor to introduce an optical signal over an optical network from another vendor.
  - MIB module to manage the OTN interface (jnxIfOtnMib)
  - MIB module to manage the Optics interface (jnxIfOpticsMib)
  - MIB module to manage OTN FRUs (jnxFruMib)
- Interoperability with other vendors' 100 Gigabit-Ethernet interfaces.
- Source MAC learning for accounting
- MAC policing
- Physical interface-level encapsulations—**vlan-ccc**, **extended-vlan-ccc**, and **extended-vlan-tcc**
- Logical interface-level encapsulation—**vlan-vpls**
- VLAN rewrite for **ccc** encapsulation
- Per-queue flow control
- 15-minute and 1-day performance monitoring and historic statistics.
  - Near-end and far-end performance monitoring
  - Threshold-crossing alarms
  - BER performance monitoring
  - FEC performance monitoring
  - Optical performance monitoring
- Insertion, monitoring, and display of OTN header overhead
- Transport interface and state model (GR-1093)

Layer 2 and Layer 3 Features

The following Layer 2 and Layer 3 features are supported on the PTX-5-100G-WDM PIC:

- Per-port destination address MAC filter.
- Per-port source address MAC filter.
- Per-physical interface source address MAC filter.
- Maximum of 1000 source MAC filter per physical interface.
- Maximum of 32,000 filter terms to share across all filter features.
- Flexible VLAN tagging.
- 802.3 ah OAM.
- 802.1 ag OAM.

OTN Alarms and Defects

The following OTN alarms and defects are supported on the PTX-5-100G-WDM PIC:

Optical Channel Alarms and Defects

- OC-LOS—Loss Of Signal
- OC-LOF—Loss Of Frame
- OC-LOM—Loss Of Multiframe
- OC-Wavelength-Lock—Wavelength Lock

Optical Channel Data Unit (ODU) Defects

- ODU-AIS—ODU Alarm Indication Signal
- ODU-BDI—ODU Backward Defect Indication
- ODU-BIAE—ODU Backward Incoming Alignment Error
- ODU-IAE—ODU Incoming Alignment Error
- ODU-LCK—ODU Locked
- ODU-LTC—ODU Loss of Tandem Connection
- ODU-OCI—ODU Open Connection Error
- ODU-SSF—ODU Server Signal Failure
- ODU-TSF—ODU Trail Signal Failure
- ODU-TTIM—ODU Trail Trace Identifier Mismatch

Optical Channel Transport Unit (OTU) Defects

- OTU-AIS—OTU Alarm Indication Signal
- OTU-BDI—OTU Backward Defect Indication
- OTU-BIAE—OTU Backward Incoming Alignment Error
- OTU-FEC-DEG—OTU Forward Error Correction Degrade
- OTU-FEC-EXCESS-FEC—OTU Forward Error Correction Excessive FEC Errors
- OTU-IAE—OTU Incoming Alignment Error
- OTU-SSF—OTU Server Signal Failure
- OTU-TSF—OTU Trail Signal Failure
- OTU-TTIM—OTU Trail Trace Identifier Mismatch

Threshold Crossing Alarms

Threshold-crossing alarms (TCAs) are activated when a certain configurable threshold—near-end measurement threshold or far-end measurement threshold—is crossed and remains so until the end of the 15-minute interval for parameters such as OTU and ODU. The following alarms are supported:

- Background block error threshold (BBE)
- Errored seconds threshold (ES)
- Severely errored seconds threshold (SES)
- Unavailable seconds threshold (UES)

Configuring OTN Interfaces on PTX-5-100G-WDM PIC

Starting from Junos OS Release 15.1F6, the the 5-port 100-Gigabit DWDM OTN PIC—PTX-5-100G-WDM—is supported on the PTX3000 and the PTX5000 routers. To configure an OTN interface on the PTX-5-100G-WDM PIC, you must configure interface-specific options, optics-specific options and OTN-related options for the interface.

To configure the interface-specific options:

1. Configure VLAN tagging at the [**edit interface *interface-name***] hierarchy level, where *interface-name* is in the **et-*fpc/pic/port*** format.

   ```
   [edit interfaces interface-name]
   user@host# set vlan-tagging
   ```

2. Configure the maximum transmission unit (MTU) size in bytes for the interface. Possible values: 256 through 16,000.

   ```
   [edit interfaces interface-name]
   user@host# set mtu value
   ```

3. Set the unit VLAN ID, family and the IP address of the interface. Possible values for the VLAN ID: 1 through 4094. Specify the family as **inet**.

   ```
   [edit interfaces interface-name unit 0]
   user@host# set vlan-id number
   user@host# set family family-name
   user@host# set address address
   ```

To configure the optics-specific options on the interface:

1. Specify the optical transmit laser output power in dBm at the [**edit interface *interface-name* optics-options**] hierarchy level. The default transmit laser output value is 0 dBm.

   [edit interfaces *interface-name* optics-options]
   user@host# set tx-power *value*

2. Specify the wavelength of the optics in nanometers. For a list of wavelengths supported, see **wavelength**.

   [edit interfaces *interface-name* optics-options]
   user@host# set wavelength nm

To configure the OTN-specific options on the interface:

1. At the [**edit interfaces *interface-name* otn-options**] hierarchy level, enable the laser on the OTN interface. The laser is disabled by default for all OTN interfaces.

   [edit interfaces *interface-name* otn-options]
   user@host# set laser-enable

2. Set a trail trace identifier for the source access point and for the destination access point for ODU and OTU on the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# set tti (odu-dapi | odu-expected-receive-dapi | odu-expected-receive-sapi | odu-sapi | otu-dapi | otu-expected-receive-dapi | otu-expected-receive-sapi | otu-sapi)

3. Specify defect triggers and the set the trigger hold time for the trigger. By default, triggers are ignored. Possible values for the trigger hold time are as follows: down and up.

   - down—Delay before marking interface down when defect occurs (1 through 65534 milliseconds)
   - up—Delay before marking interface up when defect is absent (1 through 65534 milliseconds).

   NOTE: The hold time value only impacts the alarm reporting time and does not mark an interface down when the defect occurs. To mark the interface up or down, you must also configure the physical interface hold time at the [**edit interfaces *interface-name***] hierarchy level.

   [edit interfaces *interface-name* otn-options]
   user@host# set trigger (oc-lof | oc-lom | oc-los | oc-tsf | odu-ais | odu-bdi | odu-bei | odu-iae | odu-lck | odu-oci | odu-sd | odu-ttim |opu-ptim | otu-ais | otu-bdi | otu-fec-deg | otu-fec-exe | otu-iae | otu-sd | otu-ttim) (hold-time (down *value* | up *value*) | ignore)

4. Enable the threshold-crossing alarms (TCAs) for the OTN interface along with the trigger for the defect. Threshold-crossing alarms (TCAs) are activated when a certain configurable threshold—near-end measurement threshold or far-end measurement threshold—is crossed and remains so until the end of the 15-minute interval for parameters such as OTU and ODU.

   [edit interfaces *interface-name* otn-options]
   user@host# set tca (odu-tca-bbe | odu-tca-es | odu-tca-ses | odu-tca-uas | otu-tca-bbe | otu-tca-es | otu-tca-ses | otu-tca-uas) (enable-tca | no-enable-tca | threshold)

5. Set the OTN header bytes as a transmit payload type from 0 bytes through 255 bytes for the packets that are transmitted on the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# set bytes transmit-payload-type value

6. Configure the forward error correction (FEC) mode for the OTN interface. Possible values are: generic forward error correction (GFEC), or high-gain forward error correction (HG-FEC) or soft-decision forward error correction (SD-FEC). The default forward error correction mode is SD-FEC.

   [edit interfaces *interface-name* otn-options]
   user@host# set fec (gfec |hgfec | sdfec)

7. Enable line loopback or local host loopback for the OTN interface. Loopback testing enables you to verify the connectivity of a circuit. In line loopback, instead of transmitting the signal toward the far-end device, the signal is sent back to the originating router. In local loopback, the signal is transmitted to the channel service unit (CSU) and then to the far-end device.

   [edit interfaces *interface-name* otn-options]
   user@host# set line-loopback
   user@host# set local-loopback

8. Enable an ODU locked maintenance signal on the OTN interface to send the signal pattern 01010101.

   [edit interfaces *interface-name* otn-options]
   user@host# set insert-odu-lck

9. Enable an ODU open connection indication signal on the OTN interface to send the signal pattern 01100110.

   [edit interfaces *interface-name* otn-options]
   user@host# set insert-odu-oci

10. Enable a consequent action as listed in the ITU-T G.798 standard for ODU trail trace identifier mismatch (TTIM) on the OTN interface.

   [edit interfaces *interface-name* otn-options]
   user@host# set odu-ttim-action-enable

11. Enable a consequent action as listed in the ITU-T G.798 standard for OTU trail trace identifier mismatch (TTIM) on the OTN interface.

    [edit interfaces *interface-name* otn-options]
    user@host# set out-ttim-action-enable

12. Configure the OTN payload pseudorandom binary sequence (PRBS) on the OTN interface.

    [edit interfaces *interface-name* otn-options]
    user@host# set prbs

13. Configure the line rate or speed of the OTN signal to otu4 (100 Gbps) for the OTN interface.

    NOTE: If you specify a value other than otu4, the value is ignored. To verify the line rate, use the **show interfaces *interface-name* extensive** command.

    [edit interfaces *interface-name* otn-options]
    user@host# set rate otu4

14. Configure the threshold value for signal degradation when an alarm needs to be raised. Configure the threshold value after signal degradation when the alarm needs to be cleared. When you configure the interval along with the **ber-threshold-signal-degrade *value*** statement, the bit error rate (BER) must stay above the signal degradation threshold for the configured interval after which the alarm is raised. When the interval is configured along with the **ber-threshold-clear *value*** statement, then BER must stay below the clear threshold for the configured interval after which the alarm is cleared.

    [edit interfaces *interface-name* otn-options signal-degrade]
    user@host# set ber-threshold-signal-degrade *value*
    user@host# set ber-threshold-clear *value*
    user@host# set interval *value*

15. Enable the following actions for the **preemptive-fast-reroute** statement:

    - Backward FRR—Insert the local pre-FEC status into the transmitted OTN frames and monitor the received OTN frames for the pre-FEC status.

      [edit interfaces *interface-name* otn-options preemptive-fast-reroute]
      user@host# set backward-frr-enable

    - ODU backward FRR—Insert the ODU status into the transmitted OTN frames and monitor the received OTN frames for the ODU BER status.

      [edit interfaces *interface-name* otn-options preemptive-fast-reroute]
      user@host# **set odu-backward-frr-enable**

    - Monitoring of signal degradation of pre-FEC OTN frames.

      [edit interfaces *interface-name* otn-options preemptive-fast-reroute]
      user@host# **set signal-degrade-monitor-enable**

- Monitoring of signal degradation of ODU BER in the received OTN frames.

  [edit interfaces *interface-name* otn-options preemptive-fast-reroute]
  user@host# **set odu-signal-degrade-monitor-enable**

16. Configure the following options for ODU BER signal degradation on the OTN interface:

- Configure the threshold for signal degradation for ODU BER when an alarm needs to be raised.

  [edit interfaces *interface-name* otn-options odu-signal-degrade]
  user@host# **set ber-threshold-signal-degrade** ***value***

- Configure the threshold for ODU BER after signal degradation when the alarm needs to be cleared.

  [edit interfaces *interface-name* otn-options odu-signal-degrade]
  user@host# **set ber-threshold-clear** ***value***

- When you configure the interval along with the **ber-threshold-signal-degrade** ***value*** statement, the ODU bit error rate (BER) must stay above the signal degradation threshold for the configured interval after which the alarm is raised. When the interval is configured along with the **ber-threshold-clear** ***value*** statement, then ODU BER must stay below the clear threshold for the configured interval after which the alarm is cleared.

  [edit interfaces *interface-name* otn-options odu-signal-degrade]
  user@host# **set interval** ***value***

Release History Table

Release	Description
15.1F6	Starting from Junos OS Release 15.1F6, the the 5-port 100-Gigabit DWDM OTN PIC—PTX-5-100G-WDM—is supported on the PTX3000 and the PTX5000 routers.

Understanding ODU Path Delay Measurement on OTN Networks for Performance Monitoring

Performance monitoring is an important requirement in any network, including the optical transport networks (OTN). The key parameters that impact performance are bit error rate (BER) and delay. Delays in data communication over a network impact the network latency. Network latency is the time taken for a packet of data to travel from a designated point to another designated point. If there are less delays, the network latency is low. You can measure latency by sending a packet and then receiving it as it is returned back to you; the time taken for the round-trip indicates the latency.

The optical channel data unit (ODU) path delay measurement offers in-service delay measurement. Delay (or latency) is measured by transmitting a known pattern (delay measurement pattern) in a selected bit of the delay measurement (**DM**) field and measuring the number of frames that are missed when the delay measurement pattern is received at the transmitting end. For instance, if the transmitted delay measurement bit is **1 1 1 1 1 1 1 1 0 0** and the received delay measurement bit is **1 1 1 0 0 0 0 0 0 0**, the delay measurement starts at frame 2 and ends at frame 8. This can be detected by the change in value between the transmitted bit and the received bit.

```
Frame#   10 9 8 7 6 5 4 3 2 1
Tx DM bit  1 1 1 1 1 1 1 1 0 0
Rx DM bit  1 1 1 0 0 0 0 0 0 0
```

The result of the delay measurement is 6 frames (8 - 2).

Guidelines for Configuring Delay Measurement

When you configure in-service delay measurement, we recommend that you follow certain guidelines to ensure that you obtain accurate delay measurement.

- Unidirectional delay measurement is not supported. The in-service delay measurement is specific to round-trip delay measurement and for optical channel data units only.
- Delay measurement on different framers for the MIC and PIC is different. So, the delay measurement values are different.
- Resiliency is not supported for path delay measurement.
- Links at the local and remote interfaces must be active before you configure delay measurement.
- Do not perform delay measurement tests when ODU maintenance signals are injected.
- Do not configure local loopback and network loopback with remote loopback because the loopback data is overwritten by the delay measurement pattern.

NOTE: If a link failure occurs after you begin measuring delay, delay measurement fails. You must re-enable measurement of delay on the local interface to measure delay.

Enabling ODU Path Delay Measurement on OTN Networks for Performance Monitoring

Delay measurement is disabled by default. This topic explains the broad steps for measuring the optical channel data units (ODU) path delay on optical transport networks (OTN). First, enable remote loopback on the remote interface and commit the configuration. This enables the remote interface to loop back the delay measurement pattern to the local interface. Then, start delay measurement at the local interface and view the results.

NOTE: **Do not enable remote loopback on both ends (local and remote). If you enable remote loopback on both interfaces, the delay measurement pattern is looped back continuously between the two interfaces.**

Before you start measuring delay in the ODU path on OTN, complete the following tasks:

- Ensure that the links are active at the local and remote interfaces and alarms are not configured.
- Ensure that there is a delay of 10 seconds before enabling remote loopback. Also, ensure that there is a delay of 10 seconds after enabling remote loopback at the remote interface and before you start measuring delay.
- Ensure that the delay measurement tests are not performed when ODU maintenance signals are injected.
- Ensure that the local loopback and network loopback are also not specified because the looped-back data is overwritten by the delay measurement pattern.

NOTE: If link failure occurs after you begin measuring delay, delay measurement fails. You must re-enable measurement of delay on the local interface to measure delay.

To enable ODU path delay measurement, first enable remote loopback of the delay measurement pattern on the remote interface and then start measurement of the delay.

1. Enable remote loopback on the remote interface by including the **remote-loop-enable** statement at the [**edit**] hierarchy level.

   [edit]
   user@host# set interfaces *interfacename* otn-options odu-delay-management remote-loop-enable

2. After enabling remote loopback, commit the configuration.

   [edit]
   user@host# commit

3. Start delay measurement on the local interface by including the **start-measurement** statement at the [**edit**] hierarchy level.

   [edit]
   user@host# set interface *interfacename* otn-options odu-delay-management start-measurement

4. After enabling measurement of delay on the local interface, commit the configuration.

   [edit]
   user@host# commit

5. To view the delay measurement values, from the operational mode, enter the **show interfaces extensive** command.

   user@host> show interfaces *interfacename* extensive

```
...
ODU Delay Management:
Start Measurement: True
Remote Loop Enable: False
Result: 0 micro seconds
...
```

Disabling ODU Path Delay Measurement on OTN Networks for Performance Monitoring

Delay measurement is disabled by default. If you enabled optical channel data unit (ODU) path delay measurement by using the **remote-loop-enable** and **start-measurement** statements, you can use this procedure to disable delay measurement.

NOTE: You can also use the **delete** or **deactivate** command to disable remote loopback on the remote interface. For instance, you can use the **delete interfaces *interfacename* otn-options odu-delay-management remote-loop-enable** or **deactivate interface *interfacename* otn-options odu-delay-management remote-loop-enable** command to disable remote loopback on the remote interface.

To disable ODU path delay measurement, first disable remote loopback of the delay measurement pattern on the remote interface and then stop delay measurement:

1. Stop delay measurement on the local interface by including the **stop-measurement** statement at the [**edit**] hierarchy level.

   ```
   [edit]
   user@host# set interface interfacename otn-options odu-delay-management
     stop-measurement
   ```

2. After you stop delay measurement on the local interface, commit the configuration.

   ```
   [edit]
   user@host# commit
   ```

3. Disable remote loopback on the remote interface by including the **no-remote-loop-enable** statement at the [**edit**] hierarchy level.

   ```
   [edit]
   user@host# set interfaces interfacename otn-options odu-delay-management
     no-remote-loop-enable
   ```

4. After disabling remote loopback on the remote interface, commit the configuration.

   ```
   [edit]
   user@host# commit
   ```

5. To verify that remote loopback is disabled and delay is not measured, enter the **show interfaces extensive** command, from the operational mode.

   user@host> show interfaces *interfacename* extensive

```
...
ODU Delay Management:
Start Measurement: False
Remote Loop Enable: False
Result: 0 micro seconds
...
```

CHAPTER 28

Configuring Gigabit Ethernet Accounting and Policing

Capabilities of Gigabit Ethernet IQ PICs and Gigabit Ethernet PICs with SFPs

For Gigabit Ethernet IQ PICs and Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), you can configure granular per-VLAN class-of-service (CoS) capabilities and extensive instrumentation and diagnostics on a per-VLAN and per-MAC address basis.

VLAN rewrite, tagging, and deleting enables you to use VLAN address space to support more customers and services.

VPLS allows you to provide a point-to-multipoint LAN between a set of sites in a VPN. Ethernet IQ PICs and Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router) are combined with VPLS to deliver metro Ethernet service.

For Gigabit Ethernet IQ2 and IQ2-E and 10-Gigabit Ethernet IQ2 and IQ2-E interfaces, you can apply Layer 2 policing to logical interfaces in the egress or ingress direction. Layer 2 policers are configured at the **[edit firewall]** hierarchy level. You can also control the rate of traffic sent or received on an interface by configuring a policer overhead at the **[edit chassis fpc *slot-number* pic *slot-number*]** hierarchy level.

Table 50 on page 530 lists the capabilities of Gigabit Ethernet IQ PICs and Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router).

Table 50: Capabilities of Gigabit Ethernet IQ and Gigabit Ethernet with SFPs

Capability	Gigabit Ethernet IQ (SFP)	Gigabit Ethernet (SFP)
Layer 2		
802.3ad link aggregation	Yes	Yes
Maximum VLANs per port	384	1023
Maximum transmission unit (MTU) size	9192	9192
MAC learning	Yes	Yes
MAC accounting	Yes	Yes
MAC filtering	Yes	Yes
Destinations per port	960	960
Sources per port	64	64
Hierarchical MAC policers	Yes, premium and aggregate	No, aggregate only
Multiple TPID support and IP service for nonstandard TPIDs	Yes	Yes
Multiple Ethernet encapsulations	Yes	Yes
Dual VLAN tags	Yes	No
VLAN rewrite	Yes	No
Layer 2 VPNs		
VLAN CCC	Yes	Yes
Port-based CCC	Yes	Yes
Extended VLAN CCC Virtual Metropolitan Area Network (VMAN) Tag Protocol	Yes	Yes
CoS		
PIC-based egress queues	Yes	Yes
Queued VLANs	Yes	No

Table 50: Capabilities of Gigabit Ethernet IQ and Gigabit Ethernet with SFPs (continued)

Capability	Gigabit Ethernet IQ (SFP)	Gigabit Ethernet (SFP)
VPLS	Yes	Yes

For more information about configuring VPLS, see the *Junos OS VPNs Library for Routing Devices*.

You can also configure CoS on logical IQ interfaces. For more information, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

Related Documentation

- Configuring MAC Address Accounting on page 531
- *Configuring a Policer Overhead*
- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring MAC Address Accounting

For Gigabit Ethernet IQ and Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), for Gigabit Ethernet DPCs on MX Series routers, for 100-Gigabit Ethernet Type 5 PIC with CFP, and for MPC3E, MPC4E, MPC5E, MPC5EQ, and MPC6E MPCs, you can configure whether source and destination MAC addresses are dynamically learned.

To configure MAC address accounting on an individual Ethernet interface, include the **mac-learn-enable** statement at the **[edit interfaces *interface-name* gigether-options ethernet-switch-profile]** hierarchy level:

```
[edit interfaces interface-name gigether-options ethernet-switch-profile]
mac-learn-enable;
```

To configure MAC address accounting on an aggregated Ethernet interface, include the **mac-learn-enable** statement at the **[edit interfaces ae*x* aggregated-ether-options ethernet-switch-profile]** hierarchy level:

```
[edit interfaces aex aggregated-ether-options ethernet-switch-profile]
mac-learn-enable;
```

To prohibit an interface from dynamically learning source and destination MAC addresses, do *not* include the **mac-learn-enable** statement.

To disable dynamic learning of the source and destination MAC addresses after it has been configured, you must delete **mac-learn-enable** from the configuration.

NOTE: MPCs support MAC address accounting for an individual interface or an aggregated Ethernet interface member link only after the interface has received traffic from the MAC source. If traffic is only exiting an interface, the MAC address is not learned and MAC address accounting does not occur.

MAC Address Accounting for Dynamically Learned Addresses on Aggregated Ethernet Interfaces Overview

Junos OS supports the capability to compute MAC address statistics for dynamically learned static and destination MAC addresses on physical interfaces. Starting in Junos OS Release 15.1, Junos OS enables you to configure source MAC (SMAC) address and destination MAC (DMAC) address-based accounting for MAC addresses that are dynamically learned on aggregated Ethernet (ae-) interfaces in routed mode. When you include the **mac-learn-enable** statement at the **[edit interfaces ae*x* aggregated-ether-options ethernet-switch-profile]** hierarchy level, dynamic learning of source and destination MAC addresses is enabled. By default, this capability is disabled. When dynamic learning of MAC addresses is enabled for AE interfaces in routed mode, the MAC-filter settings are updated for each of the child links of the AE bundle interface. This feature provides for both the configuration of the mac-learn-enable filter and the display of SMAC and DMAC based accounting information on the aggregated interface in the output of the **show interfaces mac-database *interface-name* mac-address *mac-address*** command.

When this functionality is enabled, source and destination MAC addresses-based accounting is supported on the routed interfaces on MX Series routers with DPCs and MPCs. Support for mixed mode LAG interfaces is also available. This feature supports MAC address accounting for AE interfaces in routed mode (for inet family). Destination MAC-based accounting is supported only for MAC addresses dynamically learned at the ingress interface, including each individual child or member link of the AE bundle. This behavior occurs because MPCs do not support destination MAC address learning. As a result, if a packet exits a child link without passing in the ingress direction through that link, destination MAC (DMAC) accounting for this packet occurs at the child link level and this data is not available at the aggregate level. Dynamic learning of MAC addresses can be supported on only the AE interface or on selective individual member links. MAC learning support on the bundle depends on the capability of individual member links. If a link in the bundle does not contain the capability to support MAC learning or accounting, it is disabled on the AE bundle.

The MAC data for the aggregated bundle is displayed by collecting data form individual child links. This data is collected when the command to display the MAC database is triggered from the CLI. This method of data collection implies that based on the number of child links and the size of the MAC database, the time take to display the database differs. This approach to obtain the current snapshot of the MAC database from the currently active child links is used instead of maintaining a database at the Routing Engine because of the dynamic nature of the MAC database and the overhead required to maintain the database information in synchronization with all the child Packet Forwarding Engines. A difference in the DMAC-based accounting for packets generated from the Routing Engine (packets sent in the host path). On DPCs, these packets are accounted in egress direction (Output Packet/Byte count), whereas on MPCs, these packets are not accounted because DMAC learning is not supported. This difference in behavior also occurs between child links on DPCs and MPCs. Because this feature to enable dynamic learning is related to collecting MAC database statistics from child links based on the command issued from the CLI, there is a impact on the time it takes to display the data on the console based on the size of the MAC database and the number of child-links spread across different FPCs. The limit on the maximum number of MAC addresses that can be learned from an interface does not apply to this dynamic learning of MAC addresses functionality.

Release History Table

Release	Description
15.1	Starting in Junos OS Release 15.1, Junos OS enables you to configure source MAC (SMAC) address and destination MAC (DMAC) address-based accounting for MAC addresses that are dynamically learned on aggregated Ethernet (ae-) interfaces in routed mode.

Accounting of the Layer 2 Overhead Attribute in Interface Statistics

On MX Series and T Series routers, you can configure the logical interface statistics to include the Layer 2 overhead size (header and trailer bytes) for both ingress and egress interfaces. Both the transit and total statistical information are computed and displayed for each logical interface. This functionality is supported on 1-Gigabit, 10-Gigabit, 40-Gigabit, and 100-Gigabit Ethernet interfaces on Dense Port Concentrators (DPCs), and Modular Port Concentrators (MPCs) on MX Series routers. Starting with Junos OS Release 13.2, configuring the logical interface statistics to include Layer 2 is supported on 10-Gigabit Ethernet interfaces on MX Series routers with MPC4E. Starting with Junos OS Release 13.3, **account-layer2-overhead** is not supported on MX Series routers with MPC3E (on both PIC and logical interface levels).

You can also configure the capability to compute the Layer 2 overhead bytes in interface statistics on Type-3, Type-4 and Type-5 Flexible Port Concentrators (FPCs) on T Series routers. To enable the Layer 2 overhead bytes to be counted in the interface statistics at the PIC level, you must use the **account-layer2-overhead** statement at the **[edit chassis fpc *slot-number* pic *pic-number*]** hierarchy level.

If you configure this capability, all the Layer 2 header details (Layer 2 header and cyclic redundancy check [CRC]) based on the Layer 2 encapsulation configured for an interface are calculated and displayed in the logical interface statistics for ingress and egress interfaces in the output of the **show interfaces** ***interface-name*** commands. For logical interfaces, the **Input bytes** and **Output bytes** fields under the Traffic statistics section in the output of the **show interfaces** ***interface-name*** **<detail | extensive>** command include the Layer 2 overhead of the packets. For logical interfaces, the Input rate and Output rate fields under the Traffic statistics section in the output of the **show interfaces** ***interface-name*** **<media | statistics>** command include the Layer 2 overhead of the packets. For logical interfaces, the values for the newly added **Egress account overhead** and **Ingress account overhead** fields display the Layer 2 overhead size for transmitted and received packets respectively.

The input and output octets at the logical interface configured on the PIC includes all the Layer 2 headers. All the logical interfaces on the PIC, including the ae and the non-ae interfaces, are processed for Layer 2 overhead accounting for the arriving and exiting packets. This method of operation impacts the transit statistics that are primarily used for subscriber accounting and billing purposes in customer networks.

Table 51 on page 534 lists the adjustment bytes that are counted based on the encapsulation on the logical interface over the Ethernet interface, when you enable accounting of Layer 2 overhead in interface statistics at the PIC level. The values for the adjustment bytes that are listed for all types of encapsulation are the same for DPCs and MPCs, with the only exception being for the VLAN CCC adjustment value. On DPCs, the VLAN CCC adjustment value is –4 bytes and on MPCs, the VLAN CCC adjustment value is +4 bytes.

Table 51: Adjustment Bytes for Logical Interfaces over Ethernet Interfaces

Encapsulation Type on Logical Interfaces	Number of Adjustment Bytes	Description
Ethernet DIXv2 (IP datagrams over Ethernet)	18	Untagged (includes CRC)
Ethernet DIXv2 (IP datagrams over Ethernet)	22	Single-tagged (includes CRC)
Ethernet DIXv2 (IP datagrams over Ethernet)	26	Double-tagged (includes CRC)
VLAN Bridge	4	CRC
VLAN CCC	4	CRC
VLAN TCC	18	Untagged (includes CRC)
VLAN TCC	22	Single-tagged (includes CRC)
VLAN TCC	26	Double-tagged (includes CRC)
VLAN VPLS	4	CRC

Guidelines for Configuring the Computation of Layer 2 Overhead in Interface Statistics

Keep the following points in mind when you configure the computation of Layer 2 overhead in interface statistics:

- When you configure a native VLAN ID on a logical interface, the Layer 2 header adjustment for input statistics is different for tagged and untagged packets. For such interfaces, if you configure the setting to account for Layer 2 overhead, incorrect statistics might be displayed.
- An untagged packet is considered as a tagged packet and an additional 4 bytes are appended to the counter values displayed in the output of the **show interface** command.
- The computed statistics might not be completely accurate in scenarios where the packets are dropped after they have been included in the interface statistics, but before the packets reach the destination.
- Label-switched interface (LSI) statistics on the ingress direction of interfaces do not include the Layer 2 overhead bytes because this functionality of accounting Layer 2 overhead is not supported for such LSI interfaces.
- Layer 2 overhead accounting is not supported for inline service (si) interfaces.
- The total statistics of interfaces do not indicate the complete Layer 2 adjusted statistics. This behavior occurs because the total statistics count is the sum of transit and local statistics. Only the transit statistics are adjusted for Layer 2 and the local statistics are not adjusted for Layer 2.
- Statistics on ae interfaces are calculated in the same manner as non-ae interfaces.
- Adjustment bytes are applicable only for transit statistics that are displayed for logical interfaces.
- For physical interfaces, the adjustment bytes for transit traffic and the non-adjusted bytes for local or protocol-specific traffic are combined and displayed in the output of the **show interfaces** command. (Segregation is not possible.)
- Layer 2 overhead accounting can be enabled at both PIC level and logical interface level.
- When the **account-layer2-overhead** statement is configured, the Layer 2 overhead size in both input and output statistics is accounted for in Dense Port Concentrator (DPCs) and Modular Port Concentrator (MPCs).
- This **account-layer2-overhead** configuration now supports Layer 2 accounting for the Ethernet bridge encapsulation.
- The Layer 2 overhead bytes in interface statistics are saved across a unified ISSU or a graceful Routing Engine switchover (GRES) operation.

Release History Table

Release	Description
13.3	Starting with Junos OS Release 13.3, **account-layer2-overhead** is not supported on MX Series routers with MPC3E (on both PIC and logical interface levels).
13.2	Starting with Junos OS Release 13.2, configuring the logical interface statistics to include Layer 2 is supported on 10-Gigabit Ethernet interfaces on MX Series routers with MPC4E.

Configuring Layer 2 Overhead Accounting in Interface Statistics

This topic contains sections that describe the configuration of Layer 2 overhead accounting for interface statistics at the PIC level and logical interface level.

Layer 2 overhead accounting can be enabled at both PIC level and logical interface level through configuration. By default, the physical interface and logical interface statistics do not account for Layer 2 overhead size (header and trailer) in both input and output statistics.

When the **account-layer2-overhead** statement is configured, the Layer 2 overhead size in both input and output statistics is accounted for in the Dense Port Concentrator (DPCs) and the Modular Port Concentrator (MPCs). This **account-layer2-overhead** configuration now supports Layer 2 accounting for the Ethernet bridge encapsulation.

Enabling the Accounting of Layer 2 Overhead in Interface Statistics at the PIC Level

You can configure the **account-layer2-overhead** statement at the **edit chassis fpc *slot-number* pic *pic-number*** hierarchy level to enable accounting of Layer 2 overhead bytes in the ingress and egress interface statistics at the PIC level.

CAUTION: **If you modify the setting for accounting of Layer 2 overhead bytes at the PIC level, the PIC is rebooted, causing all of the physical and logical interfaces to be deleted and readded on the PIC. Due to this behavior, we recommend that you exercise caution while using this feature.**

The computation method of Layer 2 overhead on different interface types is as follows:

- For Ethernet interfaces, all the Layer 2 headers are counted.

- For non-Ethernet interfaces, the Frame Relay, PPP, or Cisco HDLC headers are counted, while the bit or byte stuffing headers are excluded.

To enable accounting of Layer 2 overhead at the PIC level for ingress and egress traffic on interfaces:

1. Access a DPC or an MPC-occupied slot and the PIC where the interface is to be enabled.

   [edit chassis]
   user@host# **edit fpc *slot-number* pic *number***

2. Specify the Layer 2 overhead value in bytes that is the octet adjustment per packet added to the total octet count for ingress and egress traffic on all the interfaces in the PIC.

   [edit chassis fpc *slot-number* pic *number*]
   user@host# **set account-layer2-overhead**

Configuring Gigabit Ethernet Policers

Overview

On Gigabit Ethernet IQ and Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), you can define rate limits for premium and aggregate traffic received on the interface. These policers allow you to perform simple traffic policing without configuring a firewall filter. First you configure the Ethernet policer profile, next you classify ingress and egress traffic, then you can apply the policer to a logical interface.

For Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), the policer rates you configure can be different than the rates on the Packet Forward Engine. The difference results from Layer 2 overhead. The PIC accounts for this difference.

NOTE:
On MX Series routers with Gigabit Ethernet or Fast Ethernet PICs, the following considerations apply:

- Interface counters do not count the 7-byte preamble and 1-byte frame delimiter in Ethernet frames.
- In MAC statistics, the frame size includes MAC header and CRC before any VLAN rewrite/imposition rules are applied.
- In traffic statistics, the frame size encompasses the L2 header without CRC after any VLAN rewrite/imposition rule.

For information on understanding Ethernet frame statistics, see the *MX Series Layer 2 Configuration Guide*.

Configuring a Policer

To configure an Ethernet policer profile, include the **ethernet-policer-profile** statement at the **[edit interfaces *interface-name* gigether-options ethernet-switch-profile]** hierarchy level:

```
[edit interfaces interface-name gigether-options ethernet-switch-profile]
ethernet-policer-profile {
  policer cos-policer-name {
    aggregate {
      bandwidth-limit bps;
      burst-size-limit bytes;
    }
    premium {
      bandwidth-limit bps;
      burst-size-limit bytes;
    }
  }
}
```

In the Ethernet policer profile, the aggregate-priority policer is mandatory; the premium-priority policer is optional.

For aggregate and premium policers, you specify the bandwidth limit in bits per second. You can specify the value as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000). There is no absolute minimum value for bandwidth limit, but any value below 61,040 bps will result in an effective rate of 30,520 bps. The maximum bandwidth limit is 4.29 Gbps.

The maximum burst size controls the amount of traffic bursting allowed. To determine the burst-size limit, you can multiply the bandwidth of the interface on which you are applying the filter by the amount of time you allow a burst of traffic at that bandwidth to occur:

burst size = *bandwidth* x *allowable time for burst traffic*

If you do not know the interface bandwidth, you can multiply the maximum MTU of the traffic on the interface by 10 to obtain a value. For example, the burst size for an MTU of 4700 would be 47,000 bytes. The burst size should be at least 10 interface MTUs. The maximum value for the burst-size limit is 100 MB.

Specifying an Input Priority Map

An input priority map identifies ingress traffic with specified IEEE 802.1p priority values, and classifies that traffic as premium.

If you include a premium-priority policer, you can specify an input priority map by including the **ieee802.1 premium** statement at the **[edit interfaces *interface-name* gigether-options ethernet-policer-profile input-priority-map]** hierarchy level:

```
[edit interfaces interface-name gigether-options ethernet-policer-profile input-priority-map]
ieee802.1p premium [ values ];
```

The priority values can be from 0 through 7. The remaining traffic is classified as nonpremium (or aggregate). For a configuration example, see "Example: Configuring Gigabit Ethernet Policers" on page 544.

NOTE: **On IQ2 and IQ2-E interfaces and MX Series interfaces, when a VLAN tag is pushed, the inner VLAN IEEE 802.1p bits are copied to the IEEE bits of the VLAN or VLANs being pushed. If the original packet is untagged, the IEEE bits of the VLAN or VLANs being pushed are set to 0.**

Specifying an Output Priority Map

An output priority map identifies egress traffic with specified queue classification and packet loss priority (PLP), and classifies that traffic as premium.

If you include a premium-priority policer, you can specify an output priority map by including the **classifier** statement at the **[edit interfaces *interface-name* gigether-options ethernet-policer-profile output-priority-map]** hierarchy level:

```
[edit interfaces interface-name gigether-options ethernet-policer-profile
  output-priority-map]
classifier {
  premium {
```

```
      forwarding-class class-name {
        loss-priority (high | low);
      }
    }
  }
```

You can define a forwarding class, or you can use a predefined forwarding class. Table 52 on page 542 shows the predefined forwarding classes and their associated queue assignments.

Table 52: Default Forwarding Classes

Forwarding Class Name	Queue
best-effort	Queue 0
expedited-forwarding	Queue 1
assured-forwarding	Queue 2
network-control	Queue 3

For more information about CoS forwarding classes, see the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*. For a configuration example, see "Example: Configuring Gigabit Ethernet Policers" on page 544.

Applying a Policer

On all MX Series Router interfaces, Gigabit Ethernet IQ, IQ2, and IQ2-E PICs, and Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), you can apply input and output policers that define rate limits for premium and aggregate traffic received on the logical interface. Aggregate policers are supported on Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router).

These policers allow you to perform simple traffic policing without configuring a firewall filter.

To apply policers to specific source MAC addresses, include the **accept-source-mac** statement:

```
accept-source-mac {
  mac-address mac-address {
    policer {
      input cos-policer-name;
      output cos-policer-name;
    }
  }
}
```

You can include these statements at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number*]

- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

You can specify the MAC address as *nn:nn:nn:nn:nn:nn* or *nnnn.nnnn.nnnn*, where ***n*** is a hexadecimal number. You can configure up to 64 source addresses. To specify more than one address, include multiple **mac-address** statements in the logical interface configuration.

NOTE: On untagged Gigabit Ethernet interfaces you should not configure the **source-address-filter** statement at the **[edit interfaces ge-*fpc/pic/port* gigether-options]** hierarchy level and the **accept-source-mac** statement at the **[edit interfaces ge-*fpc/pic/port* gigether-options unit *logical-unit-number*]** hierarchy level simultaneously. If these statements are configured for the same interfaces at the same time, an error message is displayed.

On tagged Gigabit Ethernet interfaces you should not configure the **source-address-filter** statement at the **[edit interfaces ge-*fpc/pic/port* gigether-options]** hierarchy level and the **accept-source-mac** statement at the **[edit interfaces ge-*fpc/pic/port* gigether-options unit *logical-unit-number*]** hierarchy level with an identical MAC address specified in both filters. If these statements are configured for the same interfaces with an identical MAC address specified, an error message is displayed.

NOTE: If the remote Ethernet card is changed, the interface does not accept traffic from the new card because the new card has a different MAC address.

The MAC addresses you include in the configuration are entered into the router's MAC database. To view the router's MAC database, enter the **show interfaces mac-database *interface-name*** command:

user@host> **show interfaces mac-database *interface-name***

In the **input** statement, list the name of one policer template to be evaluated when packets are received on the interface.

In the **output** statement, list the name of one policer template to be evaluated when packets are transmitted on the interface.

NOTE: On IQ2 and IQ2-E PIC interfaces, the default value for maximum retention of entries in the MAC address table has changed, for cases in which the table is not full. The new holding time is 12 hours. The previous retention time of 3 minutes is still in effect when the table is full.

You can use the same policer one or more times.

If you apply both policers and firewall filters to an interface, input policers are evaluated before input firewall filters, and output policers are evaluated after output firewall filters.

Configuring MAC Address Filtering

You cannot explicitly define traffic with specific source MAC addresses to be rejected; however, for Gigabit Ethernet IQ and Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), and for Gigabit Ethernet DPCs on MX Series routers, you can block all incoming packets that do not have a source address specified in the **accept-source-mac** statement. For more information about the **accept-source-mac** statement, see "Applying a Policer" on page 542.

To enable this blocking, include the **source-filtering** statement at the **[edit interfaces *interface-name* gigether-options]** hierarchy level:

```
[edit interfaces interface-name gigether-options]
source-filtering;
```

For more information about the **source-filtering** statement, see "Configuring MAC Address Filtering for Ethernet Interfaces" on page 14.

To accept traffic even though it does not have a source address specified in the **accept-source-mac** statement, include the **no-source-filtering** statement at the **[edit interfaces *interface-name* gigether-options]** hierarchy level:

```
[edit interfaces interface-name gigether-options]
no-source-filtering;
```

Example: Configuring Gigabit Ethernet Policers

Example

This example illustrates the following:

- Configure interface **ge-6/0/0** to treat priority values 2 and 3 as premium. On ingress, this means that IEEE 802.1p priority values **2** and **3** are treated as premium. On egress, it means traffic that is classified into queue 0 or 1 with PLP of low and queue 2 or 3 with PLP of high, is treated as premium.
- Define a policer that limits the premium bandwidth to 100 Mbps and burst size to 3 k, and the aggregate bandwidth to 200 Mbps and burst size to 3 k.
- Specify that frames received from the MAC address **00:01:02:03:04:05** and the VLAN ID **600** are subject to the policer on input and output. On input, this means frames received with the source MAC address **00:01:02:03:04:05** and the VLAN ID 600 are subject to the policer. On output, this means frames transmitted from the router with the destination MAC address **00:01:02:03:04:05** and the VLAN ID **600** are subject to the policer.

Example Configuration

```
[edit interfaces]
ge-6/0/0 {
   gigether-options {
      ether-switch-profile {
         ether-policer-profile {
            input-priority-map {
               ieee-802.1p {
                  premium [ 2 3 ];
               }
            }
            output-priority-map {
               classifier {
                  premium {
                     forwarding-class best-effort {
                        loss-priority low;
                     }
                     forwarding-class expedited-forwarding {
                        loss-priority low;
                     }
                     forwarding-class assured-forwarding {
                        loss-priority high;
                     }
                     forwarding-class network-control {
                        loss-priority high;
                     }
                  }
               }
            }
            policer policer-1 {
               premium {
                  bandwidth-limit 100m;
                  burst-size-limit 3k;
               }
               aggregate {
                  bandwidth-limit 200m;
                  burst-size-limit 3k;
               }
            }
         }
      }
   }
   unit 0 {
      accept-source-mac {
         mac-address 00:01:02:03:04:05 {
            policer {
               input policer-1;
               output policer-1;
            }
         }
      }
   }
}
```

Configuring Gigabit Ethernet Two-Color and Tricolor Policers

Overview

For Gigabit Ethernet and 10-Gigabit Ethernet IQ2 and IQ2-E interfaces on M Series and T Series routers, you can configure two-color and tricolor marking policers and apply them to logical interfaces to prevent traffic on the interface from consuming bandwidth inappropriately.

Networks police traffic by limiting the input or output transmission rate of a class of traffic on the basis of user-defined criteria. Policing traffic allows you to control the maximum rate of traffic sent or received on an interface and to partition a network into multiple priority levels or classes of service.

Policers require you to apply a burst size and bandwidth limit to the traffic flow, and set a consequence for packets that exceed these limits—usually a higher loss priority, so that packets exceeding the policer limits are discarded first.

Juniper Networks router architectures support three types of policer:

- Two-color policer—A two-color policer (or “policer” when used without qualification) meters the traffic stream and classifies packets into two categories of packet loss priority (PLP) according to a configured bandwidth and burst-size limit. You can mark packets that exceed the bandwidth and burst-size limit in some way, or simply discard them. A policer is most useful for metering traffic at the port (physical interface) level.
- Single-rate tricolor marking (single-rate TCM)—A single-rate tricolor marking policer is defined in RFC 2697, *A Single Rate Three Color Marker*, as part of an assured forwarding per-hop-behavior (PHB) classification system for a Differentiated Services (DiffServ) environment. This type of policer meters traffic based on the configured committed information rate (CIR), committed burst size (CBS), and excess burst size (EBS).

  Starting in Junos OS Release 13.1, traffic is classified into three categories: Green, Red, and Yellow. Following list describes the categories:

  - Green—Burst size of the packets that arrive is less than the sum of the configured CIR and CBS.

  - Red—Burst size of the packets that arrive is greater than the sum of the configured CIR and EBS.
  - Yellow—Burst size of the packets that arrive is greater than the CBS but less than the EBS.

  Single-rate TCM is most useful when a service is structured according to packet length and not peak arrival rate.

- Two-rate Tricolor Marking (two-rate TCM)—This type of policer is defined in RFC 2698, *A Two Rate Three Color Marker*, as part of an assured forwarding per-hop-behavior (PHB) classification system for a Differentiated Services (DiffServ) environment. This type of policer meters traffic based on the configured CIR and peak information rate (PIR), along with their associated burst sizes, the CBS and EBS.

  Traffic is classified into the following three categories:

  - Green—Burst size of the packets that arrive is less than the sum of the configured CIR and CBS.
  - Red—Burst size of the packets that arrive is greater than the sum of the configured PIR and EBS.
  - Yellow—Traffic does not belong to either the green or the red category.

  Two-rate TCM is most useful when a service is structured according to arrival rates and not necessarily packet length.

NOTE: **Unlike policing (described in** "Configuring Gigabit Ethernet Policers" on page 539**), configuring two-color policers and tricolor marking policers requires that you configure a firewall filter.**

Configuring a Policer

Two-color and tricolor marking policers are configured at the **[edit firewall]** hierarchy level.

A tricolor marking policer polices traffic on the basis of metering rates, including the CIR, the PIR, their associated burst sizes, and any policing actions configured for the traffic.

To configure tricolor policer marking, include the **three-color-policer** statement with options at the **[edit firewall]** hierarchy level:

```
[edit firewall]
three-color-policer name {
  action {
    loss-priority high {
      then discard;
    }
  }
  single-rate {
    (color-aware | color-blind);
    committed-information-rate bps;
```

```
      committed-burst-size bytes;
      excess-burst-size bytes;
    }
    two-rate {
      (color-aware | color-blind);
      committed-information-rate bps;
      committed-burst-size bytes;
      peak-information-rate bps;
      peak-burst-size bytes;
    }
  }
```

For more information about configuring tricolor policer markings, see the *Routing Policies, Firewall Filters, and Traffic Policers Feature Guide* and the *Class of Service Feature Guide for Routing Devices and EX9200 Switches*.

Applying a Policer

Apply a two-color policer or tricolor policer to a logical interface to prevent traffic on the interface from consuming bandwidth inappropriately. To apply two-color or tricolor policers, include the **layer2-policer** statement:

```
layer2-policer {
  input-policer policer-name;
  input-three-color policer-name;
  output-policer policer-name;
  policer-name;
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

Use the **input-policer** statement to apply a two-color policer to received packets on a logical interface and the **input-three-color** statement to apply a tricolor policer. Use the **output-policer** statement to apply a two-color policer to transmitted packets on a logical interface and the **output-three-color** statement to apply a tricolor policer. The specified policers must be configured at the **[edit firewall]** hierarchy level. For each interface, you can configure a three-color policer or two-color input policer or output policers—you cannot configure both a three-color policer and a two-color policer.

Example: Configuring and Applying a Policer

Configure tricolor policers and apply them to an interface:

```
[edit firewall]
three-color-policer three-color-policer-color-blind {
  logical-interface-policer;
  two-rate {
    color-blind;
    committed-information-rate 1500000;
    committed-burst-size 150;
    peak-information-rate 3;
```

```
    peak-burst-size 300;
  }
}
three-color-policer three-color-policer-color-aware {
  logical-interface-policer;
  two-rate {
    color-aware;
    committed-information-rate 1500000;
    committed-burst-size 150;
    peak-information-rate 3;
    peak-burst-size 300;
  }
}
[edit interfaces ge-1/1/0]
unit 1 {
  layer2-policer {
    input-three-color three-color-policer-color-blind;
    output-three-color three-color-policer-color-aware;
  }
}
```

Configure a two-color policer and apply it to an interface:

```
[edit firewall]
policer two-color-policer {
  logical-interface-policer;
  if-exceeding {
    bandwidth-percent 90;
    burst-size-limit 300;
  }
  then loss-priority-high;
}
[edit interfaces ge-1/1/0]
unit 2 {
  layer2-policer {
    input-policer two-color-policer;
    output-policer two-color-policer;
  }
}
```

Release History Table

Release	Description
13.1	Starting in Junos OS Release 13.1, traffic is classified into three categories: Green, Red, and Yellow.

CHAPTER 29

Configuring Gigabit Ethernet Autonegotiation

Gigabit Ethernet Autonegotiation Overview

Autonegotiation is enabled by default on all Gigabit Ethernet and Tri-Rate Ethernet copper interfaces. However, you can explicitly enable autonegotiation to configure remote fault options manually.

NOTE:

- When you configure the Tri-Rate Ethernet copper interface to operate at 1 Gbps, autonegotiation must be enabled.
- On ACX Series Universal Metro Routers, when the autonegotiation is disabled, the speed has to be explicitly configured to 10–100 Mbps.
- On T4000 routers, the **auto-negotiation** command is ignored for interfaces other than Gigabit Ethernet.

Related Documentation

- Configuring Gigabit Ethernet Autonegotiation on page 551

- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring Gigabit Ethernet Autonegotiation

Configuring Gigabit Ethernet Autonegotiation with Remote Fault

To configure explicit autonegotiation and remote fault, include the **auto-negotiation** statement and the **remote-fault** option at the **[edit interfaces ge-*fpc/pic/port* gigether-options]** hierarchy level.

```
[edit interfaces ge-fpc/pic/port gigether-options]
(auto-negotiation | no-auto-negotiation) remote-fault <local-interface-online |
  local-interface-offline>
```

Configuring Flow Control

To enable flow control, include the **flow-control** statement at the **[edit interfaces ge-*fpc/pic>/port* gigether-options]** hierarchy level. For more information, see "Configuring Flow Control" on page 12.

Configuring Autonegotiation Speed on MX Series Routers

MX Series routers with Combo Line Rate DPCs and Tri-Rate Copper SFPs support autonegotiation of speed. The autonegotiation specified interface speed is propagated to CoS, routing protocols, and other system components. Half-duplex mode is not supported.

MX Series routers with IQ2 PICs connected to other devices require matching auto-negotiation configurations for both the PIC and for the device in order to achieve link up.

To specify the autonegotiation speed, use the **speed (auto | 1Gbps | 100Mbps | 10Mbps | auto-10m-100m)** statement at the **[edit interfaces ge-*fpc/pic/port*]** hierarchy level.

To set port speed negotiation to a specific rate, set the port speed to **1Gbps**, **100Mbps**, or **10Mbps**. If the negotiated speed and the interface speed do not match, the link will not be brought up.

If you set the autonegotiation speed **auto** option, then the port speed is negotiated.

Starting from Junos OS Release 14.2, the**auto-10m-100m** option allows the fixed tri-speed port to auto negotiate with ports limited by **100m** or **10m**maximum speed. This option must be enabled only for Tri-rate MPC port, that is, 3D 40x 1GE (LAN) RJ45 MIC on MX platform. This option does not support other MICs on MX platform.

You can disable auto MDI/MDIX using the **no-auto-mdix** statement at the **[edit interfaces ge-*fpc/pic/port* gigether-options]** hierarchy level.

Use the **show interfaces ge-*fpc/pic/port* brief** command to display the auto negotiation of speed and auto MDI/MDIX states.

NOTE: Starting in Junos OS Release 14.2, on MX Series routers with Tri-rate Enhanced DPC (DPCE-R-40GE-TX), when you configure the interface speed using the **auto-10m-100m** option, the speed is negotiated to the highest value possible (100 Mbps), if the same value is configured on both sides of the link. However, when you view the interface speed of the DPC, using the **show interfaces** command, the value of the speed is not accurately displayed. For instance, if you configure the speed of the Tri-rate enhanced DPC, as 100Mbps on both sides of the link, the interface speed of the DPC is negotiated to 100 Mbps. However, the interface speed of the DPC displays 1 bps. This is an issue with the **show interfaces** command only. The actual interface speed is 100 Mbps.

Displaying Autonegotiation Status

To display Gigabit Ethernet interface details, including the autonegotiation status, use the operational mode command **show interfaces ge-** ***fpc/pic/port*** **extensive**.

Table 53 on page 553 and Table 54 on page 555 provide information about the autonegotiation status on local and remote routers with fiber interfaces. The status of the link and LED can vary depending on the level of autonegotiation set and the transmit and receive fiber status.

CHAPTER 30

Stacking and Rewriting Gigabit Ethernet VLAN Tags

Stacking and Rewriting Gigabit Ethernet VLAN Tags Overview

Stacking and rewriting VLAN tags allows you to use an additional (outer) VLAN tag to differentiate between customer edge (CE) routers that share one VLAN ID. A frame can be received on an interface, or it can be internal to the system (as a result of the **input-vlan-map** statement).

On IQ2 interfaces, 10-Gigabit Ethernet LAN/WAN PIC, 40-Gigabit Ethernet MIC, 100-Gigabit Ethernet MIC, IQ2-E interfaces, and MX Series interfaces, when a VLAN tag is pushed, the inner VLAN IEEE 802.1p bits are copied to the IEEE bits of the VLAN or VLANs being pushed. If the original packet is untagged, the IEEE bits of the VLAN or VLANs being pushed are set to 0.

NOTE: When swap-by-poppush is configured on the interface, when a VLAN tag is swapped, the inner VLAN IEEE 802.1p bits are copied to the IEEE bits of the VLAN being swapped. If swap-by-poppush is not configured on the interface, the VLAN IEEE 802.1p bits of the of the VLAN being swapped remains same.

You can stack and rewrite VLAN tags on the following interfaces:

- Gigabit Ethernet
- Gigabit Ethernet IQ
- 10-Gigabit Ethernet LAN/WAN PIC
- 40-Gigabit Ethernet MIC
- 100-Gigabit Ethernet MIC
- Gigabit Ethernet IQ2 and IQ2-E
- 10-Gigabit Ethernet IQ2 and IQ2-E interfaces, and MX Series router Gigabit Ethernet Interfaces
- Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces with the VLAN encapsulation type configured to support Layer 2 tunneling protocols such as circuit cross-connect (CCC) or virtual private LAN service (VPLS) (as described in “802.1Q VLANs Overview” on page 244)

Related Documentation

- 802.1Q VLANs Overview on page 244
- Stacking and Rewriting Gigabit Ethernet VLAN Tags on page 560
- *Ethernet Interfaces Feature Guide for Routing Devices*

Stacking and Rewriting Gigabit Ethernet VLAN Tags

You can configure rewrite operations to stack (**push**), remove (**pop**), or rewrite (**swap**) tags on single-tagged frames and dual-tagged frames. If a port is not tagged, rewrite operations are not supported on any logical interface on that port.

You can configure the following VLAN rewrite operations:

- **pop**—Remove a VLAN tag from the top of the VLAN tag stack. The outer VLAN tag of the frame is removed.
- **pop-pop**—For Ethernet IQ2, 10-Gigabit Ethernet LAN/WAN PIC, and IQ2-E interfaces, remove both the outer and inner VLAN tags of the frame.
- **pop-swap**—For Ethernet IQ2, 10-Gigabit Ethernet LAN/WAN PIC, and IQ2-E interfaces, remove the outer VLAN tag of the frame, and replace the inner VLAN tag of the frame with a user-specified VLAN tag value. The inner tag becomes the outer tag in the final frame.
- **push**—Add a new VLAN tag to the top of the VLAN stack. An outer VLAN tag is pushed in front of the existing VLAN tag.
- **push-push**—For Ethernet IQ2, 10-Gigabit Ethernet LAN/WAN PIC, and IQ2-E interfaces, push two VLAN tags in front of the frame.
- **swap-push**—For Ethernet IQ2, 10-Gigabit Ethernet LAN/WAN PIC, and IQ2-E interfaces, replace the outer VLAN tag of the frame with a user-specified VLAN tag value. A user-specified outer VLAN tag is pushed in front. The outer tag becomes an inner tag in the final frame.
- **swap-swap**—For Ethernet IQ2, 10-Gigabit Ethernet LAN/WAN PIC, and IQ2-E interfaces, replace both the inner and the outer VLAN tags of the incoming frame with a user-specified VLAN tag value.

You configure VLAN rewrite operations for logical interfaces in the input VLAN map for incoming frames and in the output VLAN map for outgoing frames. To configure the input VLAN map, include the **input-vlan-map** statement:

```
input-vlan-map {
  ...interface-specific configuration...
}
```

To configure the output VLAN map, include the **output-vlan-map** statement:

```
output-vlan-map {
  ...interface-specific configuration...
}
```

You can include both statements at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

The type of VLAN rewrite operation permitted depends upon whether the frame is single-tagged or dual-tagged. Table 55 on page 562 shows supported rewrite operations and whether they can be applied to single-tagged frames or dual-tagged frames. The table also indicates the number of tags being added or removed during the operation.

Table 55: Rewrite Operations on Untagged, Single-Tagged, and Dual-Tagged Frames

Rewrite Operation	Untagged	Single-Tagged	Dual-Tagged	Number of Tags
pop	No	Yes	Yes	– 1
push	Sometimes	Yes	Yes	+1
swap	No	Yes	Yes	0
push-push	Sometimes	Yes	Yes	+2
swap-push	No	Yes	Yes	+1
swap-swap	No	No	Yes	0
pop-pop	No	No	Yes	– 2
pop-swap	No	No	Yes	– 1

The rewrite operations **push** and **push-push** can be valid in certain circumstances on frames that are not tagged. For example, a single-tagged logical interface (interface 1) and a dual-tagged logical interface (interface 2) have the following configurations:

Interface 1

```
[edit interfaces interface-name unit logical-unit-number]
input-vlan-map {
  pop;
}
output-vlan-map {
  push;
}
```

Interface 2

```
[edit interfaces interface-name unit logical-unit-number]
input-vlan-map {
  pop-pop;
}
output-vlan-map {
  push-push;
}
```

When a frame is received on the interface as a result of the **input-vlan-map** operation, the frame is not tagged. As it goes out of the second interface, the **output-vlan-map** operation **push-push** is applied to it. The resulting frame will be dual-tagged at the logical interface output.

Depending on the VLAN rewrite operation, you configure the rewrite operation for the interface in the input VLAN map, the output VLAN map, or in both the input VLAN map and the output VLAN map. Table 56 on page 563 shows what rewrite operation combinations you can configure. “None” means that no rewrite operation is specified for the VLAN map.

Table 56: Applying Rewrite Operations to VLAN Maps

	Output VLAN Map								
Input VLAN Map	none	push	pop	swap	push-push	swap-push	swap-swap	pop-pop	swap-pop
none	Yes	No	No	Yes	No	No	Yes	No	No
push	No	No	Yes	No	No	No	No	No	No
pop	No	Yes	No	No	No	No	No	No	No
swap	Yes	No	No	Yes	No	No	No	No	No
push-push	No	No	No	No	No	No	No	Yes	No
swap-push	No	No	No	No	No	No	No	No	Yes
swap-swap	Yes	No	No	No	No	No	Yes	No	No
pop-pop	No	No	No	No	Yes	No	No	No	No
pop-swap	No	No	No	No	No	Yes	No	No	No

You must know whether the VLAN rewrite operation is valid and is applied to the input VLAN map or the output VLAN map. You must also know whether the rewrite operation requires you to include statements to configure the inner and outer TPIDs and inner and outer VLAN IDs in the input VLAN map or output VLAN map. For information about configuring inner and outer TPIDs and inner and outer VLAN IDs, see "Configuring Inner and Outer TPIDs and VLAN IDs" on page 566.

Configuring Frames with Particular TPIDs to Be Processed as Tagged Frames

For Gigabit Ethernet IQ interfaces, aggregated Ethernet with Gigabit Ethernet IQ interfaces, Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), and MX Series router Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces, you can configure frames with particular TPIDs to be processed as tagged frames. To do this, you specify up to eight IEEE 802.1Q TPID values per port; a frame with any of the specified TPIDs is processed as a tagged frame; however, with IQ2 and IQ2-E interfaces, only the first four IEEE 802.1Q TPID values per port are supported. To configure the TPID values, include the **tag-protocol-id** statement:

tag-protocol-id [*tpids*];

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* gigether-options ethernet-switch-profile]**
- **[edit interfaces *interface-name* aggregated-ether-options ethernet-switch-profile]**

All TPIDs you include in input and output VLAN maps must be among those you specify at the **[edit interfaces *interface-name* gigether-options ethernet-switch-profile tag-protocol-id [*tpids*]]** or **[edit interfaces *interface-name* aggregated-ether-options ethernet-switch-profile tag-protocol-id [*tpids*]]** hierarchy level.

- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring Tag Protocol IDs (TPIDs) on PTX Series Packet Transport Routers

This topic describes how to configure the TPIDs expected to be sent or received on a particular VLAN for PTX Series Packet Transport Routers.

For other types of Juniper Networks Ethernet PICs, you could configure 8 TPIDs per port. However, the PTX Series Packet Transport Routers use MTIP and TL to classify a specific TPID and Ethernet type. For MTIP, you can configure a maximum of 8 TPIDs for each MAC chip.

As a consequence, you can specify the **tag-protocol-id** configuration statement only for the first port (**0**) of a PTX Series Ethernet PIC. If you configure **tag-protocol-id** statements on the other port, the configuration is ignored and a system error is recorded.

For example, the following is a supported configuration:

```
[edit interfaces et-2/0/0]
gigether-options {
  ethernet-switch-profile {
    tag-protocol-id [0x8100 0x9100];
  }
}
```

The **tag-protocol-id** configuration statement supports up to eightTPIDs on port **0** of a given Ethernet PIC. All eight TPIDs are populated to the two MTIPs and TLs associated with the Ethernet PIC.

- Configuring Flexible VLAN Tagging on PTX Series Packet Transport Routers on page 249

Configuring Stacked VLAN Tagging

To configure stacked VLAN tagging for all logical interfaces on a physical interface:

1. In configuration mode, go to the **[edit interfaces interface-name]** hierarchy level.

   [edit]
   user@host# edit interfaces *interface-name*

2. Include the **stacked-vlan-tagging** statement.

   [edit interfaces *interface-name*]
   user@host# set stacked-vlan-tagging

If you include the **stacked-vlan-tagging** statement in the configuration, you must configure dual VLAN tags for all logical interfaces on the physical interface. For more information, see "Stacking a VLAN Tag" on page 569.

Related Documentation

- **stacked-vlan-tagging on page 1372**
- Stacking a VLAN Tag on page 569
- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring Dual VLAN Tags

To configure dual VLAN tags on a logical interface, include the **vlan-tags** statement:

vlan-tags inner <*tpid*.>*vlan-id* outer <*tpid*.>*vlan-id*;

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

The outer tag VLAN ID range is from 1 through 511 for normal interfaces, and from 512 through 4094 for VLAN CCC or VLAN VPLS interfaces. The inner tag is not restricted.

You must also include the **stacked-vlan-tagging** statement in the configuration. See "Examples: Stacking and Rewriting Gigabit Ethernet IQ VLAN Tags" on page 579.

Related Documentation

- **unit on page 1420**
- Examples: Stacking and Rewriting Gigabit Ethernet IQ VLAN Tags on page 579
- *Ethernet Interfaces Feature Guide for Routing Devices*

Configuring Inner and Outer TPIDs and VLAN IDs

For some rewrite operations, you must configure the inner or outer tag-protocol identifier (TPID) values and inner or outer virtual local area network identifier (VLAN ID) values. These values can be applied to either the input VLAN map or the output VLAN map.

1. On Ethernet IQ, IQ2, and IQ2-E interfaces; on MX Series router Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces; and on aggregated Ethernet interfaces using Gigabit Ethernet IQ2 and IQ2-E or 10-Gigabit Ethernet PICs on MX Series routers, to configure the inner TPID, include the **inner-tag-protocol-id** statement at the following hierarchy levels:

   - **[edit interfaces *interface-name* unit *logical-unit-number* input-vlan-map]**
   - **[edit interfaces *interface-name* unit *logical-unit-number* output-vlan-map]**
   - **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* input-vlan-map]**
   - **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* output-vlan-map]**

   ```
   user@host# set inner-tag-protocol-id tpid;
   ```

2. For the inner VLAN ID, include the **inner-vlan-id** statement. For the outer TPID, include the **tag-protocol-id** statement. For the outer VLAN ID, include the **vlan-id** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level or at the **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

   ```
   input-vlan-map {
     (pop | pop-pop | pop-swap | push | push-push | swap | swap-push | swap-swap);
     inner-tag-protocol-id tpid;
     inner-vlan-id number;
     tag-protocol-id tpid;
     vlan-id number;
   }
   output-vlan-map {
     (pop | pop-pop | pop-swap | push | push-push | swap | swap-push | swap-swap);
     inner-tag-protocol-id tpid;
     inner-vlan-id number;
     tag-protocol-id tpid;
     vlan-id number;
   }
   ```

3. For aggregated Ethernet interfaces using Gigabit Ethernet IQ interfaces, include the **tag-protocol-id** statement for the outer TPID. For the outer VLAN ID, include the **vlan-id** statement at the **[edit interfaces *interface-name* unit *logical-unit-number*]** hierarchy level or at the **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]** hierarchy level.

   ```
   input-vlan-map {
   ```

```
        (pop | push | swap);
        tag-protocol-id tpid;
        vlan-id number;
    }
    output-vlan-map {
        (pop | push | swap);
        tag-protocol-id tpid;
        vlan-id number;
    }
```

The VLAN IDs you define in the input VLAN maps are stacked on top of the VLAN ID bound to the logical interface. For more information about binding a VLAN ID to the logical interface, see "802.1Q VLANs Overview" on page 244.

All TPIDs you include in input and output VLAN maps must be among those you specify at the **[edit interfaces *interface-name* gigether-options ethernet-switch-profile tag-protocol-id [*tpids*]]** hierarchy level or **[edit interfaces *interface-name* aggregated-ether-options ethernet-switch-profile tag-protocol-id [*tpids*]]** hierarchy level. For more information, see "Configuring Frames with Particular TPIDs to Be Processed as Tagged Frames" on page 563.

Table 57 on page 567 and Table 58 on page 568 specify when these statements are required. Table 57 on page 567 indicates valid statement combinations for rewrite operations for the input VLAN map. "No" means the statement must not be included in the input VLAN map for the rewrite operation. "Optional" means the statement may be optionally specified for the rewrite operation in the input VLAN map. "Any" means that you must include the **vlan-id** statement, **tag-protocol-id** statement, **inner-vlan-id** statement, or **inner-tag-protocol-id** statement.

Table 57: Rewrite Operations and Statement Usage for Input VLAN Maps

	Input VLAN Map Statements			
Rewrite Operation	vlan-id	tag-protocol-id	inner-vlan-id	inner-tag-protocol-id
push	Optional	Optional	No	No
pop	No	No	No	No
swap	Any	Any	No	No
push-push	Optional	Optional	Optional	optional
swap-push	Optional	Optional	Any	Any
swap-swap	Optional	Optional	Any	Any
pop-swap	No	No	Any	Any
pop-pop	No	No	No	No

Table 58 on page 568 indicates valid statement combinations for rewrite operations for the output VLAN map. “No” means the statement must not be included in the output VLAN map for the rewrite operation. “Optional” means the statement may be optionally specified for the rewrite operation in the output VLAN map.

Table 58: Rewrite Operations and Statement Usage for Output VLAN Maps

	Output VLAN Map Statements			
Rewrite Operation	vlan-id	tag-protocol-id	inner-vlan-id	inner-tag-protocol-id
push	No	Optional	No	No
pop	No	No	No	No
swap	No	Optional	No	No
push-push	No	Optional	No	Optional
swap-push	No	Optional	No	Optional
swap-swap	No	Optional	No	Optional
pop-swap	No	No	No	Optional
pop-pop	No	No	No	No

Input VLAN Map with inner-vlan-id Statement, Output VLAN Map with Optional inner-tag-protocol-id Statement

```
[edit interfaces interface-name unit logical-unit-number]
input-vlan-map {
  pop-swap;
  inner-vlan-id number;
}
output-vlan-map {
  pop-swap;
  inner-tag-protocol-id tpid;
}
```

Input VLAN Map with inner-tag-protocol-id Statement, Output VLAN Map with Optional inner-tag-protocol-id Statement

```
[edit interfaces interface-name unit logical-unit-number]
input-vlan-map {
  pop-swap;
  inner-tag-protocol-id tpid;
}
output-vlan-map {
  pop-swap;
  inner-tag-protocol-id tpid;
}
```

Input VLAN Map with inner-tag-protocol-id and inner-vlan-id Statements

```
[edit interfaces interface-name unit logical-unit-number]
input-vlan-map {
  pop-swap;
  inner-vlan-id number;
  inner-tag-protocol-id tpid;
```

```
}
```

Related Documentation

Stacking a VLAN Tag

To stack a VLAN tag on all tagged frames entering or exiting the interface, include the **push**, **vlan-id**, and **tag-protocol-id** statements in the input VLAN map or the output VLAN map:

```
input-vlan-map {
  push;
  vlan-id number;
  tag-protocol-id tpid;
}
output-vlan-map {
  push;
  tag-protocol-id tpid;
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]**

If you include the **push** statement in an interface's input VLAN map, see Table 56 on page 563 for information about permissible rewrite operations,

The VLAN IDs you define in the input VLAN maps are stacked on top of the VLAN ID bound to the logical interface. For more information about binding a VLAN ID to the logical interface, see "802.1Q VLANs Overview" on page 244.

All TPIDs you include in input and output VLAN maps must be among those you specify at the **[edit interfaces *interface-name* gigether-options ethernet-switch-profile tag-protocol-id [*tpids*]]** hierarchy level. For more information, see "Configuring Inner and Outer TPIDs and VLAN IDs" on page 566.

Stacking Two VLAN Tags

On Ethernet IQ, IQ2 and IQ2-E interfaces, on MX Series router Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces, and on aggregated Ethernet interfaces using Gigabit Ethernet IQ2 and IQ2-E or 10-Gigabit Ethernet PICs on MX Series routers, to push two VLAN tags in front of tagged frames entering or exiting the interface, include the **push-push** statement in the input VLAN map or the output VLAN map:

```
push-push;
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number* input-vlan-map]
- [edit interfaces *interface-name* unit *logical-unit-number* output-vlan-map]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* input-vlan-map]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* output-vlan-map]

See Table 57 on page 567 and Table 58 on page 568 for information about configuring inner and outer VLAN ID values and inner and outer TPID values required for VLAN maps.

- *Ethernet Interfaces Feature Guide for Routing Devices*

Removing a VLAN Tag

To remove a VLAN tag from all tagged frames entering or exiting the interface, include the **pop** statement in the input VLAN map or output VLAN map:

```
pop;
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number* input-vlan-map]
- [edit interfaces *interface-name* unit *logical-unit-number* output-vlan-map]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* input-vlan-map]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* output-vlan-map]

Related Documentation

- input-vlan-map on page 1203
- output-vlan-map on page 1295
- pop on page 1306
- unit on page 1420
- *Ethernet Interfaces Feature Guide for Routing Devices*

Removing the Outer and Inner VLAN Tags

On Ethernet IQ, IQ2 and IQ2-E interfaces, on MX Series router Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces, and on aggregated Ethernet interfaces using Gigabit Ethernet IQ2 and IQ2-E or 10-Gigabit Ethernet PICs on MX Series routers, to remove both the outer and inner VLAN tags of the frame, include the **pop-pop** statement in the input VLAN map or output VLAN map:

```
pop-pop;
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number* input-vlan-map]
- [edit interfaces *interface-name* unit *logical-unit-number* output-vlan-map]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* input-vlan-map]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* output-vlan-map]

See Table 57 on page 567 and Table 58 on page 568 for information about configuring inner and outer VLAN ID values and inner and outer TPID values required for VLAN maps.

Related Documentation

- input-vlan-map on page 1203

Removing the Outer VLAN Tag and Rewriting the Inner VLAN Tag

On Ethernet IQ, IQ2 and IQ2-E interfaces, on MX Series router Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces, and on aggregated Ethernet interfaces using Gigabit Ethernet IQ2 and IQ2-E or 10-Gigabit Ethernet PICs on MX Series routers, to remove the outer VLAN tag of the frame and replace the inner VLAN tag of the frame with a user-specified VLAN tag value, include the **pop-swap** statement in the input VLAN map or output VLAN map:

```
pop-swap;
```

The inner tag becomes the outer tag in the final frame.

You can include this statement at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number* input-vlan-map]**
- **[edit interfaces *interface-name* unit *logical-unit-number* output-vlan-map]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* input-vlan-map]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* output-vlan-map]**

See Table 57 on page 567 and Table 58 on page 568 for information about configuring inner and outer VLAN ID values and inner and outer TPID values required for VLAN maps.

Related Documentation

- **input-vlan-map on page 1203**
- **output-vlan-map on page 1295**
- **pop-swap on page 1308**
- **unit on page 1420**
- See Table 57 on page 567 and Table 58 on page 568 for information about configuring inner and outer VLAN ID values and inner and outer TPID values required for VLAN maps.
- *Ethernet Interfaces Feature Guide for Routing Devices*

Rewriting the VLAN Tag on Tagged Frames

To rewrite the VLAN tag on all tagged frames entering the interface to a specified VLAN ID and TPID, include the **swap**, **tag-protocol-id**, and **vlan-id** statements in the input VLAN map:

```
input-vlan-map {
  swap;
  vlan-id number;
  tag-protocol-id tpid;
}
```

To rewrite the VLAN tag on all tagged frames exiting the interface to a specified VLAN ID and TPID, include the **swap** and **tag-protocol-id** statements in the output VLAN map:

```
output-vlan-map {
  swap;
  vlan-id number;
  tag-protocol-id tpid;
}
```

You can include these statements at the following hierarchy levels:

- **[edit interfaces *interface-name* unit *logical-unit-number* input-vlan-map]**
- **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* input-vlan-map]**

You cannot include both the **swap** statement and the **vlan-id** statement in the output VLAN map configuration. If you include the **swap** statement in the configuration, the VLAN ID in outgoing frames is rewritten to the VLAN ID bound to the logical interface. For more information about binding a VLAN ID to the logical interface, see "802.1Q VLANs Overview" on page 244.

The swap operation works on the outer tag only, whether or not you include the **stacked-vlan-tagging** statement in the configuration. For more information, see "Examples: Stacking and Rewriting Gigabit Ethernet IQ VLAN Tags" on page 579.

Rewriting a VLAN Tag on Untagged Frames

Overview

You can rewrite VLAN tags on untagged incoming and outgoing frames with the ethernet-ccc and the ethernet-vpls encapsulations for the following routers:

- M120 routers and M320 routers with:
  - Gigabit Ethernet IQ PIC with SFP
  - Gigabit Ethernet IQ2 PICs with SFP
  - Gigabit Ethernet Enhanced IQ2 (IQ2E) PICs with SFP
  - 10-Gigabit Ethernet IQ2 PIC with XFP
  - 10-Gigabit Ethernet Enhanced IQ2 (IQ2E) PIC with XFP
- MX240, MX480, and MX960 routers with:
  - Gigabit Ethernet Enhanced DPC with SFP
  - Gigabit Ethernet Enhanced Queuing IP Services DPCs with SFP
  - 10-Gigabit Ethernet Enhanced DPCs with XFP
  - 10-Gigabit Ethernet Enhanced Queuing IP Services DPC with XFP

On M Series routers with Gigabit Ethernet IQ2 PICs and Gigabit Ethernet Enhanced IQ2 (IQ2E) PICs, you can perform all the rewrite VLAN tag operations.

Consider a network where two provider edges (PE) are connected by a Layer 2 circuit. PE1 is receiving traffic on an untagged port while the corresponding port on PE2 is tagged. In the normal case, packets coming from PE1 will be dropped at PE2 because it is expecting tagged packets. However, if PE1 can push a VLAN tag on the incoming packet before sending it across to PE2, you can ensure that packets are not dropped. To make it work in both directions, PE1 must strip the VLAN tag from outgoing packets. Therefore, a push on the ingress side is always paired with a pop on the egress side.

The rewrite operations represented by the following statement options are supported under **ethernet-ccc** and **ethernet-vpls** encapsulations:

- **push**—A VLAN tag is added to the incoming untagged frame.
- **pop**—VLAN tag is removed from the outgoing frame.

- **push-push**—An outer and inner VLAN tag are added to the incoming untagged frame.
- **pop-pop**—Both the outer and inner VLAN tags of the outgoing frame are removed.

IQ2 and 10-Gigabit Ethernet PICs support all rewrite operations described above. Details on the possible combinations of usage are explained later in this section.

NOTE: The **push-push** and **pop-pop** operations are not supported on the Gigabit Ethernet IQ PIC.

For the **input-vlan-map** statement, only the **push** and **push-push** options are supported because it does not make sense to remove a VLAN tag from an incoming untagged frame. Similarly, only the **pop** and **pop-pop** options are supported for the **output-vlan-map** statement. Also, with the **push** and **push-push** options, the tag parameters have to be explicitly specified. Apart from this, the other rules for configuring the **input-vlan-map** and **output-vlan-map** statements are the same as for tagged frames. Table 59 on page 575 through Table 61 on page 575 explain the rules in more detail.

For the **input-vlan-map** statement, only the **push** and **push-push** options are supported because it does not make sense to remove a VLAN tag from an incoming untagged frame. Similarly, only the **pop** and **pop-pop** options are supported for the **output-vlan-map** statement. Also, with the **push** and **push-push** options, the **vlan-id** parameters (**vlan-id** for **push** and **vlan-id** or **inner-vlan-id** for **push-push**) have to be explicitly specified. TPID however, is optional and the default value of **0x8100** is set if not configured. Apart from this, the other rules for configuring the **input-vlan-map** and **output-vlan-map** statements are the same as for tagged frames.

Table 59: Input VLAN Map Statements Allowed for ethernet-ccc and ethernet-vpls Encapsulations

Operation	vlan-id	tag-protocol-id	inner-vlan-id	inner-tag-protocol-id
push	Yes	Optional	No	Optional
push-push	Yes	Optional	Yes	Optional

Table 60: Output VLAN Map Statements Allowed for ethernet-ccc and ethernet-vpls Encapsulations

Operation	vlan-id	tag-protocol-id	inner-vlan-id	inner-tag-protocol-id
pop	No	No	No	No
pop-pop	No	No	No	No

Table 61: Rules for Applying Rewrite Operations to VLAN Maps

	Output VLAN Map		
Input VLAN Map	None	pop	pop-pop
None	Yes	No	No
push	No	Yes	No

Table 61: Rules for Applying Rewrite Operations to VLAN Maps (continued)

push-push	No	No	Yes

You can use the **show interface *interface-name*** command to display the status of a modified VLAN map for the specified interface.

Example: push and pop with Ethernet CCC Encapsulation

```
ge-3/1/0 {
  encapsulation ethernet-ccc;
  unit 0 {
    encapsulation ethernet-ccc;
    input-vlan-map {
      push;
      tag-protocol-id 0x8100;
      vlan-id 600;
    }
    output-vlan-map pop;
    family ccc;
  }
}
```

Example: push-push and pop-pop with Ethernet CCC Encapsulation

```
ge-3/1/0 {
  encapsulation ethernet-ccc;
  unit 0 {
    encapsulation ethernet-ccc;
    input-vlan-map {
      push-push;
      tag-protocol-id 0x8100;
      inner-tag-protocol-id 0x8100;
      vlan-id 600;
      inner-vlan-id 575;
    }
    output-vlan-map pop-pop;
    family ccc;
  }
}
```

Example: push and pop with Ethernet VPLS Encapsulation

```
ge-3/1/0 {
  encapsulation ethernet-vpls;
  unit 0 {
    encapsulation ethernet-vpls;
    input-vlan-map {
      push;
      tag-protocol-id 0x8100;
      vlan-id 700;
    }
    output-vlan-map pop;
    family vpls;
  }
}
```

Example: push-push and pop-pop with Ethernet VPLS Encapsulation

```
ge-3/1/0 {
  encapsulation ethernet-vpls;
  unit 0 {
    encapsulation ethernet-vpls;
    input-vlan-map {
      push-push;
      tag-protocol-id 0x8100;
      inner-tag-protocol-id 0x8100;
      vlan-id 600;
      inner-vlan-id 575;
    }
    output-vlan-map pop-pop;
    family vpls;
  }
}
```

Rewriting a VLAN Tag and Adding a New Tag

On Ethernet IQ, IQ2 and IQ2-E interfaces, on MX Series router Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces, on aggregated Ethernet interfaces using Gigabit Ethernet IQ2 and IQ2-E or 10-Gigabit Ethernet PICs on MX Series routers, and on Gigabit Ethernet and 10-Gigabit Ethernet interfaces on EX Series switches, to replace the outer VLAN tag of the incoming frame with a user-specified VLAN tag value, include the **swap-push** statement in the input VLAN map or output VLAN map:

```
swap-push
```

A user-specified outer VLAN tag is pushed in front. The outer tag becomes an inner tag in the final frame.

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number* input-vlan-map]
- [edit interfaces *interface-name* unit *logical-unit-number* output-vlan-map]

- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* input-vlan-map]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* output-vlan-map]

See Table 57 on page 567 and Table 58 on page 568 for information about configuring inner and outer VLAN ID values and inner and outer TPID values required for VLAN maps.

Rewriting the Inner and Outer VLAN Tags

On Ethernet IQ, IQ2 and IQ2-E interfaces, on MX Series router Gigabit Ethernet, Tri-Rate Ethernet copper, and 10-Gigabit Ethernet interfaces, and on aggregated Ethernet interfaces using Gigabit Ethernet IQ2 and IQ2-E or 10-Gigabit Ethernet PICs on MX Series routers, to replace both the inner and the outer VLAN tags of the incoming frame with a user-specified VLAN tag value, include the **swap-swap** statement in the input VLAN map or output VLAN map:

```
swap-swap;
```

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* unit *logical-unit-number* input-vlan-map]
- [edit interfaces *interface-name* unit *logical-unit-number* output-vlan-map]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* input-vlan-map]
- [edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* output-vlan-map]

See Table 57 on page 567 and Table 58 on page 568 for information about configuring inner and outer VLAN ID values and inner and outer TPID values required for VLAN maps.

- *Ethernet Interfaces Feature Guide for Routing Devices*

Understanding Transparent Tag Operations and IEEE 802.1p Inheritance

When **swap-by-poppush** is configured on IQ2 interfaces, 10-Gigabit Ethernet LAN/WAN PIC, IQ2-E interfaces, and MX Series interfaces, during a swap operation, the inner VLAN IEEE 802.1p bits are copied to the IEEE bits of the tag being swapped. If swap-by-poppush is not configured on the interface, the VLAN IEEE 802.1p bits of the tag being swapped remains same.

When **swap-by-poppush** is configured but the incoming packet has no inner VLAN tag (transparent tag), the IEEE 802.1p bits are set to zero .

Table 62 on page 585 describes the relationship between the VLAN map operation and the inheritance of IEEE 802.1p from the transparent tag. It assumes the presence of the transparent tag in the incoming packet. If the transparent tag is not present, the IEEE 802.1p value is set to 0.

Table 62: VLAN Map Operation and IEEE 802.1p Inheritance

Rewrite Operation	Untagged Logical Interface	Transparent tag IEEE 802.1p Inheritance	Single-tagged Logical Interface	Transparent tag IEEE 802.1p Inheritance	Change in number of tags
push-push	yes	OUTER, INNER	NA	no operation	+2
swap-push	NA	no operation	yes	OUTER, INNER	+1
push	yes	OUTER	yes	*none	+1
swap	NA	NA	yes	OUTER	0

Table 62: VLAN Map Operation and IEEE 802.1p Inheritance (continued)

Rewrite Operation	Untagged Logical Interface	Transparent tag IEEE 802.1p Inheritance	Single-tagged Logical Interface	Transparent tag IEEE 802.1p Inheritance	Change in number of tags
NOTE: *In a **push** operation on a single-tagged logical interface, none of the tags (inner, or outer) inherit the IEEE 802.1p bits from the transparent tag.					

The following section shows four different examples of the inheritance of the transparent IEEE 802.1p values into the outer and inner VLAN tags.

Figure 33 on page 586 shows an incoming packet with a transparent tag. A swap-push operation swaps the outer VLAN tag and pushes another VLAN tag. The IEEE 802.1p values are inherited from the transparent tag.

Figure 33: swap-push (transparent tag)

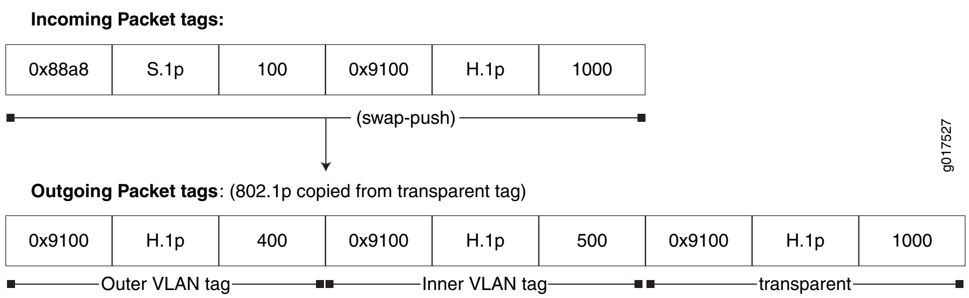

Figure 34 on page 586 shows an incoming packet with no transparent tag. A swap-push operation swaps the outer VLAN tag and pushes another VLAN tag. The IEEE 802.1p value is set to zero, as there is no transparent tag.

Figure 34: swap-push (no transparent tag)

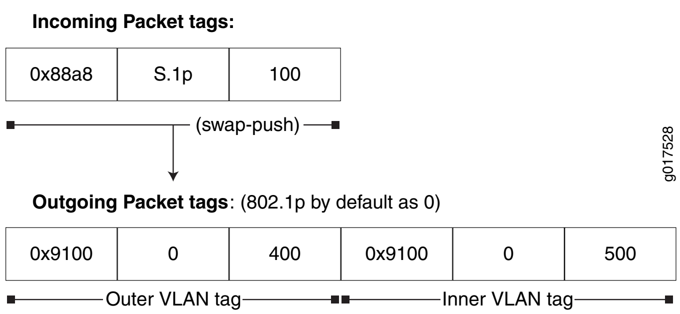

Figure 35 on page 587 shows an incoming packet with a transparent tag. A push operation pushes another VLAN tag. The IEEE 802.1p value is inherited from the transparent tag.

Figure 35: push (transparent tag)

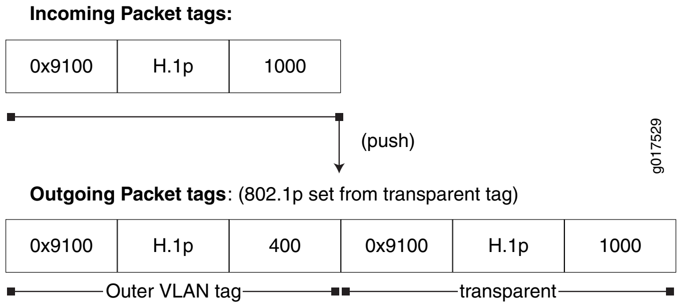

Figure 36 on page 587 shows an incoming packet with a transparent tag. A push-push operation pushes the outer and inner VLAN tags, respectively. The IEEE 802.1p values are inherited from the transparent tag.

Figure 36: push-push (transparent tag)

- Configuring IEEE 802.1p Inheritance push and swap from the Transparent Tag on page 588
- Understanding swap-by-poppush on page 587
- **swap-by-poppush on page 1379**
- *transparent*

Understanding swap-by-poppush

By default, during a swap operation, the IEEE 802.1p bits of the VLAN tag remain unchanged. When the **swap-by-poppush** operation is enabled on a logical interface, the swap operation is treated as a **pop** operation followed by **push** operation. The **pop** operation removes the existing tag and the associated IEEE 802.1p bits and the push operation copies the inner VLAN IEEE 802.1p bits to the IEEE bits of the VLAN or VLANs being pushed. As a result, the IEEE 802.1p bits are inherited from the incoming transparent tag.

In effect, **swap-by-poppush** serves as a VLAN operation property and is used along with a **swap** or **swap-push** VLAN rewrite operation, indicating the nature of the swap operation being performed.

Configuring IEEE 802.1p Inheritance push and swap from the Transparent Tag

To classify incoming packets based on the IEEE 802.1p bits from the transparent tag, include the **transparent** statement at the **[edit class-of-service interfaces** *interface-name* **unit** *logical-unit-number* **classifiers ieee-802.1 vlan-tag]** hierarchy level.

Tagged Interface Example

The following example configuration specifies the classification based on the transparent VLAN tag.

```
edit
class-of-service {
  interfaces {
    ge-3/0/1 {
      unit 0 {
        classifiers {
          ieee-802.1 default vlan-tag transparent;
        }
      }
    }
  }
}
```

To configure Junos OS to inherit the IEEE 802.1p bits from the transparent tag, include the **swap-by-poppush** statement at the **[edit interfaces** ***interface-name*** **unit** ***logical-unit-number*]** hierarchy level.

The following is a configuration to swap and push VLAN tags and allow inheritance of the IEEE 802.1p value from the transparent VLAN tag in incoming packets.

```
edit
  ge-3/0/0 {
  vlan-tagging;
  encapsulation vlan-ccc;
  unit 0 {
    encapsulation vlan-ccc;
    vlan-id 100;
    swap-by-poppush;
    input-vlan-map {
      swap-push;
      tag-protocol-id 0x9100;
      inner-tag-protocol-id 0x9100;
      vlan-id 500;
      inner-vlan-id 400;
    }
```

```
        output-vlan-map {
            pop-swap;
            inner-vlan-id 100;
            inner-tag-protocol-id 0x88a8;
        }
    }
}
```

The **swap-by-poppush** statement causes a swap operation to be done as a pop followed by a push operation. So for the outer tag, the incoming S-Tag is popped and a new tag is pushed. As a result, the S-Tag inherits the IEEE 802.1p bits from the transparent tag. The inner tag is then pushed, which results in the inner tag inheriting the IEEE 802.1p bits from the transparent tag.

Untagged Interface Example

The following is a configuration to push two VLAN tags and allow inheritance of the IEEE 802.1p value from the transparent VLAN tag in the incoming packet.

```
[edit]
ge-3/0/1 {
    encapsulation ccc;
    unit 0 {
        input-vlan-map {
            push-push;
            tag-protocol-id 0x9100;
            inner-tag-protocol-id 0x9100;
            vlan-id 500;
            inner-vlan-id 400;
        }
        output-vlan-map{
            pop-pop;
        }
    }
}
```

No additional configuration is required to inherit the IEEE 802.1p value, as the **push** operation inherits the IEEE 802.1p values by default.

The following configuration specifies the classification based on the transparent VLAN tag.

```
[edit]
class-of-service {
    interfaces {
        ge-3/0/1 {
            unit 0 {
                classifiers {
                    ieee-802.1 default vlan-tag transparent;
                }
            }
        }
    }
}
```

PART 3

Operation, Administration, and Management (OAM) for Ethernet Interfaces

CHAPTER 31

Configuring IEEE 802.1ag OAM Connectivity-Fault Management

Ethernet Operations, Administration, and Maintenance

This topic provides an overview to help you effectively configure Ethernet Operations, Administration, and Maintenance (OAM) on a network of Juniper Networks® MX Series 3D Universal Edge Routers. For more information about configuring OAM parameters on Ethernet interfaces, see the *Junos OS Network Interfaces Library for Routing Devices*.

Ethernet OAM provides the tools that network management software and network managers can use to determine how a network of Ethernet links is functioning. Ethernet OAM should:

- Rely only on the media access control (MAC) address or virtual local area network (VLAN) identifier for troubleshooting.
- Work independently of the actual Ethernet transport and function over physical Ethernet ports, or a virtual service such as pseudowire, and so on.
- Isolate faults over a flat (or single operator) network architecture or a nested or hierarchical (or multi-provider) network.

OAM can provide simple link-level information, provide performance statistics, or track end-to-end connectivity across the network. Simple link fault management (LFM) for Ethernet links is defined in IEEE 802.3ah.

IEEE 802.1ag OAM is supported on untagged, single tagged, and stacked VLAN interfaces.

Ethernet OAM functions are implemented as:

- Fault detection and notification (provided by continuity check messages)
- Path discovery (provided by the linktrace protocol)
- Fault isolation, verification, and recovery (isolation and verification are provided by a combination of protocols, while recovery is the function of protocols such as spanning tree)

The loopback protocol used in Ethernet OAM is modeled on the standard IP ping. After a fault is detected, the loopback protocol performs fault verification and isolation under the direction of a network operator.

The loopback is performed using request and response message pairs. A unicast loopback message is generated by a maintenance endpoint (MEP), and a loopback reply is generated by the destination maintenance intermediate point (MIP) or MEP.

The target MAC address is learned by the continuity check protocol or linktrace protocol. The loopback message's packet is always forwarded to a unique port by the originating MEP, as determined by a MAC table lookup or the MEP interface MAC address.

The target MIP or MEP generates a unicast loopback reply in response to the received loopback message. The loopback message follows the same path as a data packet, and intermediate bridges simply forward the packet to the destination MIP or MEP.

Ethernet OAM Connectivity Fault Management

The most complete connectivity fault management (CFM) is defined in IEEE 802.1ag. This topic emphasizes the use of CFM in a Metro Ethernet environment.

The major features of CFM are:

- Fault monitoring using the continuity check protocol. This is a neighbor discovery and health check protocol that discovers and maintains adjacencies at the VLAN or link level.
- Path discovery and fault verification using the linktrace protocol. Similar to IP traceroute, this protocol maps the path taken to a destination MAC address through one or more bridged networks between the source and destination.
- Fault isolation using the loopback protocol. Similar to IP ping, this protocol works with the continuity check protocol during troubleshooting.

CFM partitions the service network into various administrative domains. For example, operators, providers, and customers might be part of different administrative domains.

Each administrative domain is mapped into one maintenance domain providing enough information to perform its own management, thus avoiding security breaches and making end-to-end monitoring possible. Each maintenance domain is associated with a maintenance domain level from 0 through 7. Level allocation is based on the network hierarchy, where outermost domains are assigned a higher level than the innermost domains.

Customer end points have the highest maintenance domain level. In a CFM maintenance domain, each service instance is called a maintenance association. A *maintenance association* can be thought as a full mesh of maintenance endpoints (MEPs) having similar characteristics. MEPs are active CFM entities generating and responding to CFM protocol messages.

There is also a maintenance intermediate point (MIP), which is a CFM entity similar to the MEP, but more passive (MIPs only respond to CFM messages).

MEPs can be *up MEPs* or *down MEPs*. A link can connect a MEP at level 5 to a MEP at level 7. The interface at level 5 is an up MEP (because the other end of the link is at MEP level 7), and the interface at level 7 is a down MEP (because the other end of the link is at MEP level 5).

In a Metro Ethernet network, CFM is commonly used at two levels:

- By the service provider to check the connectivity among its provider edge (PE) routers
- By the customer to check the connectivity among its customer edge (CE) routers

NOTE: **The configured customer CFM level must be greater than service provider CFM level.**

In many Metro Ethernet networks, CFM is used to monitor connectivity over a VPLS and bridge network.

NOTE: **In ACX Series routers, VPLS is supported only on ACX5048 and ACX5096 routers.**

IEEE 802.1ag OAM Connectivity Fault Management Overview

Ethernet interfaces on M7i and M10i routers with the Enhanced CFEB (CFEB-E) and on M120, M320, MX Series, T Series, and PTX Series routers support the IEEE 802.1ag standard for Operation, Administration, and Management (OAM). The IEEE 802.1ag specification provides for Ethernet connectivity fault management (CFM). The goal of CFM is to monitor an Ethernet network that may comprise one or more service instances. Junos OS supports IEEE 802.1ag connectivity fault management.

NOTE: **MX Series Virtual Chassis does not support distributed inline connectivity fault management.**

ACX Series routers support CFM on aggregated Ethernet interfaces with continuity check interval of 100 milliseconds or higher.

In Junos OS Release 9.3 and later, CFM also supports aggregated Ethernet interfaces. Connectivity fault management (CFM) sessions operate in distributed mode and are processed on the Flexible PIC Concentrator (FPC) on aggregated Ethernet interfaces. As a result, graceful Routing Engine switchover (GRES) is supported on aggregated Ethernet interfaces. In releases before Junos OS Release 13.3, CFM sessions operate in centralized mode and are processed on the Routing Engine. However, CFM sessions are not supported on aggregated Ethernet interfaces if the interfaces that form the aggregated Ethernet bundle are in mixed mode. CFM sessions with a continuity check message (CCM) interval of 10 milliseconds are not supported over aggregated Ethernet interfaces.

CFM sessions are distributed by default. All CFM sessions must operate in either only distributed or only centralized mode. A mixed operation of distributed and centralized modes for CFM sessions is not supported. To disable the distribution of CFM sessions on aggregated Ethernet interfaces and make the sessions operate in centralized mode, include the **no-aggregate-delegate-processing** statement at the **[edit protocols oam ethernet connectivity-fault-management]** hierarchy level.

NOTE: As a requirement for Ethernet OAM 802.1ag to work, distributed periodic packet management (PPM) runs on the Routing Engine and Packet Forwarding Engine. You can only disable PPM on the Packet Forwarding Engine. To disable PPM on the PFE, include the **ppm no-delegate-processing** statement at the **[edit routing-options ppm]** hierarchy level.

NOTE:

- CFM sessions are supported on aggregated Ethernet interfaces if the interfaces that form the aggregated Ethernet bundle are in mixed mode when the **no-aggregate-delegate-processing** command is enabled.
- Starting in Junos OS Release 14.2, , for CFM sessions in centralized mode, we recommend that you configure a maximum of 40 CFM sessions with continuity check message (CCM) interval of 100 milliseconds (100 ms) or a maximum of 400 CFM sessions with CCM interval of 1 second (1 s). If CFM sessions are configured beyond this limit, CFM might not work as expected. You might observe issues when the state of multiple links change or when the line cards are restarted.

  Note that these limits have been derived by considering a protocol data unit (PDU) load of 400 packets per second (pps) on the Routing Engine. This limit varies depending on the Routing Engine load. If the Routing Engine experiences heavy load, expect some variations to this limit.

Starting in Junos OS Release 10.3, on interfaces configured on Modular Port Concentrators (MPCs) and Modular Interface Cards (MICs) on MX Series routers, CFM is not supported on untagged aggregated Ethernet member links. MPCs and MICs do support CFM on untagged and tagged aggregated Ethernet logical interfaces.Starting in Junos OS Release 12.3, CFM does not support Multichassis Link Aggregation (MC-LAG). Do not configure the **mc-ae** statement when you configure CFM.

Starting in Junos OS Release 11.3, on T Series and M320 routers, CFM is not supported on interfaces configured with CCC encapsulation. If you configure CFM, the system displays the following message: “**MEPs cannot be configured on ccc interface on this platform**”.

Network entities such as operators, providers, and customers may be part of different administrative domains. Each administrative domain is mapped into one maintenance domain. Maintenance domains are configured with different level values to keep them separate. Each domain provides enough information for the entities to perform their own management, perform end-to-end monitoring, and still avoid security breaches.

Starting in Junos OS Release 17.4, you can enable support for IEEE 802.1ag CFM on pseudowire service interfaces by configuring maintenance intermediate points (MIPs) on the pseudowire service interfaces. Pseudowire service interfaces support configuring of subscriber interfaces over MPLS pseudowire termination. Termination of subscriber interfaces over PW enables network operators to extend their MPLS domain from the Access/Aggregation network to the service edge and use uniform MPLS label provisioning for a larger portion of their network.

NOTE: The CFM MIP session is supported only on the pseudowire services interface and not on the pseudowire services tunnel interface.

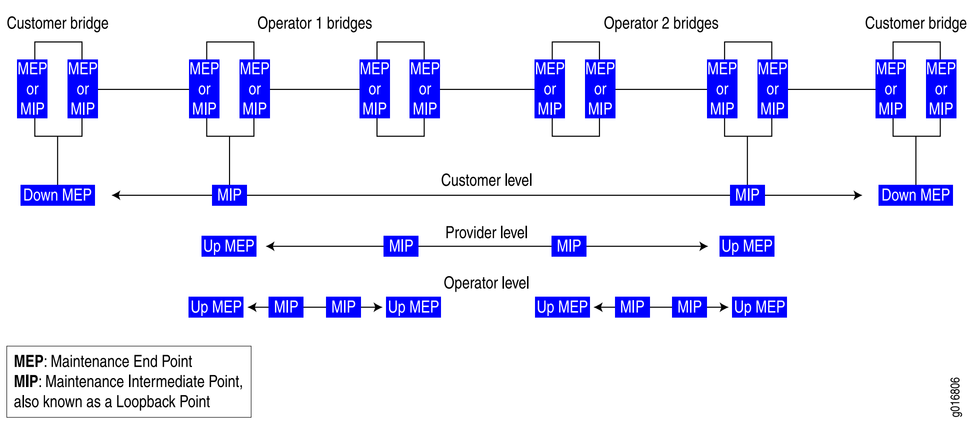
IEEE 802.1ag OAM supports graceful Routing Engine switchover (GRES). IEEE 802.1ag OAM is supported on untagged, single tagged, and stacked VLAN interfaces.

- Connectivity Fault Management Key Elements on page 598
- Best Practices for Configuring 802.1ag Ethernet OAM for VPLS on page 599

Connectivity Fault Management Key Elements

Figure 37 on page 598 shows the relationships among the customer, provider, and operator Ethernet bridges, maintenance domains, maintenance association end points (MEPs), and maintenance intermediate points (MIPs).

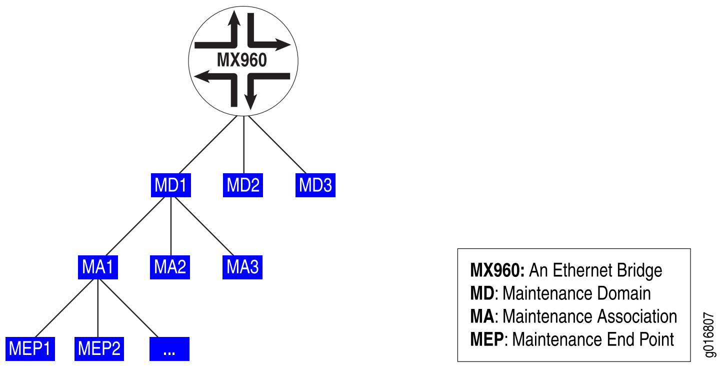
Figure 37: Relationship Among MEPs, MIPs, and Maintenance Domain Levels



NOTE: On ACX Series routers, the maintenance intermediate points (MIP) are supported only on the ACX5048 and ACX5096 routers.

A maintenance association is a set of MEPs configured with the same maintenance association identifier and maintenance domain level. Figure 38 on page 599 shows the hierarchical relationships between the Ethernet bridge, maintenance domains, maintenance associations, and MEPs.

Figure 38: Relationship Among Bridges, Maintenance Domains, Maintenance Associations, and MEPs



Best Practices for Configuring 802.1ag Ethernet OAM for VPLS

BEST PRACTICE: The logical interfaces in a VPLS routing instance may have the same or different VLAN configurations. VLAN normalization is required to switch packets correctly among these interfaces. VLAN normalization is effectively VLAN translation wherein the VLAN tags of the received packet need to be translated if they are different than the normalized VLAN tags. Configuration is described starting in "IEEE 802.1ag OAM Connectivity Fault Management Overview" on page 596 and you should further observe the additional requirements described in this section.

For MX Series routers, the normalized VLAN is specified using one of the following configuration statements in the VPLS routing instance:

- vlan-id *vlan-number*
- vlan-id none
- vlan-tags outer *outer-vlan-number* inner *inner-vlan-number*

You must configure vlan-maps explicitly on all interfaces belonging to the routing instance.

The following forwarding path considerations must be observed:

- Packet receive path:

- This is the forwarding path for packets received on the interfaces.
- 802.1ag Ethernet OAM for VPLS uses implicit interface filters and forwarding table filters to flood, accept, and drop the CFM packets.

- Packet transmit path:
  - The JUNOS Software uses the router's hardware-based forwarding for CPU-generated packets.
  - For Down MEPs, the packets are transmitted on the interface on which the MEP is configured.
  - In MX series routers, for Up MEPs, the packet must be flooded to other interfaces in the VPLS routing instance. The router creates a flood route tied to a flood next hop (with all interfaces to flood) and then sources the packet to be forwarded with this flood route.
  - The router also uses implicit-based forwarding for CPU generated packets. The result is for the flood next hop tied to the flood route to be tied to the filter term. The filter term uses match criteria to correctly identify the host- generated packets.

Release History Table

Release	Description
17.4R1	Starting in Junos OS Release 17.4, you can enable support for IEEE 802.1ag CFM on pseudowire service interfaces by configuring maintenance intermediate points (MIPs) on the pseudowire service interfaces.
14.2	Starting in Junos OS Release 14.2, , for CFM sessions in centralized mode, we recommend that you configure a maximum of 40 CFM sessions with continuity check message (CCM) interval of 100 milliseconds (100 ms) or a maximum of 400 CFM sessions with CCM interval of 1 second (1 s).
12.3	Starting in Junos OS Release 12.3, CFM does not support Multichassis Link Aggregation (MC-LAG). Do not configure the **mc-ae** statement when you configure CFM.
11.3	Starting in Junos OS Release 11.3, on T Series and M320 routers, CFM is not supported on interfaces configured with CCC encapsulation.
10.3	Starting in Junos OS Release 10.3, on interfaces configured on Modular Port Concentrators (MPCs) and Modular Interface Cards (MICs) on MX Series routers, CFM is not supported on untagged aggregated Ethernet member links. MPCs and MICs do support CFM on untagged and tagged aggregated Ethernet logical interfaces.
9.3	In Junos OS Release 9.3 and later, CFM also supports aggregated Ethernet interfaces.

Junos OS Support for Performance Monitoring Compliant with Technical Specification MEF 36

Junos OS release 16.1R1 and later supports performance monitoring that is compliant with Technical Specification MEF 36. Technical Specification MEF 36 specifies the performance monitoring MIB. The performance monitoring MIB is required to manage service operations, administration, and maintenance (OAM) implementations that satisfy the Service OAM requirements and framework specified in MEF 17 and MEF 35, the management objects specified in MEF 7.1, and the performance monitoring functions defined in ITU-T Y.1731 and IEEE 802.1ag.

You can enable MEF-36-compliant performance monitoring by configuring the measurement-interval statement at the **[edit protocols oam ethernet cfm performance-monitoring]** hierarchy level.

When MEF-36-compliant performance monitoring is enabled:

- An SNMP get next request for a variable might not fetch the current value unless an SNMP walk is performed before performing the get next request. This limitation applies only to the current statistics for delay measurement, loss measurement, and synthetic loss measurement.
- The output for the field **Current delay measurement statistics** might display a measurement interval of 0 (zero) and an incorrect timestamp until the first cycle time has expired.
- Supported data TLV size for performance monitoring protocol data units (PDUs) is 1386 bytes when MEF-36-compliant performance monitoring is enabled. The TLV size is 1400 bytes in legacy mode.
- The maximum configurable value for the lower threshold bin is 4,294,967,294.

- Frame loss ratio (FLR) is excluded in loss measurements during period of unavailability for synthetic loss measurement only. In case of loss measurement, FLR is included even during period of unavailability.
- During a period of loss of continuity (adjacency down), although SOAM PDUs are not sent, FLR and availability calculations are not stopped. These calculations are performed with the assumption of 100% loss.
- The number of SOAM PDUs that are sent during the first measurement interval might be less than expected. This is because of a delay in detecting the adjacency state at the performance monitoring session level.
- The number of SOAM PDUs transmitted during a measurement interval for a cycle time of 100 ms might not be accurate. For example, in a measurement interval of two minutes with a cycle time 100 ms, the SOAM PDUs transmitted might be in the range of 1198—2000.

Junos OS Support for Chassis ID TLV

In Release 16.1R2 and later, you can configure Junos OS to send the sender ID TLV along with the packets. The sender ID TLV is an optional TLV that is sent in continuity check messages (CCMs), loopback messages, and Link Trace Messages (LTMs), as specified in the IEEE 802.1ag standard. The sender ID TLV contains the chassis ID, which is the unique, CFM-based MAC address of the device, and the management IP address, which is an IPv4 or an IPv6 address.

The value of the **length** field in the TLV indicates whether or not the TLV contains the chassis ID information. The possible values for the **length** field are zero (**0**) or any valid number, which indicates the absence or presence of chassis ID information in the TLV, respectively.

You can enable Junos OS to send the sender ID TLV at the global level by using the **set protocols oam ethernet connectivity-fault-management sendid-tlv send-chassis-tlv** command. If the sender ID TLV is configured at the global level, then the default maintenance domain, maintenance association, and the maintenance association intermediate point (MIP) half function inherit this configuration.

You can also configure the sender ID TLV at the following hierarchy levels:

- **[edit protocols oam ethernet connectivity-fault-management]**.
- **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *maintenance-domain-name* maintenance-association *maintenance-association-name* continuity-check]**.

The sender ID TLV configuration at the maintenance-association level takes precedence over the global-level configuration.

NOTE: The sender ID TLV is supported only for 802.1ag PDUs and is not supported for performance monitoring protocol data units (PDUs).

Release History Table

Release	Description
16.1	In Release 16.1R2 and later, you can configure Junos OS to send the sender ID TLV along with the packets.

Creating a Maintenance Domain

To enable connectivity fault management (CFM) on an Ethernet interface, you must first configure a maintenance domain and specify the name of the maintenance domain. You can also specify the format of the name. For instance, if you specify the name format to be domain name service (DNS) format, you can specify the name of the maintenance domain as www.juniper.net. The default name format is ASCII character string.

NOTE: For logical interfaces, the maintenance domain name must be unique across logical systems. If you configure the same maintenance domain name across logical systems, then you receive the following error message: **error: configuration check-out failed.**

During the creation of the maintenance domain, you can also specify the maintenance domain level. The maintenance domain level indicates the nesting relationship between various maintenance domains. The maintenance domain level is embedded in each of the CFM frames.

To create a maintenance domain:

1. In configuration mode, create a maintenance domain by specifying the name and the name format at the [**edit protocols oam ethernet connectivity-fault-management**] hierarchy level.

   ```
   [edit protocols oam ethernet connectivity-fault-management]
   user@host# set maintenance-domain md-name name-format option
   ```

   NOTE: If you configure the maintenance domain name length greater than 45 octet, then the following error message is displayed: **error: configuration check-out failed.**

2. Specify the maintenance domain level by specifying the value at the [**edit protocols oam ethernet connectivity-fault-management**] hierarchy level.

   ```
   [edit protocols oam ethernet connectivity-fault-management]
   user@host# set maintenace-domain md-name level number
   ```

Configuring Maintenance Intermediate Points (MIPs)

MX Series routers support maintenance intermediate points (MIPs) for the Ethernet OAM 802.1ag CFM protocol at a bridge-domain level. This enables you to define a maintenance domain for each default level. The MIPs names are created as **default-*level-number*** at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain]** hierarchy level. Use the **bridge-domain**, **instance**, **virtual-switch**, and **mip-half-function** MIP options to specify the MIP configuration.

Use the **show oam ethernet connectivity-fault-management mip (bridge-domain | instance-name | interface-name)** command to display the MIP configurations.

To configure the maintenance intermediate point (MIP):

1. Configure a bridge domain under a user-defined virtual switch by specifying the **virtual-switch** statement and the name of the user-defined virtual switch, at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* default-*x*]** hierarchy level.

NOTE: A bridge domain must be specified by name only if it is configured by including the **vlan-id** statement under the **virtual-switch** statement. If a bridge domain is configured with a range of VLAN IDs, then the VLAN IDs must be explicitly listed after the bridge domain name.

[edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* default-*x*]
user@host# set virtual-switch *virtual-switch-name* bridge-domain *bridge-domain-name* vlan-id *value*

NOTE: You can also configure the bridge domain for the default virtual switch by including the **bridge-domain** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name*]** hierarchy level.

2. Configure the VPLS routing instance for the default maintenance domain.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name*]
   user@host# set instance *instance-name*

3. Configure the maintenance intermediate point (MIP) half function to divide the MIP fuctionality into two unidirectional segments to improve network coverage by increasing the number of MIPs that are monitored. The MIP half function also responds to loop-back and link-trace messages to identify faults.

   NOTE: Whenever a MIP is configured and a bridge domain is mapped to multiple maintenance domains or maintenance associations, it is essential that the **mip-half-function** value for all maintenance domains and maintenance associations be the same.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* default- *x*]
   user@host# set mip-half-function (none | default | explicit)

Configuring Maintenance Association Intermediate Points in ACX Series

Maintenance Intermediate Point (MIP) provides monitoring capability of intermediate points for services such as Layer 2 bridging, Layer 2 circuit, and Layer 2 VPN. ACX5048 and ACX5096 routers support MIPs for the Ethernet OAM 802.1ag CFM protocol. Use the bridge-domain, interface, and mip-half-function MIP options to specify the MIP configuration.

NOTE: ACX5048 and ACX5096 routers do not support MIP configuration on VPLS services.

NOTE: Whenever a MIP is configured and a bridge domain is mapped to multiple maintenance domains or maintenance associations, it is essential that the **mip-half-function** value for all maintenance domains and maintenance associations be the same.

To display MIP configurations, use the **show oam ethernet connectivity-fault-management mip (bridge-domain | instance-name | interface-name)** command.

The following MIP configurations are supported in ACX5048 and ACX5096 routers:

- MIP with with bridge domain
- MIP with circuit cross-connect (CCC)
- MIP with bridge domain when maintenance association end point is configured
- MIP with CCC when maintenance association end point is configured

The following sections describe MIP configuration:

Configuring the Maintenance Domain Bridge Domain

To configure the bridge domain, include the **vlans** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain** ***maintenance-domain-name*****]** hierarchy level.

NOTE: The Layer 2 CLI configurations and show commands for ACX5048 and ACX5096 routers differ compared to other ACX Series routers. For more information, see *Understanding Layer 2 Next Generation Mode on ACX Series Routers*.

Configuring the Maintenance Domain MIP Half Function

MIP Half Function (MHF) divides MIP functionality into two unidirectional segments, improves visibility with minimal configuration, and improves network coverage by increasing the number of points that can be monitored. MHF extends monitoring capability by responding to loopback and linktrace messages to help isolate faults.

Whenever a MIP is configured and a bridge domain is mapped to multiple maintenance domains or maintenance associations, it is essential that the *MIP half function* value for all maintenance domains and maintenance associations be the same. To configure the MIP half function, include the mip-half-function statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain** ***maintenance-domain-name*****]** hierarchy level.

Configuring the Maintenance Association Intermediate Points with Bridge Domain

In ACX5048 and ACX5096 routers, you can configure the MIP with bridge domain. The following is a sample to configure the MIP with bridge domain:

```
[edit protocols]
oam {
  ethernet {
    connectivity-fault-management {
      maintenance-domain default-6 {
        vlan bd1;
```

```
                mip-half-function default;
            }
        }
    }
}
```

Configuring the Maintenance Association Intermediate Points with Circuit Cross-Connect

In ACX5048 and ACX5096 routers, you can configure the MIP with circuit cross-connect (CCC). The following is a sample to configure the MIP with CCC:

```
[edit protocols]
oam {
    ethernet {
        connectivity-fault-management {
            maintenance-domain default-6 {
                interface xe-0/0/42.0;
                mip-half-function default;
            }
        }
    }
}
```

Configuring the Maintenance Association Intermediate Points with Bridge Domain when Maintenance Association End Point is Configured

In ACX5048 and ACX5096 routers, you can configure the MIP with bridge domain when a maintenance association end point (MEP) is configured. The following is a sample to configure the MIP with bridge domain when MEP is configured:

```
[edit protocols]
oam {
    ethernet {
        connectivity-fault-management {
            maintenance-domain md2 {
                level 5;
                mip-half-function default;
                maintenance-association ma2 {
                    continuity-check {
                        interval 1s;
                    }
                    mep 222 {
                        interface xe-0/0/42.0;
                        direction up;
                    }
                }
            }
        }
    }
}
```

Configuring the Maintenance Intermediate Points with Circuit Cross-Connect when Maintenance Association End Point is Configured

In ACX5048 and ACX5096 routers, you can configure the MIP with circuit cross-connect (CCC) when a maintenance association end point (MEP) is configured. The following is a sample to configure the MIP with CCC when MEP is configured:

```
[edit protocols]
oam {
   ethernet {
      connectivity-fault-management {
         maintenance-domain md2 {
            level 5;
            mip-half-function default;
            maintenance-association ma2 {
               continuity-check {
                  interval 1s;
               }
               mep 222 {
                  interface xe-0/0/42.0;
                  direction up;
               }
            }
         }
      }
   }
}
```

Creating a Maintenance Association

To create a maintenance association, include the **maintenance-association *ma-name*** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name*]** hierarchy level.

Maintenance association names can be in one of the following formats:

- As a plain ASCII character string
- As the VLAN identifier of the VLAN you primarily associate with the maintenance association
- As a two-octet identifier in the range from 0 through 65,535
- As a name in the format specified by RFC 2685

The default short name format is an ASCII character string.

To configure the maintenance association short name format, include the **short-name-format (character-string | vlan | 2octet | rfc-2685-vpn-id)** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name*]** hierarchy level.

Continuity Check Protocol Parameters Overview

The continuity check protocol is used for fault detection by maintenance end points (MEPs) within a maintenance association. The MEP periodically sends continuity check multicast messages. The continuity check protocol packets use the ethertype value 0x8902 and the multicast destination MAC address 01:80:c2:00:00:32.

The following list describes the continuity check protocol parameters you can configure:

- **interval**—Frequency of the continuity check messages (CCM) i.e time between the transmission of the CCM messages. You can specify 10 minutes (**10m**), 1 minute (**1m**), 10 seconds (**10s**), 1 second (**1s**), 100 milliseconds (**100ms**), or 10 milliseconds (**10ms**). The default value is 1 minute. For instance, if you specify the interval as 1 minute, the MEP sends the continuity check messages every minute to the receiving MEP.

  NOTE: For the continuity check message interval to be configured for 10 milliseconds, periodic packet management (PPM) runs on the Routing Engine and Packet Forwarding Engine by default. You can only disable PPM on the Packet Forwarding Engine. To disable PPM on the Packet Forwarding Engine, use the **no-delegate-processing** statement at the **[edit routing-options ppm]** hierarchy level.

  Continuity check interval of 10 milliseconds is not supported for CFM sessions over a label-switched interface (LSI).

- **hold-interval**—Frequency at which the MEP database can be flushed, if no updates occur. Receiving MEPs use the continuity check messages to build a MEP database of all MEPs in the maintenance association. The frequency is the number of minutes to wait before flushing the MEP database if no updates occur. The default value is 10 minutes.

  NOTE: Hold timer based flushing is applicable only for autodiscovered remote MEPs and not for statically configured remote MEPs.

  The hold interval logic runs a polling timer per CFM session level (not per remote MEP level) where the polling timer duration is equal to the configured hold time. When the polling timer expires, it deletes all the autodiscovered remote MEP entries which have been in the failed state for a time period equal to or greater than the configured hold time. If the remote MEP completes the hold time duration in the failed state, then flushing will not occur until the next polling timer expires. Hence remote MEP flushing may not happen exactly at the configured hold time.

- **loss-threshold**—Number of continuity check messages that can be lost before the router marks the MEP as down. The value can be from 3 to 256 protocol data units (PDUs). The default value is 3 PDUs.

Configuring Continuity Check Protocol Parameters for Fault Detection

The continuity check protocol is used for fault detection by a maintenance association end point (MEP) within a maintenance association. A MEP periodically generates and responds to continuity check multicast messages. The continuity check protocol packets use the ethertype value 0x8902 and the multicast destination MAC address 01:80:c2:00:00:32. The receiving MEPs use the continuity check messages (CCMs) to build a MEP database of all MEPs in the maintenance association.

To configure continuity check protocol parameters:

1. Specify the time to wait in minutes before flushing the MEP database, if no updates occur, with a value from 1 minute through 30,240 minutes. The default value is 10 minutes.

   NOTE: **Flushing based on the hold timer is applicable only for autodiscovered remote MEPs and not for statically configured remote MEPs.**

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* continuity-check]
   user@host# set hold-interval *minutes*

2. Specify the time to wait (duration) between the transmissions of CCMs. The duration can be one of the following values: 10 minutes (10m), 1 minute (1m), 10 seconds (10s),

1 second (1s), 100 milliseconds (100ms), or 10 milliseconds (10ms). The default value is 1 minute.

[edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* continuity-check]
user@host# set interval *duration*

3. Specify the number of continuity check messages that can be lost before the router marks the MEP as down. The value can be from 3 to 256 protocol data units (PDUs). The default value is 3 PDUs.

[edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* continuity-check]
user@host# set loss-threshold *number*

Configuring a MEP to Generate and Respond to CFM Protocol Messages

A maintenance association end point (MEP) refers to the boundary of a domain. A MEP generates and responds to connectivity fault management (CFM) protocol messages. You can configure multiple up MEPs for a single combination of maintenance association ID and maintenance domain ID for interfaces belonging to a particular VPLS service or a bridge domain. You can configure multiple down MEPs for a single instance of maintenance domain identifier and maintenance association name to monitor services provided by Virtual Private LAN service (VPLS), bridge domain, circuit cross-connect (CCC), or IPv4 domains.

For layer 2 VPNs routing instances (local switching) and EVPN routing instances, you can also configure multiple up MEPs for a single combination of maintenance association ID and maintenance domain ID on logical interfaces.. The logical interface can be configured on different devices or on the same device. To support multiple up MEPs on two IFLs, enhanced IP network services must be configured for the chassis.

You can enable automatic discovery of a MEP. With automatic discovery a MEP is enabled to accept continuity check messages (CCMs) from all remote MEPs of the same maintenance association. if automatic discovery is not enabled, the remote MEPs must be configured. If the remote MEP is not configured, the CCMs from the remote MEP are treated as errors.

Continuity measurement is provided by an existing continuity check protocol. The continuity for every remote MEP is measured as the percentage of time that remote MEP was operationally up over the total administratively enabled time. Here, the operational uptime is the total time during which the CCM adjacency is active for a particular remote MEP and the administrative enabled time is the total time during which the local MEP is active. You can also restart the continuity measurement by clearing the currently measured operational uptime and the administrative enabled time.

- Configuring a Maintenance Association End Point (MEP) on page 614
- Configuring a remote Maintenance Association End Point (MEP) on page 616

Configuring a Maintenance Association End Point (MEP)

To configure a maintenance association end point:

1. Specify an ID for the MEP at the [**edit protocols oam ethernet connectivity-fault-management maintenance-domain** ***domain-name*** **maintenance-association** ***ma-name***]. You can specify any value from 1 through 8191.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name*]
   user@host# set mep *mep-id*

2. Enable maintenance end point automatic discovery so the MEP can accept continuity check messages (CCMs) from all remote MEPs of the same maintenance association.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name* mep *mep-id*]
   user@host# set auto-discovery

3. Specify the direction in which the CCM packets are transmitted for the MEP. You can specify up or down. If you specify the direction as up, CCMs are transmitted out of every logical interface that is part of the same bridging or VPLS instance except for the interface configured on the MEP. If you specify the direction as down, CCMs are transmitted only out of the interface configured on the MEP.

NOTE: Ports in the Spanning Tree Protocol (STP) blocking state do not block CFM packets destined to a down MEP. Ports in an STP blocking state without the continuity check protocol configured do block CFM packets.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  domain-name maintenance-association ma-name mep mep-id]
user@host# set direction down
```

NOTE: Starting with Junos OS Release 12.3, for all interfaces configured on Modular Port Concentrators (MPCs) on MX Series 3D Universal Edge Routers, you no longer need to configure the **no-control-word** statement for all Layer 2 VPNs and Layer 2 circuits over which you are running CFM MEPs. For all other interfaces on MX Series routers and on all other routers and switches, you must continue to configure the **no-control-word** statement at the **[edit routing-instances *routing-instance-name* protocols l2vpn]** or **[edit protocols l2circuit neighbor *neighbor-id* interface *interface-name*]** hierarchy level when you configure CFM MEPs. Otherwise, the CFM packets are not transmitted, and the **show oam ethernet connectivity-fault-management mep-database** command does not display any remote MEPs.

4. Specify the interface to which the MEP is attached. It can be a physical interface, logical interface, or trunk interface. On MX Series routers, the MEP can be attached to a specific VLAN of a trunk interface.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  domain-name maintenance-association ma-name mep mep-id]
user@host# set interface interface-name
```

5. Specify the IEEE 802.1 priority bits that are used by continuity check and link trace messages. You can specify a value from through 7 as the priority.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  domain-name maintenance-association ma-name mep mep-id]
user@host# set priority number
```

6. Specify the lowest priority defect that generates a fault alarm whenever CFM detects a defect. Possible values include: all -defects, err-xcon, mac-rem-err-xcon, no-defect, rem-err-xcon, and xcon.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  domain-name maintenance-association ma-name mep mep-id]
user@host# set lowest-priority-defect mac-rem-err-xcon
```

7. Specify the ID of the remote MEP at the [**edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name***

maintenance-association *ma-name* mep *mep-id*]. You can specify any value from 1 through 8191.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  domain-name maintenance-association ma-namemep mep-id]
user@host# set remote-mep mep-id
```

Configuring a remote Maintenance Association End Point (MEP)

To configure a remote maintenance association end point:

1. Configure the remote MEP by specifying the MEP ID at the [**edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name* mep *mep-id***]. You can specify any value from 1 through 8191.

   ```
   [edit protocols oam ethernet connectivity-fault-management maintenance-domain
     domain-name maintenance-association ma-namemep mep-id]
   user@host# edit remote-mep mep-id
   ```

2. Specify the name of the action profile to be used for the remote MEP by including the **action-profile *profile-name*** statement at the [**edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name* mep *mep-id* remote-mep *remote-mep-id***]. The profile must be defined at the [**edit protocols oam ethernet connectivity-fault-management**] hierarchy level.

   ```
   [edit protocols oam ethernet connectivity-fault-management maintenance-domain
     domain-name maintenance-association ma-namemep mep-id remote-mep
     remote-mep-id]
   user@host# set action-profile profile-name
   ```

3. Configure the remote MEP to detect initial loss of connectivity. By default, the MEP does not generate loss-of-continuity (LOC) defect messages. When you configure the **detect-loc** statement, a loss-of-continuity (LOC) defect is detected if no continuity check message is received from the remote MEP within a period equal to 3.5 times the continuity check interval configured for the maintenance association. If a LOC defect is detected, a syslog error message is generated.

NOTE: When you configure connectivity-fault management (CFM) along with **detect-loc**, any **action-profile** configured to bring down the interface is executed if continuity check message is not received . However, the **action-profile** is not executed if you have not configured **detect-loc** and continuity check message is not received.

[edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name*mep *mep-id* remote-mep *remote-mep-id*]
user@host# set detect-loc

Configuring MEP Interfaces to Support Ethernet Frame Delay Measurements

Ethernet frame delay measurement is a useful tool for providing performance statistics or supporting or challenging Service Level Agreements (SLAs). By default, Ethernet frame delay measurement uses software for timestamping and delay calculations. You can optionally use hardware timing to assist in this process and increase the accuracy of the delay measurement results. This assistance is available on the reception path.

Before you can perform Ethernet frame delay measurements on MX Series routers, you must have done the following:

- Configured Ethernet OAM and CFM correctly
- Prepared the measurement between two compatibly configured MX Series routers
- Enabled the distributed periodic packet management daemon (ppmd)
- Avoided trying to perform Ethernet frame delay measurement on aggregated Ethernet or pseudowire interfaces, which are not supported
- Made sure the hardware-assisted timestamping is supported if that feature is configured

At the end of this configuration, you create two MX Series routers that can perform and display Ethernet frame delay measurements on Ethernet interfaces using optional hardware timestamping. By default, Ethernet frame delay measurement uses software for timestamping and delay calculations. You can optionally use hardware timing to assist in this process and increase the accuracy of the delay measurement results. This assistance is available on the reception path.

To configure hardware-assisted timestamping:

1. To enable Ethernet frame delay measurement hardware assistance on the reception path, include the **hardware-assisted-timestamping** statement at the **[edit protocols oam ethernet connectivity-fault-management performance-monitoring]** hierarchy level:

   ```
   [edit]
   protocols {
     oam {
       ethernet {
         connectivity-fault-management {
           performance-monitoring {
             hardware-assisted-timestamping; # Enable timestamping in hardware.
           }
         }
       }
     }
   ```

2. Ethernet frame delay measurement requires that distributed PPMD is enabled. Before you can gather statistics for Ethernet frame delay measurement, you must make sure that PPMD is configured properly. Without distributed PPMD, delay measurement results are not valid.

To perform Ethernet frame delay measurement, make sure that the following configuration statement is *NOT* present:

```
[edit routing-options]
ppm {
   no-delegate-processing; # This turns distributed PPMD OFF.
}
```

Configuring Service Protection for VPWS over MPLS Using the MEP Interface

You can enable service protection for a virtual private wire service (VPWS) over MPLS by specifying a working path or protect path on the MEP. Service protection provides end-to-end connection protection of the working path in the event of a failure.

To configure service protection, you must create two separate transport paths—a working path and a protect path. You can specify the working path and protect path by creating two maintenance associations. To associate the maintenance association with a path, you must configure the **interface** statement for the MEP within the maintenance association and specify the path as working or protect.

NOTE: **If the path is not specified, the session monitors the active path.**

Table 63 on page 620 describes the available service protection options.

Table 63: Service Protection Options

Option	Description
working	Specifies the working path.
protect	Specifies the protect path.

In this configuration, we enable service protection for the VPWS service. The CCM session is configured for the working path and references the CCM session configured for the protect path using the **protect-maintenance-association** statement. The name of the protect transport path for the maintenance association is configured and associated with the maintenance association for the working path.

To configure service protection for VPWS over MPLS:

1. In configuration mode, create a maintenance domain by specifying the name and the name format at the [**edit protocols oam ethernet connectivity-fault-management**] hierarchy level.

   ```
   [edit protocols oam ethernet connectivity-fault-management]
   user@host# set maintenance-domain md-name name-format option
   ```

   NOTE: **If you configure the maintenance domain name length greater than 45 octet, then the following error message is displayed: error: configuration check-out failed.**

2. Specify the maintenance domain level by specifying the value at the [**edit protocols oam ethernet connectivity-fault-management**] hierarchy level.

   ```
   [edit protocols oam ethernet connectivity-fault-management]
   ```

user@host# set maintenace-domain *md-name* level *number*

3. Create a maintenance association for the working path by specifying the name and the short name format at the [**edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name***] hierarchy level.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name*]
   user@host# set maintenance-association test-ma short-name-format *option*

4. Specify the maintenance association name used for connection protection and the name of the automatic-protection-switching profile (aps-profile) at the [**edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name***] hierarchy level.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name*]
   user@host# set protect-maintenance-association *ma-name* aps-profile *aps-profile-name*

5. Specify the time to wait between transmissions of continuity check messages at the [**edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* continuity-check**] hierarchy level. The duration can be one of the following values: 10 minutes(10m), 1 minute(1m), 10 seconds(10s), 1 second(1s), 100 milliseconds(100ms), or 10 milliseconds(10ms). The default value is 1 minute.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* continuity-check]
   user@host# set interval option

6. Specify an ID for the MEP at the [**edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name***]. You can specify any value from 1 through 8191.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name*]
   user@host# set mep *mep-id*

7. Enable maintenance end point automatic discovery so the MEP can accept continuity check messages (CCMs) from all remote MEPs of the same maintenance association.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name* mep *mep-id*]
   user@host# set auto-discovery

8. Specify the direction in which the CCM packets are transmitted for the MEP. You can specify up or down. If you specify the direction as up, CCMs are transmitted out of every logical interface that is part of the same bridging or VPLS instance except for the interface configured on the MEP. If you specify the direction as down, CCMs are transmitted only out of the interface configured on the MEP.

NOTE: Ports in the Spanning Tree Protocol (STP) blocking state do not block CFM packets destined to a down MEP. Ports in an STP blocking state without the continuity check protocol configured do block CFM packets.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  domain-name maintenance-association ma-name mep mep-id]
user@host# set direction down
```

NOTE: Starting with Junos OS Release 12.3, for all interfaces configured on Modular Port Concentrators (MPCs) on MX Series 3D Universal Edge Routers, you no longer need to configure the **no-control-word** statement for all Layer 2 VPNs and Layer 2 circuits over which you are running CFM MEPs. For all other interfaces on MX Series routers and on all other routers and switches, you must continue to configure the **no-control-word** statement at the **[edit routing-instances *routing-instance-name* protocols l2vpn]** or **[edit protocols l2circuit neighbor *neighbor-id* interface *interface-name*]** hierarchy level when you configure CFM MEPs. Otherwise, the CFM packets are not transmitted, and the **show oam ethernet connectivity-fault-management mep-database** command does not display any remote MEPs.

9. Specify the interface to which the MEP is attached. It can be a physical interface, logical interface, or trunk interface. On MX Series routers, the MEP can be attached to a specific VLAN of a trunk interface. Also, specify the transport path as working.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  domain-name maintenance-association ma-name mep mep-id]
user@host# set interface interface-name working
```

10. Create a maintenance association for the protection path by specifying the name and the short name format at the [**edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name***] hierarchy level.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  md-name]
user@host# set maintenance-association ma-name short-name-format option
```

11. Specify the time to wait between transmissions of continuity check messages at the [**edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* continuity-check**] hierarchy level. The duration can be one of the following values: 10 minutes(10m), 1 minute(1m), 10 seconds(10s), 1 second(1s), 100 milliseconds(100ms), or 10 milliseconds(10ms). The default value is 1 minute.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  md-name maintenance-association ma-name continuity-check]
```

user@host# set interval option

12. Specify an ID for the MEP at the [**edit protocols oam ethernet connectivity-fault-management maintenance-domain** ***domain-name*** **maintenance-association** ***ma-name***]. You can specify any value from 1 through 8191.

    [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name*]
    user@host# set mep *mep-id*

13. Enable maintenance end point automatic discovery so the MEP can accept continuity check messages (CCMs) from all remote MEPs of the same maintenance association.

    [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name* mep *mep-id*]
    user@host# set auto-discovery

14. Specify the direction in which the CCM packets are transmitted for the MEP. You can specify up or down. If you specify the direction as up, CCMs are transmitted out of every logical interface that is part of the same bridging or VPLS instance except for the interface configured on the MEP. If you specify the direction as down, CCMs are transmitted only out of the interface configured on the MEP.

    NOTE: Ports in the Spanning Tree Protocol (STP) blocking state do not block CFM packets destined to a down MEP. Ports in an STP blocking state without the continuity check protocol configured do block CFM packets.

    [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name* mep *mep-id*]
    user@host# set direction down

    NOTE: Starting with Junos OS Release 12.3, for all interfaces configured on Modular Port Concentrators (MPCs) on MX Series 3D Universal Edge Routers, you no longer need to configure the **no-control-word** statement for all Layer 2 VPNs and Layer 2 circuits over which you are running CFM MEPs. For all other interfaces on MX Series routers and on all other routers and switches, you must continue to configure the **no-control-word** statement at the [**edit routing-instances** ***routing-instance-name*** **protocols l2vpn**] or [**edit protocols l2circuit neighbor** ***neighbor-id*** **interface** ***interface-name***] hierarchy level when you configure CFM MEPs. Otherwise, the CFM packets are not transmitted, and the **show oam ethernet connectivity-fault-management mep-database** command does not display any remote MEPs.

15. Specify the interface to which the MEP is attached. It can be a physical interface, logical interface, or trunk interface. On MX Series routers, the MEP can be attached to a specific VLAN of a trunk interface. Also, specify the transport path as working.

    [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name* mep *mep-id*]
    user@host# set interface *interface-name* protect

Release History Table

Release	Description
12.3	Starting with Junos OS Release 12.3, for all interfaces configured on Modular Port Concentrators (MPCs) on MX Series 3D Universal Edge Routers, you no longer need to configure the **no-control-word** statement for all Layer 2 VPNs and Layer 2 circuits over which you are running CFM MEPs.
12.3	Starting with Junos OS Release 12.3, for all interfaces configured on Modular Port Concentrators (MPCs) on MX Series 3D Universal Edge Routers, you no longer need to configure the **no-control-word** statement for all Layer 2 VPNs and Layer 2 circuits over which you are running CFM MEPs.

Configuring a CFM Action Profile to Specify CFM Actions for CFM Events

You can create a connectivity fault management (CFM) action profile to define event flags and thresholds to be monitored. You can also specify the action to be taken when any of the configured events occur. When the CFM events occur, the router performs the corresponding action based on your specification. You can configure one or more events in the action profile. Alternatively, you can configure an action profile and specify default actions when connectivity to a remote maintenance association endpoint (MEP) fails.

NOTE: You cannot configure multiple actions at this time. Only one action can be configured. This limitation affects both the **action** and **clear-action** statements.

To configure the CFM action profile:

1. In configuration mode, at the [**edit protocols oam ethernet connectivity-fault-management**] hierarchy level, specify the name of the action profile and the CFM event(s). You can configure more than one event in the action profile. Possible events include: interface-status-tlv, port-status-tlv, adjacency-loss, RDI.

   [edit protocols oam ethernet connectivity-fault-management]
   user@host# set action-profile *profile-name* event [*event1*, *event2*, *event3*..]

2. Specify the action to be taken by the router when the event occurs. The action is triggered when the event occurs. If you have configured more than one event in the action profile, it is not necessary for all events to occur to trigger the action.

   [edit protocols oam ethernet connectivity-fault-management]
   user@host# set action-profile *profile-name* action *action*

3. Specify the default action to be taken by the router when connectivity to a remote MEP fails. If no action is configured, no action is taken.

   NOTE: Associating an action profile with the **interface-down** action on an up MEP CFM session running over a circuit cross-connect (CCC) interface (l2circuit/l2vpn) is not advisable and can result in a deadlock situation.

   [edit protocols oam ethernet connectivity-fault-management]
   user@host# set action-profile *profile-name* default-actions *action*

Configuring Linktrace Protocol in CFM

The linktrace protocol is used for path discovery between a pair of maintenance points. Linktrace messages are triggered by an administrator using the **traceroute** command to verify the path between a pair of MEPs under the same maintenance association. Linktrace messages can also be used to verify the path between an MEP and an MIP under the same maintenance domain. The linktrace protocol enables you to configure the time to wait for a response. If no response is received for a linktrace request message, the request and response entries are deleted after the interval expires. You can also configure the number of linktrace reply entries to be stored for the corresponding linktrace request.

The operation of IEEE 802.1ag linktrace request and response messages is similar to the operation of Layer 3 **traceroute** commands. For more information about the **traceroute** command, see the *Junos OS Administration Library*.

To configure the linktrace protocol:

1. Configure the time to wait for a linktrace response at the [**edit protocols oam ethernet connectivity-fault-management**] hierarchy level. You can specify the value in minutes or seconds. The default value is 10 minutes.

   ```
   [edit protocols oam ethernet connectivity-fault-management]
   user@host# set linktrace age time
   ```

2. Configure the number of linktrace reply entries to be stored per linktrace request. You can specify a value from 1 through 500. The default value is 100.

   ```
   [edit protocols oam ethernet connectivity-fault-management]
   user@host# set linktrace path-database-sizepath-database-size
   ```

Configuring Ethernet Local Management Interface

Ethernet Local Management Interface Overview

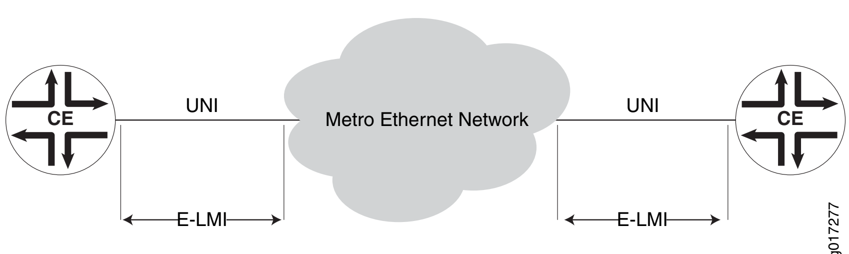
Gigabit Ethernet (**ge**), 10-Gigabit Ethernet (**xe**), and Aggregated Ethernet (**ae**) interfaces support the Ethernet Local Management Interface (E-LMI).

NOTE: On MX Series routers, E-LMI is supported on Gigabit Ethernet (ge), 10-Gigabit Ethernet (xe), and Aggregated Ethernet (ae) interfaces configured on MX Series routers with DPC only.

The E-LMI specification is available at the Metro Ethernet Forum. E-LMI procedures and protocols are used for enabling automatic configuration of the customer edge (CE) to support Metro Ethernet services. The E-LMI protocol also provides user-to-network interface (UNI) and Ethernet virtual connection (EVC) status information to the CE. The UNI and EVC information enables automatic configuration of CE operation based on the Metro Ethernet configuration.

The E-LMI protocol operates between the CE device and the provider edge (PE) device. It runs only on the PE-CE link and notifies the CE of connectivity status and configuration parameters of Ethernet services available on the CE port. The scope of the E-LMI protocol is shown in Figure 39 on page 627.

Figure 39: Scope of the E-LMI Protocol



The E-LMI implementation on ACX and MX Series routers includes only the PE side of the E-LMI protocol.

E-LMI interoperates with an OAM protocol, such as Connectivity Fault Management (CFM), that runs within the provider network to collect OAM status. CFM runs at the provider maintenance level (UNI-N to UNI-N with up MEPs at the UNI). E-LMI relies on the CFM for end-to-end status of EVCs across CFM domains (SVLAN domain or VPLS).

The E-LMI protocol relays the following information:

- Notification to the CE of the addition/deletion of an EVC (active, not active, or partially active)
- Notification to the CE of the availability state of a configured EVC
- Communication of UNI and EVC attributes to the CE:
  - UNI attributes:
    - UNI identifier (a user-configured name for UNI)
    - CE-VLAN ID/EVC map type (all-to-one bundling, service multiplexing with bundling, or no bundling)
    - Bandwidth profile is not supported (including the following features):
      - CM (coupling mode)
      - CF (color flag)
      - CIR (committed Information rate)
      - CBR (committed burst size)
      - EIR (excess information rate)
      - EBS (excess burst size)
  - EVC attributes:
    - EVC reference ID
    - EVC status type (active, not active, or partially active)
    - EVC type (point-to-point or multipoint-to-multipoint)
    - EVC ID (a user-configured name for EVC)
    - Bandwidth profile (not supported)
  - CE-VLAN ID/EVC map

E-LMI on MX Series routers supports the following EVC types:

- Q-in-Q SVLAN (point-to-point or multipoint-to-multipoint)—Requires an end-to-end CFM session between UNI-Ns to monitor the EVS status.
- VPLS (BGP or LDP) (point-to-point or multipoint-to-multipoint)—Either VPLS pseudowire status or end-to-end CFM sessions between UNI-Ns can be used to monitor EVC status.
- L2 circuit/L2VPN (point-to-point)—Either VPLS pseudowire status or end-to-end CFM sessions between UNI-Ns can be used to monitor EVC status.

NOTE: **l2-circuit and l2vpn are not supported.**

The E-LMI protocol on ACX Series routers supports Layer 2 circuit and Layer 2 VPN EVC types and enables link-loss forwarding for pseudowire (Layer 2 circuit and Layer 2 VPN) services as follows:

- Interworking between the connectivity fault management (CFM) protocol and the E-LMI protocol for Layer 2 circuit and Layer 2 VPN.
  - End-to-end CFM session between UNIs to monitor EVC status.
  - In the case of pseudowire redundancy, CFM can be used to monitor active and backup pseudowire sessions. The EVC status is declared as down to CE devices only when both the active and backup pseudowire sessions go down.
- Interworking between remote defect indication (RDI) and E-LMI for Layer 2 circuit and Layer 2 VPN.
  - If a maintenance association end point (MEP) receives an RDI bit set in a continuity check message (CCM) frame, and if RDI fault detection is enabled in the EVC configuration at **[edit protocols oam ethernet evcs *evc-id* evc-protocol *cfm* management-domain *name* management-association *name* faults rdi]**, then the pseudowire is declared as down to CE routers through E-LMI.
- If an end-to-end CFM session does not exist between UNIs, the pseudowire (Layer 2 circuit or Layer 2 VPN) up and down state triggers an asynchronous EVC state change message to CE routers through E-LMI.

NOTE: ACX Series routers do not support E-LMI for Layer 2 services (bridging).

Configuring the Ethernet Local Management Interface

To configure E-LMI, perform the following steps:

Configuring an OAM Protocol (CFM)

For information on configuring the OAM protocol (CFM), see “IEEE 802.1ag OAM Connectivity Fault Management Overview” on page 596.

Assigning the OAM Protocol to an EVC

To configure an EVC, you must specify a name for the EVC using the **evcs*evc-id*** statement at the **[edit protocols oam ethernet]** hierarchy level. You can set the EVC protocol for monitoring EVC statistics to **cfm** or **vpls** using the **evc-protocol** statement and its options at the **[edit protocols oam ethernet evcs]** hierarchy level.

You can set the number of remote UNIs in the EVC using the **remote-uni-count** ***number*** statement at the **[edit protocols oam ethernet evcs evcs-protocol]** hierarchy level. The **remote-uni-count** defaults to 1. Configuring a value greater than 1 makes the EVC multipoint-to-multipoint. If you enter a value greater than the actual number of endpoints, the EVC status will display as partially active even if all endpoints are up. If you enter a **remote-uni-count** less than the actual number of endpoints, the status will display as active, even if all endpoints are not up.

You can configure an EVC by including the **evcs** statement at the **[edit protocols oam ethernet]** hierarchy level:

```
[edit protocols oam ethernet]
evcs evc-id {
  evc-protocol (cfm (management-domain name management-association name ) | vpls
    (routing-instance name)) {
    remote-uni-count <number>; # Optional, defaults to 1
    multipoint-to-multipoint;
      # Optional, defaults to point-to-point if remote-uni-count is 1
  }
}
```

Enabling E-LMI on an Interface and Mapping CE VLAN IDs to an EVC

To configure E-LMI, include the **lmi** statement at the **[edit protocols oam ethernet]** hierarchy level:

```
[edit protocols oam ethernet]
lmi {
  polling-verification-timer value;
    # Polling verification timer (T392), defaults to 15 seconds
  status-counter count; # Status counter (N393), defaults to 4
  interface name {
    evc evc-id {
      default-evc;
      vlan-list [ vlan-ids ];
    }
    evc-map-type (all-to-one-bundling | bundling | service-multiplexing);
    polling-verification-time value; # Optional, defaults to global value
    status-counter count; # Optional, defaults to global value
    uni-id value; # Optional, defaults to interface-name
  }
}
```

You can set the status counter to count consecutive errors using the **status-counter** ***count*** statement at the **[edit protocols oam ethernet lmi]** hierarchy level. The status counter is used to determine if E-LMI is operational or not. The default value is 4.

You can set the **polling-verification-timer** ***value*** statement at the **[edit protocols oam ethernet lmi]** hierarchy level. The default value is 15 seconds.

You can enable an interface and set its options for use with E-LMI using the **interface** ***name*** statement at the **[edit protocols oam ethernet lmi]** hierarchy level. Only **ge**, **xe**, and **ae** interfaces are supported. You can use the interface **uni-id** option to specify a name for the UNI. If **uni-id** is not configured, it defaults to the name variable of **interface** ***name***.

You can specify the CE-VLAN ID/EVC map type using the **evc-map-type type** interface option. The options are **all-to-one-bundling**, **bundling**, or **service-multiplexing**. Service multiplexing is with no bundling. The default type is **all-to-one-bundling**.

To specify the EVC that an interface uses, use the **evc *evc-id*** statement at the **[edit protocols oam ethernet lmi interface *name*]** hierarchy level. You can specify an interface as the default EVC interface using the **default-evc** statement at the **[edit protocols oam ethernet lmi interface *name* evc *evc-id*]** hierarchy level. All VIDs that are not mapped to any other EVCs are mapped to this EVC. Only one EVC can be configured as the default.

You can map a list of VLANs to an EVC using the **vlan-list *vlan-id-list*** statement at the **[edit protocols oam ethernet lmi interface *name* evc *evc-id*]** hierarchy level.

Example E-LMI Configuration

- Example Topology on page 631
- Configuring PE1 on page 631
- Configuring PE2 on page 633
- Configuring Two UNIs Sharing the Same EVC on page 634

Example Topology

Figure 40 on page 631 illustrates the E-LMI configuration for a point-to-point EVC (SVLAN) monitored by CFM. In this example, VLANs 1 through 2048 are mapped to **evc1** (SVLAN 100) and 2049 through 4096 are mapped to **evc2** (SVLAN 200). Two CFM sessions are created to monitor these EVCs.

Configuring Port Status TLV and Interface Status TLV

TLVs Overview

Type, Length, and Value (TLVs) are described in the IEEE 802.1ag standard for CFM as a method of encoding variable-length and/or optional information in a PDU. TLVs are not aligned to any particular word or octet boundary. TLVs follow each other with no padding between them.

Table 64 on page 636 shows the TLV format and indicates if it is required or optional.

Table 64: Format of TLVs

Parameter	Octet (sequence)	Description
Type	1	Required. If 0, no Length or Value fields follow. If not 0, at least the Length field follows the Type field.
Length	2–3	Required if the Type field is not 0. Not present if the Type field is 0. The 16 bits of the Length field indicate the size, in octets, of the Value field. 0 in the Length field indicates that there is no Value field.
Value	4	Length specified by the Length field. Optional. Not present if the Type field is 0 or if the Length field is 0.

Various TLVs for CFM PDUs

Table 65 on page 636 shows a set of TLVs defined by IEEE 802.1ag for various CFM PDU types. Each TLV can be identified by the unique value assigned to its type field. Some type field values are reserved.

Table 65: Type Field Values for Various TLVs for CFM PDUs

TLV or Organization	Type Field
End TLV	0
Sender ID TLV	1
Port Status TLV	2
Data TLV	3
Interface Status TLV	4
Reply Ingress TLV	5
Reply Egress TLV	6
LTM Egress Identifier TLV	7
LTR Egress Identifier TLV	8
Reserved for IEEE 802.1	9 to 30
Organization-Specific TLV	31
Defined by ITU-T Y.1731	32 to 63
Reserved for IEEE 802.1	64 to 255

Not every TLV is applicable for all types of CFM PDUs.

- TLVs applicable for continuity check message (CCM):
  - End TLV
  - Sender ID TLV
  - Port Status TLV
  - Interface Status TLV
  - Organization-Specific TLV
- TLVs applicable for loopback message (LBM):
  - End TLV
  - Sender ID TLV
  - Data TLV
  - Organization-Specific TLV
- TLVs applicable for loopback reply (LBR):
  - End TLV
  - Sender ID TLV
  - Data TLV
  - Organization-Specific TLV
- TLVs applicable for linktrace message (LTM):
  - End TLV
  - LTM Egress Identifier TLV
  - Sender ID TLV
  - Organization-Specific TLV
- TLVs applicable for linktrace reply (LTR):
  - End TLV
  - LTR Egress Identifier TLV
  - Reply Ingress TLV
  - Reply Egress TLV
  - Sender ID TLV
  - Organization-Specific TLV

The following TLVs are currently supported in the applicable CFM PDUs:

- End TLV
- Reply Ingress TLV

- Reply Egress TLV
- LTR Egress Identifier TLV
- LTM Egress Identifier TLV
- Data TLV

Support for Additional Optional TLVs

The following additional optional TLVs are supported:

- Port Status TLV
- Interface Status TLV

MX Series routers support configuration of port status TLV and interface status TLV. Configuring the Port Status TLV allows the operator to control the transmission of the Port Status TLV in CFM PDUs.

NOTE: **Although Port Status TLV configuration statements are visible in the CLI on M120 and M320 routers, Port Status TLV cannot be configured on these systems. Port Status TLV can be enabled on a MEP interface only if it is a bridge logical interface, which is not possible on these systems.**

For configuration information, see the following sections:

- Port Status TLV on page 638
- Interface Status TLV on page 641

Port Status TLV

The Port Status TLV indicates the ability of the bridge port on which the transmitting MEP resides to pass ordinary data, regardless of the status of the MAC. The value of this TLV is driven by the MEP variable **enableRmepDefect**, as shown in Table 67 on page 639. The format of this TLV is shown in Table 66 on page 638.

Any change in the Port Status TLVs value triggers one extra transmission of that bridge ports MEP CCMs.

Table 66: Port Status TLV Format

Parameter	Octet (Sequence)
Type = 2	1
Length	2–3
Value (See Table 67 on page 639)	4

Table 67: Port Status TLV Values

Mnemonic	Ordinary Data Passing Freely Through the Port	Value
psBlocked	No: **enableRmepDefect** = false	1
psUp	Yes: **enableRmepDefect** = true	2

The MEP variable **enableRmepDefect** is a boolean variable indicating whether frames on the service instance monitored by the maintenance associations if this MEP are enabled to pass through this bridge port by the Spanning Tree Protocol and VLAN topology management. It is set to TRUE if:

- The bridge port is set in a state where the traffic can pass through it.
- The bridge port is running multiple instances of the spanning tree.
- The MEP interface is not associated with a bridging domain.

Configuring Port Status TLV

Junos OS provides configuration support for the Port Status TLV, allowing you to control the transmission of this TLV in CCM PDUs. The Junos OS provides this configuration at the continuity-check level. By default, the CCM does not include the Port Status TLV. To configure the Port Status TLV, use the **port-status-tlv** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *identifier* maintenance-association *identifier* continuity-check]** hierarchy level.

NOTE: Port Status TLV configuration is not mandated by IEEE 802.1ag. The Junos OS provides it in order to give more flexibility to the operator; however it receives and processes CCMs with a Port Status TLV, regardless of this configuration.

An example of the configuration statements follows:

```
protocols {
  oam {
    ethernet {
      connectivity-fault-management {
        maintenance-domain identifier {
        level number;
          maintenance-association identifier {
            continuity-check {
              interval number,
              loss-threshold number;
              hold-interval number;
              port-status-tlv; # Sets Port Status TLV
            }
          }
        }
      }
    }
```

```
  }
}
```

You cannot enable Port Status TLV transmission in the following two cases:

- If the MEP interface under the maintenance-association is not of type bridge.
- If the MEP is configured on a physical interface.

Displaying the Received Port Status TLV

The Junos OS saves the last received Port Status TLV from a remote MEP. If the received Port Status value does not correspond to one of the standard values listed in Table 67 on page 639, then the **show** command displays it as "unknown." You can display the last saved received Port Status TLV using the **show oam ethernet connectivity-fault-management mep-database maintenance-domain** ***identifier*** **maintenance-association** ***identifier*** **local-mep** ***identifier*** **remote-mep** ***identifier*** command, as in the following example:

```
user@host> show oam ethernet connectivity-fault-management mep-database
maintenance-domain md5 maintenance-association ma5 local-mep 2001 remote-mep 1001
Maintenance domain name: md5, Format: string, Level: 5
  Maintenance association name: ma5, Format: string
  Continuity-check status: enabled, Interval: 100ms, Loss-threshold: 3 frames
  MEP identifier: 2001, Direction: down, MAC address: 00:19:e2:b2:81:4a
  Auto-discovery: enabled, Priority: 0
  Interface status TLV: up, Port status TLV: up
  Interface name: ge-2/0/0.0, Interface status: Active, Link status: Up

  Remote MEP identifier: 1001, State: ok
    MAC address: 00:19:e2:b0:74:00, Type: Learned
    Interface: ge-2/0/0.0
    Last flapped: Never
    Remote defect indication: false
    Port status TLV: none # RX PORT STATUS
    Interface status TLV: none
```

Displaying the Transmitted Port Status TLV

The Junos OS saves the last transmitted Port Status TLV from a local MEP. If the transmission of the Port Status TLV has not been enabled, then the **show** command displays "none." You can display the last saved transmitted Port Status TLV using the **show oam ethernet connectivity-fault-management mep-database maintenance-domain** ***identifier*** **maintenance-association** ***identifier*** **local-mep** ***identifier*** **remote-mep** ***identifier*** command, as in the following example:

```
user@host> show oam ethernet connectivity-fault-management mep-database
maintenance-domain md5 maintenance-association ma5 local-mep 2001 remote-mep 1001
Maintenance domain name: md5, Format: string, Level: 5
  Maintenance association name: ma5, Format: string
  Continuity-check status: enabled, Interval: 100ms, Loss-threshold: 3 frames
  MEP identifier: 2001, Direction: down, MAC address: 00:19:e2:b2:81:4a
  Auto-discovery: enabled, Priority: 0
  Interface status TLV: up, Port status TLV: up # TX PORT STATUS
  Interface name: ge-2/0/0.0, Interface status: Active, Link status: Up

  Remote MEP identifier: 1001, State: ok
```

```
MAC address: 00:19:e2:b0:74:00, Type: Learned
Interface: ge-2/0/0.0
Last flapped: Never
Remote defect indication: false
Port status TLV: none
Interface status TLV: none
```

Interface Status TLV

The Interface Status TLV indicates the status of the interface on which the MEP transmitting the CCM is configured, or the next-lower interface in the IETF RFC 2863 IF-MIB. The format of this TLV is shown in Table 68 on page 641. The enumerated values are shown in Table 69 on page 641.

Table 68: Interface Status TLV Format

Parameter	Octet (Sequence)
Type = 4	1
Length	2–3
Value (See Table 69 on page 641)	4

Table 69: Interface Status TLV Values

Mnemonic	Interface Status	Value
isUp	up	1
isDown	down	2
isTesting	testing	3
isUnknown	unknown	4
isDormant	dormant	5
isNotPresent	notPresent	6
isLowerLayerDown	lowerLayerDown	7

NOTE: When the operational status of a logical interface changes from the down state (status value of 2) to the lower layer down state (status value of 7) and vice versa, the LinkDown SNMP trap is not generated. For example, if you configure an aggregated Ethernet interface bundle with a VLAN tag and add a physical interface that is in the operationally down state to the bundle, the operational status of the aggregated Ethernet logical interface bundle at that point is lower layer down (7). If you take the MIC associated with the interface offline, the LinkDown trap is not generated when the logical interface shifts from the lower layer down state to the down state.

Similarly, consider another sample scenario in which an physical interface is added to an aggregated Ethernet bundle that has VLAN tagging and the aggregated Ethernet logical interface is disabled. When the logical interface is disabled, the operational status of the logical interface changes to down. If you disable the physical interface that is part of the aggregated Ethernet bundle, the operational status of the aggregated Ethernet logical interface remains down. If you reenable the aggregated Ethernet logical interface, the operational status of it changes from down to lower layer down. The LinkDown SNMP trap is not generated at this point.

Configuring Interface Status TLV

The Junos OS provides configuration support for the Interface Status TLV, thereby allowing operators to control the transmission of this TLV in CCM PDUs through configuration at the continuity-check level.

NOTE: This configuration is not mandated by IEEE 802.1ag; rather it is provided to give more flexibility to the operator. The Junos OS receives and processes CCMs with the Interface Status TLV, regardless of this configuration.

The interface status TLV configuration is shown below:

```
protocols {
  oam {
    ethernet {
      connectivity-fault-management {
        maintenance-domain identifier {
          level number;
          maintenance-association identifier {
            continuity-check {
              interval number;
              loss-threshold number;
              hold-interval number;
              interface-status-tlv; # Sets the interface status TLV
            }
          }
        }
      }
```

```
        }
      }
    }
```

NOTE: The Junos OS supports transmission of only three out of seven possible values for the Interface Status TLV. The supported values are 1, 2, and 7. However, the Junos OS is capable of receiving any value for the Interface Status TLV.

Displaying the Received Interface Status TLV

The Junos OS saves the last received Interface Status TLV from the remote MEP. If the received Interface Status value does not correspond to one of the standard values listed in Table 68 on page 641, then the **show** command displays "unknown."

You can display this last saved Interface Status TLV using the **show oam ethernet connectivity-fault-management mep-database maintenance-domain *identifier* maintenance-association *identifier* local-mep *identifier* remote-mep *identifier*** command, as in the following example:

user@host> **show oam ethernet connectivity-fault-management mep-database maintenance-domain *md5* maintenance-association *ma5* local-mep *2001* remote-mep *1001***

```
Maintenance domain name: md5, Format: string, Level: 5
  Maintenance association name: ma5, Format: string
  Continuity-check status: enabled, Interval: 100ms, Loss-threshold: 3 frames
  MEP identifier: 2001, Direction: down, MAC address: 00:19:e2:b2:81:4a
  Auto-discovery: enabled, Priority: 0
  Interface status TLV: up, Port status TLV: up
  Interface name: ge-2/0/0.0, Interface status: Active, Link status: Up

  Remote MEP identifier: 1001, State: ok
    MAC address: 00:19:e2:b0:74:00, Type: Learned
    Interface: ge-2/0/0.0
    Last flapped: Never
    Remote defect indication: false
    Port status TLV: none
    Interface status TLV: none # displays the Interface Status TLV state
```

Displaying the Transmitted Interface Status TLV

The Junos OS saves the last transmitted Interface Status TLV from a local MEP. If the transmission of Interface Status TLV has not been enabled, then the **show** command displays "none."

You can display the last transmitted Interface Status TLV using the **show oam ethernet connectivity-fault-management mep-database maintenance-domain *identifier* maintenance-association *identifier* local-mep *identifier* remote-mep *identifier*** command, as in the following example:

user@host> **show oam ethernet connectivity-fault-management mep-database maintenance-domain *md5* maintenance-association *ma5* local-mep *2001* remote-mep *1001***

```
Maintenance domain name: md5, Format: string, Level: 5
```

```
  Maintenance association name: ma5, Format: string
  Continuity-check status: enabled, Interval: 100ms, Loss-threshold: 3 frames
  MEP identifier: 2001, Direction: down, MAC address: 00:19:e2:b2:81:4a
  Auto-discovery: enabled, Priority: 0
  Interface status TLV: up, Port status TLV: up
  Interface name: ge-2/0/0.0, Interface status: Active, Link status: Up

  Remote MEP identifier: 1001, State: ok
    MAC address: 00:19:e2:b0:74:00, Type: Learned
    Interface: ge-2/0/0.0
    Last flapped: Never
    Remote defect indication: false
    Port status TLV: none
    Interface status TLV: none
```

MAC Status Defects

The Junos OS provides MAC status defect information, indicating that one or more of the remote MEPs is reporting a failure in its Port Status TLV or Interface Status TLV. It indicates “yes” if either some remote MEP is reporting that its interface is not isUp (for example, at least one remote MEPs interface is unavailable), or if all remote MEPs are reporting a Port Status TLV that contains some value other than psUp (for example, all remote MEPs Bridge Ports are not forwarding data). There are two **show** commands you can use to view the MAC Status Defects indication.

Use the **mep-database** command to display MAC status defects:

user@host> **show oam ethernet connectivity-fault-management mep-database maintenance-domain *md6* maintenance-association *ma6***

```
Maintenance domain name: md6, Format: string, Level: 6
  Maintenance association name: ma6, Format: string
  Continuity-check status: enabled, Interval: 1s, Loss-threshold: 3 frames
  MEP identifier: 500, Direction: down, MAC address: 00:05:85:73:7b:39
  Auto-discovery: enabled, Priority: 0
  Interface status TLV: up, Port status TLV: up
  Interface name: xe-5/0/0.0, Interface status: Active, Link status: Up
  Defects:
    Remote MEP not receiving CCM            : no
    Erroneous CCM received                  : no
    Cross-connect CCM received              : no
    RDI sent by some MEP                    : no
    Some remote MEP's MAC in error state    : yes # MAC Status Defects yes/no
  Statistics:
    CCMs sent                               : 1658
    CCMs received out of sequence           : 0
    LBMs sent                               : 0
    Valid in-order LBRs received            : 0
    Valid out-of-order LBRs received        : 0
    LBRs received with corrupted data       : 0
    LBRs sent                               : 0
    LTMs sent                               : 0
    LTMs received                           : 0
    LTRs sent                               : 0
    LTRs received                           : 0
    Sequence number of next LTM request     : 0
    1DMs sent                               : 0
    Valid 1DMs received                     : 0
```

```
    Invalid 1DMs received                  : 0
    DMMs sent                              : 0
    DMRs sent                              : 0
    Valid DMRs received                    : 0
    Invalid DMRs received                  : 0
  Remote MEP count: 1
    Identifier     MAC address        State    Interface
      200      00:05:85:73:39:4a       ok    xe-5/0/0.0
```

Use the **interfaces** command to display MAC status defects:

```
user@host> show oam ethernet connectivity-fault-management interfaces detail
Interface name: xe-5/0/0.0, Interface status: Active, Link status: Up
  Maintenance domain name: md6, Format: string, Level: 6
    Maintenance association name: ma6, Format: string
    Continuity-check status: enabled, Interval: 1s, Loss-threshold: 3 frames
    Interface status TLV: up, Port status TLV: up
    MEP identifier: 500, Direction: down, MAC address: 00:05:85:73:7b:39
    MEP status: running
    Defects:
      Remote MEP not receiving CCM                : no
      Erroneous CCM received                      : no
      Cross-connect CCM received                  : no
      RDI sent by some MEP                        : no
      Some remote MEP's MAC in error state        : yes # MAC Status Defects
yes/no
    Statistics:
      CCMs sent                                   : 1328
      CCMs received out of sequence               : 0
      LBMs sent                                   : 0
      Valid in-order LBRs received                : 0
      Valid out-of-order LBRs received            : 0
      LBRs received with corrupted data           : 0
      LBRs sent                                   : 0
      LTMs sent                                   : 0
      LTMs received                               : 0
      LTRs sent                                   : 0
      LTRs received                               : 0
      Sequence number of next LTM request         : 0
      1DMs sent                                   : 0
      Valid 1DMs received                         : 0
      Invalid 1DMs received                       : 0
      DMMs sent                                   : 0
      DMRs sent                                   : 0
      Valid DMRs received                         : 0
      Invalid DMRs received                       : 0
    Remote MEP count: 1
      Identifier     MAC address        State    Interface
        200      00:05:85:73:39:4a       ok    xe-5/0/0.0
```

Configuring Remote MEP Action Profile Support

Based on values of **interface-status-tlv** and **port-status-tlv** in the received CCM packets, a specific action, such as **interface-down**, can be taken using the **action-profile** options. Multiple action profiles can be configured on the router, but only one action profile can be assigned to a remote MEP.

The action profile can be configured with at least one event to trigger the action; but the action will be triggered if any one of these events occurs. It is not necessary for all of the configured events to occur to trigger **action**.

An action-profile can be applied only at the remote MEP level.

The following example shows an action profile configuration with explanatory comments added:

```
[edit protocols oam ethernet connectivity-fault-management]
action-profile tlv-action {
  event {
    # If interface status tlv with value specified in the config is received
    interface-status-tlv down|lower-layer-down;
    # If port status tlv with value specified in the config is received
    port-status-tlv blocked;
    # If connectivity is lost to the peer */
    adjacency-loss;
  }
  action {
    # Bring the interface down */
    interface-down;
  }
  default-actions interface-down;
  }
# domains
  maintenance-domain identifier {
    # maintenance domain level (0-7)
    level number;
    # association
    maintenance-association identifier {
      mep identifier {
        interface ge-x/y/z.w;
        remote-mep identifier {
          # Apply the action-profile for the remote MEP
          action-profile tlv-action;
        }
      }
    }
  }
```

Monitoring a Remote MEP Action Profile

You can use the **show oam ethernet connectivity-fault-management mep-database** command to view the action profile status of a remote MEP, as in the following example:

show oam ethernet connectivity-fault-management mep-database remote-mep (Action Profile Event)

```
user@host> show oam ethernet connectivity-fault-management mep-database
maintenance-domain md5 maintenance-association ma5 remote-mep 200
Maintenance domain name: md5, Format: string, Level: 5
  Maintenance association name: ma5, Format: string
  Continuity-check status: enabled, Interval: 1s, Loss-threshold: 3 frames
  MEP identifier: 100, Direction: down, MAC address: 00:05:85:73:e8:ad
  Auto-discovery: enabled, Priority: 0
```

```
 Interface status TLV: none, Port status TLV: none  # last status TLVs transmitted
by the router
 Interface name: ge-1/0/8.0, Interface status: Active, Link status: Up

 Remote MEP identifier: 200, State: ok # displays the remote MEP name and state

   MAC address: 00:05:85:73:96:1f, Type: Configured
   Interface: ge-1/0/8.0
   Last flapped: Never
   Remote defect indication: false
   Port status TLV: none
   Interface status TLV: lower-layer-down
   Action profile: juniper  # displays remote MEP’s action profile identifier
     Last event: Interface-status-tlv lower-layer-down  # last remote MEP event

                                                         # to trigger action
     Action: Interface-down, Time: 2009-03-27 14:25:10 PDT (00:00:02 ago)
                                 # action occurrence time
```

Configuring MAC Flush Message Processing in CET Mode

In carrier Ethernet transport (CET) mode, MX Series routers are used as provider edge (PE) routers, and Nokia Siemens Networks A2200 Carrier Ethernet Switches (referred to as E-domain devices) that run standard-based protocols are used in the access side. On the MX Series routers, VPLS pseudowires are configured dynamically through label distribution protocol (LDP). On the E-domain devices, topology changes are detected through connectivity fault management (CFM) sessions running between the E-domain devices and the MX Series PE routers. The MX Series PE routers can bring the carrier Ethernet interface down if there is CFM connectivity loss. This triggers a local MAC flush as well as a targeted label distribution protocol (T-LDP) MAC flush notification that gets sent towards the remote MX Series PEs to trigger MAC flush on them.

In CET inter-op mode, MX Series routers need to interoperate with the Nokia Siemens Networks Ax100 Carrier Ethernet access devices (referred to as A-domain devices) that run legacy protocols. Nokia Siemens Networks A4100 and A8100 devices act as an intermediate between the MX Series PE routers and A-domain devices. These intermediate devices perform interworking function (IWF) procedures so that operations administration management (OAM) sessions can be run between MX Series routers and A-domain devices. There are no VPLS pseudowires between the MX Series PE routers and the Nokia Siemens Networks A4100 and A8100 intermediate devices, so there is no LDP protocol running between the PE routers to send topology change notifications. In order to communicate topology changes, MX Series routers can trigger a MAC flush and propagate it in the core. MX Series routers can use action profiles based upon the connection protection type length value (TLV) event. The action profile brings down the carrier edge logical interface in MX Series PE routers, which will trigger a local MAC flush and also propagate the topology change to the core using LDP notification.

For VPLS there is no end-to-end connectivity monitored. The access rings are independently monitored by running CFM down multiple end points (MEPs) on the working and protection paths for each of the services between the E-domain devices and the MX Series PE routers, and between the A-domain devices and the MX Series PE routers the IWF hosted by the Nokia Siemens Networks A-4100 devices. When there is a connectivity failure on the working path, the Nokia Siemens Networks Ax200 devices perform a switchover to the protection path, triggering a topology change notification (in the form of TLVs carried in CCM) to be sent on the active path.

Figure 41: CET inter-op Dual Homed Topology

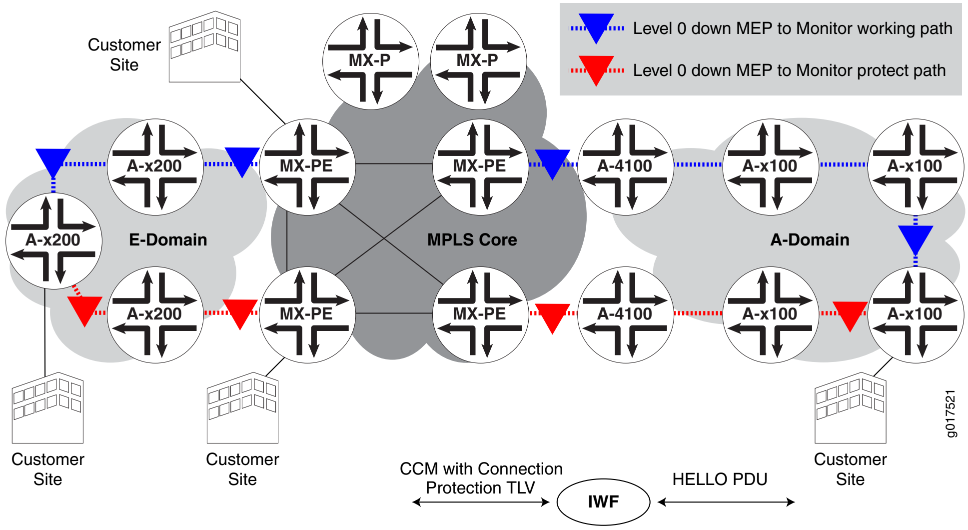

Figure 41 on page 649 describes the dual homed topology on MX Series PE routers connected to the A-domain. When an A-domain device triggers a switchover, it starts switching the service traffic to the new active path. This change is communicated in the HELLO protocol data units (PDUs) sent by that A-domain device on the working and protection paths. When the IWF in A4100 recieves these HELLO PDUs, it converts them to standard CCM messages and also inserts a connection protection TLV. The “Protection-in-use” field of the connection protection TLV is encoded with the currently active path, and is included in the CCM message. CCM messages are received by the MX Series PE routers through the VLAN spoke in A4100. In the above dual homed scenario, one MX Series PE router monitors the working path, and the other MX Series PE router monitors the protection path.

A MAC flush occurs when the CFM session that is monitoring the working path detects that the service traffic has moved to the protection path or when the CFM session that is monitoring the protection path detects that the service traffic has moved to the working path.

Figure 42: CET inter-op Dual Attached Topology

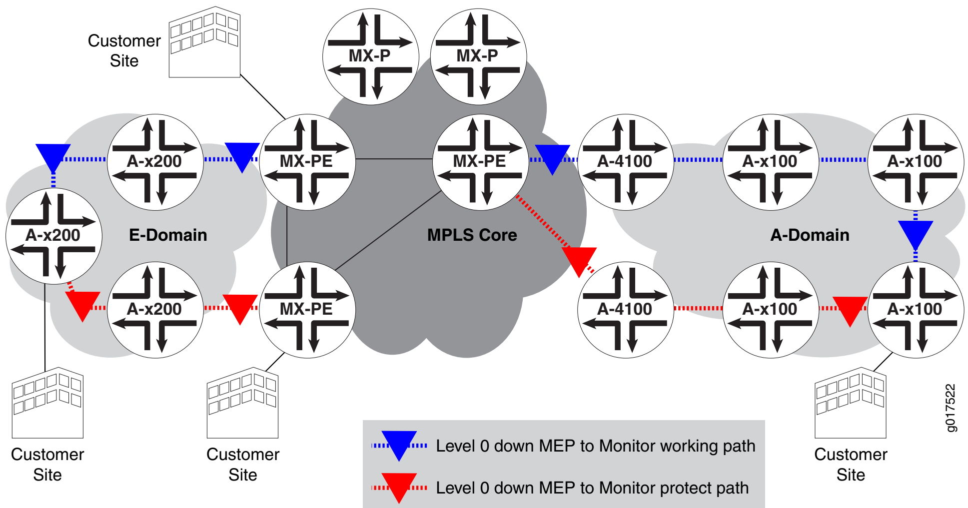

Figure 42 on page 650 describes the dual attached topology on MX Series PE routers connected to the A-domain. The MAC flush mechanism used in this case is also the same as the one used for the A-domain in the dual homed scenario (Figure 1). However in this case both the CFM sessions are hosted by only one MX Series PE router. When Ax100 in the A-domain detects topology changes, the MX Series PE router receives the connection protection TLV in the CCM message for the working and protection paths with the value of “Protection-in-use” indicating which path is the active one. Based upon the event that is generated for the CFM session, the MX Series PE router will bring down the appropriate interface which will trigger a local MAC flush.

Configuring a Connection Protection TLV Action Profile

An action profile can be configured to perform the **interface-down** action based on the values of **connection-protection-tlv** in the received CCM packets.

The following example shows an action profile configuration with explanatory comments added:

```
[edit protocols oam ethernet connectivity-fault-management]
action-profile <tlv-action> {

Example: Configuring an Action Profile Based on Connection Protection TLVs

This example shows how to configure an action profile based on the connection protection TLV for the purposes of triggering MAC flushes based on topology changes in a CET network.

- Requirements on page 651
- Overview and Topology on page 651
- Configuration on page 652

Requirements

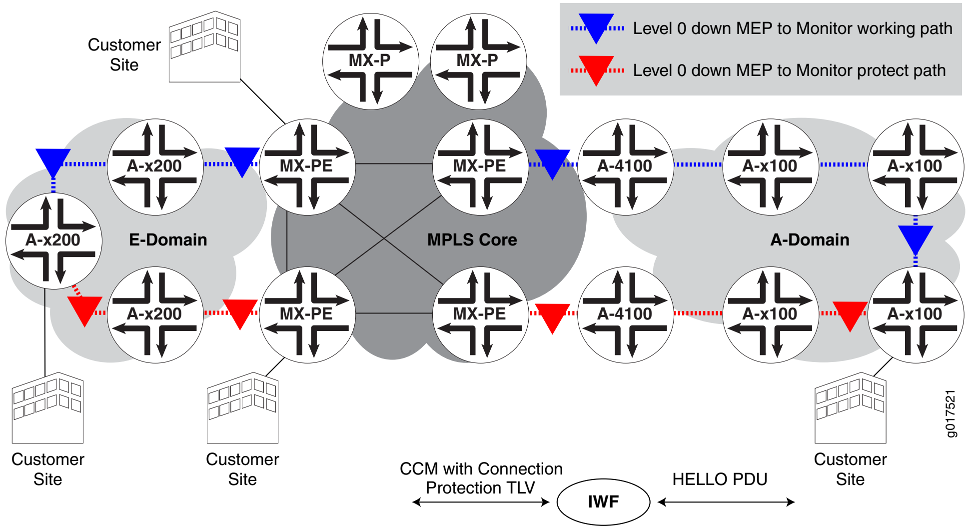
This example uses the following hardware and software components:

- Junos OS Release 11.2 or later
- A MX series PE router

Overview and Topology

The physical topology of a CET network using MX series PE routers is shown in Figure 43 on page 652

Figure 43: Topology of CET network



The following definitions describe the meaning of the device abbreviation and terms used in Figure 43 on page 652.

- Provider edge (PE) device—A device, or set of devices, at the edge of the provider network that presents the provider's view of the customer site.
- E-domain—Nokia Siemens Networks Carrier Ethernet Switches that run standard based protocols and are used in the access side.
- A-domain—Nokia Siemens Networks Carrier Ethernet Switches that run legacy protocols.

Configuration

Step-by-Step Procedure

To configure an action profile based on the connection protection TLV, preform these tasks:

1. Configure an action profile

```
[edit protocols oam ethernet connectivity-fault-management]
action-profile <tlv-action> {
  event {
```

2. If the connection protection TLV is received with a “Protection-in-use” value of SET, then the connection protection TLV should use the protection path

```
connection-protection-tlv <using-protection-path>;
```

3. If the connection protection TLV is received with a “Protection-in-use” value of RESET, then the connection protection TLV should use the working path

```
connection-protection-tlv <using-working-path>;
}
```

4. Configure the action profile to bring the interface down

```
action {
  /* Bring the interface down */
  interface-down;
}
}
```

Results Check the results of the configuration

```
[edit protocols oam ethernet connectivity-fault-management]
action-profile <tlv-action> {
  event {
    connection-protection-tlv <using-protection-path>;
    connection-protection-tlv <using-working-path>;
  }
  action {
    interface-down;
  }
}
```

Configuring M120 and MX Series Routers for CCC Encapsulated Packets

IEEE 802.1ag CFM OAM Support for CCC Encapsulated Packets Overview

Layer 2 virtual private network (L2VPN) is a type of virtual private network service used to transport customer's private Layer 2 traffic (for example, Ethernet, ATM or Frame Relay) over the service provider's shared IP/MPLS infrastructure. The service provider edge (PE) router must have an interface with circuit cross-connect (CCC) encapsulation to switch the customer edge (CE) traffic to the public network.

The IEEE 802.1ag Ethernet Connectivity Fault Management (CFM) is an OAM standard used to perform fault detection, isolation, and verification on virtual bridge LANs. M120 and MX Series routers provide CFM support for bridge/VPLS/routed interfaces and support 802.1ag Ethernet OAM for CCC encapsulated packets.

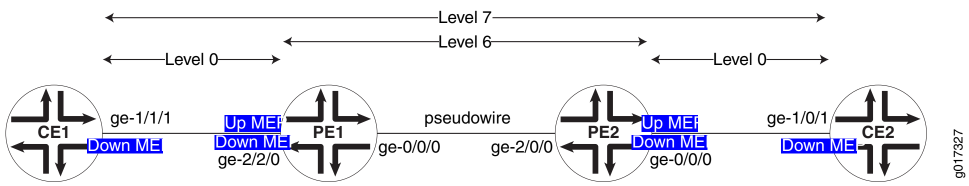
CFM Features Supported on Layer 2 VPN Circuits

CFM features supported on L2VPN circuits are as follows:

- Creation of up/down MEPs at any level on the CE-facing logical interfaces.
- Creation of MIPs at any level on the CE-facing logical interfaces.

- Support for continuity check, loopback, and linkrace protocol.
- Support for the Y1731 Ethernet Delay measurement protocol.
- Support for action profiles to bring the CE-facing logical interfaces down when loss of connectivity is detected.

Figure 44: Layer 2 VPN Topology



To monitor the L2VPN circuit, a CFM up MEP (Level 6 in Figure 44 on page 654) can be configured on the CE-facing logical interfaces of provider edge routers PE1 and PE2. To monitor the CE-PE attachment circuit, a CFM down MEP can be configured on the customer logical interfaces of CE1-PE1 and CE2-PE2 (Level 0 in Figure 44 on page 654).

Configuring CFM for CCC Encapsulated Packets

The only change from the existing CLI configuration is the introduction of a new command to create a MIP on the CE-facing interface of the PE router.

```
protocols {
  oam {
    ethernet {
      connectivity-fault-management {
        # Define a maintenance domains for each default level.
        #; These names are specified as DEFAULT_level_number
        maintenance-domain DEFAULT_x {
          # L2VPN CE interface
          interface (ge | xe)-fpc/pic/port.domain;
        }
        {
        level number;
        maintenance-association identifier {
          mep mep-id {
            direction (up | down);
            # L2 VPN CE interface on which encapsulation family CCC is configured.
            interface (ge | xe)-fpc/pic/port.domain;
            auto-discovery;
            priority number;
          }
        }
      }
    }
  }
  }
}
```

Configuring Rate Limiting of Ethernet OAM Messages

The M320 with Enhanced III FPC, M120, M7i, M10 with CFEB, and MX Series routers support rate limiting of Ethernet OAM messages. Depending on the connectivity fault management (CFM) configuration, CFM packets are discarded, sent to the CPU for processing, or flooded to other bridge interfaces. This feature allows the router to intercept incoming CFM packets for prevention of DoS attacks.

You can apply rate limiting of Ethernet OAM messages at either of two CFM policing levels, as follows:

- Global-level CFM policing—uses a policer at the global level to police the CFM traffic belonging to all the sessions.
- Session-level CFM policing—uses a policer created to police the CFM traffic belonging to one session.

To configure global-level CFM policing, include the **policer** statement and its options at the **[edit protocols oam ethernet connectivity-fault-management]** hierarchy level.

To configure session-level CFM policing, include the **policer** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* level *number* maintenance-association *ma-name*]** hierarchy level.

The following example shows a CFM policer used for rate-limiting CFM:

```
[edit]
firewall {
  policer cfm-policer {
    if-exceeding {
      bandwidth-limit 8k;
      burst-size-limit 2k;
    }
```

```
      then discard;
    }
  }
```

Case 1: Global-Level CFM Policing

This example shows a global level policer, at the CFM level, for rate-limiting CFM. The **continuity-check** ***cfm-policer*** statement at the global **[edit protocols oam ethernet connectivity-fault-management policer]** hierarchy level specifies the policer to use for policing all continuity check packets of the CFM traffic belonging to all sessions. The **other** ***cfm-policer1*** statement at the **[edit protocols oam ethernet connectivity-fault-management policer]** hierarchy level specifies the policer to use for policing all non-continuity check packets of the CFM traffic belonging to all sessions. The **all** ***cfm-policer2*** statement specifies to police all CFM packets with the specified policer *cfm-policer2*. If the **all** ***policer-name*** option is used, then the user cannot specify the previous **continuity-check** and **other** options.

```
[edit protocols oam ethernet]
connectivity-fault-management {
  policer {
    continuity-check cfm-policer;
    other cfm-policer1 ;
    all cfm-policer2;
    }
  }
```

Case 2: Session-Level CFM Policing

This example shows a session-level CFM policer used for rate-limiting CFM. The **policer** statement at the session **[edit protocols oam ethernet connectivity-fault-management maintenance-domain** ***md-name*** **maintenance-association** ***ma-name*****]** hierarchy level specifies the policer to use for policing only continuity check packets of the CFM traffic belonging to the specified session. The **other** ***cfm-policer1*** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain** ***md-name*** **maintenance-association** ***ma-name*****]** hierarchy level specifies the policer to use for policing all non-continuity check packets of the CFM traffic belonging to this session only. The **all** ***cfm-policer2*** statement specifies to police all CFM packets with the specified policer *cfm-policer2*. If the **all** ***policer-name*** option is used, then the user cannot specify the previous **continuity-check** and **other** options.

```
[edit protocols oam ethernet]
connectivity-fault-management {
  maintenance-domain md {
    level number;
    maintenance-association ma {
      continuity-check {
        interval 1s;
      }
      policer {
        continuity-check cfm-policer;
        other cfm-policer1;
        all cfm-policer2;
        }
      }
      mep 1 {
        interface ge-3/3/0.0;
        direction up;
        auto-discovery;
      }
```

```
    }
  }
```

In the case of global CFM policing, the same policer is shared across multiple CFM sessions. In per-session CFM policing, a separate policer must be created to rate-limit packets specific to that session.

NOTE:
Service-level policer configuration for any two CFM sessions on the same interface at different levels must satisfy the following constraints if the direction of the sessions is the same:

- If one session is configured with **policer all**, then the other session cannot have a **policer all** or **policer other** configuration.
- If one session is configured with **policer other**, then the other session cannot have a **policer all** or **policer other** configuration.

A commit error will occur if such a configuration is committed.

NOTE: Policers with PBB and MIPs are not supported.

Configuring Unified ISSU for 802.1ag CFM

A unified in-service software upgrade (ISSU) enables you to upgrade between two different Junos OS releases with no disruption on the control plane and with minimal disruption of traffic. Unified ISSU is automatically enabled for the Connectivity Fault

Management (CFM) protocols and interoperates between local and remote maintenance endpoints (MEPs).

The Junos OS provides support for unified ISSU using the loss threshold type length value (TLV), which is automatically enabled for CFM. TLVs are described in the IEEE 802.1ag standard for CFM as a method of encoding variable-length and optional information in a protocol data unit (PDU). The loss threshold TLV indicates the loss threshold value of a remote MEP. The loss threshold TLV is transmitted as part of the CFM continuity check messages.

NOTE: **Starting in Junos OS Release 15.1, configuring ISSU with CFM (802.1ag) is supported only on MX and PTX routers that support TLV. Interoperation with other vendors is not supported.**

During a unified ISSU, the control plane may go down for several seconds and cause CFM continuity check packets to get dropped. This may cause the remote MEP to detect a connectivity loss and mark the MEP as down. To keep the MEP active during a unified ISSU, the loss threshold TLV communicates the minimum threshold value the receiving MEP requires to keep the MEP active. The receiving MEP parses the TLV and updates the loss threshold value, but only if the new threshold value is greater than the locally configured threshold value.

An overview of CFM is described starting in "IEEE 802.1ag OAM Connectivity Fault Management Overview" on page 596, and you should further observe the additional requirements described in this topic.

Table 70 on page 658 shows the Loss Threshold TLV format.

Table 70: Loss Threshold TLV Format

Parameter	Octet (sequence)	Description
Type=31	1	Required. Required. If 0, no Length or Value fields follow. If not 0, at least the Length field follows the Type field.
Length=12	2	Required if the Type field is not 0. Not present if the Type field is 0. The 16 bits of the Length field indicate the size, in octets, of the Value field. 0 in the Length field indicates that there is no Value field.
OUI	3	Optional. Organization unique identifier (OUI), which is controlled by the IEEE and is typically the first three bytes of a MAC address (Juniper OUI 0x009069).
Subtype	1	Optional. Organizationally defined subtype.
Value	4	Optional. Loss threshold value.
Flag	4	Optional. Bit0 (identifies an ISSU is in progress) Bit1-31 (reserved)

Junos OS provides configuration support for the **convey-loss-threshold** statement, allowing you to control the transmission of the loss threshold TLV in continuity check messages PDUs. The **convey-loss-threshold** statement specifies that the loss threshold TLV must be transmitted as part of the continuity check messages. If the **convey-loss-threshold** statement is not specified, continuity check messages transmit this TLV only when a unified ISSU is in progress. The Junos OS provides this configuration at the continuity-check level. By default, continuity check messages do not include the loss threshold TLV.

To configure the convey loss threshold, use the **convey-loss-threshold** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *identifier* maintenance-association *identifier* continuity-check]** hierarchy level.

For the remote MEP, the loss threshold TLV is transmitted only during the unified ISSU if the **convey-loss-threshold** statement is not configured. The remote MEP switches back to the default loss threshold if no loss threshold TLV is received or the TLV has a default threshold value of 3.

An example of the ISSU configuration statements follows:

```
protocols {
  oam {
    ethernet {
      connectivity-fault-management {
        maintenance-domain identifier {
        level number;
          maintenance-association identifier {
            continuity-check {
              convey-loss-threshold;
              interval number;
              loss-threshold number;
              hold-interval number;
            }
          }
        }
      }
    }
  }
}
```

The Junos OS saves the last received loss threshold TLV from the remote MEP. You can display the last saved loss threshold TLV that is received by the remote MEP, using the **show oam ethernet connectivity-fault-management mep-database maintenance-domain *identifier* maintenance-association *identifier* local-mep *identifier* remote-mep *identifier*** command, as in the following example:

```
user@host> show oam ethernet connectivity-fault-management mep-database
maintenance-domain md3 maintenance-association ma5 local-mep 2 remote-mep 1
Maintenance domain name: md3, Format: string, Level: 3
  Maintenance association name: ma3, Format: string
  Continuity-check status: enabled, Interval: 1s, Loss-threshold: 3 frames
  MEP identifier: 2, Direction: up, MAC address: 00:19:e2:b0:76:be
  Auto-discovery: enabled, Priority: 0
  Interface status TLV: none, Port status TLV: none
  Connection Protection TLV: yes
```

```
    Prefer me: no, Protection in use: no, FRR Flag: no
  Interface name: xe-4/1/1.0, Interface status: Active, Link status: Up
    Loss Threshold TLV:
      Loss Threshold: 3  , Flag:    0x0

 Remote MEP identifier: 1, State: ok
    MAC address: 00:1f:12:b7:ce:79, Type: Learned
    Interface: xe-4/1/1.0
    Last flapped: Never
    Continuity: 100%, Admin-enable duration: 45sec, Oper-down duration: 0sec
    Effective loss threshold: 3 frames
    Remote defect indication: false
    Port status TLV: none
    Interface status TLV: none
    Connection Protection TLV:
      Prefer me: no, Protection in use: no, FRR Flag: no
    Loss Threshold TLV:    #Displays last received value
      Loss Threshold: 3  , Flag:    0x0
```

The Junos OS saves the last transmitted loss threshold TLV from a local MEP. You can display the last transmitted loss threshold TLV and the effective loss (operational) threshold for the remote MEP, using the **show oam ethernet connectivity-fault-management mep-database maintenance-domain** ***identifier*** **maintenance-association** ***identifier*** **local-mep** ***identifier*** **remote-mep** ***identifier*** command, as in the following example:

```
user@host> show oam ethernet connectivity-fault-management mep-database
maintenance-domain md3 maintenance-association ma5 local-mep 2 remote-mep 1
Maintenance domain name: md3, Format: string, Level: 3
  Maintenance association name: ma3, Format: string
  Continuity-check status: enabled, Interval: 1s, Loss-threshold: 3 frames
  MEP identifier: 2, Direction: up, MAC address: 00:19:e2:b0:76:be
  Auto-discovery: enabled, Priority: 0
  Interface status TLV: none, Port status TLV: none
  Connection Protection TLV: yes
    Prefer me: no, Protection in use: no, FRR Flag: no
  Interface name: xe-4/1/1.0, Interface status: Active, Link status: Up
    Loss Threshold TLV:    #Displays last transmitted value
      Loss Threshold: 3  , Flag:    0x0

   Remote MEP identifier: 1, State: ok
    MAC address: 00:1f:12:b7:ce:79, Type: Learned
    Interface: xe-4/1/1.0
    Last flapped: Never
    Continuity: 100%, Admin-enable duration: 45sec, Oper-down duration: 0sec
    Effective loss threshold: 3 frames    #Displays operational threshold
    Remote defect indication: falsePort status TLV: none
    Interface status TLV: none
    Connection Protection TLV:
      Prefer me: no, Protection in use: no, FRR Flag: no
    Loss Threshold TLV:
      Loss Threshold: 3  , Flag:    0x0
```

Release History Table

Release	Description
15.1	Starting in Junos OS Release 15.1, configuring ISSU with CFM (802.1ag) is supported only on MX and PTX routers that support TLV.

Configuring Continuity Check Messages for Better Scalability

This topic describes how to configure CCM for better scalability. Junos OS provides enhancements to trigger faster protection-switching and convergence in the event of failures in Ethernet domains for Carrier Ethernet services. These enhancements can be used when CE devices in the Ethernet domain detect faster service failures and propagates the information in the interface-status TLV of the continuity-check messages (CCMs). When CCMs are received, PE devices can perform certain actions which facilitates faster protection-switching and convergence.

To configure CCM for better scalability:

- You can apply an action profile to provide faster protection switching for point-to-point network topologies with local switching configured. See “Configuring Faster Protection Switching for Point-to-Point Network Topologies” on page 662.
- You can apply an action profile to provide faster convergence for dual-homed multipoint-to-multipoint network topologies. See “Configuring Faster Convergence for Dual-Homed Multipoint-to-Multipoint Network Topologies” on page 663.
- You can assign a primary virtual LAN (VLAN) ID in the maintenance association for increased flexibility in the number of tags. See “Configuring a Primary VLAN ID for Increased Flexibility” on page 664.
- You can configure a maintenance association to accept a different maintenance association identifier (ID) from a neighbor by including a **remote-maintenance-association** statement. See “Configuring a Remote Maintenance Association to Accept a Different ID” on page 665.

- Configuring a Remote Maintenance Association to Accept a Different ID on page 665

Configuring Faster Protection Switching for Point-to-Point Network Topologies

You can apply an action profile to provide faster protection switching for point-to-point network topologies with local switching configured. In a normal state, CCM sessions are configured on the working and protect interfaces. The CCM packets transmitted contain an interface-status TLV with the value up on the working interface and value down on the protect interface. When a link fails on the working interface, the protect interface starts receiving the interface-status TLV as up. With the profile configuration, if the interface-status TLV received on the protect interface is up, the working interface is automatically marked as **interface-down**.

To configure the **interface-status-tlv** down event, include the **interface-status-tlv down** statement at the **[edit protocols oam ethernet connectivity-fault-management action-profile *profile-name* event]** hierarchy level.

To configure **interface-down** as the action profile's action, include the **interface-down** statement at the **[edit protocols oam ethernet connectivity-fault-management action-profile *profile-name* action]** hierarchy level.

To configure **interface-down *peer-interface*** as the clear-action, include **interface-down *peer-interface*** at the **[edit protocols oam ethernet connectivity-fault-management action-profile *profile-name* clear-action]** hierarchy level.

```
[edit protocols oam]
ethernet {
  connectivity-fault-management {
    action-profile p1 {
      event {
        interface-status-tlv down;
      }
      action {
        interface-down;
      }
      clear-action {
        interface-down peer-interface;
      }
    }
  }
}
```

In this action profile configuration, when the interface-status TLV is received as up, the *peer-interface* is marked as down.

The *peer-interface* is configured in the **protect-maintenance-association** statement. Consider the following example using the **protect-maintenance-association** statement in the configuration:

```
[edit protocols oam]
ethernet {
  connectivity-fault-management {
    action-profile p1 {
      event {
        adjacency-loss;
```

```
          }
          action {
            interface-down;
          }
          clear-action {
            interface-down peer-interface;
          }
        }
        maintenance-domain nsn {
          level 5;
          maintenance-association ma1 {
            protect-maintenance-association ma2;
            continuity-check {
              interval 100ms;
              connection-protection-tlv;
            }
            mep 100 {
              interface ge-1/1/0.0;
              direction down;
              auto-discovery;
            }
          }
          maintenance-association ma2 {
            continuity-check {
              interval 100ms;
              connection-protection-tlv;
          }
          mep 101 {
              interface ge-1/2/0.0;
              direction down;
              auto-discovery;
          }
          remote-mep 100
            action-profile p1;
          }
        }
      }
    }
```

Related Documentation

Configuring Faster Convergence for Dual-Homed Multipoint-to-Multipoint Network Topologies

You can apply an action profile to provide faster convergence for dual-homed multipoint-to-multipoint network topologies. If a multipoint-to-multipoint Ethernet service uses MAC-based forwarding and stale MAC addresses exist in the learning tables, this can result in traffic black holes in the network where incoming traffic is silently discarded, without informing the source that the data did not reach its intended recipient. With the profile configuration, if the interface-status TLV received on the protect interface is up, then the interface-status TLV on the working interface is marked as down and the PE device for the protect interface propagates a remote MAC-flush message to the PE devices in the virtual private LAN service (VPLS) by using TLDP-MAC-FLUSH. The MAC flush avoids traffic blackholing due to stale mac-db entries.

To configure the **interface-status-tlv** down event, include the **interface-status-tlv down** statement at the **[edit protocols oam ethernet connectivity-fault-management action-profile *profile-name* event]** hierarchy level.

To configure **propagate-remote-flush** as the action profile's action, include the **propagate-remote-flush** statement at the **[edit protocols oam ethernet connectivity-fault-management action-profile *profile-name* action]** hierarchy level.

To configure **propagate-remote-flush** as the clear-action, include the **propagate-remote-flush** statement at the **[edit protocols oam ethernet connectivity-fault-management action-profile *profile-name* clear-action]** hierarchy level.

```
[edit protocols oam]
ethernet {
  connectivity-fault-management {
    action-profile test {
      event {
        interface-status-tlv down;
      }
      action {
        propagate-remote-mac-flush;
      }
      clear-action {
        propagate-remote-mac-flush;
      }
    }
  }
}
```

In this action profile configuration, when the incoming CCM packet contains the interface-status TLV with value down, the **propagate-remote-mac-flush** action is triggered for the action-profile.

- Configuring a CFM Action Profile to Specify CFM Actions for CFM Events on page 625

Configuring a Primary VLAN ID for Increased Flexibility

You can assign a primary virtual LAN (VLAN) ID in the maintenance association for increased flexibility in the number of tags. When a **vlan-range** or **vlan-id-list** is configured on an interface, the service OAM must run on one of the VLANs. The VLAN assigned for service monitoring is considered the primary VLAN. If a **primary-vid** is not configured, Junos OS assigns the first VLAN from the **vlan-range** or **vlan-id-list**. In earlier releases, Junos OS assigned VLAN 4095.

To configure a primary VLAN ID, you can specify the **primary-vid** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name*]** hierarchy level:

```
[edit protocols oam ethernet connectivity-fault-management]
maintenance domain md3 {
  level 3;
  maintenance-association ma3 {
    primary-vid 2000;
    continuity-check {
      interval 10ms;
      connection-protection-tlv;
    }
    mep 2 {
      interface ge-2/2/0.0;
      direction up;
      auto-discovery;
    }
  }
}
```

Related Documentation

- *connection-protection-tlv*
- Creating a Maintenance Association on page 610
- **connectivity-fault-management on page 1113**

Configuring a Remote Maintenance Association to Accept a Different ID

You can configure a maintenance association to accept a different maintenance association identifier (ID) from a neighbor by including a **remote-maintenance-association** statement. The 802.1ag CCM sessions expect the same maintenance association identifier from its neighbors. If there is a maintenance association identifier mismatch, the PDUs are marked as error PDUs. If a **remote-maintenance-association** statement is configured, a different maintenance association identifier is accepted and the 802.1ag CCM sessions do not mark the CCM PDUs as error PDUs when the maintenance-association name is the same as the name specified in the **remote-maintenance-association** statement.

To configure a remote maintenance association, include the **remote-maintenance-association** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name*]** hierarchy level:

```
[edit protocols oam ethernet connectivity-fault-management]
maintenance domain md3 {
  level 1;
  maintenance-association ma3 {
    remote-maintenance-association fix-ma;
```

```
            continuity-check {
                interval 10ms;
                connection-protection-tlv;
            }
            mep 2 {
                interval ge-2/2/0.0;
                direction up;
                auto-discovery;
            }
        }
    }
```

Using this configuration, interoperability is improved for CCMs with low-end CE devices supporting fixed maintenance association identifier configurations.

Enabling Enhanced Connectivity Fault Management Mode

You can enable enhanced connectivity fault management (CFM) mode to enable effective Ethernet OAM deployment in scaling networks. On enabling enhanced CFM mode, Junos OS supports 32, 000 maintenance association end points (MEPs) and maintenance intermediate points (MIPs) each per chassis for bridge, VPLS, L2VPN, and CCC domains. In previous releases, Junos OS supports 8, 000 MEPs and 8000 MIPS per chassis. If you do not enable enhanced CFM, Junos OS continues to support existing number of MIPs and MEPs per chassis.

NOTE: To support enhanced CFM mode, configure the network services mode on the router as **enhanced-ip**. If the network services mode is not **enhanced-ip**, and you have enabled enhanced CFM, the following warning message is displayed:
[edit protocols oam ethernet]
'connectivity-fault-management'
enhanced ip is not effective please configure enhanced ip and give router reboot

To enable enhanced CFM mode, perform the following steps:

1. In configuration mode, go to the **[edit protocols oam ethernet connectivity-fault-management]** hierarchy level.

   ```
   [edit]
   user@host# edit protocols oam ethernet connectivity-fault-management
   ```

2. Enable effective Ethernet OAM deployment by enabling enhanced CFM mode.

```
[edit protocols oam ethernet connectivity-fault-management ]
user@host# set enhanced-cfm-mode
```

3. Commit the mode change. A warning message is displayed asking you to restart CFM. If you do not restart CFM, CFM is automatically restarted by Junos OS.

```
[edit protocols oam ethernet connectivity-fault-management ]
user@host # commit
[edit protocols oam ethernet]
'connectivity fault management'
CFM mode change is catastrophic. cfmd will be restarted
commit complete
```

4. To verify if the enhanced CFM mode has been configured, use the **show oam ethernet connectivity-fault-management state** command.

```
[edit protocols oam ethernet connectivity-fault-management ]
user@host# run show oam ethernet connectivity-fault-management
 enhanced-cfm-mode;
 traceoptions {
     file cfmd.log size 1g;
 }
 maintenance-domain md6 {
     level 6;
     maintenance-association ma6 {
         continuity-check {
             interval 1s;
         }
         mep 102 {
             interface ge-0/0/0.0;
             direction up;
         }
     }
 }
```

Understanding CFM Monitoring between CE and PE Devices

You can enable connectivity fault management (CFM) monitoring between provider edge devices and customer edge devices when the customer edge device is not a Juniper device. When the interface is down, CFM propagates the status of the interface in the CC messages. The CC message informs the customer edge device that the provider edge device is down.

You can configure CFM monitoring using either of the following two options:

- Interface Status TLV (Type, Length, and Value)—You can enable connectivity fault management (CFM) monitoring between provider edge devices and customer edge devices when the customer edge device is not a Juniper device by using Interface Status TLV. When the interface is down, CFM propagates the status of the interface using interface status TLV. The Interface Status TLV indicates the status of the interface on which the MEP transmitting the CCM is configured, or the next-lower interface in the

IETF RFC 2863 IF-MIB. Thus, the customer edge device is aware that the provider edge device is down. To configure CFM monitoring using Interface Status TLV, use the **interface-status-tlv** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *maintenance-domain* maintenance-association *maintenance-association* continuity-check** hierarchy level. This is the standard option.

- RDI (Remote Defect Indication)—Starting in Junos OS Release 17.3R1, you can enable connectivity fault management (CFM) monitoring between provider edge devices and customer edge devices when the customer edge device is not a Juniper device by using the remote defect indication (RDI) bit. When you enable CFM monitoring, CFM propagates the status of the provider edge device via the remote defect indication (RDI) bit in the CC messages. Thus, the customer edge device is aware that the provider edge device is down. The RDI bit is cleared when the service is back up. To configure CFM monitoring using the RDI bit, use the **interface-status-send-rdi** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *maintenance-domain* maintenance-association *maintenance-association* continuity-check** hierarchy level. This option is required if the customer edge device does not support Interface Status TLV.

NOTE: **When the interface is set to CCC down and you have configured RDI, then RDI bit is sent. CFM does not monitor the status of the interface. If CCC down is set when the interface is not standby, RDI bit is sent with the CC messages if you have configured RDI.**

Single Active Multi-homing Use Case using RDI bit

Consider the following topology where there are two provider edge devices (PE1 and PE2) as well as two customer edge devices (CE1 and CE2). PE1 is in active state while PE2 is in standby state. CFM down MEP is configured between the PE and CE. CFM detects that the CCC down and because CFM down MEP is configured, the CC messages generated have the RDI bit. The CC messages from PE2 to CE2 have the RDI bit set to indicate the blocked state. When PE2 becomes active, CCM down is cleared and the RDI bit is cleared from the subsequent CC messages.

Active/Active Multihoming Use case using RDI bit

Consider the topology where there are two provider edge devices (PE1 and PE2) and two customer edge devices (CE1 and CE2). PE1 is in active state while PE2 is in standby state. If CFM down MEP is not configured between the PE and CE to monitor the link connectivity, the CC messages generated do not have the RDI bit. CFM down MEP is configured between the PE and CE. CFM detects that the CCC down and because CFM down MEP is configured, the CC messages generated have the RDI bit. The CC messages from PE2 to CE2 have the RDI bit set to indicate the blocked state. When PE2 becomes active, CCM down is cleared and the RDI bit is cleared from the subsequent CC messages.

Release History Table

Release	Description
17.3R1	Starting in Junos OS Release 17.3R1, you can enable connectivity fault management (CFM) monitoring between provider edge devices and customer edge devices when the customer edge device is not a Juniper device by using the remote defect indication (RDI) bit.

Example: Configuring Ethernet CFM on Physical Interfaces

This example shows the configuration of Ethernet connectivity fault management (CFM) on physical interfaces.

Requirements

This example uses the following hardware and software components:

- Junos OS Release 9.3 or later.

Overview

CFM can be used to monitor the physical link between two routers. This functionality is similar to that supported by the IEEE 802.3ah LFM protocol.

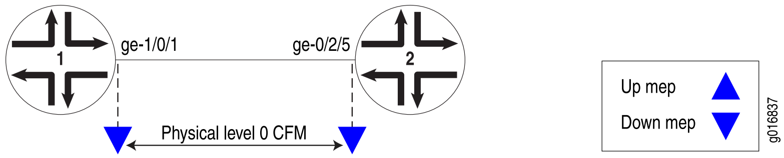
In Junos OS Release 9.3 and later, CFM also supports aggregated Ethernet interfaces. On interfaces configured on Modular Port Concentrators (MPCs) and Modular Interface Cards (MICs) on MX Series routers, CFM is not supported on untagged aggregated Ethernet member links. MPCs and MICs do support CFM on untagged and tagged aggregated Ethernet logical interfaces.

NOTE: **The configurations in this example are only partial examples of complete and functional router configurations. Do not copy these configurations and use them directly on an actual system.**

Configuration

In the following example, two routers (Router 1 and Router 2) are connected by a point-to-point Gigabit Ethernet link. The link between these two routers is monitored using CFM. This is shown in Figure 45 on page 670. The single boundary is a “down mep” in CFM terminology.

Figure 45: Ethernet CFM on Physical Interfaces



To configure Ethernet CFM on physical interfaces, perform these tasks:

CLI Quick Configuration Router 1

Configure the interface and CFM:

```
[edit]
interfaces ge-1/0/1 {
  unit 0 {
    family inet;
  }
}

protocols {
  oam {
    ethernet {
      connectivity-fault-management {
        maintenance-domain private {
          level 0;
          maintenance-association private-ma {
            continuity-check {
              interval 1s;
            }
            mep 100 {
              interface ge-1/0/1;
              direction down;
              auto-discovery;
            }
          }
        }
      }
    }
  }
}
```

The configuration on Router 2 mirrors that on Router 1, with the exception of the *mep-id*.

Router 2

Configure the interface and CFM:

```
[edit]
interfaces ge-0/2/5 {
  unit 0 {
    family inet;
  }
}

protocols {
```

```
  oam {
    ethernet {
      connectivity-fault-management {
        maintenance-domain private {
          level 0;
          maintenance-association private-ma {
            continuity-check {
              interval 1s;
            }
            mep 200 {
              interface ge-0/2/5;
              direction down;
              auto-discovery;
            }
          }
        }
      }
    }
  }
}
```

To verify that the physical interface is configured correctly for CFM, use the **show interface** command. To verify the CFM configuration, use one or more of the **show oam ethernet connectivity-fault-management** commands listed in the CLI Explorer.

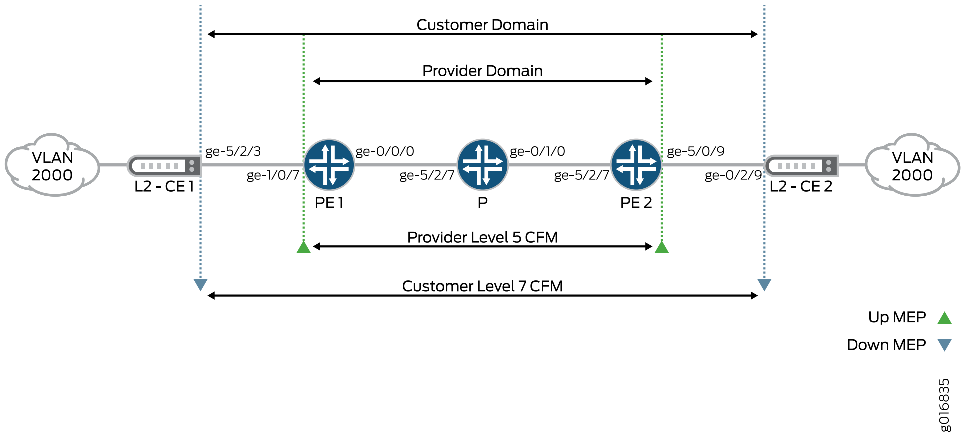
Example: Configuring Ethernet CFM over VPLS

In this example, both the customer and service provider are running Ethernet CFM over a VPLS and a multiprotocol label switching (MPLS) network. The network is shown in Figure 47 on page 676. The customer has configured Ethernet CFM on MX Series routers L2-CE1 and L2-CE2. The service provider has configured Ethernet CFM on MX Series routers PE1, P, and PE2.

NOTE: The configurations in this example are only partial examples of complete and functional router configurations. Do not copy these configurations and use them directly on an actual system.

The service provider is using CFM level 5 and the customer is using CFM level 7. The boundaries are marked with “up mep” and “down mep” CFM terminology in the figure.

Figure 47: Ethernet OAM with VPLS



NOTE: The logical interfaces in a VPLS routing instance might have the same or different VLAN configurations. VLAN normalization is required to switch packets correctly among these interfaces. Normalization supports automatic mapping of VLANs and performs operations on VLAN tags to achieve the desired translation. See *Configuring a Normalized VLAN for Translation or Tagging*.

NOTE:

The following forwarding path considerations must be observed:

- Packet receive path:
  - This is the forwarding path for packets received on the interfaces.
  - 802.1ag Ethernet OAM for VPLS uses implicit interface filters and forwarding table filters to flood, accept, and drop the CFM packets.
- Packet transmit path:
  - Junos OS uses the router's hardware-based forwarding for CPU-generated packets.
  - For down MEPs, the packets are transmitted on the interface on which the MEP is configured.
  - In MX series routers, for up MEPs, the packets must be flooded to other interfaces in the VPLS routing instance. The router creates a flood route tied to a flood next hop (with all interfaces to flood) and then sources the packets to be forwarded with this flood route.

The following are the configurations of the VPLS and CFM on the service provider routers.

Configuration of PE1

```

IEEE 802.3ah OAM Link-Fault Management Overview

Ethernet interfaces capable of running at 100 Mbps or faster on EX Series switches, PTX Series, MX Series, M Series (except M5 and M10 routers), and T Series routers support the IEEE 802.3ah standard for Operation, Administration, and Management (OAM). You can configure IEEE 802.3ah OAM on Ethernet point-to-point direct links or links across Ethernet repeaters. The IEEE 802.3ah standard meets the requirement for OAM capabilities as Ethernet moves from being solely an enterprise technology to being a WAN and access technology, as well as being backward-compatible with existing Ethernet technology. Junos OS supports IEEE 802.3ah link-fault management.

The features of link-fault management are:

- Discovery
- Link monitoring
- Remote fault detection
- Remote loopback

Starting in Junos OS Release 17.3R1, the Ethernet link fault management daemon (lfmd) runs on the backup Routing Engine as well when graceful Routing Engine switchover (GRES) is configured.

The following features are not supported:

- Ethernet running on top of a Layer 2 protocol, such as Ethernet over ATM, is not supported in OAM configurations.
- Remote loopback is not supported on the 10-Gigabit Ethernet LAN/WAN PIC with SFP+.
- The remote loopback feature mentioned in section 57.2.11 of IEEE 802.3ah is not supported on T4000 routers.

NOTE: **Aggregated Ethernet member links will now use the physical MAC address as the source MAC address in 802.3ah OAM packets.**

Release History Table

Release	Description
17.3R1	Starting in Junos OS Release 17.3R1, the Ethernet link fault management daemon (lfmd) runs on the backup Routing Engine as well when graceful Routing Engine switchover (GRES) is configured.

Understanding Ethernet OAM Link Fault Management for ACX Series Routers

The Juniper Networks Junos operating system (Junos OS) for Juniper Networks ACX Series routers allows the Ethernet interfaces on these routers to support the IEEE 802.3ah standard for the Operation, Administration, and Maintenance (OAM) of Ethernet in access networks. The standard defines OAM link fault management (LFM). You can configure IEEE 802.3ah OAM LFM on point-to-point Ethernet links that are connected either directly or through Ethernet repeaters. The IEEE 802.3ah standard meets the requirement for OAM capabilities even as Ethernet moves from being solely an enterprise technology to a WAN and access technology, and the standard remains backward compatible with the existing Ethernet technology.

Ethernet OAM provides tools that network management software and network managers can use to determine how a network of Ethernet links is functioning. Ethernet OAM should:

- Rely only on the media access control (MAC) address or virtual LAN identifier for troubleshooting.
- Work independently of the actual Ethernet transport and function over physical Ethernet ports or a virtual service such as a pseudowire.
- Isolate faults over a flat (or single-operator) network architecture or nested or hierarchical (or multiprovider) networks.

The following OAM LFM features are supported on ACX Series routers:

- Discovery and Link Monitoring

  The discovery process is triggered automatically when OAM is enabled on the interface. The discovery process permits Ethernet interfaces to discover and monitor the peer on the link if it also supports the IEEE 802.3ah standard. You can specify the discovery mode used for IEEE 802.3ah OAM support. In active mode, the interface discovers and monitors the peer on the link if the peer also supports IEEE 802.3ah OAM functionality. In passive mode, the peer initiates the discovery process. After the discovery process has been initiated, both sides participate in the process. The router performs link monitoring by sending periodic OAM protocol data units (PDUs) to advertise OAM mode, configuration, and capabilities.

  You can specify the number of OAM PDUs that an interface can skip before the link between peers is considered down.

- Remote Fault Detection

  Remote fault detection uses flags and events. Flags are used to convey the following:

  - **Link Fault** means a loss of signal
  - **Dying Gasp** means an unrecoverable condition such as a power failure. In this condition, the local peer informs the remote peer about the failure state. When the remote peer receives a dying-gasp PDU, it takes an action corresponding to the action profile configured with the **link-adjacency-loss** event.

    NOTE: ACX5096 and ACX5048 routers do not support dying-gasp.

    ACX Series routers can generate and receive dying-gasp packets. When LFM is configured on an interface, a dying-gasp PDU is generated for the interface on the following failure conditions:

    - Power failure
    - Packet Forwarding Engine panic or a crash

  - **Critical Event** means an unspecified vendor-specific critical event.

  You can specify the interval at which OAM PDUs are sent for fault detection.

NOTE: ACX Series routers support the receipt of dying-gasp packets, but cannot generate them.

- Remote Loopback Mode

  Remote loopback mode ensures link quality between the router and a remote peer during installation or troubleshooting. In this mode, when the interface receives a frame that is not an OAM PDU or a PAUSE frame, it sends it back on the same interface on which it was received. The link appears to be in the active state. You can use the returned loopback acknowledgement to test delay, jitter, and throughput.

  If a remote data terminal equipment (DTE) supports remote loopback mode, Junos OS can place the remote DTE into loopback mode. When you place a remote DTE into loopback mode, the interface receives the remote loopback request and puts the interface into remote loopback mode. When the interface is in remote loopback mode, all frames except OAM PDUs and PAUSE frames are looped back. No changes are made to the frames. OAM PDUs continue to be sent and processed.

Configuring IEEE 802.3ah OAM Link-Fault Management

You can configure threshold values for fault events that trigger the sending of link event TLVs when the values exceed the threshold. To set threshold values for fault events on an interface, include the **event-thresholds** statement at the **[edit protocols oam ethernet link-fault-management interface]** hierarchy level.

You can also configure OAM threshold values within an action profile and apply the action profile to multiple interfaces. To create an action profile, include the **action-profile** statement at the **[edit protocols oam ethernet link-fault-management]** hierarchy level.

You can configure Ethernet OAM either on an aggregate interface or on each of its member links. However, we recommend that you configure Ethernet OAM on the aggregate interface, and this will internally enable Ethernet OAM on the member links.

To view OAM statistics, use the **show oam ethernet link-fault-management** operational mode command. To clear OAM statistics, use the **clear oam ethernet link-fault-management statistics** operational mode command. To clear link-fault management state information and restart the link discovery process on Ethernet interfaces, use the **clear oam ethernet link-fault-management state** operational mode command. For more information about these commands, see the CLI Explorer.

Configuring Ethernet 802.3ah OAM on PTX Series Packet Transport Routers

The IEEE 802.3ah standard for Operation, Administration, and Management (OAM) provides a specification for *Ethernet in the first mile (EFM)* connectivity. EFM defines how Ethernet can be transmitted over new media types using new Ethernet physical layer (PHY) interfaces. You can configure IEEE 802.3ah OAM on Ethernet point-to-point direct links or links across Ethernet repeaters. The IEEE 802.3ah OAM standard meets the requirement for OAM capabilities as Ethernet moves from being solely an enterprise technology to being a WAN and access technology, as well as being backward-compatible with existing Ethernet technology.

For Ethernet interfaces capable of running at 100 Mbps or faster, the IEEE 802.3ah OAM standard is supported on numerous Juniper Networks routers and switches. This topic describes configuration support for IEEE 802.3ah OAM features on PTX Series Packet Transport Routers.

Beginning in Junos OS Release 12.1, PTX Series routers support the following IEEE 802.3ah OAM features at the physical interface level:

- Discovery and link monitoring
- Fault signaling and detection
- Periodic packet management (PPM) processing

- Action profile support
- Graceful Routing Engine switchover (GRES)

To configure 802.3ah OAM support for Ethernet interfaces, include the **oam** statement at the **[edit protocols]** hierarchy level:

```
oam {
  ethernet {
    link-fault-management {
      interfaces {
        interface-name {
          pdu-interval interval;
          link-discovery (active | passive);
          pdu-threshold count;
        }
      }
    }
  }
}
```

Enabling IEEE 802.3ah OAM Support

To enable IEEE 802.3ah OAM support, include the **interface** statement at the **[edit protocols oam ethernet link-fault-management]** hierarchy level:

[edit protocols oam ethernet link-fault-management interface *interface-name*]

When you enable IEEE 802.3ah OAM on a physical interface, the discovery process is automatically triggered.

Configuring Link Discovery

When the IEEE 802.3ah OAM protocol is enabled on a physical interface, the discovery process is automatically triggered. The discovery process permits Ethernet interfaces to discover and monitor the peer on the link if it also supports the IEEE 802.3ah standard.

You can specify the discovery mode used for IEEE 802.3ah OAM support. The discovery process is triggered automatically when OAM IEEE 802.3ah functionality is enabled on a port. Link monitoring is done when the interface sends periodic OAM PDUs.

To configure the discovery mode, include the **link-discovery** statement at the **[edit protocol oam ethernet link-fault-management interface *interface-name*]** hierarchy level:

```
[edit protocol oam ethernet link-fault-management interface interface-name]
link-discovery (active | passive);
```

In active mode, the interface discovers and monitors the peer on the link if the peer also supports IEEE 802.3ah OAM functionality. In passive mode, the peer initiates the discovery process. After the discovery process has been initiated, both sides participate in discovery.

Configuring the OAM PDU Interval

Periodic OAM PDUs are sent to perform link monitoring.

You can specify the periodic OAM PDU sending interval for fault detection.

To configure the sending interval, include the **pdu-interval** statement at the **[edit protocol oam ethernet link-fault-management interface *interface-name*]** hierarchy level:

```
[edit protocol oam ethernet link-fault-management interface interface-name]
pdu-interval interval;
```

The periodic OAM PDU interval range is from 100 through 1000 milliseconds. The default sending interval is 1000 milliseconds.

- Example: Configuring IEEE 802.3ah OAM Support on an Interface on page 710

Configuring the OAM PDU Threshold

You can specify the number of OAM PDUs that an interface can miss before the link between peers is considered down.

To configure the number of PDUs that can be missed from the peer, include the **pdu-threshold** statement at the **[edit protocol oam ethernet link-fault-management interface *interface-name*]** hierarchy level:

```
[edit protocol oam ethernet link-fault-management interface interface-name]
pdu-threshold threshold-value;
```

The threshold value range is from 3 through 10. The default is three PDUs.

Configuring Threshold Values for Local Fault Events on an Interface

You can configure threshold values on an interface for the local errors that trigger the sending of link event TLVs.

To set the error threshold values for sending event TLVs, include the **frame-error**, **frame-period**, **frame-period-summary**, and **symbol-period** statements at the **[edit protocols oam ethernet link-fault-management interface *interface-name* event-thresholds]** hierarchy level:

```
[edit protocol oam ethernet link-fault-management interface interface-name]
event-thresholds {
  frame-error count;
  frame-period count;
  frame-period-summary count;
  symbol-period count;
}
```

Disabling the Sending of Link Event TLVs

You can disable the sending of link event TLVs.

To disable the monitoring and sending of PDUs containing link event TLVs in periodic PDUs, include the **no-allow-link-events** statement at the **[edit protocols oam ethernet link-fault-management interface *interface-name* negotiation-options]** hierarchy level:

```
[edit protocol oam ethernet link-fault-management interface interface-name
  negotiation-options]
no-allow-link-events;
```

Detecting Remote Faults

Fault detection is either based on flags or fault event type, length, and values (TLVs) received in OAM protocol data units (PDUs). Flags that trigger a link fault are:

- Critical Event
- Dying Gasp
- Link Fault

The link event TLVs are sent by the remote DTE by means of event notification PDUs. Link event TLVs are:

- Errored Symbol Period Event
- Errored Frame Event
- Errored Frame Period Event
- Errored Frame Seconds Summary Event

Enabling Dying Gasp Functionality

Dying gasp means an unrecoverable condition such as a power failure. In this condition, the local peer informs the remote peer about the failure state. When the remote peer receives a dying-gasp PDU, it takes an action corresponding to the action profile configured with the **link-adjacency-loss** event. Dying gasp helps to avoid file system corruption.

NOTE: ACX5096 and ACX5048 routers do not support dying-gasp.

ACX Series routers can generate and receive dying-gasp packets. When LFM is configured on an interface, a dying-gasp PDU is generated for the interface on the following failure conditions:

- Power failure

- Packet Forwarding Engine panic or a crash

ACX Series routers support the following CLI statements to enable dying-gasp functionality:

- **dgasp-int**—Enables dying-gasp functionality.
- **dgasp-usb**—Resets USB port during dying-gasp event.

The **dgasp-int** and **dgasp-usb** CLI statements are added under the **[edit system]** hierarchy to enable dying-gasp functionality.

To enable dying-gasp functionality, you need to configure the **dgasp-int** and **dgasp-usb** CLI statements as shown below:

```
root@host% cli
root@host> configure
Entering configuration mode

[edit]
root@host# set system dgasp-int

[edit]
root@host# set system dgasp-usb

[edit]
root@host# commit

commit complete

[edit]
root@host# show system
dgasp-int;
dgasp-usb;
```

The dying-gasp functionality is disabled by default.

Configuring an OAM Action Profile

You can create an action profile to define event fault flags and thresholds and the action to be taken. You can then apply the action profile to one or more interfaces.

To configure an action profile, include the **action-profile** statement at the **[edit protocols oam ethernet link-fault-management]** hierarchy level:

```
action-profile profile-name {
  action {
    syslog;
    link-down;
    send-critical-event;
  }
  event {
    link-adjacency-loss;
```

```
        link-event-rate {
          frame-error count;
          frame-period count;
          frame-period-summary count;
          symbol-period count;
        }
        protocol-down;
      }
    }
```

NOTE: Starting from Junos OS Release 14.2, whenever link-fault management (LFM) with an action profile is configured to mark the interface as down (by including the link-down statement at the [edit protocols oam ethernet link-fault-management] hierarchy level), the port is placed in the blocked state (STP state). In such a state of the interface, data traffic is not transmitted out on that interface. Because the connectivity-fault management (CFM) downstream maintenance MEPs come up on blocked ports, the CFM sessions come up properly. However, the interface is down and the interface status TLV does not contain the correct status. Only if you configure the port status TLV, the actual status of the port is reflected. The interface status TLV does not carry the actual state of the port.

Specifying the Actions to Be Taken for Link-Fault Management Events

You can specify the action to be taken by the system when the configured link-fault event occurs. Multiple action profiles can be applied to a single interface. For each action-profile, at least one event and one action must be specified. The actions are taken only when all of the events in the action profile are true. If more than one action is specified, all the actions are executed.

You might want to set a lower threshold for a specific action such as logging the error and set a higher threshold for another action such as sending a critical event TLV.

To specify the action, include the **action** statement at the **[edit protocols oam ethernet link-fault-management action-profile *profile-name*]** hierarchy level:

```
[edit protocol oam ethernet link-fault-management action-profile profile-name]
event {
  link-adjacency-loss;
  protocol-down;
}
action {
  syslog;
  link-down;
  send-critical-event;
}
```

To create a system log entry when the link-fault event occurs, include the **syslog** statement.

To administratively disable the link when the link-fault event occurs, include the **link-down** statement.

To send IEEE 802.3ah link event TLVs in the OAM PDU when a link-fault event occurs, include the **send-critical-event** statement.

NOTE: If multiple actions are specified in the action profile, all of the actions are executed in no particular order.

Monitoring the Loss of Link Adjacency

You can specify actions be taken when link adjacency is lost. When link adjacency is lost, the system takes the action defined in the **action** statement of the action profile.

To configure the system to take action when link adjacency is lost, include the **link-adjacency-loss** statement at the **[edit protocols oam ethernet link-fault-management action-profile *profile-name* event]** hierarchy level:

```
[edit protocol oam ethernet link-fault-management action-profile profile-name]
link-adjacency-loss;
```

Monitoring Protocol Status

The CCC-DOWN flag is associated with a circuit cross-connect (CCC) connection, Layer 2 circuit, and Layer 2 VPN, which send the CCC-DOWN status to the kernel. The CCC-DOWN flag indicates that the CCC is down. The CCC-DOWN status is sent to the kernel when the CCC connection, Layer 2 circuit, or Layer 2 VPN is down. This in turn, brings down the CE-facing PE interface associated with the CCC connection, Layer 2 circuit, or Layer 2 VPN.

When the CCC-DOWN flag is signaled to the IEEE 802.3ah protocol, the system takes the action defined in the **action** statement of the action profile. For additional information about Layer 2 circuits, see the Junos OS Layer 2 Circuits Feature Guide, Junos OS VPNs Configuration Guide.

To monitor the IEEE 802.3ah protocol, on the CE-facing PE interface, include the **protocol-down** statement at the **[edit protocols oam ethernet link-fault-management action-profile *profile-name* event]** hierarchy level:

1. In configuration mode, go to the **[edit protocols oam ethernet link-fault-management action-profile profile-name event]** hierarchy level.

```
[edit]
user@host# edit protocols oam ethernet link-fault-management action-profile
   profile-name event
```

2. Include the **protocol-down** statement.

```
[edit protocols oam ethernet link-fault-management action-profile profile-name event]
user@host# set protocol-down
```

NOTE: If multiple events are specified in the action profile, all the events must occur before the specified action is taken.

Configuring Threshold Values for Fault Events in an Action Profile

You can configure link event thresholds for received error events that trigger the action specified in the **action** statement. You can then apply the action profile to one or more interfaces.

To configure link event thresholds, include the **link-event-rate** statement at the **[edit protocols oam ethernet link-fault-management action-profile *profile-name* event]** hierarchy level:

```
link-event-rate {
  frame-error count;
  frame-period count;
  frame-period-summary count;
  symbol-period count;
}
```

Applying an Action Profile

You can apply an action profile to one or more interfaces.

To apply an action profile to an interface, include the **apply-action-profile** statement at the **[edit protocols oam ethernet link-fault-management action-profile interface *interface-name*]** hierarchy level:

```
[edit protocol oam ethernet link-fault-management interface interface-name]
apply-action-profile profile-name;
```

Related Documentation

- Configuring the OAM PDU Threshold on page 694

Setting a Remote Interface into Loopback Mode

You can configure the software to set the remote DTE into loopback mode on the following interfaces:

- IQ2 and IQ2-E Gigabit Ethernet interfaces
- Ethernet interfaces on the MX Series routers or EX Series switches

Junos OS can place a remote DTE into loopback mode (if remote-loopback mode is supported by the remote DTE). When you place a remote DTE into loopback mode, the interface receives the remote-loopback request and puts the interface into remote-loopback mode. When the interface is in remote-loopback mode, all frames except OAM PDUs are looped back without any changes made to the frames. OAM PDUs continue to be sent to the management plane and processed.

To configure remote loopback, include the **remote-loopback** statement at the **[edit protocol oam ethernet link-fault-management interface *interface-name*]** hierarchy level:

```
[edit protocol oam ethernet link-fault-management interface interface-name]
remote-loopback;
```

To take the remote DTE out of loopback mode, remove the **remote-loopback** statement from the configuration.

Related Documentation

- Configuring Link Discovery on page 692
- Configuring the OAM PDU Interval on page 693

Enabling Remote Loopback Support on the Local Interface

You can allow a remote DTE to set a local interface into remote loopback mode on IQ2 and IQ2-E Gigabit Ethernet interfaces and all Ethernet interfaces on the MX Series routers and EX Series switches. When a remote-loopback request is sent by a remote DTE, the Junos OS places the local interface into loopback mode. When an interface is in loopback mode, all frames except OAM PDUs are looped back without any changes to the frames. OAM PDUs continue to be sent to the management plane and processed. By default, the remote loopback feature is not enabled.

To enable remote loopback, include the **allow-remote-loopback** statement at the **[edit protocol oam ethernet link-fault-management interface *interface-name* negotiation-options]** hierarchy level:

```
[edit protocol oam ethernet link-fault-management interface interface-name
   negotiation-options]
allow-remote-loopback;
```

NOTE: Activation of OAM remote loopback may result in data frame loss.

Enabling Nonstop Routing for Ethernet Link Fault Management on Backup Routers

Starting in Junos OS Release 17.3R1, the Ethernet link fault management daemon (lfmd) runs on the backup Routing Engine as well when graceful Routing Engine switchover (GRES) is configured. When the lfmd daemon runs on the backup Routing Engine as well, the link fault management states are kept in sync and so minimal effort is required by the lfmd daemon post switch over.

To enable Nonstop routing for Ethernet LFM on backup routers:

1. Enable graceful Routing Engine switchover. By default, GRES is disabled. To enable GRES, include the **graceful-switchover** statement at the [**edit chassis redundancy**] hierarchy level. By default, Nonstop routing is disabled. When you enable GRES, NSR is enabled.

   ```
   [edit chassis redundancy]
   user@host# set graceful-switchover
   ```

2. Synchronize the Routing Engine configuration. To synchronize the master Routing Engine configuration with the backup, include the **synchronize** statement at the [**edit system**] hierarchy level.

   ```
   [edit system]
   user@host# set commit synchronize
   ```

3. After enabling nonstop routing, commit the configuration.

   ```
   [edit routing options]
   user@host# commit
   ```

4. To verify if nonstop routing is enabled on the backup router, at the operational mode, use the **show oam ethernet link-fault-management** command on the master router and then the backup router. Because you have enabled synchronization, the output of the master router and the backup router is identical. However, the statistics maintained by the master router are not synchronized with the backup router..

Example: Configuring IEEE 802.3ah OAM Support on an Interface

Configure 802.3ah OAM support on a 10-Gigabit Ethernet interface:

```
[edit]
protocols {
  oam {
    ethernet {
      link-fault-management {
        interface xe-0/0/0 {
          link-discovery active;
          pdu-interval 800;
          pdu-threshold 4;
          remote-loopback;
          negotiation-options {
            allow-remote-loopback;
          }
          event-thresholds {
            frame-error 30;
            frame-period 50;
            frame-period summary 40;
            symbol-period 20;
          }
        }
      }
    }
  }
}
```

Example: Configuring IEEE 802.3ah OAM Support for an Interface on ACX Series

Junos OS for ACX Series routers allows the Ethernet interfaces on these routers to support the IEEE 802.3ah standard for the Operation, Administration, and Maintenance (OAM) of Ethernet in access networks. The standard defines OAM link fault management (LFM). You can configure IEEE 802.3ah OAM LFM on point-to-point Ethernet links that are connected either directly or through Ethernet repeaters.

This example describes how to enable and configure OAM on a Gigabit Ethernet interface.

Requirements

This example uses the following hardware and software components:

- Junos OS Release 12.2 or later for ACX Series routers.
- An ACX1000 or ACX2000 router.

Overview and Topology

In this example, you configure a 10-Gigabit Ethernet interface on an ACX Series router with 802.3ah OAM support, which includes: link discovery, protocol data units (PDUs), remote loopback, negotiation, and event thresholds.

Configuring IEEE 802.3ah OAM on an ACX Series Router

CLI Quick Configuration

To quickly configure IEEE 802.3ah Ethernet OAM, copy the following commands and paste them into the CLI:

```
edit
edit protocols oam ethernet link-fault-management
set interface xe-0/0/0 link-discovery active pdu-interval 800 pdu-threshold 4
  remote-loopback negotiation-options allow-remote-loopback
set interface xe-0/0/0 event-thresholds frame-error 30 frame-period 50
  frame-period-summary 40 symbol-period 20
```

Step-by-Step Procedure

To configure IEEE 802.3ah OAM support on an interface:

1. Enable IEEE 802.3ah OAM support on an interface:

   ```
   [edit protocols oam ethernet link-fault-management]
   ```

   user@router1# **set** interface (OAM Link-Fault Management) **xe-0/0/0**

2. Specify that the interface initiates the discovery process by setting the link discovery mode to **active**:

   user@router# **set interface xe-0/0/0** link-discovery **active**

3. Set the periodic OAM PDU-sending interval (in milliseconds) to 800:

   user@router# **set interface xe-0/0/0** pdu-interval **800**

4. Define the number of OAM PDUs to miss before an error is logged as 4:

   user@router# **set interface xe-0/0/0** pdu-threshold **4**

5. Configure the remote interface into loopback mode so that all frames except OAM PDUs are looped back without any changes:

   user@router# **set interface xe-0/0/0** remote-loopback

6. Configure remote loopback support for the local interface:

   user@router# **set interface xe-0/0/0** negotiation-options allow-remote-loopback

7. Set the threshold count for sending frame error events to 30:

   user@router# **set interface xe-0/0/0** event-thresholds frame-error **30**

8. Set the threshold count for sending frame period error events to 50:

   user@router# **set interface xe-0/0/0** event-thresholds frame-period **50**

9. Configure the threshold count for sending frame period summary error events to 40:

   user@router# **set interface xe-0/0/0** event-thresholds frame-period-summary **40**

10. Set the threshold count for sending symbol period events to 20:

    user@router# **set interface xe-0/0/0** event-thresholds symbol-period **20**

Results

Check the results of the configuration:

```
[edit]
user@router# show
```

```
[edit]
protocols {
  oam {
    ethernet {
      link-fault-management {
        interface xe-0/0/0 {
          link-discovery active;
          pdu-interval 800;
          pdu-threshold 4;
          remote-loopback;
          negotiation-options {

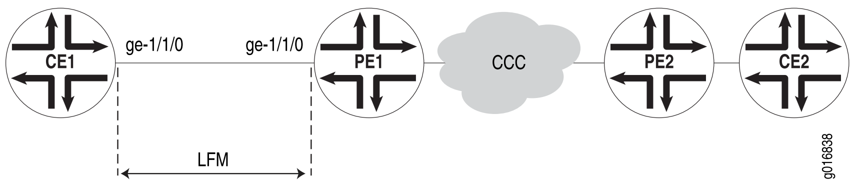
Example: Configuring Ethernet LFM Between Provider Edge and Customer Edge

In this example, LFM is enabled on an IP link between the provider edge (PE) and customer edge (CE) interfaces. If the link goes down, the fault will be detected by LFM and the interfaces on both sides will be marked **Link-Layer-Down**. This results in notifications to various subsystems (for example, routing) which will take appropriate action.

The link running LFM is shown in Figure 48 on page 714.

Figure 48: Ethernet LFM Between Provider Edge and Customer Edge



To configure Ethernet LFM on an IP link between PE and CE interfaces:

1. Configure LFM on the PE router:

```
[edit]
interfaces ge-1/1/0 {
   unit 0 {
      family inet {
         address 11.11.11.1/24;
      }
   }
}
protocols {
   oam {
      ethernet {
         link-fault-management {
            interface ge-1/1/0 {
               pdu-interval 1000;
               pdu-threshold 5;
            }
         }
      }
   }
}
```

2. Configure LFM on the CE router:

```
[edit]
interfaces ge-1/1/0 {
   unit 0 {
      family inet {
         address 11.11.11.2/24;
      }
   }
}
protocols {
   oam {
```

```
        ethernet {
            link-fault-management {
                interface ge-1/1/0 {
                    pdu-interval 1000;
                    pdu-threshold 5;
                }
            }
        }
    }
}
```

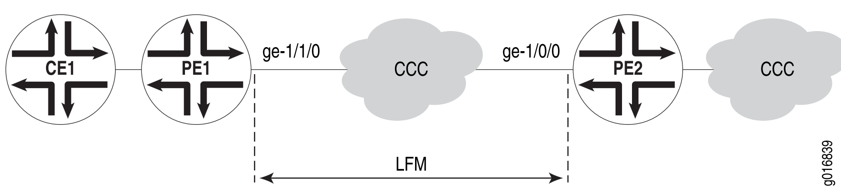
Example: Configuring Ethernet LFM for CCC

In this example, LFM is configured between two PEs (PE1 and PE2) connected using CCC. With LFM in place, a link fault will be detected immediately, instead of depending on routing protocols to find the fault on end-to-end CCC connection. This also helps in detecting the exact failed link instead of only finding that the end-to-end CCC connectivity has failed. Also, because LFM runs at the link-layer level, it does not need a IP address to operate and so can be used where bidirectional fault detection (BFD) cannot.

The links running LFM are shown in Figure 49 on page 715.

Figure 49: Ethernet LFM for CCC



To configure Ethernet LFM between two PEs connected using CCC:

1. Configure LFM on the PE1 router with CCC:

```
[edit]
interfaces ge-1/1/0 {
    encapsulation ethernet-ccc;
    unit 0;
}
protocols {
    oam {
        ethernet {
            link-fault-management {
                interface ge-1/1/0 {
```

```
                pdu-interval 1000;
                pdu-threshold 5;
              }
            }
          }
        }
      }
```

2. Configure LFM on the PE2 router with CCC:

```
[edit]
interfaces ge-1/0/0 {
  encapsulation ethernet-ccc;
  unit 0;
}
protocols {
  oam {
    ethernet {
      link-fault-management {
        interface ge-1/0/0 {
          pdu-interval 1000;
          pdu-threshold 5;
        }
      }
    }
  }
}
```

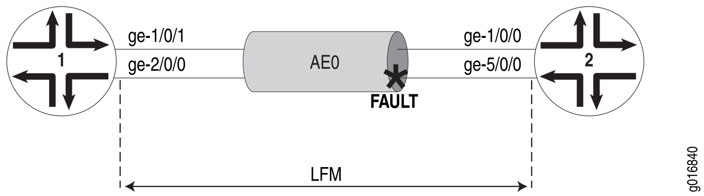
Example: Configuring Ethernet LFM for Aggregated Ethernet

In this example, LFM is configured on an aggregated Ethernet interface (AE0) between Router 1 and Router 2. When configured on aggregated Ethernet, LFM runs on all the individual member links. LFM is enabled or disabled on the member links as they are added or deleted from the aggregation group. The status of individual links is used to determine the status of the aggregated interface.

The use of LFM with aggregated Ethernet is shown in Figure 50 on page 717.

Figure 50: Ethernet LFM for Aggregated Ethernet



To configure LFM on an aggregated Ethernet interface between two routers:

1. Configure LFM on Router 1 for AE0:

```
[edit]
chassis {
   aggregated-devices {
      ethernet {
         device-count 1;
      }
   }
}
interfaces ge-1/0/1 {
   gigether-options {
      802.3ad ae0;
   }
}
interfaces ge-2/0/0 {
   gigether-options {
      802.3ad ae0;
   }
}
interfaces ae0 {
   unit 0 {
      family inet {
         address 11.11.11.2/24;
      }
   }
}
protocols {
   oam {
      ethernet {
         link-fault-management {
            interface ae0;
         }
      }
   }
}
```

2. Configure LFM on Router 2 for AE0:

```
[edit]
chassis {
   aggregated-devices {
      ethernet {
         device-count 1;
      }
```

```
    }
}
interfaces ge-1/0/0 {
    gigether-options {
        802.3ad ae0;
    }
}
interfaces ge-5/0/0 {
    gigether-options {
        802.3ad ae0;
    }
}
interfaces ae0 {
    unit 0 {
        family inet {
            address 11.11.11.1/24;
        }
    }
}
protocols {
    oam {
        ethernet {
            link-fault-management {
                interface ae0;
            }
        }
    }
}
```

Related Documentation

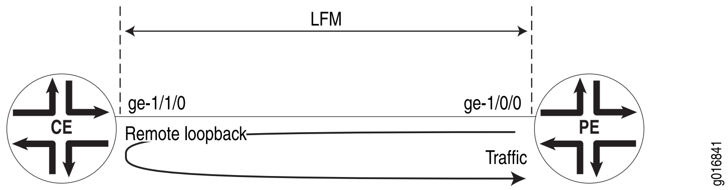
- Example: Configuring Ethernet LFM for CCC on page 715
- Example: Configuring Ethernet LFM with Loopback Support on page 718

Example: Configuring Ethernet LFM with Loopback Support

In this example, LFM is configured between provider edge (PE) router and the customer edge (CE) router. The PE router can put the CE router in remote loopback mode. This allows the PE to have all the traffic sent to the CE router looped back for diagnostics purposes, as shown in Figure 51 on page 719.

Figure 51: Ethernet LFM with Loopback Support



To configure LFM between a PE router and a CE router:

1. Configure LFM loopback on the PE router:

```
[edit]
interfaces ge-1/0/0 {
   unit 0 {
      family inet {
         address 11.11.11.1/24;
      }
   }
}
protocols {
   oam {
      ethernet {
         link-fault-management {
            interface ge-1/0/0 {
               pdu-interval 1000;
               pdu-threshold 5;
               remote-loopback;
            }
         }
      }
   }
}
```

2. Configure LFM loopback on the CE router:

```
[edit]
interfaces ge-1/1/0 {
   unit 0 {
      family inet {
         address 11.11.11.2/24;
      }
   }
}
protocols {
   oam {
      ethernet {
         link-fault-management {
            interface ge-1/1/0 {
               pdu-interval 1000;
               pdu-threshold 5;
               negotiation-options {
                  allow-remote-loopback;
               }
            }
```

```
            }
         }
      }
   }
```

NOTE: If the **negotiation options allow-remote-loopback** statement on the CE router is deleted before removing the CE router from remote loopback mode, traffic flow between the PE router and CE router is affected. Hence, delete the **remote-loopback** statement on the PE router before deleting the **negotiation-options allow-remote-loopback** statement on the CE router.

CHAPTER 33

Configuring ITU-T Y.1731 Ethernet Service OAM

Ethernet Frame Delay Measurements Overview

ITU-T Y.1731 Frame Delay Measurement Feature

The IEEE 802.3-2005 standard for Ethernet Operations, Administration, and Maintenance (OAM) defines a set of link fault management mechanisms to detect and report link faults on a single point-to-point Ethernet LAN.

Junos OS supports key OAM standards that provide for automated end-to-end management and monitoring of Ethernet service by service providers:

- *IEEE Standard 802.1ag*, also known as “Connectivity Fault Management (CFM).”
- *ITU-T Recommendation Y.1731*, which uses different terminology than IEEE 802.1ag and defines Ethernet service OAM features for fault monitoring, diagnostics, and performance monitoring.

These capabilities allow operators to offer binding service-level agreements (SLAs) and generate new revenues from rate- and performance-guaranteed service packages that are tailored to the specific needs of their customers.

ACX Series routers support proactive and on-demand modes.

NOTE: **ACX5048 and ACX5096 routers supports only software-based time stamping for delay measurement.**

Ethernet CFM

The IEEE 802.1ag standard for connectivity fault management (CFM) defines mechanisms to provide for end-to-end Ethernet service assurance over any path, whether a single link or multiple links spanning networks composed of multiple LANs.

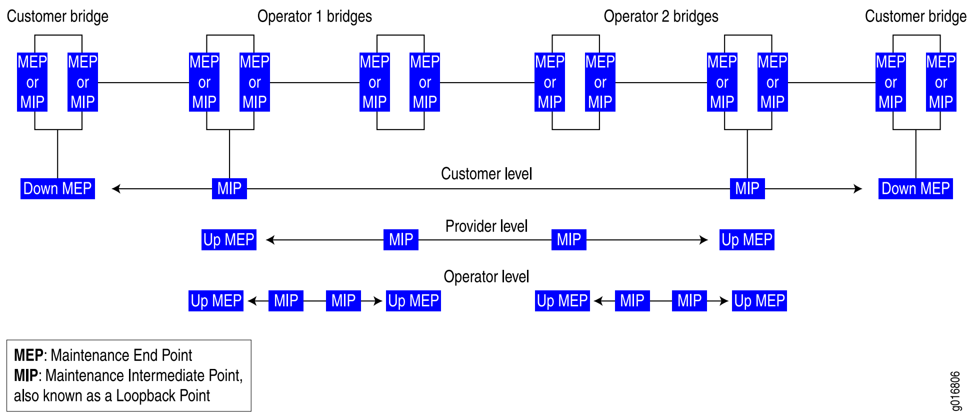
For Ethernet interfaces on M320, MX Series, and T Series routers, Junos OS supports the following key elements of the Ethernet CFM standard:

- Fault monitoring using the IEEE 802.1ag Ethernet OAM Continuity Check protocol
- Path discovery and fault verification using the IEEE 802.1ag Ethernet OAM Linktrace protocol
- Fault isolation using the IEEE 802.1ag Ethernet OAM Loopback protocol

In a CFM environment, network entities such as network operators, service providers, and customers may be part of different administrative domains. Each administrative domain is mapped into one maintenance domain. Maintenance domains are configured with different level values to keep them separate. Each domain provides enough information for the entities to perform their own management and end-to-end monitoring, and still avoid security breaches.

Figure 52 on page 724 shows the relationships among the customer, provider, and operator Ethernet bridges, maintenance domains, maintenance association end points (MEPs), and maintenance intermediate points (MIPs).

Figure 52: Relationship of MEPs, MIPs, and Maintenance Domain Levels



NOTE: On ACX Series routers, the maintenance intermediate points (MIP) is supported only on the ACX5048 and ACX5096 routers.

Ethernet Frame Delay Measurement

Two key objectives of OAM functionality are to measure quality-of-service attributes such as frame delay and frame delay variation (also known as “frame jitter”). Such measurements can enable you to identify network problems before customers are impacted by network defects.

Junos OS supports Ethernet frame delay measurement between MEPs configured on Ethernet physical or logical interfaces on MX Series routers. Ethernet frame delay measurement provides fine control to operators for triggering delay measurement on a given service and can be used to monitor SLAs. Ethernet frame delay measurement also collects other useful information, such as worst and best case delays, average delay, and average delay variation. The Junos OS implementation of Ethernet frame delay measurement (ETH-DM) is fully compliant with the ITU-T Recommendation Y.1731, *OAM Functions and Mechanisms for Ethernet-based Networks*. The recommendation defines OAM mechanisms for operating and maintaining the network at the Ethernet service layer, which is called the "ETH layer" in ITU-T terminology.

MX Series routers with modular port concentrators (MPCs) and 10-Gigabit Ethernet MPCs with SFP+ support ITU-T Y.1731 functionality on VPLS for frame-delay and delay-variation.

NOTE: MX Series Virtual Chassis does not support Ethernet frame delay measurement (DM).

One-Way Ethernet Frame Delay Measurement

In one-way ETH-DM mode, a series of frame delay and frame delay variation values are calculated based on the time elapsed between the time a measurement frame is sent from the initiator MEP at one router and the time when the frame is received at the receiver MEP at the other router.

NOTE: ACX Series routers do not support one-way Ethernet frame delay measurement.

1DM Transmission

When you start a one-way frame delay measurement, the router sends 1DM frames—frames that carry the protocol data unit (PDU) for a one-way delay measurement—from the initiator MEP to the receiver MEP at the rate and for the number of frames you specify. The router marks each 1DM frame as drop-ineligible and inserts a timestamp of the transmission time into the frame.

1DM Reception

When an MEP receives a 1DM frame, the router that contains the receiver MEP measures the one-way delay for that frame (the difference between the time the frame was received and the timestamp contained in the frame itself) and the delay variation (the difference between the current and previous delay values).

One-Way ETH-DM Statistics

The router that contains the receiver MEP stores each set of one-way delay statistics in the ETH-DM database. The ETH-DM database collects up to 100 sets of statistics for any given CFM session (pair of peer MEPs). You can access these statistics at any time by displaying the ETH-DM database contents.

One-Way ETH-DM Frame Counts

Each router counts the number of one-way ETH-DM frames sent and received:

- For an initiator MEP, the router counts the number of 1DM frames sent.
- For a receiver MEP, the router counts the number of valid 1DM frames received and the number of invalid 1DM frames received.

Each router stores ETH-DM frame counts in the CFM database. The CFM database stores CFM session statistics and, for interfaces that support ETH-DM, any ETH-DM frame counts. You can access the frame counts at any time by displaying CFM database information for Ethernet interfaces assigned to MEPs or for MEPs in CFM sessions.

Synchronization of System Clocks

The accuracy of one-way delay calculations depends on close synchronization of the system clocks at the initiator MEP and receiver MEP.

The accuracy of one-way delay variation is not dependent on system clock synchronization. Because delay variation is simply the difference between consecutive one-way delay values, the out-of-phase period is eliminated from the frame jitter values.

NOTE: **For a given one-way Ethernet frame delay measurement, frame delay and frame delay variation values are available only on the router that contains the receiver MEP.**

Two-Way Ethernet Frame Delay Measurement

In two-way ETH-DM mode, frame delay and frame delay variation values are based on the time difference between when the initiator MEP transmits a request frame and receives a reply frame from the responder MEP, subtracting the time elapsed at the responder MEP.

DMM Transmission

When you start a two-way frame delay measurement, the router sends delay measurement message (DMM) frames— frames that carry the PDU for a two-way ETH-DM request—from the initiator MEP to the responder MEP at the rate and for the number of frames you specify. The router marks each DMM frame as drop-ineligible and inserts a timestamp of the transmission time into the frame.

DMR Transmission

When an MEP receives a DMM frame, the responder MEP responds with a delay measurement reply (DMR) frame, which carries ETH-DM reply information and a copy of the timestamp contained in the DMM frame.

DMR Reception

When an MEP receives a valid DMR, the router that contains the MEP measures the two-way delay for that frame based on the following sequence of timestamps:

1. TI_{TxDMM}
2. TR_{RxDMM}
3. TR_{TxDMR}
4. TI_{RxDMR}

A two-way frame delay is calculated as follows:

$$[TI_{RxDMR} - TI_{TxDMM}] - [TR_{TxDMR} - TR_{RxDMM}]$$

The calculation show that frame delay is the difference between the time at which the initiator MEP sends a DMM frame and the time at which the initiator MEP receives the associated DMR frame from the responder MEP, minus the time elapsed at the responder MEP.

The delay variation is the difference between the current and previous delay values.

Two-Way ETH-DM Statistics

The router that contains the initiator MEP stores each set of two-way delay statistics in the ETH-DM database. The ETH-DM database collects up to 100 sets of statistics for any given CFM session (pair of peer MEPs). You can access these statistics at any time by displaying the ETH-DM database contents.

Two-Way ETH-DM Frame Counts

Each router counts the number of two-way ETH-DM frames sent and received:

- For an initiator MEP, the router counts the number DMM frames transmitted, the number of valid DMR frames received, and the number of invalid DMR frames received.
- For a responder MEP, the router counts the number of DMR frames sent.

Each router stores ETH-DM frame counts in the CFM database. The CFM database stores CFM session statistics and, for interfaces that support ETH-DM, any ETH-DM frame counts. You can access the frame counts at any time by displaying CFM database information for Ethernet interfaces assigned to MEPs or for MEPs in CFM sessions.

NOTE: **For a given two-way Ethernet frame delay measurement, frame delay and frame delay variation values are available only at the router that contains the initiator MEP.**

Choosing Between One-Way and Two-Way ETH-DM

One-way frame delay measurement requires that the system clocks at the initiator MEP and receiver MEP are closely synchronized. Two-way frame delay measurement does not require synchronization of the two systems. If it is not practical for the clocks to be synchronized, two-way frame delay measurements are more accurate.

When two systems are physically close to each other, their one-way delay values are very high compared to their two-way delay values. One-way delay measurement requires that the timing for the two systems be synchronized at a very granular level, and MX Series routers currently do not support this granular synchronization.

Restrictions for Ethernet Frame Delay Measurement

The following restrictions apply to the Ethernet frame delay measurement feature:

- The ETH-DM feature is not supported on label-switched interface (LSI) pseudowires.

  The ETH-DM feature is supported on aggregated Ethernet interfaces.

- Hardware-assisted timestamping for ETH-DM frames in the reception path is only supported for MEP interfaces on Enhanced DPCs and Enhanced Queuing DPCs in MX Series routers. For information about hardware-assisted timestamping, see "Guidelines for Configuring Routers to Support an ETH-DM Session" on page 768 and "Enabling the Hardware-Assisted Timestamping Option" on page 779.
- Ethernet frame delay measurements can be triggered only when the distributed periodic packet management daemon (**ppm**) is enabled. For more information about this limitation, see "Guidelines for Configuring Routers to Support an ETH-DM Session" on page 768 and "Ensuring That Distributed ppm Is Not Disabled" on page 776.
- You can monitor only one session at a time to the same remote MEP or MAC address. For more information about starting an ETH-DM session, see "Starting an ETH-DM Session" on page 780.
- ETH-DM statistics are collected at only one of the two peer routers in the ETH-DM session. For a one-way ETH-DM session, you can display frame ETH-DM statistics at the receiver MEP only, using ETH-DM-specific **show** commands. For a two-way ETH-DM session, you can display frame delay statistics at the initiator MEP only, using the same ETH-DM-specific **show** commands. For more information, see "Managing ETH-DM Statistics and ETH-DM Frame Counts" on page 784.
- ETH-DM frame counts are collected at both MEPs and are stored in the respective CFM databases.
- If graceful Routing Engine switchover (GRES) occurs, any collected ETH-DM statistics are lost, and ETH-DM frame counts are reset to zeroes. Therefore, the collection of ETH-DM statistics and ETH-DM frame counters has to be restarted, after the switchover is complete. GRES enables a router with dual Routing Engines to switch from a master Routing Engine to a backup Routing Engine without interruption to packet forwarding. For more information, see the *Junos OS High Availability Library for Routing Devices*.
- Accuracy of frame delay statistics is compromised when the system is changing (such as from reconfiguration). We recommend performing Ethernet frame delay measurements on a stable system.

Ethernet Frame Loss Measurement Overview

The key objectives of the OAM functionality are to measure quality-of-service attributes such as frame delay, frame delay variation (also known as "frame jitter"), and frame loss. Such measurements enable you to identify network problems before customers are impacted by network defects. For more information about Ethernet frame delay measurement, see "Ethernet Frame Delay Measurements Overview" on page 723.

Junos OS supports Ethernet frame loss measurement (ETH-LM) between maintenance association end points (MEPs) configured on Ethernet physical or logical interfaces on MX Series routers and is presently supported only for VPWS service. ETH-LM is used by operators to collect counter values applicable for ingress and egress service frames. These counters maintain a count of transmitted and received data frames between a pair of MEPs. Ethernet frame loss measurement is performed by sending frames with ETH-LM information to a peer MEP and similarly receiving frames with ETH-LM information from the peer MEP. This type of frame loss measurement is also known as single-ended Ethernet loss measurement.

NOTE: MX Series Virtual Chassis does not support Ethernet frame loss measurement (ETH-LM).

ETH-LM supports the following frame loss measurements:

- Near-end frame loss measurement—Measurement of frame loss associated with ingress data frames.
- Far-end frame loss measurement—Measurement of frame loss associated with egress data frames.

NOTE: The proactive and dual-ended loss measurement functionality of ITU-T Y1731 is not supported on the ACX Series routers.

The ETH-LM feature is supported on aggregated Ethernet interfaces.

NOTE: Starting Junos OS Release 16.1, the Ethernet loss measurement (ETH-LM) results are inaccurate when connectivity fault management (CFM) and performance monitoring (PM) PDUs received locally at a maintenance endpoint (MEP) as classified as belonging to the yellow class or a packet loss priority (PLP) of medium-high. This problem of incorrect results is specific to Ethernet loss measurement for CFM sessions of down MEPs. The Ethernet loss measurement statistics are inaccurate in the following scenarios:

- Ethernet loss measurement is working on a CFM session for a MEP in down state
- CFM PDUs received on the logical interface of the down MEP are classified by the classifier as yellow or medium-high PLP
- A packet is identified as yellow when the input classifier marks the PLP as medium-high.

The problem of discrepancies with Ethernet loss measurement results is not observed when you configure Ethernet loss measurement in colorless mode. To avoid this problem of inaccurate loss measurement results, provision all local CFM PDUs as green or with the PLP as high.

NOTE: Starting with Junos OS Release 16.1, performance monitoring for connectivity fault management (by including the **performance-monitoring** statement and its substatements at the **[edit protocols oam ethernet connectivity-fault-management]** hierarchy level) is not supported when the network-to-network (NNI) or egress interface is an aggregated Ethernet interface with member links on DPCs.

Release History Table

Release	Description
16.1	Starting Junos OS Release 16.1, the Ethernet loss measurement (ETH-LM) results are inaccurate when connectivity fault management (CFM) and performance monitoring (PM) PDUs received locally at a maintenance endpoint (MEP) as classified as belonging to the yellow class or a packet loss priority (PLP) of medium-high.
16.1	Starting with Junos OS Release 16.1, performance monitoring for connectivity fault management (by including the **performance-monitoring** statement and its substatements at the **[edit protocols oam ethernet connectivity-fault-management]** hierarchy level) is not supported when the network-to-network (NNI) or egress interface is an aggregated Ethernet interface with member links on DPCs.

Service-Level Agreement Measurement

Service-level agreement (SLA) measurement is the process of monitoring the bandwidth, delay, delay variation (jitter), continuity, and availability of a service (E-Line or E-LAN). It enables you to identify network problems before customers are impacted by network defects.

NOTE:
The Ethernet VPN services can be classified into:

- Peer-to-peer-services (E-Line services)—The E-Line services are offered using MPLS-based Layer 2 VPN virtual private wire service (VPWS).
- Multipoint-to-multipoint services (E-LAN services)—The E-LAN services are offered using MPLS-based virtual private LAN service (VPLS).

For more information, see the *Junos VPNs Configuration Guide*.

In Junos OS, SLA measurements are classified into:

- On-demand mode—In on-demand mode, the measurements are triggered through the CLI. For more information, see "On-Demand Mode for SLA Measurement" on page 732.
- Proactive mode—In proactive mode, the measurements are triggered by an iterator application. For more information, see "Proactive Mode for SLA Measurement" on page 733.

For more information about frame delay measurement, see "Ethernet Frame Delay Measurements Overview" on page 723. For more information about frame loss measurement, see "Ethernet Frame Loss Measurement Overview" on page 729. Note that Ethernet frame delay measurement and Ethernet frame loss measurement are not supported on the **ae** interface.

Related Documentation

- Proactive Mode for SLA Measurement on page 733.
- On-Demand Mode for SLA Measurement on page 732.

On-Demand Mode for SLA Measurement

In on-demand mode, the measurements are triggered by the user through the CLI.

When the user triggers the delay measurement through the CLI, the delay measurement request that is generated is as per the frame formats specified by the ITU-T Y.1731 standard. For two-way delay measurement, the server-side processing can be delegated to the Packet Forwarding Engine to prevent overloading on the Routing Engine. For more information, see "Configuring Routers to Support an ETH-DM Session" on page 775. When the server-side processing is delegated to the Packet Forwarding Engine, the delay measurement message (DMM) frame **receive** counters and delay measurement reply (DMR) frame **transmit** counters are not displayed by the **show** command.

When the user triggers the loss measurement through the CLI, the router sends the packets in standard format along with the loss measurement TLV. By default, the **session-id-tlv** argument is included in the packet to allow concurrent loss measurement sessions from same local MEP. You can also disable the session ID TLV by using the **no-session-id-tlv** argument.

Single-ended ETH-LM is used for on-demand operation, administration, and maintenance purposes. An MEP sends frames with ETH-LM request information to its peer MEP and receives frames with ETH-LM reply information from its peer MEP to carry out loss measurements. The protocol data unit (PDU) used for a single-ended ETH-LM request is referred to as a loss measurement message (LMM) and the PDU used for a single-ended ETH-LM reply is referred to as a loss measurement reply (LMR).

- Proactive Mode for SLA Measurement on page 733
- Configuring Routers to Support an ETH-DM Session on page 775.

Proactive Mode for SLA Measurement

In proactive mode, SLA measurements are triggered by an iterator application. An iterator is designed to periodically transmit SLA measurement packets in form of ITU-Y.1731-compliant frames for two-way delay measurement or loss measurement on MX Series routers. This mode differs from on-demand SLA measurement, which is user initiated. The iterator sends periodic delay or loss measurement request packets for each of the connections registered to it. Iterators make sure that measurement cycles do not occur at the same time for the same connection to avoid CPU overload. Junos OS supports proactive mode for VPWS. For an iterator to form a remote adjacency and to become functionally operational, the continuity check message (CCM) must be active between the local and remote MEP configurations of the connectivity fault management (CFM). Any change in the iterator adjacency parameters resets the existing iterator statistics and restarts the iterator. Here, the term adjacency refers to a pairing of two endpoints (either connected directly or virtually) with relevant information for mutual understanding, which is used for subsequent processing. For example, the iterator adjacency refers to the iterator association between the two endpoints of the MEPs.

For every DPC or MPC, only 30 iterator instances for a cycle time value of 10 milliseconds (ms) are supported. In Junos OS, 255 iterator profile configurations and 2000 remote MEP associations are supported.

Iterators with cycle time value less than 100 ms are supported only for infinite iterators, whereas the iterators with cycle time value greater than 100 ms are supported for both finite and infinite iterators. Infinite iterators are iterators that run infinitely until the iterator is disabled or deactivated manually.

NOTE: **ACX5048 and ACX5096 routers supports iterator cycle time of only 1 second and above.**

A VPWS service configured on a router is monitored for SLA measurements by registering the connection (here, the connection is a pair of remote and local MEPs) on an iterator and then initiating periodic SLA measurement frame transmission on those connections. The end-to-end service is identified through a maintenance association end point (MEP) configured at both ends.

For two-way delay measurement and loss measurement, an iterator sends a request message for the connection in the list (if any) and then sends a request message for the connection that was polled in the former iteration cycle. The back-to-back request messages for the SLA measurement frames and their responses help in computing delay variation and loss measurement.

The Y.1731 frame transmission for a service attached to an iterator continues endlessly unless intervened and stopped by an operator or until the iteration-count condition is met. To stop the iterator from sending out any more proactive SLA measurement frames, the operator must perform one of the following tasks:

- Enable the **deactivate sla-iterator-profile** statement at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance association *ma-name* mep *mep-id* remote-mep *mep-id*]** hierarchy level. For more information, see "Verifying the Configuration of an Iterator Profile" on page 756.
- Provision a **disable** statement under the corresponding iterator profile at the **[edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles *profile-name*]** hierarchy level. For more information, see "Configuring an Iterator Profile" on page 754.

Ethernet Delay Measurements and Loss Measurement by Proactive Mode

In two-way delay measurement, the delay measurement message (DMM) frame is triggered through an iterator application. The DMM frame carries an iterator type, length, and value (TLV) in addition to the fields described in standard frame format and the server copies the iterator TLV from the DMM frame to the delay measurement reply (DMR) frame.

In one-way delay variation computation using the two-way delay measurement method, the delay variation computation is based on the timestamps that are present in the DMR frame (and not the 1DM frame). Therefore, there is no need for client-side and server-side clocks to be in sync. Assuming that the difference in their clocks remains constant, the one-way delay variation results are expected to be fairly accurate. This method also eliminates the need to send separate 1DM frames just for the one-way delay variation measurement purpose.

In proactive mode for loss measurement, the router sends packets in standard format along with loss measurement TLV and iterator TLV.

Ethernet Failure Notification Protocol Overview

The Failure Notification Protocol (FNP) is a failure notification mechanism that detects failures in Point-to-Point Ethernet transport networks on MX Series routers. If a node link fails, FNP detects the failure and sends out FNP messages to the adjacent nodes that a circuit is down. Upon receiving the FNP message, nodes can redirect traffic to the protection circuit.

NOTE: FNP is supported on E-Line services only.

An E-Line service provides a secure Point-to-Point Ethernet connectivity between two user network interfaces (UNIs). E-Line services are a protected service and each service has a working circuit and protection circuit. CFM is used to monitor the working and protect paths. CCM intervals result in failover time in hundreds of milliseconds or a few seconds. FNP provides service circuit failure detection and propagation in less than 50ms and provide 50ms failover for E-Line services.

The MX router acts as a PE node and handles the FNP messages received on the management VLAN and the FNP messages received on both the Ethernet interfaces and PWs created for the management VPLS. MX-series routers do not initiate FNP messages and responds only to FNP messages generated by devices in the Ethernet Access network. FNP can be enabled only on logical interfaces that are part of a VPLS routing instance, and no physical interfaces in that VPLS routing instance should have CCM configured. FNP can be enabled only on one logical interface per physical interface.

All E-Line services are configured as layer 2 circuits with edge protection. A VLAN associated with the working circuit or protection circuit must map to a logical interface. No trunk port or access port is supported in the ring link for VLANs used by E-LINE services. FNP does not control the logical interface associated with protection circuit. Only E-Line service whose termination point is not in an MX node is controlled by FNP.

FNP supports graceful restart and the Graceful Routing Engine switchover (GRES) features.

Ethernet Synthetic Loss Measurement Overview

Ethernet synthetic loss measurement (ETH-SLM) is an application that enables the calculation of frame loss by using synthetic frames instead of data traffic. This mechanism can be considered as a statistical sample to approximate the frame loss ratio of data traffic. Each maintenance association end point (MEP) performs frame loss measurements, which contribute to unavailable time.

A near-end frame loss specifies frame loss associated with ingress data frames and a far-end frame loss specifies frame loss associated with egress data frames. Both near-end and far-end frame loss measurements contribute to near-end severely errored seconds and far-end severely errored seconds that are used in combination to determine unavailable time. ETH-SLM is performed using synthetic loss message (SLM) and synthetic loss reply (SLR) frames. ETH-SLM facilitates each MEP to perform near-end and far-end synthetic frame loss measurements by using synthetic frames because a bidirectional service is defined as unavailable if either of the two directions is determined to be unavailable.

There are the two types of frame loss measurement, defined by the ITU-T Y.1731 standards, ETH-LM and ETH-SLM. Junos OS supports only single-ended ETH-SLM. In single-ended ETH-SLM, each MEP sends frames with the ETH-SLM request information to its peer MEP and receives frames with ETH-SLM reply information from its peer MEP to perform synthetic loss measurements. Single-ended ETH-SLM is used for proactive or on-demand OAM to perform synthetic loss measurements applicable to point-to-point Ethernet connection. This method allows a MEP to initiate and report far-end and near-end loss measurements associated with a pair of MEPs that are part of the same maintenance entity group (MEG).

NOTE: **MX Series Virtual Chassis does not support Ethernet synthetic loss measurement (ETH-SLM).**

Single-ended ETH-SLM is used to perform on-demand or proactive tests by initiating a finite amount of ETH-SLM frames to one or multiple MEP peers and receiving the ETH-SLM reply from the peers. The ETH-SLM frames contain the ETH-SLM information that is used to measure and report both near-end and far-end synthetic loss measurements. Service-level agreement (SLA) measurement is the process of monitoring the bandwidth, delay, delay variation (jitter), continuity, and availability of a service. It enables you to identify network problems before customers are impacted by network defects. In proactive mode, SLA measurements are triggered by an iterator application. An iterator is designed to periodically transmit SLA measurement packets in the form of ITU-Y.1731-compliant frames for synthetic frame loss measurement . This mode differs from on-demand SLA measurement, which is user initiated. In on-demand mode, the measurements are triggered by the user through the CLI. When the user triggers the ETH-SLM through the CLI, the SLM request that is generated is as per the frame formats specified by the ITU-T Y.1731 standard.

NOTE: **ACX5048 and ACX5096 routers support ETH-SLM for Layer 2 services.**

Scenarios for Configuration of ETH-SLM

ETH-SLM measures near-end and far-end frame loss between two MEPs that are part of the same MEG level. You can configure ETH-SLM to measure synthetic loss for both upward-facing or upstream MEP and downward-facing or downstream MEP. This section describes the following scenarios for the operation of ETH-SLM:

Upstream MEP in MPLS Tunnels

Consider a scenario in which a MEP is configured between the user network interfaces (UNIs) of two MX Series routers, MX1 and MX2, in the upstream direction. MX1 and MX2 are connected over an MPLS core network. ETH-SLM measurements are performed between the upstream MEP in the path linking the two routers. Both MX1 and MX2 can initiate on-demand or proactive ETH-SLM, which can measure both far-end and near-end loss at MX1 and MX2, respectively. The two UNIs are connected using MPLS-based Layer 2 VPN virtual private wire service (VPWS).

Downstream MEP in Ethernet Networks

Consider a scenario in which a MEP is configured between two MX Series routers, MX1 and MX2, on the Ethernet interfaces in the downstream direction. MX1 and MX2 are connected in an Ethernet topology and downstream MEP is configured toward the Ethernet network. ETH-SLM measurements are performed between the downstream MEP in the path linking the two routers. ETH-SLM can be measured in the path between these two routers.

Consider another scenario in which a MEP is configured in the downstream direction and service protection for a VPWS over MPLS is enabled by specifying a working path or protect path on the MEP. Service protection provides end-to-end connection protection of the working path in the event of a failure. To configure service protection, you must create two separate transport paths—a working path and a protect path. You can specify the working path and protect path by creating two maintenance associations. To associate the maintenance association with a path, you must configure the MEP interface in the maintenance association and specify the path as working or protect.

In a sample topology, an MX Series router, MX1, is connected to two other MX Series routers, MX2 and MX3, over an MPLS core. The connectivity fault management (CFM) session between MX1 and MX2 is the working path on the MEP and the CFM session between MX1 and MX3 is the protect path on the MEP. MX2 and MX3 are, in turn, connected on Ethernet interfaces to MX4 in the access network. Downstream MEP is configured between MX1 and MX4 that passes through MX2 (working CFM session) and also between MX1 and MX4 that passes through MX3 (protected CFM session). ETH-SLM is performed between these downstream MEPs. In both the downstream MEPs, the configuration is performed on MX1 and MX4 UNIs, similar to upstream MEP.

Format of ETH-SLM Messages

Synthetic loss messages (SLMs) support single-ended Ethernet synthetic loss measurement (ETH-SLM) requests. This topic contains the following sections that describe the formats of the SLM protocol data units (PDUs), SLR PDUs, and the data iterator type length value (TLV).

SLM PDU Format

The SLM PDU format is used by a MEP to transmit SLM information. The following components are contained in SLM PDUs:

- Source MEP ID—Source MEP ID is a 2-octet field where the last 13 least significant bits are used to identify the MEP transmitting the SLM frame. MEP ID is unique within the MEG.
- Test ID—Test ID is a 4-octet field set by the transmitting MEP and is used to identify a test when multiple tests run simultaneously between MEPs (including both concurrent on-demand and proactive tests).
- TxFCf—TxFCf is a 4-octet field that carries the number of SLM frames transmitted by the MEP toward its peer MEP.

The following are the fields in an SLM PDU:

- MEG Level—Configured maintenance domain level in the range 0–7.
- Version—0.
- OpCode—Identifies an OAM PDU type. For SLM, it is 55.
- Flags—Set to all zeros.
- TLV Offset—16.
- Source MEP ID—A 2-octet field used to identify the MEP transmitting the SLM frame. In this 2-octet field, the last 13 least significant bits are used to identify the MEP transmitting the SLM frame. MEP ID is unique within the MEG.

- RESV—Reserved fields are set to all zeros.
- Test ID—A 4-octet field set by the transmitting MEP and used to identify a test when multiple tests run simultaneously between MEPs (including both concurrent on-demand and proactive tests).
- TxFCf—A 4-octet field that carries the number of SLM frames transmitted by the MEP toward its peer MEP.
- Optional TLV—A data TLV may be included in any SLM transmitted. For the purpose of ETH-SLM, the value part of data TLV is unspecified.
- End TLV—All zeros octet value.

SLR PDU Format

The synthetic loss reply (SLR) PDU format is used by a MEP to transmit SLR information. The following are the fields in an SLR PDU:

- MEG Level—A 3-bit field the value of which is copied from the last received SLM PDU.
- Version—A 5-bit field the value of which is copied from the last received SLM PDU.
- OpCode—Identifies an OAM PDU type. For SLR, it is set as 54.
- Flags—A 1-octet field copied from the SLM PDU.
- TLV Offset—A 1-octet field copied from the SLM PDU.
- Source MEP ID—A 2-octet field copied from the SLM PDU.
- Responder MEP ID—A 2-octet field used to identify the MEP transmitting the SLR frame.
- Test ID—A 4-octet field copied from the SLM PDU.
- TxFCf—A 4-octet field copied from the SLM PDU.
- TxFCb—A 4 octet field. This value represents the number of SLR frames transmitted for this test ID.
- Optional TLV—The value is copied from the SLM PDU, if present.
- End TLV—A 1-octet field copied from the SLM PDU.

Data Iterator TLV Format

The data iterator TLV specifies the data TLV portion of the Y.1731 data frame. The MEP uses a data TLV when the MEP is configured to measure delay and delay variation for different frame sizes. The following are the fields in a data TLV:

- Type—Identifies the TLV type; value for this TLV type is Data (3).
- Length—Identifies the size, in octets, of the Value field containing the data pattern. The maximum value of the Length field is 1440.
- Data pattern—An *n*-octet (*n* denotes length) arbitrary bit pattern. The receiver ignores it.

Transmission of ETH-SLM Messages

The ETH-SLM functionality can process multiple synthetic loss message (SLM) requests simultaneously between a pair of MEPs. The session can be a proactive or an on-demand SLM session. Each SLM request is identified uniquely by a test ID.

A MEP can send SLM requests or respond to SLM requests. A response to an SLM request is called a synthetic loss reply (SLR). After a MEP determines an SLM request by using the test ID, the MEP calculates the far-end and near-end frame loss on the basis of the information in the SLM message or the SLM protocol data unit (PDU).

A MEP maintains the following local counters for each test ID and for each peer MEP being monitored in a maintenance entity for which loss measurements are to be performed:

- TxFCl—Number of synthetic frames transmitted toward the peer MEP for a test ID. A source MEP increments this number for successive transmission of synthetic frames with ETH-SLM request information while a destination or receiving MEP increments this value for successive transmission of synthetic frames with the SLR information.
- RxFCl—Number of synthetic frames received from the peer MEP for a test ID. A source MEP increments this number for successive reception of synthetic frames with SLR information while a destination or receiving MEP increments it for successive reception of synthetic frames with ETH-SLM request information.

The following sections describe the phases of processing of SLM PDUs to determine synthetic frame loss:

Initiation and Transmission of SLM Requests

A MEP periodically transmits an SLM request with the OpCode field set as 55. The MEP generates a unique Test ID for the session, adds the source MEP ID, and initializes the local counters for the session before SLM initiation. For each SLM PDU transmitted for the session (test ID), the local counter TxFCl is sent in the packet.

No synchronization is required of the test ID value between initiating and responding MEPs because the test ID is configured at the initiating MEP, and the responding MEP uses the test ID it receives from the initiating MEP. Because ETH-SLM is a sampling technique, it is less precise than counting the service frames. Also, the accuracy of measurement depends on the number of SLM frames used or the period for transmitting SLM frames.

Reception of SLMs and Transmission of SLRs

After the destination MEP receives a valid SLM frame from the source MEP, an SLR frame is generated and transmitted to the requesting or source MEP. The SLR frame is valid if the MEG level and the destination MAC address match the receiving MEP's MAC address. All the fields in the SLM PDUs are copied from the SLM request except for the following fields:

- The source MAC address is copied to the destination MAC address and the source address contains the MEP's MAC address.
- The value of the OpCode field is changed from SLM to SLR (54).
- The responder MEP ID is populated with the MEP's MEP ID.
- TxFCb is saved with the value of the local counter RxFCl at the time of SLR frame transmission.
- An SLR frame is generated every time an SLM frame is received; therefore, RxFCl in the responder is equal to the number of SLM frames received and also equal to the number of SLR frames sent. At the responder or receiving MEP, RxFCl equals TxFCl.

Reception of SLRs

After an SLM frame (with a given TxFCf value) is transmitted, a MEP expects to receive a corresponding SLR frame (carrying the same TxTCf value) within the timeout value from its peer MEP. SLR frames that are received after the timeout value (5 seconds) are discarded. With the information contained in SLR frames, a MEP determines the frame loss for the specified measurement period. The measurement period is a time interval during which the number of SLM frames transmitted is statistically adequate to make a measurement at a given accuracy. A MEP uses the following values to determine near-end and far-end frame loss during the measurement period:

- Last received SLR frame's TxFCf and TxFCb values and the local counter RxFCl value at the end of the measurement period. These values are represented as TxFCf[tc], TxFCb[tc], and RxFCl[tc], where tc is the end time of the measurement period.
- SLR frame's TxFCf and TxFCb values of the first received SLR frame after the test starts and local counter RxFCl at the beginning of the measurement period. These values are represented as TxFCf[tp], TxFCb[tp], and RxFCl[tp], where tp is the start time of the measurement period.

For each SLR packet that is received, the local RxFCl counter is incremented at the sending or source MEP.

Computation of Frame Loss

Synthetic frame loss is calculated at the end of the measurement period on the basis of the value of the local counters and the information from the last frame received. The last received frames contains the TxFCf and TxFCb values. The local counter contains the RxFCl value. Using these values, frame loss is determined using the following formula:

Frame loss (far-end) = TxFCf – TxFCb

Frame loss (near-end) = TxFCb – RxFCl

Guidelines for Configuring ETH-SLM

Keep the following points in mind when you configure the ETH-SLM functionality:

- The monitoring application for Ethernet OAM is initiated in the master Routing Engine. When a stateful switchover process occurs, the monitoring application is disabled. For on-demand ETH-SLM, graceful Routing Engine switchover (GRES) support is not applicable. For proactive ETH-SLM, the service-level agreement (SLA) iterators are restored during a stateful switchover process. If the adjacencies do not time out, the ETH-SLM statistics are preserved and proactive ETH-SLM supports GRES.
- ETH-SLM is initiated only when the MEP session is up. Unified in-service software upgrade (ISSU) support for ETH-SLM depends on the unified ISSU support for CFM. For CFM, unified ISSU is supported using the loss threshold TLV to avoid CFM connectivity loss during the upgrade. The receiving or the destination MEP increases the threshold time during the termination of sessions. If you start a unified ISSU operation when on-demand ETH-SLM is in progress, the SLM request and reply messages are lost at the local Packet Forwarding Engine.

  When an on-demand ETH-SLM is requested, if the local source MEP undergoes a unified ISSU, a message is displayed stating that the MEP is undergoing a unified ISSU. If the remote MEP is undergoing a unified ISSU (detected through the loss threshold TLV), a message is displayed stating that the remote MEP is undergoing a unified ISSU. Also, if it is not possible to identify whether unified ISSU is in progress on a remote MEP, the SLM packets are lost at the system where unified ISSU is in progress and the loss calculation results do not provide a valid cause for the loss. Unified ISSU is not supported for both on-demand and proactive ETH-SLM.
- The maximum number of SLA iterator profiles that can be configured in the system is 255.

- ETH-SLM is not supported for virtual private LAN service (VPLS) (point-to-multipoint measurements are not supported). The ETH-SLM frames are not generated with multicast class 1 destination address. Similarly, ETH-SLM does not respond to ETH-SLM requests with multicast DA. ETH-SLM for VPLS for point-to-point Ethernet connection is supported using directed unicast destination MAC addresses, although point-to-multipoint topologies are not supported.
- A unicast destination address may be used in provisioned environments for point-to-point connections. However, it requires that the unicast destination address of the downstream MEP must have been configured on the MEP transmitting an alarm indication signal (AIS).
- ETH-SLM is not supported on downstream MEPs on label-switched interfaces (LSIs).
- ETH-SLM is supported on aggregated Ethernet (ae) interfaces
- The number of ETH-SLM sessions for proactive ETH-SLM that can be supported is limited to the total number of iterators that can be supported in the system. This limitation includes the iterator support for other measurement types such as loss, statistical frame loss, and two-way delay. A new iterator type, SLM, is added to support ETH-SLM. The total number of SLA iterators that you can configure in the system is equal to the total number of iterations supported in the system.
- For on-demand SLM, the minimum period between two SLM requests is 100 milliseconds.
- For proactive SLM, the minimum period between two SLM requests is 10 milliseconds for distributed mode and 100 milliseconds for non-distributed mode.
- ETH-SLM frames are always marked as drop-ineligible in compliance with the ITU-T Y.1731 standard.

Starting a Proactive ETH-SLM Session

To start a proactive Ethernet synthetic loss measurement (ETH-SLM) session, you must configure the Ethernet interfaces on maintenance association end points (MEPs) on which packets transmitted with synthetic frame loss need to be analyzed. You must then create an iterator profile to transmit service-level agreement (SLA) measurement packets for ETH-SLM and associate the local and remote MEPs with the profile.

- Configuring MEP Interfaces on page 744
- Configuring an Iterator Profile for ETH-SLM on page 745
- Associating the Iterator Profile with MEPs for ETH-SLM on page 746

Configuring MEP Interfaces

Before you can start an Ethernet synthetic frame loss measurement session across an Ethernet service, you must configure two ACX Series routers to support ETH-SLM.

To configure an Ethernet interface on an ACX Series router to support ETH-SLM:

1. On each router, configure two physical or logical Ethernet interfaces connected by a VLAN. The following configuration is typical for single-tagged logical interfaces:

```
[edit interfaces]
interface {
  ethernet-interface-name {
    vlan-tagging;
    unit logical-unit-number {
      vlan-id vlan-id; # Both interfaces on this VLAN
    }
  }
}
```

   Both interfaces will use the same VLAN ID.

2. On each router, attach peer MEPs to the two interfaces. The following configuration is typical:

```
[edit protocols]
oam {
  ethernet {
    connectivity-fault-management {
      maintenance-domain md-name { # On both routers
        level number;
        maintenance-association ma-name { # On both routers
          continuity-check {
            interval 100ms;
            hold-interval 1;
          }
          mep mep-id { # Attach to VLAN interface
            auto-discovery;
            direction (up | down);
            interface interface-name;
            priority number;
          }
        }
      }
    }
  }
}
```

Configuring an Iterator Profile for ETH-SLM

You can create an iterator profile with its parameters to periodically transmit SLA measurement packets in the form of ITU-Y.1731-compliant frames for synthetic loss measurement.

NOTE: ACX5048 and ACX5096 routers supports iterator cycle time of only 1 second and above.

To create an iterator profile:

1. In configuration mode, go to the following hierarchy level:

   [edit]
   user@host# **edit protocols oam ethernet connectivity-fault-management performance-monitoring**

2. Configure the SLA measurement monitoring iterator:

   [edit protocols oam ethernet connectivity-fault-management performance-monitoring]
   user@host# **edit sla-iterator-profiles**

3. Configure an iterator profile—for example, i1:

   [edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles]
   user@host# **set i1**

4. (Optional) Configure the cycle time, which is the amount of time (in milliseconds) between back-to-back transmission of SLA frames for one connection, with a value from 10 through 3,600,000. The default value is 1000 ms.

   [edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles i1]
   user@host# **set cycle-time *cycle-time-value***

5. (Optional) Configure the iteration period, which indicates the maximum number of cycles per iteration (the number of connections registered to an iterator cannot exceed this value), with a value from 1 through 2000. The default value is 2000.

   [edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles i1]
   user@host# **set iteration-period *iteration-period-value***

6. Configure the measurement type as synthetic loss measurement.

   [edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles i1]
   user@host# **set measurement-type slm**

7. Configure the **disable** statement to stop the iterator (that is, disable the iterator profile).

   [edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles i1]
   user@host# **set disable**

8. Verify the configuration.

   [edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles]
   user@host# **show i1**
   cycle-time *cycle-time-value*;
   iteration-period *iteration-period-value*;
   measurement-type slm;

Associating the Iterator Profile with MEPs for ETH-SLM

You can associate a remote maintenance association end point (MEP) with more than one iterator profile.

To configure a remote MEP with an iterator profile:

1. In configuration mode, go to the following hierarchy level:

   user@host# **edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id***

2. Configure the remote MEP ID with a value from 1 through 8191.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id*]
   user@host# **set remote-mep *remote-mep-id***

3. Set the iterator profile.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id* remote-mep *remote-mep-id*]
   user@host# **set sla-iterator-profile *profile-name***

4. (Optional) Set the size of the data TLV portion of the Y.1731 data frame with a value from 1 through 1400 bytes. The default value is 1.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id* remote-mep *remote-mep-id* sla-iterator-profile *profile-name*]
   user@host# **set data-tlv-size *size***

5. (Optional) Set the iteration count, which indicates the number of iterations for which this connection should partake in the iterator for acquiring SLA measurements, with a value from 1 through 65,535. The default value is 0 (that is, infinite iterations).

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id* remote-mep *remote-mep-id* sla-iterator-profile *profile-name*] user@host# **set** iteration-count ***count-value***

6. (Optional) Set the priority, which is the **vlan-pcp** value that is sent in the Y.1731 data frames, with a value from 0 through 7. The default value is 0.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id* remote-mep *remote-mep-id* sla-iterator-profile *profile-name*]
   user@host# **set** priority ***priority-value***

7. Verify the configuration.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id* remote-mep *remote-mep-id*]
   user@host# **show**
   sla-iterator-profile *profile-name* {
     data-tlv-size *size*;
     iteration-count *count-value*;
     priority *priority-value*;
   }

Starting an On-Demand ETH-SLM Session

To start an on-demand Ethernet synthetic loss measurement (ETH-SLM) session, type the **monitor ethernet synthetic-loss-measurement one-way** command in operational mode, and specify the peer MEP by its MAC address or by its MEP identifier.

For example:

```
user@host> monitor ethernet synthetic-loss-measurement 00:05:85:73:39:4a
maintenance-domain md6 maintenance-association ma6 count 10
ETH-SLM request to 00:05:85:73:39:4a, interface ge-1/0/0.0
      Synthetic Loss measurement statistics:
       SLM packets sent                             : 100
       SLR packets received                         : 100
       Accumulated SLM statistics:
       Local TXFC1 value                            : 100
       Local RXFC1 value                            : 100
```

```
Last Received SLR frame TXFCf(tc)          : 100
Last Received SLR frame TXFCb(tc)          : 100
SLM Frame Loss:
Frame Loss (far-end)                       : 0 (0.00 %)
Frame Loss (near-end)                      : 0 (0.00 %)
```

NOTE: If you attempt to monitor delays to a nonexistent MAC address, you must press **Ctrl + C** to explicitly quit the **monitor ethernet synthetic-loss-measurement** command and return to the CLI command prompt.

Managing ETH-SLM Statistics and ETH-SLM Frame Counts

Displaying ETH-SLM Statistics Only

Purpose Display on-demand ETH-SLM statistics.

By default, the **show oam ethernet connectivity-fault-management synthetic-loss-statistics** command displays on-demand ETH-SLM statistics for MEPs in the specified CFM maintenance association within the specified CFM maintenance domain.

Action

- To display the on-demand ETH-SLM statistics collected for MEPs belonging to maintenance association **ma1** within maintenance domain **md1**:

user@host> **show oam ethernet connectivity-fault-management synthetic-loss-statistics maintenance-domain md1 maintenance-association ma1**

- To display the on-demand ETH-SLM statistics collected for ETH-SLM sessions for the local MEP **201** belonging to maintenance association **ma2** within maintenance domain **md2**:

  user@host> **show oam ethernet connectivity-fault-management synthetic-loss-statistics maintenance-domain md2 maintenance-association ma2 local-mep 201**

- To display the on-demand ETH-SLM statistics collected for ETH-SLM sessions from local MEPs belonging to maintenance association **ma3** within maintenance domain **md3** to the remote MEP **302**:

  user@host> **show oam ethernet connectivity-fault-management synthetic-loss-statistics maintenance-domain md3 maintenance-association ma3 remote-mep 302**

Meaning The output displays on-demand ETH-SLM statistics for MEPs in the specified maintenance association within the specified maintenance domain. For details about the output of this command and the descriptions of the output fields, see **show oam ethernet connectivity-fault-management synthetic-loss-statistics**.

See Also

- **show oam ethernet connectivity-fault-management synthetic-loss-statistics**

Displaying ETH-SLM Statistics and Frame Counts

Purpose Display on-demand ETH-SLM statistics and ETH-SLM frame counts.

By default, the **show oam ethernet connectivity-fault-management mep-statistics** command displays on-demand ETH-SLM statistics and frame counts for MEPs in the specified CFM maintenance association within the specified CFM maintenance domain.

Action

- To display the on-demand ETH-SLM statistics and ETH-SLM frame counts for MEPs in maintenance association **ma1** within maintenance domain **md1**:

  user@host> **show oam ethernet connectivity-fault-management mep-statistics maintenance-domain md1 maintenance-association ma1**

- To display the on-demand ETH-SLM statistics and ETH-SLM frame counts for the local MEP **201** in maintenance association **ma2** within maintenance domain **md2**:

  user@host> **show oam ethernet connectivity-fault-management mep-statistics maintenance-domain md2 maintenance-association ma2 local-mep 201**

- To display the on-demand ETH-SLM statistics and ETH-SLM frame counts for the local MEP in maintenance association **ma3** within maintenance domain **md3** that participates in an ETH-SLM session with the remote MEP **302**:

`user@host>` **show oam ethernet connectivity-fault-management mep-statistics maintenance-domain ma3 maintenance-association ma3 remote-mep 302**

Meaning The output displays on-demand ETH-SLM statistics and ETH-SLM frame counts for MEPs in the specified maintenance association within the specified maintenance domain. For details about the output of this command and the descriptions of the output fields, see **show oam ethernet connectivity-fault-management mep-statistics**.

See Also

- **show oam ethernet connectivity-fault-management mep-statistics**

Displaying ETH-SLM Frame Counts for MEPs by Enclosing CFM Entity

Purpose Display on-demand ETH-SLM frame counts for CFM maintenance association end points (MEPs).

By default, the **show oam ethernet connectivity-fault-management mep-database** command displays CFM database information for MEPs in the specified CFM maintenance association within the specified CFM maintenance domain.

NOTE: At the router attached to the initiator MEP for a one-way session, or at the router attached to the receiver MEP for a two-way session, you can only display the ETH-SLM frame counts and not the MEP database details.

Action

- To display CFM database information (including ETH-SLM frame counts) for all MEPs in MA **ma1** within maintenance domain **md1**:

  `user@host>` **show oam ethernet connectivity-fault-management mep-database maintenance-domain ma1 maintenance-association ma1**

- To display CFM database information (including ETH-SLM frame counts) only for the local MEP **201** in MA **ma1** within maintenance domain **md1**:

  `user@host>` **show oam ethernet connectivity-fault-management mep-database maintenance-domain md2 maintenance-association ma2 local-mep 201**

- To display CFM database information (including ETH-SLM frame counts) only for the remote MEP **302** in MA **ma3** within maintenance domain **md3**:

  `user@host>` **show oam ethernet connectivity-fault-management mep-database maintenance-domain ma3 maintenance-association ma3 remote-mep 302**

Meaning The output displays ETH-SLM frame counts for MEPs within a particular maintenance domain, or for a specific local or remote MEP. For details about the output of this command and the descriptions of the output fields, see **show oam ethernet connectivity-fault-management mep-database**.

See Also
- **show oam ethernet connectivity-fault-management mep-database**

Displaying ETH-SLM Frame Counts for MEPs by Interface or Domain Level

Purpose Display on-demand ETH-SLM frame counts for CFM maintenance association end points (MEPs).

By default, the **show oam ethernet connectivity-fault-management interfaces** command displays CFM database information for MEPs attached to CFM-enabled Ethernet interfaces on the router or at a maintenance domain level. For Ethernet interfaces that support ETH-SLM, any frame counts are also displayed when you specify the **detail** or **extensive** command option.

NOTE: **At the router attached to the initiator MEP, you can only display the ETH-SLM frame counts and not the MEP database details.**

Action
- To display CFM database information (including ETH-SLM frame counts) for all MEPs attached to CFM-enabled Ethernet interfaces on the router:

  `user@host>` **show oam ethernet connectivity-fault-management interfaces detail**

- To display CFM database information (including ETH-SLM frame counts) only for the MEPs attached to CFM-enabled router interface **ge-5/2/9.0**:

  `user@host>` **show oam ethernet connectivity-fault-management interfaces ge-5/2/9.0 detail**

- To display CFM database information (including ETH-SLM frame counts) only for MEPs enclosed within CFM maintenance domains at level **6**:

  `user@host>` **show oam ethernet connectivity-fault-management interfaces level 6 detail**

Meaning The output displays ETH-SLM frame counts for MEPs for the specified interface. For details about the output of this command and the descriptions of the output fields, see **show oam ethernet connectivity-fault-management interfaces**.

See Also
- **show oam ethernet connectivity-fault-management interfaces**

Clearing ETH-SLM Statistics and Frame Counts

Purpose Clear the on-demand ETH-SLM statistics and ETH-SLM frame counts.

By default, statistics and frame counts are deleted for all MEPs attached to CFM-enabled interfaces on the router. However, you can filter the scope of the command by specifying an interface name.

Action

- To clear the on-demand ETH-SLM statistics and ETH-SLM frame counts for all MEPs attached to CFM-enabled interfaces on the router:

  `user@host>` **clear oam ethernet connectivity-fault-management synthetic-loss-measurement**

- To clear the on-demand ETH-SLM statistics and ETH-SLM frame counts only for MEPs attached to the logical interface **ge-0/5.9.0**:

  `user@host>` **clear oam ethernet connectivity-fault-management synthetic-loss-measurement ge-0/5/9.0**

Clearing Iterator Statistics

Purpose

Clear the existing iterator statistics and proactive ETH-SLM counters.

Multiple iterators can be associated with remote MEP. However, by default, only one result pertaining to one iterator profile can be cleared.

Action

- To clear the iterator statistics for remote MEP **1** and iterator profile **i1** with MEPs belonging to the maintenance association **ma1** within the maintenance domain **default-1**:

  `user@host>` **clear oam ethernet connectivity-fault-management sla-iterator-statistics sla-iterator i1 maintenance-domain default-1 maintenance-association ma1 local-mep 1 remote-mep *1***

- To clear the iterator statistics for remote MEP **1** and iterator profile **i2** with MEPs belonging to the maintenance association **ma1** within the maintenance domain **default-1**:

  `user@host>` **clear oam ethernet connectivity-fault-management sla-iterator-statistics sla-iterator i2 maintenance-domain default-1 maintenance-association ma1 local-mep 1 remote-mep 1**

Related Documentation

Troubleshooting Failures with ETH-SLM

Problem

Description: The Ethernet synthetic loss measurement (ETH-SLM) application is not working properly for calculation of frame loss using synthetic frames instead of data traffic

Solution Perform the following steps to analyze and debug any problems with the ETH-SLM functionality.

1. Ensure that ETH-SLM is configured (either proactive or on-demand) to initiate SLM frames. Verify the configuration settings.

2. Examine any failures that might have occurred in the CFM session for which the ETH-SLM feature is enabled. The CFM session must be in the up state for the ETH-SLM functionality to work correctly. Use the **show oam ethernet connectivity-fault-management mep-database maintenance-domain** ***md-name*** **maintenance-association** ***ma-name*** **local-mep** ***mep-id*** **remote-mep** ***remote-mep-id*** command to verify whether the CFM session is in the up state.

3. If the MEP sessions are active, use the appropriate show command to verify the ETH-SLM statistics and to analyze if ETH-SLM frames are transmitted or received.

4. If the transmission of ETH-SLM frames does not happen correctly after you attempt all of the preceding troubleshooting steps, enable the tracing operations for Ethernet CFM by including the **traceoptions** statement at the [**edit protocols oam ethernet connectivity-fault-management**] hierarchy level.

```
[edit protocols oam ethernet connectivity-fault-management]
traceoptions {
  file <filename> <files number  <match regular-expression microsecond-stamp>>
    <size size> <world-readable | no-world-readable>;
  flag flag;
  no-remote-trace;
}
```

Configuring an Iterator Profile

You can create an iterator profile with its parameters to periodically transmit SLA measurement packets in the form of ITU-Y.1731-compliant frames for delay measurement or loss measurement.

To create an iterator profile:

1. In configuration mode, go to the following hierarchy level:

   [edit]
   user@host# **edit protocols oam ethernet connectivity-fault-management performance-monitoring**

2. Configure the SLA measurement monitoring iterator:

   [edit protocols oam ethernet connectivity-fault-management performance-monitoring]
   user@host# **edit** sla-iterator-profiles

3. Configure an iterator profile—for example, i1:

   [edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles]
   user@host# **set i1**

4. (Optional) Configure the cycle time, which is the amount of time (in milliseconds) between back-to-back transmission of SLA frames for one connection, with values from 10 through 3,600,000. The default value is 1000 ms.

   [edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles i1]
   user@host# **set** cycle-time ***cycle-time-value***

5. (Optional) Configure the iteration period, which indicates the maximum number of cycles per iteration (the number of connections registered to an iterator cannot exceed this value), with values from 1 through 2000. The default value is 2000.

   [edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles i1]
   user@host# **set** iteration-period ***iteration-period-value***

6. Configure the measurement type as loss measurement, statistical frame-loss measurement, or two-way delay measurement.

   [edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles i1]
   user@host# **set** measurement-type **(loss | statistical-frame-loss | two-way-delay)**

7. (Optional) Configure the calculation weight for delay with values from 1 through 65,535. The default value is 1 (applicable only for two-way delay measurement).

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
   sla-iterator-profiles i1]
user@host# set calculation-weight delay delay-value
```

8. (Optional) Configure the calculation weight for delay variation with values from 1 through 65,535. The default value is 1 (applicable only for two-way delay measurement).

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
   sla-iterator-profiles i1]
user@host# set calculation-weight delay-variation delay-variation-value
```

9. (Optional) Configure the threshold value for average frame delay, in microseconds, for two-way Ethernet frame delay measurement (ETH-DM). When the configured threshold for average frame delay is exceeded, an SNMP trap is generated for ETH-DM. The range is from 1 through 4294967295 microseconds.

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
   sla-iterator-profiles i1]
user@host# set avg-fd-twoway-threshold avg-fd-twoway-threshold-value
```

10. (Optional) Configure the threshold value for average frame delay variation, in microseconds, for two-way Ethernet frame delay measurement (ETH-DM). When the configured threshold for average frame delay variationis exceeded, an SNMP trap is generated for ETH-DM. The range is from 1 through 4294967295 microseconds.

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
   sla-iterator-profiles i1]
user@host# set avg-ifdv-twoway-threshold avg-ifdv-twoway-threshold-value
```

11. (Optional) Configure the threshold value for average frame loss ratio, in milli-percent, in the upward or forward direction for Ethernet loss measurement (ETH-LM) and Ethernet synthetic loss measurement (ETH-SLM). When the configured threshold for average forward frame loss ratio is exceeded, an SNMP trap is generated for ETH-LM and ETH-SLM. The range is from 1 through 100000 milli-percent.

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
   sla-iterator-profiles i1]
user@host# set avg-flr-forward-threshold avg-flr-forward-threshold-value
```

12. (Optional) Configure the threshold value for average frame loss ratio, in milli-percent, in the backward or downstream direction for Ethernet loss measurement (ETH-LM) and Ethernet synthetic loss measurement (ETH-SLM). When the configured threshold for average backward frame loss ratio is exceeded, an SNMP trap is generated for ETH-LM and ETH-SLM. The range is from 1 through 100000 milli-percent.

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
   sla-iterator-profiles i1]
user@host# set avg-flr-backward-threshold avg-flr-backward-threshold-value
```

13. Configure the **disable** statement to stop the iterator (that is, disable the iterator profile).

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
  sla-iterator-profiles i1]
user@host# set disable
```

14. Verify the configuration.

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
  sla-iterator-profiles]
user@host# show i1
  cycle-time cycle-time-value;
  iteration-period iteration-period-value;
  measurement-type (loss | two-way-delay);
  avg-fd-twoway-threshold avg-fd-twoway-threshold-value;
  avg-ifdv-twoway-threshold avg-ifdv-twoway-threshold-value;
  avg-flr-forward-threshold avg-flr-forward-threshold-value;
  avg-flr-backward-threshold avg-flr-backward-threshold-value;
  calculation-weight {
    delay delay-weight;
    delay-variation delay-variation-weight;
  }
  calculation-weight {
    delay delay-weight;
    delay-variation delay-variation-weight;
  }
```

Verifying the Configuration of an Iterator Profile

The following topics illustrate the configuration of an iterator profile for a two-way delay measurement, for loss measurement, and for a remote maintenance association end point (MEP). The topics also illustrate disabling an iterator profile with the **disable** statement for two-way measurement and deactivating an iterator profile with the **deactivate** command for a remote MEP.

- Displaying the Configuration of an Iterator Profile for Two-way Delay Measurement on page 757
- Displaying the Configuration of an Iterator Profile for Loss Measurement on page 757
- Displaying the Configuration of a Remote MEP with an Iterator Profile on page 758
- Disabling an Iterator Profile on page 759

Displaying the Configuration of an Iterator Profile for Two-way Delay Measurement

Purpose Display the configuration of an iterator profile for two-way delay measurement as configured in the “Configuring an Iterator Profile” on page 754 topic with the following values:

- **profile-name—i1**
- **cycle-time—1000** milliseconds
- **iteration-period—2000** cycles per second
- **delay—1**
- **delay-variation—1**:

Action To display information about the iterator profile, run the **show** command at the **[edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles]** hierarchy level:

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
  sla-iterator-profiles]
user@host# show
i1 {
  cycle-time 1000;
  iteration-period 2000;
  measurement-type two-way-delay;
  calculation-weight {
    delay 1;
    delay-variation 1;
  }
}
```

Meaning The configuration for an iterator profile for two-way measurement is displayed as expected with set values.

Displaying the Configuration of an Iterator Profile for Loss Measurement

Purpose Display the configuration of an iterator profile for loss measurement as configured in the “Configuring an Iterator Profile” on page 754 topic with the following values:

- **profile-name—12**
- **cycle-time—1000** milliseconds
- **iteration-period—2000** cycles per second

Action To display information about the iterator profile, run the **show** command at the **[edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles]** hierarchy level:

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring
  sla-iterator-profiles]
user@host# show
12 {
  cycle-time 1000;
  iteration-period 2000;
  measurement-type loss;
}
```

Meaning The configuration for an iterator profile for loss measurement is displayed as expected with set values.

Displaying the Configuration of a Remote MEP with an Iterator Profile

Purpose Display the configuration of a remoteMEP as configured in the “Configuring a Remote MEP with an Iterator Profile” on page 765 topic with the following values:

- **profile-name—i3**
- **maintenance-domain—default-1**
- **maintenance-association—1**
- **short-name-format—2octet**
- **mep—1**
- **remote-mep—1**
- **data-tlv-size—1**
- **iteration-count—1**
- **priority—1**

Action To display information about the remote MEP, run the **show** command at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain default-1 maintenance association ma1 mep 1 remote-mep 1]** hierarchy level:

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  default-1 maintenance association 1 short-name-format 2octet mep 1 remote-mep 1]
user@host# show
sla-iterator-profile i3 {
  data-tlv-size 1;
  iteration-count 1;
  priority 1;
}
```

Meaning The configuration for a remote MEP for two-way measurement is displayed as expected with set values.

Disabling an Iterator Profile

Purpose To disable an iterator profile for two-way delay measurement and for a remote MEP.

Action

- To disable an iterator profile (for example, i1) with the **disable** configuration command for two-way measurement at the **[edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles i1]** hierarchy level:

  ```
  [edit protocols oam ethernet connectivity-fault-management performance-monitoring
    sla-iterator-profiles i1]
  user@host# disable
  ```

- To disable an iterator profile for a remote MEP (for example, i2) with the **deactivate** configuration command at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain default-1 maintenance association ma1 mep 1 remote-mep 1]** hierarchy level:

  ```
  [edit protocols oam ethernet connectivity-fault-management maintenance-domain
    default-1 maintenance association ma1 mep 1 remote-mep 1]
  user@host# deactivate sla-iterator-profile i2
  ```

Displaying Iterator Statistics

Purpose Retrieve and display iterator statistics.

Muliple iterators can be associated with a remote MEP. However, by default, only one result pertaining to one iterator profile is displayed.

Action

- To display the iterator statistics for remote MEP **1** and iterator profile **i1** with MEPs belonging to the maintenance association **ma1** and within the maintenance domain **default-1** (here, the iterator profile **i1** is configured for two-way delay measurement):

  ```
  user@host> show oam ethernet connectivity-fault-management sla-iterator-statistics
  sla-iterator i1 maintenance-domain default-1 maintenance-association ma1 local-mep 1
  remote-mep 1
  ```

```
Iterator statistics:
Maintenance domain: md6, Level: 6
Maintenance association: ma6, Local MEP id: 1000
Remote MEP id: 103, Remote MAC address: 00:90:69:0a:43:92
Iterator name: i1, Iterator Id: 1
Iterator cycle time: 10ms, Iteration period: 1 cycles
Iterator status: running, Infinite iterations: true
Counter reset time: 2010-03-19 20:42:39 PDT (2d 18:24 ago)
Reset reason: Adjacency flap

Iterator delay measurement statistics:
Delay weight: 1, Delay variation weight: 1
DMM sent                                       : 23898520
DMM skipped for threshold hit                  : 11000
DMM skipped for threshold hit window           : 0
DMR received                                   : 23851165
DMR out of sequence                            : 1142
DMR received with invalid time stamps          : 36540
Average two-way delay                          : 129 usec
Average two-way delay variation                : 15 usec
Average one-way forward delay variation        : 22 usec
Average one-way backward delay variation       : 22 usec
Weighted average two-way delay                 : 134 usec
Weighted average two-way delay variation       : 8 usec
Weighted average one-way forward delay variation  : 6 usec
Weighted average one-way backward delay variation : 2 usec
```

Output fields are listed in the approximate order in which they appear.

Table 71: Displaying Iterator Statistics for Ethernet Delay Measurement Output Fields

Output Field Name	Output Field Description
Maintenance domain	Maintenance domain name.
Level	Maintenance domain level configured.
Maintenance association	Maintenance association name.
Local MEP id	Numeric identifier of the local MEP.
Remote MEP id	Numeric identifier of the remote MEP.
Remote MAC address	Unicast MAC address of the remote MEP.
Iterator name	Name of iterator.
Iterator Id	Numeric identifier of the iterator.
Iterator cycle time	Number of cycles (in milliseconds) taken between back-to-back transmission of SLA frames for this connection
Iteration period	Maximum number of cycles per iteration
Iterator status	Current status of iterator whether running or stopped.

Table 71: Displaying Iterator Statistics for Ethernet Delay Measurement Output Fields (continued)

Output Field Name	Output Field Description
Infinite iterations	Status of iteration as infinite or finite.
Counter reset time	Date and time when the counter was reset.
Reset reason	Reason to reset counter.
Delay weight	Calculation weight of delay.
Delay variation weight	Calculation weight of delay variation.
DMM sent	Delay measurement message (DMM) PDU frames sent to the peer MEP in this session.
DMM skipped for threshold hit	Number of DMM frames sent to the peer MEP in this session skipped during threshold hit.
DMM skipped for threshold hit window	Number of DMM frames sent to the peer MEP in this session skipped during the last threshold hit window.
DMR received	Number of delay measurement reply (DMR) frames received.
DMR out of sequence	Total number of DMR out of sequence packets received.
DMR received with invalid time stamps	Total number of DMR frames received with invalid timestamps.
Average two-way delay	Average two-way frame delay for the statistics displayed.
Average two-way delay variation	Average two-way “frame jitter” for the statistics displayed.
Average one-way forward delay variation	Average one-way forward delay variation for the statistics displayed in microseconds.
Average one-way backward delay variation	Average one-way backward delay variation for the statistics displayed in microseconds.
Weighted average two-way delay	Weighted average two-way delay for the statistics displayed in microseconds.
Weighted average two-way delay variation	Weighted average two-way delay variation for the statistics displayed in microseconds.
Weighted average one-way forward delay variation	Weighted average one-way forward delay variation for the statistics displayed in microseconds.
Weighted average one-way backward delay variation	Weighted average one-way backward delay variation for the statistics displayed in microseconds.

- To display the iterator statistics for remote MEP **1** and iterator profile **i2** with MEPs belonging to the maintenance association **ma1** and within the maintenance domain **default-1** (here, the iterator profile **i1** is configured for loss measurement):

```
user@host> show oam ethernet connectivity-fault-management sla-iterator-statistics
sla-iterator i2 maintenance-domain default-1 maintenance-association ma1 local-mep 1
remote-mep 1
Iterator statistics:
Maintenance domain: md6, Level: 6
Maintenance association: ma6, Local MEP id: 1000
Remote MEP id: 103, Remote MAC address: 00:90:69:0a:43:92
Iterator name: i2, Iterator Id: 2
Iterator cycle time: 1000ms, Iteration period: 2000 cycles
Iterator status: running, Infinite iterations: true
Counter reset time: 2010-03-19 20:42:39 PDT (2d 18:25 ago)
Reset reason: Adjacency flap

Iterator loss measurement statistics:
LMM sent                              : 238970
LMM skipped for threshold hit         : 60
LMM skipped for threshold hit window  : 0
LMR received                          : 238766
LMR out of sequence                   : 43

Accumulated transmit statistics:
Near-end (CIR)                        : 0
Far-end (CIR)                         : 0
Near-end (EIR)                        : 0
Far-end (EIR)                         : 0

Accumulated loss statistics:
Near-end (CIR)                        : 0 (0.00%)
Far-end (CIR)                         : 0 (0.00%)
Near-end (EIR)                        : 0 (0.00%)
Far-end (EIR)                         : 0 (0.00%)

Last loss measurement statistics:
Near-end (CIR)                        : 0
Far-end (CIR)                         : 0
Near-end (EIR)                        : 0
Far-end (EIR)                         : 0
```

Output fields are listed in the approximate order in which they appear.

Table 72: Displaying Iterator Statistics for Ethernet Loss Measurement Output Fields

Output Field Name	Output Field Description
Maintenance domain	Maintenance domain name.
Level	Maintenance domain level configured.
Maintenance association	Maintenance association name.
Local MEP id	Numeric identifier of the local MEP.
RemoteMEP identifier	Numeric identifier of the remote MEP.

Table 72: Displaying Iterator Statistics for Ethernet Loss Measurement Output Fields (continued)

Output Field Name	Output Field Description
Remote MAC address	Unicast MAC address of the remote MEP.
Iterator name	Name of iterator.
Iterator Id	Numeric identifier of the iterator.
Iterator cycle time	Number of cycles (in milliseconds) taken between back-to-back transmission of SLA frames for this connection
Iteration period	Maximum number of cycles per iteration
Iterator status	Current status of iterator whether running or stopped.
Infinite iterations	Status of iteration as infinite or finite.
Counter reset time	Date and time when the counter was reset.
Reset reason	Reason to reset counter.
LMM sent	Number of loss measurement message (LMM) PDU frames sent to the peer MEP in this session.
LMM skipped for threshold hit	Number of LMM frames sent to the peer MEP in this session skipped during threshold hit.
LMM skipped for threshold hit window	Number of LMM frames sent to the peer MEP in this session skipped during the last threshold hit window.
LMR received	Number of LMRs frames received.
LMR out of sequence	Total number of LMR out of sequence packets received.
Near-end (CIR)	Frame loss associated with ingress data frames for the statistics displayed.
Far-end (CIR)	Frame loss associated with egress data frames for the statistics displayed.
Near-end (EIR)	Frame loss associated with ingress data frames for the statistics displayed.
Far-end (EIR)	Frame loss associated with egress data frames for the statistics displayed.

Clearing Iterator Statistics

Purpose

Clear iterator statistics.

Multiple iterators can be associated with remote MEP. However, by default, only one result pertaining to one iterator profile can be cleared.

Action

- To clear the iterator statistics for remote MEP **1** and iterator profile **i1** with MEPs belonging to the maintenance association **ma1** and within the maintenance domain **default-1**:

  `user@host>` **clear oam ethernet connectivity-fault-management sla-iterator-statistics sla-iterator i1 maintenance-domain default-1 maintenance-association ma1 local-mep 1 remote-mep** ***1***

- To clear the iterator statistics for remote MEP **1** and iterator profile **i2** with MEPs belonging to the maintenance association **ma1** and within the maintenance domain **default-1**:

  `user@host>` **clear oam ethernet connectivity-fault-management sla-iterator-statistics sla-iterator i2 maintenance-domain default-1 maintenance-association ma1 local-mep 1 remote-mep 1**

Configuring a Remote MEP with an Iterator Profile

You can associate a remote maintenance association end point (MEP) with more than one iterator profile.

To configure a remote MEP with an iterator profile:

1. In configuration mode, go to the following hierarchy level:

   user@host# **edit protocols oam ethernet connectivity-fault-management maintenance-domain** ***md-name*** **maintenance-association** ***ma-name*** mep ***mep-id***

2. Configure the remote MEP with values from 1 through 8191.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id*]
   user@host# **set** remote-mep ***remote-mep-id***

3. Set the iterator profile.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id* remote-mep *remote-mep-id*]
   user@host# **set** sla-iterator-profile ***profile-name***

4. (Optional) Set the size of the data TLV portion of the Y.1731 data frame with values from 1 through 1400 bytes. The default value is 1.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id* remote-mep *remote-mep-id* sla-iterator-profile *profile-name*]
   user@host# **set** data-tlv-size ***size***

5. (Optional) Set the iteration count, which indicates the number of iterations for which this connection should partake in the iterator for acquiring SLA measurements, with values from 1 through 65,535. The default value is 0 (that is, infinite iterations).

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id* remote-mep *remote-mep-id* sla-iterator-profile *profile-name*]
   user@host# **set** iteration-count ***count-value***

6. (Optional) Set the priority, which is the **vlan-pcp** value that is sent in the Y.1731 data frames, with values from 0 through 7. The default value is 0.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id* remote-mep *remote-mep-id* sla-iterator-profile *profile-name*]
   user@host# **set** priority ***priority-value***

7. Verify the configuration.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  md-name maintenance-association ma-name mep mep-id remote-mep
  remote-mep-id]
user@host# show
sla-iterator-profile profile-name {
  data-tlv-size size;
  iteration-count count-value;
  priority priority-value;
}
```

Damping CFM performance Monitoring Traps and Notifications to Prevent Congestion of The NMS

You can dampen the performance monitoring threshold-crossing traps and notifications that are generated every time a threshold-crossing event occurs to prevent congestion of the network management system (NMS).

Damping limits the number of jnxSoamPmThresholdCrossingAlarm traps sent to the NMS by summarizing the flap occurrences over a period of time, known as the flap trap timer, and sends a single jnxSoamPmThresholdFlapAlarm notification to the NMS. You can configure the duration of the flap trap timer to any value from 1 through 360 seconds.

The jnxSoamPmThresholdFlapAlarm notification is generated and sent when the following conditions are met:

- At least one flap has occurred when the flap timer has expired.
- You changed the value of the flap trap timer, which caused the timer to stop.

You can enable damping at the global level for the iterator or you can enable damping at the individual threshold type of the iterator. For instance, to enable damping at the global level, for the iterator, use the following command: **set protocols oam ethernet cfm performance-monitoring sla-iterator-profiles** ***profile-name*** **flap-trap-monitor**. To enable damping at a specific threshold type, for the **avg-fd-twoway-threshold**, use the following command: **set protocols oam ethernet cfm performance-monitoring sla-iterator-profiles** ***profile-name*** **avg-fdv-twoway-threshold flap-trap-monitor**.

You can also disable damping.

Configuring Statistical Frame Loss Measurement for VPLS Connections

Using proactive statistical frame loss measurement, you can monitor VPLS connections on MX Series routers . Statistical frame loss measurement allows you to monitor the quality of Ethernet connections for service level agreements (SLAs). Point-to-point and multipoint-to-multipoint connections configured on MX Series routers can be monitored by registering the connection on an iterator and initiating periodic SLA measurement of frame transmissions on the connections.

Iterators periodically transmit SLA measurement packets using ITU-Y.1731 compliant frames. The iterator sends periodic measurement packets for each of the connections registered to it. These measurement cycles are transmitted in such a way as to not overlap, reducing the processing demands placed on the CPU. The measurement packets are exchanged between the source user network interface (UNI) port and the destination UNI port, providing a sequence of timed performance measurements for each UNI pair. The Frame Loss Ratio (FLR) and connection availability can be computed from these measurements using statistics.

The following steps outline how to configure statistical frame loss measurement for VPLS connections:

1. To configure proactive ETH-DM measurement for a VPLS connection, see "Guidelines for Configuring Routers to Support an ETH-DM Session" on page 768.

2. To enable statistical loss measurement for a VPLS connection, configure an iterator for the VPLS connection using the **sla-iterator-profiles** statement at the **[edit protocols oam ethernet connectivity-fault-management performance-monitoring]** hierarchy level. For detailed instructions, see "Configuring an Iterator Profile" on page 754.

3. As part of the iterator configuration, include the **statistical-frame-loss** option for the **measurement-type** statement at the **[edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles *profile-name*]** hierarchy level.

4. Once you have enabled the iterator, you can display the statistical frame loss for a VPLS connection by issuing the **show oam ethernet connectivity-fault-management sla-iterator-statistics sla-iterator** ***identifier*** **maintenance-domain** ***name*** **maintenance-association** ***name*** **local-mep** ***identifier*** **remote-mep** ***identifier*** command.

- Verifying the Configuration of an Iterator Profile on page 756

Guidelines for Configuring Routers to Support an ETH-DM Session

Keep the following guidelines in mind when configuring routers to support an Ethernet frame delay measurement (ETH-DM) session:

- Configuration Requirements for ETH-DM on page 768
- Configuration Options for ETH-DM on page 768

Configuration Requirements for ETH-DM

You can obtain ETH-DM information for a link that meets the following requirements:

- The measurements can be performed between peer maintenance association endpoints (MEPs) on two routers.
- The two MEPs must be configured on two Ethernet physical interfaces or on two Ethernet logical interfaces. For more information, see "Configuring a MEP to Generate and Respond to CFM Protocol Messages" on page 613.
- The two MEPs must be configured—on their respective routers—under the same maintenance association (MA) identifier. For more information, see "Creating a Maintenance Association" on page 610.
- On both routers, the MA must be associated with the same maintenance domain (MD) name. For more information, see "Creating a Maintenance Domain" on page 603.
- On both routers, periodic packet management (PPM) must be running on the Routing Engine and Packet Forwarding Engine, which is the default configuration. You can disable PPM on the Packet Forwarding Engine only. However, the Ethernet frame delay measurement feature requires that distributed PPM remain enabled on the Packet Forwarding Engine of both routers. For more information about **ppm**, see the *Junos OS Routing Protocols Library*.
- If the PPM process (**ppm**) is disabled on the Packet Forwarding Engine, you must re-enable it. Re-enabling distributed **ppm** entails restarting the **ethernet-connectivity-fault-management** process, which causes all connectivity fault management (CFM) sessions to re-establish. For more information about CFM sessions, see "Configuring Ethernet Local Management Interface" on page 627.

NOTE: **The Ethernet frame delay measurement feature is supported only for MEPs configured on Ethernet physical or logical interfaces on DPCs in MX Series routers. The ETH-DM feature is not supported on aggregated Ethernet interfaces or LSI pseudowires.**

Configuration Options for ETH-DM

By default, the ETH-DM feature calculates frame delays using software-based timestamping of the ETH-DM PDU frames sent and received by the MEPs in the session. As an option that can increase the accuracy of ETH-DM calculations when the DPC is loaded with heavy traffic in the receive direction, you can enable hardware-assisted timestamping of session frames in the receive direction.

Related Documentation

- Ethernet Frame Delay Measurements Overview on page 723
- Configuring Routers to Support an ETH-DM Session on page 775

Guidelines for Starting an ETH-DM Session

Keep the following guidelines in mind when preparing to start an Ethernet frame delay measurement (ETH-DM) session:

- ETH-DM Session Prerequisites on page 769
- ETH-DM Session Parameters on page 769
- Restrictions for an ETH-DM Session on page 770

ETH-DM Session Prerequisites

Before you can start an ETH-DM session, you must configure two MX Series routers to support ETH-DM by defining the two CFM-enabled physical or logical Ethernet interfaces on each router. This entails creating and configuring CFM maintenance domains, maintenance associations, and maintenance association end points on each router. For more information about enabling CFM on an Ethernet interface, see "Creating a Maintenance Domain" on page 603.

NOTE: **The Ethernet frame delay measurement feature is supported only for maintenance association end points configured on Ethernet physical or logical interfaces on DPCs in MX Series routers. The ETH-DM feature is not supported on aggregated Ethernet interfaces or LSI pseudowires.**

For specific information about configuring routers to support ETH-DM, see "Guidelines for Configuring Routers to Support an ETH-DM Session" on page 768 and "Configuring Routers to Support an ETH-DM Session" on page 775.

ETH-DM Session Parameters

You can initiate a one-way or two-way ETH-DM session by entering the **monitor ethernet delay-measurement** operational command at a router that contains one end of the service for which you want to measure frame delay. The command options specify the ETH-DM session in terms of the CFM elements:

- The type of ETH-DM measurement (one-way or two-way) to be performed.
- The Ethernet service for which the ETH-DM measurement is to be performed:
  - CFM maintenance domain—Name of the existing maintenance domain (MD) for which you want to measure Ethernet frame delays. For more information, see "Creating a Maintenance Domain" on page 603.

  - CFM maintenance association—Name of an existing maintenance association (MA) within the maintenance domain. For more information, see "Creating a Maintenance Association" on page 610.
  - Remote CFM maintenance association end point—The unicast MAC address or the numeric identifier of the remote maintenance association end point (MEP)—the physical or logical interface on the remote router that resides in the specified MD and is named in the specified MA—with which to perform the ETH-DM session. For more information, see "Configuring a MEP to Generate and Respond to CFM Protocol Messages" on page 613.

- Optional specifications:
  - Count—You can specify the number of ETH-DM requests to send for this frame delay measurement session. The range is from 1 through 65,535 frames. The default value is 10 frames.

    NOTE: Although you can trigger frame delay collection for up to 65,535 ETH-DM requests at a time, a router stores only the last 100 frame delay statistics per CFM session (pair of peer MEPs).

  - Frame interval—You can specify the number of seconds to elapse between ETH-DM frame transmittals. The default value is 1 second.

For more detailed information about the parameters you can specify to start an ETH-DM session, see the **monitor ethernet delay-measurement** operational command description in the CLI Explorer.

Restrictions for an ETH-DM Session

The following restrictions apply to an ETH-DM session:

- You cannot run multiple simultaneous ETH-DM sessions with the same remote MEP or MAC address.
- For a given ETH-DM session, you can collect frame delay information for a maximum of 65,535 frames.
- For a given CFM session (pair of peer MEPs), the ETH-DM database stores a maximum of 100 statistics, with the older statistics being "aged out" as newer statistics are collected for that pair of MEPs.
  - For one-way delay measurements collected within the same CFM session, the 100 most recent ETH-DM statistics can be retrieved at any point of time at the router on which the receiver MEP is defined.
  - For two-way delay measurements collected within the same CFM session, the 100 most recent ETH-DM statistics can be retrieved at any point of time at the router on which the initiator MEP is defined.

  Depending on the number of frames exchanged in the individual ETH-DM sessions, the ETH-DM database can contain statistics collected through multiple ETH-DM sessions.

- If graceful Routing Engine switchover (GRES) occurs, any collected ETH-DM statistics are lost, and ETH-DM frame counts are reset to zeroes. GRES enables a router with dual Routing Engines to switch from a master Routing Engine to a backup Routing Engine without interruption to packet forwarding. For more information, see the *Junos OS High Availability Library for Routing Devices*.
- Accuracy of frame delay data is compromised when the system is changing (such as from reconfiguration). We recommend performing Ethernet frame delay measurements on a stable system.

- **monitor ethernet delay-measurement** operational command

Guidelines for Managing ETH-DM Statistics and ETH-DM Frame Counts

ETH-DM Statistics

Ethernet frame delay statistics are the frame delay and frame delay variation values determined by the exchange of frames containing ETH-DM protocol data units (PDUs).

- For a one-way ETH-DM session, statistics are collected in an ETH-DM database at the router that contains the receiver MEP. For a detailed description of one-way Ethernet frame delay measurement, including the exchange of one-way delay PDU frames, see "Ethernet Frame Delay Measurements Overview" on page 723.
- For a two-way ETH-DM session, statistics are collected in an ETH-DM database at the router that contains the initiator MEP. For a detailed description of two-way Ethernet frame delay measurement, including the exchange of two-way delay PDU frames, see "Ethernet Frame Delay Measurements Overview" on page 723.

A CFM database stores CFM-related statistics and—for Ethernet interfaces that support ETH-DM—the 100 most recently collected ETH-DM statistics for that pair of MEPs. You can view ETH-DM statistics by using the **delay-statistics** or **mep-statistics** form of the **show oam ethernet connectivity-fault-management** command to display the CFM statistics for the MEP that collects the ETH-DM statistics you want to view.

Table 73 on page 772 describes the ETH-DM statistics calculated in an ETH-DM session.

Table 73: ETH-DM Statistics

Field Name	Field Description
One-way delay (μsec)†	For a one-way ETH-DM session, the frame delay, in microseconds, collected at the receiver MEP. To display frame delay statistics for a given one-way ETH-DM session, use the **delay-statistics** or **mep-statistics** form of the **show oam ethernet connectivity-fault-management** command at the receiver MEP for that session.
Two-way delay (μsec)	For a two-way ETH-DM session, the frame delay, in microseconds, collected at the initiator MEP. When you start a two-way frame delay measurement, the CLI output displays each DMR frame receipt timestamp and corresponding DMM frame delay and delay variation collected as the session progresses. To display frame delay statistics for a given two-way ETH-DM session, use the **delay-statistics** or **mep-statistics** form of the **show oam ethernet connectivity-fault-management** command at the initiator MEP for that session.
Average delay†	When you start a two-way frame delay measurement, the CLI output includes a runtime display of the average two-way frame delay among the statistics collected for the ETH-DM session only. When you display ETH-DM statistics using a **show** command, the **Average delay** field displays the average one-way and two- frame delays among all ETH-DM statistics collected at the CFM session level. For example, suppose you start two one-way ETH-DM sessions for 50 counts each, one after the other. If, after both measurement sessions complete, you use a **show** command to display 100 ETH-DM statistics for that CFM session, the **Average delay** field displays the average frame delay among all 100 statistics.
Average delay variation†	When you start a two-way frame delay measurement, the CLI output includes a runtime display of the average two-way frame delay variation among the statistics collected for the ETH-DM session only. When you display ETH-DM statistics using a **show** command, the **Average delay variation** field displays the average one-way and two- frame delay variations among all ETH-DM statistics collected at the CFM session level.
Best-case delay†	When you start a two-way frame delay measurement, the CLI output includes a runtime display of the lowest two-way frame delay value among the statistics collected for the ETH-DM session only. When you display ETH-DM statistics using a **show** command, the **Best case delay** field displays the lowest one-way and two-way frame delays among all ETH-DM statistics collected at the CFM session level.
Worst-case delay†	When you start a two-way frame delay measurement, the CLI output includes a runtime display of the highest two-way frame delay value among the statistics collected for the ETH-DM session only. When you display ETH-DM statistics using a **show** command, the **Worst case delay** field displays the highest one-way and two-way frame delays among all statistics collected at the CFM session level.

Table 73: ETH-DM Statistics (continued)

Field Name	Field Description
[†]When you start a one-way frame delay measurement, the CLI output displays **NA** (“not available”) for this field. One-way ETH-DM statistics are collected at the remote (receiver) MEP. Statistics for a given one-way ETH-DM session are available only by displaying CFM statistics for the receiver MEP.	

ETH-DM Statistics Retrieval

At the receiver MEP for a one-way session, or at the initiator MEP for a two-way session, you can display all ETH-DM statistics collected at a CFM session level by using the following operational commands:

- **show oam ethernet connectivity-fault-management delay-statistics maintenance-domain *md-name* maintenance-association *ma-name* <local-mep *mep-id*> <remote-mep *mep-id*> <count *count*>**
- **show oam ethernet connectivity-fault-management mep-statistics maintenance-domain *md-name* maintenance-association *ma-name* <local-mep *mep-id*> <remote-mep *mep-id*> <count *count*>**

ETH-DM Frame Counts

The number of ETH-DM PDU frames exchanged in a ETH-DM session are stored in the CFM database on each router.

Table 74 on page 773 describes the ETH-DM frame counts collected in an ETH-DM session.

Table 74: ETH-DM Frame Counts

Field Name	Field Description
1DMs sent	Number of one-way delay measurement (1DM) PDU frames sent to the peer MEP in this session. Stored in the CFM database of the MEP initiating a one-way frame delay measurement.
Valid 1DMs received	Number of valid 1DM frames received. Stored in the CFM database of the MEP receiving a one-way frame delay measurement.
Invalid 1DMs received	Number of invalid 1DM frames received. Stored in the CFM database of the MEP receiving a one-way frame delay measurement.
DMMs sent	Number of delay measurement message (DMM) PDU frames sent to the peer MEP in this session. Stored in the CFM database of the MEP initiating a two-way frame delay measurement.
DMRs sent	Number of delay measurement reply (DMR) frames sent (in response to a received DMM). Stored in the CFM database of the MEP responding to a two-way frame delay measurement.

Table 74: ETH-DM Frame Counts (continued)

Field Name	Field Description
Valid DMRs received	Number of valid DMR frames received. Stored in the CFM database of the MEP initiating a two-way frame delay measurement.
Invalid DMRs received	Number of invalid DMR frames received. Stored in the CFM database of the MEP initiating a two-way frame delay measurement.

ETH-DM Frame Count Retrieval

Each router counts the number of ETH-DM frames sent or received and stores the counts in a CFM database.

Frame Counts Stored in CFM Databases

You can display ETH-DM frame counts for MEPs assigned to specified Ethernet interfaces or for specified MEPs in CFM sessions by using the following operational commands:

- **show oam ethernet connectivity-fault-management interfaces** (**detail** | **extensive**)
- **show oam ethernet connectivity-fault-management mep-database maintenance-domain** ***md-name*** **maintenance-association** ***ma-name*** <**local-mep** ***mep-id***> <**remote-mep** ***mep-id***>

One-Way ETH-DM Frame Counts

For a one-way ETH-DM session, delay statistics are collected at the receiver MEP only, but frame counts are collected at both MEPs. As indicated in Table 74 on page 773, one-way ETH-DM frame counts are tallied from the perspective of each router in the session:

- At the initiator MEP, the router counts the number of 1DM frames sent.
- At the receiver MEP, the router counts the number of valid 1DM frames received and the number of invalid 1DM frames received.

You can also view one-way ETH-DM frame counts—for a receiver MEP—by using the **show oam ethernet connectivity-fault-management mep-statistics** command to display one-way statistics and frame counts together.

Two-Way ETH-DM Frame Counts

For a two-way ETH-DM session, delay statistics are collected at the initiator MEP only, but frame counts are collected at both MEPs. As indicated in Table 74 on page 773, two-way ETH-DM frame counts are tallied from the perspective of each router in the session:

- At the initiator MEP, the router counts the number of DMM frames sent, valid DMR frames received, and invalid DMR frames received.
- At the responder MEP, the router counts the number of DMR frames sent.

You can also view two-way ETH-DM frame counts—for an initiator MEP—by using the **show oam ethernet connectivity-fault-management mep-statistics** command to display two-way statistics and frame counts together.

Configuring Routers to Support an ETH-DM Session

Configuring MEP Interfaces

Before you can start an Ethernet frame delay measurement session across an Ethernet service, you must configure two MX Series routers to support ETH-DM.

To configure an Ethernet interface on a MX Series router to support ETH-DM:

1. On each router, configure two physical or logical Ethernet interfaces connected by a VLAN. The following configuration is typical for single-tagged logical interfaces:

```
[edit interfaces]
interface {
   ethernet-interface-name {
      vlan-tagging;
      unit logical-unit-number {
         vlan-id vlan-id; # Both interfaces on this VLAN
      }
   }
}
```

   Both interfaces will use the same VLAN ID.

2. On each router, attach peer MEPs to the two interfaces. The following configuration is typical:

```
[edit protocols]
oam {
   ethernet {
```

```
        connectivity-fault-management {
          maintenance-domain md-name { # On both routers
            level number;
            maintenance-association ma-name { # On both routers
              continuity-check {
                interval 100ms;
                hold-interval 1;
              }
              mep mep-id { # Attach to VLAN interface
                auto-discovery;
                direction (up | down);
                interface interface-name;
                priority number;
              }
            }
          }
        }
      }
    }
```

Ensuring That Distributed ppm Is Not Disabled

By default, the router's period packet management process (**ppm**) runs sessions distributed to the Packet Forwarding Engine in addition to the Routing Engine. This process is responsible for periodic transmission of packets on behalf of its various client processes, such as Bidirectional Forwarding Detection (BFD), and it also receives packets on behalf of client processes.

In addition, **ppm** handles time-sensitive periodic processing and performs such processes as sending process-specific packets and gathering statistics. With **ppm** processes running distributed on both the Routing Engine and the Packet Forwarding Engine, you can run such processes as BFD on the Packet Forwarding Engine.

Distributed ppm Required for ETH-DM

Ethernet frame delay measurement requires that **ppm** remains distributed to the Packet Forwarding Engine. If **ppm** is not distributed to the Packet Forwarding Engines of both routers, ETH-DM PDU frame timestamps and ETH-DM statistics are not valid.

Before you start ETH-DM, you must verify that the following configuration statement is *NOT* present:

```
[edit]
routing-options {
  ppm {
    no-delegate-processing;
  }
}
```

If distributed **ppm** processing is disabled (as shown in the stanza above) on either router, you must re-enable it in order to use the ETH-DM feature.

Procedure to Ensure that Distributed ppm is Not Disabled

To ensure that distributed **ppm** is not disabled on a router:

1. Display the packet processing management (PPM) configuration to determine whether distributed **ppm** is disabled.

   - In the following example, distributed **ppm** is enabled on the router. In this case, you do not need to modify the router configuration:

     ```
     [edit]
     user@host# show routing-options
     ppm;
     ```

   - In the following example, distributed **ppm** is disabled on the router. In this case, you must proceed to Step 2 to modify the router configuration:

     ```
     [edit]
     user@host show routing-options
     ppm {
       no-delegate-processing;
     }
     ```

2. Modify the router configuration to re-enable distributed **ppm** and restart the Ethernet OAM Connectivity Fault Management process *ONLY IF* distributed **ppm** is disabled (as determined in the previous step).

   a. Before continuing, make any necessary preparations for the possible loss of connectivity on the router.

      Restarting the **ethernet-connectivity-fault-management** process has the following effect on your network:

      - All connectivity fault management (CFM) sessions re-establish.
      - All ETH-DM requests on the router terminate.
      - All ETH-DM statistics and frame counts reset to 0.

   b. Modify the router configuration to re-enable distributed **ppm**. For example:

      ```
      [edit]
      user@host# delete routing-options ppm no-delegate-processing
      ```

   c. Commit the updated router configuration. For example:

      ```
      [edit]
      user@host# commit and-quit
      commit complete
      exiting configuration mode
      ```

   d. To restart the Ethernet OAM Connectivity-Fault-Management process, enter the **restart ethernet-connectivity-fault-management <gracefully | immediately | soft>** operational mode command. For example:

      ```
      user@host> restart ethernet-connectivity-fault-management
      Connectivity fault management process started, pid 9893
      ```

Connectivity fault management (CFM) sessions operate in centralized mode over AE interfaces by default. Y.1731 performance monitoring (PM) is supported on centralized CFM sessions over AE interfaces. Also, distribution of CFM session over AE interfaces to line cards is supported from Junos OS Release 13.3. To enable the distribution of CFM sessions and to operate in centralized mode, include the **ppm delegate-processing** statement at the **[edit routing-options ppm]** hierarchy level. The mechanism that enables distribution of CFM sessions over AE interfaces provides the underlying infrastructure to support PM over AE interfaces. In addition, periodic packet management (PPM) handles time-sensitive periodic processing and performs such processes as sending process-specific packets and gathering statistics. With PPM processes running distributed on both the Routing Engine and the Packet Forwarding Engine, you can run performance monitoring processes on the Packet Forwarding Engine.

Enabling the Hardware-Assisted Timestamping Option

By default, Ethernet frame delay measurement uses software for timestamping transmitted and received ETH-DM frames. For Ethernet interfaces, you can optionally use hardware timing to assist in the timestamping of received ETH-DM frames to increase the accuracy of delay measurements.

Enabling hardware-assisted timestamping of received frames can increase the accuracy of ETH-DM calculations when the DPC is loaded with heavy traffic in the receive direction.

To enable Ethernet frame delay measurement hardware assistance on the reception path, include the **hardware-assisted-timestamping** statement at the **[edit protocols oam ethernet connectivity-fault-management performance-monitoring]** hierarchy level:

```
[edit protocols]
oam {
  ethernet {
    connectivity-fault-management {
      performance-monitoring {
        hardware-assisted-timestamping;
      }
    }
  }
}
```

Configuring the Server-Side Processing Option

You can delegate the server-side processing (for both two-way delay measurement and loss measurement) to the Packet Forwarding Engine to prevent overloading on the Routing Engine. By default, the server-side processing is done by the Routing Engine.

To configure the server-side processing option:

1. In configuration mode, go to the following hierarchy level:

   ```
   user@host# edit protocols oam ethernet connectivity-fault-management
     performance-monitoring
   ```

2. Configure the server-side processing option.

   ```
   [edit protocols oam ethernet connectivity-fault-management performance-monitoring]
   user@host# set delegate-server-processing
   ```

3. Verify the configuration.

   ```
   [edit protocols oam ethernet connectivity-fault-management]
   user@host# show
   performance-monitoring {
     delegate-server-processing;
   ```

}

Starting an ETH-DM Session

Using the monitor ethernet delay-measurement Command

After you have configured two MX Series routers to support ITU-T Y.1731 Ethernet frame delay measurement (ETH-DM), you can initiate a one-way or two-way Ethernet frame delay measurement session from the CFM maintenance association end point (MEP) on one of the routers to the peer MEP on the other router.

To start an ETH-DM session between the specified local MEP and the specified remote MEP, enter the **monitor ethernet delay-measurement** command at operational mode. The syntax of the command is as follows:

monitor ethernet delay-measurement
(one-way | two-way)
maintenance-domain *md-name*
maintenance-association *ma-name*
(*remote-mac-address* | mep *remote-mep-id*)
<count *frame-count*>
<wait *interval-seconds*>
<priority *802.1p value*>
<size>
<no-session-id-tlv>
<xml>

For a one-way frame delay measurement, the command displays a runtime display of the number of 1DM frames sent from the initiator MEP during that ETH-DM session. One-way frame delay and frame delay variation measurements from an ETH-DM session are collected in a CFM database at the router that contains the receiver MEP. You can retrieve ETH-DM statistics from a CFM database at a later time.

For a two-way frame delay measurement, the command displays two-way frame delay and frame delay variation values for each round-trip frame exchange during that ETH-DM session, as well as a runtime display of useful summary information about the session: average delay, average delay variation, best-case delay, and worst-case delay. Two-way frame delay and frame delay variation values measurements from an ETH-DM session are collected in a CFM database at the router that contains the initiator MEP. You can retrieve ETH-DM statistics from a CFM database at a later time.

NOTE: Although you can trigger frame delay collection for up to 65,535 ETH-DM requests at a time, a router stores only the last 100 frame delay statistics per CFM session (pair of peer MEPs).

For a complete description of the **monitor ethernet delay-measurement** operational command, see the CLI Explorer.

- monitor ethernet delay-measurement on page 1477

Starting a One-Way ETH-DM Session

To start a one-way Ethernet frame delay measurement session, enter the **monitor ethernet delay-measurement one-way** command from operational mode, and specify the peer MEP by its MAC address or by its MEP identifier.

For example:

```
user@host> monitor ethernet delay-measurement one-way 00:05:85:73:39:4a
maintenance-domain md6 maintenance-association ma6 count 10
One-way ETH-DM request to 00:05:85:73:39:4a, Interface xe-5/0/0.0
1DM Frames sent : 10
--- Delay measurement statistics ---
Packets transmitted: 10
Average delay: NA, Average delay variation: NA
Best case delay: NA, Worst case delay: NA
```

NOTE: If you attempt to monitor delays to a nonexistent MAC address, you must type **Ctrl + C** to explicitly quit the **monitor ethernet delay-measurement** command and return to the CLI command prompt.

See Also

- monitor ethernet delay-measurement on page 1477

Starting a Two-Way ETH-DM Session

To start a two-way Ethernet frame delay measurement session, enter the **monitor ethernet delay-measurement two-way** command from operational mode, and specify the peer MEP by its MAC address or by its MEP identifier.

For example:

```
user@host> monitor ethernet delay-measurement two-way 00:05:85:73:39:4a
maintenance-domain md6 maintenance-association ma6 count 10
Two-way ETH-DM request to 00:05:85:73:39:4a, Interface xe-5/0/0.0
DMR received from 00:05:85:73:39:4a Delay: 100 usec Delay variation: 0 usec
DMR received from 00:05:85:73:39:4a Delay: 92 usec  Delay variation: 8 usec
DMR received from 00:05:85:73:39:4a Delay: 92 usec  Delay variation: 0 usec
DMR received from 00:05:85:73:39:4a Delay: 111 usec Delay variation: 19 usec
DMR received from 00:05:85:73:39:4a Delay: 110 usec Delay variation: 1 usec
DMR received from 00:05:85:73:39:4a Delay: 119 usec Delay variation: 9 usec
DMR received from 00:05:85:73:39:4a Delay: 122 usec Delay variation: 3 usec
DMR received from 00:05:85:73:39:4a Delay: 92 usec  Delay variation: 30 usec
DMR received from 00:05:85:73:39:4a Delay: 92 usec  Delay variation: 0 usec
DMR received from 00:05:85:73:39:4a Delay: 108 usec Delay variation: 16 usec

--- Delay measurement statistics ---
Packets transmitted: 10, Valid packets received: 10
Average delay: 103 usec, Average delay variation: 8 usec
Best case delay: 92 usec, Worst case delay: 122 usec
```

NOTE: If you attempt to monitor delays to a nonexistent MAC address, you must type **Ctrl + C** to explicitly quit the **monitor ethernet delay-measurement** command and return to the CLI command prompt.

Starting a One-Way ETH-DM Session

To start a one-way Ethernet frame delay measurement session, enter the **monitor ethernet delay-measurement one-way** command from operational mode, and specify the peer MEP by its MAC address or by its MEP identifier.

For example:

```
user@host> monitor ethernet delay-measurement one-way 00:05:85:73:39:4a
maintenance-domain md6 maintenance-association ma6 count 10
One-way ETH-DM request to 00:05:85:73:39:4a, Interface xe-5/0/0.0
1DM Frames sent : 10
--- Delay measurement statistics ---
Packets transmitted: 10
Average delay: NA, Average delay variation: NA
Best case delay: NA, Worst case delay: NA
```

NOTE: If you attempt to monitor delays to a nonexistent MAC address, you must type **Ctrl + C** to explicitly quit the **monitor ethernet delay-measurement** command and return to the CLI command prompt.

Related Documentation

Starting a Two-Way ETH-DM Session

To start a two-way Ethernet frame delay measurement session, enter the **monitor ethernet delay-measurement two-way** command from operational mode, and specify the peer MEP by its MAC address or by its MEP identifier.

For example:

```
user@host> monitor ethernet delay-measurement two-way 00:05:85:73:39:4a
maintenance-domain md6 maintenance-association ma6 count 10
Two-way ETH-DM request to 00:05:85:73:39:4a, Interface xe-5/0/0.0
DMR received from 00:05:85:73:39:4a Delay: 100 usec Delay variation: 0 usec
DMR received from 00:05:85:73:39:4a Delay: 92 usec  Delay variation: 8 usec
DMR received from 00:05:85:73:39:4a Delay: 92 usec  Delay variation: 0 usec
DMR received from 00:05:85:73:39:4a Delay: 111 usec Delay variation: 19 usec
DMR received from 00:05:85:73:39:4a Delay: 110 usec Delay variation: 1 usec
DMR received from 00:05:85:73:39:4a Delay: 119 usec Delay variation: 9 usec
DMR received from 00:05:85:73:39:4a Delay: 122 usec Delay variation: 3 usec
DMR received from 00:05:85:73:39:4a Delay: 92 usec  Delay variation: 30 usec
DMR received from 00:05:85:73:39:4a Delay: 92 usec  Delay variation: 0 usec
DMR received from 00:05:85:73:39:4a Delay: 108 usec Delay variation: 16 usec

--- Delay measurement statistics ---
Packets transmitted: 10, Valid packets received: 10
Average delay: 103 usec, Average delay variation: 8 usec
Best case delay: 92 usec, Worst case delay: 122 usec
```

NOTE: If you attempt to monitor delays to a nonexistent MAC address, you must type **Ctrl + C** to explicitly quit the **monitor ethernet delay-measurement** command and return to the CLI command prompt.

Managing ETH-DM Statistics and ETH-DM Frame Counts

Displaying ETH-DM Statistics Only

Purpose Display ETH-DM statistics.

By default, the **show oam ethernet connectivity-fault-management delay-statistics** command displays ETH-DM statistics for MEPs in the specified CFM maintenance association (MA) within the specified CFM maintenance domain (MD).

Action

- To display the ETH-DM statistics collected for MEPs belonging to MA **ma1** and within MD **md1**:

  `user@host>` **show oam ethernet connectivity-fault-management delay-statistics maintenance-domain ma1 maintenance-association ma1**

- To display the ETH-DM statistics collected for ETH-DM sessions for the local MEP **201** belonging to MA **ma2** and within MD **md2**:

  `user@host>` **show oam ethernet connectivity-fault-management delay-statistics maintenance-domain md2 maintenance-association ma2 local-mep 201**

- To display the ETH-DM statistics collected for ETH-DM sessions from local MEPs belonging to MA **ma3** and within MD **md3** to remote MEP **302**:

  `user@host>` **show oam ethernet connectivity-fault-management delay-statistics maintenance-domain md3 maintenance-association ma3 remote-mep 302**

See Also

- **show oam ethernet connectivity-fault-management delay-statistics on page 2029**

Displaying ETH-DM Statistics and Frame Counts

Purpose Display ETH-DM statistics and ETH-DM frame counts.

By default, the **show oam ethernet connectivity-fault-management mep-statistics** command displays ETH-DM statistics and frame counts for MEPs in the specified CFM maintenance association (MA) within the specified CFM maintenance domain (MD).

Action

- To display the ETH-DM statistics and ETH-DM frame counts for MEPs in MA **ma1** and within MD **md1**:

```
user@host> show oam ethernet connectivity-fault-management mep-statistics
maintenance-domain md1 maintenance-association ma1
```

- To display the ETH-DM statistics and ETH-DM frame counts for the local MEP **201** in MA **ma2** and within MD **md2**:

```
user@host> show oam ethernet connectivity-fault-management mep-statistics
maintenance-domain md2 maintenance-association ma2 local-mep 201
```

- To display the ETH-DM statistics and ETH-DM frame counts for the local MEP in MD **md3** and within MA **ma3** that participates in an ETH-DM session with the remote MEP **302**:

```
user@host> show oam ethernet connectivity-fault-management mep-statistics
maintenance-domain ma3 maintenance-association ma3 remote-mep 302
```

See Also

- show oam ethernet connectivity-fault-management mep-statistics on page 2066

Displaying ETH-DM Frame Counts for MEPs by Enclosing CFM Entity

Purpose Display ETH-DM frame counts for CFM maintenance association end points (MEPs).

By default, the **show oam ethernet connectivity-fault-management mep-database** command displays CFM database information for MEPs in the specified CFM maintenance association (MA) within the specified CFM maintenance domain (MD).

NOTE: At the router attached to the initiator MEP for a one-way session, or at the router attached to the receiver MEP for a two-way session, you can only display ETH-DM frame counts.

Action

- To display CFM database information (including ETH-DM frame counts) for all MEPs in MA **ma1** within MD **md1**:

```
user@host> show oam ethernet connectivity-fault-management mep-database
maintenance-domain ma1 maintenance-association ma1
```

- To display CFM database information (including ETH-DM frame counts) only for local MEP **201** in MA **ma1** within MD **md1**:

```
user@host> show oam ethernet connectivity-fault-management mep-database
maintenance-domain md2 maintenance-association ma2 local-mep 201
```

- To display CFM database information (including ETH-DM frame counts) only for remote MEP **302** in MD **md3** within MA **ma3**:

```
user@host> show oam ethernet connectivity-fault-management mep-database
maintenance-domain ma3 maintenance-association ma3 remote-mep 302
```

See Also

- show oam ethernet connectivity-fault-management mep-database on page 2055

Displaying ETH-DM Frame Counts for MEPs by Interface or Domain Level

Purpose Display ETH-DM frame counts for CFM maintenance association end points (MEPs).

By default, the **show oam ethernet connectivity-fault-management interfaces** command displays CFM database information for MEPs attached to CFM-enabled Ethernet interfaces on the router or at a maintenance domain level. For Ethernet interfaces that support ETH-DM, any frame counts are also displayed when you specify the **detail** or **extensive** command option.

NOTE: At the router attached to the initiator MEP for a one-way session, or at the router attached to the receiver MEP for a two-way session, you can only display ETH-DM frame counts.

Action

- To display CFM database information (including ETH-DM frame counts) for all MEPs attached to CFM-enabled Ethernet interfaces on the router:

  `user@host>` **show oam ethernet connectivity-fault-management interfaces detail**

- To display CFM database information (including ETH-DM frame counts) only for the MEPs attached to CFM-enabled router interface **ge-5/2/9.0**:

  `user@host>` **show oam ethernet connectivity-fault-management interfaces ge-5/2/9.0 detail**

- To display CFM database information (including ETH-DM frame counts) only for MEPs enclosed within CFM maintenance domains (MDs) at level **6**:

  `user@host>` **show oam ethernet connectivity-fault-management interfaces level 6 detail**

See Also

- show oam ethernet connectivity-fault-management interfaces on page 2037

Clearing ETH-DM Statistics and Frame Counts

Purpose Clear the ETH-DM statistics and ETH-DM frame counts.

By default, statistics and frame counts are deleted for all MEPs attached to CFM-enabled interfaces on the router. However, you can filter the scope of the command by specifying an interface name.

Action

- To clear the ETH-DM statistics and ETH-DM frame counts for all MEPs attached to CFM-enabled interfaces on the router:

  `user@host>` **clear oam ethernet connectivity-fault-management statistics**

- To clear the ETH-DM statistics and ETH-DM frame counts only for MEPs attached to the logical interface **ge-0/5.9.0**:

  `user@host>` **clear oam ethernet connectivity-fault-management statistics ge-0/5/9.0**

See Also

Displaying ETH-DM Statistics Only

Purpose

Display ETH-DM statistics.

By default, the **show oam ethernet connectivity-fault-management delay-statistics** command displays ETH-DM statistics for MEPs in the specified CFM maintenance association (MA) within the specified CFM maintenance domain (MD).

Action

- To display the ETH-DM statistics collected for MEPs belonging to MA **ma1** and within MD **md1**:

  `user@host>` **show oam ethernet connectivity-fault-management delay-statistics maintenance-domain ma1 maintenance-association ma1**

- To display the ETH-DM statistics collected for ETH-DM sessions for the local MEP **201** belonging to MA **ma2** and within MD **md2**:

  `user@host>` **show oam ethernet connectivity-fault-management delay-statistics maintenance-domain md2 maintenance-association ma2 local-mep 201**

- To display the ETH-DM statistics collected for ETH-DM sessions from local MEPs belonging to MA **ma3** and within MD **md3** to remote MEP **302**:

  `user@host>` **show oam ethernet connectivity-fault-management delay-statistics maintenance-domain md3 maintenance-association ma3 remote-mep 302**

Related Documentation

- show oam ethernet connectivity-fault-management delay-statistics on page 2029

Displaying ETH-DM Statistics and Frame Counts

Purpose

Display ETH-DM statistics and ETH-DM frame counts.

By default, the **show oam ethernet connectivity-fault-management mep-statistics** command displays ETH-DM statistics and frame counts for MEPs in the specified CFM maintenance association (MA) within the specified CFM maintenance domain (MD).

Action

- To display the ETH-DM statistics and ETH-DM frame counts for MEPs in MA **ma1** and within MD **md1**:

  `user@host>` **show oam ethernet connectivity-fault-management mep-statistics maintenance-domain md1 maintenance-association ma1**

- To display the ETH-DM statistics and ETH-DM frame counts for the local MEP **201** in MA **ma2** and within MD **md2**:

  `user@host>` **show oam ethernet connectivity-fault-management mep-statistics maintenance-domain md2 maintenance-association ma2 local-mep 201**

- To display the ETH-DM statistics and ETH-DM frame counts for the local MEP in MD **md3** and within MA **ma3** that participates in an ETH-DM session with the remote MEP **302**:

  `user@host>` **show oam ethernet connectivity-fault-management mep-statistics maintenance-domain ma3 maintenance-association ma3 remote-mep 302**

Related Documentation

- show oam ethernet connectivity-fault-management mep-statistics on page 2066

Displaying ETH-DM Frame Counts for MEPs by Enclosing CFM Entity

Purpose

Display ETH-DM frame counts for CFM maintenance association end points (MEPs).

By default, the **show oam ethernet connectivity-fault-management mep-database** command displays CFM database information for MEPs in the specified CFM maintenance association (MA) within the specified CFM maintenance domain (MD).

NOTE: At the router attached to the initiator MEP for a one-way session, or at the router attached to the receiver MEP for a two-way session, you can only display ETH-DM frame counts.

Action

- To display CFM database information (including ETH-DM frame counts) for all MEPs in MA **ma1** within MD **md1**:

`user@host>` **show oam ethernet connectivity-fault-management mep-database maintenance-domain ma1 maintenance-association ma1**

- To display CFM database information (including ETH-DM frame counts) only for local MEP **201** in MA **ma1** within MD **md1**:

  `user@host>` **show oam ethernet connectivity-fault-management mep-database maintenance-domain md2 maintenance-association ma2 local-mep 201**

- To display CFM database information (including ETH-DM frame counts) only for remote MEP **302** in MD **md3** within MA **ma3**:

  `user@host>` **show oam ethernet connectivity-fault-management mep-database maintenance-domain ma3 maintenance-association ma3 remote-mep 302**

Related Documentation

Displaying ETH-DM Frame Counts for MEPs by Interface or Domain Level

Purpose Display ETH-DM frame counts for CFM maintenance association end points (MEPs).

By default, the **show oam ethernet connectivity-fault-management interfaces** command displays CFM database information for MEPs attached to CFM-enabled Ethernet interfaces on the router or at a maintenance domain level. For Ethernet interfaces that support ETH-DM, any frame counts are also displayed when you specify the **detail** or **extensive** command option.

NOTE: At the router attached to the initiator MEP for a one-way session, or at the router attached to the receiver MEP for a two-way session, you can only display ETH-DM frame counts.

Action

- To display CFM database information (including ETH-DM frame counts) for all MEPs attached to CFM-enabled Ethernet interfaces on the router:

  `user@host>` **show oam ethernet connectivity-fault-management interfaces detail**

- To display CFM database information (including ETH-DM frame counts) only for the MEPs attached to CFM-enabled router interface **ge-5/2/9.0**:

  `user@host>` **show oam ethernet connectivity-fault-management interfaces ge-5/2/9.0 detail**

- To display CFM database information (including ETH-DM frame counts) only for MEPs enclosed within CFM maintenance domains (MDs) at level **6**:

  `user@host>` **show oam ethernet connectivity-fault-management interfaces level 6 detail**

Related Documentation

- show oam ethernet connectivity-fault-management interfaces on page 2037

Clearing ETH-DM Statistics and Frame Counts

Purpose Clear the ETH-DM statistics and ETH-DM frame counts.

Configuring MEP Interfaces

Before you can start an Ethernet frame delay measurement session across an Ethernet service, you must configure two MX Series routers to support ETH-DM.

To configure an Ethernet interface on a MX Series router to support ETH-DM:

1. On each router, configure two physical or logical Ethernet interfaces connected by a VLAN. The following configuration is typical for single-tagged logical interfaces:

   ```
   [edit interfaces]
   interface {
     ethernet-interface-name {
       vlan-tagging;
       unit logical-unit-number {
         vlan-id vlan-id; # Both interfaces on this VLAN
       }
     }
   }
   ```

   Both interfaces will use the same VLAN ID.

2. On each router, attach peer MEPs to the two interfaces. The following configuration is typical:

   ```
   [edit protocols]
   oam {
   ```

```
ethernet {
  connectivity-fault-management {
    maintenance-domain md-name { # On both routers
      level number;
      maintenance-association ma-name { # On both routers
        continuity-check {
          interval 100ms;
          hold-interval 1;
        }
        mep mep-id { # Attach to VLAN interface
          auto-discovery;
          direction (up | down);
          interface interface-name;
          priority number;
        }
      }
    }
  }
}
}
```

Ensuring That Distributed ppm Is Not Disabled

By default, the router's period packet management process (**ppm**) runs sessions distributed to the Packet Forwarding Engine in addition to the Routing Engine. This process is responsible for periodic transmission of packets on behalf of its various client processes, such as Bidirectional Forwarding Detection (BFD), and it also receives packets on behalf of client processes.

In addition, **ppm** handles time-sensitive periodic processing and performs such processes as sending process-specific packets and gathering statistics. With **ppm** processes running distributed on both the Routing Engine and the Packet Forwarding Engine, you can run such processes as BFD on the Packet Forwarding Engine.

Distributed ppm Required for ETH-DM

Ethernet frame delay measurement requires that **ppm** remains distributed to the Packet Forwarding Engine. If **ppm** is not distributed to the Packet Forwarding Engines of both routers, ETH-DM PDU frame timestamps and ETH-DM statistics are not valid.

Before you start ETH-DM, you must verify that the following configuration statement is *NOT* present:

```
[edit]
routing-options {
  ppm {
    no-delegate-processing;
  }
}
```

If distributed **ppm** processing is disabled (as shown in the stanza above) on either router, you must re-enable it in order to use the ETH-DM feature.

Procedure to Ensure that Distributed ppm is Not Disabled

To ensure that distributed **ppm** is not disabled on a router:

1. Display the packet processing management (PPM) configuration to determine whether distributed **ppm** is disabled.

   - In the following example, distributed **ppm** is enabled on the router. In this case, you do not need to modify the router configuration:

     ```
     [edit]
     user@host# show routing-options
     ppm;
     ```

   - In the following example, distributed **ppm** is disabled on the router. In this case, you must proceed to Step 2 to modify the router configuration:

     ```
     [edit]
     user@host show routing-options
     ppm {
        no-delegate-processing;
     }
     ```

2. Modify the router configuration to re-enable distributed **ppm** and restart the Ethernet OAM Connectivity Fault Management process *ONLY IF* distributed **ppm** is disabled (as determined in the previous step).

   a. Before continuing, make any necessary preparations for the possible loss of connectivity on the router.

      Restarting the **ethernet-connectivity-fault-management** process has the following effect on your network:

      - All connectivity fault management (CFM) sessions re-establish.
      - All ETH-DM requests on the router terminate.
      - All ETH-DM statistics and frame counts reset to 0.

   b. Modify the router configuration to re-enable distributed **ppm**. For example:

      ```
      [edit]
      user@host# delete routing-options ppm no-delegate-processing
      ```

   c. Commit the updated router configuration. For example:

      ```
      [edit]
      user@host# commit and-quit
      commit complete
      exiting configuration mode
      ```

   d. To restart the Ethernet OAM Connectivity-Fault-Management process, enter the **restart ethernet-connectivity-fault-management <gracefully | immediately | soft>** operational mode command. For example:

      ```
      user@host> restart ethernet-connectivity-fault-management
      Connectivity fault management process started, pid 9893
      ```

Connectivity fault management (CFM) sessions operate in centralized mode over AE interfaces by default. Y.1731 performance monitoring (PM) is supported on centralized CFM sessions over AE interfaces. Also, distribution of CFM session over AE interfaces to line cards is supported from Junos OS Release 13.3. To enable the distribution of CFM sessions and to operate in centralized mode, include the **ppm delegate-processing** statement at the **[edit routing-options ppm]** hierarchy level. The mechanism that enables distribution of CFM sessions over AE interfaces provides the underlying infrastructure to support PM over AE interfaces. In addition, periodic packet management (PPM) handles time-sensitive periodic processing and performs such processes as sending process-specific packets and gathering statistics. With PPM processes running distributed on both the Routing Engine and the Packet Forwarding Engine, you can run performance monitoring processes on the Packet Forwarding Engine.

Enabling the Hardware-Assisted Timestamping Option

By default, Ethernet frame delay measurement uses software for timestamping transmitted and received ETH-DM frames. For Ethernet interfaces, you can optionally use hardware timing to assist in the timestamping of received ETH-DM frames to increase the accuracy of delay measurements.

Enabling hardware-assisted timestamping of received frames can increase the accuracy of ETH-DM calculations when the DPC is loaded with heavy traffic in the receive direction.

To enable Ethernet frame delay measurement hardware assistance on the reception path, include the **hardware-assisted-timestamping** statement at the **[edit protocols oam ethernet connectivity-fault-management performance-monitoring]** hierarchy level:

```
[edit protocols]
oam {
  ethernet {
    connectivity-fault-management {
      performance-monitoring {
        hardware-assisted-timestamping;
      }
    }
  }
}
```

Enabling Inline Transmission of Continuity Check Messages for Maximum Scaling

Scaling is the ability of a system to handle increasing amounts of work and to continue to function well. Scaling can refer to increasing capacity and the ability to handle increasing workload, number of subscribers or sessions, hardware components, and so on. Continuity check protocol is used for fault detection within a maintenance association. The maintenance association end points (MEPs) send continuity check messages (CCMs) periodically. The time between the transmissions of CCMs is known as the interval. The receiving MEP maintains a database of all MEPs in the maintenance association.

By default, CCMs are transmitted by the CPU of a line card, such as a Modular Port Concentrator (MPC). If the duration between transmissions of CCMs is low or if the CCMs for a specific line card scale, then we recommend that you delegate transmission of CCMs to the forwarding ASIC (that is, to the hardware) by enabling inline transmission of CCMs. Inline transmission of CCMs is also known as inline keepalives or Inline-KA. Inline transmission enables the system to handle more connectivity fault management (CFM) sessions per line card. By enabling inline transmission of CCMs, you can achieve maximum scaling of CCMs.

To enable inline transmission of CCMs, perform the following steps:

1. In configuration mode, go to the **[edit protocols oam ethernet connectivity-fault-management performance-monitoring]** hierarchy level.

   ```
   [edit]
   user@host# edit protocols oam ethernet connectivity-fault-management
     performance-monitoring
   ```

2. Delegate transmission of CCMs to hardware by enabling hardware-assisted keepalives.

   ```
   [edit protocols oam ethernet connectivity-fault-management performance-monitoring]
   user@host# set hardware-assisted-keepalives enable
   ```

   NOTE: Inline transmission of CCMs is not enabled when there is a CFM session already established. To enable inline transmission, you must first deactivate the CFM session using the **deactivate** command and then reactivate the CFM session using the **activate** command.

To disable inline transmission, use the hardware-assisted-keepalives **disable** statement. After disabling inline transmission, you must reboot the router for the changes to take effect.

Enabling Inline Mode Of Performance Monitoring To Achieve Maximum Scaling

Performance monitoring is useful for studying the traffic pattern in a network over a period of time. It helps to identify network problems before you are impacted by network defects.

By default, performance monitoring packets are handled by the CPU of a line-card, such as Modular Port Concentrator (MPC). Enabling inline mode of performance monitoring delegates the processing of the protocol data units (PDUs) to the forwarding ASIC (that is, to the hardware). By enabling inline mode of performance monitoring, the load on the CPU of the line-card is reduced and you can configure an increased number of performance monitoring sessions and achieve maximum scaling for service OAM performance monitoring sessions. On MX Series routers, you can configure inline mode of performance monitoring only if the network services mode on the router is configured to **enhanced-ip** and enhanced connectivity fault management (**enhanced-cfm-mode**)) is configured.

By enabling inline mode of performance monitoring, you can achieve maximum scaling for performance monitoring sessions. To achieve maximum scaling for performance monitoring sessions, you must enable scaling of continuity check messages (CCMs) sessions. To enable scaling of CCM sessions, enable inline transmission of continuity check messages. For more information on inline transmission of continuity check messages, see "Enabling Inline Transmission of Continuity Check Messages for Maximum Scaling" on page 795. To view the supported scaling values for CCM and PM, see "Supported Inline CCM and Inline PM Scaling Values" on page 798.

Inline mode of performance monitoring is supported only for proactive mode of frame delay measurement (Two-way Delay Measurements) and synthetic loss measurements (SLM)sessions. Performance monitoring functions configured using the iterator profile (CFM)are referred to as proactive performance monitoring. Inline mode of performance monitoring for frame loss measurement using service frames (LM) is not supported.

NOTE: **MPC3E (MX-MPC3E-3D) and MPC4E (MPC4E-3D-32XGE-SFPP and MPC4E-3D-2CGE-8XGE) do not support inline mode of performance monitoring. User-defined Data TLV is not supported if you have configured inline mode of performance monitoring. Also, only 12 history records per PM sessions are supported.**

We recommend that you enable inline mode of performance monitoring before you configure the performance monitoring sessions as the change may interfere with the existing performance monitoring sessions.

To enable inline mode of performance monitoring, perform the following steps:

1. In configuration mode, go to the **[edit chassis]** hierarchy level and configure the network services mode of the router. The network service mode of the router must be configured as **enhanced ip** to enable enhanced connectivity fault management (CFM) mode.

NOTE: If the network services mode is not **enhanced-ip**, and you have enabled enhanced CFM, the following warning message is displayed:
[edit protocols oam ethernet]
'connectivity-fault-management'
enhanced ip is not effective please configure enhanced ip and give router reboot

```
[edit chassis]
user@host# set network-services enhanced-ip
```

2. In configuration mode, go to the **[edit protocols oam ethernet connectivity-fault-management]** hierarchy level and enable enhanced connectivity fault management mode by using the **enhanced-cfm-mode** option.

```
[edit]
user@host# set protocols oam ethernet connectivity-fault-management
  enhanced-cfm-mode
```

3. In configuration mode, go to the **[edit protocols oam ethernet connectivity-fault-management performance-monitoring]** hierarchy level. Configure the enhanced iterator profile by using the **enhanced-sla-iterator** option and specify the measurement interval by using the **measurement-interval** option.

```
[edit]
user@host# edit protocols oam ethernet connectivity-fault-management
  performance-monitoring enhanced-sla-iterator measurement-interval value
```

4. Enable inline performance monitoring.

NOTE: You can enable inline mode of performance monitoring for both the originator and the responder of the service OAM performance monitoring sessions by using the **hardware-assisted-pm** command.

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring]
user@host# set hardware-assisted-pm
```

5. (Optional) Enable inline transmission of CCMs to enable better scaling if inline transmission of CCMs is not automatically enabled.

NOTE: You can achieve better scaling if both inline performance monitoring and inline transmission of CCMs is enabled.

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring]
user@host# set hardware-assisted-keepalives enable
```

6. Commit the configuration.

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring]
user@host# commit
```

- *hardware-assisted-pm*
- Supported Inline CCM and Inline PM Scaling Values on page 798

Supported Inline CCM and Inline PM Scaling Values

This topic lists the scaling values for inline mode of performance monitoring and inline transmission of continuity check messages. The scaling values are based on the different cycle-time interval values. Each table lists the maximum number of connectivity fault management (CFM) sessions and performance monitoring (PM) sessions per line card and per chassis when you configure inline CCM, enhanced CFM, and enhanced PM by using the **hardware-assisted-keepalives**, **enhanced-cfm-mode**, and **hardware-assisted-pm** options.

NOTE: The scaling values do not consider the load from other protocols in the system and so the actual realized scaling values for line card and chassis vary depending on other protocol configurations and scaling in the system. We recommend that you configure DDoS for CFM. Limit the number of CFM packets, that are sent to the CPU of the line card, to 3000. Limiting the number of packets safeguards the CPU from scaled CFM configurations of various CFM protocol events.

Table 75 on page 798 lists the maximum number of connectivity fault management (CFM) sessions and performance monitoring (PM) sessions per line card and per chassis when you configure both the CCM interval and the PM interval as 1 second.

Table 75: Scaling Values for CFM and PM (CCM Interval: 1 sec and PM Interval: 1 sec)

CFM Line Card Scale	PM Line Card Scale	CFM Chassis Scale	PM Chassis Scale
4000	4500	16000	16000
6000	3750	16000	16000
7000	3375	16000	16000
8000	3000	16000	16000

Table 76 on page 799 lists the maximum number of connectivity fault management (CFM) sessions and performance monitoring (PM) sessions per line card and per chassis when you configure the CCM interval as 1 second and the PM interval as 100 milliseconds.

Table 76: Scaling Values for CFM and PM (CCM Interval: 1 sec and PM interval: 100 ms)

CFM Line Card Scale	PM Line Card Scale	CFM Chassis Scale	PM Chassis Scale
4000	450	12000	4000
6000	375	12000	4000
7000	337	12000	4000
8000	300	12000	4000

Table 77 on page 799 lists the maximum number of connectivity fault management (CFM) sessions and performance monitoring (PM) sessions per line card and per chassis when you configure the CCM interval as 100 milliseconds and the PM interval as 1 second.

Table 77: Scaling Values for CFM and PM (CCM Interval: 100 ms and PM interval: 1 sec)

CFM Line Card Scale	PM Line Card Scale	CFM Chassis Scale	PM Chassis Scale
4000	3000	8000	6000
3000	3750	8000	6000
2000	4500	8000	6000
1000	4500	8000	6000

Table 78 on page 799 lists the maximum number of connectivity fault management (CFM) sessions and performance monitoring (PM) sessions per line card and per chassis when you configure both the CCM interval and the PM interval as 100 milliseconds.

Table 78: Scaling Values for CFM and PM (CCM Interval: 100 ms and PM interval: 100 ms)

CFM Line Card Scale	PM Line Card Scale	CFM Chassis Scale	PM Chassis Scale
4000	300	8000	3000
3000	375	8000	3000
2000	450	8000	3000
1000	450	8000	3000

Configuring Connectivity Fault Management for Interoperability During Unified In-Service Software Upgrades

Starting in Release 17.1, Junos OS connectivity fault management (CFM), during a unified in-service software upgrade (ISSU), works when the peer device is not a Juniper Networks router. Interoperating with the router of another vendor, the Juniper Networks router retains session information and continues to transmit continuity check message (CCM) PDUs during the unified ISSU. Connectivity fault management continues to operate.

This feature requires the following conditions be met:

- Packet Forwarding Engine keepalives must be enabled to provide inline transmission of CCMs. The feature does not work when the CCMs are transmitted by the CPU of a line card, which is the default transmission method.
- The interval between CCMs must be 1 second.

CFM interoperability during a unified ISSU is supported on the following MPCs: MPC1, MPC2, MPC2-NG, MPC3-NG, MPC5, and MPC6.

To enable CFM interoperability with third-party devices across a unified ISSU:

1. Enable inline keepalives.

```
[edit protocols oam ethernet connectivity-fault-management performance-monitoring]
user@host# set hardware-assisted-keepalives enable
```

2. Set the CCM interval to 1 second.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  md-name maintenance-association ma-name continuity-check]
user@host# set interval 1s
```

Release History Table

Release	Description
17.1	Starting in Release 17.1, Junos OS connectivity fault management (CFM), during a unified in-service software upgrade (ISSU), works when the peer device is not a Juniper Networks router.

Using the monitor ethernet delay-measurement Command

After you have configured two MX Series routers to support ITU-T Y.1731 Ethernet frame delay measurement (ETH-DM), you can initiate a one-way or two-way Ethernet frame delay measurement session from the CFM maintenance association end point (MEP) on one of the routers to the peer MEP on the other router.

To start an ETH-DM session between the specified local MEP and the specified remote MEP, enter the **monitor ethernet delay-measurement** command at operational mode. The syntax of the command is as follows:

monitor ethernet delay-measurement
(one-way | two-way)
maintenance-domain *md-name*
maintenance-association *ma-name*
(*remote-mac-address* | mep *remote-mep-id*)
<count *frame-count*>
<wait *interval-seconds*>
<priority *802.1p value*>
<size>
<no-session-id-tlv>
<xml>

For a one-way frame delay measurement, the command displays a runtime display of the number of 1DM frames sent from the initiator MEP during that ETH-DM session. One-way frame delay and frame delay variation measurements from an ETH-DM session are collected in a CFM database at the router that contains the receiver MEP. You can retrieve ETH-DM statistics from a CFM database at a later time.

For a two-way frame delay measurement, the command displays two-way frame delay and frame delay variation values for each round-trip frame exchange during that ETH-DM session, as well as a runtime display of useful summary information about the session: average delay, average delay variation, best-case delay, and worst-case delay. Two-way frame delay and frame delay variation values measurements from an ETH-DM session are collected in a CFM database at the router that contains the initiator MEP. You can retrieve ETH-DM statistics from a CFM database at a later time.

NOTE: Although you can trigger frame delay collection for up to 65,535 ETH-DM requests at a time, a router stores only the last 100 frame delay statistics per CFM session (pair of peer MEPs).

For a complete description of the **monitor ethernet delay-measurement** operational command, see the CLI Explorer.

Related Documentation

Managing ETH-LM Statistics

Displaying ETH-LM Statistics

Purpose Display the ETH-LM statistics.

By default, the **show oam ethernet connectivity-fault-management loss-statistics maintenance-domain** ***md-name*** **maintenance-association** ***ma-name*** command displays ETH-LM statistics for MEPs in the specified CFM maintenance association (MA) within the specified CFM maintenance domain (MD).

The following list consists of the CFM-related operational mode commands that have been enhanced to display ETH-LM statistics:

- The **show oam ethernet connectivity-fault-management interfaces detail** command is enhanced to display ETH-DM and ETH-LM statistics for MEPs in the specified CFM maintenance association (MA) within the specified CFM maintenance domain (MD).
- The **show oam ethernet connectivity-fault-management mep-statistics** command is enhanced to display ETH-DM and ETH-LM statistics and frame counts for MEPs in the specified CFM maintenance association (MA) within the specified CFM maintenance domain (MD).
- The **show oam ethernet connectivity-fault-management mep-database** command is enhanced to display ETH-DM and ETH-LM frame counters for MEPs in the specified CFM maintenance association (MA) within the specified CFM maintenance domain (MD).

Action

- To display the ETH-LM statistics for all MEPs attached to CFM-enabled interfaces on the router:

  `user@host>` **show oam ethernet connectivity-fault-management loss-statistics**

- To display the ETH-DM statistics collected for MEPs belonging to MA **ma1** and within MD **md1**:

  `user@host>` **show oam ethernet connectivity-fault-management delay-statistics maintenance-domain md1 maintenance-association ma1**

- To display the ETH-DM statistics and ETH-DM frame counts for MEPs in MA **ma1** and within MD **md1**:

  `user@host>` **show oam ethernet connectivity-fault-management mep-statistics maintenance-domain md1 maintenance-association ma1**

- To display CFM database information (including ETH-DM frame counts) for all MEPs in MA **ma1** within MD **md1**:

`user@host>` **show oam ethernet connectivity-fault-management mep-database maintenance-domain md1 maintenance-association ma1**

Configuring the Failure Notification Protocol

This topic describes how to configure the Ethernet Operations, Administration, and Maintenance (OAM) Failure Notification Protocol (FNP) on MX Series routers. The FNP detects link failures in a Carrier Ethernet network and broadcasts FNP messages when a failure occurs to all nodes affected by the link failure. To configure FNP functionality, include the **fnp** statement at the **[edit protocols oam ethernet]** hierarchy level:

```
[edit protocols oam]
ethernet {
   fnp {
      interval <100ms | 1s | 10s | 1m | 10m>;
      loss-threshold number
      interface interface name {
         domain-id domain-id
      }
   }
}
```

The **interval** statement specifies the time between the transmission of FNP messages. You can specify 10 minutes (10m), 1 minute (1m), 10 seconds (10s), 1 second (1s), and 100 milliseconds (100ms). The **loss-threshold** statement specifies how many FNP messages can be lost before the FNP message is considered aged out and flushed. You must include the **interface *interface-name*** statement with the **domain-id *domain-id*** statement. The **domain-id** statement specifies a domain ID for the route. FNP messages can be received and processed on MX Series routers, but generating FNP messages is not supported.

The **show oam ethernet fnp interface**, **show oam ethernet fnp status**, and **show oam ethernet fnp messages** operational commands display the configured information.

FNP can be enabled only on logical interfaces that are part of a VPLS routing instance, and none of the logical interfaces in the VPLS routing instance should have CCM configured. FNP can be enabled on only one logical interface per physical interface.

Ethernet Alarm Indication Signal (ETH-AIS) Function Overview

Ethernet alarm indication signal (ETH-AIS) function enables a service provider deploying an Ethernet service to determine whether a connectivity fault exists at the provider's domain level or at a level below. When the fault occurs at the provider's domain level, the service provider addresses the fault, and when the fault occurs at a level below, the provider can either ignore the fault or contact the relevant authorities to address the fault.

The following sections explain ETH-AIS, few use cases which determine when to generate and propagate ETH-AIS packets, and associated terms in detail:

Understanding ETH-AIS in a Maintenance Domain

ITU-T developed Y.1731 as a recommendation for Operation, Administration, and Maintenance (OAM) functions and mechanisms for Ethernet-based networks, including

OAM functions such as ETH-AIS, Ethernet locked signal (ETH-LCK), Ethernet test signal (ETH-Test), Ethernet automatic protection switching (ETH-APS), Ethernet maintenance communication channel (ETH-MCC), Ethernet experimental OAM (ETH-EXP), Ethernet vendor-specific OAM (ETH-VSP), and performance monitoring. For information about maintenance domain and related terms, see "Terms Defined" on page 808.

According to the Y.1731 standards, a server MEP is a combined function of the server layer termination function and the server Ethernet services layer adaptation function. The server MEP notifies the Ethernet services (ETH) layer MEPs when it detects a failure. The server layer termination function then runs the OAM mechanisms specific to the server layer and the alarms are suppressed at the server layer by ETH-AIS.

Note that ETH-AIS is not applicable to Spanning Tree Protocol (STP) networks.

ETH-AIS enables you to suppress alarms when a fault condition is detected. Using ETH-AIS, a service provider can differentiate between faults at different levels.

ETH-AIS provides many advantages that include:

- Service providers need not raise alarms if there are lower-level failures.
- Service providers can provide a refund to their subscribers or avail a refund from their Internet provider based on service unavailability.

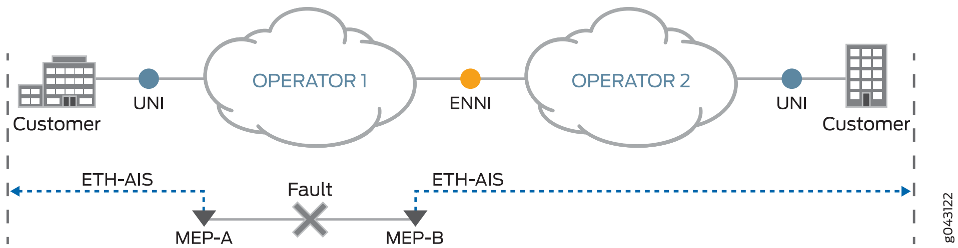
MX Series routers support ITU-T Y.1731 ETH-AIS to provide fault management for service providers who provide carrier Ethernet services using IEEE 802.1ag standard.

NOTE: MX Series Virtual Chassis does not support Ethernet alarm indication signal (ETH-AIS).

Fault Detection in a Maintenance Domain

In the scenario depicted in Figure 1 on page xyz, you have a service provider level and a customer level. Two service providers—*Operator-1* and *Operator-2*—are considered for illustration purposes. Assume that a fault occurs in Operator-1 maintenance domain-level that has MEP-A and MEP-B at its maintenance domain-level boundaries. To notify the faults to a network management system and to avoid notification of alarms from the customer level for the same fault, MEP-A and MEP-B transmit an alarm indication signal (AIS) on opposite directions, thereby signaling the higher levels and the Operator-2 network about the fault, so that the alarms are suppressed.

Signaling is achieved through transmission and propagation of AIS protocol data units (PDUs). You must enable AIS explicitly on all the MEPs at the service provider level. A MEP that is configured to issue frames with ETH-AIS information is generally at the server layer and continues to transmit periodic frames with ETH-AIS information until the defect condition is cleared. When a client MEP receives the ETH-AIS frames, it suppresses loss-of-continuity alarms associated with its peer MEPs.



Note that in the absence of AIS, a client MEP resumes generating loss-of-continuity alarms when it detects the loss-of-continuity defect conditions from its server layer.

For point-to-point Ethernet services layer connectivity, a MEP has only one peer MEP. Therefore, there is no ambiguity regarding the peer MEP for which the MEP should suppress alarms when it receives the ETH-AIS information.

For multipoint Ethernet services layer connectivity, a MEP that receives ETH-AIS information cannot determine the exact MEP that encountered the fault and, therefore, cannot isolate the exact peer MEP to suppress the alarms. To avoid this scenario, Y.1731 recommends suppressing alarms for all peer MEPs in the same domain level irrespective of connectivity status in a multipoint Ethernet services layer connectivity setup.

Table 79 on page 807 lists the operational mode commands that you can use in a maintenance domain to check the various parameters pertaining to a MEP.

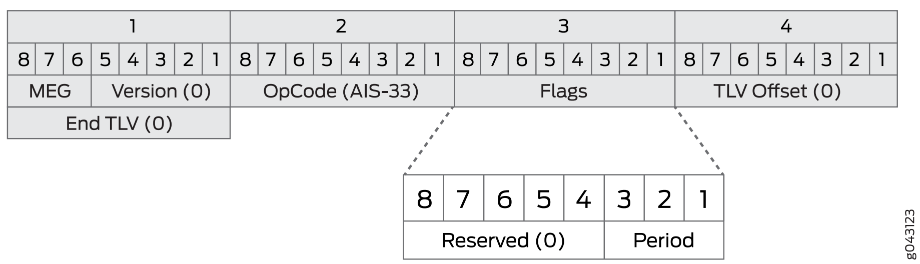
Terms Defined

- AIS transmission—A MEP upon detecting a defect condition transmits AIS frames in a direction opposite to its peer MEPs. The periodicity of AIS frames transmission is on the basis of the AIS transmission period. An AIS transmission period of 1 second is recommended. The first AIS frame must always be transmitted immediately following the detection of a defect condition.
- AIS reception—Upon receiving an AIS frame, a MEP examines it to ensure that the frame's maintenance domain level is the same as its own maintenance domain level. The *period* field in the frame indicates the period at which the AIS frames can be expected. When a MEP receives an AIS frame, it detects the defect condition. After detection, when no AIS frames are received within an interval of 3.5 times—the AIS transmission period indicated in the AIS frames received—the MEP clears the AIS defect condition. When the AIS condition is cleared and defects still exist, then the MEPs continue to report alarms.
- AIS PDU format—The fields of the AIS PDU format are:



a. MEG Level—Also called the maintenance domain level, it is a 3-bit field that is used to carry the maintenance domain level of the client MEG.

b. Version—Value is always 0.

c. OpCode—Value for this PDU type is AIS (33).

d. Flags—The first five bits are reserved and are set to 0. The 3-bit information element carried in the three least significant bits are referred to as the period that contains the value of AIS transmission periodicity as illustrated in Table 80 on page 808:

Table 80: AIS Transmission Periodicity

Flags [3:1]	Period Value	Comments
000-011	Invalid value	Invalid value for AIS
100	1s	1 frame per second
101	Invalid value	Invalid value for AIS
110	1 min	1 frame per minute
111	Invalid value	Invalid value for AIS

e. TLV offset—Set to 0.

f. End TLV—All-zeroes octet value.

- Server layer and client layer—These layers are part of the ITU-T Recommendation G.805 transport network functional model. This model is based on the concept of layering within a transport network. A transport network is divided into several independent transport layer networks that have a client-server association between adjacent layer networks.
- Maintenance domain—To enable connectivity fault management (CFM) on an Ethernet interface, maintenance domains, maintenance associations, and maintenance end points (MEPs) are created and configured in a network. You can configure up to eight maintenance domain levels in a network. Each maintenance domain level is a part of the network where the connectivity issues can be monitored and corrected. Provider domain and customer domain are some examples for maintenance domains. Each maintenance domain has a maintenance association. Each maintenance association includes MEPs and maintenance intermediate points (MIPs) in that domain. The MEPs are located at the boundary of the domain and the MIPs are located within the domain. MEPs generate and transmit continuity check messages (CCMs) at configured intervals to the entire maintenance association to check the connectivity in the network.
- Ethernet services (ETH) layer—A layer in the metro Ethernet network model, where this layer is responsible for the OAM services that are required to support the Ethernet services in the network.

Ethernet Alarm Indication Signal Overview

ACX Series routers support ITU-T Y.1731 Ethernet Alarm Indication Signal function (ETH-AIS) to provide fault management for service providers. ETH-AIS enables you to suppress alarms when a fault condition is detected. Using ETH-AIS, an administrator can differentiate between faults at customer level or faults at provider level.

The advantage of ETH-AIS is:

- Customers need not raise alarms due to lower level failures.
- Customers can get refund based on service unavailability.

When a fault condition is detected, a maintenance end point (MEP) generates ETH-AIS packets to the configured client levels for a specified duration until the fault condition is cleared. Any MEP configured to generate ETH-AIS packets signals to a level higher than its own. A MEP receiving ETH-AIS recognizes that the fault is at a lower level and then suppresses alarms at current level.

ACX Series routers support ETH-AIS PDU generation for server MEPs based on the following defect conditions:

- Loss of connectivity (physical link loss detection)

- Layer 2 circuit or Layer 2 VPN down

Alarm indication signaling is done through the transmission and propagation of ETH-AIS PDUs. ETH-AIS should be enabled on MEPs. A MEP which is configured to issue packets with ETH-AIS information is generally of server layer and continues to transmit periodic packets with ETH-AIS information until the defect condition is cleared. CFM MEPs, upon receiving ETH-AIS PDUs, suppresses loss of continuity alarms associated with its peer MEPs. A MEP resumes loss of continuity alarm generation upon detecting loss of continuity defect conditions in the absence of an ETH-AIS condition.

For point-to-point Ethernet connectivity, a MEP has only a single peer MEP. Therefore, a MEP suppress alarms on its peer MEP when it receives the ETH-AIS information.

For multi-point Ethernet connectivity, a MEP which receives ETH-AIS information cannot determine the exact MEP encountered a fault condition and therefore it will not be able to isolate the exact peer MEP for alarm suppression. ITU-T Y.1731 recommends suppressing alarms for all peer MEPs irrespective of the connectivity status.

AIS transmission—A MEP upon detecting a defect condition transmits ETH-AIS PDUs in a direction opposite to its peer MEPs. The transmission of ETH-AIS PDUs is based on a configured ETH-AIS transmission period. An ETH-AIS transmission period of 1 second is recommended. The first ETH-AIS PDU must be transmitted immediately following the detection of a defect condition.

AIS reception—A MEP upon receiving ETH-AIS PDUs examines it to ensure that its maintenance domain (MD) level corresponds to the same MD level. Upon receiving an ETH-AIS PDU, the MEP detects a defect condition. Following the detection of a defect condition, if there are no ETH-AIS PDUs received within an interval of 3.5 times the ETH-AIS transmission period indicated in the ETH-AIS PDUs received earlier, the MEP clears the defect condition. After the fault condition is cleared, MEPs continue to report alarms.

NOTE: ACX Series routers do not support ITU-T Y.1731 ETH-AIS for layer 2 services (bridging).

The following are the limitations for server MEP

- Triggering of ETH-AIS messages over services (Layer 2 circuit and Layer 2 VPN) by the link-loss server MEP is done on a best-effort manner. This is because the transmission of ETH-AIS messages is independent of the service status and there is no guarantee for delivering the ETH-AIS messages before service goes down.
- Pseudowire protection with CFM-MEP session is not monitored by the server-MEP because an entity to monitor pseudowire protection already exists for the service (Layer 2 circuit and Layer 2 VPN).

Configuring ETH-AIS on a CFM MEP

MX Series routers support ITU-T Y.1731 Ethernet alarm indication signal (ETH-AIS) function to provide fault management for service providers. ETH-AIS enables the service provider to suppress alarms when a fault condition is detected.

The following points are to be noted when ETH-AIS is configured in a maintenance domain:

- Transmitting or receiving of AIS on a MEP does not override the **lowest-priority-defect** statement configured at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name* mep *mep-id*]** hierarchy level. Therefore, alarms are reported according to the defect priority configured.
- Alarms are reported even when the higher domain levels exchange CCMs at a faster rate than the lower domain levels.
- Maintenance association intermediate point (MIP) is transparent to ETH-AIS frames—that is, the MIPs do not perform any action in response to ETH-AIS frames.
- When the service provider requests the MEP to generate an AIS for a lower level or for the same level, the request is rejected.
- AIS generation is stopped when the MEP clears the remote MEP within the maintenance association.
- When the **auto-discovery** statement is enabled for a MEP, the remote MEP information is cleared after the configured hold interval expires.

The following tasks explain how to enable ETH-AIS in a maintenance domain, configure an action to be taken when a defect is detected, and to attach the action profile to a CFM MEP:

1. Configuring an Action Profile on page 811
2. Configuring an Action to Be Taken When an AIS Alarm Is Detected on page 812
3. Attaching the Action Profile to a CFM MEP on page 813

Configuring an Action Profile

To configure an action profile for ETH-AIS:

1. Go to the **[edit protocols oam ethernet connectivity-fault-management]** hierarchy level.

   ```
   [edit]
   user@host# edit protocols oam ethernet connectivity-fault-management
   ```

2. Configure an action profile to use when one or more remote MEPs are down.

   ```
   [edit protocols oam ethernet connectivity-fault-management]
   user@host# edit action-profile action-profile-name
   ```

3. Configure an event that needs to be monitored.

[edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name*]
user@host# **edit event**

4. Configure the defect condition that generates an alarm indication signal.

   [edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name* event]
   user@host# **edit ais-trigger-condition**

5. Configure the **adjacency-loss** statement to inform the operator when the physical connectivity is lost between the peer MEPs.

   [edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name* event ais-trigger-condition]
   user@host# **set adjacency-loss**

6. Configure the **all-defects** statement to inform the operator that all possible defects must be considered to raise the alarm indication signal.

   [edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name* event ais-trigger-condition]
   user@host# **set all-defects**

7. Configure the **cross-connect-ccm** statement to inform the operator when cross-connect continuity check messages (CCMs) are received by the MEP and to raise an alarm indication signal in response.

   [edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name* event ais-trigger-condition]
   user@host# **set cross-connect-ccm**

8. Configure the **erroneous-ccm** statement to inform the operator when CCMs with unexpected MEP ID or maintenance domain level are received by the MEP and an AIS alarm is raised in response.

   [edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name* event ais-trigger-condition]
   user@host# **set erroneous-ccm**

9. Configure the **receive-ais** statement to inform the operator that an AIS message has been received from the peer MEP in its own maintenance level.

   [edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name* event ais-trigger-condition]
   user@host# **set receive-ais**

Configuring an Action to Be Taken When an AIS Alarm Is Detected

Configure an action to be taken when an AIS alarm is detected.

1. Go to the **[edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name* action]** hierarchy level.

[edit]
user@host# **edit protocols oam ethernet connectivity-fault-management action-profile** *action-profile-name* **action**

2. Configure the **log-and-generate-ais** statement to log the event that generated the AIS message.

   [edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name* action]
   user@host# **edit log-and-generate-ais**

3. Configure the interval between AIS messages that are to be received by the MEP as 1 minute or 1 second.

   [edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name* action log-and-generate-ais]
   user@host# **set interval (1m | 1s)**

4. Configure the server maintenance domain level range of the MEP from 1 through 7.

   [edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name* action log-and-generate-ais]
   user@host# **set level** ***level***

5. Configure the 802.1p priority of the AIS packet from 1 through 7.

   [edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name* action log-and-generate-ais]
   user@host# **set priority** ***level***

Attaching the Action Profile to a CFM MEP

After configuring an event and an action to be monitored in an action profile, you must attach the action profile to a CFM MEP.

1. Go to the **[edit protocols oam ethernet connectivity-fault-management]** hierarchy level.

   [edit]
   user@host# **edit protocols oam ethernet connectivity-fault-management**

2. Configure the maintenance domain with a name.

   [edit protocols oam ethernet connectivity-fault-management]
   user@host# **edit maintenance-domain** ***md-name***

3. Configure the maintenance domain with a client maintenance entity group (MEG) level or maintenance association level—the level which the client layer maintenance association intermediate point (MIPs) and the MEPs exist—from 0 through 7.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name*]
   user@host# **edit level** ***level***

NOTE: You cannot configure a maintenance domain level that is lower than or equal to the maintenance association level that it is associated with.

4. Configure the maintenance association.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name*]
   user@host# **edit maintenance-association** ***ma-name***

5. Configure the continuity check that is performed on all the MEPs in a domain level by sending CCMs with an interval between two CCMs—100 miiliseconds, 10 milliseconds, 1 second, 10 seconds, 1 minute, or 10 minutes—and the number of CCMs that are to be lost before marking a MEP as down.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name*]
   user@host# **set continuity-check interval (100ms | 10m | 10ms | 1m | 1s)**
   user@host# **set continuity-check loss-threshold** ***value***

6. Configure the MEP with an identifier from 1 through 8192.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name*]
   user@host# **set mep** ***mep-id***

7. Attach the configured action profile to the MEP.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id*]
   user@host# **set action-profile** ***action-profile-name***

8. Configure the interface of the MEP over which the CCMs are transmitted.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id*]
   user@host# **set interface** ***interface-name***

9. Configure the direction for the CCMs to travel to the next MEP as up or down.

   [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id*]
   user@host# **set direction (down | up)**

10. Configure the 802.1p priority for the CCMs and link-trace packet from 0 through 7.

    [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id*]
    user@host# **set priority** ***priority-value***

Related Documentation

- Ethernet Alarm Indication Signal (ETH-AIS) Function Overview on page 805

Configuring Alarm Indication Signal on ACX Series Routers

ACX Series routers support ITU-T Y.1731 Ethernet Alarm Indication Signal function (ETH-AIS) to provide fault management for service providers. ETH-AIS enables you to suppress alarms when a fault condition is detected.

To support ETH-AIS transmission, the following configuration information is required by a CFM MEP:

- Client Maintenance Entity Group level—Maintenance Entity Group (MEG) level at which the immediate client layer Maintenance Domain Intermediate Points (MIPs) and Maintenance Association End Points (MEPs) exist.
- ETH-AIS transmission period—Determines the ETH-AIS PDU transmission interval.
- Priority—Determines the priority of packets with ETH-AIS information. This is optional.

To configure ETH-AIS in CFM MEP, you need to:

- Configure an action profile with ETH-AIS action
- Attach the action profile to the CFM MEP

To configure an action profile with ETH-AIS action, include the following statements at the [edit protocols oam ethernet connectivity-fault-management] hierarchy level:

```
[edit protocols oam ethernet connectivity-fault-management]
action-profile action-profile-name {
  event {
    adjacency-loss;
    all-defects;
    cross-connect-ccm;
    errored-ccm;
    receive-ais;
  }
  action {
    log-and-generate-ais {
      level [1-7];
      interval 1s | 1m ;
      priority [0-7];
    }
    log-ais;
  }
}
```

To attach an action profile to a CFM MEP, include the following statements at the [edit protocols oam ethernet connectivity-fault-management] hierarchy level:

```
maintenance-domain maintenenace-domain-name {
level level-number;
  maintenance-association maintenance-domain-name {
    continuity-check {
      interval 1s;
```

```
            loss-threshold 3;
          }
          mep mep-id {
            interface interface-name;
            direction up | down;
            priority priority-value;
            action-profile action-profile-name;
          }
        }
      }
```

NOTE: You cannot configure a maintenance domain level that is lower than or equal to the level that it is associated with.

To support ETH-AIS transmission, the following configuration information required by a server MEP:

- Server MEP definition—Defines the association of server MEP identifier to the server layer.
  - For Layer 2 circuit and Layer 2 VPN, the logical interface connected to a customer network (UNI) would be the identifier for the server layer that needs to be monitored by the server MEP.
  - For physical link loss detection, the physical interface under Ethernet protocol would be the identifier for the server layer that needs to be monitored by the server MEP.
- Association of server MEP defect—Defines the association of server MEP defects to ETH-AIS action.
- Association action profile and server MEP—Defines the binding of server MEP and action profile.

To configure ETH-AIS in server MEP, you need to:

- Create an action profile with ETH-AIS action for server MEP defects.
- Attach the action profile to a server MEP

To create an action profile, include the following statements at the [edit protocols oam ethernet connectivity-fault-management] hierarchy level:

```
[edit protocols oam ethernet connectivity-fault-management]
action-profile action-profile-name {
  event {
    server-mep-defects {
      link-loss-defect;
      l2circuit-defect;
      l2vpn-defect;
    }
  }
  action {
    log-and-generate-ais {
      level 1...n;
      interval 1 second | 1 minute;
```

```
            priority dot1p [range 0-7];
        }
    }
}
```

To attach an action profile to a server MEP, include the following statement at the [edit protocols oam ethernet connectivity-fault-management] hierarchy level:

```
[edit protocols oam ethernet connectivity-fault-management]
server-mep mep-identifier {
    protocol l2circuit | l2vpn | ethernet {
        interface interface-name;
    }
    action-profile action-profile-name;
}
```

Example: Configuring One-Way Ethernet Frame Delay Measurements with Single-Tagged Interfaces

This example uses two MX Series routers: **MX-1** and **MX-2**. The configuration creates a CFM down MEP session on a VLAN-tagged logical interface connecting the two (**ge-5/2/9** on Router **MX-1** and **ge-0/2/5** on Router **MX-2**).

NOTE: These are not complete router configurations.

Configuration on Router **MX-1**:

```
[edit]
interfaces {
    ge-5/2/9 {
        vlan-tagging;
        unit 0 {
            vlan-id 512;
        }
    }
}
protocols {
    oam {
        ethernet {
            connectivity-fault-management {

    Average one-way delay          : 312 usec
    Average one-way delay variation: 11 usec
    Best case one-way delay        : 255 usec
```

NOTE: When two systems are close to each other, their one-way delay values are very high compared to their two-way delay values. This is because one-way delay measurement requires the timing for the two systems to be synchronized at a very granular level and MX Series routers do not support this granular synchronization. However, two-way delay measurement does not require synchronized timing, making two-way delay measurements more accurate.

Example: Configuring Two-Way Ethernet Frame Delay Measurements with Single-Tagged Interfaces

This example uses two MX Series routers: **MX-1** and **MX-2**. The configuration creates a CFM down MEP session on a VLAN-tagged logical interface connecting the two (**ge-5/2/9** on Router **MX-1** and **ge-0/2/5** on Router **MX-2**).

NOTE: These are not complete router configurations.

Configuration on Router **MX-1**:

```
[edit]
interfaces {
  ge-5/2/9 {
    vlan-tagging;
    unit 0 {
      vlan-id 512;
    }
  }
}
protocols {
  oam {
    ethernet {
      connectivity-fault-management {
        traceoptions {
          file eoam_cfm.log size 1g files 2 world-readable;
          flag all;
        }
        linktrace {
          path-database-size 255;
          age 10s;
        }
        maintenance-domain md6 {
          level 6;
          maintenance-association ma6 {
            continuity-check {
              interval 100ms;
              hold-interval 1;
            }
            mep 201 {
              interface ge-5/2/9.0;
              direction down;
              auto-discovery;
```

```
                }
              }
            }
          }
        }
      }
    }
```

Configuration on Router **MX-2**:

```
[edit]
interfaces {
  ge-0/2/5 {
    vlan-tagging;
    unit 0 {
      vlan-id 512;
    }
  }
}
protocols {
  oam {
    ethernet {
      connectivity-fault-management {
        traceoptions {
          file eoam_cfm.log size 1g files 2 world-readable;
          flag all;
        }
        linktrace {
          path-database-size 255;
          age 10s;
        }
        maintenance-domain md6 {
          level 6;
          maintenance-association ma6 {
            continuity-check {
              interval 100ms;
              hold-interval 1;
            }
            mep 101 {
              interface ge-0/2/5.0;
              direction down;
              auto-discovery;
            }
          }
        }
      }
    }
  }
}
```

From Router **MX-1**, start a two-way delay measurement to Router **MX-2**.

```

Example: Configuring Ethernet Frame Delay Measurements with Untagged Interfaces

Ethernet frame delay measurements are supported on untagged interfaces. All commands are the same as for tagged interfaces. Only the configurations are different. This section shows the untagged interface configurations for Routers **MX-1** and **MX-2**.

NOTE: **These are not complete router configurations.**

Example: Measuring Ethernet Frame Loss for Single-Tagged LMM/LMR PDUs

This example illustrates how to configure Ethernet frame loss measurement (ETH-LM) for single-tagged Loss Measurement Message (LMM)/Loss Measurement Reply (LMR) protocol data units (PDUs). By configuring ETH-LM, you can measure the Ethernet frame loss that occur in your network.

Requirements

This example uses the following hardware and software components:

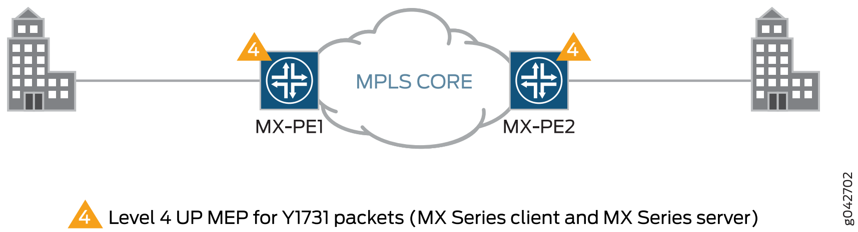
- Two MX Series 3D Universal Edge Routers with Rev-B Dense Port Concentrators (DPCs)
- Junos OS Release 14.2 or later

Overview and Topology

Junos OS supports Ethernet frame loss measurement (ETH-LM) between maintenance association end points (MEPs) configured on Ethernet physical or logical interfaces on Rev-B Dense Port Concentrators (DPCs) in MX Series routers. Additionally, the Y.1731 functionality supports ETH-LM only for an end-to-end connection that uses Virtual Private Wire Service (VPWS). This example illustrates how to configure ETH-LM for single-tagged LMM/LMR PDUs with input and output VLAN map configured as **swap**.

Figure 53 on page 829 shows the topology used in this example. VPWS service is configured between two MX Sereies routers, MX-PE1 and MX PE2.

Figure 53: VPWS Service Configured Between Two MX Series Routers



MX-PE1 router has two Ethernet interfaces, **ge-5/0/4** and **ge-5/1/9**. Virtual LAN (VLAN) is configured on **ge-5/0/4** and MPLS is configured on the **ge-5/1/9** interface. The **ge-5/0/4.11** interface is used to configure the Layer 2 virtual circuit with MX-PE2 router. The UP MEP, **mep 2**, is attached to the **ge-5/0/4.11** interface. The three-color policer firewall filter is also configured for the MX-PE1 router.

Similarly, MX-PE2 router has two Ethernet interfaces, **ge-8/0/8** and **ge-8/0/9**. Virtual LAN (VLAN) is configured on **ge-8/0/8** and MPLS is configured on the **ge-8/0/9** interface. The **ge-8/0/8.11** interface is used to configure the Layer 2 virtual circuit with MX-PE1 router. The UP MEP, **mep 1**, is attached to the **ge-8/0/8.11** interface. The three-color policer firewall filter is also configured for the MX-PE2 router.

Configuration

- Configuring Router PE1 on page 831
- Configuring Router PE2 on page 834

CLI Quick Configuration

To quickly configure ETH-LM for single-tagged LMM/LMR PDUs, copy the following commands, remove any line breaks, and then paste the commands into the CLI of each device.

On Router PE1:

```
[edit]
set interfaces ge-5/0/4 encapsulation flexible-ethernet-services
set interfaces ge-5/0/4 unit 11 encapsulation vlan-ccc

Configuring Router PE1

Step-by-Step Procedure

To configure Router PE1:

1. Configure the interfaces.

```
[edit]
user@PE1# edit interfaces
[edit interfaces]
user@PE1# set ge-5/0/4 encapsulation flexible-ethernet-services
user@PE1# set ge-5/0/4 unit 11 encapsulation vlan-ccc
user@PE1# set ge-5/0/4 unit 11 layer2-policer input-three-color abc
user@PE1# set ge-5/0/4 unit 11 family ccc
user@PE1# set ge-5/1/9 enable
user@PE1# set ge-5/1/9 unit 0 family inet address 12.1.1.1/24
user@PE1# set ge-5/1/9 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 4.4.4.4/32
```

2. Configure the VLAN.

```
[edit interfaces]
user@PE1# set ge-5/0/4 flexible-vlan-tagging
user@PE1# set ge-5/0/4 unit 11 vlan-id 2000
user@PE1# set ge-5/0/4 unit 11 input-vlan-map swap
user@PE1# set ge-5/0/4 unit 11 input-vlan-map vlan-id 4094
user@PE1# set ge-5/0/4 unit 11 output-vlan-map swap
```

3. Configure the router identifier to identify the routing device.

```
[edit]
user@PE1# edit routing-options
[edit routing-options]
user@PE1# set router-id 4.4.4.4
```

4. Configure MPLS, OSPF, and LDP protocols.

```
[edit]
user@PE1# edit protocols
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
```

```
user@PE1# set ldp interface all
user@PE1# set ldp interface fxp0.0 disable
```

5. Configure the Layer 2 circuit.

```
[edit protocols]
user@PE1# set l2circuit neighbor 3.3.3.3 interface ge-5/0/4.11 virtual-circuit-id 1003
user@PE1# set l2circuit neighbor 3.3.3.3 interface ge-5/0/4.11 no-control-word
```

6. Configure the MEP.

```
[edit protocols]
user@PE1# set oam ethernet connectivity-fault-management
  performance-monitoring delegate-server-processing
user@PE1# set oam ethernet connectivity-fault-management maintenance-domain
  md level 4
user@PE1# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma continuity-check interval 1s
user@PE1# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma mep 2 interface ge-5/0/4.11
user@PE1# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma mep 2 direction up
user@PE1# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma mep 2 remote-mep 1
```

7. Configure the firewall.

```
[edit]
user@PE1# edit firewall
[edit firewall]
user@PE1# set three-color-policer abc logical-interface-policer
user@PE1# set three-color-policer abc two-rate color-blind
user@PE1# set three-color-policer abc two-rate committed-information-rate 10m
user@PE1# set three-color-policer abc two-rate committed-burst-size 1500
user@PE1# set three-color-policer abc two-rate peak-information-rate 20m
user@PE1# set three-color-policer abc two-rate peak-burst-size 15k
```

8. Commit the configuration.

```
[edit]
user@PE1# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-options**, and **show firewall** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

Configuring Router PE2

Step-by-Step Procedure

To configure Router PE2:

1. Configure the interfaces.

```
[edit]
```

```
user@PE2# edit interfaces
[edit interfaces]
user@PE2# set ge-8/0/8 encapsulation flexible-ethernet-services
user@PE2# set ge-8/0/8 unit 11 encapsulation vlan-ccc
user@PE2# set ge-8/0/8 unit 11 layer2-policer input-three-color abc
user@PE2# set ge-8/0/8 unit 11 family ccc
user@PE2# set ge-8/0/9 enable
user@PE2# set ge-8/0/9 unit 0 family inet address 12.1.1.1/24
user@PE2# set ge-8/0/9 unit 0 family mpls
user@PE2# set ae0 unit 0 family inet
user@PE2# set lo0 unit 0 family inet address 3.3.3.3/32
```

2. Configure the VLAN.

```
[edit interfaces]
user@PE2# set ge-8/0/8 flexible-vlan-tagging
user@PE2# set ge-8/0/8 unit 11 vlan-id 2000
user@PE2# set ge-8/0/8 unit 11 input-vlan-map swap
user@PE2# set ge-8/0/8 unit 11 input-vlan-map vlan-id 4094
user@PE2# set ge-8/0/8 unit 11 output-vlan-map swap
```

3. Configure the router identifier to identify the routing device.

```
[edit]
user@PE2# edit routing-options
[edit routing-options]
user@PE2# set router-id 3.3.3.3
```

4. Configure MPLS, OSPF, and LDP protocols.

```
[edit]
user@PE2# edit protocols
[edit protocols]
user@PE2# set mpls interface all
user@PE2# set mpls interface fxp0.0 disable
user@PE2# set ospf area 0.0.0.0 interface all
user@PE2# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PE2# set ldp interface all
user@PE2# set ldp interface fxp0.0 disable
```

5. Configure the Layer 2 circuit.

```
[edit protocols]
user@PE2# set l2circuit neighbor 4.4.4.4 interface ge-8/0/8.11 virtual-circuit-id
  1003
user@PE2# set l2circuit neighbor 3.3.3.3 interface ge-8/0/8.11 no-control-word
```

6. Configure the MEP.

```
[edit protocols]
user@PE2# set oam ethernet connectivity-fault-management maintenance-domain
  md level 4
user@PE2# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma continuity-check interval 1s
```

```
user@PE2# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma mep 1 interface ge-8/0/8.11
user@PE2# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma mep 1 direction up
user@PE2# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma mep 1 remote-mep 2
```

7. Configure the firewall.

```
[edit]
user@PE2# edit firewall
[edit firewall]
user@PE2# set three-color-policer abc logical-interface-policer
user@PE2# set three-color-policer abc two-rate color-blind
user@PE2# set three-color-policer abc two-rate committed-information-rate 10m
user@PE2# set three-color-policer abc two-rate committed-burst-size 1500
user@PE2# set three-color-policer abc two-rate peak-information-rate 20m
user@PE2# set three-color-policer abc two-rate peak-burst-size 15k
```

8. Commit the configuration.

```
[edit]
user@PE2# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-options**, and **show firewall** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

    }
  }
}
```

Verification

To start monitoring the Ethernet frame loss, issue the **monitor ethernet loss-measurement maintenance-domain md maintenance-association ma mep 1** command. Frame loss is calculated by collecting the counter values applicable for ingress and egress service frames where the counters maintain a count of transmitted and received data frames between a pair of MEPs. The loss measurement statistics are retrieved as the output of the **monitor ethernet loss-measurement** command. You can also issue the **show oam ethernet connectivity-fault-management interfaces detail ge-5/0/4.11** command to display ETH-LM statistics.

Viewing ETH-LM

Purpose View the ETH-LM statistics.

Action From operational mode, enter the **show oam ethernet connectivity-fault-management interfaces detail ge-5/0/4.11** command.

```
user@PE1> show oam ethernet connectivity-fault-management interfaces detail ge-5/0/4.11
Interface name: ge-5/0/4.11 , Interface status: Active, Link status: Up

      1     00:05:85:76:e5:30       ok   ge-5/0/4.11
```

Meaning The Ethernet interface details and statistics are displayed. This output indicates that the **ge-5/0/4.11** interface is active and its link status is **up**. Its maintenance domain name is **md** and its level is **4**. The MEP identifier of the **ge-5/0/4.11** interface is indicated as **2** and its direction is **up**. Under the statistics section, the output indicates that **10** LMMs were sent and **10** valid LMRs were received by the interface.

Example: Measuring Ethernet Frame Loss for Dual-Tagged LMM/LMR PDUs

This example illustrates how to configure Ethernet frame loss measurement (ETH-LM) for dual-tagged Loss Measurement Message (LMM)/Loss Measurement Reply (LMR) protocol data units (PDUs). By configuring ETH-LM, you can measure the Ethernet frame loss that occur in your network.

Requirements

This example uses the following hardware and software components:

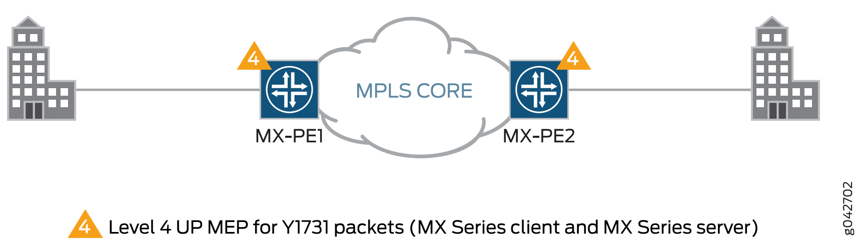
- Two MX Series 3D Universal Edge Routers with Rev-B Dense Port Concentrators (DPCs)
- Junos OS Release 14.2 or later

Overview and Topology

Junos OS supports Ethernet frame loss measurement (ETH-LM) between maintenance association end points (MEPs) configured on Ethernet physical or logical interfaces on Rev-B Dense Port Concentrators (DPCs) in MX Series routers. Additionally, the Y.1731 functionality supports ETH-LM only for an end-to-end connection that uses Virtual Private Wire Service (VPWS). This example illustrates how to configure ETH-LM for dual tagged LMM/LMR PDUs with input and output VLAN map configured as **swap-swap**.

Figure 54 on page 840 shows the topology used in this example. VPWS service is configured between two MX Sereies routers, MX-PE1 and MX PE2.

Figure 54: VPWS Service Configured Between Two MX Series Routers



MX-PE1 router has two Ethernet interfaces, **ge-5/0/4** and **ge-5/1/9**. Virtual LAN (VLAN) is configured on **ge-5/0/4** and MPLS is configured on the **ge-5/1/9** interface. The **ge-5/0/4.11** interface is used to configure the Layer 2 virtual circuit with MX-PE2 router.

The UP MEP, **mep 2**, is attached to the **ge-5/0/4.11** interface. The three-color policer firewall filter is also configured for the MX-PE1 router.

Similarly, MX-PE2 router has two Ethernet interfaces, **ge-8/0/8** and **ge-8/0/9**. Virtual LAN (VLAN) is configured on **ge-8/0/8** and MPLS is configured on the **ge-8/0/9** interface. The **ge-8/0/8.11** interface is used to configure the Layer 2 virtual circuit with MX-PE1 router. The UP MEP, **mep 1**, is attached to the **ge-8/0/8.11** interface. The three-color policer firewall filter is also configured for the MX-PE2 router.

Configuration

Configuring Router PE1

Step-by-Step Procedure

To configure Router PE1:

1. Configure the interfaces.

```
[edit]
user@PE1# edit interfaces
[edit interfaces]
user@PE1# set ge-5/0/4 encapsulation flexible-ethernet-services
user@PE1# set ge-5/0/4 unit 11 encapsulation vlan-ccc
user@PE1# set ge-5/0/4 unit 11 layer2-policer input-three-color abc
user@PE1# set ge-5/0/4 unit 11 family ccc
user@PE1# set ge-5/1/9 enable
user@PE1# set ge-5/1/9 unit 0 family inet address 12.1.1.1/24
user@PE1# set ge-5/1/9 unit 0 family mpls
user@PE1# set lo0 unit 0 family inet address 4.4.4.4/32
```

2. Configure the VLAN.

```
[edit interfaces]
user@PE1# set ge-5/0/4 flexible-vlan-tagging
user@PE1# set ge-5/0/4 unit 11 vlan-tags outer 2000 inner 1000
user@PE1# set ge-5/0/4 unit 11 input-vlan-map swap-swap
user@PE1# set ge-5/0/4 unit 11 input-vlan-map vlan-id 4094
user@PE1# set ge-5/0/4 unit 11 input-vlan-map inner-vlan-id 4093
user@PE1# set ge-5/0/4 unit 11 output-vlan-map swap-swap
```

3. Configure the router identifier to identify the routing device.

```
[edit]
user@PE1# edit routing-options
[edit routing-options]
user@PE1# set router-id 4.4.4.4
```

4. Configure MPLS, OSPF, and LDP protocols.

```
[edit]
user@PE1# edit protocols
[edit protocols]
user@PE1# set mpls interface all
user@PE1# set mpls interface fxp0.0 disable
user@PE1# set ospf area 0.0.0.0 interface all
user@PE1# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PE1# set ldp interface all
user@PE1# set ldp interface fxp0.0 disable
```

5. Configure the Layer 2 circuit.

```
[edit protocols]
user@PE1# set l2circuit neighbor 3.3.3.3 interface ge-5/0/4.11 virtual-circuit-id 1003
user@PE1# set l2circuit neighbor 3.3.3.3 interface ge-5/0/4.11 no-control-word
```

6. Configure the MEP.

```
[edit protocols]
user@PE1# set oam ethernet connectivity-fault-management
  performance-monitoring delegate-server-processing
user@PE1# set oam ethernet connectivity-fault-management maintenance-domain
  md level 4
user@PE1# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma continuity-check interval 1s
user@PE1# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma mep 2 interface ge-5/0/4.11
user@PE1# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma mep 2 direction up
user@PE1# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma mep 2 remote-mep 1
```

7. Configure the firewall.

```
[edit]
user@PE1# edit firewall
[edit firewall]
user@PE1# set three-color-policer abc logical-interface-policer
user@PE1# set three-color-policer abc two-rate color-blind
user@PE1# set three-color-policer abc two-rate committed-information-rate 10m
user@PE1# set three-color-policer abc two-rate committed-burst-size 1500
user@PE1# set three-color-policer abc two-rate peak-information-rate 20m
user@PE1# set three-color-policer abc two-rate peak-burst-size 15k
```

8. Commit the configuration.

```
[edit]
user@PE1# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-options**, and **show firewall** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

Configuring Router PE2

Step-by-Step Procedure

To configure Router PE2:

1. Configure the interfaces.

```
[edit]
user@PE2# edit interfaces
[edit interfaces]
user@PE2# set ge-8/0/8 encapsulation flexible-ethernet-services
user@PE2# set ge-8/0/8 unit 11 encapsulation vlan-ccc
user@PE2# set ge-8/0/8 unit 11 layer2-policer input-three-color abc
user@PE2# set ge-8/0/8 unit 11 family ccc
user@PE2# set ge-8/0/9 enable
user@PE2# set ge-8/0/9 unit 0 family inet address 12.1.1.1/24
user@PE2# set ge-8/0/9 unit 0 family mpls
```

```
user@PE2# set ae0 unit 0 family inet
user@PE2# set lo0 unit 0 family inet address 3.3.3.3/32
```

2. Configure the VLAN.

```
[edit interfaces]
user@PE2# set ge-8/0/8 flexible-vlan-tagging
user@PE2# set ge-8/0/8 unit 11 vlan-tags outer 2000 inner 1000
user@PE2# set ge-8/0/8 unit 11 input-vlan-map swap-swap
user@PE2# set ge-8/0/8 unit 11 input-vlan-map vlan-id 4094
user@PE2# set ge-8/0/8 unit 11 input-vlan-map inner-vlan-id 4093
user@PE2# set ge-8/0/8 unit 11 output-vlan-map swap-swap
```

3. Configure the router identifier to identify the routing device.

```
[edit]
user@PE2# edit routing-options
[edit routing-options]
user@PE2# set router-id 3.3.3.3
```

4. Configure MPLS, OSPF, and LDP protocols.

```
[edit]
user@PE2# edit protocols
[edit protocols]
user@PE2# set mpls interface all
user@PE2# set mpls interface fxp0.0 disable
user@PE2# set ospf area 0.0.0.0 interface all
user@PE2# set ospf area 0.0.0.0 interface fxp0.0 disable
user@PE2# set ldp interface all
user@PE2# set ldp interface fxp0.0 disable
```

5. Configure the Layer 2 circuit.

```
[edit protocols]
user@PE2# set l2circuit neighbor 4.4.4.4 interface ge-8/0/8.11 virtual-circuit-id
  1003
user@PE2# set l2circuit neighbor 3.3.3.3 interface ge-8/0/8.11 no-control-word
```

6. Configure the MEP.

```
[edit protocols]
user@PE2# set oam ethernet connectivity-fault-management maintenance-domain
  md level 4
user@PE2# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma continuity-check interval 1s
user@PE2# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma mep 1 interface ge-8/0/8.11
user@PE2# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma mep 1 direction up
user@PE2# set oam ethernet connectivity-fault-management maintenance-domain
  md maintenance-association ma mep 1 remote-mep 2
```

7. Configure the firewall.

```
[edit]
user@PE2# edit firewall
[edit firewall]
user@PE2# set three-color-policer abc logical-interface-policer
user@PE2# set three-color-policer abc two-rate color-blind
user@PE2# set three-color-policer abc two-rate committed-information-rate 10m
user@PE2# set three-color-policer abc two-rate committed-burst-size 1500
user@PE2# set three-color-policer abc two-rate peak-information-rate 20m
user@PE2# set three-color-policer abc two-rate peak-burst-size 15k
```

8. Commit the configuration.

```
[edit]
user@PE2# commit
```

Results From configuration mode, confirm your configuration by entering the **show interfaces**, **show protocols**, **show routing-options**, and **show firewall** commands. If the output does not display the intended configuration, repeat the instructions in this example to correct the configuration.

```

      peak-information-rate 20m;
      peak-burst-size 15k;
    }
  }
}
```

Verification

To start the Ethernet frame loss measurement session, issue the **monitor ethernet loss-measurement maintenance-domain md maintenance-association ma mep 1** command. Frame loss is calculated by collecting the counter values applicable for ingress and egress service frames where the counters maintain a count of transmitted and received data frames between a pair of MEPs. The loss measurement statistics are retrieved as the output of the **monitor ethernet loss-measurement** command. You can also issue the **show oam ethernet connectivity-fault-management interfaces detail ge-5/0/4.11** command to display ETH-LM statistics.

Viewing ETH-LM

Purpose View the ETH-LM statistics.

Action From operational mode, enter the **show oam ethernet connectivity-fault-management interfaces detail ge-5/0/4.11** command.

```
user@PE1> show oam ethernet connectivity-fault-management interfaces detail ge-5/0/4.11
Interface name: ge-5/0/4.11 , Interface status: Active, Link status: Up
  Maintenance domain name: md, Format: string, Level: 4
    Maintenance association name: ma, Format: string
    Continuity-check status: enabled, Interval: 1s, Loss-threshold: 3 frames
    Interface status TLV: none, Port status TLV: none
    Connection Protection TLV: no
    MEP identifier: 2, Direction: up, MAC address: 00:24:dc:9b:96:76
    MEP status: running
    Defects:
```

```
    Remote MEP not receiving CCM                 : no
    Erroneous CCM received                       : no
    Cross-connect CCM received                   : no
    RDI sent by some MEP                         : no
    Some remote MEP's MAC in error state         : no

  Remote MEP count: 1
    Identifier     MAC address        State    Interface
        1      00:05:85:76:e5:30       ok   ge-5/0/4.11
```

Meaning

The Ethernet interface details and statistics are displayed. This output indicates that the **ge-5/0/4.11** interface is active and its link status is **up**. Its maintenance domain name is **md** and its level is **4**. The MEP identifier of the **ge-5/0/4.11** interface is indicated as **2** and its direction is **up**. Under the statistics section, the output indicates that **10** LMMs were sent and **10** valid LMRs were received by the interface.

Triggering an Ethernet Frame Delay Measurements Session

Before Ethernet frame delay measurement statistics can be displayed, they must be collected. To trigger Ethernet frame delay measurement, use the **monitor ethernet delay-measurement (one-way | two-way) (*remote-mac-address* | mep *identifier*) maintenance-domain *name* maintenance-association *ma-id* [count *count*] [wait *time*]** operational command.

The fields for this command are described in Table 81 on page 852.

Table 81: Monitor Ethernet Delay Command Parameters

Parameter	Parameter Range	Description
one-way or **two-way**	NA	Perform a one-way or two-way (round-trip) delay measurement.
remote-mac-address	Unicast MAC address	Send delay measurement frames to the destination unicast MAC address (use the format xx:xx:xx:xx:xx:xx). Multicast MAC addresses are not supported.
mep *identifier*	1–8191	The MEP identifier to use for the measurement. The discovered MAC address for this MEP identifier is used.
maintenance-domain *name*	Existing MD name	Specifies an existing maintenance domain (MD) to use for the measurement.
maintenance-association *ma-id*	Existing MA identifier	Specifies an existing maintenance association (MA) identifier to use for the measurement.
count *count*	1–65535 (default: 10)	(Optional) Specifies the number of Ethernet frame delay frames to send. The default is 10.
wait *time*	1–255 seconds (default: 1)	(Optional) Specifies the number of seconds to wait between frames. The default is 1 second.

If you attempt to monitor delays to a nonexistent MAC address, you must exit the application manually using **^C**:

```
user@host> monitor ethernet delay-measurement two-way 00:11:22:33:44:55
Two-way ETH-DM request to 00:11:22:33:44:55, Interface ge-5/2/9.0
^C
--- Delay measurement statistics ---
Packets transmitted: 10, Valid packets received: 0
Average delay: 0 usec, Average delay variation: 0 usec
Best case delay: 0 usec, Worst case delay: 0 usec
```

Viewing Ethernet Frame Delay Measurements Statistics

Once Ethernet frame delay measurement statistics have been collected, they can be displayed.

To retrieve the last 100 Ethernet frame delay measurement statistics per remote MEP or per CFM session, two types of **show** commands are provided:

- For all OAM frame counters and Ethernet frame delay measurement statistics
- For Ethernet frame delay measurement statistics only

To retrieve all Ethernet frame delay measurement statistics for a given session, use the **show oam ethernet connectivity-fault-management mep-statistics maintenance-domain *name* maintenance-association *name* [local-mep *identifier*] [remote-mep *identifier*] [count *count*]** command.

To retrieve only Ethernet frame delay measurement statistics for a given session, use the **show oam ethernet connectivity-fault-management delay-statistics maintenance-domain *name* maintenance-association *name* [local-mep *identifier*] [remote-mep *identifier*] [count *count*]** command.

NOTE: The only difference in the two commands is the use of the **mep-statistics** and **delay-statistics** keyword.

The fields for these commands are described in Table 82 on page 853.

Table 82: Show Ethernet Delay Command Parameters

Parameter	Parameter Range	Description
maintenance-domain *name*	Existing MD name	Specifies an existing maintenance domain (MD) to use.
maintenance-association *ma-id*	Existing MA identifier	Specifies an existing maintenance association (MA) identifier to use.
local-mep *identifier*	1–8191	When a MEP has been specified, display statistics only for the local MEP.
remote-mep *identifier*	1–8191	When a MEP has been specified, display statistics only for the discovered MEP.
count *count*	1–100 (default:100)	The number of entries to display in the results table. By default, all 100 entries are displayed if they exist.

NOTE: For each MEP, you will see frame counters for sent and received Ethernet frame delay measurement frames whenever MEP statistics are displayed.

CHAPTER 34

Configuring Ethernet Ring Protection

Ethernet Ring Protection

Link failure is often an unavoidable part of networking. However, there are methods of improving the reliability of a router or bridge network even when link failures occur. For example, SONET/SDH seal-healing rings are frequently used to add a level of robustness to router networks. This ring protection switching is now extended to Ethernet links. You can configure Ethernet ring protection for a series of two or more systems so that if one link fails, traffic is rerouted around the failure on the ring.

The basic idea of Ethernet ring protection is to use one specific link to protect the whole ring. This special link is the ring protection link (RPL). When all links are up and running, the RPL blocks traffic and remains idle. The RPL itself is controlled by the designated RPL owner node. There is only one RPL owner node on the ring and the RPL owner node is responsible for blocking the RPL interface under normal operating conditions. However, if a link failure occurs on the ring, the RPL owner node is responsible for unblocking the RPL interface and protection–switching the traffic on the alternate path around the ring. An Ethernet ring automatic protection switching (R-APS) messaging protocol coordinates the protection activities of all nodes on the ring. The APS blocks traffic over the failed link and unblocks traffic over the RPL.

When the failed link is repaired, the traffic reverts to its normal pattern. That is, the RPL owner blocks the RPL link and unblocks traffic over the cleared link.

Two or more nodes form a ring. Links between the nodes form a chain, with the last node also connecting the first. Every ring node therefore has two ports related to the ring, one in each direction. In this chapter, these directions are referred to as east and west.

Every node on the ring is one of two types:

- RPL owner node—This node owns the RPL and blocks or unblocks the RPL as conditions require. This node initiates the R-APS message.
- Normal node—All other nodes on the ring (that is, those that are not the RPL owner node) operate as normal nodes and have no special role on the ring.

In addition to roles, each node on the Ethernet ring can be in one of several states:

- Init—The node is not yet participating in the ring.
- Idle—The node is performing normally (there is no link failure on the ring). In this state, traffic is unblocked on both ring ports, except for the RPL owner node, which blocks the RPL port (the other RPL owner port is unblocked).
- Protection—When a failure occurs on the ring, a normal node will have traffic blocked on the ring port that connects to the failed link. The RPL owner, if it is not at one end of the failed link, will then unblock the RPL port so both ports are active.

NOTE: **The R-APS protocol does not detect the number of RPL owner nodes configured on the ring. You must configure only one RPL and RPL owner per ring or protection switching will not work properly.**

Ethernet ring protection only works when one link on the ring fails. Multiple link failures will break the ring and cause protection switching to fail.

Several restrictions apply to Ethernet ring protection:

- The Ethernet ring protection configured as a single instance only works at the physical level (adjacent nodes must be directly connected). The ring protection operates at the interface (port) level and not at the VLAN level.
- Manual (command-based) switching to protection mode is not supported.
- Nonrevertive switching is not supported. When the link failure is cleared, traffic always returns to normal operation.
- The interconnection of multiple rings for protection purposes is not supported.

You can configure Ethernet ring protection to optomize traffic load-balancing by using multiple ring instances. For more information about multiple ring instances, see “Ethernet Ring Protection Using Ring Instances for Load Balancing” on page 857

Ethernet Ring Protection Using Ring Instances for Load Balancing

Juniper Network MX Series 3D Universal Edge Routers support Ethernet ring protection (ERP) to help achieve high reliability and network stability. ERP is used in router or bridge networks to protect against link failure. A single-ring topology is configured that uses one specific link called a ring protection link (RPL) to protect the whole ring. When all links are up and running, the RPL blocks traffic and remains idle. However, if a link fails, the RPL routes traffic to bypass the failure on the ring.

NOTE: **To learn how ERP works in a single-ring topology, see “Ethernet Ring Protection” on page 855.**

MX Series routers now support ERP ring instances. Whereas traffic in a single-ring topology follows the same path, traffic within ring instances allows some traffic to pass through one path while other traffic can follow a different path. Dividing traffic in this way supports traffic load balancing in the physical ring.

Ring instances are like traffic channels that contain different sets of virtual LANS (VLANs). A ring instance is responsible for the protection of a subset of VLANs that transport traffic over the physical ring. When ring instances are configured for the ring, each ring instance should have its own RPL owner, an east and a west interface, and a ring protection link end.

Each ring instance has a control channel and a specific data channel. A data channel is a group of bridge domain VLAN IDs. All VLAN IDs within the same ring interface share the same data-forwarding properties controlled by the ERP. If no data channel is defined in the ring configuration, ERP will only operate on the physical link instead of as a ring instance using logical links.

When operating ERP in a topology with other protocols, the following considerations should be observed:

- If a physical interface is part of an Ethernet ring, it cannot be configured for Spanning Tree Protocol (STP) or Multiple Spanning Tree Protocol (MSTP).
- ERP and Per-VLAN Spanning Tree (PVST) can be configured on the same topology as long as PVST doesn't share the same VLAN with any Ethernet ring instance configured on the physical port.
- If ERP is configured only as a physical ring instance (a ring without a data channel) in a topology also configured for PVST, ERP checks the PVST configuration on two ring interfaces and automatically creates a data channel excluding VLANs used by PVST.

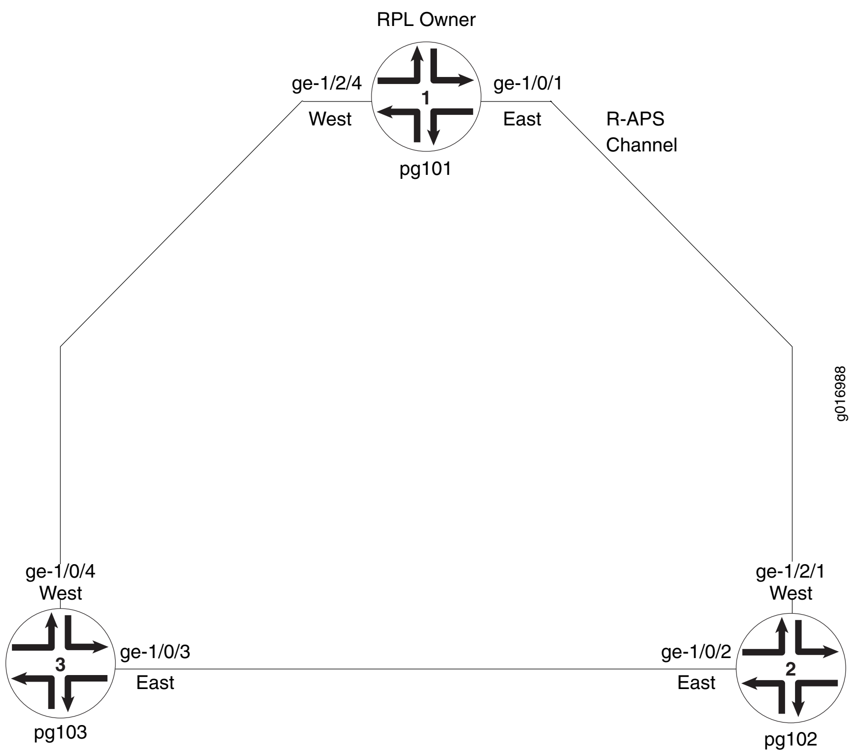
Example: Configuring Ethernet Ring Protection for MX Series Routers

This example configures Ethernet ring protection for three MX Series router nodes:

Example Topology

The links connecting the three MX Series routers are shown in Figure 55 on page 858.

Figure 55: Ethernet Ring Protection Example Nodes



This example uses the following topology details for Ethernet ring protection:

- Router 1 is the RPL owner. The node identification for Router 1 is MAC address **00:01:01:00:00:01**.
- The RPL link is **ge-1/0/1.1** (this is also the R-APS messaging control channel).
- Traffic flows among the nodes in the configured bridge domains. (That is, only the control channels are configured.)

- Router 1's east control channel interface is **ge-1/0/1.1** (the RPL) and the west control channel interface is **ge-1/2/4.1**. The protection group is **pg101**.
- Router 2's east control channel interface is **ge-1/0/2.1** (the RPL) and the west control channel interface is **ge-1/2/1.1**. The protection group is **pg102**.
- Router 3's east control channel interface is **ge-1/0/3.1** (the RPL) and the west control channel interface is **ge-1/0/4.1**. The protection group is **pg103**.

NOTE: Although not strictly required for physical ring protection, this example configures Ethernet OAM with MEPs.

Router 1 (RPL Owner) Configuration

To configure Router 1 (the RPL owner):

1. Configure the interfaces:

```
[edit]
interfaces {
  ge-1/0/1 {
    vlan-tagging;
    encapsulation flexible-ethernet-services;
    unit 1 {
      encapsulation vlan-bridge;
      vlan-id 100;
    }
  }
  ge-1/2/4 {
    vlan-tagging;
    encapsulation flexible-ethernet-services;
    unit 1 {
      encapsulation vlan-bridge;
      vlan-id 100;
    }
  }
  irb {
    unit 0 {
      family inet {
        address address 192.1.1.11/24;
      }
    }
  }
}
```

2. Configure the bridge domain:

```
[edit]
bridge-domains {
  bd1 {
    domain-type bridge;
    vlan-id 100;
    interface ge-1/2/4.1;
    interface ge-1/0/1.1;
```

```
        routing-interface irb.0;
      }
    }
```

3. Configure the Ethernet ring protection group:

```
[edit]
protocols {
  protection-group {
    ethernet-ring pg101 {
      node-id 00:01:01:00:00:01;
      ring-protection-link-owner;
      east-interface {
        control-channel ge-1/0/1.1;
        }
      ring-protection-link-end;
      west-interface {
        control-channel ge-1/2/4.1;
      }
    }
  }
}
```

4. Configure Ethernet OAM:

```
[edit]
protocols {
  oam {
    ethernet {
      connectivity-fault-management {
        action-profile rmep-defaults {
          default-action {
            interface-down;
          }
        }
        maintenance-domain d1 {
          level 0;
          maintenance-association 100 {
            mep 1 {
              interface ge-1/0/1;
              remote-mep 2 {
                action-profile rmep-defaults;
              }
            }
          }
        }
        maintenance-domain d2 {
          level 0;
          maintenance-association 100 {
            mep 1 {
              interface ge-1/2/4;
              remote-mep 2 {
                action-profile rmep-defaults;
              }
            }
          }
        }
```

```
            }
          }
        }
      }
```

Router 2 Configuration

To configure Router 2:

1. Configure the interfaces:

```
[edit]
interfaces {
  ge-1/0/2 {
    vlan-tagging;
    encapsulation flexible-ethernet-services;
    unit 1 {
      encapsulation vlan-bridge;
      vlan-id 100;
    }
  }
  ge-1/2/1 {
    vlan-tagging;
    encapsulation flexible-ethernet-services;
    unit 1 {
      encapsulation vlan-bridge;
      vlan-id 100;
    }
  }
  irb {
    unit 0 {
      family inet {
        address address 192.1.1.22/24;
      }
    }
  }
}
```

2. Configure the bridge domain:

```
[edit]
bridge-domains {
  bd1 {
    domain-type bridge;
    vlan-id 100;
    interface ge-1/2/1.1;
    interface ge-1/0/2.1;
    routing-interface irb.0;
  }
}
```

3. Configure the Ethernet protection group:

```
[edit]
protocols {
  protection-group {
    ethernet-ring pg102 {
```

```
            node-id 00:22:22:22:22:22;
            east-interface {
                control-channel ge-1/0/2.1;
            }
            west-interface {
                control-channel ge-1/2/1.1;
            }
        }
    }
}
```

4. Configure Ethernet OAM:

```
[edit]
protocols {
    oam {
        ethernet {
            connectivity-fault-management {
                action-profile rmep-defaults {
                    default-action {
                        interface-down;
                    }
                }
                maintenance-domain d1 {
                    level 0;
                    maintenance-association 100 {
                        mep 2 {
                            interface ge-1/2/1;
                            remote-mep 1 {
                                action-profile rmep-defaults;
                            }
                        }
                    }
                }
                maintenance-domain d3 {
                    level 0;
                    maintenance-association 100 {
                        mep 1 {
                            interface ge-1/0/2;
                            remote-mep 2 {
                                action-profile rmep-defaults;
                            }
                        }
                    }
                }
            }
        }
    }
}
```

Router 3 Configuration

To configure Router 3:

1. Configure the interfaces:

```
[edit]
interfaces {
   ge-1/0/4 {
      vlan-tagging;
      encapsulation flexible-ethernet-services;
      unit 1 {
         encapsulation vlan-bridge;
         vlan-id 100;
      }
   }
   ge-1/0/3 {
      vlan-tagging;
      encapsulation flexible-ethernet-services;
      unit 1 {
         encapsulation vlan-bridge;
         vlan-id 100;
      }
   }
   irb {
      unit 0 {
         family inet {
            address 192.1.1.33/24;
         }
      }
   }
}
```

2. Configure the bridge domain:

```
[edit]
bridge-domains {
   bd1 {
      domain-type bridge;
      vlan-id 100;
      interface ge-1/0/4.1;
      interface ge-1/0/3.1;
      routing-interface irb.0;
   }
}
```

3. Configure the Ethernet protection group:

```
[edit]
protocols {
   protection-group {
      ethernet-ring pg103 {
         node-id 00:33:33:33:33:33;
         east-interface {
            control-channel ge-1/0/3.1;
         }
         west-interface {
            control-channel ge-1/0/4.1;
         }
      }
   }
}
```

4. Configure Ethernet OAM:

```
[edit]
protocols {
   oam {
      ethernet {
         connectivity-fault-management {
            action-profile rmep-defaults {
               default-action {
                  interface-down;
               }
            }
            maintenance-domain d2 {
               level 0;
               maintenance-association 100 {
                  mep 2 {
                     interface ge-1/0/4;
                     remote-mep 1 {
                        action-profile rmep-defaults;
                     }
                  }
               }
            }
            maintenance-domain d3 {
               level 0;
               maintenance-association 100 {
                  mep 2 {
                     interface ge-1/0/3;
                     remote-mep 1 {
                        action-profile rmep-defaults;
                     }
                  }
               }
            }
         }
      }
   }
}
```

Example: Configuring Load Balancing Within Ethernet Ring Protection for MX Series Routers

MX Series routers support Ethernet ring protection (ERP) to help achieve high reliability and network stability. ERP is used in router or bridge networks to protect against link failure. A single-ring topology is configured that uses one specific link called a ring protection link (RPL) to protect the whole ring. When all links are up and running, the

RPL blocks traffic and remains idle. However, if a link fails, the RPL routes traffic to bypass the failure on the ring.

MX Series routers now support ERP ring instances. Whereas traffic in a ring topology follows the same path, traffic within a ring instance uses data channels to allow some traffic to pass through one path while other traffic can follow a different one. Dividing traffic in this way supports traffic load-balancing in the ring.

This example describes how to use ERP with ring instances to load-balance traffic while still providing network protection from link failure:

Requirements

This example uses the following hardware and software components:

- Two MX Series routers acting as core switches
- One MX Series router acting as an aggregation switch
- Junos OS Release 10.2 or later for MX Series routers

Overview and Topology

Figure 56 on page 866 displays the topology for this example. The topology contains three MX Series routers. CS1 and CS2 act as core routers in the topology, and AS1 acts as an aggregation switch. Each router has two ring instances, ring-1 and ring-2. All nodes on the ring coordinate protection activities by exchanging messages through the Ethernet ring automatic protection switching (R-APS) messaging protocol. Each ring instance has an RPL owner. The ring-1 RPL owner is CS1; the ring-2 RPL owner is CS2. The RPL owners block or unblock the RPL as conditions require and initiate R-APS messages.

Each ring instance has two interface ports (an east interface and a west interface) that participate in the instance. Interface **ge-2/0/8.0**, the west interface on CS2, is the ring protection link end where ring-2's RPL terminates. Interface **ge-3/2/4.0**, the east interface on CS1, is the ring protection link end where ring-1's RPL terminates.

Each ring instance has a data channel. A data channel is a group of bridge domain virtual LAN (VLAN) IDs. All VLAN IDs within the same ring interface share the same data-forwarding properties controlled by the ERP. The data channel on ring-1 is [200, 300]. The data channel on ring-2 is [500, 600].

Two customer site switches are connected to AS1. Customer site 1 uses VLANs 200 and 300. Customer site 2 uses VLANs 500 and 600.

Figure 56: ERP with Multiple Protection Instances Configured on Three MX Series Routers

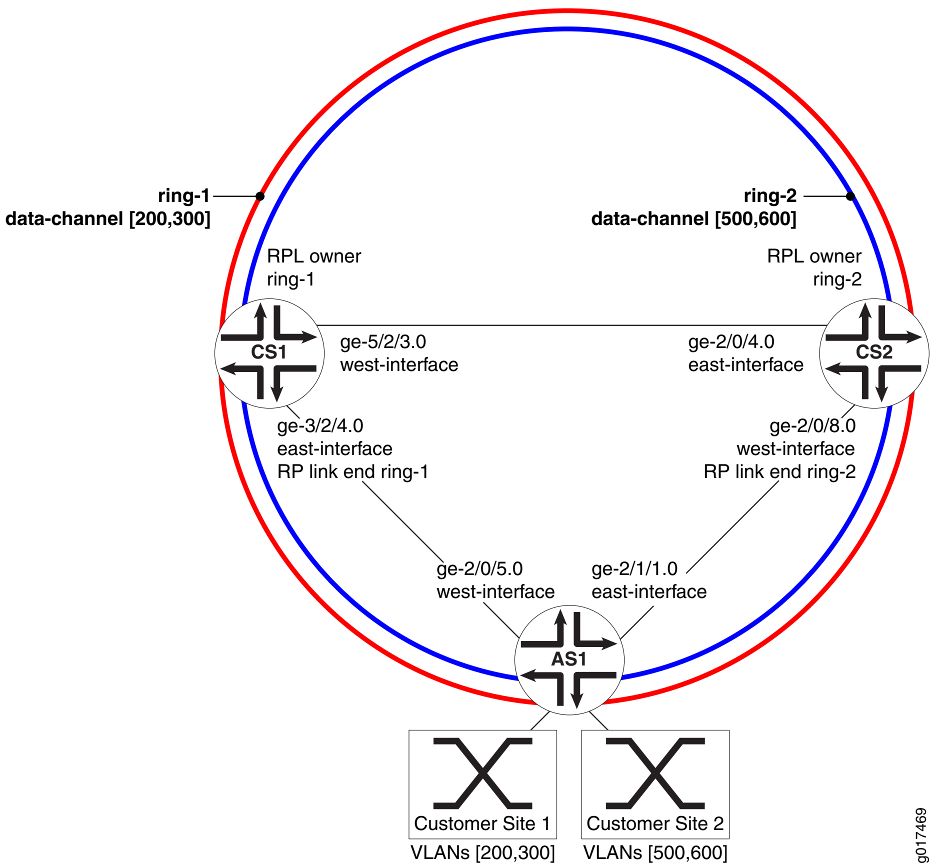

Table 83 on page 866 describes the components of the example topology.

Table 83: Components of the Network Topology

Property	Settings
Ring instances	• **ring-1**—Data channel [200,300] • **ring-2**—Data channel [500,600]
Customer sites	Two customer sites are connected to AS 1: • Customer site 1, VLAN 200 and VLAN 300 • Customer site 2, VLAN 500 and VLAN 600

Table 83: Components of the Network Topology (continued)

Property	Settings

CS1 router	CS1 has the following protection group properties:
	• RPL owner—**ring-1**.
	• East interface—**ge-3/2/4.0**.
	• West interface—**ge-5/2/3.0**.
	• Data channel for **ring-1**—**VLAN 200**, **VLAN 300**.
	• Data channel for **ring-2**—**VLAN 500**, **VLAN 600**.
	• Ring protection link end for **ring-1**—**ge-3/2/4.0**.
	CS1 has the following routing and bridging properties:
	• Routing instance—**vs**.
	• Bridge domains:
	  ◦ **bd100** is associated with **vlan-id 100**.
	  ◦ **bd101** is associated with **vlan-id 101**.
	  ◦ **bd200** is associated with **vlan-id 200**.
	  ◦ **bd300** is associated with **vlan-id 300**.
	  ◦ **bd500** is associated with **vlan-id 500**.
	  ◦ **bd600** is associated with **vlan-id 600**.

CS2 router	CS2 has the following protection group properties: • RPL owner—**ring-2**. • East interface—**ge-2/0/4.0**. • West interface—**ge-2/0/8.0**. • Ring protection link end for **ring-2**—**ge-2/0/8.0**. • Data channel for **ring-1**—**VLAN 200**, **VLAN 300**. • Data channel for **ring-2**—**VLAN 500**, **VLAN 600**. CS2 has the following bridging properties: • **bd100** is associated with **vlan-id 100**. • **bd101** is associated with **vlan-id 101**. • **bd200** is associated with **vlan-id 200**. • **bd300** is associated with **vlan-id 300**. • **bd500** is associated with **vlan-id 500**. • **bd600** is associated with **vlan-id 600**.

Table 83: Components of the Network Topology (continued)

Property	Settings
AS1 router	AS1 has the following protection group properties: • East interface—**ge-2/0/5.0**. • West interface—**ge-2/1/1.0**. • Data channel for **ring-1—VLAN 200**, **VLAN 300**. • Data channel for **ring-2—VLAN 500**, **VLAN 600**. AS1 has the following bridging properties: • **bd100** is associated with **vlan-id 100**. • **bd101** is associated with **vlan-id 101**. • **bd200** is associated with **vlan-id 200**. • **bd300** is associated with **vlan-id 300**. • **bd500** is associated with **vlan-id 500**. • **bd600** is associated with **vlan-id 600**.

Configuration

To enable ERP with ring instances on CS1, CS2, and AS1, perform these tasks:

- Configuring ERP on CS1 on page 868
- Configuring ERP on CS2 on page 871
- Configuring ERP on AS1 on page 874

Configuring ERP on CS1

CLI Quick Configuration

To quickly configure CS1 for ERP, copy the following commands and paste them into the switch terminal window of CS1:

```
[edit]
set interfaces ge-3/2/4 vlan-tagging
set interfaces ge-3/2/4 unit 0 family bridge interface-mode trunk
set interfaces ge-3/2/4 unit 0 family bridge vlan-id-list 100-1000
set interfaces ge-5/2/3 vlan-tagging
set interfaces ge-5/2/3 unit 0 family bridge interface-mode trunk
set interfaces ge-5/2/3 unit 0 family bridge vlan-id-list 100-1000
set protocols protection-group ethernet-ring ring-1 ring-protection-link-owner
set protocols protection-group ethernet-ring ring-1 east-interface control-channel ge-3/2/4.0
set protocols protection-group ethernet-ring ring-1 east-interface control-channel vlan 100
set protocols protection-group ethernet-ring ring-1 east-interface ring-protection-link-end
set protocols protection-group ethernet-ring ring-1 west-interface control-channel ge-5/2/3.0
set protocols protection-group ethernet-ring ring-1 west-interface control-channel vlan 100
set protocols protection-group ethernet-ring ring-1 data-channel vlan [200, 300]
set protocols protection-group ethernet-ring ring-2 east-interface control-channel ge-3/2/4.0
set protocols protection-group ethernet-ring ring-2 east-interface control-channel vlan 101
set protocols protection-group ethernet-ring ring-2 west-interface control-channel ge-5/2/3.0
set protocols protection-group ethernet-ring ring-2 west-interface control-channel vlan 101
set protocols protection-group ethernet-ring ring-2 data-channel vlan [500, 600]
set routing-instances vs instance-type virtual-switch
set routing-instances vs interface ge-3/2/4.0
set routing-instances vs interface ge-5/2/3.0
```

```
set routing-instances vs bridge-domains bd101 vlan-id 101
set routing-instances vs bridge-domains bd200 vlan-id 200
set routing-instances vs bridge-domains bd300 vlan-id 300
set routing-instances vs bridge-domains bd500 vlan-id 500
set routing-instances vs bridge-domains bd600 vlan-id 600
```

Step-by-Step Procedure

To configure ERP on CS1:

1. Configure the trunk interface **ge-3/2/4** to connect CS1 to CS2 and the trunk interface **ge-5/2/3** to connect CS1 to AS, and configure the **family** statement as **bridge** with a VLAN ID list of 100 through 1000:

```
[edit interfaces]
user@cs1# set ge-3/2/4 vlan-tagging
user@cs1# set ge-3/2/4 unit 0 family bridge interface-mode trunk
user@cs1# set ge-3/2/4 unit 0 family bridge vlan-id-list 100-1000
user@cs1# set ge-5/2/3 vlan-tagging
user@cs1# set ge-5/2/3 unit 0 family bridge interface-mode trunk
user@cs1# set ge-5/2/3 unit 0 family bridge vlan-id-list 100-1000
```

2. Enable ERP, specifying the control channels and data channels for **ring-1** and **ring-2**, and configure **ring-1** as the ring protection link owner:

NOTE: Always configure the **east-interface** statement first, before configuring the **west-interface** statement.

```
[edit protection-group]
user@cs1# set ethernet-ring ring-1 ring-protection-link-owner
user@cs1# set ethernet-ring ring-1 east-interface control-channel ge-3/2/4.0
user@cs1# set ethernet-ring ring-1 east-interface control-channel vlan 100
user@cs1# set ethernet-ring ring-1 east-interface ring-protection-link-end
user@cs1# set ethernet-ring ring-1 west-interface control-channel ge-5/2/3.0
user@cs1# set ethernet-ring ring-1 west-interface control-channel vlan 100
user@cs1# set ethernet-ring ring-1 data-channel vlan [200, 300]
user@cs1# set ethernet-ring ring-2 east-interface control-channel ge-3/2/4.0
user@cs1# set ethernet-ring ring-2 east-interface control-channel vlan 101
user@cs1# set ethernet-ring ring-2 west-interface control-channel ge-5/2/3.0
user@cs1# set ethernet-ring ring-2 west-interface control-channel vlan 101
user@cs1# set ethernet-ring ring-2 data-channel vlan [500, 600]
```

3. Configure the routing instance, the bridge domains, and the VLAN IDs associated with each bridge domain:

```
[edit routing-instances]
user@cs1# set vs instance-type virtual-switch
user@cs1# set vs interface ge-3/2/4.0
user@cs1# set vs interface ge-5/2/3.0
user@cs1# set vs bridge-domains bd100 vlan-id 100
user@cs1# set vs bridge-domains bd101 vlan-id 101
user@cs1# set vs bridge-domains bd200 vlan-id 200
user@cs1# set vs bridge-domains bd300 vlan-id 300
user@cs1# set vs bridge-domains bd500 vlan-id 500
```

```
user@cs1# set vs bridge-domains bd600 vlan-id 600
```

Results Check the results of the configuration:

```
user@cs1> show configuration
interfaces {
  ge-3/2/4 {
    vlan-tagging;
    unit 0 {
      family bridge {
        interface-mode trunk;
        vlan-id-list 100-1000;
      }
    }
  }
  ge-5/2/3 {
    vlan-tagging;
    unit 0 {
      family bridge {
        interface-mode trunk;
        vlan-id-list 100-1000;
      }
    }
  }
  protocols {
    protection-group {
      ethernet-ring ring-1 {
        east-interface {
          control-channel {
            ge-3/2/4.0;
            vlan 100;
          }
          ring-protection-link-end;
        }
        west-interface {
          control-channel {
            ge-5/2/3.0;
            vlan 100;
          }
        }
        data-channel {
          vlan [ 200 300 ];
        }
      }
    }
    protection-group {
      ethernet-ring ring-2{
        east-interface {
          control-channel {
            ge-3/2/4.0;
            vlan 101;
          }
        }
        west-interface {
```

```
            control-channel {
              ge-5/2/3.0;
              vlan 101;
            }
          }
          data-channel {
            vlan [ 500 600 ];
          }
        }
      }
    }
    routing-instances {
      vs {
        instance-type virtual-switch;
        interface ge-3/2/4.0;
        interface ge-5/2/3.0;
        bridge-domains {
          bd100 {
            vlan-id 100;
          }
          bd101 {
            vlan-id 101;
          }
          bd200 {
            vlan-id 200;
          }
          bd300 {
            vlan-id 300;
          }
          bd500 {
            vlan-id 500;
          }
          bd600 {
            vlan-id 600;
          }
        }
      }
    }
  }
```

Configuring ERP on CS2

CLI Quick Configuration

To quickly configure CS2 for ERP, copy the following commands and paste them into the switch terminal window of CS2:

```
[edit]
set interfaces ge-2/0/4 unit 0 family bridge interface-mode trunk
set interfaces ge-2/0/4 unit 0 family bridge vlan-id-list 100-1000
set interfaces ge-2/0/8 unit 0 family bridge interface-mode trunk
set interfaces ge-2/0/8 unit 0 family bridge vlan-id-list 100-1000
set protocols protection-group ethernet-ring ring-1 east-interface control-channel ge-2/0/4.0
set protocols protection-group ethernet-ring ring-1 east-interface control-channel vlan 100
set protocols protection-group ethernet-ring ring-1 west-interface control-channel ge-2/0/8.0
set protocols protection-group ethernet-ring ring-1 west-interface control-channel vlan 100
set protocols protection-group ethernet-ring ring-1 data-channel vlan [200, 300]
```

```
set protocols protection-group ethernet-ring ring-2 ring-protection-link-owner
set protocols protection-group ethernet-ring ring-2 east-interface control-channel ge-2/0/4.0
set protocols protection-group ethernet-ring ring-2 east-interface control-channel vlan 101
set protocols protection-group ethernet-ring ring-2 west-interface control-channel ge-2/0/8.0
set protocols protection-group ethernet-ring ring-2 west-interface ring-protection-link-end
set protocols protection-group ethernet-ring ring-2 west-interface control-channel vlan 101
set protocols protection-group ethernet-ring ring-2 data-channel vlan [500, 600]
set bridge-domains bd100 vlan-id 100
set bridge-domains bd101 vlan-id 101
set bridge-domains bd200 vlan-id 200
set bridge-domains bd300 vlan-id 300
set bridge-domains bd500 vlan-id 500
set bridge-domains bd600 vlan-id 600
```

Step-by-Step Procedure

To configure ERP on CS2:

1. Configure the trunk interface **ge-2/0/4** to connect CS2 to CS1 and trunk interface **ge-2/0/8** to connect CS2 to CS1, and configure the **family** statement as **bridge** with a VLAN ID list of 100 through 1000:

```
[edit interfaces]
user@cs2# set ge-2/0/4 unit 0 family bridge interface-mode trunk
user@cs2# set ge-2/0/4 unit 0 family bridge vlan-id-list 100-1000
user@cs2# set ge-2/0/8 unit 0 family bridge interface-mode trunk
user@cs2# set ge-2/0/8 unit 0 family bridge vlan-id-list 100–1000
```

2. Enable ERP, specifying the control channels and data channels for **ring-1** and **ring-2**, and configure **ring-2** as the ring protection link owner:

NOTE: Always configure the **east-interface** statement first, before configuring the **west-interface** statement.

```
[edit protection-group]
user@cs2# set ethernet-ring ring-1 east-interface control-channel ge-2/0/4.0
user@cs2# set ethernet-ring ring-1 east-interface control-channel vlan 100
user@cs2# set ethernet-ring ring-1 west-interface control-channel ge-2/0/8.0
user@cs2# set ethernet-ring ring-1 west-interface control-channel vlan 100
user@cs2# set ethernet-ring ring-2 data-channel vlan [200, 300]
user@cs2# set ethernet-ring ring-2 east-interface control-channel ge-2/0/4.0
user@cs2# set ethernet-ring ring-2 east-interface control-channel vlan 101
user@cs2# set ethernet-ring ring-2 ring-protection-link-owner
user@cs2# set ethernet-ring ring-2 west-interface control-channel ge-2/0/8.0
user@cs2# set ethernet-ring ring-2 west-interface control-channel vlan 101
user@cs2# set ethernet-ring ring-2 west-interface ring-protection-link-end
user@cs2# set ethernet-ring ring-2 data-channel vlan [500, 600]
```

3. Configure the routing instance, the bridge domains, and the VLAN IDs associated with each bridge domain:

```
[edit bridge-domains]
user@cs2# set bd100 vlan-id 100
user@cs2# set bd101 vlan-id 101
user@cs2# set bd200 vlan-id 200
```

```
user@cs2# set bd300 vlan-id 300
user@cs2# set bd500 vlan-id 500
user@cs2# set bd600 vlan-id 600
```

Results Check the results of the configuration:

```
user@cs2> show configuration
interfaces {
  ge-2/0/4 {
    unit 0 {
      family bridge {
        interface-mode trunk;
        vlan-id-list 100-1000;
      }
    }
  }
  ge-2/0/8 {
    unit 0 {
      family bridge {
        interface-mode trunk;
        vlan-id-list 100-1000;
      }
    }
  }
  protocols {
    protection-group {
      ethernet-ring ring-1 {
        east-interface {
          control-channel {
            ge-2/0/4.0;
            vlan 100;
          }
        }
        west-interface {
          control-channel {
            ge-2/0/8.0;
            vlan 100;
          }
        }
        data-channel {
          vlan [200, 300];
        }
      }
    }
    ethernet-ring ring-2 {
      east-interface {
        control-channel {
          ge-2/0/4.0;
          vlan 101;
        }
      }
      west-interface {
        control-channel {
          ge-2/0/8.0;
```

```
                vlan 101;
              }
              ring-protection-link-end;
            }
            data-channel {
              vlan [500, 500];
            }
          }
        }
        bridge-domains {
          bd100 {
            vlan-id 100;
          }
          bd101 {
            vlan-id 101;
          }
          bd200 {
            vlan-id 200;
          }
          bd300 {
            vlan-id 300;
          }
          bd500 {
            vlan-id 500;
          }
          bd600 {
            vlan-id 600;
          }
        }
      }
```

Configuring ERP on AS1

CLI Quick Configuration

To quickly configure AS1 for ERP, copy the following commands and paste them into the switch terminal window of AS1:

```
[edit]
set interfaces ge-2/0/5 unit 0 family bridge interface-mode trunk
set interfaces ge-2/0/5 unit 0 family bridge vlan-id-list 100-1000
set interfaces ge-2/1/1 unit 0 family bridge interface-mode trunk
set interfaces ge-2/1/1 unit 0 family bridge vlan-id-list 100-1000
set protocols protection-group ethernet-ring ring-1 east-interface control-channel ge-2/0/5.0
set protocols protection-group ethernet-ring ring-1 east-interface control-channel vlan 100
set protocols protection-group ethernet-ring ring-1 west-interface control-channel ge-2/1/1.0
set protocols protection-group ethernet-ring ring-1 west-interface control-channel vlan 100
set protocols protection-group ethernet-ring ring-1 data-channel vlan [200, 300]
set protocols protection-group ethernet-ring ring-2 east-interface control-channel ge-2/0/5.0
set protocols protection-group ethernet-ring ring-2 east-interface control-channel vlan 101
set protocols protection-group ethernet-ring ring-2 west-interface control-channel ge-2/1/1.0
set protocols protection-group ethernet-ring ring-2 west-interface control-channel vlan 101
set protocols protection-group ethernet-ring ring-2 data-channel vlan [500, 600]
set bridge-domains bd100 vlan-id 100
set bridge-domains bd101 vlan-id 101
set bridge-domains bd200 vlan-id 200
set bridge-domains bd300 vlan-id 300
set bridge-domains bd500 vlan-id 500
```

set bridge-domains bd600 vlan-id 600

Step-by-Step Procedure

To configure ERP on AS1:

1. Configure the trunk interface **ge-2/0/5** to connect CS2 to CS1 and trunk interface **ge-2/1/1** to connect CS2 to CS1, and configure the **family** statement as **bridge** with a VLAN ID list of 100 through 1000:

```
[edit interfaces]
user@as1# set ge-2/0/5 unit 0 family bridge interface-mode trunk
user@as1# set ge-2/0/5 unit 0 family bridge vlan-id-list 100-1000
user@as1# set ge-2/1/1 unit 0 family bridge interface-mode trunk
user@as1# set ge-2/1/1 unit 0 family bridge vlan-id-list 100
```

2. Enable ERP, specifying the control channels and data channels for **ring-1** and **ring-2**:

NOTE: Always configure the **east-interface** statement first, before configuring the **west-interface** statement.

```
[edit protection-group]
user@as1# set ethernet-ring ring-1 east-interface control-channel ge-2/0/5.0
user@as1# set ethernet-ring ring-1 east-interface control-channel vlan 100
user@as1# set ethernet-ring ring-1 west-interface control-channel ge-2/1/1.0
user@as1# set ethernet-ring ring-1 west-interface control-channel vlan 100
user@as1# set ethernet-ring ring-2 east-interface control-channel ge-2/0/5.
user@as1# set ethernet-ring ring-2 east-interface control-channel vlan 101
user@as1# set ethernet-ring ring-2 west-interface control-channel ge-2/1/1.0
user@as1# set ethernet-ring ring-2 west-interface control-channel vlan 101
user@as1# set ethernet-ring ring-2 data-channel vlan [500, 600]
```

3. Configure the routing instance, the bridge domains, and the VLAN IDs associated with each bridge domain:

```
[edit bridge-domains]
user@as1# set bd100 vlan-id 100
user@as1# set bd101 vlan-id 101
user@as1# set bd200 vlan-id 200
user@as1# set bd300 vlan-id 300
user@as1# set bd500 vlan-id 500
user@as1# set bd600 vlan-id 600
```

Results

Check the results of the configuration:

```
user@as1> show configuration
interfaces {
  ge-2/0/5 {
    unit 0 {
      family bridge {
        interface-mode trunk;
        vlan-id-list 100-1000
      }
```

```
        }
    }
    ge-2/1/1 {
        unit 0 {
            family bridge {
                interface-mode trunk;
                vlan-id-list 100-1000
            }
        }
    }
    protocols {
        protection-group {
            ethernet-ring ring-1 {
                east-interface {
                    control-channel {
                        ge-2/0/5.0;
                        vlan 100;
                    }
                }
                west-interface {
                    control-channel {
                        ge-2/1/1.0;
                        vlan 100;
                    }
                }
                data-channel {
                    vlan [200, 300];
                }
            }
        }
    }
    protection-group {
        ethernet-ring ring-2 {
            east-interface {
                control-channel {
                    ge-2/0/5.0;
                    vlan 101;
                }
            }
            west-interface {
                control-channel {
                    ge-2/1/1.0;
                    vlan 101;
                }
            }
            data-channel {
                vlan [500, 600];
            }
        }
    }
    bridge-domains {
        bd100 {
            vlan-id 100;
        }
        bd101 {
            vlan-id 101;
```

```
        }
        bd200 {
          vlan-id 200;
        }
        bd300 {
          vlan-id 300;
        }
        bd500 {
          vlan-id 500;
        }
        bd600 {
          vlan-id 600;
        }
      }
    }
```

Verification

To confirm that the ERP configuration for multiple ring instances is operating, perform these tasks:

Verifying the Ethernet Protection Ring on CS1

Purpose Verify that ERP is enabled on CS1.

Action Show the status of the ring automatic protection switching (R-APS) messages to determine if there is a ring failure:

```
user@cs1>show protection-group ethernet-ring aps

Ethernet Ring Name   Request/state  No Flush  Ring Protection  Originator  Remote
 Node ID
                                               Link Blocked
ring-1               NR             No         Yes              Yes
ring-2               NR             No         Yes              No
13:22:af:31:fc:00
```

Meaning The output displayed shows that protection groups **ring-1** and **ring-2** have a **Request/state** of **NR**, meaning there is no request for APS on the ring. If a **Request/state** of **SF** is displayed, it indicates there is a signal failure on the ring. The output also shows that the ring protection link is not blocked. The **No Flush** field displays **No**, indicating that MAC addresses will be flushed when the ring nodes receive this message first time. A value of **Yes** would indicate MAC address flushing is not needed. The **Originator** field for **ring-1** displays **yes**, indicating that this node is an R-APS originator.

Verifying the Data Channel CS1

Purpose Verify the forwarding state of the data channel.

Action List the interfaces acting as the control channels and their respective data channels (represented by the Spanning Tree Protocol (STP) index number):

```
user@cs1>show protection-group ethernet-ring data-channel
Ethernet ring data channel parameters for protection group ring-1

Interface     STP index   Forward State
ge-3/2/4      122         forwarding
ge-5/2/3      123         forwarding

Ethernet ring data channel parameters for protection group ring-2

Interface     STP index   Forward State

ge-3/2/4      124         discarding
ge-5/2/3      125         forwarding
```

Meaning The output displayed shows the STP index number used by each interface in ring instances **ring-1** and **ring-2**. The STP index controls the forwarding behavior for a set of VLANs on the data channel of a ring instance on a ring interface. For ring instances, there are multiple STP index numbers (here representing VLANs 200, 300, 500, and 600). The **Forward State** shows whether the data channel is **forwarding** or **discarding** traffic.

Verifying the VLANs on CS1

Purpose Verify the data channel logical interfaces and the VLAN IDs controlled by a ring instance data channel.

Action List dynamic VLAN membership:

```
user@cs1>show protection-group ethernet-ring vlan
Ethernet ring IFBD parameters for protection group ring-1

Interface     Vlan     STP Index    Bridge Domain
ge-3/2/4      200      122          vs/bd200
ge-5/2/3      200      123          vs/bd200
ge-3/2/4      300      122          vs/bd300
ge-5/2/3      300      123          vs/bd300

Ethernet ring IFBD parameters for protection group ring-2
```

```
Interface     Vlan     STP Index     Bridge Domain
ge-3/2/4      500      124           vs/bd500
ge-5/2/3      500      125           vs/bd500
ge-3/2/4      600      124           vs/bd600
ge-5/2/3      600      125           vs/bd600
```

Meaning The output displayed shows the ring interfaces **ge-3/2/4** and **ge-5/2/3** in protection groups **ring-1** and **ring-2**. For **ring-1**, VLAN 200 and VLAN 300 are being supported on both **STP Index 122** and **123** on bridge domains **bd200** and **bd300**. For **ring-2**, VLAN 500 and VLAN 600 are being supported on both **STP Index 124** and **125** on bridge domains **bd500** and **bd600**. The data channel controls the traffic on the VLAN IDs to facilitate load balancing.

Verifying the Ethernet Protection Ring on CS2

Purpose Verify that ERP is enabled on CS2.

Action Show the status of the ring APS (R-APS) messages to determine if there is a ring failure:

```
user@cs2>show protection-group ethernet-ring aps

Ethernet Ring Name    Request/state  No Flush  Ring Protection  Originator  Remote
 Node ID
                                               Link Blocked
Ring-1                 NR             No        No                No
00:21:59:03:ff:d0
Ring-2                 NR             No        Yes               Yes
```

Meaning The output displayed shows that protection groups **ring-1** and **ring-2** have a **Request/state** of **NR**, meaning there is no request for APS on the ring. If a **Request/state** of **SF** is displayed, it indicates there is a signal failure on the ring. The output also shows that the ring protection link is not blocked. The **No Flush** field displays **No**, indicating that MAC addresses will be flushed when the ring nodes receive this message first time. A value of **Yes** would indicate MAC address flushing is not needed. The **Originator** field for **ring-1** displays **yes**, indicating that this node is an R-APS originator. The **Originator** field for **ring-2** displays **No**, indicating that this node is not an R-APS originator.

Verifying the Data Channel CS2

Purpose Verify the forwarding state of the data channel.

Action List the interfaces acting as the control channels and their respective data channels (represented by the STP index number):

```
user@cs2> show protection-group ethernet-ring data-channel
Ethernet ring data channel parameters for protection group ring-1
```

```
Interface     STP index  Forward State
ge-2/0/4      44         forwarding
ge-2/0/8      45         forwarding

Ethernet ring data channel parameters for protection group ring-2

Interface     STP index  Forward State
ge-2/0/4      46         forwarding
ge-2/0/8      47         discarding
```

Meaning The output displayed shows the STP index number used by each interface in ring instances **ring-1** and **ring-2**. The STP index controls the forwarding behavior for a set of VLANs on the data channel of a ring instance on a ring interface. For ring instances, there are multiple STP index numbers (here representing VLANs 200, 300, 500, and 600). The **Forward State** shows whether the data channel is **forwarding** or **discarding** traffic.

Verifying the VLANs on CS2

Purpose Verify the data channel logical interfaces and the VLAN IDs controlled by a ring instance data channel.

Action List dynamic VLAN membership:

```
user@cs2> show protection-group ethernet-ring vlan
Ethernet ring IFBD parameters for protection group ring-1

Interface     Vlan     STP Index     Bridge Domain
ge-2/0/4      200      44            default-switch/bd200
ge-2/0/8      200      45            default-switch/bd200
ge-2/0/4      300      44            default-switch/bd300
ge-2/0/8      300      45            default-switch/bd300

Ethernet ring IFBD parameters for protection group ring-2

Interface     Vlan     STP Index     Bridge Domain
ge-2/0/4      500      46            default-switch/bd500
ge-2/0/8      500      47            default-switch/bd500
ge-2/0/4      600      46            default-switch/bd600
ge-2/0/8      600      47            default-switch/bd600
```

Meaning The output displayed shows the ring interfaces **ge-2/0/4** and **ge-2/0/8** in protection groups **ring-1** and **ring-2**. For **ring-1**, VLAN 200 and VLAN 300 are being supported on both **STP Index 44** and **45** on bridge domains **bd200** and **bd300**. For **ring-2**, VLAN 500 and VLAN 600 are being supported on both **STP Index 46** and **47** on bridge domains **bd500** and **bd600**. The data channel controls the traffic on the VLAN IDs to facilitate load balancing.

Verifying the Ethernet Protection Ring on AS1

Purpose Verify that ERP is enabled on AS1.

Action Show the status of the ring APS (R-APS) messages to determine if there is a ring failure:

```
user@as1> show protection-group ethernet-ring aps

Ethernet Ring Name    Request/state  No Flush  Ring Protection  Originator  Remote
 Node ID
                                                 Link Blocked
Ring-1                 NR             No         Yes               No
00:21:59:03:ff:d0
Ring-2                 NR             No         Yes               No
13:22:af:31:fc:00
```

Meaning The output displayed shows that protection groups **ring-1** and **ring-2** have a **Request/state** of **NR**, meaning there is no request for APS on the ring. If a **Request/state** of **SF** is displayed, it indicates there is a signal failure on the ring. The output also shows that the ring protection link is not blocked. The **No Flush** field displays **No**, indicating that MAC addresses will be flushed when the ring nodes receive this message first time. A value of **Yes** would indicate MAC address flushing is not needed. The **Originator** field for **ring-1** and **ring-2** displays **No**, indicating that this node is not the R-APS originator.

Verifying the Data Channels on AS1

Purpose Verify the forwarding state of the data channel.

Action List the interfaces acting as the control channels and their respective data channels (represented by the STP index number):

```
user@as1>show protection-group ethernet-ring data-channel
Ethernet ring data channel parameters for protection group ring-1

Interface     STP index  Forward State
ge-2/0/5      22         forwarding
ge-2/1/1      23         forwarding

Ethernet ring data channel parameters for protection group ring-2

Interface     STP index  Forward State
ge-2/0/5      24         forwarding
ge-2/1/1      25         forwarding
```

Meaning The output displayed shows the STP index number used by each interface in ring instances **ring-1** and **ring-2**. The STP index controls the forwarding behavior for a set of VLANs on the data channel of a ring instance on a ring interface. For ring instances, there are multiple STP index numbers (here representing VLANs 200, 300, 500, and 600). The **Forward**

State shows whether the data channel is **forwarding** or **discarding** traffic. All data channels are forwarding traffic.

Verifying the VLANs on AS1

Purpose Verify the data channel logical interfaces and the VLAN IDs controlled by a ring instance data channel.

Action List dynamic VLAN membership:

```
user@as1>show protection-group ethernet-ring vlan

Ethernet ring IFBD parameters for protection group ring-1

Interface     Vlan     STP Index     Bridge Domain
ge-2/0/5      200      22            default-switch/bd200
ge-2/1/1      200      23            default-switch/bd200
ge-2/0/5      300      22            default-switch/bd300
ge-2/1/1      300      23            default-switch/bd300

Ethernet ring IFBD parameters for protection group ring-2

Interface     Vlan     STP Index     Bridge Domain
ge-2/0/5      500      24            default-switch/bd500
ge-2/1/1      500      25            default-switch/bd500
ge-2/0/5      600      24            default-switch/bd600
ge-2/1/1      600      25            default-switch/bd600
```

Meaning The output displayed shows the ring interfaces **ge-2/0/5** and **ge-2/1/1** in protection groups **ring-1** and **ring-2**. For **ring-1**, VLAN 200 and VLAN 300 are being supported on both **STP Index 22** and **23** on bridge domains **bd200** and **bd300**. For **ring-2**, VLAN 500 and VLAN 600 are being supported on both **STP Index 24** and **25** on bridge domains **bd500** and **bd600**. The data channel controls the traffic on the VLAN IDs to facilitate load-balancing.

Example: Viewing Ethernet Ring Protection Status—Normal Ring Operation

Under normal operating conditions, when Ethernet ring protection is configured correctly, the ring protection link (RPL) owner (Router 1 in the configuration example) will see the following:

Router 1 Operational Commands (Normal Ring Operation)

```
user@router1> show protection-group ethernet-ring aps
Ethernet Ring Name   Request/state   No Flush   Ring Protection Link Blocked
pg101                NR              No         Yes
```

```
Originator  Remote Node ID
Yes
```

Note that the ring protection link is blocked and the node is marked as the originator of the protection.

```
user@router1> show protection-group ethernet-ring interface
Ethernet ring port parameters for protection group pg101

Interface    Control Channel  Forward State  Ring Protection Link End
ge-1/0/1     ge-1/0/1.1       discarding     Yes
ge-1/2/4     ge-1/2/4.1       forwarding     No

Signal Failure  Admin State
Clear          IFF ready
Clear          IFF ready
```

Note that the protection interface is discarding while the other interface is forwarding.

```
user@router1> show protection-group ethernet-ring node-state
Ethernet ring    APS State    Event         Ring Protection Link Owner
pg101            idle         NR-RB         Yes

Restore Timer  Quard Timer  Operation state
disabled       disabled    operational
```

Note that Router 1 is the owner and timers are disabled.

```
user@router1> show protection-group ethernet-ring statistics group-name pg101
Ethernet Ring statistics for PG pg101
RAPS sent                         : 1
RAPS received                     : 0
Local SF happened:                : 0
Remote SF happened:               : 0
NR event happened:                : 0
NR-RB event happened:             : 1
```

Note that only minimal RAPS messages have been sent to establish the ring.

Under normal operating conditions, the other routers on the ring (Router 2 and Router 3) will see the following similar output:

Router 2 and Router 3 Operational Commands (Normal Ring Operation)

```
user@router2> show protection-group ethernet-ring aps
Ethernet Ring Name  Request/state  No Flush  Ring Protection Link Blocked
pg102               NR             No        Yes

Originator  Remote Node ID
No          00:01:01:00:00:01
```

Router 3 will see almost identical information.

```
user@router2> show protection-group ethernet-ring interface
Ethernet ring port parameters for protection group pg102
```

```
Interface     Control Channel  Forward State  Ring Protection Link End
ge-1/2/1      ge-1/2/1.1       forwarding     No
ge-1/0/2      ge-1/0/2.1       forwarding     No

Signal Failure  Admin State
Clear          IFF ready
Clear          IFF ready
```

Note that both interfaces are forwarding. Router 3 will see almost identical information.

```
user@router2> show protection-group ethernet-ring node-state
Ethernet ring     APS State     Event        Ring Protection Link Owner
pg102             idle          NR-RB        No

Restore Timer  Quard Timer  Operation state
disabled       disabled    operational
```

Note that Router 2 is not the owner. Router 3 will see almost identical information.

```
user@router2> show protection-group ethernet-ring statistics group-name pg102
Ethernet Ring statistics for PG pg102
RAPS sent                         : 0
RAPS received                     : 1
Local SF happened:                : 0
Remote SF happened:               : 0
NR event happened:                : 0
NR-RB event happened:             : 1
```

Router 3 will see almost identical information.

Example: Viewing Ethernet Ring Protection Status—Ring Failure Condition

This section assumes that Ethernet ring protection is configuring correctly, that Router 1 is the ring protection link (RPL) owner, and that there is a link failure between Router 2 and Router 3 in the configuration example.

Router 1 Operational Commands (Ring Failure Condition)

```
user@router1> show protection-group ethernet-ring aps
Ethernet Ring Name  Request/state  No Flush  Ring Protection Link Blocked
pg101               SF             NO        No

Originator  Remote Node ID
No          00:01:02:00:00:01
```

Note that the ring protection link is no longer blocked and the node is no longer marked as originator.

```
user@router1> show protection-group ethernet-ring interface
Ethernet ring port parameters for protection group pg101

Interface    Control Channel  Forward State  Ring Protection Link End
ge-1/0/1     ge-1/0/1.1       forwarding     Yes
ge-1/2/4     ge-1/2/4.1       forwarding     No

Signal Failure  Admin State
Clear           IFF ready
Clear           IFF ready
```

Note that the protection interface is now forwarding (so is the other interface).

```
user@router1> show protection-group ethernet-ring node-state
how protection-group ethernet-ring node-state
Ethernet ring    APS State    Event         Ring Protection Link Owner
pg101            protected    SF            Yes

Restore Timer  Quard Timer  Operation state
disabled       disabled     operational
```

Note that Router 1 has recorded the span failure (SF).

```
user@router1> show protection-group ethernet-ring statistics group-name pg101
Ethernet Ring statistics for PG pg101
RAPS sent                        : 1
RAPS received                    : 1
Local SF happened:               : 0
Remote SF happened:              : 1
NR event happened:               : 0
NR-RB event happened:            : 1
```

Note that the R-APS messages have recorded the remote failure.

Under a failure condition, the other routers on the ring (Router 2 and Router 3) will see the following similar output:

Router 2 and Router 3 Operational Commands (Failure Condition)

```
user@router2> show protection-group ethernet-ring aps
Ethernet Ring Name  Request/state  No Flush  Ring Protection Link Blocked
pg102               SF             No        No

Originator  Remote Node ID
Yes         00:00:00:00:00:00
```

Note the failure event (SF). Router 3 will see almost identical information.

```
user@router2> show protection-group ethernet-ring interface
Ethernet ring port parameters for protection group pg102

Interface    Control Channel  Forward State  Ring Protection Link End
ge-1/2/1     ge-1/2/1.1       forwarding     No
```

```
ge-1/0/2      ge-1/0/2.1       discarding     No

Signal Failure  Admin State
Clear           IFF ready
set             IFF ready
```

Note that the failed interface (**ge-1/0/2.1**) is not forwarding. Router 3 will see almost identical information.

```
user@router2> show protection-group ethernet-ring node-state
Ethernet ring     APS State     Event         Ring Protection Link Owner
pg102             idle          NR-RB         No

Restore Timer  Quard Timer  Operation state
disabled       disabled     operational
```

Note that Router 2 is not the owner. Router 3 will see almost identical information.

```
user@router2> show protection-group ethernet-ring statistics group-name pg102
Ethernet Ring statistics for PG pg102
RAPS sent                       : 1
RAPS received                   : 1
Local SF happened:              : 1
Remote SF happened:             : 0
NR event happened:              : 0
NR-RB event happened:           : 1
```

Note that the R-APS messages have recorded the remote failure. Router 3 will see almost identical information.

CHAPTER 35

CFM Action Profile to Bring Down a Group of Logical Interfaces

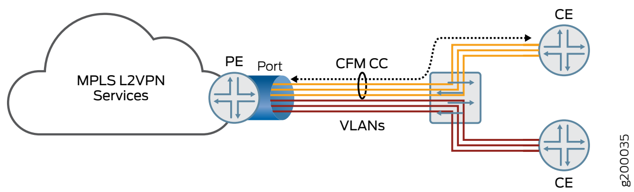
CFM Action Profile to Bring Down a Group of Logical Interfaces Overview

With growing networks, there is a requirement of monitoring a large number of services using CFM. To monitor each service, one session per service logical interface is required. If the services are large in number, this method does not scale as the number of sessions are limited. Instead of one CFM session per service, a single CFM session can monitor multiple services.

Also, there are scenarios where the user-to-network interface (UNI) device needs to be brought down based on sessions on network-to-network Interface (NNI) logical interface. Here, the NNI logical interface refers to core interface and UNI physical interface refers to access interface hosting multiple service logical interfaces. Based on core interface monitoring, you can bring down service logical interfaces associated with access interface.

Figure 57 on page 888 illustrates a topology where a number of services destined to customer-edge (CE) routers share a single port on a provider-edge (PE) router. Each service uses one logical interface. A set of services or logical interfaces (colored in yellow) are destined to one CE router and a set of services or logical interfaces colored in red are destined to another CE router. To monitor each service, you need dedicated down maintenance association end point (MEP) sessions for each service. You can bring down the service by bringing down the service logical interface whenever the session goes down. However, this approach is not scalable if we have large number of services. Monitoring the CFM session on the physical interface is also not feasible because multiple CE routers might be connected and the services to other CE router could be disrupted. To address this issue of monitoring multiple services with a single session, you can create a CCM action profile to bring down a group of logical interfaces by using a CFM session that is configured on a single logical interface.

Figure 57: Topology of Multiple VLAN Services Sharing a Single Port on PE Router Destined to Multiple CE Routers



You can configure CCM action profiles for the following scenarios:

- To bring down a group of logical interfaces all having the same parent port when CCM monitoring session is running on one of the logical interface but on a different parent port.
- To bring down a group of logical interfaces when CCM monitoring session is running on one of the logical interfaces, all belonging to the same parent port.
- To bring down the port, when the CCM monitoring session is running on one of the logical interfaces of a different parent port.

Benefits of Creating CFM Action Profile to Bring Down a Group of Logical Interfaces

- Reduces resource requirement in scaled networks where multiple services need to be monitored.
- Avoids the need to create individual MEP sessions for each service in a topology that includes multiple services to be monitored, thereby enhancing the performance and scalability of the network.

Related Documentation

- Configuring a CFM Action Profile to Bring Down a Group of Logical Interfaces on page 888

Configuring a CFM Action Profile to Bring Down a Group of Logical Interfaces

To monitor multiple services or IFLs using CFM session configured on a single logical interface, you can create a CCM action profile to bring down a group of logical interfaces. You need to define an action to bring down the interface group in the action profile. You will then define the interface device name and the number of logical interfaces that have to be brought down. A logical interface is represented by a combination of the **interface-device-name** and **unit-list**. The following steps explain the procedure to bring down a group of logical interfaces when the **interface-device-name** and/or **unit-list** are specified.

1. In configuration mode, at the [**edit protocols oam ethernet connectivity-fault-management**] hierarchy level, specify the name of the action profile and the CFM event(s). You can configure more than one event in the action profile.

   [edit protocols oam ethernet connectivity-fault-management]
   user@host# set action-profile *profile-name* event [*event1*, *event2*, *event3*..]

For example,

```
user@host# set action-profile AP_test event adjacency-loss rdi
```

NOTE: The action **interface-group-down** will not be supported with events other than adjacency-loss and RDI. Any other events configured results in a commit error.

2. In configuration mode, at the [**edit protocols oam ethernet connectivity-fault-management action-profile *profile-name***] hierarchy level, define the action to bring down the interface group.

```
[edit protocols oam ethernet connectivity-fault-management action-profile AP-test ]
user@host# set action interface-group-down
```

NOTE: The action **interface-group-down** will not be supported with other interface related actions. Any other actions configured results in a commit error.

3. At the [**edit protocols oam ethernet connectivity-fault-management**] hierarchy level, define the maintenance domain. Specify the maintenance-association parameters.

```
[edit protocols oam ethernet connectivity-fault-management]
user@host# set maintenance-domain domain-name  level number
  maintenance-association ma-name continuity-check interval 1s
```

For example,

```
user@host# set maintenance-domain md6 level 6 maintenance-association ma6
  continuity-check interval 1s
```

4. At the **edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name***, define the maintenance association endpoint and the associated parameters.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  md-name maintenance-association ma-name]
user@host# set mep mep-id interface interface-name direction down remote -mep
  mep-id
```

For example,

```
user@host# set mep 101 interface ge-0/0/0.0 direction down remote -mep 102
```

5. If the action-profile has **interface-group-down** action configured, it is mandatory to configure the **interface-group** at the RMEP level. In the configuration mode at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id* remote-mep *mep-id* action-profile *profile-name*** include the **interface-group** statement to bring down the interface group marked with the action profile as **interface-group-down**.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  md-name maintenance-association ma-name mep mep-id remote-mep mep-id
  action-profile profile-name]
user@host# set interface-group
```

For example,

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  md6 maintenance-association ma6 mep 101 remote-mep 102 action-profile AP_test]
user@host# set interface-group
```

NOTE: If the **interface-group** configuration is not included in the RMEP configuration. The configuration results in commit error.

6. A logical interface is represented by a combination of the **interface-device-name** and **unit-list**. Configure the device interface name and the number of logical interfaces at the **[edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id* remote-mep *mep-id* action-profile *profile-name* interface-group**.

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  md-name maintenance-association ma-name mep mep-id remote-mep mep-id
  action-profile profile-name interface-group]
user@host# set interface interface-name
user@host# set unit-list logical-interface-unit-number
```

For example,

```
[edit protocols oam ethernet connectivity-fault-management maintenance-domain
  md6 maintenance-association ma6 mep 101 remote-mep 102 action-profile AP_test
  interface-group]
user@host# set interface ge-0/0/0.0
user@host# set unit-list 1223-3344
```

In this configuration example, the interface ge-0/0/0.0 is brought down.

NOTE:

- At least one of the **interface-group** parameters, **interface-device-name** or **unit-list** must be configured. If the interface device name is not configured, the MEP interface is considered as the device name and the logical interface on that device is brought down.
- If the **unit-list** parameter exceeds the recommended limit, a commit error occurs.
- If the *interface-device-name* is not specified in the **interface-group**, the logical interface numbers mentioned in **unit-list** for the physical interface is brought down.
- If the *unit-list* is not specified in the **interface-group**, IFLs are brought down for the configured interface.

7. Verify the configuration using **show protocols oam** command.

   [edit]
   user@host# **show protocols oam**

```
ethernet {
    connectivity-fault-management {
        action-profile AP_TEST {
            event {
                adjacency-loss;
                rdi;
            }
            action {
                interface-group-down;
            }
        }
        maintenance-domain md6 {
            level 6;
            maintenance-association ma6 {
                continuity-check {
                    interval 1s;
                }
                mep 102 {
                    interface ge-0/0/0.0;
                    direction down;
                    remote-mep 103 {
                        action-profile AP_TEST;
                        interface-group {
                          ge-0/0/1;
                           unit-list [12 23-33 44];
                        }
                    }
                }
            }
        }
    }
}
```

Troubleshooting Information

CHAPTER 36

Monitoring and Troubleshooting Ethernet Interfaces

Configuring Interface Diagnostics Tools to Test the Physical Layer Connections

Configuring Loopback Testing

Loopback testing allows you to verify the connectivity of a circuit. You can configure any of the following interfaces to execute a loopback test: aggregated Ethernet, Fast Ethernet, Gigabit Ethernet, E1, E3, *N*xDS0, serial, SONET/SDH, T1, and T3.

The physical path of a network data circuit usually consists of segments interconnected by devices that repeat and regenerate the transmission signal. The transmit path on one device connects to the receive path on the next device. If a circuit fault occurs in the form of a line break or a signal corruption, you can isolate the problem by using a loopback test. Loopback tests allow you to isolate segments of the circuit and test them separately.

To do this, configure a *line loopback* on one of the routers. Instead of transmitting the signal toward the far-end device, the line loopback sends the signal back to the originating router. If the originating router receives back its own Data Link Layer packets, you have verified that the problem is beyond the originating router. Next, configure a line loopback farther away from the local router. If this originating router does not receive its own Data Link Layer packets, you can assume that the problem is on one of the segments between the local router and the remote router's interface card. In this case, the next troubleshooting step is to configure a line loopback closer to the local router to find the source of the problem.

The following types of loopback testing are supported by Junos OS:

- DCE local—Loops packets back on the local data circuit-terminating equipment (DCE).
- DCE remote—Loops packets back on the remote DCE.
- Local—Useful for troubleshooting physical PIC errors. Configuring local loopback on an interface allows transmission of packets to the channel service unit (CSU) and then to the circuit toward the far-end device. The interface receives its own transmission, which includes data and timing information, on the local router's PIC. The data received from the CSU is ignored. To test a local loopback, issue the **show interfaces *interface-name*** command. If PPP keepalives transmitted on the interface are received by the PIC, the **Device Flags** field contains the output **Loop-Detected**.
- Payload—Useful for troubleshooting the physical circuit problems between the local router and the remote router. A payload loopback loops data only (without clocking information) on the remote router's PIC. With payload loopback, overhead is recalculated.
- Remote—Useful for troubleshooting the physical circuit problems between the local router and the remote router. A remote loopback loops packets, including both data and timing information, back on the remote router's interface card. A router at one end of the circuit initiates a remote loopback toward its remote partner. When you configure a remote loopback, the packets received from the physical circuit and CSU are received by the interface. Those packets are then retransmitted by the PIC back toward the CSU and the circuit. This loopback tests all the intermediate transmission segments.

Table 84 on page 896 shows the loopback modes supported on the various interface types.

Table 84: Loopback Modes by Interface Type

Interface	Loopback Modes	Usage Guidelines
Aggregated Ethernet, Fast Ethernet, Gigabit Ethernet	Local	“Configuring Ethernet Loopback Capability” on page 18
Circuit Emulation E1	Local and remote	*Configuring E1 Loopback Capability*
Circuit Emulation T1	Local and remote	*Configuring T1 Loopback Capability*
E1 and E3	Local and remote	*Configuring E1 Loopback Capability* and *Configuring E3 Loopback Capability*
*N*xDS0	Payload	*Configuring NxDS0 IQ and IQE Interfaces*, *Configuring T1 and NxDS0 Interfaces*, *Configuring Channelized OC12/STM4 IQ and IQE Interfaces (SONET Mode)*, *Configuring Fractional E1 IQ and IQE Interfaces*, and *Configuring Channelized T3 IQ Interfaces*

Table 84: Loopback Modes by Interface Type (continued)

Interface	Loopback Modes	Usage Guidelines
Serial (V.35 and X.21)	Local and remote	*Configuring Serial Loopback Capability*
Serial (EIA-530)	DCE local, DCE remote, local, and remote	*Configuring Serial Loopback Capability*
SONET/SDH	Local and remote	*Configuring SONET/SDH Loopback Capability to Identify a Problem as Internal or External*
T1 and T3	Local, payload, and remote	*Configuring T1 Loopback Capability* and *Configuring T3 Loopback Capability* See also *Configuring the T1 Remote Loopback Response*

To configure loopback testing, include the **loopback** statement:

user@host# loopback *mode*;

You can include this statement at the following hierarchy levels:

- [edit interfaces *interface-name* aggregated-ether-options]
- [edit interfaces *interface-name* ds0-options]
- [edit interfaces *interface-name* e1-options]
- [edit interfaces *interface-name* e3-options]
- [edit interfaces *interface-name* fastether-options]
- [edit interfaces *interface-name* gigether-options]
- [edit interfaces *interface-name* serial-options]
- [edit interfaces *interface-name* sonet-options]
- [edit interfaces *interface-name* t1-options]
- [edit interfaces *interface-name* t3-options]

Configuring BERT Testing

To configure BERT:

- Configure the duration of the test.

  [edit interfaces *interface-name interface-type*-options]
  user@host#bert-period *seconds*;

  You can configure the BERT period to last from 1 through 239 seconds on some PICs and from 1 through 240 seconds on other PICs. By default, the BERT period is 10 seconds.

- Configure the error rate to monitor when the inbound pattern is received.

[edit interfaces *interface-name interface-type*-options]
user@host#bert-error-rate *rate*;

rate is the bit error rate. This can be an integer from 0 through 7, which corresponds to a bit error rate from 10^{-0} (1 error per bit) to 10^{-7} (1 error per 10 million bits).

- Configure the bit pattern to send on the transmit path.

  [edit interfaces *interface-name interface-type*-options]
  user@host#bert-algorithm *algorithm*;

  algorithm is the pattern to send in the bit stream. For a list of supported algorithms, enter a **?** after the **bert-algorithm** statement; for example:

```
[edit interfaces t1-0/0/0 t1-options]

user@host# set bert-algorithm ?
Possible completions:
  pseudo-2e11-o152     Pattern is 2^11 -1 (per 0.152 standard)
  pseudo-2e15-o151     Pattern is 2^15 - 1 (per 0.152 standard)
  pseudo-2e20-o151     Pattern is 2^20 - 1 (per 0.151 standard)
  pseudo-2e20-o153     Pattern is 2^20 - 1 (per 0.153 standard)
        ...
```

For specific hierarchy information, see the individual interface types.

NOTE: The four-port E1 PIC supports only the following algorithms:

```
pseudo-2e11-o152     Pattern is 2^11 -1 (per 0.152 standard)
pseudo-2e15-o151     Pattern is 2^15 - 1 (per 0.151 standard)
pseudo-2e20-o151     Pattern is 2^20 - 1 (per 0.151 standard)
pseudo-2e23-o151     Pattern is 2^23 (per 0.151 standard)
```

When you issue the **help** command from the CLI, all BERT algorithm options are displayed, regardless of the PIC type, and no commit check is available. Unsupported patterns for a PIC type can be viewed in system log messages.

NOTE: The 12-port T1/E1 Circuit Emulation (CE) PIC supports only the following algorithms:

```
all-ones-repeating    Repeating one bits
all-zeros-repeating   Repeating zero bits
alternating-double-ones-zeros  Alternating pairs of ones and zeros
alternating-ones-zeros  Alternating ones and zeros
pseudo-2e11-o152      Pattern is 2^11 -1 (per 0.152 standard)
pseudo-2e15-o151      Pattern is 2^15 - 1 (per 0.151 standard)
pseudo-2e20-o151      Pattern is 2^20 - 1 (per 0.151 standard)
pseudo-2e7            Pattern is 2^7 - 1
pseudo-2e9-o153       Pattern is 2^9 - 1 (per 0.153 standard)
repeating-1-in-4      1 bit in 4 is set
repeating-1-in-8      1 bit in 8 is set
repeating-3-in-24     3 bits in 24 are set
```

When you issue the **help** command from the CLI, all BERT algorithm options are displayed, regardless of the PIC type, and no commit check is available. Unsupported patterns for a PIC type can be viewed in system log messages.

NOTE: The IQE PICs support only the following algorithms:

```
all-ones-repeating    Repeating one bits
all-zeros-repeating   Repeating zero bits
alternating-double-ones-zeros  Alternating pairs of ones and zeros
alternating-ones-zeros  Alternating ones and zeros
pseudo-2e9-o153      Pattern is 2^9  -1 (per 0.153 (511 type) standard)
pseudo-2e11-o152     Pattern is 2^11 -1 (per 0.152 and 0.153 (2047 type)
 standards)
pseudo-2e15-o151      Pattern is 2^15 -1 (per 0.151 standard)
pseudo-2e20-o151      Pattern is 2^20 -1 (per 0.151 standard)
pseudo-2e20-o153      Pattern is 2^20 -1 (per 0.153 standard)
pseudo-2e23-o151      Pattern is 2^23 -1 (per 0.151 standard)
repeating-1-in-4      1 bit in 4 is set
repeating-1-in-8      1 bit in 8 is set
repeating-3-in-24     3 bits in 24 are set
```

When you issue the **help** command from the CLI, all BERT algorithm options are displayed, regardless of the PIC type, and no commit check is available. Unsupported patterns for a PIC type can be viewed in system log messages.

NOTE: BERT is supported on the PDH interfaces of the Channelized SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP and the DS3/E3 MIC. The following BERT algorithms are supported:

```
all-ones-repeating            Repeating one bits
all-zeros-repeating           Repeating zero bits
alternating-double-ones-zeros Alternating pairs of ones and zeros
alternating-ones-zeros        Alternating ones and zeros
repeating-1-in-4              1 bit in 4 is set
repeating-1-in-8              1 bit in 8 is set
repeating-3-in-24             3 bits in 24 are set
pseudo-2e9-o153               Pattern is 2^9 - 1 (per 0.153 standard)
pseudo-2e11-o152              Pattern is 2^11 - 1 (per 0.152 standard)
pseudo-2e15-o151              Pattern is 2^15 - 1 (per 0.151 standard)
pseudo-2e20-o151              Pattern is 2^20 - 1 (per 0.151 standard)
pseudo-2e20-o153              Pattern is 2^20 - 1 (per 0.153 standard)
pseudo-2e23-o151              Pattern is 2^23 (per 0.151 standard)
```

Table 85 on page 900 shows the BERT capabilities for various interface types.

Table 85: BERT Capabilities by Interface Type

Interface	T1 BERT	T3 BERT	Comments
12-port T1/E1 Circuit Emulation	Yes (ports 0–11)	—	• Limited algorithms
4-port Channelized OC3/STM1 Circuit Emulation	Yes (port 0–3)	—	• Limited algorithms
E1 or T1	Yes (port 0–3)	Yes (port 0–3)	• Single port at a time • Limited algorithms
E3 or T3	Yes (port 0–3)	Yes (port 0–3)	• Single port at a time
Channelized OC12	—	Yes (channel 0–11)	• Single channel at a time • Limited algorithms • No bit count
Channelized STM1	Yes (channel 0–62)	—	• Multiple channels • Only one algorithm • No error insert • No bit count
Channelized T3 and Multichannel T3	Yes (channel 0–27)	Yes (port 0–3 on channel 0)	• Multiple ports and channels • Limited algorithms for T1 • No error insert for T1 • No bit count for T1

These limitations do not apply to channelized IQ interfaces. For information about BERT capabilities on channelized IQ interfaces, see *Channelized IQ and IQE Interfaces Properties*.

Starting and Stopping a BERT Test

Before you can start the BERT test, you must disable the interface. To do this, include the **disable** statement at the **[edit interfaces *interface-name*]** hierarchy level:

```
[edit interfaces interface-name]
disable;
```

After you configure the BERT properties and commit the configuration, begin the test by issuing the **test interface *interface-name* *interface-type*-bert-start** operational mode command:

```
user@host> test interface interface-name interface-type-bert-start
```

The test runs for the duration you specify with the **bert-period** statement. If you want to terminate the test sooner, issue the **test interface *interface-name* *interface-type*-bert-stop** command:

```
user@host> test interface interface-name interface-type-bert-stop
```

For example:

```
user@host> test interface t3-1/2/0 t3-bert-start
user@host> test interface t3-1/2/0 t3-bert-stop
```

To view the results of the BERT test, issue the **show interfaces extensive | find BERT** command:

```
user@host> show interfaces interface-name extensive | find BERT
```

For more information about running and evaluating the results of the BERT procedure, see the CLI Explorer.

NOTE: To exchange BERT patterns between a local router and a remote router, include the **loopback remote** statement in the interface configuration at the remote end of the link. From the local router, issue the **test interface** command.

Monitor Fast Ethernet and Gigabit Ethernet Interfaces

By monitoring Fast Ethernet and Gigabit Ethernet interfaces, you begin to isolate Fast Ethernet and Gigabit Ethernet interface problems when they occur.

To monitor your Fast Ethernet and Gigabit Ethernet interfaces, follow these steps:

1. Display the Status of Fast Ethernet Interfaces on page 903
2. Display the Status of Gigabit Ethernet Interfaces on page 904
3. Display the Status of a Specific Fast Ethernet or Gigabit Ethernet Interface on page 905
4. Display Extensive Status Information for a Specific Fast Ethernet or Gigabit Ethernet Interface on page 907
5. Monitor Statistics for a Fast Ethernet or Gigabit Ethernet Interface on page 910

Display the Status of Fast Ethernet Interfaces

Purpose To display the status of Fast Ethernet interfaces, use the following Junos OS command-line interface (CLI) operational mode command:

Action user@host> **show interfaces terse (fe* | ge*)**

Sample Output

```
user@host> show interfaces terse fe*
Interface       Admin Link Proto Local                 Remote
fe-2/1/0        up    up
fe-2/1/0.0      up    up   inet  10.116.115.217/29
fe-3/0/2        up    down
fe-3/0/2.0      up    down
```

```
fe-3/0/3        up    up
fe-3/0/3.0      up    up   inet  192.168.223.65/30
fe-4/1/0        down  up
fe-4/1/0.0      up    down inet  10.150.59.133/30
fe-4/1/1        up    up
fe-4/1/1.0      up    up   inet  10.150.59.129/30
fe-4/1/2        up    down
fe-4/1/2.0      up    down
```

Meaning The sample output lists only the Fast Ethernet interfaces. It shows the status of both the physical and logical interfaces. For a description of what the output means, see Table 88 on page 904.

Table 88: Status of Fast Ethernet Interfaces

Physical Interface	Logical Interface	Status Description
fe-2/1/0 Admin Up Link Up	fe-2/1/0.0 Admin Up Link Up	This interface has both the physical and logical links up and running.
fe-3/0/2 Admin Up Link Down	fe-3/0/2.0 Admin Up Link Down	This interface has the physical link down, the link layer down, or both down (**Link Down**). The logical link is also down as a result.
fe-4/1/0 Admin Down Link Up	fe-4/1/0.0 Admin Up Link Down	This interface is administratively disabled and the physical link is healthy (**Link Up**), but the logical interface is not established. The logical interface is down because the physical link is disabled.
fe-4/1/2 Admin Up Link Down	fe-4/1/2.0 Admin Up Link Down	This interface has both the physical and logical links down.

See Also

- Display the Status of Gigabit Ethernet Interfaces on page 904

Display the Status of Gigabit Ethernet Interfaces

Purpose To display the status of Gigabit Ethernet interfaces, use the following Junos OS command-line interface (CLI) operational mode command:

Sample Output Action

```
user@host> show interfaces terse ge*
Interface        Admin Link Proto Local                 Remote
ge-2/2/0         down  down
ge-2/2/0.0       up    down inet  65.113.23.105/30
ge-2/3/0         up    up
ge-2/3/0.0       up    up   inet  65.115.56.57/30
ge-3/1/0         up    up
ge-3/1/0.0       up    up   inet  65.115.56.193/30
ge-3/2/0         up    down
```

Meaning This sample output lists only the Gigabit Ethernet interfaces. It shows the status of both the physical and logical interfaces. See Table 89 on page 905 for a description of what the output means.

Table 89: Status of Gigabit Ethernet Interfaces

Physical Interface	Logical Interface	Status Description
ge-2/2/0 **Admin Down** **Link Down**	**ge-2/2/0.0** **Admin Up** **Link Down**	This interface is administratively disabled (**Admin Down**). Both the physical and logical links are down (**Link Down**).
ge-2/3/0 **Admin Up** **Link Up**	**ge-2/3/0.0** **Admin Up** **Link Up**	This interface has both the physical and logical links up and running.
ge-3/2/0 **Admin Up** **Link Down**	**ge-3/2/0.0** **Admin Up** **Link Down**	This interface has both the physical link and the logical interface down.

See Also

- Display the Status of Fast Ethernet Interfaces on page 903

Display the Status of a Specific Fast Ethernet or Gigabit Ethernet Interface

Purpose To display the status of a specific Fast Ethernet or Gigabit Ethernet interface when you need to investigate its status further, use the following Junos OS CLI operational mode command:

Action user@host> **show interfaces (fe-*fpc/pic/port* | ge-*fpc/pic/port*)**

Sample Output 1

The following sample output is for a Fast Ethernet interface with the physical link up:

```
user@host> show interfaces fe-2/1/0
Physical interface: fe-2/1/0, Enabled, Physical link is Up
  Interface index: 31, SNMP ifIndex: 35
  Description: customer connection
  Link-level type: Ethernet, MTU: 1514, Source filtering: Disabled
  Speed: 100mbps, Loopback: Disabled, Flow control: Enabled
  Device flags   : Present Running
  Interface flags: SNMP-Traps
  Link flags     : None

  Input rate     : 25768 bps (11 pps), Output rate: 1576 bps (3 pps)
  Active alarms  : None
  Active defects : None
  Logical interface fe-2/1/0.0 (Index 2) (SNMP ifIndex 43)
    Flags: SNMP-Traps, Encapsulation: ENET2
    Protocol inet, MTU: 1500, Flags: Is-Primary
      Addresses, Flags: Is-Preferred Is-Primary
        Destination: 10.116.151.218/29, Local: 10.119.115.217
        Broadcast: 10.116.151.225
```

Sample Output 2

The following output is for a Gigabit Ethernet interface with the physical link up:

```
user@host> show interfaces ge-3/1/0
Physical interface: ge-3/1/0, Enabled, Physical link is Up
  Interface index: 41, SNMP ifIndex: 55
  Description: customer connection
  Link-level type: Ethernet, MTU: 1514, Source filtering: Disabled
  Speed: 1000mbps, Loopback: Disabled, Flow control: Enabled
  Device flags   : Present Running
  Interface flags: SNMP-Traps
  Link flags     : None
  Current address: 00:90:69:85:71:99, Hardware address: 00:90:69:85:71:99
  Input rate     : 7412216 bps (1614 pps), Output rate: 2431184 bps (1776 pps)
  Active alarms  : None
  Active defects : None
  Logical interface ge-3/1/0.0 (Index 11) (SNMP ifIndex 57)
    Flags: SNMP-Traps, Encapsulation: ENET2
    Protocol inet, MTU: 1500
      Addresses, Flags: Is-Preferred Is-Primary
        Destination: 10.117.65.192/30, Local: 10.115.65.193
        Broadcast: 10.115.65.195
```

Meaning The first line of sample output 1 and 2 shows that the physical link is up. This means that the physical link is healthy and can pass packets. Further down the sample output, look for active alarms and defects. If you see active alarms or defects, to further diagnose the problem, see Step 3, "Display Extensive Status Information for a Specific Fast Ethernet or Gigabit Ethernet Interface" on page 907, to display more extensive information about the Fast Ethernet interface and the physical interface that is down.

Display Extensive Status Information for a Specific Fast Ethernet or Gigabit Ethernet Interface

Purpose To display extensive status information about a specific Fast Ethernet or Gigabit Ethernet interface, use the following Junos OS CLI operational mode command:

Action user@host> **show interfaces (fe-*fpc/pic/port* | ge-*fpc/pic/port*) extensive**

Sample Output

The following sample output is for a Fast Ethernet interface:

```
user@router> show interfaces fe-1/3/3 extensive
Physical interface: fe-1/3/3, Enabled, Physical link is Up
  Interface index: 47, SNMP ifIndex: 38
  Description: Test
  Link-level type: Ethernet, MTU: 1514, Source filtering: Disabled
  Speed: 100mbps, Loopback: Disabled, Flow control: Enabled
  Device flags   : Present Running
  Interface flags: SNMP-Traps
  Link flags     : None
  Current address: 00:90:69:8d:2c:de, Hardware address: 00:90:69:8d:2c:de
  Statistics last cleared: 2002-01-11 23:03:09 UTC (1w2d 23:54 ago)
  Traffic statistics:

    Link partner: Full-duplex, Flow control: None
  PFE configuration:
    Destination slot: 1, Stream number: 15
    CoS transmit queue bandwidth:
      Queue0: 95, Queue1: 0, Queue2: 0, Queue3: 5
    CoS weighted round-robin:
      Queue0: 95, Queue1: 0, Queue2: 0, Queue3: 5
  Logical interface fe-1/3/3.0 (Index 8) (SNMP ifIndex 69)
    Description: Test
    Flags: SNMP-Traps, Encapsulation: ENET2
    Protocol inet, MTU: 1500, Flags: None
      Addresses, Flags: Is-Preferred Is-Primary
        Destination: 10.115.107.192/29, Local: 10.115.107.193
        Broadcast: 10.115.107.199
```

Meaning The sample output shows where the errors might be occurring and includes autonegotiation information. See Table 90 on page 908 for a description of errors to look for.

Table 90: Errors to Look For

Error	Meaning
Policed discards	Discarded frames that were not recognized or were not of interest.
L2 channel errors	Packets for which the router could not find a valid logical interface. For example, the packet is for a virtual LAN (VLAN) that is not configured on the interface.
MTU	The maximum transmission unit (MTU) must match the interface of either the router at the remote end of the Fast Ethernet or Gigabit Ethernet link, or that of the switch.
Input DA rejects	Number of packets with a destination Media Access Control (MAC) address that is not on the accept list. It is normal to see this number increment.
Input SA rejects	Number of packets with a source MAC address that is not on the accept list. This number only increments when source MAC address filtering is configured.

If the physical link is down, look at the active alarms and defects for the Fast Ethernet or Gigabit Ethernet interface and diagnose the Fast Ethernet or Gigabit Ethernet media accordingly. See “Checklist for Locating Fast Ethernet and Gigabit Ethernet Alarms and Counters” on page 927 for an explanation of Fast Ethernet and Gigabit Ethernet alarms.

Table 91 on page 909 lists and describes some MAC statistics errors to look for.

Table 91: MAC Statistics Errors

Error	Meaning
CRC/Align errors	The total number of packets received that had a length (excluding framing bits, but including FCS octets) of between 64 and 1518 octets, inclusive, but had either a bad FCS with an integral number of octets (**FCS Error**) or a bad FCS with a non-integral number of octets (**Alignment Error**).
MAC control frames	The number of MAC control frames.
MAC pause frames	The number of MAC control frames with **pause** operational code.
Jabber frames	The total number of packets received that were longer than 1518 octets (excluding framing bits, but including FCS octets), and had either an FCS error or an alignment error. Note that this definition of jabber is different from the definition in IEEE-802.3 section 8.2.1.5 (10BASE5) and section 10.3.1.4 (10BASE2). These documents define jabber as the condition where any packet exceeds 20 ms. The allowed range to detect jabber is between 20 ms and 150 ms.
Fragment frames	The total number of packets received that were less than 64 octets in length (excluding framing bits, but including FCS octets), and had either an FCS error an alignment error. Note that it is entirely normal for fragment frames to increment because both runts (which are normal occurrences due to collisions) and noise hits are counted.

Autonegotiation is the process that connected Ethernet interfaces use to communicate the information necessary to interoperate. Table 92 on page 909 explains the autonegotiation information of the **show interface *interface-name* extensive** command output.

Table 92: Autonegotiation Information

Autonegotiation Field Information	Explanation
Negotiation status: Incomplete	The **Negotiation status** field shows **Incomplete** when the Ethernet interface has the speed or link mode configured.
Negotiation status: No autonegotiation	The **Negotiation status** field shows **No autonegotiation** when the remote Ethernet interface has the speed or link mode configured, or does not perform autonegotiation.
Negotiation status: Complete **Link partner status: OK**	The **Negotiation status** field shows **Complete** and the **Link partner** field shows **OK** when the Ethernet interface is connected to a device that performs autonegotiation and the autonegotiation process completes successfully.
Link partner: Half-duplex	The **Link partner** field can be **Full-duplex** or **Half-duplex** depending on the capability of the attached Ethernet device.
Flow control: Symmetric/asymmetric	The **Flow control** field displays the types of flow control supported by the remote Ethernet device.

Monitor Statistics for a Fast Ethernet or Gigabit Ethernet Interface

Purpose To monitor statistics for a Fast Ethernet or Gigabit Ethernet interface, use the following Junos OS CLI operational mode command:

Action user@host> **monitor interface (fe-*fpc/pic/port* | ge-*fpc/pic/port*)**

CAUTION: We recommend that you use the **monitor interface fe-*fpc/pic/port*** or **monitor interface ge-*fpc/pic/port*** command only for diagnostic purposes. Do not leave these commands on during normal router operations because real-time monitoring of traffic consumes additional CPU and memory resources.

Sample Output

The following sample output is for a Fast Ethernet interface:

```
user@host> monitor interface fe-2/1/0
Interface: fe-2/1/0, Enabled, Link is Up
Encapsulation: Ethernet, Speed: 100mbps
Traffic statistics:                                             Current Delta
  Input bytes:              282556864218 (14208 bps)                  [40815]
  Output bytes:              42320313078 (384 bps)                      [890]
  Input packets:               739373897 (11 pps)                       [145]
  Output packets:              124798688 (1 pps)                         [14]
Error statistics:
  Input errors:                        0                                  [0]
  Input drops:                         0                                  [0]
  Input framing errors:                0                                  [0]
  Policed discards:              6625892                                  [6]
  L3 incompletes:                     75                                  [0]
  L2 channel errors:                   0                                  [0]
  L2 mismatch timeouts:                0                                  [0]
  Carrier transitions:                 1                                  [0]
  Output errors:                       0                                  [0]
  Output drops:                        0                                  [0]
  Aged packets:                        0                                  [0]
Active alarms : None
Active defects: None
Input MAC/Filter statistics:
  Unicast packets              464751787                                [154]
  Packet error count                   0                                  [0]
```

Meaning Use the information from this command to help narrow down possible causes of an interface problem.

NOTE: If you are accessing the router from the console connection, make sure you set the CLI terminal type using the **set cli terminal** command.

The statistics in the second column are the cumulative statistics since the last time they were cleared using the **clear interfaces statistics** ***interface-name*** command. The statistics in the third column are the cumulative statistics since the **monitor interface** ***interface-name*** command was executed.

If the input errors are increasing, verify the following:

1. Check the cabling to the router and have the carrier verify the integrity of the line. To verify the integrity of the cabling, make sure that you have the correct cables for the interface port. Make sure you have single-mode fiber cable for a single-mode interface and multimode fiber cable for a multimode interface.
2. For a fiber-optic connection, measure the received light level at the receiver end and make sure that it is within the receiver specification of the Ethernet interface. See "Fiber-Optic Ethernet Interface Specifications" on page 911 for the fiber-optic Ethernet interface specifications.
3. Measure the transmit light level on the Tx port to verify that it is within specification. See "Fiber-Optic Ethernet Interface Specifications" on page 911 for the optical specifications.

Fiber-Optic Ethernet Interface Specifications

Table 93 on page 911 shows the specifications for fiber-optic interfaces for Juniper Networks routers.

Table 93: Fiber-Optic Ethernet Interface Specifications

Fiber-Optic Ethernet Interface	Length	Wavelength	Average Launch Power	Receiver Saturation	Receiver Sensitivity
Gigabit Ethernet					
Duplex SC connector					
LH optical interface	49.5-mile 70-km reach on 8.2-micrometer SMF	1480 to 1580 nm	-3 to +2 dBm	-3 dBm	-23 dBm (BER 1012) for SMF
LX optical interface	6.2-mile 10-km reach on 9/125-micrometer SMF 1804.5-ft 550-m reach on 62.5/125- and 50/125-micrometer MMF	1270 to 1355 nm	-11 to -3 dBm	-3 dBm	-19 dBm
SX optical interface	656-ft 200-m reach on 62.5/125-micrometer MMF 1640-ft 500-m reach on 50/125-micrometer MMF	830 to 860 nm	-9.5 to -4 dBm	-3 dBm	-17 dBm
Fast Ethernet 8-Port					

Table 93: Fiber-Optic Ethernet Interface Specifications (continued)

Fiber-Optic Ethernet Interface	Length	Wavelength	Average Launch Power	Receiver Saturation	Receiver Sensitivity
FX optical interface with MT-RJ connector	1.24-mile 2-km reach on 62.5/125-micrometer MMF	1270 to 1380 nm	-20 to -14 dBm	-14 dBm	-34 dBm

Performing Loopback Testing for Fast Ethernet and Gigabit Ethernet Interfaces

Checklist for Using Loopback Testing for Fast Ethernet and Gigabit Ethernet Interfaces

Purpose To use loopback testing to isolate Fast Ethernet and Gigabit Ethernet interface problems.

Action Table 94 on page 912 provides links and commands for using loopback testing for Fast Ethernet and Gigabit Ethernet interfaces.

Table 94: Checklist for Using Loopback Testing for Fast Ethernet and Gigabit Ethernet Interfaces

Tasks	Command or Action
“Diagnose a Suspected Hardware Problem with a Fast Ethernet or Gigabit Ethernet Interface” on page 913	
1. Create a Loopback on page 914	
a. Create a Physical Loopback for a Fiber-Optic Interface on page 914	Connect the transmit port to the receive port.

Table 94: Checklist for Using Loopback Testing for Fast Ethernet and Gigabit Ethernet Interfaces (continued)

Tasks	Command or Action
b. Create a Loopback Plug for an RJ-45 Ethernet Interface on page 914	Cross pin 1 (TX+) and pin 3 (RX+) together, and pin 2 (TX-) and pin 6 (RX-) together.
c. Configure a Local Loopback on page 915	**[edit interfaces *interface-name* (fastether-options | gigether-options)]** **set loopback** **show** **commit**
2. Verify That the Fast Ethernet or Gigabit Ethernet Interface Is Up on page 916	**show interfaces (fe-*fpc/pic/port* | ge-*fpc/pic/port*)**
3. Configure a Static Address Resolution Protocol Table Entry on page 919	**show interfaces ge-*fpc/pic/port*** **[edit interfaces *interface-name* unit *logical-unit-number* family inet address *address]*** **set arp *ip-address* mac *mac-address* show** **commit** **run show arp no-resolve**
4. Clear Fast Ethernet or Gigabit Ethernet Interface Statistics on page 923	**clear interfaces statistics fe-*fpc/pic/port* | ge-*fpc/pic/port***
5. Ping the Fast Ethernet or Gigabit Ethernet Interface on page 924	**ping *remote-IP-address* bypass-routing interface (fe-*fpc/pic/port* | ge-*fpc/pic/port* count 100 rapid**
6. Check for Fast Ethernet or Gigabit Ethernet Interface Error Statistics on page 925	**show interfaces (fe-*fpc/pic/port* | ge-*fpc/pic/port*) extensive**
"Diagnose a Suspected Circuit Problem" on page 927	Perform Steps 2 through 8 from "Diagnose a Suspected Hardware Problem with a Fast Ethernet or Gigabit Ethernet Interface" on page 913.

Diagnose a Suspected Hardware Problem with a Fast Ethernet or Gigabit Ethernet Interface

Problem **Description:** When you suspect a hardware problem, take the following steps to help verify if there is a problem.

Solution To diagnose a suspected hardware problem with the Ethernet interface, follow these steps:

- Create a Loopback on page 914
- Verify That the Fast Ethernet or Gigabit Ethernet Interface Is Up on page 916
- Configure a Static Address Resolution Protocol Table Entry on page 919

- Clear Fast Ethernet or Gigabit Ethernet Interface Statistics on page 923
- Check for Fast Ethernet or Gigabit Ethernet Interface Error Statistics on page 925

Create a Loopback

You can create a physical loopback or configure a local loopback to help diagnose a suspected hardware problem. Creating a physical loopback is recommended because it allows you to test and verify the transmit and receive ports. If a field engineer is not available to create the physical loopback, you can configure a local loopback for the interface. The local loopback creates a loopback internally in the Physical Interface Card (PIC).

1. Create a Physical Loopback for a Fiber-Optic Interface on page 914
2. Create a Loopback Plug for an RJ-45 Ethernet Interface on page 914
3. Configure a Local Loopback on page 915

Create a Physical Loopback for a Fiber-Optic Interface

Action

To create a physical loopback at the port, connect the transmit port to the receive port using a known good fiber cable.

NOTE: **Make sure you use single-mode fiber for a single-mode port and multimode fiber for a multimode port.**

Meaning

When you create and then test a physical loopback, you are testing the transmit and receive ports of the PIC. This action is recommended if a field engineer is available to create the physical loop as it provides a more complete test of the PIC.

See Also

- Create a Loopback Plug for an RJ-45 Ethernet Interface on page 914
- Configure a Local Loopback on page 915
- Verify That the Fast Ethernet or Gigabit Ethernet Interface Is Up on page 916
- Configure a Static Address Resolution Protocol Table Entry on page 919

Create a Loopback Plug for an RJ-45 Ethernet Interface

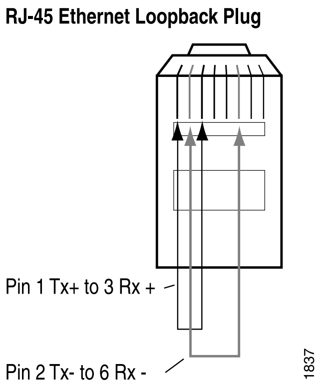
Action

To create a loopback plug, cross pin 1 (TX+) and pin 3 (RX+) together, and cross pin 2 (TX-) and pin 6 (RX-) together. You need the following equipment to create the loopback:

- A 6-inch long CAT5 cable
- An RJ-45 connector
- A crimping tool

Figure 58 on page 915 illustrates how to create a loopback plug for an RJ-45 Ethernet interface.

Figure 58: RJ-45 Ethernet Loopback Plug



Meaning

When you create and then test a physical loopback, you are testing the RJ-45 interface of the PIC. This action is recommended if a field engineer is available to create the physical loop as it provides a more complete test of the PIC.

See Also

- Configure a Local Loopback on page 915
- Verify That the Fast Ethernet or Gigabit Ethernet Interface Is Up on page 916
- Configure a Static Address Resolution Protocol Table Entry on page 919
-

Configure a Local Loopback

Action

To configure a local loopback without physically connecting the transmit port to the receive port, follow these steps:

1. In configuration mode, go to the following hierarchy level:

   [edit]
   user@host# **edit interfaces** ***interface-name*** (fastether-options | gigether-options)

2. Configure the local loopback:

   [edit interfaces *interface-name* (fastether-options | gigether-options)]
   user@host# **set loopback**

3. Verify the configuration:

   user@host# **show**

   For example:

   ```
   [edit interfaces fe-1/0/0 fastether-options]
   user@host# show
   loopback;
   ```

4. Commit the change:

   user@host# **commit**

   For example:

   ```
   [edit interfaces fe-1/0/0 fastether-options]
   user@host# commit
   commit complete
   ```

When you create a local loopback, you create an internal loop on the interface being tested. A local loopback loops the traffic internally on that PIC. A local loopback tests the interconnection of the PIC but does not test the transmit and receive ports. On an Ethernet interface, you cannot create a remote loopback, therefore there is no option to use a **local** or **remote** statement. Simply including the **loopback** statement at the **[edit interfaces *interface-name* (fastether-options | gigether-options]** hierarchy level, places the interface into local loopback mode.

NOTE: **Remember to delete the loopback statement after completing the test.**

Verify That the Fast Ethernet or Gigabit Ethernet Interface Is Up

Purpose Display the status of the Fast Ethernet or Gigabit Ethernet interface to provide the information you need to determine whether the physical link is up or down.

Action To verify that the status of the Fast Ethernet or Gigabit Ethernet interface is up, use the following Junos OS command-line interface (CLI) operational mode command:

user@host> **show interfaces (fe-*fpc/port* | ge-*fpc/pic/port*)**

Sample Output

```
user@host# show interfaces ge-4/0/6 extensive
Physical interface: ge-4/0/6, Enabled, Physical link is Up
  Interface index: 144, SNMP ifIndex: 516, Generation: 147
  Link-level type: Ethernet, MTU: 1514, Speed: 1000mbps, BPDU Error: None,
  MAC-REWRITE Error: None, Loopback: Enabled, Source filtering: Disabled,
  Flow control: Enabled, Auto-negotiation: Enabled, Remote fault: Online

```

Meaning

The sample output shows that the link is up and there are no alarms in this loopback configuration. When an internal loopback is configured, the physical loopback should come up without an alarm.

Sample Output

When you see that the physical link is down, there may be a problem with the port. The following output is an example of the show interfaces fe-*fpc/pic/port* command when the physical link is down:

```
user@router> show interfaces fe-1/3/0
Physical interface: fe-1/3/0, Enabled, Physical link is Down
  Interface index: 44, SNMP ifIndex: 35
  Link-level type: Ethernet, MTU: 1514, Source filtering: Disabled
  Speed: 100mbps, Loopback: Disabled, Flow control: Enabled
  Device flags   : Present Running Down
  Interface flags: Hardware-Down SNMP-Traps
  Link flags     : None
  Current address: 00:90:69:8d:2c:db, Hardware address: 00:90:69:8d:2c:db
  Input rate     : 0 bps (0 pps), Output rate: 0 bps (0 pps)
  Active alarms : LINK
  Active defects : LINK
  MAC statistics:
    Input octets: 0, Input packets: 0, Output octets: 0, Output packets: 0
  Filter statistics:
    Filtered packets: 0, Padded packets: 0, Output packet errors: 0
  Autonegotiation information:
    Negotiation status: Incomplete, Link partner status: Down
    Reason: Link partner autonegotiation failure
    Link partner: Half-duplex, Flow control: None
```

Meaning The sample output shows that the physical link is down and there are active alarms and defects.

Table 95 on page 919 presents problem situations and actions for a physical link that is down.

Table 95: Problems and Solutions for a Physical Link That Is Down

Problem	Action
Cable mismatch	Verify that the fiber connection is correct.
Damaged and/or dirty cable	Verify that the fiber can successfully loop a known good port of the same type.
Too much or too little optical attenuation	Verify that the attenuation is correct per the PIC optical specifications.
The transmit port is not transmitting within the dBm optical range per the specifications	Verify that the Tx power of the optics is within range of the PIC optical specification.
Mismatch between the cable type and the port	Verify that a single-mode fiber cable is connected to a single-mode interface and that a multimode fiber cable is connected to a multimode interface. (This problem does not always cause the physical link to go down; errors and dropped packets are sometimes the result.)

Configure a Static Address Resolution Protocol Table Entry

Purpose

Configure a static Address Resolution Protocol (ARP) entry to allow a packet to be sent out of a looped Ethernet interface.

NOTE: Remove the static ARP entry at the end of the loop test after you have completed the tests and monitored interface traffic.

Action

To configure a static ARP table entry for a Gigabit Ethernet interface, follow these steps. You can follow the same procedure to configure a static ARP entry for a Fast Ethernet interface.

1. Find the Media Access Control (MAC) address for the Gigabit Ethernet interface:

   user@host> **show interfaces ge-*fpc/pic/port***

```
Physical interface: ge-4/0/6, Enabled, Physical link is Up
  Interface index: 144, SNMP ifIndex: 516, Generation: 147
  Link-level type: Ethernet, MTU: 1514, Speed: 1000mbps, BPDU Error: None,
  MAC-REWRITE Error: None, Loopback: Enabled, Source filtering: Disabled,
  Flow control: Enabled, Auto-negotiation: Enabled, Remote fault: Online
  Device flags   : Present Running Loop-Detected
  Interface flags: SNMP-Traps Internal: 0x4000

```

2. In configuration mode, go to the following hierarchy level:

[edit]
user@host# **edit interfaces** *interface-name* **unit** *logical-unit-number* **family inet address** *address*

3. Configure the static ARP entry:

   user@host# **set arp** *ip-address* **mac** *mac-address*

4. Commit the configuration:

   user@host# **commit**

5. Verify that the static ARP entry is installed:

   [edit interfaces ge-4/0/6 unit 0 family inet address 10.108.120.1/30]
   user@host# **run show arp no-resolve**

```

52:54:00:de:88:5f 10.204.128.45   fxp0.0               none
52:54:00:48:03:b7 10.204.128.46   fxp0.0               none
```

Meaning

The sample output is for Step 1 through Step 6 and shows that a static ARP entry was configured on Gigabit Ethernet interface **ge-4/0/6**.

Clear Fast Ethernet or Gigabit Ethernet Interface Statistics

Purpose

You can reset the Fast Ethernet and Gigabit Ethernet interface statistics. Resetting the statistics provides a clean start so that previous input/output errors and packet statistics do not interfere with the current diagnostics.

Action

To clear all statistics for the interface, use the following Junos OS CLI operational mode command:

user@host> **clear interfaces statistics** (**fe-***fpc/pic/port* | **ge-***fpc/pic/port*)

Sample Output

```
user@host> clear interfaces statistics ge-4/0/6
user@host>
```

Meaning

This command clears the interface statistics counters for the Gigabit Ethernet interface only.

Ping the Fast Ethernet or Gigabit Ethernet Interface

Purpose Use the ping command to verify the loopback connection.

Action To send ping packets from the Ethernet interface, use the following Junos OS CLI operational mode command:

user@host> **ping** ***remote-IP-address*** **bypass-routing interface (fe-*fpc/pic/port* | ge-*fpc/pic/port*) count 100 rapid**

Sample Output

```
user@router> ping 10.108.120.2 bypass-routing interface ge-7/2/1 count 100 rapid
PING 10.108.120.2 (10.108.120.2): 56 data bytes

.36 bytes from 10.108.120.1: Time to live exceeded
```

Meaning The sample output shows that the time to live (TTL) expired, indicating that the link is receiving the frames from the ping test. The MAC address used is the same as the physical address of the port being tested because this allows the port to accept the frames from the ping test. As the packet is looped over the link, you expect to receive a TLL exceeded message for each ping sent. These messages are generated because the ping packets are repeatedly looped between the router and the physical loopback. When the packet is sent to the other end of the link, which does not exist, the loopback returns the packet back to the same interface, where it is again subjected to the Packet Forwarding Engine fabric for routing. After the route lookup, the TTL is decremented, and the packet is again sent out of the looped interface. This process repeats until the packed is either lost, or the TLL expires with subsequent TTL expired message displayed. Should any errors occur, the packet is discarded and a time-out error is displayed, rather than the expected TTL expired message. Note that the default TTL for ICMP echo packets in Junos OS is 64. This means a given test packet must be successfully sent and received 63 times before a TTL expired message can be generated. You can alter the TTL value to adjust the tolerance for loss, for example, a value of 255 is the most demanding test because now the packet must be sent and received error free 254 times.

Check for Fast Ethernet or Gigabit Ethernet Interface Error Statistics

Purpose Persistent interface error statistics indicate that you need to open a case with the Juniper Networks Technical Assistance Center (JTAC).

Action To check the local interface for error statistics, use the following Junos OS CLI operational mode command:

user@host> **show interfaces (fe-*fpc/pic/port* | ge-*fpc/pic/port*) extensive**

Sample Output

```
user@router> show interfaces ge-4/0/6 extensive
Physical interface: ge-4/0/6, Enabled, Physical link is Up  Interface index: 144, SNMP

Meaning Check for any error statistics. There should not be any input or output errors. If there are any persistent input or output errors, open a case with the Juniper Networks Technical

Assistance Center (JTAC) at **support@juniper.net**, or at 1-888-314-JTAC (within the United States) or 1-408-745-9500 (from outside the United States).

Diagnose a Suspected Circuit Problem

Purpose When you suspect a circuit problem, it is important to work with the transport-layer engineer to resolve the problem. The transport-layer engineer may create a loop to the router from various points in the network. You can then perform tests to verify the connection from the router to that loopback in the network.

Action After the transport-layer engineer has created the loop to the router from the network, you must verify the connection from the router to the loopback in the network. Follow Step 2 through Step 8 in "Diagnose a Suspected Hardware Problem with a Fast Ethernet or Gigabit Ethernet Interface" on page 913. Keep in mind that any problems encountered in the test indicate a problem with the connection from the router to the loopback in the network.

By performing tests to loopbacks at various points in the network, you can isolate the source of the problem.

Locating the Fast Ethernet and Gigabit Ethernet LINK Alarm and Counters

Checklist for Locating Fast Ethernet and Gigabit Ethernet Alarms and Counters

Purpose To locate LINK alarm and major counters associated with Fast Ethernet and Gigabit Ethernet interfaces.

Action Table 96 on page 927 provides links and commands for locating LINK alarm and major counters for Fast Ethernet and Gigabit Ethernet interfaces.

Table 96: Checklist for Locating Fast Ethernet and Gigabit Ethernet Alarms and Counters

Tasks	Command or Action
"Display the Fast Ethernet or Gigabit Ethernet Interface LINK Alarm" on page 928	**show interfaces (fe-*fpc/pic/port* | ge-*fpc/pic/port*) extensive**
"Fast Ethernet and Gigabit Ethernet Counters" on page 929

Display the Fast Ethernet or Gigabit Ethernet Interface LINK Alarm

Problem **Description:** To display the Fast Ethernet or Gigabit Ethernet LINK alarm, use the following Junos OS command-line interface (CLI) operational mode command:

Solution user@host> **show interfaces (fe-*fpc/pic/port* | ge-*fpc/pic/port*) extensive**

Sample Output

The following sample output is for a Fast Ethernet interface:

```
user@host> show interfaces fe-1/3/3 extensive
Physical interface: fe-1/3/3, Enabled, Physical link is Down
  Interface index: 47, SNMP ifIndex: 38
  Description: Test
  Link-level type: Ethernet, MTU: 1514, Source filtering: Disabled
  Speed: 100mbps, Loopback: Disabled, Flow control: Enabled
  Device flags   : Present Running
  Interface flags: SNMP-Traps

        Destination: 10.115.107.192/29, Local: 10.115.107.193
        Broadcast: 10.115.107.199
```

Meaning

The sample output shows where the alarm and other errors might be occurring and any counters that are incrementing. The only alarm associated with Fast Ethernet or Gigabit Ethernet interfaces is the LINK alarm. A LINK alarm indicates a physical problem. To isolate where the physical problem might be occurring, conduct loopback testing. See “Checklist for Using Loopback Testing for Fast Ethernet and Gigabit Ethernet Interfaces” on page 912 for information on conducting a loopback test.

NOTE: Since link status is polled once every second, some items that require fast link down detection, such as Multiprotocol Label Switching (MPLS) fast reroute, take longer to execute.

Fast Ethernet and Gigabit Ethernet Counters

Problem **Description:** Table 97 on page 930 shows the major counters that appear in the output for the **show interfaces fe-*fpc/pic/port* extensive** and the **show interfaces ge-*fpc/pic/port* extensive** commands. These counters generally increment when there is a problem with a Fast Ethernet or Gigabit Ethernet interface. In the **Counters** column, the counters are listed in the order in which they are displayed in the output.

Table 97: Major Fast Ethernet and Gigabit Ethernet Counters

Counter	Description	Reason for Increment
Input Errors:		
Errors	The sum of the incoming frame aborts and frame check sequence (FCS) errors.	
Policed discards	The frames discarded by the incoming packet match code.	The frames were discarded because they were not recognized or of interest. Usually, this field reports protocols that the Junos OS does not handle.
Drops	The number of packets dropped by the output queue of the I/O Manager application-specific integrated circuit (ASIC).	If the interface is saturated, this number increments once for every packet that is dropped by the ASIC's random early detection (RED) mechanism.
L3 incompletes	The number of packets discarded due to the packets failing Layer 3 header checks.	This counter increments when the incoming packet fails Layer 3 (usually IPv4) checks of the header. For example, a frame with less than 20 bytes of available IP header would be discarded and this counter would increment.
L2 channel errors	The errors that occur when the software could not find a valid logical interface (such as **fe-1/2/3.0**) for an incoming frame.	This error increments when, for example, a lookup for a virtual LAN (VLAN) fails.
L2 mismatch timeouts	The count of malformed or short packets.	The malformed or short packets cause the incoming packet handler to discard the frame and be unreadable.
FIFO errors	The number of first in, first out (FIFO) errors in the receive direction as reported by the ASIC on the Physical Interface Card (PIC).	The value in this field should always be 0. If this value is not zero, cabling could be badly organized or the PIC could be broken.
Output Errors		
Errors	The sum of outgoing frame aborts and FCS errors.	
Collisions	The number of Ethernet collisions.	The Fast Ethernet PIC supports only full-duplex operation, so this number should always remain 0. If it is incrementing, there is a software bug.
Drops	The number of packets dropped by the output queue of the I/O Manager ASIC.	If the interface is saturated, this number increments once for every packet that is dropped by the ASIC's RED mechanism.
Aged packets	The number of packets that remained in shared packet SDRAM for so long that the system automatically purged them.	The value in this field should never increment. If it increments, it is probably a software bug or broken hardware.

Table 97: Major Fast Ethernet and Gigabit Ethernet Counters (continued)

Counter	Description	Reason for Increment
HS link FCS errors, FIFO errors	The number of errors on the high-speed links between the ASICs responsible for handling the router interfaces.	The value in this field should always be 0. If it increments, either the FPC or the PIC is broken.
Miscellaneous Counters		
Input DA rejects	The number of packets that the filter rejected because the destination Media Access Control (MAC) address of the packet is not on the accept list.	It is normal for this value to increment. When it increments very quickly and no traffic is entering the router from the far-end system, either there is a bad Address Resolution Protocol (ARP) entry on the far-end system, or multicast routing is not on and the far-end system is sending many multicast packets to the local router (which the router is rejecting).
Output packet pad count	The number of packets that the filter padded to the minimum Ethernet size (60 bytes) before giving the packet to the MAC hardware.	Usually, padding is done only on small ARP packets, but some very small Internet Protocol (IP) packets can also require padding. If this value increments rapidly, either the system is trying to find an ARP entry for a far-end system that does not exist, or it is misconfigured.
Output packet error count	Number of packets with an indicated error that the filter was given to transmit.	These packets are usually aged packets or are the result of a bandwidth problem on the FPC hardware. On a normal system, the value of this field should not increment.
CAM destination filters, CAM source filters	The number of entries in the content-addressable memory (CAM) dedicated to destination and source MAC address filters.	There can be up to 64 source entries. If source filtering is disabled, which is the default, the value for these fields should be 0.

Troubleshooting: 10-Gigabit Ethernet Port Stuck in Down State

Problem

Description: 10-Gigabit Ethernet port is stuck in DPC or PIC down state.

Environment: Juniper Networks T Series and MX Series routers. Refer to the related documentation section for more information.

Symptoms: The device has failed to initialize because the Ethernet port is down.

Diagnosis

Try disabling and reenabling the interface and resetting the transceiver and cable. If the interface remains down, it can be stuck in DPC or PIC down state.

Does the router function normally after disabling and reenabling the interface and resetting the transceiver and cable?

Yes:

The system is not stuck in DPC or PIC down state. Disabling and reenabling the interface or resetting the transceiver, and cable resolved the issue.

No:

The interface might be stuck in DPC or PIC down state. Refer to the "To resolve the issue" on page 932 section for recovery options.

1.

Resolution ***To resolve the issue***

From the aforementioned diagnosis, you ascertain that the interface is stuck in DPC or PIC down state.

This is not a hardware defect. Implement one of the following solutions on the backup Routing Engine to resolve this issue:

- Reset the PIC.
- Toggle the framing mode.

1. In configuration mode, go to the **[edit interfaces]** hierarchy level.

   user@host1# **edit interfaces** ***interface name***

2. Toggle the framing mode. In the following configuration, WAN-PHY mode is toggled.

   [edit interfaces *interface-name* is in the et-*fpc/pic/port*
   user@host1# **set framing wan-phy**
   user@host1# **commit**
   user@host1# **framing {**
   user@host1# **wan-phy;**
   user@host1# **}**
   user@host1# **delete framing**
   user@host1# **commit**

3. Reset the PIC (T Series Routers)

   user@host1# **request chassis pic fpc-slot** ***x*** **pic-slot** ***y*** **offline**
   user@host1# **request chassis pic fpc-slot** ***x*** **pic-slot** ***y*** **online**

4. Reset the PIC (MX Series Routers)

   user@host1# **request chassis fpc slot** ***x*** **offline**
   user@host1# **request chassis fpc slot** ***x*** **online**

PART 5

Configuration Statements and Operational Commands

CHAPTER 37

Configuration Statements (OTN)

alarm (optics-options)

Syntax

```
alarm low-light–alarm {
  (link-down | syslog);
}
```

Hierarchy Level

[edit interfaces *interface-name* optics-options]

Release Information

Statement introduced in Junos OS Release 10.0.
Statement introduced in Junos OS Release 12.1 for EX Series switches.

Description

Specify the action to take if the receiving optics signal is below the optics low-light alarm threshold.

Options

link-down—Drop the 10-Gigabit Ethernet link and marks link as down.

syslog—Write the optics information to the system log.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- 100-Gigabit Ethernet OTN Options Configuration Overview on page 475

backward-frr-enable

Syntax (backward-frr-enable | no-backward-frr-enable);

Hierarchy Level [edit interfaces *interface-name* otn-options preemptive-fast-reroute]

Release Information Statement introduced in Junos OS Release 13.2 for PTX Series routers.

Description Enable or disable backward fast reroute status insertion.

Enable backward fast reroute to insert local pre-forward error correction (FEC) bit error rate (BER) status into transmitted OTN frames, notifying the remote interface. The remote interface can use the information to reroute traffic to a different interface. When you enable backward fast reroute and also enable pre-FEC BER monitoring including the signal-degrade-monitor-enable statement, notification of signal degradation and rerouting of traffic occurs in less time than that required through a Layer 3 protocol.

NOTE: **When you configure pre-FEC BER signal degrade monitoring, we recommend that you configure both the signal-degrade-monitor-enable and backward-frr-enable statements.**

You can also configure the pre-FEC BER thresholds that raise or clear a signal degrade alarm and the time interval for the thresholds. If the BER thresholds and interval are not configured, the default values are used. Include the ber-threshold-signal-degrade ***value***, ber-threshold-clear ***value***, and interval ***value*** statements at the **[edit interfaces *interface-name*** otn-options signal-degrade**]** hierarchy level to configure the BER thresholds and time interval. See "Understanding Pre-FEC BER Monitoring and BER Thresholds" on page 477 for more information about pre-FEC BER monitoring and determining BER threshold settings.

Default By default, backward fast reroute insertion is disabled.

Options **backward-frr-enable**—Enable backward fast reroute status insertion.

no-backward-frr-enable—Do not enable backward fast reroute status insertion.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

ber-threshold-clear

Syntax ber-threshold-clear *value*;

Hierarchy Level [edit interfaces *interface-name* otn-options signal-degrade]
[edit interfaces *interface-name* otn-options odu-signal-degrade]

Release Information Statement introduced in Junos OS Release 13.2 for PTX Series routers.
Statement introduced in Junos OS Release 15.1F6 for MPC5E, MIC6-100G-CFP2 on MPC6E on MX240, MX480, MX960, MX2010, and MX2020 routers.

Description Specify bit error rate (BER) threshold to clear the interface alarm for signal degradation.

You can configure the BER clear threshold to customize the BER that will clear an interface alarm when signal degrade monitoring is enabled.

NOTE: Configuring a high BER threshold for signal degradation and a long interval might cause the internal counter register to be saturated. Such a configuration is ignored by the router, and the default values are used instead. A system log message is logged for this error.

If you configure the BER thresholds at the **[edit interfaces *interface-name* otn-options signal-degrade]** hierarchy level, then the thresholds are calculated using the pre-forward error correction (pre-FEC) BER (the BER before FEC correction). These thresholds are used for pre-FEC BER monitoring. See "Understanding Pre-FEC BER Monitoring and BER Thresholds" on page 477 for more information about pre-FEC BER monitoring and determining BER threshold settings.

If you configure the BER thresholds at the **[edit interfaces *interface-name* otn-options odu-signal-degrade]** hierarchy level, then the thresholds are calculated using the post-FEC BER (the BER after FEC correction). This BER is referred to as the optical channel data unit (ODU) BER.

NOTE: You can configure ODU BER thresholds only at the **[edit interfaces *interface-name* otn-options odu-signal-degrade]** hierarchy level on the P2-100GE-OTN PIC.

Table 98 on page 941 shows the default values for pre-FEC BER and ODU BER signal degrade threshold values for different PICs. If the BER signal degrade threshold is not configured, the default value is used.

Table 98: Default Clear Threshold Values

PIC or MPC	Default Pre-FEC BER Clear Threshold Value	Default ODU BER Clear Threshold Value
P1-PTX-2-100G-WDM	3.0E–3	Not supported
P2-100GE-OTN	3.0E–3	1.0E–9
P1-PTX-24-10G-W-SFPP	3.0E–3	Not supported
MIC6-100G-CFP2	1.0E-6	1.0E-9
MPC5E	1.0E-6	1.0E-9

To configure the threshold that raises the signal degrade alarm, include the ber-threshold-signal-degrade statement at the same hierarchy level. To configure the time interval during which the BER must stay above or below the configured thresholds to raise or clear the alarm, include the interval statement at the same hierarchy level.

NOTE: For the P1-PTX-2-100G-WDM PIC, the BER must stay above the signal degradation threshold for ten consecutive intervals for the alarm to be raised and the BER must stay below the clear threshold for ten consecutive intervals for the alarm to be cleared. For example, if the interval is configured as 10 ms, then the BER must stay above the signal degradation threshold for 100 ms (10 ms * 10 intervals) for the alarm to be raised, or below the clear threshold for 100 ms for the alarm to be cleared.

Options

Values: ***value***—BER threshold for clearing the signal degradation in scientific notation. Both the mantissa and exponent are configurable. Enter the value in the format *x*E-*n*, where *x* is the mantissa and *n* is the exponent. For example, 4.5E-3.

Range: The mantissa must be a decimal number. There is no limit on the number of digits before or after the decimal point.The exponent must be an integer from 0 through 9.

Default: See Table 98 on page 941 for the default values.

BEST PRACTICE: Always set the **ber-threshold-clear** ***value*** lower than the **ber-threshold-signal-degrade** *value*. For the FEC limits, see the table describing the signal degrade and clear thresholds after configuration in "Understanding Pre-FEC BER Monitoring and BER Thresholds" on page 477.

NOTE: In Junos OS Release 13.2R1, only the exponent is valid input for the BER threshold value, and the mantissa is not configurable. The BER threshold value is 1.0E–*n* where *n* > 0, and the valid range of *n* is from 1 through 10.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

ber-threshold-signal-degrade

Syntax ber-threshold-signal-degrade *value*;

Hierarchy Level [edit interfaces *interface-name* otn-options signal-degrade]
[edit interfaces *interface-name* otn-options odu-signal-degrade]

Release Information Statement introduced in Junos OS Release 13.2 for PTX Series routers.
Statement introduced in Junos OS Release 15.1F6 for MPC5E, MIC6-100G-CFP2 on MPC6E on MX240, MX480, MX960, MX2010, and MX2020 routers.

Description Specify the bit error rate (BER) threshold to raise an interface alarm for signal degradation.

You can configure the BER signal degrade threshold to customize the BER that will raise an interface alarm when signal degrade monitoring is enabled.

NOTE: Configuring a high BER threshold for signal degradation and a long interval might cause the internal bit error counter register to get saturated. For example, for the P1-PTX-2-100G-WDM PIC, the internal bit error counter gets saturated when the error count reaches 2E+29. Therefore, the value of ber-threshold-signal-degrade * line rate / interval must be less than 2E+29 to avoid saturation. Assuming a fixed PIC line rate of 1.27E+11 bits per second and an interval of 1000 ms, the **ber-threshold-signal-degrade** value must be less than 4.22E–3.

If the value of the ber-threshold-signal-degrade * line rate / interval exceeds the saturation limit, the configuration is ignored by the router, and the default values are used instead. A system log message is logged for this error.

If you configure the BER thresholds at the **[edit interfaces *interface-name* otn-options signal-degrade]** hierarchy level, then the thresholds are calculated using the pre-forward error correction (pre-FEC) BER (the BER before FEC correction). These thresholds are used for pre-FEC BER monitoring. See “Understanding Pre-FEC BER Monitoring and BER Thresholds” on page 477 for more information about pre-FEC BER monitoring and determining BER threshold settings.

If you configure the BER thresholds at the **[edit interfaces *interface-name* otn-options odu-signal-degrade]** hierarchy level, then the thresholds are calculated using the post-FEC BER (the BER after FEC correction). This BER is referred to as the optical channel data unit (ODU) BER.

NOTE: You can configure ODU BER thresholds only at the **[edit interfaces *interface-name* otn-options odu-signal-degrade]** hierarchy level on the P2-100GE-OTN PIC.

Table 99 on page 944 shows the default values for pre-FEC BER and ODU BER signal degrade threshold values for different PICs. If the BER signal degrade threshold is not configured, the default value is used.

Table 99: Default Signal Degrade Threshold Values

PIC or MPC	Default Pre-FEC BER Signal Degrade Threshold Value	Default ODU BER Signal Degrade Threshold Value
P1-PTX-2-100G-WDM	7.5E–3	Not supported
P2-100GE-OTN	7.5E–3	1.0E–6
P1-PTX-24-10G-W-SFPP	7.5E–3	Not supported
MIC6-100G-CFP2	1.14E-5	1.0E-06
MPC5E	1.14E-5	1.0E-06

To configure the threshold that clears the signal degrade alarm, include the **ber-threshold-clear** statement at the same hierarchy level. To configure the time interval during which the BER must stay above or below the configured thresholds to raise or clear the alarm, include the **interval** statement at the same hierarchy level.

NOTE: For the P1-PTX-2-100G-WDM PIC, the BER must stay above the signal degradation threshold for ten consecutive intervals for the alarm to be raised and the BER must stay below the clear threshold for ten consecutive intervals for the alarm to be cleared. For example, if the interval is configured as 10 ms, then the BER must stay above the signal degradation threshold for 100 ms (10 ms * 10 intervals) for the alarm to be raised, or below the clear threshold for 100 ms for the alarm to be cleared.

Options

value—BER threshold for signal degradation in scientific notation. Both the mantissa and exponent are configurable. Enter the value in the format *x*E–*n*, where *x* is the mantissa and *n* is the exponent. For example, 4.5E–3.

Range: The mantissa must be a decimal number. There is no limit on the number of digits before or after the decimal point.The exponent must be an integer from 0 through 9.

Default: See Table 99 on page 944.

NOTE: In Junos OS Release 13.2R1, only the exponent is valid input for the BER threshold value, the mantissa is not configurable. The BER threshold value is 1.0E–*n* where *n* > 0, and the valid range of *n* is from 1 through 10.

BEST PRACTICE: To enable proactive protection before packet loss occurs, set the **ber-threshold-signal-degrade** *value* below the FEC limit. For the FEC limits, see the table describing the signal degrade and clear thresholds after configuration in "Understanding Pre-FEC BER Monitoring and BER Thresholds" on page 477.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

bypass

Syntax (bypass | no-bypass);

Hierarchy Level [edit interfaces *interface-name* otn-options odu-delay-management]

Release Information Statement introduced in Junos OS Release 13.2 for PTX Series routers.

Description Pass or do not pass the delay measurement (DM) value through a node.

Default If you omit the bypass statement, the default behavior is to disable ODU delay management options.

By default, do not pass the DM value through a node.

Options **bypass**—Pass the DM value through a node.

no-bypass—Do not pass the DM value through a node.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

bytes (otn-options)

Syntax bytes transmit-payload-type *value*;

Hierarchy Level [edit interfaces *interface-name* otn-options]

Release Information Statement introduced in Junos OS Release 13.2 for PTX Series routers.

Description Specify the transmit payload type on OTN header bytes.

Options *value*—Transmit payload type.

Range: 0 through 255 bytes

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

fec

Syntax fec (efec | gfec | gfec-sdfec |hgfec | sd-fec | ufec | none);

Hierarchy Level [edit interfaces *interface-name* otn-options]

Release Information Statement introduced in Junos OS Release 9.4.
Statement and **gfec-sdfec** option introduced in Junos OS Release 13.2 for PTX Series routers. with P1-PTX-2-100G-WDM PIC.
Options **efec**, **gfec**, and **ufec** introduced in Junos OS Release 13.3 for MX Series routers. with MPC5E-100G10G, MPC5E-40G10G, MIC6-10G-OTN, and MIC6-100G-CFP2.
Options **efec**, **gfec**, and **ufec** introduced in Junos OS Release 14.1 for PTX Series routers. with P1-PTX-24-10G-W-SFPP.
Option **hgfec** introduced in Junos OS Release 15.1F5 for MX Series Routers with MIC3-100G-DWDM MIC.
Option **sdfec** introduced in Junos OS Release 15.1F5 for MX Series Routers with MIC3-100G-DWDM MIC.
Option **sdfec** introduced in Junos OS Release 15.1F6 for PTX Series Routers with PTX-5-100G-WDM PIC.

Description Enable forward error correction (FEC) mode.

Default If you do not specify a mode, the default mode is **gfec**. On PTX Series routers with P1-PTX-2-100G-WDM, the default value is **gfec-sdfec**. On PTX Series routers with PTX-5-100G-WDM and on MX Series routers with MIC3-100G-DWDM, the default value is **sdfec**.

Options efec—(M Series, MX Series routers and PTX Series routers only) G.975.1 I.4 enhanced forward error correction (EFEC) is configured to detect and correct bit errors. This mode is supported only on 10G ports and not supported on the 40G and 100G ports.

gfec—(M series, MX Series routers and PTX Series routers only) G.709 generic forward error correction (GFEC) mode is configured to detect and correct bit errors.

gfec-sdfec—(PTX Series routers only) GFEC and soft-decision forward error correction (SD-FEC) modes are configured to detect and correct bit errors.

hgfec—(MX Series routers only) High gain forward error correction mode is configured to detect and correct bit errors.

sdfec—(MX Series routers and PTX Series routers only) Soft-decision forward error correction mode is configured to detect and correct bit errors.

none—(M Series and MX Series routers only) FEC mode is not configured.

NOTE: On MX Series routers with MIC3-100G-DWDM and PTX Series routers with PTX-5-100G-WDM, none option is not supported. The fec mode must be enabled on the MIC3-100G-DWDM MIC and the PTX-5-100G-WDM PIC.

ufec—(MX Series routers and PTX Series routers only) G.975.1 I.7 Ultra Forward Error Correction (UFEC) mode is configured to detect and correct bit errors. This mode is supported only on 10G ports and not supported on the 40G and 100G ports.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

fixed-stuff-bytes

Syntax (fixed-stuff-bytes | no-fixed-stuff-bytes);

Hierarchy Level [edit interfaces *interface-name* otn-options rate]

Release Information Statement introduced in Junos OS Release 9.4.

Description Enable or disable fixed stuff bytes.

Default By default, no fixed stuff bytes are set.

Options **fixed-stuff-bytes**—Fixed stuff bytes 11.0957 Gbps.

no-fixed-stuff-bytes—No fixed stuff bytes 11.0491 Gbps.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- 10-Gigabit Ethernet OTN Options Configuration Overview on page 465

interval

Syntax interval *value*;

Hierarchy Level [edit interfaces *interface-name* otn-options signal-degrade]
[edit interfaces *interface-name* otn-options odu-signal-degrade]

Release Information Statement introduced in Junos OS Release 13.2 for PTX Series routers.
Statement introduced in Junos OS Release 15.1F6 for MPC5E, MIC6-100G-CFP2 on MPC6E on MX240, MX480, MX960, MX2010, and MX2020 routers.

Description Specify the interval for which the BER must stay above the signal degradation threshold—as configured in the ber-threshold-signal-degrade ***value*** statement—for the alarm to raised. After an alarm is raised, if the BER returns below the clear threshold—as configured in the ber-threshold-clear ***value*** statement—for the specified interval, the alarm is cleared.

NOTE: Configuring a high BER threshold for signal degradation and a long interval might cause the internal counter register to be saturated. Such a configuration is ignored by the router, and the default values are used instead. A system log message is logged for this error.

If you configure the BER thresholds at the **[edit interfaces *interface-name* otn-options signal-degrade]** hierarchy level, then the thresholds are calculated using the pre-forward error correction (pre-FEC) BER (the BER before FEC correction). These thresholds are used for pre-FEC BER monitoring. See “Understanding Pre-FEC BER Monitoring and BER Thresholds” on page 477 for more information about pre-FEC BER monitoring and determining BER threshold settings.

If you configure the BER thresholds at the **[edit interfaces *interface-name* otn-options odu-signal-degrade]** hierarchy level, then the thresholds are calculated using the post-FEC BER (the BER after FEC correction). This BER is referred to as the optical channel data unit (ODU) BER.

NOTE: You can configure ODU BER thresholds only at the [edit interfaces *interface-name* otn-options odu-signal-degrade] hierarchy level on the P2-100GE-OTN PIC.

Options ***value***—Time interval in milliseconds.

NOTE: For the P1-PTX-2-100G-WDM PIC, the BER must stay above the signal degradation threshold for ten consecutive intervals for the alarm to be raised and the BER must stay below the clear threshold for ten consecutive intervals for the alarm to be cleared. For example, if the interval is configured as 10 ms, then the BER must stay above the signal degradation threshold for 100 ms (10 ms * 10 intervals) for the alarm to be raised, or below the clear threshold for 100 ms for the alarm to be cleared.

NOTE: For P1-PTX-24-10G-W-SFPP PIC and P2-100GE-OTN PIC, when the router cannot configure BER with the given interval, it selects an optimum interval that is supported for the given BER configuration. If the router is still not able to support the configuration (for example, with a wider gap between the degrade set and clear values), the default values are used and a log is generated.

For the P2-10G-40G-QSFPP PIC, the time interval is supported in multiples of 100 ms. For example, when you configure the interval as 10 ms, then it is rounded off to the nearest multiple of 100 ms.

Range: 1 ms through 1000 ms.

Default: 100 ms.

NOTE: For the P2-100GE-OTN PIC, the default value is 10 ms.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Release Information Statement introduced in Junos OS Release 14.1R2 for P2-100GE-OTN PIC in PTX5000 routers.
Statement introduced in Junos OS Release 14.2 for P2-100GE-OTN PIC in PTX5000 routers.
Statement introduced in Junos OS Release 15.1F6 for MPC5E, MIC6-100G-CFP2 on MPC6E on MX240, MX480, MX960, MX2010, and MX2020 routers.

Description Disable preemptive fast reroute (FRR) ODU backward FRR insertion.

Default By default, FRR ODU backward FRR insertion is disabled.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

[edit interfaces *interface-name* otn-options]

Release Information

Statement introduced in Junos OS Release 14.1R2 for P2-100GE-OTN PIC in PTX5000 routers.
Statement introduced in Junos OS Release 14.2 for P2-100GE-OTN PIC in PTX5000 routers.
Statement introduced in Junos OS Release 15.1F6 for MPC5E, MIC6-100G-CFP2 on MPC6E on MX240, MX480, MX960, MX2010, and MX2020 routers.

Description

Specify optical channel data unit (ODU) signal degradation threshold-related values.

Default

If you omit the **odu-signal-degrade** statement, the default threshold values are used.

The following are the default threshold values for optical channel data unit (ODU) signal degradation for the P2-100GE-OTN PIC:

- ber-threshold-clear—1E-09
- ber-threshold-signal-degrade—1E-06
- interval—10 ms

The following are the default threshold values for optical channel data unit (ODU) signal degradation for the MPC5E and the MIC6-100G-CFP2 MIC:

- ber-threshold-clear—1.14E-5
- ber-threshold-signal-degrade—1.0E-6
- interval—10 ms

Options

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

remote-loop-enable

Syntax (remote-loop-enable | no-remote-loop-enable);

Hierarchy Level [edit interfaces *interface-name* otn-options odu-delay-management]

Release Information Statement introduced in Junos OS Release 17.1 for 100-Gigabit OTN DWDM PIC with CFP2 on PTX3000 and PTX5000 routers.
Statement introduced in Junos OS Release 17.1 for 100-Gigabit OTN DWDM MIC with CFP2-ACO on MX240, MX480, MX960, MX2010, and MX2020 routers with MPC3E and MPC3E-NG.

Description Enable the remote interface to loop back the delay measurement pattern to the local interface. Delay is measured by transmitting a known pattern (delay measurement pattern) in a selected bit of the delay measurement (**DM**) field and measuring the number of frames that are missed when the delay measurement pattern is received at the transmitting end (local interface).

NOTE: Do not enable remote loopback on both ends (local and remote). If you enable remote loopback on both interfaces, the delay measurement pattern is looped back continuously between the two interfaces.

Default Delay measurement is disabled by default.

Options **remote-loop-enable**—Enables loopback of the delay measurement pattern at the remote interface.

no-remote-loop-enable—Disables loopback of the delay measurement pattern at the remote interface.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

signal-degrade

Syntax

```
signal-degrade {
  ber-threshold-clear value;
  ber-threshold-signal-degrade value;
  interval value;
}
```

Hierarchy Level [edit interfaces *interface-name* otn-options]

Release Information Statement introduced in Junos OS Release 13.2 for PTX Series routers.
Statement introduced in Junos OS Release 13.3 for MX Series routers.
.

Description Specify bit error rate (BER) signal degradation thresholds and time interval for raising and clearing alarms for optical transport network (OTN) links.

Default If you omit the **signal-degrade** statement, the default threshold values are used.

Options The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

signal-degrade-monitor-enable

Syntax (signal-degrade-monitor-enable | no-signal-degrade-monitor-enable);

Hierarchy Level [edit interfaces *interface-name* otn-options preemptive-fast-reroute]

Release Information Statement introduced in Junos OS Release 13.2 for PTX Series routers.

Description Enable or disable pre-forward error correction (FEC) bit error rate (BER) monitoring.

With pre-FEC BER monitoring enabled, when the configured pre-FEC BER signal degrade threshold is reached, the PIC stops forwarding packets to the remote interface and raises an interface alarm. Ingress packets continue to be processed. If pre-FEC BER monitoring is used with MPLS fast reroute or another link protection method, then traffic is rerouted to a different interface.

You can also configure backward fast reroute to insert local pre-FEC BER status into transmitted OTN frames, notifying the remote interface of signal degradation. The remote interface can use the information to reroute traffic to a different interface. If you use pre-FEC BER monitoring together with backward fast reroute, then notification of signal degradation and rerouting of traffic occurs in less time than that required through a Layer 3 protocol. To configure backward fast reroute, include the backward-frr-enable statement at the same hierarchy level.

NOTE: **When you configure pre-FEC BER signal degrade monitoring, we recommend that you configure both the signal-degrade-monitor-enable and backward-frr-enable statements.**

You can also configure the pre-FEC BER thresholds that raise or clear a signal degrade alarm and the time interval for the thresholds. If the BER thresholds and interval are not configured, the default values are used. Include the ber-threshold-signal-degrade ***value***, ber-threshold-clear ***value***, and interval ***value*** statements at the **[edit interfaces *interface-name*** otn-options signal-degrade**]** hierarchy level to configure the BER thresholds and time interval. See “Understanding Pre-FEC BER Monitoring and BER Thresholds” on page 477 for more information about pre-FEC BER monitoring and determining BER threshold settings.

Default By default, pre-FEC BER signal degrade monitoring is disabled.

Options **signal-degrade-monitor-enable**—Enable pre-FEC BER signal degrade monitoring.

no-signal-degrade-monitor-enable—Do not enable pre-FEC BER signal degrade monitoring.

Required Privilege Level
interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

tca

Syntax tca *tca-identifier* (enable-tca | no-enable-tca) (threshold *number* | threshold-24hrs *number*)

Hierarchy Level [edit interfaces *interface-name* optics-options]

[edit interfaces *interface-name* otn-options]

Release Information Statement introduced in Junos OS Release 14.2 on the PTX Series.

Description TCAs can give the management system an early indication as to the state of the associated entity when it crosses a certain threshold. TCAs can be set for both minimum and maximum values for gauges and only maximum values for counters. The timely detection of TCAs is essential to proactively manage the interface. TCAs are not an indication of a fault, but rather an indication that the entity may be close to a fault. You can choose which TCAs you want monitored by enabling the TCA. You can either keep the default threshold settings or change the settings.

Enable threshold crossing alerts (TCAs) for the following:

- Optical channel data unit (ODU)
- Optical channel transport unit (OTU)
- Laser power
- Laser temperature

Default By default, TCAs are not enabled.

Options *tca-identifier* —At the otn-options hierarchy level, it can be one of the following:

- **odu-tca-bbe**—ODU background block error threshold-crossing defect trigger
- **odu-tca-bbe-fe**—ODU far-end background block error threshold-crossing defect trigger
- **odu-tca-es**—ODU errored seconds threshold-crossing defect trigger
- **odu-tca-es-fe**—ODU far-end errored seconds threshold-crossing defect trigger
- **odu-tca-ses**—ODU severely errored seconds threshold-crossing defect trigger
- **odu-tca-ses-fe**—ODU far-end severely errored seconds threshold-crossing defect trigger
- **odu-tca-uas**—ODU unavailable seconds threshold-crossing defect trigger
- **odu-tca-uas-fe**—ODU far-end unavailable seconds threshold-crossing defect trigger
- **otu-tca-bbe**—OTU background block error threshold-crossing defect trigger
- **otu-tca-bbe-fe**—OTU far-end background block error threshold-crossing defect trigger
- **otu-tca-es**—OTU errored seconds threshold-crossing defect trigger

- **otu-tca-es-fe**—OTU far-end errored seconds threshold-crossing defect trigger
- **otu-tca-fec-ber**—OTU forward error correction bit error rate threshold-crossing defect trigger
- **otu-tca-ses**—OTU severely errored seconds threshold-crossing defect trigger
- **otu-tca-ses-fe**—OTU far-end severely errored seconds threshold-crossing defect trigger
- **otu-tca-uas**—OTU unavailable seconds threshold-crossing defect trigger
- **otu-tca-uas-fe**—OTU far-end unavailable seconds threshold-crossing defect trigger

tca-identifier —At the optics-options hierarchy level, it can be one of the following:

- **carrier-frequency-offset-high-tca**—Carrier frequency high threshold setting trigger
- **carrier-frequency-offset-low-tca**—Carrier frequency low threshold setting trigger
- **rx-power-high-tca**—Rx power high threshold setting trigger
- **rx-power-low-tca**—Rx power low threshold setting trigger
- **temperature-high-tca**—Temperature high threshold setting trigger
- **temperature-low-tca**—Temperature low threshold setting trigger
- **tx-power-high-tca**—Tx power high threshold setting trigger
- **tx-power-low-tca**—Tx power low threshold setting trigger

enable-tca | no-enable-tca—To enable or disable the threshold crossing alert.

threshold | threshold-24hrs:

- threshold *number*—Set the 15-minute interval threshold.
- threshold-24hrs *number*—Set the 24-hour interval threshold.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

transport-monitoring

Syntax transport-monitoring;

Hierarchy Level [edit interfaces]

Release Information Statement introduced in Junos OS Release 14.2 for PTX5000 and PTX3000 routers.

Description Monitor the performance and state of packet transport for OTN and optics modules. The following statistics are monitored:

- Packet transport for ninety-six 15–minute intervals for the current 24 hours.
- Cumulative data of the current 24 hours.
- Cumulative data of the previous 24 hours.

If this statement is configured, transport monitoring related information is shown in the output of **show interface transport** command and corresponding MIBs are available. If this option is disabled, an error is shown in the output and corresponding MIBs are not available.

Required Privilege Level system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

trigger

Syntax trigger *trigger-identifier* (hold-time *hold-time-value* | ignore);

Hierarchy Level [edit interfaces *interface-name* otn-options]

Release Information Statement introduced in Junos OS Release 9.4.
Statement introduced in Junos OS Release 13.2 for PTX Series routers.

Description Specify defect triggers.

Default By default, triggers are ignored.

Options *trigger-identifier*—(For M Series, MX Series, SRX Series, and T Series routers only) Trigger identifier. It can be one of the following:

- **oc-lof**—Optical channel Loss of Frame defect trigger.
- **oc-lom**—Optical channel Loss of Multiframe defect trigger.
- **oc-los**—Optical channel Loss of Signal defect trigger.
- **oc-wavelength-lock**—Optical channel Wavelength Lock defect trigger.
- **odu-ais**—Optical channel data unit (ODU) Alarm Indication Signal defect trigger.
- **odu-bbe-th**—ODU Background Block Error Threshold defect trigger.
- **odu-bdi**—ODU Backward Defect Indication defect trigger.
- **odu-bei**—(MX Series routers only) ODU Backward Error Indication defect trigger.
- **odu-es-th**—ODU Errored Seconds Threshold defect trigger.
- **odu-iae**—(MX Series routers only) ODU Incoming Alignment Error defect trigger.
- **odu-lck**—ODU Locked defect trigger.
- **odu-oci**—ODU Open Connection Indication defect trigger.
- **odu-sd**—ODU Signal Degrade defect trigger.
- **odu-ses-th**—ODU Severely Errored Seconds Threshold defect trigger.
- **odu-tca-es**—(MX Series routers only) ODU Errored Seconds Threshold crossing defect trigger.
- **odu-tca-ses**—(MX Series routers only) ODU Severely Errored Seconds Threshold crossing defect trigger.
- **odu-tca-uas**—(MX Series routers only) ODU Unavailable Seconds Threshold crossing defect trigger.
- **odu-ttim**—ODU Trail Trace Identifier Mismatch defect trigger.
- **opu-ptim**—(MX Series routers only) Payload Type Identifier Mismatch defect trigger.

- **odu-uas-th**—ODU Unavailable Seconds Threshold defect trigger.
- **opu-ptm**—Optical Channel Payload (OPU) Payload Type Mismatch defect trigger.
- **otu-ais**—Optical Channel Transport Unit (OTU) Alarm Indication Signal defect trigger.
- **otu-bbe-th**—OTU Background Block Error Threshold defect trigger.
- **otu-bdi**—OTU Backward Defect Indication defect trigger.
- **otu-es-th**—OTU Errored Seconds Threshold defect trigger.
- **otu-fec-deg**—OTU FEC Degrade defect trigger.
- **otu-fec-exe**—OTU FEC Excessive Error defect trigger.
- **otu-iae**—OTU Incoming Alignment defect trigger.
- **otu-sd**—OTU Signal Degrade defect trigger.
- **otu-ses-th**—OTU Severely Errored Seconds Threshold defect trigger.
- **otu-tca-es**—(MX Series routers only) OTU Errored Seconds Threshold crossing defect trigger.
- **otu-tca-ses**—(MX Series routers only) OTU Severely Errored Seconds Threshold crossing defect trigger.
- **otu-tca-uas**—(MX Series routers only) OTU Unavailable Seconds Threshold crossing defect trigger.
- **otu-ttim**—OTU Trail Trace Identifier Mismatch defect trigger.
- **otu-uas-th**—OTU Unavailable Seconds Threshold defect trigger.

trigger-identifier—(For PTX Series routers only) Trigger identifier. It can be one of the following:

- **oc-lof**—Optical channel Loss of Frame defect trigger.
- **oc-lom**—Optical channel Loss of Multiframe defect trigger.
- **oc-los**—Optical channel Loss of Signal defect trigger.
- **oc-tsf**—Optical channel TOE security functionality (TSF) defect trigger.
- **oc-wavelength-lock**—Optical channel Wavelength Lock defect trigger.
- **odu-ais**—ODU Alarm Indication Signal defect trigger.
- **odu-bdi**—ODU Backward Defect Indication defect trigger.
- **odu-bei**—ODU Backward Error Indication defect trigger.
- **odu-iae**—ODU IAE defect trigger.
- **odu-lck**—ODU Locked defect trigger.
- **odu-oci**—ODU Open Connection Indication defect trigger.

- **otu-tca-uas-fe**—OTU far-end Unavailable Seconds Threshold crossing defect trigger.
- **otu-ttim**—OTU Trail Trace Identifier Mismatch defect trigger.

hold-time *hold-time-value*—Hold time value. It can be one of the following:

- **down**—Delay before marking interface down when defect occurs (1..65534 milliseconds).
- **up**—Delay before marking interface up when defect is absent (1..65534 milliseconds).

NOTE: The trigger hold time value alone does not mark an interface to be up when the defect is absent or mark an interface to be down when the defect occurs. The hold time value only impacts the alarm reporting time. To mark an interface up or down, you must also configure the physical interface hold time at the [edit interfaces *interface-name* hierarchy level].

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

tti

Syntax tti *tti-identifier*;

Hierarchy Level [edit interfaces *interface-name* otn-options]

Release Information Statement introduced in Junos OS Release 9.4.
Statement introduced in Junos OS Release 13.2 for PTX Series routers.
Statement introduced in Junos OS Release 13.3 for MX Series routers.

Description Specify trace identifier options.

Options *tti-identifier*—Trace identifier. It can be one of the following:

- **odu-dapi**—Optical Channel Data Unit (ODU) Destination Access Point Identifier.
- **odu-expected-receive-dapi**—ODU Expected Receive Destination Access Point Identifier.
- **odu-expected-receive-sapi**—ODU Expected Receive Source Access Point Identifier.
- **odu-sapi**—ODU Source Access Point Identifier.
- **otu-dapi**—Optical Channel Transport Unit (OTU) Destination Access Point Identifier.
- **otu-expected-receive-dapi**—OTU Expected Receive Destination Access Point Identifier.
- **otu-expected-receive-sapi**—OTU Expected Receive Source Access Point Identifier.
- **otu-sapi**—OTU Source Access Point Identifier.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

tx-power

Syntax tx-power *dbm*;

Hierarchy Level [edit interfaces *interface-name* optics-options]

Release Information Statement introduced in Junos OS Release 13.2 for PTX Series routers.

Description Transmit laser output power (dBm).

Default If you don’t specify a value, the default transmit laser output power is –2 dBm.

Options ***dbm***—Transmit power value.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

warning

Syntax

```
warning low-light-warning {
   (link-down | syslog);
}
```

Hierarchy Level [edit interfaces *interface-name* optics-options]

Release Information

Statement introduced in Junos OS Release 10.0.
Statement introduced in Junos OS Release 12.1 for EX Series switches.
Statement introduced in Junos OS Release 13.2 for PTX Series routers.

Description Specifies the action to take if the receiving optics signal is below the optics low-light warning threshold.

Options

link-down—Drop the 10-Gigabit Ethernet link and marks link as down.

syslog—Write the optics information to the system log.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

wavelength

Syntax wavelength *nm*;

Hierarchy Level [edit interfaces *interface-name* optics-options]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1 for EX Series switches.
Statement introduced in Junos OS Release 13.2 for PTX Series routers.

Description For 10-Gigabit or 100-Gigabit Ethernet DWDM interfaces only, configure full C-band ITU-Grid tunable optics.

Options *nm*—Wavelength value. It can be one of the following:

NOTE: **All values are displayed. However, if you configure a value that is not supported by the device, an error message is displayed and the device is not tuned to the specified wavelength.**

- **1528.38**—1528.38 nanometers (nm), corresponds to a 50-GHz grid
- **1528.77**—1528.77 nm, corresponds to 50-GHz and 100-GHz grids
- **1529.16**—1529.16 nm, corresponds to a 50-GHz grid
- **1529.55**—1529.55 nm, corresponds to 50-GHz and 100-GHz grids
- **1529.94**—1529.94 nm, corresponds to a 50-GHz grid
- **1530.33**—1530.33 nm, corresponds to 50-GHz and 100-GHz grids
- **1530.72**—1530.72 nm, corresponds to a 50-GHz grid
- **1531.12**—1531.12 nm, corresponds to 50-GHz and 100-GHz grids
- **1531.51**—1531.51 nm, corresponds to a 50-GHz grid
- **1531.90**—1531.90 nm, corresponds to 50-GHz and 100-GHz grids
- **1532.29**—1532.29 nm, corresponds to a 50-GHz grid
- **1532.68**—1532.68 nm, corresponds to 50-GHz and 100-GHz grids

avg-fd-twoway-threshold

Syntax
avg-fd-twoway-threshold *avg-fd-twoway-threshold-value* {
flap-trap-monitor *seconds*;}

Hierarchy Level
[edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles *profile-name*]

Release Information
Statement introduced in Junos OS Release 15.1 for MX Series routers.

Description
Configure the threshold value for average frame delay, in microseconds, for two-way Ethernet frame delay measurement (ETH-DM). When the configured threshold for average frame delay is exceeded, an SNMP trap is generated for ETH-DM. SNMP traps are triggered if you configure either the average frame-delay threshold or the average inter-frame delay variance threshold. If you do not configure either the frame-delay threshold or the frame delay variation threshold, no SNMP traps are generated. You can configure these threshold values only with a two-way ETH-DM SLA iterator.

Frame delay refers to the difference, in microseconds, between the time a frame is sent and when it is received. Frame delay variation refers to the difference, in microseconds, between consecutive frame delay values. Frame delay variation is sometimes called "frame jitter." For one-way Ethernet frame delay measurement, only the receiver MEP (on the remote system) collects statistics. For two-way Ethernet frame delay measurement, only the initiator MEP (on the local system) collects statistics.

Options
avg-fd-twoway-threshold-value—Threshold value for average frame delay, in microseconds, for two-way ETH-DM.

Range: 1 through 4294967295 microseconds

flap-trap-monitor *seconds*—Duration in seconds, for summarizing flap occurrences and send out a single jnxSoamPm ThresholdFlapAlarm notification to the network management system (NMS).

Range: 1 through 360 seconds

Required Privilege Level
Configure—To enter configuration mode.
Control—To modify any configuration.

avg-ifdv-twoway-threshold *avg-ifdv-twoway-threshold-value*; {
flap-trap-monitor *seconds*; }

Hierarchy Level

[edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles *profile-name*]

Release Information

Statement introduced in Junos OS Release 15.1 for MX Series routers.

Description

Configure the threshold value for average frame delay variation, in microseconds, for two-way Ethernet frame delay measurement (ETH-DM). When the configured threshold for average frame delay variation is exceeded, an SNMP trap is generated for ETH-DM. SNMP traps are triggered if you configure either the average frame-delay threshold or the average inter-frame delay variance threshold. If you do not configure either the frame-delay threshold or the frame delay variation threshold, no SNMP traps are generated. You can configure these threshold values only with a two-way ETH-DM SLA iterator.

Frame delay refers to the difference, in microseconds, between the time a frame is sent and when it is received. Frame delay variation refers to the difference, in microseconds, between consecutive frame delay values. Frame delay variation is sometimes called "frame jitter." For one-way Ethernet frame delay measurement, only the receiver MEP (on the remote system) collects statistics. For two-way Ethernet frame delay measurement, only the initiator MEP (on the local system) collects statistics. In two-way ETH-DM mode, frame delay and frame delay variation values are based on the time difference between when the initiator MEP transmits a request frame and receives a reply frame from the responder MEP, subtracting the time elapsed at the responder MEP.

Options

avg-ifdv-twoway-threshold-value—Threshold value for average frame delay variation, in microseconds, for two-way ETH-DM.

Range: 1 through 4294967295 microseconds

flap-trap-monitor *seconds*—Duration in seconds, for summarizing flap occurrences and send out a single jnxSoamPm ThresholdFlapAlarm notification to the network management system (NMS).

Range: 1 through 360 seconds

Required Privilege Level

configure—To enter configuration mode.
control—To modify any configuration.

avg-flr-forward-threshold

Syntax avg-flr-forward-threshold *avg-flr-forward-threshold-value*;{
flap-trap-monitor *seconds*; }

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles *profile-name*]

Release Information Statement introduced in Junos OS Release 15.1 for MX Series routers.

Description Configure the threshold value for average frame loss ratio, in milli-percent, in the upstream or forward direction for Ethernet loss measurement (ETH-LM) and Ethernet synthetic loss measurement (ETH-SLM). When the configured threshold for average forward frame loss ratio is exceeded, an SNMP trap is generated for ETH-LM and ETH-SLM. SNMP traps are triggered if you configure either the average backward frame loss ratio threshold or the average forward frame loss ratio threshold. If you do not configure either the average backward frame loss ratio threshold or the average forward frame loss ratio threshold, no SNMP traps are generated. You can configure these threshold values with an SLA iterator for ETH-SLM and ETH-LM.

ETH-SLM is an application that enables the calculation of frame loss by using synthetic frames instead of data traffic. This mechanism can be considered as a statistical sample to approximate the frame loss ratio of data traffic.

Options ***avg-flr-forward-threshold-value***—Threshold value for average frame loss ratio in the forward or upstream direction, in milli-percent, for ETH-SLM and ETH-LM.

Range: 1 through 100000 milli-percent

flap-trap-monitor *seconds*—Duration in seconds, for summarizing flap occurrences and send out a single jnxSoamPm ThresholdFlapAlarm notification to the network management system (NMS).

Range: 1 through 360 seconds

Required Privilege Level configure—To enter configuration mode.
control—To modify any configuration.

avg-flr-backward-threshold

Syntax
avg-flr-backward-threshold *avg-flr-backward-threshold-value*;{
flap-trap-monitor *seconds*; }

Hierarchy Level
[edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles *profile-name*]

Release Information
Statement introduced in Junos OS Release 15.1 for MX Series routers.

Description
Configure the threshold value for average frame loss ratio, in milli-percent, in the backward or downstream direction for Ethernet loss measurement (ETH-LM) and Ethernet synthetic loss measurement (ETH-SLM). When the configured threshold for average backward frame loss ratio is exceeded, an SNMP trap is generated for ETH-LM and ETH-SLM. SNMP traps are triggered if you configure either the average backward frame loss ratio threshold or the average forward frame loss ratio threshold. If you do not configure either the average backward frame loss ratio threshold or the average forward frame loss ratio threshold, no SNMP traps are generated. You can configure these threshold values with an SLA iterator for ETH-SLM and ETH-LM.

ETH-SLM is an application that enables the calculation of frame loss by using synthetic frames instead of data traffic. This mechanism can be considered as a statistical sample to approximate the frame loss ratio of data traffic.

Options
avg-flr-backward-threshold-value—Threshold value for average frame loss ratio in the backward or downstream direction, in milli-percent, for ETH-SLM and ETH-LM.

Range: 1 through 100000 milli-percent

flap-trap-monitor *seconds*—Duration in seconds, for summarizing flap occurrences and send out a single jnxSoamPm ThresholdFlapAlarm notification to the network management system (NMS).

Range: 1 through 360 seconds

Required Privilege Level
configure—To enter configuration mode.
control—To modify any configuration.

calculation-weight

Syntax

```
calculation-weight {
  delay delay-value;
  delay-variation delay-variation-value;
}
```

Hierarchy Level

[edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles *profile-name*]

Release Information

Statement introduced in Junos OS Release 11.1.
Statement introduced in Junos OS Release 11.4 for EX Series switches.

Description

Configure the calculation weight for delay and delay variation.

NOTE: This option is applicable only for two-way delay measurement.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

Configure—To enter configuration mode.
Control—To modify any configuration.

clear-action (CFM)

Syntax

```
clear-action {
  interface-down peer-interface;
}
```

Hierarchy Level

[edit protocols oam ethernet connectivity-fault-management action-profile *profile-name*]

Release Information

Statement introduced in Junos OS Release 11.4.

Description

Clear the action or actions to be taken when the connectivity fault management event occurs. You cannot configure multiple actions at this time. Only one action can be configured. This limitation affects both the **action** and **clear-action** statements.

Options

peer-interface—Name of the peer interface.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

continuity-check

Syntax

```
continuity-check {
  convey-loss-threshold;
  hold-interval minutes;
  interface-status-tlv;
  interval (10m | 10s | 1m | 1s| 100ms | 10ms);
  loss-threshold number;
  port-status-tlv;
}
```

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name*]

Release Information Statement introduced in Junos OS Release 8.4.

Description Specify continuity check protocol options.

Options

convey-loss-threshold—Enable loss-threshold-tlv transmission.

hold-interval *minutes*—Specify the continuity check hold-interval, in minutes.

interface-status-tlv—Enable interface-status-tlv transmission.

interval *(10m | 10s | 1m | 1s| 100ms | 10ms)*—Specify the continuity check interval.

loss-threshold *minutes*—Specify the loss-threshold, in minutes.

port-status-tlv—Enable port-status-tlv transmission.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

convey-loss-threshold

Syntax convey-loss-threshold;

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name* continuity-check]

Description Enable loss-threshold-tlv transmission.

During a unified ISSU, the control plane may go down for several seconds and cause CFM continuity check packets to get dropped. This may cause the remote maintenance endpoint (MEP) to detect a connectivity loss and mark the MEP as down. To keep the MEP active during a unified ISSU, the loss threshold TLV communicates the minimum threshold value the receiving MEP requires to keep the MEP active. The receiving MEP parses the TLV and updates the loss threshold value, but only if the new threshold value is greater than the locally configured threshold value. You can control the transmission of the loss threshold TLV in continuity check messages PDUs. The **convey-loss-threshold** statement specifies that the loss threshold TLV must be transmitted as part of the continuity check messages. If the statement is not specified, continuity check messages transmit this TLV only when a unified ISSU is in progress.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

cross-connect-ccm

Syntax cross-connect-ccm;

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name* event ais-trigger-condition]

Release Information Statement introduced in Junos OS Release 14.2.

Description Configure the defect condition that raises an alarm indication signal when any cross-connect continuity check messages (CCMs) are received by the MEP.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

detect-loc

Syntax detect-loc;

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id* remote-mep *mep-id*]

[edit protocols oam ethernet link-fault-management interface *interface-name*]

Release Information Statement introduced in Junos OS Release 14.2.

Description Specify whether Ethernet OAM continuity checks are performed for an individual remote maintenance end point (MEP).

When you configure the **detect-loc** statement at [**edit protocols oam ethernet link-fault-management interface** ***interface-name***] hierarchy level, a loss-of-continuity (LOC) defect is raised when the peer is not found within a period that is equal to 3 times the current keepalive pdu interval. When an LOC defect is raised, a syslog error message is generated .

NOTE: When you configure the **detect-loc** statement at the [**edit protocols oam ethernet link-fault-management interface** ***interface-name***] hierarchy level, any **action-profile** configured to bring down the interface is executed when an LOC defect is detected. However, the **action-profile** is not executed if you have not configured **detect-loc** statement the **detect-loc** statement at the [**edit protocols oam ethernet link-fault-management interface** ***interface-name***] hierarchy level.

To view the current LOC status of an interface, execute the **show oam ethernet link-fault-management** command.

Default The MEP does not generate LOC defect messages by default.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

hardware-assisted-timestamping

Syntax hardware-assisted-timestamping;

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management performance-monitoring]

Release Information Statement introduced in Junos OS Release 9.5.

Description For Ethernet interfaces on Enhanced and Enhanced Queuing Dense Port Concentrators (DPCs) in MX Series routers only, enable hardware-assisted timestamping support for Ethernet frame delay measurement.

By default, the ETH-DM feature calculates frame delays using software-based timestamping of the ETH-DM PDU frames sent and received by the MEPs in the session. As an option that can increase the accuracy of ETH-DM calculations when the DPC is loaded with heavy traffic in the receive direction, you can enable hardware-assisted timestamping of session frames in the receive direction.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

hardware-assisted-keepalives

Syntax hardware-assisted-keepalives [enable | disable];

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management performance-monitoring]

Release Information Statement introduced in Junos OS Release 14.2R1.

Description For Ethernet interfaces on Modular Port Concentrators (MPCs) in MX Series routers only, delegate the transmission of the continuity check messages (CCMs) to the forwarding ASIC (that is, to the hardware) by enabling inline transmission of CCMs. Inline transmission of CCMs is also known as Inline-KA.

By default, CCMs are transmitted by the CPU of the MPC and not by the hardware. If the duration between transmissions of CCMs is low or if the CCMs for a specific line card scale, we recommend that you enable delegation of the transmission of CCMs to the hardware. By enabling inline transmission of CCMs, you can achieve maximum scaling of CCMs.

NOTE: The supported CCM interval values for MPC7E and MPC2E NG Q (MPC2E-3D-NG-Q) are 100ms, 10ms, and 1s.

Default Inline transmission is disabled by default.

Options **enable**—Enable inline transmission of CCMs.

NOTE: Inline transmission of CCMs is not enabled when there is a CFM session already established. To enable inline transmission, you must first deactivate the CFM session using the **deactivate** command and then reactivate the CFM session using the **activate** command.

disable—Disable inline transmission of CCMs.

NOTE: After disabling inline transmission of CCMs, you must reboot the router for the changes to take effect.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

interface-status-send-rdi

Syntax interface-status-send-rdi *interface-status-send-rdi*;

Hierarchy Level [edit logical-systems *name* protocols oam ethernet connectivity-fault-management maintenance-domain *name* maintenance-association *name* continuity-check],
[edit protocols oam ethernet connectivity-fault-management maintenance-domain *name* maintenance-association *name* continuity-check]

Release Information Statement introduced in Junos OS Release 17.3R1 for MX Series Routers.

Description Configure CFM to propagate the status of the provider edge device via the remote defect indication (RDI) bit in the CC messages when the interface is down. When the status of the EVPN provider edge device is standby, the EVPN VPWS service is notified and it sets the interface status to CCC-down. When the interface status is CCC-down, it indicates that the provider edge service is down. When you enable CFM monitoring, CFM propagates the status of the provider edge device via the remote defect indication (RDI) bit in the CC messages. Thus, the customer edge device is aware that the provider edge device is down.

Usually, when the interface goes down, CFM propagates the status of the provider edge device via the interface status TLV. If the customer edge device does not support the interface status TLV, you can use the RDI bit to propagate the status of the provider edge device.

Required Privilege Level routing—To view this statement in the configuration.

Related Documentation

interval

Syntax interval (100ms | 10m | 10ms | 10s | 1m | 1s);

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name* continuity-check]

Release Information Statement introduced in Junos OS Release 8.4.
Option **10ms** introduced in Junos OS Release 9.1.
Third-party interoperability during a unified in-service software upgrade (ISSU) introduced in Junos OS Release 17.1.

Description Configure the interval between successive transmissions of continuity check messages (CCMs) as part of the connectivity fault detection strategy. When the receiving maintenance association end point (MEP) does not receive a CCM at the configured interval, the **loss-threshold** statement determines how many CCMs can be lost before the sending MEP is marked as down. The **hold-interval** statement then determines the frequency at which the database of MEPs in the maintenance association (MA) is flushed in the absence of updates.

During a unified in-service software upgrade (ISSU), Junos OS connectivity fault management (CFM) works when the peer device is not a Juniper Networks router. Interoperating with the router of another vendor, the Juniper Networks router retains session information and continues to transmit CCM (continuity check message) PDUs during the unified ISSU upgrade. For this feature to work, you must enable Packet Forwarding Engine keepalives with the **hardware-assisted-keepalives** statement, and configure the interval between CCMs to be 1 second with **interval** statement.

NOTE: For the continuity check message interval to be configured for 10 milliseconds, periodic packet management (PPM) runs on the Routing Engine and Packet Forwarding Engine by default. You can disable PPM only on the Packet Forwarding Engine. To disable PPM on the Packet Forwarding Engine, use the no-delegate-processing statement at the [edit routing-options ppm] hierarchy level.

NOTE: A continuity check interval of 10 milliseconds is not supported for CFM sessions over a label-switched interface (LSI).

Options **100ms**—100 milliseconds.

10m—10 minutes.

10ms—10 milliseconds.

10s—10 seconds.

1m—1 minute.

1s—1 second.

Default: 1m

Syntax iteration-period *iteration-period-value*;

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles *profile-name*]

Release Information Statement introduced in Junos OS Release 11.1.
Statement introduced in Junos OS Release 11.4 for EX Series switches.

Description Configure the iteration period, which is the maximum number of cycles per iteration (that is, the number of connections registered to an iterator cannot exceed this value).

Options ***iteration-period-value***—Maximum number of cycles per iteration.

Range: 1 through 2000

Default: 2000

Required Privilege Level Configure—To enter configuration mode.
Control—To modify any configuration.

Related Documentation

level

Syntax

level *number*;

Hierarchy Level

[edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name*]

Release Information

Statement introduced in Junos OS Release 8.4.
Statement introduced in junos os release 12.1X48 for PTX Series Packet Transport Routers.

Description

A number used in connectivity fault management (CFM) messages to identify the maintenance association. The number is embedded in each of the CFM frames. CFM messages within a given level are processed by maintenance end points (MEPs) at the same level. For example, the operator domain can be level 0, the provider domain can be level 3, and the customer domain can be level 7.

Options

number—A number used to identify the maintenance domain to which the CFM message belongs.

Range: 0 through 7

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Creating a Maintenance Domain on page 603

level (CFM MEP)

Syntax level *value*;

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name* action log-and-generate-ais]

Release Information Statement introduced in Junos OS Release 14.2.

Description Configure the server maintenance domain level for the MEP.

Options **value**—Maintenance domain level.

Range: 1 through 7

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation
- Ethernet Alarm Indication Signal (ETH-AIS) Function Overview on page 805

linktrace

Syntax

```
linktrace {
  age (30m | 10m | 1m | 30s | 10s);
  path-database-size path-database-size;
}
```

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management]

Release Information Statement introduced in Junos OS Release 8.5.

Description Configure connectivity fault management linktrace parameters.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation
- Configuring Linktrace Protocol in CFM on page 626

log-and-generate-ais

Syntax

```
log-and-generate-ais {
  interval (1m | 1s);
  level level;
  priority level;
}
```

Hierarchy Level

[edit protocols oam ethernet connectivity-fault-management action-profile *action-profile-name* action]

Release Information

Statement introduced in Junos OS Release 14.2.

Description

Configure the action be taken when an AIS alarm is detected. The action includes generating and logging the AIS statistics along with the interval between AIS messages, the server maintenance domain level, and the priority of the AIS message.

Options

The other statements are explained separately.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Ethernet Alarm Indication Signal (ETH-AIS) Function Overview on page 805
- Configuring ETH-AIS on a CFM MEP on page 811

loss-threshold

Syntax loss-threshold *number*;

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name* continuity-check]

Release Information Statement introduced in Junos OS Release 8.4.
Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers.

Description Specify the number of continuity check messages lost before marking the remote MEP as down. The value can be from 3 to 256 protocol data units (PDUs). The default value is 3 PDUs.

Options *number*—The number of continuity check messages that can be lost before the remote MEP is considered down.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Continuity Check Protocol Parameters Overview on page 611
- Configuring Continuity Check Protocol Parameters for Fault Detection on page 612

lowest-priority-defect

Syntax lowest-priority-defect (all-defects | err-xcon | mac-rem-err-xcon | no-defect | rem-err-xcon | xcon)

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name* mep *mep-id*]

Release Information Statement introduced in Junos OS Release 10.0.

Description Specify the lowest priority defect that is allowed to generate a Fault Alarm whenever CFM detects a defect. This configuration is done at the MEP level.

Options Specify one of the following lowest priority defect options:

all-defects—Allows all defects.

err-xcon—Allows only erroneous CCM and cross-connect CCM defects.

mac-rem-err-xcon—Allows only MAC, not receiving CCM, erroneous CCM, and cross-connect defects.

no-defect—Allows no defects.

rem-err-xcon—Allows only not receiving CCM, erroneous CCM, and cross-connect CCM defects.

xcon—Allows only cross-connect CCM defects.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

maintenance-association

Syntax

```
maintenance-association ma-name {
  short-name-format (character-string | vlan | 2octet | rfc-2685-vpn-id);
  protect-maintenance-association protect-ma-name;
  remote-maintenance-association remote-ma-name;
  continuity-check {
    hold-interval minutes;
    interval (10m | 10s | 1m | 1s| 100ms);
    loss-threshold number;
  }
  mep mep-id {
    auto-discovery;
    direction (up | down);
    interface interface-name (protect | working);
    lowest-priority-defect (all-defects | err-xcon | mac-rem-err-xcon | no-defect |
      rem-err-xcon | xcon );
    priority number;
    remote-mep mep-id {
      action-profile profile-name;
      sla-iterator-profile profile-name {
        data-tlv-size size;
        iteration-count count-value;
        priority priority-value;
      }
    }
  }
}
```

Hierarchy Level

[edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name*]

Release Information

Statement introduced in Junos OS Release 8.4.
Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers.

Description

Configure the name of the maintenance association in IEEE-compliant format.

Options

ma-name—The name of the maintenance association within the maintenance domain.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

maintenance-domain

Syntax

```
maintenance-domain domain-name {
  bridge-domain name <vlan-id [ vlan-ids ]>;
  instance vpls-instance-name;
  level number;
  maintenance-association ma-name {
    protect-maintenance-association  protect-ma-name;
    remote-maintenance-association  remote-ma-name;
    short-name-format (character-string | vlan | 2octet | rfc-2685-vpn-id);
    continuity-check {
      hold-interval minutes;
      interval (10m | 10s | 1m | 1s| 100ms);
      loss-threshold number
    }
    mep mep-id {
      auto-discovery;
      direction (up | down);
      interface interface-name (protect | working);
      lowest-priority-defect (all-defects | err-xcon | mac-rem-err-xcon | no-defect |
        rem-err-xcon | xcon );
      priority number;
      remote-mep mep-id {
        action-profile profile-name;
        sla-iterator-profile profile-name {
          data-tlv-size size;
          iteration-count count-value;
          priority priority-value;
        }
      }
    }
    mip-half-function(none | default | explicit);
    name-format (character-string | none | dns | mac+2oct);
  }
  virtual-switch name {
    bridge-domain name <vlan-id [ vlan-ids ]>;
  }
}
```

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management]

Release Information Statement introduced in Junos OS Release 8.4.
Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers.
Support for multiple down MEP introduced in Junos OS Release 15.1R1 for MX Series Routers.

Description Configure the name of the maintenance domain in IEEE-compliant format.

NOTE: For MX Series Routers, you can configure multiple down MEPs for a single instance of maintenance domain identifier and maintenance association name to monitor services provided on Virtual Private LAN Service (VPLS), bridge, circuit cross-connect (CCC), and IPv4 domains.

Options *domain-name*—Name of the maintenance domain.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

measurement-interval

Syntax measurement-interval (5|15|30|60)

Hierarchy Level [edit protocols oam ethernet cfm performance-monitoring]

[edit protocols oam ethernet cfm performance-monitoring sla-iterator-profiles *profile-name*]

Release Information

Description Configure measurement interval to be used for a performance monitoring session. You must configure the measurement-interval at the **[edit protocols oam ethernet cfm performance-monitoring]** hierarchy level, which is a global level parameter. You can override the configured value by specifying a measurement-interval for the iterator profile at the **[edit protocols oam ethernet cfm performance-monitoring sla-taerator-profiles *profile-name*]** hierarchy level.

NOTE: When you configure when MEF-36-compliant performance monitoring, you must also configure an **enhanced-sla-iterator** at the **[edit protocols oam ethernet cfm performance-monitoring]** hierarchy level.

Default 15 minutes

Required Privilege Level configure—To enter configuration mode.
control—To modify any configuration.

Related Documentation

- IEEE 802.1ag OAM Connectivity Fault Management Overview on page 596
- Junos OS Support for Performance Monitoring Compliant with Technical Specification MEF 36 on page 601

measurement-type

Syntax measurement-type (loss | statistical-loss-measurement | two-way-delay);

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management performance-monitoring sla-iterator-profiles *profile-name*]

Release Information Statement introduced in Junos OS Release 11.1.
The **statistical-loss-measurement** option introduced in Junos OS Release 11.2.

Description Configure the measurement type for the service level agreement (SLA) frames. An SLA frame is a type of packet used to measure frame loss in Ethernet connections.

Options **loss**—Use Y.1731-compliant line module (LM) frames to measure frame loss.

statistical-loss-measurement— Use Y.1731-compliant two-way data module (DM) frames to statistically measure frame loss.

two-way-delay—Use Y.1731-compliant two-way DM frames to measure frame loss.

Required Privilege Level Configure—To enter configuration mode.
Control—To modify any configuration.

Related Documentation

- Configuring an Iterator Profile on page 754

mep

Syntax

```
mep mep-id {
  action-profile action-profile-name
  auto-discovery;
  direction (up | down);
  interface interface-name (protect | working);
  priority number;
  remote-mep mep-id {
    action-profile profile-name;
    sla-iterator-profile profile-name {
      data-tlv-size size;
      iteration-count count-value;
      priority priority-value;
    }
  }
}
```

Hierarchy Level

[edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name*]

Release Information

Statement introduced in Junos OS Release 8.4.

Description

The numeric identifier of the maintenance association end point (MEP) within the maintenance association.

Options

mep *mep-id*—Specify the numeric identifier of the MEP.

Range: 1 through 8191

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

mip-half-function

Syntax

mip-half-function (none | default | explicit);

Hierarchy Level

[edit protocols oam ethernet connectivity-fault-managementmaintenance-domain *md-name*],
[edit protocols oam ethernet connectivity-fault-managementmaintenance-association *ma-name*]

Release Information

Statement introduced in Junos OS Release 9.6.

Description

Specify the OAM Ethernet CFM maintenance domain MIP half functions.

NOTE: Whenever a MIP is configured and a bridge domain is mapped to multiple maintenance domains or maintenance associations, it is essential that the **mip-half-function** value for all maintenance domains and maintenance associations are the same.

Options

none—Specify to not use the mip-half-function.

default—Specify to use the default mip-half-function.

explicit—Specify an explicit mip-half-function.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

name-format

Syntax name-format (character-string | none | dns | mac+2oct);

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name*]

Release Information Statement introduced in Junos OS Release 8.4.
Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers.

Description Specify the format of the maintenance domain name.

Options **character-string**—The name is an ASCII character string.

none—The maintenance domain name is not used.

dns—The name is in domain name service (DNS) format. For example: www.juniper.net.

mac+2oct—Name is the MAC address plus a two-octet maintenance association identifier. For example: 08:00:22:33:44:55.100.

Default: character-string

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Creating a Maintenance Association on page 610
- Creating a Maintenance Domain on page 603

path-database-size

Syntax path-database-size *path-database-size*;

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management linktrace]

Release Information Statement introduced in Junos OS Release 8.5.

Description Number of linktrace reply entries to be stored per linktrace request.

Options **path-database-size**—Database size.

Range: 1 through 255

Default: 64

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Configuring Linktrace Protocol in CFM on page 626

performance-monitoring

Syntax

```
performance-monitoring {
  delegate-server-processing;
  hardware-assisted-timestamping;
  hardware-assisted-keepalives;
  sla-iterator-profiles {
    profile-name {
      avg-fd-twoway-threshold;
      avg-ifdv-twoway-threshold;
      avg-flr-forward-threshold;
      avg-flr-backward-threshold;
      disable;
      calculation-weight {
        delay delay-weight;
        delay-variation delay-variation-weight;
      }
      cycle-time milliseconds;
      iteration-period connections;
      measurement-type (loss | statistical-frame-loss | two-way-delay);
    }
  }
}
```

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management]

Release Information Statement introduced in Junos OS Release 9.5.

Description Specify performance monitoring support for Ethernet frame delay measurement.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level Configure—To enter configuration mode.
Control—To modify any configuration.

policer (CFM Global)

Syntax

```
policer {
  all cfm-policer-name;
  continuity-check cfm-policer-name;
  other cfm-policer-name;
  }
}
```

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management]

Release Information Statement introduced in Junos OS Release 10.0.

Description Specify a policer at the global level to police the CFM traffic belonging to all sessions.

Options

continuity-check *cfm-policer-name*—Police all continuity check packets with the policer specified.

other *cfm-policer-name*—Police all non-continuity check packets with the policer specified.

all *cfm-policer-name*—Police all CFM packets with policer specified. If the **all** option is used, then you cannot specify above two options.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Configuring Rate Limiting of Ethernet OAM Messages on page 655
- **policer (CFM Session) on page 1040**

policer (CFM Session)

Syntax

```
policer {
  all cfm-policer-name;
  continuity-check cfm-policer-name;
  other cfm-policer-name;
  }
}
```

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management maintenance-domain *name* level *number* maintenance-association *name*]

Release Information Statement introduced in Junos OS Release 10.0.

Description Specify a separate policer to rate-limit packets specific to that session.

Options

- **continuity-check** ***cfm-policer-name***—Police continuity check packets belonging to this session.

  other ***cfm-policer-name***—Police all non-continuity check packets belonging to this session.

  all ***cfm-policer-name***—Police all CFM packets belonging to this session. If the **all** option is used, then you cannot specify the above two options.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

port-status-tlv

Syntax port-status-tlv blocked;

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management action-profile *tlv-action* event]
[edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name* continuity-check]

Release Information Statement introduced in Junos OS Release 9.6.

Description Define an **action-profile** consisting of various events and the action. Based on values of **port-status-tlv** in the received CCM packets, specific action such as *interface-down* can be taken using action-profile options.

Options **blocked**—When the incoming CCM packet contains port status TLV with value blocked, the action will be triggered for this action-profile.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

priority (OAM Connectivity-Fault Management)

Syntax

priority *number*;

Hierarchy Level

[edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id*]

For EX Series Switches:

[edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name* mep *mep-id*]

Release Information

Statement introduced in Junos OS Release 8.4.

Description

IEEE 802.1p priority bits used by the continuity check messages.

Options

number—Configure the IEEE 802.1p priority bits to be used in the VLAN header of the CFM packets.

Range: 0 through 7

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Configuring a MEP to Generate and Respond to CFM Protocol Messages on page 613

protocol (Server MEP)

Syntax

```
protocol (l2circuit | l2vpn | ethernet) {
  interface interface-name;
}
```

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management]

Release Information Statement introduced in Junos OS Release 14.2.

Description Configure the protocol as Layer 2 circuit, Layer 2 VPN, or Ethernet and associate the interface to the protocol that needs to be monitored for ETH-AIS.

Options

l2circuit—Configure the protocol for the server MEP as Layer 2 circuit.

l2vpn—Configure the protocol for the server MEP as Layer 2 VPN.

ethernet—Configure the protocol for the server MEP as Ethernet.

interface *interface-name*—The interface that is to be associated with the protocol that needs monitoring for ETH-AIS.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

remote-maintenance-association (OAM)

Syntax remote-maintenance-association *remote-ma-name*;

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name*]

Release Information Statement introduced in Junos OS Release 11.4.

Description Configure the name of the remote maintenance association.

Options ***remote-ma-name***—Name of the remote maintenance association.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Configuring a MEP to Generate and Respond to CFM Protocol Messages on page 613

remote-mep

Syntax

```
remote-mep mep-id {
  action-profile profile-name;
  sla-iterator-profile profile-name {
    data-tlv-size size;
    iteration-count count-value;
    priority priority-value;
  }
  detect-loc;
}
```

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id*]

Release Information Statement introduced in Junos OS Release 8.4.

Description Configure the numeric identifier of the remote maintenance association end point (MEP) within the maintenance association.

Options *mep-id*—Numeric identifier of the MEP.

Range: 1 through 8191

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level Configure—To enter configuration mode.
Control—To modify any configuration.

Related Documentation

- Configuring a MEP to Generate and Respond to CFM Protocol Messages on page 613

sendid-tlv

Syntax

```
sendid-tlv {
  send-chassis-tlv;
}
```

Hierarchy Level

[edit protocols oam ethernet connectivity-fault-management]
[edit protocols oam ethernet connectivity-fault-management maintenance-domain *maintenance-domain-name* maintenance-association *maintenance-association-name* continuity-check]

Release Information Statement introduced in Junos OS Release 16.1R2.

Description Configures Junos OS to send the sender ID TLV along with the packets. The sender ID TLV is an optional TLV that is sent in continuity check messages (CCMs), loopback messages, and Link Trace Messages (LTMs), as specified in the IEEE 802.1ag standard. TLVs (type, length, and value) are described in the IEEE 802.1ag standard for Connectivity Fault Management (CFM) as a method of encoding variable-length and optional information in a protocol data unit (PDU).

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Junos OS Support for Chassis ID TLV on page 602

short-name-format

Syntax short-name-format (character-string | vlan | 2octet | rfc-2685-vpn-id);

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management maintenance-domain *domain-name* maintenance-association *ma-name*]

Release Information Statement introduced in Junos OS Release 8.4.
Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers.

Description Specify the name format of the maintenance association name.

Options **character-string**—The name is an ASCII character string.

vlan—The primary VLAN identifier.

2octet—A number in the range 0 through 65,535.

rfc-2685-vpn-id—A VPN identifier that complies with RFC 2685.

Default: character-string

NOTE: The PTX Series Packet Transport Routers support the **vlan** and **2octet** options only.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Creating a Maintenance Association on page 610

sla-iterator-profile

Syntax

```
sla-iterator-profile profile-name {
  data-tlv-size size;
  iteration-count count-value;
  priority priority-value;
}
```

Hierarchy Level

[edit protocols oam ethernet connectivity-fault-management maintenance-domain *md-name* maintenance-association *ma-name* mep *mep-id* remote-mep *remote-mep-id*]

Release Information

Statement introduced in Junos OS Release 11.1.

Description

Configure a remote MEP with an iterator profile and specify the options.

Options

profile-name—Name of the iterator profile configured for a remote MEP. For more information about configuring a remote MEP with an iterator profile, see "Configuring a Remote MEP with an Iterator Profile" on page 765.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

Configure—To enter configuration mode.
Control—To modify any configuration.

Related Documentation

sla-iterator-profiles

Syntax

```
sla-iterator-profiles {
  profile-name {
    avg-fd-twoway-threshold;
      avg-ifdv-twoway-threshold;
      avg-flr-forward-threshold;
      avg-flr-backward-threshold;
      calculation-weight {
      delay delay-weight;
      delay-variation delay-variation-weight;
    }
    cycle-time milliseconds;
    flap-trap-monitor seconds
    iteration-period iteration-period-value;
    measurement-type (loss | statistical-frame-loss | two-way-delay);
  }
}
```

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management performance-monitoring]

Release Information Statement introduced in Junos OS Release 11.1.

Description Configure an iterator application and specify the iterator profile options.

Options *profile-name*—Name of the iterator profile. For more information about configuring the iterator profile, see "Configuring an Iterator Profile" on page 754.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level Configure—To enter configuration mode.
Control—To modify any configuration.

CHAPTER 39

Configuration Statements

802.3ad

Syntax

```
802.3ad {
  primary | backup;
  ae interface-number ;
  lacp {
    port-priority priority-number;
  }
  link-index index-number
  distribution-list distribution-list-number
}
```

Hierarchy Level

[edit interfaces *interface-name* fastether-options],
[edit interfaces *interface-name* gigether-options]

Release Information

Statement introduced before Junos OS Release 7.4.
primary and **backup** options added in Junos OS Release 8.3.

Description

Specify aggregated Ethernet logical interface number.

Options

bundle—Join an aggregated Ethernet interface.

ae *interface-number*—Aggregated Ethernet logical interface number. For MX Series routers running Junos release 14.2R3 and later you can configure a maximum of 1000 aggregated interfaces. On MX2010 and MX2020 routers you can configure a maximum of 800 aggregated interfaces.

primary | backup—For link protection configurations, specify the link as primary link or backup link for egress traffic.

lacp—Configure Link Aggregation Control Protocol. Specify the port priority in the range 0 through 65535. Default port-priority is 127.

link-index—Specify the desired child link index within the aggregated Ethernet Interface. Index number of the logical interface reflects its initialization sequence.

distribution-list—For targeted distribution, specify the distribution list to which the interface belongs.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Configuring an Aggregated Ethernet Interface on page 108

accept-source-mac

Syntax

```
accept-source-mac {
  mac-address mac-address {
    policer {
      input cos-policer-name;
      output cos-policer-name;
    }
  }
}
```

Hierarchy Level

[edit interfaces *interface-name* unit *logical-unit-number*],
[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1X48 for PTX Packet Transport Routers.
Statement introduced in Junos OS Release 13.2 for the QFX Series.

Description

For Gigabit Ethernet intelligent queuing (IQ) interfaces only, accept traffic from and to the specified remote media access control (MAC) address.

The **accept-source-mac** statement is equivalent to the **source-address-filter** statement, which is valid for aggregated Ethernet, Fast Ethernet, and Gigabit Ethernet interfaces only. To allow the interface to receive packets from specific MAC addresses, include the **accept-source-mac** statement.

On untagged Gigabit Ethernet interfaces, you should not configure the **source-address-filter** statement and the **accept-source-mac** statement simultaneously. On tagged Gigabit Ethernet interfaces, you should not configure the **source-address-filter** statement and the **accept-source-mac** statement with an identical MAC address specified in both filters.

The remaining statements are explained separately. See CLI Explorer.

NOTE: The policer statement is not supported on PTX Series Packet Transport Routers.

NOTE: On QFX platforms, if you configure source MAC addresses for an interface using the *static-mac* or *persistent-learning* statements and later configure a different MAC address for the same interface using the **accept-source-mac** statement, the MAC addresses that you previously configured for the interface remain in the ethernet-switching table and can still be used to send packets to the interface.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

access-concentrator

Syntax access-concentrator *name*;

Hierarchy Level [edit dynamic-profiles *profile-name* interfaces demux0 unit *logical-unit-number* family pppoe],
[edit dynamic-profiles *profile-name* interfaces *interface-name* unit *logical-unit-number* family pppoe],
[edit interfaces *interface-name* unit *logical-unit-number* family pppoe],
[edit interfaces *interface-name* unit *logical-unit-number* pppoe-options],
[edit interfaces *interface-name* unit *logical-unit-number* pppoe-underlying-options],
[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family pppoe],
[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* pppoe-options],
[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* pppoe-underlying-options]

Release Information Statement introduced before Junos OS Release 7.4.
Support at the **[edit interfaces *interface-name* unit *logical-unit-number* pppoe-underlying-options]** and **[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* pppoe-underlying-options]** hierarchy levels introduced in Junos OS Release 10.1.
Support at the **[edit ... family pppoe]** hierarchies introduced in Junos OS Release 11.2.

Description Configure an alternative access concentrator name in the AC-NAME tag in a PPPoE control packet for use with a dynamic PPPoE subscriber interface. If you do not configure the access concentrator name, the AC-NAME tag contains the system name.

NOTE: The **[edit ... family pppoe]** hierarchies are supported only on MX Series routers with MPCs.

Options *name*—Name of the access concentrator.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

adaptive

Syntax

```
adaptive {
  pps;
  scan-interval multiple;
  tolerance tolerance-percentage;
}
```

Hierarchy Level [edit interfaces ae*x* aggregated-ether-options load-balance]

Release Information Statement introduced in Junos OS Release 13.2R3 for MX Series Routers.
Statement introduced in Junos OS Release 14.1 for PTX Series Packet Transport Routers.
Statement introduced in Junos OS Release 15.1X53-D10 for the QFX Series.

Description Correct a genuine traffic imbalance by using a feedback mechanism to distribute the traffic across the links of an aggregated Ethernet bundle.

Options **pps**—(PTX Series only) The type of traffic rate among the members of the AE bundle is measured packets per second. The default rate type is bytes per second.

scan-interval *multiple*—(PTX Series only) Scan interval, as a multiple of a 30-second interval.

Range: 1 through 5

Default: 1

tolerance *tolerance-percentage*—(MX Series and PTX Series) Limit to the variance in the packet traffic flow to the aggregated Ethernet links in a percentage.

Range: 1 through 100 percent

Default: 20 percent

Required Privilege Level interface - To view this statement in the configuration.
interface-control - To add this statement to the configuration.

        bandwidth-threshold bits-per-second {
          priority;
        }
      }
      route ip-address/mask routing-instance instance-name priority-cost cost;
    }
    virtual-address [ addresses ];
  }
}
```

Hierarchy Level [edit interfaces *interface-name* unit *logical-unit-number* family *family*],

[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family *family*]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 11.1 for the QFX Series.

Description Configure the interface address.

Options *address*—Address of the interface.

- In Junos OS Release 13.3 and later, when you configure an IPv6 host address and an IPv6 subnet address on an interface, the commit operation fails.
- In releases earlier than Junos OS Release 13.3, when you use the same configuration on an interface, the commit operation succeeds, but only one of the IPv6 addresses that was entered is assigned to the interface. The other address is not applied.

NOTE: If you configure the same address on multiple interfaces in the same routing instance, Junos OS uses only the first configuration, and the remaining address configurations are ignored and can leave interfaces without an address. Interfaces that do not have an assigned address cannot be used as a donor interface for an unnumbered Ethernet interface.

For example, in the following configuration the address configuration of interface xe-0/0/1.0 is ignored:

```
interfaces {
  xe-0/0/0 {
    unit 0 {
      family inet {
        address 192.168.1.1/8;
      }
    }
  }
  xe-0/0/1 {
    unit 0 {
     family inet {
       address 192.168.1.1/8;
     }
  }
}
```

For more information on configuring the same address on multiple interfaces, see *Configuring the Interface Address*.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

NOTE: The edit logical-systems hierarchy is not available on QFabric systems.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

advertisement-interval

Syntax advertisement-interval *seconds*;

Hierarchy Level [edit protocols lldp],
[edit routing-instances *routing-instance-name* protocols lldp]

Release Information Statement introduced in Junos OS Release 9.6 for MX Series and T Series routers.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 14.1X53-D20 for OCX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D20 for OCX Series switches.

Description Configure an interval for LLDP advertisement.

For switches configured for Link Layer Discovery Protocol, configure the frequency at which LLDP advertisements are sent.

The **advertisement-interval** value must be greater than or equal to four times the **transmit-delay** value, or an error will be returned when you attempt to commit the configuration.

NOTE: The default value of **transmit-delay** is 2 seconds. If you configure the **advertisement-interval** as less than 8 seconds and you do not configure a value for **transmit-delay**, the default value of **transmit-delay** is automatically changed to 1 second in order to satisfy the requirement that the **advertisement-interval** value must be greater than or equal to four times the **transmit-delay** value.

Default Disabled.

Options *seconds*—Interval between LLDP advertisement.

Default: 30

Range: 5 through 32768

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Related Documentation

age

Syntax age (30m | 10m | 1m | 30s | 10s);

Hierarchy Level [edit protocols oam ethernet connectivity-fault-management linktrace]

Release Information Statement introduced in Junos OS Release 8.5.

Description Time to wait (in minutes or seconds) for a response. If no response is received, the request and response entry is deleted from the linktrace database.

Default 10 minutes

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Configuring Linktrace Protocol in CFM on page 626

agent-specifier

Syntax

```
agent-specifier {
  aci circuit-id-string ari remote-id-string {
    drop;
    delay seconds;
    terminate;
    dynamic-profile profile-name;
    routing-instance routing-instance-name;
    static-interface interface-name;
  }
}
```

Hierarchy Level [edit protocols pppoe service-name-tables *table-name* service *service-name*]

Release Information Statement introduced in Junos OS Release 10.0.
drop, **delay**, **terminate**, **dynamic-profile**, **routing-instance**, and **static-interface** options introduced in Junos OS Release 10.2.

Description Specify the action taken by the interface for the specified agent circuit identifier/agent remote identifier (ACI/ARI) pair when the interface receives a PPPoE Active Discovery Initiation (PADI) control packet that includes the vendor-specific tag with ACI/ARI pair information. You can configure an ACI/ARI pair for a named service, **empty** service, or **any** service in a PPPoE service name table. A maximum of 8000 ACI/ARI pairs are supported per PPPoE service name table. You can distribute the ACI/ARI pairs in any combination among the named, **empty**, and **any** service entries in the service name table.

You can use an asterisk (*) as a wildcard character to match ACI/ARI pairs, the ACI alone, or the ARI alone. The asterisk can be placed only at the beginning, the end, or both the beginning and end of the identifier string. You can also specify an asterisk alone for either the ACI or the ARI. You cannot specify only an asterisk for both the ACI and the ARI. When you specify a single asterisk as the identifier, that identifier is ignored in the PADI packet.

For example, suppose you care about matching only the ACI and do not care what value the ARI has in the PADI packet, or even whether the packet contains an ARI value. In this case you can set the ***remote-id-string*** to a single asterisk. Then the interface ignores the ARI received in the packet and the interface takes action based only on matching the specified ACI.

Default The default action is terminate.

Options **aci *circuit-id-string***—Identifier for the agent circuit ID that corresponds to the DSLAM interface that initiated the service request. This is a string of up to 63 characters.

ari *remote-id-string*—Identifier for the subscriber associated with the DSLAM interface that initiated the service request. This is a string of up to 63 characters.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

```

Hierarchy Level

[edit system]

[edit interfaces *interface-name* unit *logical-unit-number* family inet address *address*],

[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number* family inet address *address*]

NOTE: The **edit logical-systems** hierarchy is not available on QFabric systems.

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 11.1 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description

For Ethernet, Fast Ethernet, and Gigabit Ethernet interfaces only, configure Address Resolution Protocol (ARP) table entries, mapping IP addresses to MAC addresses. You can enable backup VRRP routers to learn ARP requests for VRRP-IP to VRRP-MAC address translation. You can also set the time interval between ARP updates.

NOTE: By default, an ARP policer is installed that is shared among all the Ethernet interfaces on which you have configured the **family inet** statement. By including the **arp** statement at the **[edit interfaces *interface-name* unit *logical-unit-number* family inet policer]** hierarchy level, you can apply a specific ARP-packet policer to an interface. This feature is not available on EX Series switches.

When you need to conserve IP addresses, you can configure an Ethernet interface to be unnumbered by including the **unnumbered-address** statement at the **[edit interfaces *interface-name* unit *logical-unit-number* family inet]** hierarchy level.

NOTE: For EX-Series switches, set only the time interval between ARP updates.

Options

ip-address—IP address to map to the MAC address. The IP address specified must be part of the subnet defined in the enclosing **address** statement.

mac *mac-address*—MAC address to map to the IP address. Specify the MAC address as six hexadecimal bytes in one of the following formats: ***nnnn.nnnn.nnnn*** or ***nn*:*nn*:*nn*:*nn*:*nn*:*nn***. For example, **0000.5e00.5355** or **00:00:5e:00:53:55**.

multicast-mac *mac-address*—Multicast MAC address to map to the IP address. Specify the multicast MAC address as six hexadecimal bytes in one of the following formats: ***nnnn.nnnn.nnnn*** or ***nn*:*nn*:*nn*:*nn*:*nn*:*nn***. For example, **0000.5e00.5355** or **00:00:5e:00:53:55**.

publish—(Optional) Have the router or switch reply to ARP requests for the specified IP address. If you omit this option, the router or switch uses the entry to reach the destination but does not reply to ARP requests.

NOTE: For unicast MAC addresses only, if you include the **publish** option, the router or switch replies to proxy ARP requests.

aging-timer—Time interval in minutes between ARP updates. In environments where the number of ARP entries to update is high (for example, on routers only, metro Ethernet environments), increasing the time between updates can improve system performance.

passive-learning (QFX-Series only)—Configure backup VRRP routers or switches to learn the ARP mappings (IP-to-MAC address) for hosts sending the requests. By default, the backup VRRP router drops these requests; therefore, if the master router fails, the backup router must learn all entries present in the ARP cache of the master router. Configuring passive learning reduces transition delay when the backup router is activated.

Required Privilege Level
interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.
system—To view this statement in the configuration.
system-control—To add this statement to the configuration.

asynchronous-notification

Syntax
(asynchronous-notification | no-asynchronous-notification);

Hierarchy Level
[edit interfaces ge-*fpc/pic/port* gigether-options]

Release Information
Statement introduced in Junos OS Release 8.3.
Statement introduced in Junos OS Release 12.2 for ACX Series Universal Metro Routers.

Description
(MX Series routers, T Series routers) For all Gigabit Ethernet interfaces (1-Gigabit, 10-Gigabit, and 100-Gigabit), configure support for notification of link down alarm generation and transfer.

(M120 and M320 routers) For all 10-Gigabit Ethernet PIC interfaces, configure support for notification of link down alarm generation and transfer.

- **asynchronous-notification**—Support notification of link down alarm generation and transfer.
- **no-asynchronous-notification**—Prohibit notification of link down alarm generation and transfer.

Default
Support for notification of link down alarm generation and transfer is not enabled.

Required Privilege Level
interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

auto-negotiation

Syntax (auto-negotiation | no-auto-negotiation) <remote-fault (local-interface-online | local-interface-offline)>;

Hierarchy Level [edit interfaces *interface-name* ether-options],
[edit interfaces *interface-name* gigether-options],
[edit interfaces ge-*pim*/0/0 switch-options switch-port *port-number*]

Release Information Statement introduced in Junos OS Release 7.6.
Statement introduced in Junos OS Release 9.0 for EX Series switches.
Statement introduced in Junos OS Release 12.2 for ACX Series Universal Metro Routers.

Description For Gigabit Ethernet interfaces on M Series, MX Series, T Series, TX Matrix routers, and ACX Series routers explicitly enable autonegotiation and remote fault. For EX Series switches, explicitly enable autonegotiation only.

- **auto-negotiation**—Enables autonegotiation. This is the default.
- **no-auto-negotiation**—Disable autonegotiation. When autonegotiation is disabled, you must explicitly configure the link mode and speed.

When you configure Tri-Rate Ethernet copper interfaces to operate at 1 Gbps, autonegotiation must be enabled.

NOTE: On EX Series switches, an interface configuration that disables autonegotiation and manually sets the link speed to 1 Gbps is accepted when you commit the configuration; however, if the interface you are configuring is a Tri-Rate Ethernet copper interface, the configuration is ignored as invalid and autonegotiation is enabled by default.

To correct the invalid configuration and disable autonegotiation:

1. Delete the **no-auto-negotiation** statement and commit the configuration.
2. Set the link speed to 10 or 100 Mbps, set **no-auto-negotiation**, and commit the configuration.

On EX Series switches, if the link speed and duplex mode are also configured, the interfaces use the values configured as the desired values in the negotiation. If autonegotiation is disabled, the link speed and link mode must be configured.

NOTE: On T4000 routers, the **auto-negotiation** command is ignored for interfaces other than Gigabit Ethernet.

NOTE: On ACX Series routers, when you configure fiber interfaces (fiber media mode) to operate at 1 Gbps, you need to always enable autonegotiation (**auto-negotiation**) to negotiate the speed and duplex settings. You cannot disable autonegotiation (**no-auto-negotiation**) in the fiber media mode. In copper interfaces (copper media mode), autonegotiation is enabled by default. To disable autonegotiation, you need to explicitly configure the link speed to 10 or 100 Mbps, set **no-auto-negotiation**, and commit the configuration.

Default Autonegotiation is automatically enabled. No explicit action is taken after the autonegotiation is complete or if the negotiation fails.

Options **remote-fault (local-interface-online | local-interface-offline)**—(Optional) For M Series, MX Series, T Series, TX Matrix routers, and ACX Series routers only, manually configure remote fault on an interface.

Default: local-interface-online

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

bandwidth-limit (Policer for Gigabit Ethernet Interfaces)

Syntax

bandwidth-limit *bps*;

Hierarchy Level

[edit interfaces *interface-name* gigether-options ethernet-switch-profile ethernet-policer-profile policer *cos-policer-name* aggregate],
[edit interfaces *interface-name* gigether-options ethernet-switch-profile ethernet-policer-profile policer *cos-policer-name* premium]

Release Information

Statement introduced before Junos OS Release 7.4.

Description

Define a policer to apply to nonpremium traffic.

Options

bps—Bandwidth limit, in bits per second. Specify either as a complete decimal number or as a decimal number followed by the abbreviation **k** (1000), **m** (1,000,000), or **g** (1,000,000,000).

Range: 32 Kbps through 32 gigabits per second (Gbps). For IQ2 and IQ2-E interfaces 65,536 bps through 1 Gbps. For 10-Gigabit IQ2 and IQ2-E interfaces 65,536 bps through 10 Gbps.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

bfd-liveness-detection (LAG)

Syntax

bfd-liveness-detection {
  authentication {
    algorithm *algorithm-name*;
    key-chain *key-chain-name*;
    loose-check;
  }
  detection-time {
    threshold *milliseconds*;
  }
  holddown-interval *milliseconds*;
  local-address *bfd-local-address*;
  minimum-interval *milliseconds*;
  minimum-receive-interval *milliseconds*;
  multiplier *number*;
  neighbor *bfd-neighbor-address*;
  no-adaptation;
  transmit-interval {
    minimum-interval *milliseconds*;
    threshold *milliseconds*;
  }
  version (1 | automatic);
}

Hierarchy Level **[edit interfaces aex aggregated-ether-options]**

Release Information Statement introduced in Junos OS Release 13.3.

Description Configure Bidirectional Forwarding Detection (BFD) timers and authentication for aggregated Ethernet interfaces.

Options

holddown-interval *milliseconds*— Specify a time limit, in milliseconds, indicating the time that a BFD session remains up before a state change notification is sent. If the BFD session goes down and then comes back up during the hold-down interval, the timer is restarted.

Range: 0 through 255,000

Default: 0

local-address *bfd-local-address*— Specify the loopback address or the AE interface address of the source of the BFD session.

NOTE: Beginning with Release 16.1R2, Junos OS checks and validates the configured micro BFD **local-address** against the interface or loopback IP address before the configuration commit. Junos OS performs this check on both IPv4 and IPv6 micro BFD address configurations, and if they do not match, the commit fails.

minimum-interval *milliseconds*— Specify a minimum time interval after which the local routing device transmits a BFD packet and then expects to receive a reply from the BFD neighbor. Optionally, instead of using this statement, you can configure the minimum transmit and receive intervals separately using the **transmit-interval minimum-interval** statement.

Range: 1 through 255,000

minimum-receive-interval *milliseconds*— Specify the minimum time interval after which the routing device expects to receive a reply from the BFD neighbor.

Range: 1 through 255,000

multiplier *number*— Specify the number of BFD packets that were not received by the BFD neighbor before the originating interface is declared down.

Range: 1 through 255

neighbor *bfd-neighbor-address*— Specify the loopback address or the AE interface address of a remote destination to send BFD packets.

no-adaptation— Disable the BFD adaptation. Include this statement if you do not want the BFD sessions to adapt to changing network conditions. We recommend that you do not disable BFD adaptation unless it is preferable not to have BFD adaptation enabled in your network.

version— Configure the BFD version to detect (BFD version 1) or autodetect (the BFD version).

NOTE: **The version option is not supported on the QFX Series.**

Default: automatic

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

cak (MX Series)

Syntax cak *hexadecimal-number*;

Hierarchy Level [edit security macsec connectivity-association *connectivity-association-name* pre-shared-key]

Release Information Statement introduced in Junos OS Release 15.1 for MX240, MX480, and MX960 routers. Statement introduced in Junos OS Release 17.3R1 for MX10003 3D Universal Edge Routers.

Description Specifies the connectivity association key (CAK) for a pre-shared key.

A pre-shared key includes a connectivity association key name (CKN) and a CAK. A pre-shared key is exchanged between two devices at each end of a point-to-point link to enable MACsec using dynamic security keys. The MACsec Key Agreement (MKA) protocol is enabled once the pre-shared keys are successfully exchanged. The pre-shared key—the CKN and CAK—must match on both ends of a link

Default No CAK exists, by default.

Options ***hexadecimal-number***—The key name, in hexadecimal format.

The key name is 32 hexadecimal characters in length. If you enter a key name that is less then 32 characters long, the remaining characters are set to 0.

On MX10003 router, to maximize the security, it is recommended to configure CAK of even length.

- If you configure CAK of length that is less than 32 hexadecimal digits and if cipher-suite is gcm-aes-128/gcm-aes-256 and less than 64 hexadecimal digits, then the following warning message is displayed:**warning: To maximize security, recommend configuring all 32 digits of pre-shared-key cak** or **warning: To maximize security, recommend configuring all 64 digits of pre-shared-key cak**
- On MX10003 router, if you configure the length of CAK to an odd value, then the following warning message is displayed: **To maximize security, it is recommended to configure pre-shared-key cak of even length**

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation
- *Configuring Media Access Control Security (MACsec) on MX Series Routers*

captive-portal (MX Series in Enhanced LAN Mode)

Syntax (captive-portal | no-captive-portal);

Hierarchy Level [edit protocols authentication-access-control]

Release Information Statement introduced in Junos OS Release 14.2 for MX240, MX480, and MX960 routers in enhanced LAN mode.

Description Specify whether captive portal authentication needs to be enabled or disabled. You can set up captive portal authentication (hereafter referred to as captive portal) on a switch to redirect Web browser requests to a login page that requires the user to input a username and password. Upon successful authentication, the user is allowed to continue with the original page request and subsequent access to the network.

Default Not enabled

Options **captive-portal**—Enable captive portal authentication.

no-captive-portal—Disable captive portal authentication.

Required Privilege Level security—To view this statement in the configuration.
security-control—To add this statement to the configuration.

captive-portal-custom-options (MX Series in Enhanced LAN Mode)

Syntax

captive-portal-custom-options {
  banner-message *string*;
  footer-bgcolor *color*;
  footer-message *string*;
  footer-text-color *color*;
  form-header-bgcolor *color*;
  form-header-message *string*;
  form-header-text-color *color*;
  form-reset-label *label name*;
  form-submit-label *label name*;
  header-bgcolor *color*;
  header-logo *filename*;
  header-message *string*;
  header-text-color *color*;
  post-authentication-url *url-string*;
}

Hierarchy Level [edit protocols]

Release Information Statement introduced in Junos OS Release 14.2 for MX240, MX480, and MX960 routers in enhanced LAN mode.

Description Specify the design elements of a captive portal login page.

Options

banner-message—The first screen displayed before the captive portal login page is displayed—for example, a disclaimer message.

Range: 1–2047 characters

footer-bgcolor —The hexadecimal color code for the color of the footer bar across the bottom of the captive portal login page—for example, #2E8B57 (sea green).

Values: # symbol followed by six characters.

footer-message—Text message displayed in the footer bar across the bottom of the captive portal login page.

Range: 1–2047 characters

Default: **Copyright @2010, Juniper Networks Inc.**

footer-text-color — Color of the text in the footer.

Default: The default color is white.

form-header-bgcolor —The hexadecimal color code for the background color of the header bar across the top of the form area of the captive portal login page.

Values: # symbol followed by six characters.

form-header-message—Text message displayed in the header bar across the top of the form area of the captive portal login page.

Range: 1–255 characters

Default: **Captive Portal User Authentication**

form-header-text-color—Color of the text in the form header.

Default: The default color is black.

form-reset-label—Label displayed in the button that the user can select to clear the username and password fields on the form.

Range: 1–255 characters

Default: **Reset**

form-submit-label —Label displayed in the button that the user selects to submit their login information—for example, **Log In** .

Range: 1–255 characters

Default: **Log In**

header-bgcolor—The hexadecimal color code for the color of the header bar across the top of the captive portal login page.

Values: # symbol followed by six characters.

header-logo—Filename of the file containing the image of the logo displayed at the top of the captive portal login page. The image file can be in GIF, JPEG, or PNG format.

Default: The Juniper Networks logo

header-message—Text displayed in the header bar across the bottom of the captive portal login page.

Range: 1–2047 characters

Default: **User Authentication**

header-text-color—Color of the text in the header.

Default: The default color is white.

post-authentication-url—URL to which the users are directed upon successful authentication—for example **www.mycafe.com**.

Range: 1–255 characters

Default: The page originally requested by the user.

Required Privilege Level

routing—To view this statement in the configuration.
routing–control—To add this statement to the configuration.

centralized

Syntax centralized;

Hierarchy Level [edit protocols lacp ppm]

Release Information Statement introduced in Junos OS Release 9.4 for MX Series routers.
Statement introduced in Junos OS Release 10.2 for EX Series switches.
Statement introduced in Junos OS Release 11.3 for the QFX Series.
Statement introduced in Junos OS Release 14.1X53-D20 for the OCX Series.

Description Disable distributed periodic packet management (PPM) processing for Link Aggregation Control Protocol (LACP) packets and run all PPM processing for LACP packets on the Routing Engine.

This statement disables distributed PPM processing for only LACP packets. You can disable distributed PPM processing for all packets that use PPM and run all PPM processing on the Routing Engine by configuring the **no-delegate-processing** statement in the **[edit routing-options ppm]** hierarchy.

BEST PRACTICE: We generally recommend that you disable distributed PPM only if Juniper Networks Customer Service advises you to do so. You should disable distributed PPM only if you have a compelling reason to disable it.

Default Distributed PPM processing is enabled for all packets that use PPM.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

cipher-suite (MACsec)

Syntax

cipher-suite *encryption-algorithm-name*;

Hierarchy Level

[edit security macsec connectivity-association *connectivity-association-name*]

Release Information

Statement introduced in Junos OS Release 16.2R1 for MX240, MX480, MX960, MX2020, and MX2010 routers.
Statement introduced in Junos OS Release 17.2R1 for QFX Series switches.
Statement introduced in Junos OS Release 17.3R1 for JNP-MIC1-MACSEC MIC on MX10003 routers.
Statement introduced in Junos OS Release 18.2R1 for EX Series switches.

Description

Specify the set of ciphers used to encrypt traffic on an Ethernet link that is secured with Media Access Control Security (MACsec). The encryption used by MACsec ensures that the data in the Ethernet frame cannot be viewed by anybody monitoring traffic on the link. MACsec encryption is optional and user-configurable. The configured cipher suites should be the same between MACsec peers.

MACsec utilizes the Galois/Counter Mode Advanced Encryption Standard (GCM-AES). The default cipher suite used for MACsec is GCM-AES-128, with a maximum key length of 128 bits. MACsec also supports GCM-AES-256, with a maximum key length of 256 bits.

GCM–AES–128 and GCM–AES–256 use a 32-bit packet number as part of the initial value that has to be unique for every packet sent with a given secure association key (SAK). When the permutations of the 32-bit packet number are exhausted, the SAK much be refreshed. The frequency of SAK refreshes can be reduced by using a cipher suite with Extended Packet Numbering (XPN), which increases the size of the packet number to 64-bits. Both GCM-AES-128 and GCM-AES-256 are available with XPN.

NOTE: When enabling MACsec on a QFX10016 or QFX10008 switch, we recommend using either the GCM-AES-XPN-128 or GCM-AES-XPN-256 cipher suite.

Default

If the **cipher-suite** statement is not configured, the default cipher suite used for encryption is GCM-AES-128.

Options

gcm-aes-128—GCM-AES-128 has a maximum key size of 128 bits.

gcm-aes-xpn-128—GCM-AES-XPN-128 has a maximum key size of 128 bits and extended packet number.

gcm-aes-256—GCM-AES-256 has a maximum key size of 256 bits.

gcm-aes-xpn-256—GCM-AES-XPN-256 has a maximum key size of 256 bits and extended packet number.

Required Privilege Level

admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

ckn (MX Series)

Syntax ckn *hexadecimal-number*;

Hierarchy Level [edit security macsec connectivity-association *connectivity-association-name* pre-shared-key]

Release Information Statement introduced in Junos OS Release 15.1 for MX240, MX480, and MX960 routers.
Statement introduced in Junos OS Release 17.3R1 for MX10003 3D Universal Edge Routers.

Description Specifies the connectivity association key name (CKN) for a pre-shared key.

A pre-shared key includes a CKN and a connectivity association key (CAK). A pre-shared key is exchanged between two devices at each end of a point-to-point link to enable MACsec using dynamic security keys. The MACsec Key Agreement (MKA) protocol is enabled once the pre-shared keys are successfully exchanged. The pre-shared key—the CKN and CAK—must match on both ends of a link

Default No CKN exists, by default.

Options *hexadecimal-number*—The key name, in hexadecimal format.

The key name is 32 hexadecimal characters in length. If you enter a key name that is less then 32 characters long, the remaining characters are set to 0.

- On MX10003 router, if you configure the length of CKN to the value less than 64 hexadecimal digits, then the following warning message is displayed:

  warning: To maximize security, recommend configuring all 64 digits of pre-shared-key ckn

- On MX10003 router, if you configure the length of CKN to an odd value, then the commit will not be successful and the following error message is displayed:

  error: ckn: 'abcde': Must be an even-length string up to 64 hexadecimal digits (0-9, a-f, A-F)

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

community-vlans (MX Series)

Syntax community-vlans [*number number-number*];

Hierarchy Level [edit bridge-domains *bridge-domain-name*],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* bridge-options],
[edit logical-systems *logical-system-name* routing-instances *routing-instance-name* bridge-domains *bridge-domain-name* ,
[edit routing-instances *routing-instance-name* bridge-domains *bridge-domain-name*],

Release Information Statement introduced in Junos OS Release 14.2 for MX240, MX480, and MX960 routers.

Description Configure the specified community VLAN to be a secondary VLAN of the specified primary VLAN. A *community* VLAN is used to transport frames among members of a community, which is a subset of users within the VLAN, and to forward frames upstream to the primary VLAN.

NOTE: When you specify this configuration statement, the VLAN ID of a logical interface that you associate with a bridge domain that matches with the VLAN ID or list of IDs that you specify using the **community-vlans** state is treated as a community port.

Options *number*—Individual VLAN IDs separated by a space.

Required Privilege Level system—To view this statement in the configuration.
system–control—To add this statement to the configuration.

Related Documentation

compatibility-version

Syntax compatibility-version;

Hierarchy Level [edit protocols protection-group ethernet-ring *ring-name*]

Release Information Statement introduced in Junos OS Release 14.2.

Description Specify the compatible version mode to be used. When compatibility-version is set to value 1, the node operates in ITU-T Recommendation G.8032/Y.1344 version 1 compatible mode. In this mode all the supported external commands are blocked, ring-id is forced to be 1 and mode of operation is set to revertive mode.

Options

- **1**—Use ITU-T Recommendation G.8032/Y.1344 compatibile mode version 1.
- **2**—Use ITU-T Recommendation G.8032/Y.1344 compatibile mode version 2.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

data-channel

Syntax

```
data-channel {
  vlan number;
}
```

Hierarchy Level

[edit protocols protection-group ethernet-ring *ring-name*]

Release Information

Statement introduced in Junos OS Release 10.2.
Statement introduced in Junos OS Release 12.1 for EX Series switches.
Statement introduced in Junos OS Release 14.153-D10 for QFX Series switches.

Description

For Ethernet ring protection, configure a data channel to define a set of VLAN IDs that belong to a ring instance.

VLANs specified in the data channel use the same topology used by the ERPS PDU in the control channel. Therefore, if a ring interface is blocked in the control channel, all traffic in the data channel is also blocked on that interface.

Options

vlan ***number***—Specify (by VLAN ID) one or more VLANs that belong to a ring instance.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

delay (PPPoE Service Name Tables)

Syntax delay *seconds*;

Hierarchy Level [edit protocols pppoe service-name-tables *table-name* service *service-name*],
[edit protocols pppoe service-name-tables *table-name* service *service-name* agent-specifier aci *circuit-id-string* ari *remote-id-string*]

Release Information Statement introduced in Junos OS Release 10.0.
Support at **[edit protocols pppoe service-name-tables *table-name* service *service-name* agent-specifier aci *circuit-id-string* ari *remote-id-string*]** hierarchy level introduced in Junos OS Release 10.2.

Description Configure the PPPoE underlying interface on the router to wait a specified number of seconds after receiving a PPPoE Active Discovery Initiation (PADI) control packet from a PPPoE client before sending a PPPoE Active Discovery Offer (PADO) packet to indicate that it can service the client request

The router (PPPoE server) does not check whether another server has already sent a PADO packet during the delay period in response to the PPPoE client's PADI packet. It is up to the PPPoE client to determine whether another PPPoE server has responded to its PADI request, or if it must respond to the delayed PADO packet to establish a PPPoE session.

Options *seconds*—Number of seconds that the PPPoE underlying interface waits after receiving a PADI packet from a PPPoE client before sending a PADO packet in response.

Range: 1 through 120 seconds

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

device-count

Syntax device-count *number*;

Hierarchy Level [edit chassis aggregated-devices ethernet]
[edit chassis aggregated-devices sonet]

Release Information Statement introduced before Junos OS Release 7.4.
Statement functionality updated in Junos OS Release 14.2, as described below.

Description Configure the number of aggregated logical devices available to the router.

Starting in Junos release 14.2, for MX series routers, aggregate Ethernet interfaces created under a logical system can be individually named. Prior to 14.2, ae interfaces were named automatically (AE1, AE2) etc. upon setting the device count. This change allows administrators to use custom naming schemes. System resources are only allocated for named ae interfaces, regardless of how many were declared in the device count. (In Junos 14.2 and earlier, ae naming occurred automatically up to the number specified for device count, and system resources were allocated whether a given ae interface was used or not.)

Options *number*—Set the number of aggregated logical devices that will be available for configuration.

NOTE: **Starting with Junos OS Release 13.2, a maximum of 64 aggregated interfaces are supported for link aggregation of SONET/SDH interfaces. In releases before Junos OS Release 13.2, a maximum of 16 aggregated interfaces are supported for link aggregation of SONET/SDH interfaces.**

Range: 1 - 496. The upper limit for this value is system specific.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

direction (MX Series)

Syntax direction (inbound | outbound);

Hierarchy Level [edit security macsec connectivity-association *connectivity-association-name* secure-channel *secure-channel-name*]

Release Information Statement introduced in Junos OS Release 15.1 for MX240, MX480, and MX960 routers.

Description Configure whether the secure channel applies MACsec security to traffic entering or leaving an interface.

If you need to apply MACsec on traffic entering and leaving an interface, you need to create one secure channel to apply MACsec on incoming traffic and another secure channel to apply MACsec on outgoing traffic within the same connectivity association. When you associate the connectivity association with an interface, MACsec is applied on traffic entering and leaving that interface.

You only use this configuration option when you are configuring MACsec using static secure association keys (SAK) security mode. When you are configuring MACsec using static connectivity association keys (CAK) security mode, two secure channels that are not user-configurable—one inbound secure channel and one outbound secure channel—are automatically created within the connectivity association.

Default This statement does not have a default value.

If you have configured a secure channel to enable MACsec using static SAK security mode, you must specify whether the secure channel applies MACsec to traffic entering or leaving an interface. A candidate configuration that contains a secure channel that has not configured a direction cannot be committed.

Options **inbound**—Enable MACsec security on traffic entering the interface that has applied the secure channel.

outbound—Enable MACsec security on traffic leaving the interface that has applied the secure channel.

The remaining statements are explained separately.

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

domain-id

Syntax domain-id *domain-id*;

Hierarchy Level [edit logical-systems *logical-system-name* routing-instances *routing-instance-name* protocols (ospf | ospf3)],
[edit routing-instances *routing-instance-name* protocols (ospf | ospf3)]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.0 for EX Series switches.

Description Specify a domain ID for a route. The domain ID identifies the OSPF domain from which the route originated.

Options ***domain-id***—You can specify either an IP address or an IP address and a local identifier using the following format: ***ip-address*:*local-identifier***. If you do not specify a local identifier with the IP address, the identifier is assumed to have a value of 0.

Default: If the router ID is not configured in the routing instance, the router ID is derived from an interface address belonging to the routing instance.

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

drop (PPPoE Service Name Tables)

Syntax
drop;

Hierarchy Level
[edit protocols pppoe service-name-tables *table-name* service *service-name*],
[edit protocols pppoe service-name-tables *table-name* service *service-name* agent-specifier aci *circuit-id-string* ari *remote-id-string*]

Release Information
Statement introduced in Junos OS Release 10.0.
Support at **[edit protocols pppoe service-name-tables *table-name* service *service-name* agent-specifier aci *circuit-id-string* ari *remote-id-string*]** hierarchy level introduced in Junos OS Release 10.2.

Description
Direct the router to drop (ignore) a PPPoE Active Discovery Initiation (PADI) control packet received from a PPPoE client that contains the specified service name tag or agent circuit identifier/agent remote identifier (ACI/ARI) information. This action effectively denies the client's request to provide the specified service, or to accept requests from the subscriber or subscribers represented by the ACI/ARI information.

Required Privilege Level
interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation
- *Configuring PPPoE Service Name Tables*

dynamic-profile (PPPoE Service Name Tables)

Syntax dynamic-profile *profile-name*;

Hierarchy Level [edit protocols pppoe service-name-tables *table-name* service *service-name*],
[edit protocols pppoe service-name-tables *table-name* service *service-name* agent-specifier aci *circuit-id-string* ari *remote-id-string*]

Release Information Statement introduced in Junos OS Release 10.2.

Description Specify a dynamic profile to instantiate a dynamic PPPoE interface. You can associate a dynamic profile with a named service entry, **empty** service entry, or **any** service entry configured in a PPPoE service name table, or with an agent circuit identifier/agent remote identifier (ACI/ARI) pair defined for these services.

The dynamic profile associated with a service entry in a PPPoE service name table overrides the dynamic profile associated with the PPPoE underlying interface on which the dynamic PPPoE interface is created.

If you include the **dynamic-profile** statement at the **[edit protocols pppoe service-name-tables *table-name* service *service-name* agent-specifier aci *circuit-id-string* ari *remote-id-string*]** hierarchy level, you cannot also include the **static-interface** statement at this level. The **dynamic-profile** and **static-interface** statements are mutually exclusive for ACI/ARI pair configurations.

Options ***profile-name***—Name of the dynamic profile that the router uses to instantiate a dynamic PPPoE interface.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

east-interface

Syntax

```
east-interface {
  node-id mac-address;
  control-channel channel-name {
    vlan number;
    interface name interface-name
  }
  interface-none
  ring-protection-link-end;
}
```

Hierarchy Level

[edit protocols protection-group ethernet-ring *ring-name*]

Release Information

Statement introduced in Junos OS Release 9.4.
Statement introduced in Junos OS Release 12.1 for EX Series switches.
Statement introduced in Junos OS Release 14.153-D10 for QFX Series switches.

Description

Define one of the two interface ports for Ethernet ring protection, the other being defined by the **west-interface** statement at the same hierarchy level. The interface must use the control channel's logical interface name. The control channel is a dedicated VLAN channel for the ring port.

EX Series switches do not use the node-id statement--the node ID is automatically configured on the switches using the MAC address.

NOTE: Always configure this port first, before configuring the **west-interface** statement.

NOTE: The Node ID is not configurable on EX Series switches. The node ID is automatically configured using the MAC address.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

egress-policer-overhead

Syntax egress-policer-overhead *bytes*;

Hierarchy Level [edit chassis fpc *slot-number* pic *pic-number*]

Release Information Statement introduced before Junos OS Release 11.1.

Description Add the specified number of bytes to the actual length of an Ethernet frame when determining the actions of Layer 2 policers, MAC policers, or queue rate limits applied to output traffic on the line card. You can configure egress policer overhead to account for egress *shaping* overhead bytes added to output traffic on the line card.

On M Series and T Series routers, this statement is supported on Gigabit Ethernet Intelligent Queuing 2 (IQ2) PICs and Enhanced IQ2 (IQ2E) PICs. On MX Series routers, this statement is supported for interfaces configured on Dense Port Concentrators (DPCs).

NOTE: **This statement is not supported on Modular Interface Cards (MICs) or Modular Port Concentrators (MPCs) in MX Series routers.**

Options *bytes*—Number of bytes added to a packet exiting an interface.

Range: 0–255 bytes

Default: 0

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*],
[edit interfaces rlsq *number* unit *logical-unit-number*]
[edit protocols evpn]

Release Information Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers (**ethernet**,**vlan-ccc**, and **vlan-tcc** options only).
Statement introduced in Junos OS Release 12.2 for the ACX Series Universal Metro Routers. Only the **atm-ccc-cell-relay** and **atm-ccc-vc-mux** options are supported on ACX Series routers.
Statement introduced in Junos OS Release 17.3R1 for QFX10000 Series switches (**ethernet-ccc** and **vlan-ccc** options only).

Description Configure a logical link-layer encapsulation type. Not all encapsulation types are supported on the switches. See the switch CLI.

Options **atm-ccc-cell-relay**—Use ATM cell-relay encapsulation.

atm-ccc-vc-mux—Use ATM virtual circuit (VC) multiplex encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

atm-cisco-nlpid—Use Cisco ATM network layer protocol identifier (NLPID) encapsulation. When you use this encapsulation type, you can configure the **inet** family only.

atm-mlppp-llc—For ATM2 IQ interfaces only, use Multilink Point-to-Point (MLPPP) over AAL5 LLC. For this encapsulation type, your router must be equipped with a Link Services or Voice Services PIC. MLPPP over ATM encapsulation is not supported on ATM2 IQ OC48 interfaces.

atm-nlpid—Use ATM NLPID encapsulation. When you use this encapsulation type, you can configure the **inet** family only.

atm-ppp-llc—(ATM2 IQ interfaces and MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP only) Use PPP over AAL5 LLC encapsulation.

atm-ppp-vc-mux—(ATM2 IQ interfaces and MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP only) Use PPP over ATM AAL5 multiplex encapsulation.

atm-snap—(All interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) Use ATM subnetwork attachment point (SNAP) encapsulation.

atm-tcc-snap—Use ATM SNAP encapsulation on translational cross-connect (TCC) circuits.

atm-tcc-vc-mux—Use ATM VC multiplex encapsulation on TCC circuits. When you use this encapsulation type, you can configure the **tcc** family only.

atm-vc-mux—(All interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) Use ATM VC multiplex encapsulation. When you use this encapsulation type, you can configure the **inet** family only.

ether-over-atm-llc—(All IP interfaces including MX Series routers with MPC/MIC interfaces using the ATM MIC with SFP) For interfaces that carry IP traffic, use Ethernet over ATM LLC encapsulation. When you use this encapsulation type, you cannot configure multipoint interfaces.

ether-vpls-over-atm-llc—For ATM2 IQ interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.

ether-vpls-over-fr—For E1, T1, E3, T3, and SONET interfaces only, use the Ethernet virtual private LAN service (VPLS) over Frame Relay encapsulation to support Bridged Ethernet over Frame Relay encapsulated TDM interfaces for VPLS applications, per RFC 2427, *Multiprotocol Interconnect over Frame Relay*.

NOTE: **The SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP, the Channelized SONET/SDH OC3/STM1 (Multi-Rate) MIC with SFP, and the DS3/E3 MIC do not support Ethernet over Frame Relay encapsulation.**

ether-vpls-over-ppp—For E1, T1, E3, T3, and SONET interfaces only, use the Ethernet virtual private LAN service (VPLS) over Point-to-Point Protocol (PPP) encapsulation to support Bridged Ethernet over PPP-encapsulated TDM interfaces for VPLS applications.

ethernet—Use Ethernet II encapsulation (as described in RFC 894, *A Standard for the Transmission of IP Datagrams over Ethernet Networks*).

ethernet-ccc—Use Ethernet CCC encapsulation on Ethernet interfaces.

ethernet-vpls—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard Tag Protocol ID (TPID) values.

NOTE: The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.

ethernet-vpls-fr—Use in a VPLS setup when a CE device is connected to a PE router over a time-division multiplexing (TDM) link. This encapsulation type enables the PE router to terminate the outer layer 2 Frame Relay connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use the MAC address to forward the packet into a given VPLS instance.

frame-relay-ccc—Use Frame Relay encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

frame-relay-ether-type—Use Frame Relay ether type encapsulation for compatibility with Cisco Frame Relay. The physical interface must be configured with flexible-frame-relay encapsulation.

frame-relay-ether-type-tcc—Use Frame Relay ether type TCC for Cisco-compatible Frame Relay on TCC circuits to connect different media. The physical interface must be configured with flexible-frame-relay encapsulation.

frame-relay-ppp—Use PPP over Frame Relay circuits. When you use this encapsulation type, you can configure the **ppp** family only.

frame-relay-tcc—Use Frame Relay encapsulation on TCC circuits for connecting different media. When you use this encapsulation type, you can configure the **tcc** family only.

gre-fragmentation—For adaptive services interfaces only, use GRE fragmentation encapsulation to enable fragmentation of IPv4 packets in GRE tunnels. This encapsulation clears the do not fragment (DF) bit in the packet header. If the packet's size exceeds the tunnel's maximum transmission unit (MTU) value, the packet is fragmented before encapsulation.

multilink-frame-relay-end-to-end—Use MLFR FRF.15 encapsulation. This encapsulation is used only on multilink, link services, and voice services interfaces and their constituent T1 or E1 interfaces, and is supported on LSQ and redundant LSQ interfaces.

multilink-ppp—Use MLPPP encapsulation. This encapsulation is used only on multilink, link services, and voice services interfaces and their constituent T1 or E1 interfaces.

ppp-over-ether—Use PPP over Ethernet encapsulation to configure an underlying Ethernet interface for a dynamic PPPoE logical interface on M120 and M320 routers with Intelligent Queuing 2 (IQ2) PICs, and on MX Series routers with MPCs.

ppp-over-ether-over-atm-llc—(MX Series routers with MPCs using the ATM MIC with SFP only) For underlying ATM interfaces, use PPP over Ethernet over ATM LLC encapsulation. When you use this encapsulation type, you cannot configure the interface address. Instead, configure the interface address on the PPP interface.

vlan-bridge—Use Ethernet VLAN bridge encapsulation on Ethernet interfaces that have IEEE 802.1Q tagging, flexible-ethernet-services, and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID.

vlan-ccc—Use Ethernet virtual LAN (VLAN) encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

vlan-vci-ccc—Use ATM-to-Ethernet interworking encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.

vlan-tcc—Use Ethernet VLAN encapsulation on TCC circuits. When you use this encapsulation type, you can configure the **tcc** family only.

vlan-vpls—Use Ethernet VLAN encapsulation on VPLS circuits.

vxlan—Use VXLAN data plane encapsulation for EVPN.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 9.5.
Statement introduced in Junos OS Release 11.1 for EX Series switches.
Statement introduced in Junos OS Release 12.1X48 for PTX Series Packet Transport Routers (**flexible-ethernet-services**, **ethernet-ccc**, and **ethernet-tcc** options only).

Description

For M Series, MX Series, QFX Series, T Series, PTX Series, specify the physical link-layer encapsulation type.

For SRX Series, specify logical link layer encapsulation.

NOTE: Not all encapsulation types are supported on the switches. See the switch CLI.

Default

ppp—Use serial PPP encapsulation.

Physical Interface Options and Logical Interface Options

[Warning: element unresolved in stylesheets: <title> (in <config-options>). This is probably a new element that is not yet supported in the stylesheets.]

Physical Interface Options and Logical Interface Options

For physical interfaces:

NOTE: Frame Relay, ATM, PPP, SONET, and SATSOP options are not supported on EX Series switches.

- **atm-ccc-cell-relay**—Use ATM cell-relay encapsulation.
- **atm-pvc**—Defined in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*. When you configure physical ATM interfaces with ATM PVC encapsulation, an RFC 2684-compliant ATM Adaptation Layer 5 (AAL5) tunnel is set up to route the ATM cells over a Multiprotocol Label Switching (MPLS) path that is typically established between two MPLS-capable routers using the Label Distribution Protocol (LDP).
- **cisco-hdlc**—Use Cisco-compatible High-Level Data Link Control (HDLC) framing. E1, E3, SONET/SDH, T1, and T3 interfaces can use Cisco HDLC encapsulation. Two related versions are supported:
  - CCC version (**cisco-hdlc-ccc**)—The logical interface does not require an encapsulation statement. When you use this encapsulation type, you can configure the **ccc** family only.
  - TCC version (**cisco-hdlc-tcc**)—Similar to CCC and has the same configuration restrictions, but used for circuits with different media on either side of the connection.
- **cisco-hdlc-ccc**—Use Cisco-compatible HDLC framing on CCC circuits.
- **cisco-hdlc-tcc**—Use Cisco-compatible HDLC framing on TCC circuits for connecting different media.
- **ethernet-bridge**—Use Ethernet bridge encapsulation on Ethernet interfaces that have bridging enabled and that must accept all packets.
- **ethernet-over-atm**—For interfaces that carry IPv4 traffic, use Ethernet over ATM encapsulation. When you use this encapsulation type, you cannot configure multipoint interfaces. As defined in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*, this encapsulation type allows ATM interfaces to connect to devices that support only bridge protocol data units (BPDUs). Junos OS does not completely support bridging, but accepts BPDU packets as a default gateway. If you use the router as an edge device, then the router acts as a default gateway. It accepts Ethernet LLC/SNAP frames with IP or ARP in the payload, and drops the rest. For packets destined to the Ethernet LAN, a route lookup is done using the destination IP address. If the route lookup yields a full address match, the packet is encapsulated with an LLC/SNAP and MAC header, and the packet is forwarded to the ATM interface.
- **ethernet-tcc**—For interfaces that carry IPv4 traffic, use Ethernet TCC encapsulation on interfaces that must accept packets carrying standard TPID values. For 8-port, 12-port, and 48-port Fast Ethernet PICs, TCC is not supported.

- **ethernet-vpls**—Use Ethernet VPLS encapsulation on Ethernet interfaces that have VPLS enabled and that must accept packets carrying standard TPID values. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.
- **ethernet-vpls-fr**—Use in a VPLS setup when a CE device is connected to a PE device over a time division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer Layer 2 Frame Relay connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use the MAC address to forward the packet into a given VPLS instance.
- **ethernet-vpls-ppp**—Use in a VPLS setup when a CE device is connected to a PE device over a time division multiplexing (TDM) link. This encapsulation type enables the PE device to terminate the outer Layer 2 PPP connection, use the 802.1p bits inside the inner Ethernet header to classify the packets, look at the MAC address from the Ethernet header, and use it to forward the packet into a given VPLS instance.
- **ether-vpls-over-atm-llc**—For ATM intelligent queuing (IQ) interfaces only, use the Ethernet virtual private LAN service (VPLS) over ATM LLC encapsulation to bridge Ethernet interfaces and ATM interfaces over a VPLS routing instance (as described in RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*). Packets from the ATM interfaces are converted to standard ENET2/802.3 encapsulated Ethernet frames with the frame check sequence (FCS) field removed.
- **extended-frame-relay-ccc**—Use Frame Relay encapsulation on CCC circuits. This encapsulation type allows you to dedicate DLCIs 1 through 1022 to CCC. When you use this encapsulation type, you can configure the **ccc** family only.
- **extended-frame-relay-ether-type-tcc**—Use extended Frame Relay ether type TCC for Cisco-compatible Frame Relay for DLCIs 1 through 1022. This encapsulation type is used for circuits with different media on either side of the connection.
- **extended-frame-relay-tcc**—Use Frame Relay encapsulation on TCC circuits to connect different media. This encapsulation type allows you to dedicate DLCIs 1 through 1022 to TCC.
- **extended-vlan-bridge**—Use extended VLAN bridge encapsulation on Ethernet interfaces that have IEEE 802.1Q VLAN tagging and bridging enabled and that must accept packets carrying TPID 0x8100 or a user-defined TPID.
- **extended-vlan-ccc**—Use extended VLAN encapsulation on CCC circuits with Gigabit Ethernet and 4-port Fast Ethernet interfaces that must accept packets carrying 802.1Q values. Extended VLAN CCC encapsulation supports TPIDs 0x8100, 0x9100, and 0x9901. When you use this encapsulation type, you can configure the **ccc** family only. For 8-port, 12-port, and 48-port Fast Ethernet PICs, extended VLAN CCC is not supported. For 4-port Gigabit Ethernet PICs, extended VLAN CCC is not supported.
- **extended-vlan-tcc**—For interfaces that carry IPv4 traffic, use extended VLAN encapsulation on TCC circuits with Gigabit Ethernet interfaces on which you want to use 802.1Q tagging. For 4-port Gigabit Ethernet PICs, extended VLAN TCC is not supported.

- **extended-vlan-vpls**—Use extended VLAN VPLS encapsulation on Ethernet interfaces that have VLAN 802.1Q tagging and VPLS enabled and that must accept packets carrying TPIDs 0x8100, 0x9100, and 0x9901. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

  NOTE: **The built-in Gigabit Ethernet PIC on an M7i router does not support extended VLAN VPLS encapsulation.**

- **flexible-ethernet-services**—For Gigabit Ethernet IQ interfaces and Gigabit Ethernet PICs with small form-factor pluggable transceivers (SFPs) (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), and for Gigabit Ethernet interfaces, use flexible Ethernet services encapsulation when you want to configure multiple per-unit Ethernet encapsulations. Aggregated Ethernet bundles can use this encapsulation type. This encapsulation type allows you to configure any combination of route, TCC, CCC, Layer 2 virtual private networks (VPNs), and VPLS encapsulations on a single physical port. If you configure flexible Ethernet services encapsulation on the physical interface, VLAN IDs from 1 through 511 are no longer reserved for normal VLANs.
- **flexible-frame-relay**—For IQ interfaces only, use flexible Frame Relay encapsulation when you want to configure multiple per-unit Frame Relay encapsulations. This encapsulation type allows you to configure any combination of TCC, CCC, and standard Frame Relay encapsulations on a single physical port. Also, each logical interface can have any DLCI value from 1 through 1022.
- **frame-relay**—Use Frame Relay encapsulation is defined in RFC 1490, *Multiprotocol Interconnect over Frame Relay*. E1, E3, link services, SONET/SDH, T1, T3, and voice services interfaces can use Frame Relay encapsulation.
- **frame-relay-ccc**—Use Frame Relay encapsulation on CCC circuits. This encapsulation is same as standard Frame Relay for DLCIs 0 through 511. DLCIs 512 through 1022 are dedicated to CCC. The logical interface must also have **frame-relay-ccc** encapsulation. When you use this encapsulation type, you can configure the **ccc** family only.
- **frame-relay-ether-type**—Use Frame Relay ether type encapsulation for compatibility with the Cisco Frame Relay. IETF frame relay encapsulation identifies the payload format using NLPID and SNAP formats. Cisco-compatible Frame Relay encapsulation uses the Ethernet type to identify the type of payload.

  NOTE: **When the encapsulation type is set to Cisco-compatible Frame Relay encapsulation, ensure that the LMI type is set to ANSI or Q933-A.**

- **frame-relay-ether-type-tcc**—Use Frame Relay ether type TCC for Cisco-compatible Frame Relay on TCC circuits to connect different media. This encapsulation is Cisco-compatible Frame Relay for DLCIs 0 through 511. DLCIs 512 through 1022 are dedicated to TCC.

- **frame-relay-port-ccc**—Use Frame Relay port CCC encapsulation to transparently carry all the DLCIs between two customer edge (CE) routers without explicitly configuring each DLCI on the two provider edge (PE) routers with Frame Relay transport. The connection between the two CE routers can be either user-to-network interface (UNI) or network-to-network interface (NNI); this is completely transparent to the PE routers. When you use this encapsulation type, you can configure the **ccc** family only.
- **frame-relay-tcc**—This encapsulation is similar to Frame Relay CCC and has the same configuration restrictions, but used for circuits with different media on either side of the connection.
- **generic-services**—Use generic services encapsulation for services with a hierarchical scheduler.
- **multilink-frame-relay-uni-nni**—Use MLFR UNI NNI encapsulation. This encapsulation is used on link services, voice services interfaces functioning as FRF.16 bundles, and their constituent T1 or E1 interfaces, and is supported on LSQ and redundant LSQ interfaces.
-
- **ppp**—Use serial PPP encapsulation. This encapsulation is defined in RFC 1661, *The Point-to-Point Protocol (PPP) for the Transmission of Multiprotocol Datagrams over Point-to-Point Links*. PPP is the default encapsulation type for physical interfaces. E1, E3, SONET/SDH, T1, and T3 interfaces can use PPP encapsulation.
- **ppp-ccc**—Use serial PPP encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only.
- **ppp-tcc**—Use serial PPP encapsulation on TCC circuits for connecting different media. When you use this encapsulation type, you can configure the **tcc** family only.
- **vlan-ccc**—Use Ethernet VLAN encapsulation on CCC circuits. VLAN CCC encapsulation supports TPID 0x8100 only. When you use this encapsulation type, you can configure the **ccc** family only.

- **vlan-vci-ccc**—Use ATM-to-Ethernet interworking encapsulation on CCC circuits. When you use this encapsulation type, you can configure the **ccc** family only. All logical interfaces configured on the Ethernet interface must also have the encapsulation type set to **vlan-vci-ccc**.
- **vlan-vpls**—Use VLAN VPLS encapsulation on Ethernet interfaces with VLAN tagging and VPLS enabled. Interfaces with VLAN VPLS encapsulation accept packets carrying standard TPID values only. On M Series routers, except the M320 router, the 4-port Fast Ethernet TX PIC and the 1-port, 2-port, and 4-port, 4-slot Gigabit Ethernet PICs can use the Ethernet VPLS encapsulation type.

NOTE:
- Label-switched interfaces (LSIs) do not support VLAN VPLS encapsulation. Therefore, you can only use VLAN VPLS encapsulation on a PE-router-to-CE-router interface and not a core-facing interface.
- Starting with Junos OS release 13.3, a commit error occurs when you configure **vlan-vpls** encapsulation on a physical interface and configure **family inet** on one of the logical units. Previously, it was possible to commit this invalid configuration.

For logical interfaces:

- **frame-relay**—Configure a Frame Relay encapsulation when the physical interface has multiple logical units, and the units are either point to point or multipoint.
- **multilink-frame-relay-uni-nni**—Link services interfaces functioning as FRF.16 bundles can use Multilink Frame Relay UNI NNI encapsulation.
- **ppp**—For normal mode (when the device is using only one ISDN B-channel per call). Point-to-Point Protocol is for communication between two computers using a serial interface.
- **ppp-over-ether**—This encapsulation is used for underlying interfaces of pp0 interfaces.

Required Privilege Level interface—To view this statement in the configuration.

encryption (MACsec for MX Series)

Syntax encryption;

Hierarchy Level [edit security macsec connectivity-association *connectivity-association-name* secure-channel *secure-channel-name*]

Release Information Statement introduced in Junos OS Release 15.1 for MX240, MX480, and MX960 routers.

Description Enable MACsec encryption within a secure channel.

You can enable MACsec without enabling encryption. If a connectivity association with a secure channel that has not enabled MACsec encryption is associated with an interface, traffic is forwarded across the Ethernet link in clear text. You are, therefore, able to view this unencrypted traffic when you are monitoring the link. The MACsec header is still applied to the frame, however, and all MACsec data integrity checks are run on both ends of the link to ensure the traffic has not been tampered with and does not represent a security threat.

Traffic traversing a MAC-enabled point-to-point Ethernet link traverses the link at the same speed regardless of whether encryption is enabled or disabled. You cannot increase the speed of traffic traversing a MACsec-enabled Ethernet link by disabling encryption.

This command is used to enable encryption when MACsec is configured using secure association key (SAK) security mode only. When MACsec is configuring using static connectivity association key (CAK) security mode, the encryption setting is configured outside of the secure channel using the **no-encryption** configuration statement.

Default MACsec encryption is disabled when MACsec is configured using static SAK security mode, by default.

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

enhanced-convergence

Syntax enhanced-convergence;

Hierarchy Level [edit interfaces ae*X* aggregated-ether-options mc-ae]
[edit interfaces irb unit *unit-number*]

Release Information Statement introduced in Junos OS Release 15.1R1.
Statement introduced in Junos OS Release 15.1X53-D60 for the QFX Series.

Description

NOTE: On EX9200 and QFX10000 switches, enhanced convergence is applicable for unicast traffic only—for example, when a MAC address is learned over an MC-AE interface, or an ARP entry is resolved over an MC-AE interface.

Improves Layer 2 and Layer 3 convergence time when a multichassis aggregated Ethernet (MC-AE) link goes down or comes up in a bridge domain or VLAN. Convergence time is improved because the traffic on the MC-AE interface is switched to the interchassis link (ICL) without waiting for a MAC address update.

If you have configured an IRB interface over an MC-AE interface that has enhanced convergences enabled, then you must configure enhanced convergence on the IRB interface as well. Enhanced convergence must be enabled for both Layer 2 and Layer 3 interfaces.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

[edit interfaces *interface-name* aggregated-ether-options ethernet-switch-profile]

Release Information

Statement introduced before Junos OS Release 7.4.

Description

NOTE: On QFX Series standalone switches, this statement hierarchy is only supported on the Enhanced Layer 2 Switching CLI.

For Gigabit Ethernet IQ, 10-Gigabit Ethernet, Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), and 100-Gigabit Ethernet Type 5 PIC with CFP, configure a class of service (CoS)-based policer. Policing applies to the inner VLAN identifiers, not to the outer tag. For Gigabit Ethernet interfaces with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router), the **premium** policer is not supported.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

[edit interfaces *interface-name* ether-options]

Release Information

Statement introduced before Junos OS Release 7.4.
Statement introduced in Junos OS Release 12.2 for ACX Series Universal Metro Routers.
Statement introduced in Junos OS Release 13.2 for the QFX Series.
Statement introduced in Junos OS Release 13.2X50-D15 for the EX Series switches.

Description

NOTE: On QFX Series standalone switches, the **ethernet-policer-profile** CLI hierarchy and the **mac-learn-enable** statement are supported only on the Enhanced Layer 2 Switching CLI.

For Gigabit Ethernet IQ, 10-Gigabit Ethernet IQ2 and IQ2-E, and Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC, aggregated Ethernet with Gigabit Ethernet IQ interfaces, the built-in Gigabit Ethernet port on the M7i router); 100-Gigabit

Ethernet Type 5 PIC with CFP; and Gigabit Ethernet, 10-Gigabit Ethernet, 40-Gigabit Ethernet, and aggregated Ethernet interfaces on EX Series switches, configure VLAN tag and MAC address accounting and filtering properties.

The remaining statements are explained separately. See CLI Explorer.

NOTE: When you gather interfaces into a bridge domain, the **no-mac-learn-enable** statement at the **[edit interfaces *interface-name* gigether-options ethernet-switch-profile]** hierarchy level is not supported. You must use the **no-mac-learning** statement at the **[edit bridge-domains *bridge-domain-name* bridge-options interface *interface-name*]** hierarchy level to disable MAC learning on an interface in a bridge domain. For information on disabling MAC learning for a bridge domain, see the *MX Series Layer 2 Configuration Guide*.

Default If the **ethernet-switch-profile** statement is not configured, Gigabit Ethernet IQ and Gigabit Ethernet PICs with SFPs (except the 10-port Gigabit Ethernet PIC and the built-in Gigabit Ethernet port on the M7i router) behave like Gigabit Ethernet interfaces.

Required Privilege Level
interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

evc-protocol cfm

Syntax

```
evc-protocol cfm {
  maintenance-association association-name | vpls routing-instance routing-id;
  maintenance-domain domain-id;
  mep-id mep-id;
}
```

Hierarchy Level [edit protocols oam ethernet evcs]

Release Information Statement introduced in Junos OS Release 9.5.
mep-id ***mep-id*** statement introduced in Junos OS Release 15.1.

Description Specify connectivity fault management (CFM) or virtual private LAN service (VPLS) as the Ethernet virtual connection (EVC) protocol.

Options

management-domain ***domain-id***—(Optional) For CFM, specify the CFM management domain.

management-association ***association-id***—(Optional) For CFM, specify the CFM management association.

routing-instance ***instance-id***—(Optional) For VPLS, specify the VPLS routing instance.

mep-id ***mep-id***—(Required for CFM) Identifier for the maintenance association endpoint

NOTE: This option is available on MX Series routers only.

Range: 1 through 8191

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

    symbol-period count;
    }
  protocol-down;
}
```

Syntax: EX Series Switches and NFX Series Devices

```
event {
  link-adjacency-loss;
  link-event-rate {
    frame-error  count;
    frame-period count;
    frame-period-summary  count;
    symbol-period count;
  }
}
```

Hierarchy Level

[edit protocols oam ethernet link-fault-management action-profile]

Release Information

Statement introduced in Junos OS Release 8.5 for MX, M, T, ACX Series routers, SRX Series firewalls and EX Series switches.
Statement introduced in Junos OS Release 9.4 for EX Series switches and NFX devices.

Description

Configure link events in an action profile for Ethernet OAM link fault management (LFM).

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level

interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.
routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

event-thresholds

Syntax

```
event-thresholds {
  frame-error count;
  frame-period count;
  frame-period-summary count;
  symbol-period count;
}
```

Hierarchy Level [edit protocols oam link-fault-management interface *interface-name*]

Release Information Statement introduced in Junos OS Release 8.4.

Description Configure threshold limit values for link events in periodic OAM PDUs.

The remaining statements are explained separately. See CLI Explorer.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

exclude-protocol (MX Series)

Syntax exclude-protocol *protocol-name*;

Hierarchy Level [edit security macsec connectivity-association *connectivity-association-name*]

Release Information Statement introduced in Junos OS Release 15.1 for MX240, MX480, and MX960 routers.

Description Specifies protocols whose packets are not secured using Media Access Control Security (MACsec) when MACsec is enabled on a link using static connectivity association key (CAK) security mode.

When this option is enabled in a connectivity association that is attached to an interface, MACsec is not enabled for all packets of the specified protocols that are sent and received on the link.

Default Disabled.

All packets are secured on a link when MACsec is enabled, with the exception of all types of Spanning Tree Protocol (STP) packets.

Options ***protocol-name***—Specifies the name of the protocol that should not be MACsec-secured. Options include:

- **cdp**—Cisco Discovery Protocol.
- **lacp**—Link Aggregation Control Protocol.
- **lldp**—Link Level Discovery Protocol.

Required Privilege Level admin—To view this statement in the configuration.
admin-control—To add this statement to the configuration.

Related Documentation

exercise

Syntax request protection-group ethernet-aps exercise md <md> ma <ma>

Hierarchy Level [edit protocols protection-group ethernet-aps]

Description This configuration statement is used to test if APS is operating correctly, it does not interrupt regular APS operations.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Related Documentation

- Ethernet Automatic Protection Switching Overview on page 213

failover-delay

Syntax failover-delay *milliseconds*;

Hierarchy Level [edit protocols vrrp]

Release Information Statement introduced in Junos OS Release 9.4.

Description Configure the failover delay for VRRP and VRRP for IPv6 operations.

Options ***milliseconds***—Specify the failover delay time, in milliseconds.

Range: 50 through 2000

Required Privilege Level routing—To view this statement in the configuration.
routing-control—To add this statement to the configuration.

Hierarchy Level [edit interfaces *interface-name* unit *logical-unit-number*],
[edit logical-systems *logical-system-name* interfaces *interface-name* unit *logical-unit-number*]

Release Information Statement introduced before Junos OS Release 7.4.
Option **max-sessions-vsa-ignore** introduced in Junos OS Release 11.4.

Description Configure protocol family information for the logical interface.

NOTE: Not all subordinate statements are available to every protocol family.

Options *family*—Protocol family:

- **any**—Protocol-independent family used for Layer 2 packet filtering

  NOTE: This option is not supported on T4000 Type 5 FPCs.

- **bridge**—(M Series and T Series routers only) Configure only when the physical interface is configured with **ethernet-bridge** type encapsulation or when the logical interface is configured with **vlan-bridge** type encapsulation. You can optionally configure this protocol family for the logical interface on which you configure VPLS.
- **ethernet-switching**—(M Series and T Series routers only) Configure only when the physical interface is configured with **ethernet-bridge** type encapsulation or when the logical interface is configured with **vlan-bridge** type encapsulation
- **ccc**—Circuit cross-connect protocol suite. You can configure this protocol family for the logical interface of CCC physical interfaces. When you use this encapsulation type, you can configure the **ccc** family only.
- **inet**—Internet Protocol version 4 suite. You must configure this protocol family for the logical interface to support IP protocol traffic, including Open Shortest Path First (OSPF), Border Gateway Protocol (BGP), Internet Control Message Protocol (ICMP), and Internet Protocol Control Protocol (IPCP).
- **inet6**—Internet Protocol version 6 suite. You must configure this protocol family for the logical interface to support IPv6 protocol traffic, including Routing Information Protocol for IPv6 (RIPng), Intermediate System-to-Intermediate System (IS-IS), BGP, and Virtual Router Redundancy Protocol for IPv6 (VRRP).
- **iso**—International Organization for Standardization Open Systems Interconnection (ISO OSI) protocol suite. You must configure this protocol family for the logical interface to support IS-IS traffic.
- **mlfr-end-to-end**—Multilink Frame Relay FRF.15. You must configure this protocol or multilink Point-to-Point Protocol (MLPPP) for the logical interface to support multilink bundling.
- **mlfr-uni-nni**—Multilink Frame Relay FRF.16. You must configure this protocol or **mlfr-end-to-end** for the logical interface to support link services and voice services bundling.
- **multilink-ppp**—Multilink Point-to-Point Protocol. You must configure this protocol (or **mlfr-end-to-end**) for the logical interface to support multilink bundling.
- **mpls**—Multiprotocol Label Switching (MPLS). You must configure this protocol family for the logical interface to participate in an MPLS path.
- **pppoe**—Point-to-Point Protocol over Ethernet
- **tcc**—Translational cross-connect protocol suite. You can configure this protocol family for the logical interface of TCC physical interfaces.

- **tnp**—Trivial Network Protocol. This protocol is used to communicate between the Routing Engine and the router's packet forwarding components. The Junos OS automatically configures this protocol family on the router's internal interfaces only, as discussed in *Understanding Internal Ethernet Interfaces*.
- **vpls**—(M Series and T Series routers only) Virtual private LAN service. You can optionally configure this protocol family for the logical interface on which you configure VPLS. VPLS provides an Ethernet-based point-to-multipoint Layer 2 VPN to connect customer edge (CE) routers across an MPLS backbone. When you configure a VPLS encapsulation type, the **family vpls** statement is assumed by default.

  MX Series routers support dynamic profiles for VPLS pseudowires, VLAN identifier translation, and automatic bridge domain configuration.

  For more information about VPLS, see the *Junos OS VPNs Library for Routing Devices*.

The remaining statements are explained separately. Search for a statement in CLI Explorer or click a linked statement in the Syntax section for details.

Required Privilege Level
interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

fast-aps-switch

Syntax fast-aps-switch;

Hierarchy Level [edit interfaces *interface-name* sonet-options aps]

Release Information Statement introduced in Junos OS Release 12.1.

Description (M320 routers with Channelized OC3/STM1 Circuit Emulation PIC with SFP only, EX Series switches, and MX series routers with Channelized OC3/STM1 Circuit Emulation PIC with SFP only using container interfaces) Reduce the Automatic Protection Switching (APS) switchover time in Layer 2 circuits.

NOTE:

- The fast APS switching feature is supported only within a single chassis on a MX series router using a container interface.
- Configuring this statement reduces the APS switchover time only when the Layer 2 circuit encapsulation type for the interface receiving traffic from a Layer 2 circuit neighbor is SAToP.
- When the **fast-aps-switch** statement is configured in revertive APS mode, you must configure an appropriate value for revert time to achieve reduction in APS switchover time.
- To prevent the logical interfaces in the data path from being shut down, configure appropriate hold-time values on all the interfaces in the data path that support TDM.
- The **fast-aps-switch** statement cannot be configured when the APS **annex-b** option is configured.
- The interfaces that have the **fast-aps-switch** statement configured cannot be used in virtual private LAN service (VPLS) environments.

Required Privilege Level interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.

Release Information
Statement introduced in Junos OS Release 8.1.
Support for aggregated Ethernet added in Junos OS Release 9.0.
Statement introduced in Junos OS Release 12.1x48 for PTX Series Packet Transport Routers.
Statement introduced in Junos OS Release 13.2X50-D15 for EX Series switches.
Statement introduced in Junos OS Release 13.2X51-D20 for the QFX Series.

Description Support simultaneous transmission of 802.1Q VLAN single-tag and dual-tag frames on logical interfaces on the same Ethernet port, and on pseudowire logical interfaces.

This statement is supported on M Series and T Series routers, for Fast Ethernet and Gigabit Ethernet interfaces only on Gigabit Ethernet IQ2 and IQ2-E, IQ, and IQE PICs, and for aggregated Ethernet interfaces with member links in IQ2, IQ2-E, and IQ PICs or in MX Series DPCs, or on Ethernet interfaces for PTX Series Packet Transport Routers or 100-Gigabit Ethernet Type 5 PIC with CFP.

This statement is supported on Gigabit Ethernet, 10-Gigabit Ethernet, 40-Gigabit Ethernet, and aggregated Ethernet interfaces on EX Series and QFX Series switches.

Required Privilege Level
interface—To view this statement in the configuration.
interface-control—To add this statement to the configuration.
